Dress (fig. 4).—The diving dress is a combination suit which is made of two layers of tanned twill with pure rubber between, and which envelops the whole body from foot to neck, the sleeves being fitted with vulcanized rubber cuffs which make a watertight joint round the diver's wrists. The dress is also fitted with a vulcanized rubber collar, which is secured to the corselet, or breastplate, of the helmet in such a manner as to render all watertight.

Air Pipe.—The diver's air pipe is flexible and non-collapsible. At the ends are fitted metal couplings for securing the pipe to the pump and helmet respectively.

Boots.—To maintain himself in an upright position under water, the diver wears heavily weighted boots (about 32 lb. the pair).

Weights.—Two lead weights, 40 lb. each, one on the back and one on the chest, ensure the diver's equilibrium under water.

Life-line.—The diver's life-line is for use in case of emergency, for hauling the diver to the surface, and also for making signals, the diver and his attendant having a pre-arranged code in which varying numbers of pulls or jerks on the life-line have definite meanings. When the telephone is provided, the telephone wires are embedded in the life-line.

Diver's *Telephone* (fig. 5).—This most useful instrument was introduced by Siebe, Gorman & Co. and is used to-day throughout the British and many other navies. Means are provided whereby the attendant at the surface can converse with No. 1 or with No. 2 diver, or with both together. He can also put No. 1 diver into communication with No. 2, himself hearing their conversation. The telephone wires are embedded in the life-line, which has metal connections at each end for attaching to helmet and battery box. The diver's telephone receiver is situated generally in the crown of the helmet, and the transmitter between the front glass and one of the side glasses. The diver can ring a bell or buzzer at the surface by pressing with his chin a contact-piece situated inside the helmet.

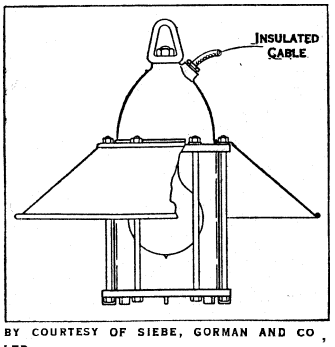
FIG. 5.—TELEPHONE APPARATUS WHICH ENABLES DIVERS TO CONVERSE WITH ATTENDANTS AND ONE ANOTHER

Submarine Electric Lamps. (fig. 6).—Very many forms of submarine lamps are available. Of these, the most widely used are those which incorporate incandescent electric bulbs, ranging in candle-power from 5,000 down to about 50, the former being supplied with current from the surface, the latter being self-contained with accumulator batteries in a watertight case.

Air Pumps.—Diver's air pumps are of various patterns, depending principally upon the depth of water in which work is being carried out, since the greater the depth of water the greater the quantity of air required by the diver. The pumps are of the reciprocating type and are mostly manually operated. Fig. 7 shows the Siebe-Gorman two-cylinder double-acting pump (removed from its teak chest) adopted by the British Admiralty. Pressure gauges are provided which indicate the pressure of air which the pump is supplying, and the depth at which the diver is working. The cylinders are water-jacketted to ensure a supply of cool air to the diver.

Air *Compressors* driven by electric motors, oil and steam engines are sometimes employed. In these cases the air is delivered into steel reservoirs, the divers' air pipes being connected to an air control panel which receives its air from the reservoir, so that in case of a breakdown of the motive power, a reserve of air sufficient to bring the diver safely to the surface is assured. A typical machine of this description is shown in fig. 8. In the pearl and sponge fisheries the small boats from which the divers work are sometimes propelled by oil engines which also drive the air compressors.



BY COURTESY OF SIEBE, GORMAN AND CO, LTD.

FIG. 6.—3000 CANDLE-POWER SUBMARINE ELECTRIC LAMP, WITH REFLECTOR

The type of air pumping apparatus employed varies with the depth of water and the conditions under which the diving operations are conducted. Examples of manually-operated and power-driven pumps are shown.

The Diver's Air Supply.—The diver's air supply must be adequate both in volume and pressure—the volume sufficient to ensure proper ventilation of the helmet, and the pressure fully equal to that which corresponds to the depth of water at which the diver msy be working In fresh air, there is only ·03% of carbon dioxide, and, at ordinary atmospheric pressure, no ill effects are felt

until 3% of the gas is present. As a diver descends, the pressure is increased and the effect of a small percentage of carbon dioxide in his helmet becomes greater.

J. S. Haldane, who conducted deep diving experiments for the British Admiralty, found from a large number of analyses of air issuing from the diver's helmet, that 1·5cu.ft. of air per minute would be needed to keep the percentage of carbon dioxide at a safe level. This volume of air is required at all depths, so that the actual quantities required at different depths down to 231ft. are as follows:—

Depth in fathoms	Depth in feet	Pressure per sq. in. above atmospheric pressure, in lb.	Quantity of air at atmospheric pressure required per min. by the diver cu. ft.
0 . . .	0		1·5
5½ . . .	33	14·7	3·0

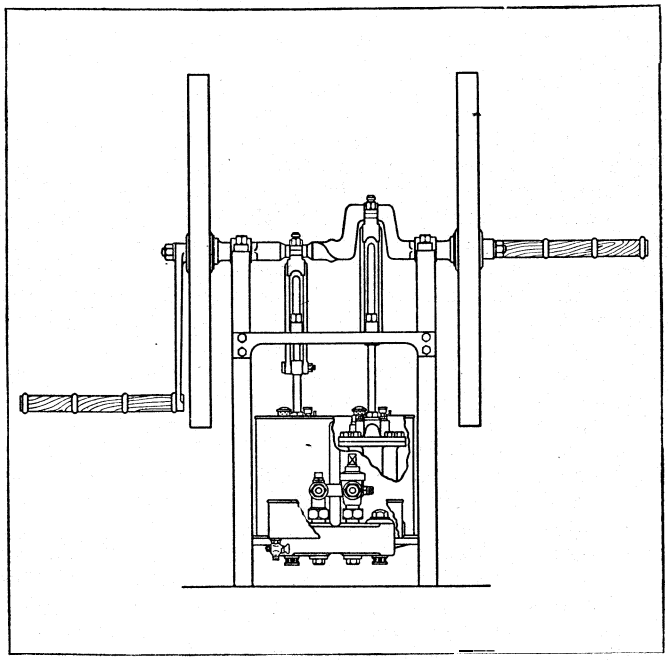
38½ . . .	231	102·8	12·0

Effects **of** Air Pressure on **the** Diver.—When a diver descends into the sea, the extra air pressure to which he is subjected is instantly transmitted to the whole inside of his body. At great depths his blood vessels and tissues become saturated with nitrogen. It should be remembered that a gas in contact with a liquid on which it has no chemical action is absorbed by the liquid in amounts proportional to the pressure of the gas at the time. In the lungs we have the blood practically in contact with the air, which consists of three important gases—oxygen, nitrogen and carbon dioxide. Of these, the nitrogen alone can remain and accumulate in the blood; the oxygen is used up by the tissues, and the breathing prevents the pressure of carbon dioxide from increasing, so that the only gas which accumulates in abnormal quantity in the blood when the diver is under pressure is the nitrogen.



BY COURTESY OF SIEBE, GORMAN AND CO., LTD.

FIG. 7.— MANUALLY OPERATED 2 CYLINDER DOUBLE-ACTING DIVERS' AIR PUMP. SHOWING VALVES AND AIR-DISTRIBUTING ARRANGEMENT FOR ONE OR TWO DIVERS

When gas is forced into a soda-water bottle under pressure, the water appears to be unchanged so long as the pressure is kept up, but the moment the pressure is reduced, by the removal of the cork, we see the gas come bubbling off the liquid. J. S. Haldane has applied the analogy to diving. He says: "The diver is the soda-water bottle, and his blood the fluid in the bottle. As the diver descends, nitrogen under pressure is forced into contact with his blood, which takes up the nitrogen from the air. So long as he stays below under that pressure, his blood appears to be unaltered; when however, he rises, the excess of nitrogen that the blood has taken up begins slowly to bubble off; if the blood were as fluid as water, it would come off as rapidly as from the soda water. Fortunately for the diver, the blood is a thickish, albuminous fluid, in which bubbles do not readily form, and, as far as we can see, it can retain about twice the amount in solution that water can keep at any given pressure. Every diver knows that it is quite safe to come up from a depth of five or six fathoms to the surface as

quickly as he likes; the reason for this will now be easily understood, since at such a depth the blood has only twice as much nitrogen in it as it has on the surface, and, therefore, bubbles are unlikely to form. **If,** *however, the diver has been for any considerable time at, say, 180ft.,* and then comes up too quickly, it is almost certain that bubbles will form and cause serious symptoms, such as paralysis of the legs (diver's palsy), severe pains in the joints and muscles, etc. Not only is the air taken up by the blood, but the tissues of the body also get saturated with it. In the case of the blood, the saturation is very quick; it is probable, indeed, that the blood leaving the lungs is always saturated to the existing pressure, but the tissues take up the gas at a much slower rate—a rate which depends on the blood supply. Where this is good, as in the brain and spinal cord, the saturation is quick, but in the fibrous tissues about the joints, etc., saturation is very slow. Those tissues which are saturated quickly also give up their surplus nitrogen quickly, and those which saturate slowly also desaturate slowly."

FIG 8.— OIL-ENGINE DRIVEN AIR COMPRESSING SET. WITH STEEL AIR RECEIVER. FOR SUPPLYING AIR TO 4 DIVERS SIMULTANEOUSLY

The compressed air, after being cooled, is delivered into air receiver, whence it passes to four control valves, to which are connected divers' air tubes

In ascending, the diver is decompressing himself, and it is this gradual decompression that is the most important factor in the prevention of accidents from the formation of bubbles of nitrogen. The dangers are to be avoided by working to the following schedule drawn up by Prof. Haldane, during which there is but little chance of the diver getting dangerously saturated with nitrogen. It is important that the diver descend as fast as his air supply will allow him, for every minute spent in descending is time lost, since his body is becoming saturated.

Compressed **Air** Illness.—Although the rules laid down are calculated completely to prevent compressed air illness, cases do sometimes occur, owing to accidents or mistakes, where the diver comes up too quickly from deep water. In such cases, whether the diver has already shown symptoms of compressed air illness or

On some deep diving operations, however, a Siebe-Gorman Re-compression chamber, as fig. g, is provided, the use of which is a much better and more comfortable method of treatment than sending the diver into deep water again. This chamber is of steel, provided with a bench on which the diver can sit or lie, electric light, telephone, etc. Windows are provided through which the diver can be watched during the process of decompression; a small hand air-lock attached to the chamber allows refreshments, etc., to be passed into him. It is usually found sufficient to raise the pressure in the chamber to 30 lb., but it should never exceed 45 lb. As soon as the diver is relieved of any symptoms, the pressure is allowed to fall at the following rates:—

When the pressure in the chamber Is—	Pressure may be allowed to fall at a rate not faster than—
Between 45 lb. and 30 lb.	1 lb. in three minutes.
" 30 " " 15 "	1 " " five "
Below 15 "	1 " " eight "

Helium and Oxygen for Deep **Sea** Diving.—Some years ago the proposal was made by Prof. Elihu Thomson, F.R.S., of Swampscott, Mass., U.S.A., to use helium in place of nitrogen in the atmosphere supplied to divers engaged in deep sea work, and the practical utility of this suggestion has been demonstrated recently by experiments conducted at the Government Bureau of Mines, U.S.A. Helium has a solubility in water nearly 40% less than nitrogen; therefore, during exposure to compressed air, nearly 40% less gas will be dissolved in the watery part of the body. The rate of diffusion of helium is 2·64 times that of nitrogen, its molecular weight being 4 against 28 for nitrogen Helium will thus escape from the lungs much more quickly than nitrogen during decompression. Experiments on animals have so far shown that the safe decomposition time for helium and nitrogen is somewhere about 1 to 3 or 4. To reduce the decompression periods to one-third or one-fourth would be a very great advantage.

Greatest Depths for Useful Work.—The greatest depth at which useful work has been accomplished by divers is 27jft. This was at the salvage of the U.S.A. submarine "F4," sunk off Honolulu, by divers of the United States Navy using the British Admiralty decompression system described in the present article. The Spanish diver, Erostarbe, recovered £9,000 worth of silver bars from a depth of 182ft. Siebe, Gorman & Co.'s chief diver, the late Alexander Lambert, salved £70,000 worth of Spanish gold coin from the wreck of the "Alphonse XII" sunk in 16jft. off Las Palmas. W. Ridyard brought up £50,000 worth of dollars from the "Hamilla Mitchell" lying in 1joft. of water. These are a few examples of treasury recovery notable by reason of the great depths involved. But there have been many cases where far larger sums have been recovered from lesser depths, *e.g.*, the case of the "Laurentic" in 130ft., sunk during the World War, with gold on board to the value of five million pounds sterling, all but £40,000 worth of which was recovered by British naval divers. Then there is the case of the "Oceanic" from which specie, etc., to the value of £700,000 was salved by divers.

The sponge divers of the Mediterranean work at a maximum depth of about 150ft., but they make exceedingly short stays on the bottom, and so, in most cases, avoid risk of pressure troubles. The pearl divers of Australia usually work at about 120ft. Submarine operations on the great majority of harbour, dock and bridge works are conducted at depths of from 40 to Soft. The weighted tools employed by divers differ very little from those used by workmen on *terra firma.* Pneumatic tools, worked by compressed air conveyed from the surface through flexible tubes, are great aids, particularly in rock-blasting work.

Self-contained Diving Apparatus (fig. 10).—The first really practicable self-contained diving apparatus was designed by H A. Fleuss, working in conjunction with Siebe and Gorman, about 50 years ago. The original apparatus enabled a diver to do good work in the flooded Severn tunnel in 1882. The diver on that occasion had to travel nearly a quarter of a mile through the workings-encountering all sorts of obstacles, floating timber, etc., on his journey—to a heading in which he had to close an iron door and a sluice valve. Later, Fleuss and R. H. Davis improved the apparatus considerably. The apparatus supplies a

British type diving armour, side view, showing ball-and-socket joints of arm and leg coverings. 9. British type diving suit. Light weight flanged construction gives strength

factitious, but perfectly respirable air by means of regenerating devices, thus making him independent of the surface. His dress, helmet and boots are of the ordinary patterns. Attached to a leather equipment carried on his back is (1) a cylinder of oxygen and air in certain proportions (it is dangerous to breathe pure oxygen at pressures above one atmosphere plus, hence the dilution); (2) a reducing valve connected to the cylinder, and passing the gas into the helmet through a tube connection at the requisite pressure and volume; (3) a watertight chamber, containing caustic soda, also connected by tube to the helmet. The diver's exhaled air is passed through the caustic soda, which takes up the carbonic acid, and, thus purified, comes back into the helmet where it mixes with the fresh oxygen and air which is constantly passing from the cylinder. This process of regeneration goes on automatically for from 45 minutes to two hours, according to the depth at which the diver may be working. The apparatus can be used at depths down to 150ft.

Recently, Neufeldt and Kuhnke have constructed a diving dress of steel and aluminium alloy, which, they claim, enables the wearer to do the work of a diver in the ordinary (flexible) dress. This diving suit is independent of outside air supply, and is designed to withstand the pressure due to the head of water at which the diver is working. The diver, therefore, breathes air at normal atmospheric pressure, thereby eliminating the effects due to excessive air pressure. Connection with the ship can be maintained by a cable and communication effected by a telephone. A diver equipped with the dress has recently (Aug. 1928) worked on the wreck of the Belgian steamer "Elizabethville," sunk in 1917 off Belle Isle, at a depth of 240 feet.

Diving Bells.—The first designer of the diving bell may have received inspiration from the water spider which makes its home in a bell-shaped chamber of silk, anchored, orifice downwards, by silken threads to water-weeds, etc. The hairs which cover the hinder part of the spider's body are long and hooked at the ends, and have the power of entangling air, so that, when it dives beneath the surface, the insect is partially enveloped in a bubble. The bell when first made is, of course, full of water. To expel the water, the spider disengages the bubble of air inside the bell, and so displaces a little water, the operation being repeated until the water is replaced entirely by air, the latter being re-oxygenated by the same process. Pressure of water increases with its depth. Sink a diving bell to a depth of, say 33ft., and the air inside it will be compressed to about one-half its original volume, and the bell itself will be half filled with water. But keep up a supply of air at a pressure a little above that which is equal to the depth at which the bell is submerged, and you will not only keep the water down to the lower edge of the bell, you will also ventilate it and enable its occupants to work for hours at a stretch.

FIG. 10— FEATURES OF THE SELF-CONTAINED DIVING DRESS, AN APPARATUS WHICH NEEDS NO AIR SUPPLY FROM THE SURFACE

1. Front view, showing emergency oxygen and air cylinder in weighted chamber
2. Back view, showing oxygen and air cylinder, and exhaled-air purifying chamber
3. New German self-contained diving dress, invented by Neufeldt and Kuhnke. Made of cast steel cylinders, it permits diver to explore freely at depth of 40 fathoms (240 feet)

Tradition gives Roger Bacon, in 1250, the credit of being the originator of the diving bell, but actual records are not to be had. Of the records preserved to us, the most trustworthy is the description in the *Philosophical Transactions of the Royal Society*, 1717, of Dr. Edmund Halley's bell, constructed of wood, and supplied with air by means of two closed barrels, with a hole in the bottom, and with a leathern tube, connected at the top, the open end of the tube falling below the bottom of the barrel. The barrels were lowered and raised alternately. When the tubes were taken into the bell, the pressure of water, acting through the hole in the bottom of the barrel, forced the enclosed air into the bell.

FIG. 11.— SECTIONAL VIEW OF A DIVING BELL OF THE ORDINARY TYPE Open at the bottom, the water is kept out by compressed air pumped down from the surface. Illustration shows inlet valve, lenses, telephonic apparatus, electric lamps, folding seats, behind which are slabs of cast iron serving as ballast to give the necessary sinking weight to the bell

Fig. 11 illustrates one of several Siebe-Gorman ordinary diving bells, built of steel, as used during the construction of the National Harbour at Dover. Each measured 17ft. long by 10½ft wide by 7ft. high, and weighed 35 tons. It was lighted electrically, and fitted with telephonic apparatus which enabled the bell divers to converse with the engineers and crane and compressor attendants at the surface. Air was supplied to the bell by a steam-driven compressor housed on the gantry which carried the travelling cranes for lowering and raising the bell through the water to a maximum depth of 60ft., and also for lowering the concrete blocks. The air tube for the compressor was connected to a non-return air inlet valve fitted in the crown of the bell. As in the case of the diving dress, an adequate supply of air at the right pressure is maintained to ensure proper ventilation of the bell, the excess escaping at the lower edge of the latter. The bell divers were employed in levelling the sea-bed in readiness to receive the blocks, which weighed 40 tons apiece. Having levelled one section, the bell was moved to the next. The blocks were then lowered, and were placed in position by helmet divers. The bell divers, clad in woollen suits and watertight thigh boots, worked in two-hour to three-hour shifts. The cost of such a bell, with air compressor, telephone and electric lamps, is about £2,000.

The air-lock diving bell comprises a steel working chamber similar to the ordinary diving bell already described, with the addition of a steel shaft attached to the roof. At the upper end of the shaft is an airtight door, and about 8ft. below this is another similar door, the space between the two forming an air-lock. When the men wish to enter the bell, they pass through the first door and close it after them, and then open a valve and let into the lock compressed air from the working chamber till the pressure is equalized; they then open the second door and pass into the main shaft, closing the door after them. Access to the working

chamber is by ladder, secured to the side of the shaft. When returning to the surface, they reverse the operation, opening the lower door, entering the lock and closing the door again; then opening a valve to release the air pressure, when the upper door is opened and the men emerge to atmosphere. Some bells of this type are fitted with two shafts each with its air-lock—one for the passage of the bell men, the other for materials.

See R. H. Davis, *A Diving Manual* (1920); *Report* of *British Admiralty Deep Diving committee* (1907); *U.S.A. Bureau of Mines Report* on possibilities in the use of Welium-Oxygen Mixtures as a Mitigation of Caisson disease (16th Annual Report, 1926).

(R. H. D.)

DIVERTIMENTO (Fr. *Divertissement*), in music, a class of work popular in the 18th century and in the nature of an orchestral suite, consisting of several movements, usually light and simple in character. Mozart wrote many. Serenade and cassation were other names for much the same kind of composition. The same term was also applied to chamber pieces of a similar kind and sometimes to works for one instrument only. In its French form (Divertissement) the term has a wider significance, including pot-pourris, ballets of a light and loosely constructed character (as opposed to the more serious ballet d'action), music played between the acts of a play, and so on.

DIVERTISSEMENT: see DIVERTIMENTO.

DIVES-SUR-MER, a small port and seaside resort of northwestern France in the department of Calvados, on the Dives, 15 m. N.E. of Caen by road. Pop. (1936) 5,183. Dives is the harbour whence William the Conqueror sailed to England in 1066. In the porch of its church (14th and 15th centuries) a tablet records the names of some of his companions. The town has a picturesque inn, adapted from a building dating partly from the 16th century, and market buildings dating from the 14th to the 16th centuries. The coast near Dives has many small watering-places, Cabourg (to the west) and Beuzeval and Houlgate (to the east) being practically united with it. There are large metallurgical works with electric motive power close to the town.

DIVIDE, a term used technically, chiefly in America, for any high ridge forming a water-parting between two valleys. For special senses of the verb "to divide" see DIVISION. In a parliamentary sense, to divide (involving a separation between Aye and No) is to take the opinion of the House by voting on the subject before it.

DIVIDEND, the net profit periodically divided among the proprietors of a joint stock company or corporation in proportion to their respective holdings and as determined by the class of their holdings. From Lat. *dividendum,* a thing to be divided.

Dividend is not interest, although the word dividend is frequently applied to payments of interest; and a failure to pay dividends to shareholders does not, like a failure to pay interest on borrowed money, lay a company open to being declared bankrupt. In bankruptcy a dividend is the proportionate share of the proceeds of the debtor's estate received by a creditor. In England, the Companies Acts provide that no dividend shall be payable except out of the profits arising from the business of the company, but, in the case of companies incorporated by special act of parliament for the construction of railways and other public works which cannot be completed for a considerable time, it is sometimes provided that interest may during construction be paid to the subscribers for shares out of capital. Dividends (excluding occasional distributions in the form of shares) are ordinarily payable in cash.

Preference and Ordinary **Dividends.**—Most companies divide their capital into at least two classes, called "preference" shares and "ordinary" shares, of which the former are entitled out of the profits of the company to a preferential dividend at a fixed rate, and the latter to whatever remains after payment of the preferential dividend and any fixed charges. Before, however, a dividend is paid, a part of the profits is often carried to a "reserve fund." The dividend on preference shares is either "cumulative" or contingent on the profits of each separate year or half year. When cumulative, if the profits of any one year are insufficient to pay it in full, the deficiency has to be made good out of subsequent profits. **A** cumulative preferential dividend is sometimes said to be "guaranteed," and preferential dividends payable by all English companies registered under the Companies Acts 1862 to 1908 are cumulative unless stipulated to be otherwise. There is a growing practice of issuing "deferred" shares which are entitled to no dividends until prior classes of shares receive specified rates of dividend; their speculative character makes them popular and they often stand at high premiums.

Maximum and Sliding Scale Dividends.—Certain British public companies are forbidden by statute to pay dividends in excess of a prescribed maximum rate, but this restriction has been happily modified in some instances, notably in the case of gas companies, by the institution of a sliding scale, under which a gas company may so regulate the price of gas to be charged to consumers that any reduction of an authorized standard price entitles the company to make a proportionate increase of the authorized dividend, and any increase above the standard price involves a proportionate decrease of dividend.

Dividends are usually declared yearly or half-yearly; and before any dividend can be paid it is, as a rule, necessary for the directors to submit to the shareholders, at a general meeting called for the purpose, the accounts of the company, with a report by themselves on its position and their recommendation as to the rate of the dividend. And they have power to pay on account of the dividend for the year, without consulting the shareholders, an "interim dividend," which on ordinary shares is generally at a much lower rate than the final or regular dividend.

Bonus Dividends.—An exceptionally high dividend is often distributed in the shape of a dividend at the usual rate supplemented by an additional dividend or "bonus." Payment of dividends is made by means of cheques sent by post, called "dividend warrants." All dividends are subject to income-tax, and by most companies dividends are paid "less income-tax," in which case the tax is deducted from the amount of dividend payable to each proprietor. When paid without such deduction a dividend is said to be "free of income-tax." In the latter case, however, the company has to make provision for payment of the tax before declaring the dividend, and the amount of its divisible profits and the rate of dividend which it is able to declare are consequently to that extent reduced.

With few exceptions, the prices of securities dealt in on the London Stock Exchange include any accruing dividend not paid up to the date of purchase. At a certain day, after the dividend is declared, the stock or share is dealt in on the Stock Exchange as ex dividend (or "xd"), which means that the current dividend is paid not to the buyer but to the previous holder, and the price of the stock is lower to that extent. The expression "cum dividend" is used to signify that the price of the security dealt in includes a dividend which, in the absence of any stipulation, might be supposed to belong to the seller of the security. On the New York Stock Exchange the invariable practice is to sell stock with the "dividend on" until the company's books are closed, after which it is usually sold "ex dividend." The bonus dividend is designated as an extra dividend; it may be paid in cash or stock. (*See* STOCK EXCHANGE; CUM DIVIDEND.)

DIVIDING ENGINE, an instrument used in engineering and physics for constructing finely divided scales, ruling the diffraction—gratings used in spectroscopy (*q.v.*) and so on. (*See* GRADUATION.)

DIVIDIVI, the native and commercial name for the astringent pods of Caesalpinia coriaria, a leguminous shrub of the subfamily Caesalpinioideae, growing in open, semi-arid regions, especially above tidal flats of the coast from Mexico to northern South America and the West Indies. The plant is between 20 and 30 ft. in height and bears white flowers. The pods are flattened and curl up in drying; they are about $\frac{3}{4}$ in. broad, from 2 to 3 in. long and of a rich brown colour. Dividivi was first brought to Europe from Caracas in 1768. The pods yield a high percentage of tannin of exceptional qualities.

DIVINATION, the process of obtaining knowledge of secret or future things by means of oracles, omens or astrology, from contact with superhuman or divine sources. Divination is practised in all grades of culture. The information is commonly held

to come directly or indirectly from superior, non-human sources. In the Bornean cult of the hawk the divine bird is regarded as knowing the future, or as a mere messenger. Divination is largely employed to discover the cause of death, where it is assumed to be due to magic. In some cases the spirit of the dead man is held to give the information, in others the living magician is the source of the knowledge.

Divinatory methods may be classified as: (a) internal, conditioned by change in the consciousness of the soothsayer; (b) external (a) Internal methods depend on (i.) sensory or (ii.) motor automatisms, or (iii.) mental impressions, for their results. (*i.*) Crystal-gazing is analogous to dreams, except that the vision is voluntarily initiated, though little, if at all, under the control of the scryer. Shell-hearing and similar methods are less common. In these the information is gained by hearing a voice. (*ii.*) The divining rod (*q.v.*) is the best known example of this class. In mediaeval and modern times water-divining or dowsing (*q.v.*) has been largely and successfully used. Similarly a sieve held suspended gives indications by turning; and divination by a suspended ring is found from Europe in the west to China and Japan in the east. The ordeal by the Bible and key is equally popular; the book is suspended by a key tied in with its wards between the leaves and supported on two persons' fingers, and the whole turns round when the name of the guilty person is mentioned. Divination by automatic writing is practised in China. Trance speaking may be found in any stage of culture and in many cases the procedure of the magician or shaman induces a state of auto-hypnotism; at a higher stage these utterances are termed oracles (*q.v.*) and are believed to be the result of inspiration. (*iii.*) Observation shows that by the aid of mental impressions, akin to clairvoyance (*q.v.*), fortunes are told successfully by means of palmistry or by laying the cards; for the same "lie" of the cards may be diversely interpreted to meet different cases. In other cases the impression is involuntary or less consciously sought, as in dreams (*q.v.*), which, however, are sometimes induced for purposes of divination by the process known as incubation or temple sleep. Dreams are sometimes regarded as visits to or from gods or the souls of the dead, sometimes as signs to be interpreted symbolically. (b) In external divination the process is by inference from external facts. The methods are very various. (*i.*) The casting of lots, sortilege, was common in classical antiquity. Similarly dice are thrown for purposes of sortilege; the astragali or knucklebones, used in children's games at the present day, were implements of divination. In Polynesia the coco-nut is spun like a teetotum to discover a thief. In ancient times the poets were often consulted, more especially Virgil, whence the name sortes virgilianae, just as the Bible is used for drawing texts in our own day, especially in Germany. (ii.) In haruspication, or the inspection of entrails, in *scapulomancy* or divination by the speal-bone or shoulder-blade, in divination by footprints in ashes, the diviner must take active steps to secure the conditions necessary to divination. (See also HEPATOSCOPY.) (iii.) In the case of augury and omens (*q.v.*), the behaviour and cries of birds, and meeting with ominous animals, etc., may be voluntarily observed. (iv.) Astrology (*q.v.*) still finds believers among people of good education. (v.) In other cases the tie that binds the subject of divination with the omen-giving object is sympathy. The name of the life-index is given to a tree, animal or other object believed to be united by sympathetic ties to a human being so that the fate of the latter is reflected in the condition of the former. (See the articles AUGURS, ORACLE, ASTROLOGY, OMEN, etc.)

DIVING: see DIVERS AND DIVING APPARATUS.

DIVINING-ROD. The art of using a divining-rod for discovering something hidden is of immemorial antiquity, and the Roman *virgula* divina, used in taking auguries by means of casting bits of stick, is described by Cicero and Tacitus. The particular form of virgula *furcata,* or forked twig of hazel or willow, described by G. Agricola (De re metallica, 1546), and in Sebastian Munster's Cosmography in the early part of the 16th century, used especially for discovering metallic lodes or water beneath the earth, must be distinguished from the general superstition. The "dowsing" or divining-rod dates from its use by prospectors for minerals in the German (Harz mountains) mining districts in the 15th century. The *Schlagruthe* (striking-rod) or forked twig of the German miners was brought to England by the merchant venturers of Queen Elizabeth's days for those engaged in the Cornish mines. As mining declined in Cornwall its use was transferred to water finding.

In modern times the professional dowser (q.v.) is a "water finder," and there has been a good deal of investigation of his claims to be able to locate underground water, where it is not known to exist, by the use of a forked hazel twig which, twisting in his hands, leads him by its directing power to the place where a boring should be made. A widespread faith exists, based on frequent success, in the dowser's power. Prof. Sir W. F. Barrett was satisfied that the rod twists without any intention or voluntary deception on the part of the dowser, and ascribed the phenomenon to "motor-automatism" on the part of the dowser, a reflex action excited by some stimulus upon his mind, which may be either a subconscious suggestion or an actual impression (obscure in its nature) from an external object or an external mind; both sorts of stimulus are possible, so that the dowser himself may infer that the stimulus is an external object (like water). Like the "homing instinct" of certain birds and animals, the dowser's power lies beneath the level of conscious perception; and the forked twig acts as an index of some material or other mental disturbance within him, which otherwise he could not interpret. Not all dowsers use a rod. Some use a willow rod, or withy, others a hazel twig (the traditional material), others a beech or holly twig, or one from any other tree; others even a piece of wire or watch-spring. The best dowsers have generally been more or less illiterate men, engaged in some humble vocation.

DIVISION, a general term for the action of breaking up a whole into parts (from Lat. dividere, to break up into parts, separate). Thus, in political economy, the phrase "division of labour" implies the assignment to particular workmen of the various portions of a whole piece of work; in mathematics division is the process of finding how many times one number or quantity, the "divisor," is contained in another, the "dividend" (see ARITHMETIC and ALGEBRA); in the musical terminology of the 17th and 18th centuries, the term was used for rapid passages consisting of a few slow notes amplified into a florid passage, *i.e.,* into a larger number of quick ones. The word is used also in concrete senses for the parts into which a thing is divided, *e.g.,* a division of an army, an administrative or electoral division; similarly, a "division" is taken in a legislative body when votes are recorded for and against a proposed measure.

In logic, division is a technical term for the process by which a genus or wider class is differentiated into its sub-classes or species. Thus the genus "animal" may be divided, according to the habitat of the various kinds, into animals which live on land, those which live in water, those which live in the air. Each of these may be subdivided according to whether their constituent members do or do not possess certain other qualities The basis of each division is called the *fundamentum* divisionis. It is clear that there can be no division in respect of those qualities which make the genus what it is. The various species are all alike in the possession of the generic attributes, but differ in other respects; they are "variations on the same theme" (Joseph, Introduction to Logic, 1906); each one has the generic, and also certain peculiar, qualities (*differentiae*), which latter distinguish them from other species of the same genus. The process of division is thus the obverse of classification (*q.v.*); it proceeds from genus to species,

whereas classification begins with the particulars and rises through species to genera. In the exact sciences, and indeed in all argument both practical and theoretical, accurate division is of great importance. It is governed by the following rules. (1) *Division must be exhaustive;* all the members of the genus must find a place in one or other of the species. Rectilinear figures are not correctly divided into triangles and quadrilaterals because there are rectilinear figures which have more than four sides. On the other hand, triangles can be divided into equilateral, isosceles and scalene, since no other kind of triangle can exist. (2) *Division must be exclusive,* that is, each species must be complete in itself and not contain members of another species. No member of a genus must be included in more than one of the species. (3) In every division *there must be but one principle* (*fundamentum divisionis*). The members of a genus may differ from one another in many respects; *e.g.,* books may be divided according to external form into quarto, octavo, etc., or according to binding into calf, cloth, paper-backed and so on. They cannot, however, be divided logically into quarto, paper-backed, novels and remainders. When more than one principle is used at the same time in a division it is called "cross division." (4) *Division must proceed gradually* ("Divisio non facit saltum"); *i.e.,* the genus must be resolved into the next ("proximate") species. To go straight from a *summum genus* to very small species is of no scientific value.

It is to be observed that logical division is concerned exclusively with universals or concepts; division is of genus and species, not of particulars. Two other kinds of division are recognized: *metaphysical division,* the distinction in thought of the various qualities possessed by an individual thing (a piece of lead has weight, colour, etc.), and *physical division* or *partition,* the breaking up of an object into its parts (a watch is thought of as being composed of case, dial, works, etc.). Logical division is closely allied with logical definition (*q.v.*).

In military science, "division" is the term which is given to a higher formation of an army. The infantry division is a permanent formation of all arms, and it is provided with all the necessary means for subsisting, marching, and fighting independently of any other formation. Divisions as we know them to-day were first formed by the French in 1770; but it was not till a hundred years later that they became a permanent part of the army in peace time. At the opening of the World War the French division, which may be taken as typical of European practice, comprised two infantry brigades, each of two 3-battalion regiments, a cavalry squadron, two artillery groups each of three 6-gun batteries, engineer, medical and administrative units, in all 12,000 men and 36 guns. The Prussian army introduced the divisional system at the opening of the Wars of Liberation in 1813, and it was adopted for the whole German army after the war of 1866, and continued in essentials unchanged down to 1914. Other European armies were slower to follow suit, but by the end of the 19th century practically all had done so.

In the British army the division had been the highest tactical and administrative unit throughout all the wars from the Peninsular to the Boer War; but it did not really become a part of the peace-time organization till the period of Lord Haldane's reforms in 1906. At the opening of the World War the British division differed in some important particulars from its continental counterparts, consisting as it did of three infantry brigades, each of four battalions, four artillery brigades, each of three 6-gun batteries, one 60-pdr. battery, three field companies of engineers, three field ambulances, a signal company, and administrative units such as the divisional ammunition column, a supply train and a veterinary section. Numerically it was considerably stronger than the average Continental division.

During the World War in all the belligerent armies the division became the tactical and administrative unit. Various modifications took place in its internal composition: by 1918 the strength of the infantry had been greatly reduced, though the number of machine-guns and automatic weapons had increased; divisional cavalry had disappeared; and the proportion of artillery and administrative units was larger. The majority of the remodelled armies of the post-war period show similar tendencies in the composition of their higher formations. The division tends more and more to become the kernel of peace-time armies. The numerical reduction of the infantry has gone hand in hand with a re-armament which has greatly increased its fire power and its potentialities for attack and defence, including defence against tanks. Divisional cavalry on the other hand has been generally reintroduced; while the lavish artillery allotment necessary for position war has been reduced to an amount considered more suitable for mobile operations. Finally, the mechanization of transport has considerably increased the radius of action of the whole formation.

In the British army, however, these tendencies have perhaps been less marked than elsewhere. The 4-battalion infantry brigades have been retained; the artillery, signal, engineer and medical units remain much as before the war, and no divisional cavalry has been allotted. The great increase in infantry fire power has, however, been fully maintained, and the mechanization of transport has proceeded further than in any other army; so that though the framework of the British division has changed but little in broad outline, it is to-day a far more powerful engine of war than its prototype which took the field in Aug. 1914.

Cavalry divisions were first formed in war in the time of the first Napoleon; but though they became part of the French peace-time organization in 1875, the Germans, in common with the majority of European armies, had few or none in peace, and formed them as required on the outbreak of war. They usually comprised six regiments, organized in two or three brigades, with horse artillery and ancillary units. Since the World War, in which, after the early stages, at any rate in the European theatres, cavalry were rarely able to carry out their normal functions, the general tendency has been to remodel them as light divisions, of which cavalry form only a proportion of the combatant strength; mechanized units, such as armoured cars, motor machine-guns, cyclists, artillery and mechanical transport, have been added to increase mobility and fire power. (*See* ARMY.)

United States Army.—The division is at present the highest tactical and administrative command in the United States army in time of peace. Prior to the World War the regiment was the highest. Provisional manoeuvre divisions were assembled in Texas in 1911 and again in 1913, largely under the influence of conditions on the Mexican border. Theirs, however, was only a transitory existence. The 1928 divisional organization of the army of the United States is a World War development. It preserves on the one hand the designations which have become historic on the battlefields of France and Flanders, and on the other hand embodies the results of World War experience. The actual strength of the army necessitates, however, the maintenance of these divisions in highly skeletonized form. The command consists of two infantry brigades of two regiments each; a field artillery brigade of two regiments, with a total of 48 French 75 mm. guns; one regiment of engineers; a medical regiment; an observation squadron; division trains and special troops, such as military police, tank, signal, ordnance and headquarters companies, complete the organization of an infantry division which is commanded by a major general. The total war strength of this organization is 20,030 officers and enlisted men. In a single column it occupies 28·1 m. road space and requires 72 standard type railway trains for its transportation.

DIVORCE. It is the general rule that marriage is contracted for an indefinite length of time or for life, although even in the latter case it may very frequently be dissolved, for some reason or other, during the lifetime of the partners.

Lower Culture Groups.—Among a few uncivilized peoples marriage is said to be indissoluble or divorce unknown, and among many others divorce is said to be rare or marriage as a rule to last for life; but there are also many tribes in which divorce is reported to be of frequent occurrence or marriage of very short duration. Owing to the defective character of the information it is impossible to say anything definite about the comparative prevalence of lifelong unions and of divorce among the lower races in general, or about the duration of marriage at the different grades of economic culture compared with one another. It is interesting, however, to note the universal ar almost universal

prevalence of lifelong unions among some of the lower hunters and incipient agriculturists, such as the Veddas of Ceylon, the Andamanese, the Orang Mamaq and Orang Akit of Sumatra, and the "pure" tribes of the Malay Peninsula. Somewhat more definite than the information we possess of the actual prevalence of divorce among the simpler peoples are the statements as to the circumstances in which their customs allow it to he practised. Among a large number of tribes the husband is said to be able to dissolve the marriage at will or on the slightest grounds or pretexts, and in the majority of these cases a similar right is granted to the wife. But we are also frequently told that a man must not divorce his wife and a wife not separate from her husband without just or good cause. The most generally recognized ground for divorce is probably adultery on the part of the wife; and among some peoples the wife is said to have a right to divorce an unfaithful husband. A very frequent cause of divorce is barrenness in the wife, while the birth of a child may make marriage indissoluble; and sometimes we are told that the wife can effect divorce if the husband proves impotent. There are a variety of other recognized grounds for divorce more or less frequently found in the savage world. A man may divorce his wife if she is lazy or neglectful; if she suffers from a foul or incurable disease; if she becomes too old; if all her children die; or, of course, if she deserts him The wife. again, may dissolve the marriage if the husband neglects or ill-treats her, if he deserts her or if she has a strong repugnance to him. Among some natives of Eastern Central Africa the wife may divorce a husband who fails to sew her clothes. Among the Shans of Burma, should the husband take to drinking or otherwise misbehave, the wife has the right to turn him adriit and to retain all the goods and money of the partnership.

Early China and Japan.—Among the peoples of ancient civilization the stability of marriage is not less variable than it is among the lower races. The old penal code of China says that if a man repudiates his wife "without her having broken the matrimonial connection by the crime of adultery or otherwise, and without her having furnished him with any of the seven justifying causes of divorce," he shall in every such case be punished with 80 blows. The seven causes in question are: barrenness. lasciviousness, disregard of the husband's parents, talkativeness, thievish propensities, envious and suspicious temper and inveterate infirmity. Yet none of these seven causes will justify a divorce if the wife has mourned three years for the husband's parents, if the family has become rich since the marriage after being poor previously, or if the wife has no parents living to receive her back again. In practice, however, the husband's power of divorce was no doubt greater than it was according to the letter of the law. On the other hand, it does not seem that either law or public opinion justified a wife in deserting her husband or demanding a separation from him. The divorce law of the Japanese Taihō code was substantially the same as that in China, but practically a wife could be divorced at the pleasure of her husband under any slight or flimsy pretext. As in China, the wife had no legal right to demand a divorce from her husband on any ground. This was the case till the year 1873, when a law was enacted which for the first time allowed the wife to bring an action of divorce against the husband; and the new civil code, promulgated in 1896–98, went further in the same direction. Prof. Hozumi, in his commentaries on this code, says that it places husband and wife on an equal footing with regard to the right of divorce; but it does not seem that mere adultery on the part of the husband gives the wife a right to divorce him, although he can divorce an unfaithful wife. Divorces are very frequent in Japan, but since the new code came into force their number has rapidly decreased. In 1897 the proportion of divorces to marriages was 34%, in 1900 it was 18·5%.

Semitic Peoples.—Among Semitic peoples the husband has had, or still has, the legal right of repudiating his wife at will. In Babylonia, according to the Laws of Hammurabi, however, the wife and even a concubine had certain pecuniary guarantees against arbitrary divorce, and she might also herself in certain circumstances claim a divorce, or at least separation. The right of the husband to repudiate his wife at his pleasure is the central thought in the system of Jewish divorce law; and the Rabbis neither did nor could set it aside, although they gradually tempered its severity by numerous restrictive measures. It ceased to exist in practice, and was at last, in the earlier part of the 11th century, formally abolished, whereas the husband retained the right to divorce his wife if a good cause could be shown. On the other hand. the wife has no right to divorce her husband But the Mishnah allowed her to sue for divorce, and if the court decided that she mas entitled to be divorced the husband was forced to give her a bill of divorce, although he was supposed to give it of his own free will and accord At Jewish law the wife may demand a bill of divorce from her husband if he repeatedly ill-treats her, if he is guilty of notorious dissoluteness of morals, if he wastes his property and refuses to support her, if he suffers from some loathsome chronic disease contracted after marriage, if he is physically impotent, and for a few other reasons. For divorce by mutual agreement no specific causes are required. As the ancient Hebrews, so the pagan Arabs permitted the husband to repudiate his wife whenever he pleased, and subsequently this unlimited customary right was crystallized in Mohammed's law. And at Mohammedan, as at Jewish law, the wife can never divorce her husband, although she may take steps leading to the dissolution of her marriage. When she desires 2 divorce, she may obtain from him a release from the marriage contract by giving up either her settled dower or some other property; and when the husband is guilty of conduct that makes the matrimonial life intolerable to the wife or when he fails to fulfil his engagements, she has the right of preferring a complaint before the judge and demanding a divorce by authority of justice. But the facility with which Mohammedan women can effect a dissolution of their marriage is influenced by local custom. So also the frequency of divorce differs considerably in diffcrcnt parts of the Mohammedan world. In some parts it is practised to an extent that is almost without a parallel; whereas among the Mohammeddns of India the husband seldom exercises his right to divorce his wife without any special reason. This may be due to Hindu influence.

Hindu Practice.—With orthodox Hindus marriage is a religious sacrament which cannot be revoked A woman convicted of adultery may be deprived of her status and turned out of her caste, but even in this case divorce in the ordinary sense is an impossibility. The law, however, was not always equally stringent. At present the orthodox Hindu law of divorce is more or less disregarded by certain low castes in the north of India and by many castes, both high and low, in the south. among whom usage has superseded texts; agreeably to such usage the granting of a divorce, or the recognition of a divorce as one properly made, is the duty of the caste.

Early Greeks and Romans.—Among the Greeks and Romans in the early days, as among the Hindus, marriage evidently was a union of great stability, although in later times, contrary to what was the case among the Aryans of India, it became extremely easy and frequent. Among the Greeks of the Homeric age divorce seems to have been almost unknown, but afterwards it became an everyday event in Greece. According to Attic law the husband could repudiate his wife whenever he liked and without stating any motives, while the wife could demand a divorce by appealing to the Archon and stating the motives for her demand. A Roman marriage was perhaps at no time indissoluble, but the specifically patrician kind of marriage, by *confarreatio,* was at any rate very nearly so. The other fcrms of marriage, not being of the same mystical and sacramental character, could be dissolved without difficulty. The husband's legal authority in regard to the dissolution of a marriage with *manus* was absolute, whereas in the old law a wife *in manu* was as little a free party to the act of divorce as a child was a free party to that of emancipation. Yet in practice the husband's right was no doubt more or less checked by public opinion and, as it seems, even by the Censors; it was said that for 500 years no one took advantage of the liberty of divorce. In regard to a "free" marriage. which implied that the wife did not fall under the *manus* of her husband, the rule of divorce was very different: the dissolution of such a marriage

could be brought about either by mutual agreement between both parties or by the will of one party only. The rules of divorce that were recognized in the case of a free marriage were afterwards practically extended to marriages with *manus;* and in the end marriages with *manus* fell into disuse altogether. Towards the close of the Republican era and during the Empire divorce was very frequent among the upper classes; almost all the well-known ladies of the Ciceronian age were divorced at least once.

Celtic and Teutonic Peoples.—In the Celtic law-books, various rules relate to divorce, from which we may draw the conclusion that separation of married couples was by no means an uncommon occurrence. In ancient Ireland it might take place either by mutual consent or as the outcome of legal proceedings; and with reference to the latter kind of separation, one of the Breton law tracts specifies seven different causes for which a married woman may separate from cohabitation without losing her dowry. According to the old customary law of the Teutonic peoples a marriage could be dissolved by agreement between the husband and the woman's kin; and the husband was entitled to repudiate his wife if she was sterile or guilty of conjugal infidelity and perhaps for some other offences. On the other hand the wife had originally no right to dissolve the marriage.

Divorce (legal) is the dissolution, in whole or in part, of the tie of marriage. In the main the practice in the legal systems of the civilized world is derived from the Roman law and the teachings and canons of the Christian religion. In countries in which the Roman Catholic creed is supreme, subject to certain exceptions indicated later, complete divorce *a vinculo matrimonii* (the bond of marriage) is not legally possible, though the same result may be achieved in rare cases by the ecclesiastical courts declaring that the marriage was a nullity owing to duress or other causes. The partial decree of divorce *a mensa et thoro* (from bed and board), which is still the practice in the Irish Free State and other Roman Catholic countries, and in English law is represented by judicial separation, leaves the parties still married, neither being able to remarry during the lifetime of the other. In the end it was due to the spread of Christianity and the authority of the Church of Rome that marriage came to be regarded not merely as a civil contract but as a sacred bond net lightly to be severed by the spouses or by the State.

How far the Founder of the Christian religion laid down any moral law in regard to divorce has always been a matter of controversy, owing to the form of His declaration that has come down to us, and the different conceptions then existing of the connubial relations, monogamy, so far as a husband was concerned, not having been established. The rule of the Mosaic law was expressed as follows: "When a man hath taken a wife, and married her, and it come to pass that she find no favour in his eyes, because he hath found some uncleanness in her, then let him write her a bill of divorcement, and give it in her hand, and send her out of his house. And when she is departed out of his house, she may go and be another man's wife" (Deut. xxiv. 1–2).

The Pharisees asked Jesus: "Is it lawful for a man to put away his wife for every cause?" Jesus replied: "What God hath joined together let no man put asunder," and also said: "Moses, because of the hardness of your hearts, suffered you to put away your wives; but from the beginning it was not so." Then came the declaration which is the main basis of the canon law: "Whosoever shall put away his wife, except it be for fornication, committeth adultery; and whoso marrieth her which is put away doth commit adultery" (Matt. xix.). Practically the same formula was used in the Sermon on the Mount (Matt. v. 32) and also in Luke xvi. 18, and Mark x. 11–12.

The Roman Church has always interpreted the exception of fornication as applying only to incontinence by the wife before marriage discovered by the husband after marriage, and has treated it, not as just cause for dissolution of marriage, but as invalidating the marriage itself. It will be observed also that right down to the present century incontinence has been regarded as a matrimonial offence only if committed by the wife. In most countries where the civil law allows complete divorce husband and wife are now on an equal footing as to the grounds of divorce. In England the jurisdiction of the divorce court extends to nullity (*q.v.*) jactitation and restitution of conjugal rights *(see* below) and legitimation (*q.v.*).

The Roman Law of Divorce.—The history of divorce took its earliest colour from that conception of the *patria potestas,* or the power of the head of the family over its members, which enters so deeply into the jurisprudence of ancient Rome. The wife was transferred at marriage to the authority of her husband, *in manus,* and consequently became so far subject to him that he could, at his will, renounce his rule over her, and terminate his companionship, subject at least to an adjustment of the pecuniary rights which were disturbed by such action. As early, however, as the time of Romulus, it is said that the State asserted its interest in the permanence of marriage by forbidding the repudiation of wives unless they were guilty of adultery or of drinking wine, on pain of forfeiture of the whole of an offender's property, one-half of which went to the wife, the other to Ceres. But the law of the XII. Tables, in turn, allowed freedom of divorce. At last the *lex Julia de adulteriis,* while recognizing a power of divorce both in the husband and in the wife, imposed on it, in the public interest, serious restrictions and consequences. It required a written bill of divorce *(libellus repudii)* to be given in the presence of seven witnesses, who must be Roman citizens of age, and the divorce must be publicly registered. In this way a wife could divorce a lunatic husband, or the *paterfamilias* of a lunatic wife could divorce her from her husband. The *lex Julia* was followed by a series of acts of legislation extending and modifying its provisions.

In AD. 449 the law of divorce was rendered simpler and more facile by Theodosius and Valentinian.

The modification in the civil law of Rome effected by Justinian under the joint influence of the previous law of Rome and that of Christianity was remarkable. Divorce by mutual consent, hitherto, as we have seen, absolutely free, was prohibited except in three cases: (1) when the husband was impotent; (2) when either husband or wife desired to enter a monastery; and (3) when either of them was in captivity for a certain length of time. At a later period Justinian, under the influence of the Christian idea of marriage, placed a further restriction or even prohibition on divorce by consent by enacting that spouses dissolving a marriage by mutual consent should forfeit all their property, and be confined for life in a monastery, which was to receive one-third of the forfeited property, the remaining two-thirds going to the children of the marriage. The prohibitions of Justinian on divorce by consent were repealed by Justin, his successor.

Justinian further re-enacted, with some modifications, the power of divorce by a husband or wife against the will of the other. Divorce by a wife was allowed in five cases: (1) the husband being party or privy to conspiracy against the State; (2) attempting his wife's life, or failing to disclose to her plots against it; (3) attempting to induce his wife to commit adultery; (4) accusing his wife falsely of adultery; (5) taking a woman to live in the house with his wife, or, after warning, frequenting a house in the same town with any woman other than his wife. A husband was allowed to divorce his wife for any one of seven reasons: (1) failure to disclose to her husband plots against the State; (2)

adultery; (3) attempting or failing to disclose plots against her husband's life; (4) frequenting dinners or balls with other men against her husband's wishes; (5) remaining from home against the wishes of her husband except with her parents; (6) going to the circus, theatre or amphitheatre without the knowledge of, or contrary to the prohibition of, her husband; (7) procuring abortion.

The canon law of Rome was based on two main principles: (1) That there could be no divorce a *vinculo matrimonii,* but only a mensa et thoro, *i.e.,* separation. (2) That no divorce could be had at the will of the parties, but only by the sentence of an ecclesiastical court, The papal canon law allowed a divorce a mensa et *thoro* for six causes: (1) adultery or unnatural offences; (2) impotency; (3) cruelty; (4) infidelity; (5) entering into religion; (6) consanguinity. The church, however, always assumed to itself the right to grant licences for an absolute divorce.

Divorce in England. — In England the law of divorce, being based on the canon law of Rome, was practically unchanged until the Matrimonial Causes Act 1857. Divorce a mensa et thoro could only be granted by the ecclesiastical courts, which were invested with this jurisdiction until 1857. These were the courts of the various dioceses, including that of the archbishop of Canterbury, the court of arches, and that of the archbishop of York, the consistory court of York. An appeal lay to special delegates appointed by the Crown ad koc, until in 1836 the judicial committee of the privy council was given this appellate jurisdiction. Adultery and cruelty were the main grounds for this sort of divorce allowed by the ecclesiastical courts, and the principles acted upon by those courts are still those imposed by statute upon the present courts in regard to judicial separation, except that desertion was added by the 1857 act as a ground for a decree. As regards adultery a mere confession by a spouse of her guilt was not regarded by the canon law as a safe ground for a decree, if uncorroborated, and in the present practice in cases for dissolution of marriage a confession has to be supported by some sort of circumstantial evidence in the English court. In general the principle was accepted, and is still the rule, that if an illicit affection is proved and there are opportunities by association to gratify a guilty passion, then a prima facie case is made out, justifying a decree if there is no defence.

As regards cruelty the definition accepted by the ecclesiastical courts as that of the canon law is the same now. It was accepted by the House of Lords in *Russell* v. Russell (1897, A.C. 395), in which "legal cruelty" was defined as conduct of such a character as to have caused danger to life, limb or health (bodily or mental), or as to give rise to a reasonable apprehension of such danger. Those who wish to read the classic exposition on the subject of legal cruelty should read the judgment of Lord Stowell, one of the greatest English masters of the civil and canon law, in the case of Evans v. Evans (1790, 1. Hagg. Con., 35). Since then there have been innumerable decisions all showing that the court is not bound by any cast-iron rule in its interpretation of what constitutes cruelty within the range of this definition.

Apart from a bare denial the canon law allowed three grounds of answer: (1) *Compensatio criminis,* or the committal by the spouse bringing the charge of the same matrimonial offence, in which case the petitioner could be refused relief; (2) Condonation: the complete forgiveness of the offendingspouse by the other with full knowledge of the facts. Resumption by a husband of marital relations with his wife when he has full knowledge of her adultery is conclusive proof of condonation under the English divorce law, but resumption by a wife of marital relations with a guilty husband, with full knowledge, is not necessarily conclusive proof of condonation on her part. A matrimonial offence even of a different kind revives the former one, even if condoned. Condonation was a bar to relief, and still is. (3) Connivance: this is also a bar to relief, and always was, as it was held that a man could not avail himself of a charge if he did not appear with clean hands. The presumption of law is against connivance, and the intention must be clearly shown for the court to refuse the petitioner relief. The petitioner need not be the active agent in the adultery of the other spouse. He may be guilty of connivance merely by neglect or indifference, though in that case the modern plea under the English statute law would probably come under the head of conduct conducing, which is in some cases hardly distinguishable from connivance, and may equally be held a bar to relief.

Collusion between the parties for the purpose of presenting a false case to the court was also held by the ecclesiastical courts to be a bar to relief, whether it was an agreement to give the appearance of having committed adultery when none had occurred or merely to withhold material facts from the knowledge of the court. In the present law of divorce in England collusion may be held to exist not only when a false case is presented, but also where there is a good case. Thus in a recent suit where the husband made provision for the future of his wife pending divorce proceedings Lord Merrivale, president, though granting a decree, uttered a warning against any transaction pending divorce proceedings which raised a suspicion of collusion. In a more recent case a divorce petition was dismissed in the first place owing to an agreement by which the petitioner received a certain sum in advance in respect of damages from the co-respondent, and his second petition on a later charge was dismissed because by taking such sum he had connived at the further adultery of his wife.

The ecclesiastical courts provided for the pecuniary rights of the wife by granting to her alimony during the progress of a suit, and a proper allowance after its termination in cases in which she was successful. Such payments were dependent on the pecuniary means, or faculties, as they were termed, of the husband, and were subject to subsequent increase or diminution in proper cases. But the ecclesiastical courts did not deal with the custody of the children of the marriage, it being probably considered that that matter could be determined by the' common law rights of the father, or by the intervention of the court of chancery.

As regards suits for divorce any substantial delay might lead to the imputation of acquiescence or even condonation. To that extent, at least, the maxim *vigilantibus* non dormientibus jura *subveniunt* applied. Desertion by either party to a marriage, except as giving rise to a suit for restitution, was not treated as an offence by canon law in England. It formed no ground for a suit for divorce, and constituted no answer to such a suit by way of recrimination. It might indeed deprive a husband of his remedy if it amounted to connivance, or perhaps even if it amounted only to culpable neglect.

Conjugal rights are those rights which a husband and wife have to each other's society. When either party continues to refuse to render these rights to the other, they may be enforced by a suit for the restitution of conjugal rights. Until the grounds of complete divorce were equalized in 1923, the procedure of restitution was mainly used by wives to shorten the statutory period of desertion, non-compliance by the husband with a decree being followed by the wife's petition for divorce on the dual grounds of adultery and desertion.

Jactitation of marriage is a persistent claim by a person of a marriage falsely alleged to have taken place between himself or herself and the complainant, who petitions for a decree enjoining perpetual silence on the person alleging such marriage in regard to it. In these days such a remedy is rarely required, though it was not an uncommon proceeding when "Fleet" and other irregular marriages were frequent and rights to property were involved. The procedure might still be useful for obtaining a declaration as to the validity of a disputed marriage in cases where the procedure under the Legitimacy Declaration Act 1858, now re-enacted in the Supreme Court of Judicature (Consolidation) Act 1925, is not convenient or applicable. The most historic case in which jactitation arose was the duchess of Kingston's case in 1776, reported in the State Trials. The last reported case was in 1922 when the petition was dismissed.

Criminal Conversation. — Up to the Matrimonial Causes Act 1857, a husband could bring an action for damages against his wife's paramour (action for criminal conversation). It was a common law suit, and the damages were estimated according to the loss he was supposed to have suffered by the seduction and loss of his wife. This procedure was abolished by the

1857 act and engrafted upon the new procedure in divorce, by way of a separate prayer for damages against the co-respondent in a petition for dissolution. In theory the damages are assessed on the same principle, though in practice a jury often fixes the amount at a figure calculated to inflict a severe punishment on the co-respondent. If a petitioner for divorce or the respondent (husband) die before the petition comes to trial, the petition is "abated," *i.e.,* abandoned, the matrimonial tie having been dissolved by death. But if it is the respondent wife who dies the husband's prayer for damages against the co-respondent may be pursued to trial.

It was for some time supposed after the Reformation that the sentences of divorce pronounced by the ecclesiastical courts acquired the effect of allowing remarriage, and such divorces were in some cases granted. In Lord Northampton's case in the reign of Edward VI. the delegates pronounced in favour of a second marriage after a divorce a mensa et *thoro*. It was, however, finally decided in *Foljambe's* case, in the 44th year of Elizabeth, that a marriage validly contracted could not be dissolved for any cause. In 1669 a private act of parliament was granted in the case of Lord de Roos, and this was followed by another in the case of the duke of Norfolk in 1692. Such acts were, however, rare until the accession of the House of Hanover, only five acts passing before that period. The jurisdiction thus assumed by parliament to grant absolute divorces was exercised with great care.

The Act **of** 1857.—The Matrimonial Causes Act (which came into operation on Jan. 1, 1858) embodied two main principles: 1. The constitution of a lay court for the administration of all matters connected with divorce. 2. The transfer to that court, with as little change as possible, of the powers exercised in matrimonial matters by (a) the House of Lords, (b) the ecclesiastical courts, (c) the courts of common law.

The functions of the new court, termed "The Court for Divorce and Matrimonial Causes," were practically entrusted to the judge of the court of probate (which was also established in 1857), termed the "Judge Ordinary," who thus in matters of probate and divorce became the representative of the former ecclesiastical jurisdiction. The parties to a suit obtained the right of trial by jury of all disputed questions of fact; and the rules of evidence of the common law courts were made to apply. An appeal to the full court was given in all matters, which the judge ordinary was enabled to hear sitting alone.

1. To this court were transferred all the powers of the ecclesiastical courts with regard to suits for divorce a *mensa* et tlzoro, to which the name was given of suits for "judicial separation," nullity, restitution of conjugal rights, and jactitation of marriage, and in all such proceedings it was expressly enacted (s. 22 [now comprised in ss. 32 and 103 of the Judicature (Consolidation) Act 1925]) that the court should act on principles and rules as nearly as possible conformable to the principles and rules of the ecclesiastical courts. Judicial separation could be obtained by either husband or wife for adultery, or cruelty, or desertion continued for two or more years.

2. There were also transferred to the court powers equivalent to those exercised by the legislature in granting absolute divorce. The husband could obtain a divorce for adultery, the wife could obtain a divorce for adultery coupled with cruelty or desertion for two or more years, and also for incestuous or bigamous adultery, or rape, or unnatural offences. As has been explained above, connivance, condonation or collusion continued to be absolute bars to divorce, and the court was given discretion to refuse relief where the petitioners had been guilty of adultery or conduct conducing to the respondent's adultery or had delayed unreasonably in prosecuting his suit.

This act assigned a new force to desertion. The ecclesiastical law regarded it only as suggestive of connivance or culpable neglect. But the act of 1857 made it (1) a ground of judicial separation if continued for two years, (2) a ground in part of dissolution of marriage if continued for the same period, (3) a bar, in the discretion of the court, to a petition for dissolution, though it was not made a bar to a suit for judicial separation.

S. 32 provided, in case of dissolution, for maintenance of the wife by the husband on principles similar to those recognized by the ecclesiastical courts, and s. 45 for the settlement of the property of a guilty wife on her husband or children. By later acts of 1859 and 1878 provision was made for altering settlements made in view or in consequence of a marriage. The act (s. 35) provides also in all divorce proceedings, and also in those **of** nullity, for provision for the custody, maintenance and education of children by the court. It was made obligatory to join an alleged adulterer in the suit, and damages (s. 33) might be claimed against him, and he might be ordered to pay the cost of the proceedings (s. 34).

The act of 1857 also provided (s. 21) that a wife deserted by her husband might apply to a magistrate in petty sessions and obtain an order which had the effect of protecting her earnings and property, and during the currency of such order of protection a wife was to be in the same position as if she had obtained an order for judicial separation. The effect of this section appears to have been small; but the Summary Jurisdiction (Married Women) Act 1895, now reinforced by the Summary Jurisdiction (Separation and Maintenance) Act 1925, has afforded a cheap and speedy remedy to all classes. The act of 1857 made no provision as to the name to be borne by a wife after a divorce; and this omission led to litigation in the case of a peer's wife, in *Cowley* v. *Cowley* (1901, A.C. 450), in which Lady Cowley was allowed to retain her status.

By the Act of 1860 a very important change was made, having for its object a practical mode of preventing divorces in cases of connivance and collusion or of misconduct of the petitioner. It was provided that a claim of dissolution (a provision afterwards extended to decrees of nullity) should in the first instance be a decree nisi, which should not be made absolute until the expiration of a period then fixed at not less than three, but by subsequent legislation enlarged to not less than six, months. During the interval which elapsed between the decree nisi and such decree being made absolute, power was given to any person to intervene in the suit and show cause why the decree should not be made absolute, by reason of the same having been obtained by collusion, or by reason of material facts not having been brought before the court. At any time before the decree was made absolute, the queen's proctor, if led to suspect that the parties were acting in collusion for the purpose of obtaining a divorce contrary to the justice of the case, might under the direction of the attorney-general intervene and allege such case of collusion. It was established in Sloggett v. Sloggett (1928, 44 The Times L.R., 394) that it was open to the king's proctor by direction of the court to intervene during the progress of a divorce suit before decree *nisi* and to call new evidence, not only when collusion is in question but in regard to other matters.

By an act of 1866 the court was given power to order a guilty husband to make provision for the maintenance of his former wife on the marriage being dissolved, and by an act of 1907 the court was enabled in suitable cases to order the husband to make similar provision when he was the petitioner and she the guilty spouse. From time to time the law of evidence in the divorce court was varied by statute until in 1869 it was enacted that no witness in any proceeding should be asked or be bound to answer any question tending to show that he or she had been guilty of adultery, unless in the same proceeding such witness had given evidence in disproof of alleged adultery.

The Law of Domicile.—No petition for dissolution of marriage can be granted in England unless the husband is domiciled in this country at the commencement of the proceedings. If such domicile is established the court may adjudicate even if the parties are not British subjects, or the marriage was contracted abroad, or at the time of the marriage the parties were not domiciled in England. The wife's domicile is that of her husband. It has been suggested by a series of judicial *obiter* dicta that if a man desert his wife and acquire a domicile abroad the wife may still petition for dissolution of her marriage in the divorce court, but the point has not yet been definitely decided. It has been held, however, that if a woman domiciled in England marry a foreigner domiciled

abroad, and the latter obtains under the law of his domicil a decree of nullity not recognized by English law, she may petition for divorce despite the foreign decree. As regards judicial separation the test of jurisdiction is either residence of both parties, irrespective of domicil or nationality, in England at the time of the institution of the suit, or where the parties are domiciled in England. The English court does not recognize a divorce purporting to be made by a foreign tribunal with reference to persons domiciled in England. This principle was maintained In the prosecution of Earl Russell on a technical charge of bigamy before the House of Lords in 1901, it being held that if a divorce were refused a man in England he would not be relieved from the guilt of re-marrying by securing an American divorce.

Summary Proceedings for Separation. — The legislature has sought to extend the relief afforded by the courts in matrimonial causes by a procedure fairly to be considered within the reach of all classes. In 1895 an act was passed which re-enacted in an improved form the provisions of an act of 1878 of similar effect. By the act of 1895 power was given to a married woman whose husband (1) has been guilty of an aggravated assault upon her within the Offences against the Person Act 1861, or (2) convicted on indictment of an assault on her and sentenced to pay a fine of more than £5 or to imprisonment for more than two months, or (3) shall have deserted her, or (4) been guilty of persistent cruelty to her or wilful neglect to maintain her or her infant children, *and* by *such cruelty or neglect shall have caused her to leave and live aport from him,* to apply to a court of summary jurisdiction and to obtain an order containing all or any of the following provisions: — (1) that the applicant be not forced to cohabit with her husband, (2) that the applicant have the custody of any children under 16 years of age, (3) that the husband pay to her an allowance not exceeding £2 a week. (The words in *italics* have been repealed by the Separation and Maintenance Act 1925, with the result that a wife may now apply to the magistrates notwithstanding that she has not left her home owing to her husband's neglect and cruelty.) The act provides that no married woman guilty of adultery should be granted relief, but with the very important proviso, altering as it does the rule of the common law, that the husband has not conduced or connived at, or by wilful neglect or misconduct conduced to, such adultery.

Recent Developments. — The above is a summary of the law of divorce up to 1910. Since then there have been developments. statutory and otherwise, which may be classified as follows: (1) Matrimonial Causes Act 1923; (2) Poor Persons Rules of litigation; Divorce on Assize; (3) The Decision in *Russell* v. *Russell,* 1924; (4) Extended exercise of the court's discretion; (5) Judicial Proceedings (Regulation of Reports) Act 1926.

The royal commission on divorce and matrimonial causes, after sitting for three years, completed its monumental labours in Nov. 1912, and by a majority report recommended important changes in the substantive law of divorce. The more important recommendations of the majority report were as follows: (a) Hearing of divorce locally by commissioners of the High Court. (b) Powers of magistrates to make orders having the permanent effect of a decree of judicial separation to be abolished, and a simple process in the High Court with that object to be made available; husbands to be entitled to separate orders on the grounds of cruelty, habitual drunkenness, and wilful desertion, equally with wives. (c) Amendment of law so as to place the two sexes on an equal footing as regards the grounds of divorce. (d) New grounds for divorce: (i.) desertion for three years; (ii.) cruelty; (iii.) incurable insanity after five years' confinement; (iv.) habitual drunkenness found incurable after three years from first order of separation; **(v.)** imprisonment under commuted death sentence. (e) Habitual drunkenness as a ground for judicial separation. (f) Provision for overcoming difficulties of jurisdiction as to domicil and residence. (g) (i.) Unsoundness of mind, actual or incipient, at the time of the marriage, if unknown to the petitioner, and (ii.) if a spouse is suffering from a venereal disease unknown to the other, or the wife is pregnant by another man, both at the time of the marriage, to be grounds for nullity. (g) Provision for proceedings in *forma pauperis.* (h) No reports of divorce suits until a case is finished, and divorce judges to forbid or limit reports at their discretion.

In their minority report Dr. Lang (archbishop of York), Sir William Anson, and Sir Lewis Dibdin confined their recommendations to placing the sexes on the same basis as to grounds of divorce, and to accepting the above recommendations as to the ground for nullity, plus that of wilful refusal to consummate the marriage.

By the Matrimonial Causes Act 1923 (sometimes called the Entwhistle Act from the name of its chief sponsor), it was provided that since July 18, 1923, any act of adultery by a husband would entitle his wife to a divorce. This act was repealed but re-embodied in the Judicature (Consolidation) Act 1925. Thus the royal commission's proposal in (c) above was carried into effect, and an immense change made in the law of divorce, in keeping with the spirit of the Sex Disqualification (Removal) Act 1919 (*q.v.*) but in contradistinction to the principle which actuated the divorce statutes of the 19th century. Thus a woman may now divorce her husband for a single act of infidelity. As a consequence of the alteration in the law the number of wives' petitions has increased in a marked degree. Moreover the procedure of restitution of conjugal rights, mostly utilized up to 1923 for the purpose of shortening the statutory period of two years for desertion, has become extremely rare.

By the Administration of Justice Act 1920, provision was made for the local hearing of undefended divorce suits on assize, and of defended Poor Persons' divorce suits, if this venue was suitable In the last year for which statistics are available the number of proceedings commenced in matrimonial causes under the Poor Persons' Rules was 2,150 of which the majority were tried on circuit. This procedure, coupled with the Poor Persons' system, has brought divorce within the range of people whose small means formerly discouraged this resort to the court, and to this extent the recommendations of the divorce commission (a) and (g) have been followed.

By the majority of three law lords to two the House of Lords in *Russell* v. *Russell* (1924, A.C. 687) effected a retrograde movement in the law of evidence by denying to spouses the right of stating on oath anything as to the posaibility of marital access, if such evidence would tend to bastardize a child. The judge of first instance and three lords justices of appeal had admitted the evidence in question, and the majority decision reversed the accustomed practice of the divorce court. The decision has involved undue hardship on poor litigants, but subsequent judgments have reduced its effect to the lowest possible range. If this had been the law before, hundreds of War divorce suits depending on the evidence of the husbands' *simpliciter* as to non-access, in cases where their wives had given birth to children, would have been abortive, owing to the difficulties of securing independent evidence.

Notably since the War, the attitude of the court has changed in several important respects in the direction of greater humanity. Lord Merrivale in his judgment in *Wilson* v. *Wilson* (1920, P. 20) showed that in exercising his discretion in favour of a spouse who had himself been guilty of adultery, such action was not inconsistent with the interests of morality at large. The old rule that a guilty mother was not entitled to access to her children was overcome by the decision of the court of appeal in B. v. B. (1924, p. 174). On the other hand one result of equalizing the grounds of divorce was the marked increase in the number of wives' suits in which the charge was based on a solitary incident at a hotel In March 1928 Lord Merrivale called a halt to this kind of petition by declaring that he would not grant decrees in cases where the real facts seemed to be cloaked by an artificial procedure.

By the Judicial Proceedings (Regulation of Reports) Act 1926, the reporting of matrimonial causes by newspapers was limited to the names, address and occupations of the parties and witnesses, legal submissions, summings-up and judgments, and verdicts of juries. Thus the recommendation of the divorce commission, (h) above, has been dealt with in more drastic fashion than was proposed.

The Matrimonial **Causes Act, 1937.**—This act was promoted

by a private member of parliament, Mr. **A. P.** Herbert, and, after interesting discussions in both houses of parliament, was finally passed in July 1937 to take effect from Jan. 1, 1938. It was largely based upon the recommendations of the royal commission published in 1912. To adultery as grounds for divorce were added desertion for three years, cruelty, and unsoundness of mind regarded, after five years' duration, as incurable. No divorce proceedings could be initiated until three years after the date of marriage; but the courts were given power to reduce this period in cases of exceptional hardship or depravity. A feature of the Act is that it lays no compulsion whatever upon the Church in the matter of re-marriage of divorced persons, leaving the Church free to recognize or not in practice the law of the land.

Divorce in Other Countries. — So far as matrimonial laws are concerned Scotland, Ireland and the British dominions overseas are just as independent of the Engish law as foreign countries.

In *Scotland* marriages may be judicially dissolved for two causes, adultery and wilful desertion. Condonation is a bar to relief as in England, and so are connivance or conduct conducing, pleaded in defence as *lenocinium.* If the petitioning spouse has been guilty of adultery it is no bar to a divorce, though it may be set up by the accused spouse by way of counteraction. Delay in prosecuting the suit has to be taken into account by the court, but is rarely a bar to relief. Collusion is also guarded against, the lord advocate being equipped with much the same powers as the king's proctor in England. As regards an action for dissolution on the ground of desertion, the petitioner must prove that the desertion has been wilful from the beginning, and has continued for four years. In such a case it is a good answer that the petitioner has been guilty of adultery. Actions for judicial separation may be raised for adultery or cruelty, and since 1908 the sheriff has had jurisdiction in judicial separation.

In *Ireland* there is no absolute divorce, but the courts may grant divorce *a mensa et thoro,* and a petitioner may secure a complete dissolution by act of parliament. Both Northern Ireland and the Irish Free State have had freedom to legislate in this matter since 1922, but have made no statutory change.

In *Canada* though divorce is a matter exclusively within the control of the Dominion parliament that body has not seen fit to pass any such act, with the result that there is no complete divorce in the provinces of Alberta, Manitoba, Ontario, Quebec and Saskatchewan, but as the other four provinces, British Columbia, New Brunswick, Nova Scotia, and Prince Edward Island, each had jurisdiction in divorce before the federating act of 1867 was passed, they still retain this jurisdiction. The Dominion parliament can pass special acts of divorce in individual cases, as was done in England prior to the act of 1857. There is no absolute divorce in *Newfoundland.*

In the Commonwealth of *Australia* the grounds of complete divorce vary according to the State, but, generally, they are wider than in England, including conduct which would only justify a judicial separation in England.

In ***New Zealand*** the grounds of absolute divorce are (1) adultery; (2) wilful desertion for five years; (3) habitual drunkenness for four years coupled with cruelty or desertion by the husband and neglect of household duties by the wife; (4) commuted life sentence or sentence of seven years, penal servitude; (5) incurable lunacy for at least ten years.

In the Union of *South Africa* the Roman-Dutch Law is in operation for the most part, the grounds of divorce being (1) adultery or unnatural offences; (2) malicious desertion; (3) lifelong imprisonment.

As regards European countries there is no complete divorce where the Church of Rome still preserves its ancient powers and influence.

In *Italy* a husband may secure a divorce *a mensa et thoro* on the ground of his wife's adultery, and the wife is entitled to the same decree if her husband keeps a concubine in such a way as to constitute a grave indignity to his wife, or if he voluntarily deserts her or fails to make a home for her, or is guilty of violence, threats or cruelty endangering her safety or health, or if he is sentenced for a grave crime. The Italian courts do not recognize foreign divorce decrees relating to Italian subjects. In *Spain* and *Portugal* the law is practically the same as in Italy.

In *Germany* complete divorce is allowed on the grounds of adultery, an attempt by one spouse to kill the other, desertion for a year, bigamy, incest and certain gross crimes, insanity for three years, dishonest or immoral conduct. If the innocent spouse prosecutes, the spouse guilty of adultery may be sent to prison for not more than six months. A husband may forbid his divorced wife to use his name. Judicial separation is granted on the same grounds, but either party may later apply to have the decree made into a complete divorce.

In *Austria* the grounds for complete divorce are adultery, conviction for a crime for which the penalty could be five years' imprisonment, malicious desertion, cruelty or conduct endangering life or health and invincible aversion. A judicial separation is allowed in the same grounds, and also by mutual consent. In *Hungary* the law is very similar.

Dissolution of marriage by mutual consent is allowed in several European countries. Thus in *Belgium* this course is permitted, subject to the approval of the court. The other grounds of complete divorce in Belgium are the adultery of the wife, the adultery of the husband only if he has brought a concubine to the home, cruelty and conviction for infamous offence. The law on separation was modified by a law of March 20, 1927. There has to be an interval of ten months before remarriage. In *Switzerland* also the marriage may be dissolved by mutual consent on grounds deemed sufficient by the court; specific grounds are cruelty or dishonourable treatment, wilful desertion for three years, incurable insanity or mental disease of three years' duration, and in cases of gross antagonism a couple may be granted a trial separation for two years, followed by a divorce if there is no reconciliation.

In *Sweden* a divorce is granted after the expiry of a year from the date of a judicial separation allowed on the ground of aversion, if there has been no reconciliation; other grounds of divorce are adultery, six years' absence by one spouse without news, insanity for three years, conduct endangering life and imprisonment for life. These are judicial grounds, but a divorce may also be pronounced by means of the royal prerogative against a person who has been the subject of a sentence for a grave crime, or on proof of violence, insobriety or prodigality. In *Norway* and *Denmark* the grounds are very similar, and in the former country a royal decree of divorce may be obtained by mutual request after three years of separation. In *Holland* judicial separation is allowed on the usual grounds of the canon law, and complete divorce can be secured for each of the following grounds: adultery, wilful desertion for five years, unnatural offences, life imprisonment and absence for ten years. The court sits *in camera.*

In *Russia* under the present code of the Soviets complete divorce is obtainable either by mutual consent, or on the application of husband or wife subject to the approval of the court. The decree does not become absolute until after the time for appeal has expired. Under the imperial law the grounds for divorce used to be adultery, bigamy, impotence at the time of marriage, absence of one spouse without any news for five years. exile to Siberia and loss of civil rights. In *Japan* a complete divorce is allowed by mutual consent with notice to the registrar, and also on the respective grounds of the wife's adultery, the husband's cruelty or desertion or his being sentenced for a grave offence, or three years' absence without knowledge.

Under the *Jewish* laws there is no distinction between nullity and divorce, the grounds of divorce being bigamy, breach of the law of affinity, the wife's adultery, the husband's leprosy or vice or neglect, the wife's refusal of marital rights for a year or by her cursing her father-in-law in her husband's presence; a divorce may also be obtained by mutual consent. Jews in most countries however are bound by the national laws.

In *France* the law of divorce has had a chequered history. Before the Revolution the Roman canon law prevailed, marriage was considered indissoluble, and only divorce a *mensa et thoro,* known as *la séparation d'habitation,* was permitted; though it would appear that in the earliest age of the monarchy divorce a *vinculo matrimonii* was allowed. But the Revolution swept away

marriage among the institutions which it overwhelmed, and by the law of Sept. 20, 1792, so great facility was given for divorce *a vinculo matrimonii* as practically to terminate the obligations of marriage. A reaction came with the Code Napoléon, yet even under that system of law divorce was fairly easy. On the restoration of the monarchy in 1816 divorce *a vinculo* was abolished.

Divorce was re-enacted by a law of July 27, 1884, the provisions of which were simplified by laws of 1886 and 1907. But a wide departure was made by these laws from the terms of the Code Napoléon. Divorce by consent was not permitted, and the following became the causes for which divorce was allowed: (1) Adultery by either party to the marriage at the suit of the other, without, in the case of adultery by the husband, the aggravation of introduction of the concubine into the home required by the Code; (2) violence (*excès*) or cruelty (*sévices*); (3) *injures* gmves, acts reflecting on honour or reputation, and such things as unjustifiable refusal of marital rights or habitual drunkenness, and (4) *peine afflictive* et *infamante,* a legal punishment involving corporal confinement and moral degradation.

In addition to its recognition of full divorce, the French law recognizes *séparation* de corps. The grounds are the same as those for a divorce; and if a *séparation* de corps has existed for three years, it may be turned into a divorce upon the application of either party to the court.

On a divorce both parties are at liberty to remarry. The husband could remarry at once; but the wife (art. 296 of the Code) was only allowed to remarry after an interval of ten months By the act of 1907, this article was abolished, and the wife allowed to remarry as soon as the judgment or decree granting the divorce has been entered, providing 300 days have elapsed. Under the law of March 26, 1924, art. 295 was amended in favour of greater, but not complete, freedom of remarriage of the parties divorced, not still in a state of wedlock. The publication of divorce proceedings in the press is forbidden under heavy penalties. After a divorce the wife may not continue to use the name of her divorced husband. An appeal may be brought against a decree of divorce within two months; and a decree made on appeal is subject to revision by the court of cassation within two months. A decree must be transcribed in the Register of Civil Status before it becomes absolute. (Cf. Woodland v. Woodland, 44 The Times L.R. 495.) (ST. H.; C. Mo.)

UNITED STATES

According to American practice, divorce is the termination by proper legal authority, sometimes legislatively but usually judicially, of a marriage which up to the time of the decree was legal and binding. It is to be distinguished from a decree of nullity of marriage, which is simply a legal determination that no legal marriage has ever existed between the two parties. It is also to be distinguished from a decree of separation, which permits or commands the parties to live apart, but does not completely and for all purposes sever the marriage tie. The matrimonial law of England, as at the time of the Declaration of Independence, forms part of the common law of the United States. But as no ecclesiastical courts have ever existed there, the law must be considered to have been inoperative.

Upon the subject of divorce in the United States and foreign countries a careful investigation was made by the former American Department of Labour, its report covering the years 1867–86; further reports for the period 1887–1906 have been published by the Federal Census Bureau. The number of divorces was in 1886 over 25,000, and in 1906 was over 72,000, about double the number reported for that year from the rest of the Christian world. The number in 1916 was over 112,000, and in 1926 nearly 181,000, indicating an increase, 1906–16, of 56% and 1916–26 of 61%, about four times as rapid as the increase of population. The number of divorces annually to each 100,000 people has increased as follows: 1867, 27; 1877, 34; 1887, 47; 1897, 62; 1906, 86; 1916, 113; 1926, 154.

The several States differ in divorce-rate, from South Carolina, with no provision for legal divorce, to Oregon, where the rate is more than twice and Nevada where it is more than eight times the average for the country. In general the rate is about the same in the North as in the South, but greater in the Central States than in the Eastern, and in the Western than in the Central. The several State groups had in 1926 the following divorce rates per 100,000 married persons: Middle Atlantic (New York, New Jersey and Pennsylvania) 147; New England, 227; South Atlantic, 249; East South Central, 425; West North Central, 426; East North Central, 459; Mountain, 543; West South Central, 654; Pacific, 656; being an average for the United States of 378, and showing that all six central and western groups had rates above the average. Although the divorce-rate in the United States has increased rapidly and steadily, in 60 years, distinct tendencies are traceable in different regions. In the North Atlantic group the rate rose by 165%, in the North Central by 352%, in the Western by 400%, but in the South Atlantic by 1,090%, and in the South Central by 1,340%. This very rapid increase in the South was largely due to the spread of divorce among the emancipated negroes.

Grounds of Divorce.—Each State determines for itself the causes for which divorce may be granted, and no general statement is therefore possible. The cause pleaded is seldom an index to the motives which caused the suit to be brought. This is determined by the character of the law rather than by the state of mind of the parties; and so far as the individuals are concerned, the ground alleged is thus a cloak rather than a clue or revelation. Still those causes which have been enacted into law by the various State legislatures do indicate the pleas which have been endorsed by the social judgment of the respective communities. In the United States exclusive of Alaska and the recent insular accessions there are 49 different jurisdictions in the matter of divorce. Six out of every seven allow divorce for desertion, adultery or cruelty; and of the 179,397 divorces reported with their causes in 1926 nearly 80% were granted for some one of these three causes, viz., 39% for cruelty, 32% for desertion and 9% for adultery. Probably nearly 7% more were for some combination of these causes. Three other grounds for divorce are admitted as legal in many or most American States, viz., imprisonment in 39, habitual drunkenness in 38 and neglect to provide in 22. About 98% of American divorces are granted on some one or more of these six grounds. In general the legislation on the subject of the causes allowed for divorce is most restrictive in the States on the Atlantic coast, from New York to South Carolina inclusive, and is least so in the Western States. The slight expense of obtaining a divorce in many of the States, and the lack of publicity which is given to the suit, are also important reasons for the great number of decrees issued. The importance of the former consideration is reflected in the fact that the divorce-rate for the United States as a whole shows clearly, in its fluctuations, the influences of good and bad times. When times are good and the income of the working and industrial classes likely to be assured, the divorce-rate rises. In periods of industrial depression it falls, fluctuating thus in the same way and probably for the same reason that the marriage-rate in industrial communities fluctuates. In two-thirds of the divorce suits the wife is the plaintiff, and the proportion has risen slightly in the 40 years. In the Northern States the percentage issued to wives (1887–1906) was 71, while in the Southern States it was only 56. But where both parties desire a decree, and each has a legal ground to urge, a jury will usually listen more favourably to a woman's suit.

Divorce is probably especially frequent among the native population of the United States, and among these probably more common in the city than in the country. This statement cannot be established absolutely, since statistics afford no means of distinguishing the native from the foreign-born applicants. It is, however, the most obvious reason for explaining the fact that, while in Europe the city divorce-rate is from three to five times as great as that of the surrounding country, the difference in the United States between the two regions is very much less. In other words, the great number of foreigners in American cities probably tends to obscure by a low divorce-rate the high rate of the native population. Divorce is certainly more common in the

New England States than in any others on the Atlantic coast north of Florida, and it is not unlikely that wherever the New England families have gone divorce is more frequent than elsewhere. For example, it is much more common in the northern counties of Ohio settled largely from New England than in the southern counties settled largely from the Middle Atlantic States.

There are two statements frequently made regarding divorce in the United States which do not find warrant in the statistics on the subject. The first is that the real motive for divorce with one or both parties is the desire for marriage to a third person. The second is, that a very large proportion of divorces are granted to persons who move from one jurisdiction to another in order to avail themselves of lax divorce laws. On the first point the American statistics are practically silent, since, in issuing a marriage licence to parties one or both of whom have been previously divorced, no record is ordinarily made of the fact. In Connecticut, however, for a number of years this information was required; and, if the statements were trustworthy, the number of persons remarrying each year was about one-third the total number of persons divorcing, which is probably a rate not widely different from that of widows and widowers of the same age. Foreign figures for Switzerland, Holland and Berlin indicate that in those regions the proportion of the divorced who remarry speedily is about the same as that of wido s and widowers. What statistical evidence there is on the subject therefore tends to discredit this popular opinion. The evidence on the second point is more nearly conclusive, and has gone far towards decreasing the demand for a constitutional amendment allowing a federal marriage and divorce law. About four-fifths of all the divorces granted in the United States were issued to parties who were married in the State in which the decree of divorce was later made; and when from the remaining one-fifth are deducted those in which the parties migrated for other reasons thdn a desire to obtain an easy divorce, the remainder would constitute a very small, almost a negligible, fraction of the total number.

Social Results. — It is difficult, perhaps impossible, to say how far the frequency of divorce in the United States has been or is a social injury; or to what extent it has weakened or undermined the ideal of marriage as a lifelong union. The prevalence of divorce in the United States among the native population, in urban communities, among the New England element, in the middle classes of society, and among those of the Protestant faith, indicates how closely this social phenomenon is interlaced with much that is characteristic and valuable in American civilization. In this respect, too, the United States perhaps represents the later stage of a tendency which has been at work in Europe at least since the Reformation. Certainly the divorce-rate is increasing in nearly every civilized country. Decrees of nullity of marriage and decrees of separation not absolutely terminating the marriage relation are relatively far less prevalent than they were in the mediaeval and early modern period, and many persons who under former conditions would have obtained relief from unsatisfactory unions through one or the other of these avenues now resort to divorce. The increasing proportion of the community who have an income sufficient to pay the requisite legal fees is also a factor of great importance. The belief in the family as an institution ordained of God, decreed to continue "till death us do part," and in its relations typifying and perpetuating many holy religious ideas, probably became weakened in the United States during the 19th century, along with a weakening of other religious conceptions; and it is yet to be determined whether a substitute for these ideas can be developed under the guidance of the motive of social utility or individual desire. In this respect the United States is, as Gladstone once wrote, a *tribus praerogativa*, but we need not too readily despond of the outcome.

The great source of American statistical infonnation is the governmental report of over 1,000 pages, *A Report on Marriage and Divorce in the United States 1867 to 1886, including an Appendix relating to Marriage and Divorce in Certain Countries of Europe*, by Carroll D. Wright, commissioner of labour; together with the further report for 1887 to 1906. The statistics contained in the former volume have been analysed and interpreted in W. F. Willcox, *The Divorce Problem. A Study in Statistics* (1891, 1897) Further interpretations are contained in an article in the *Political Science Quarterly* for March *1893*, entitled "A Study in Vital Statistics." The best legal treatise is probably Bishop on *Marriage, Divorce and Judicial Separation See* also *J. P.* Lichtenberger, *Divorce: A Study in Social Causation* (1909); Walker Gwynne, *Divorce in America under State and Church* (1925); and E. R. Mowrer, *Family Disorganization* (1927). (W. F. W.)

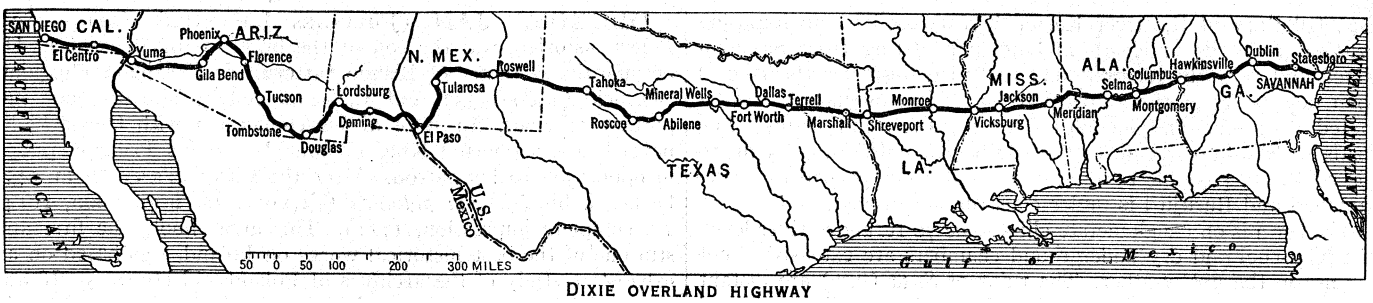
DIWANIYEH, a town in Iraq in 31° 58' N. and 4j° E. about 40 m. below Hilla on the Euphrates, here crossed by a floating bridge, and on the Baghdad-Basra railway. The town is a frontier post on the edge of the desert, and is a strategic military point.

DIX, DOROTHEA LYNDE (1802–1887), American philanthropist, was born at Hampden (Me.), April 4, 1802. About 1821 she opened a school in Boston. From 1824 to 1830 she wrote books of devotion and stories for children. Her *Conversations on Common Things* (1824) had reached its 60th edition by 1869. In 1841 she became interested in the condition of gaols and almshouses, investigating especially the treatment of the pauper insane. Her memorial to the State legislature resulted in improved treatment of the insane, and she then extended her work into many other States. By 1847 she had visited 18 State penitentiaries, 300 county gaols and houses of correction, and over 500 almshouses. Her labours resulted in the establishment of many insane asylums, and in the founding of many additional gaols and almshouses conducted on a reformed plan. In 1854 she became interested in the condition of the insane in Scotland, and her report opened the way for sweeping reforms. She extended her work into the Channel islands, and then to France, Italy, Austria, Greece, Turkey, Russia, Sweden, Norway, Denmark, Holland, Belgium and a part of Germany. Her work resulted in the establishment of two asylums for the insane in Japan. She was superintendent of women nurses during the Civil War; and her labours on behalf of defectives were continued after the war. She died at Trenton (N.J.), July 17, 1887.

See Francis Tiffany, *Life of Dorothea Lynde Dix* (Boston, 1892).

DIX, JOHN ADAMS (1798–1879), American soldier and political leader, was born at Boscawen, N.H., on July 24, 1798. He studied at Phillips Exeter academy and at the College of Montreal, and as a boy took part in the War of 1812. In July 1828, having attained the rank of captain, he resigned from the army, and for two years practised law at Cooperstown, N.Y. He soon became prominent as one of the leaders of the Democratic Party in the State and for many years was a member of the so-called "Albany regency" (*q.v.*), a group of Democrats who between about 1820 and 1850 exercised a virtual control over their party in New York. In 1833–39 he was secretary of State and superintendent of schools in New York, and in this capacity made valuable reports concerning the public schools of the State, and a report (1836) which led to the publication of the *Natural History of the State of New York* (1842–66). From 1845 to 1849 he was a United States senator from New York. In May 1860 he became postmaster of New York city, and from January until March 1861 he was secretary of the Treasury of the United States, in which capacity he issued (Jan. 29, 1861) to a revenue officer at New Orleans a famous order containing the words, "If any one attempts to haul down the American flag, shoot him on the spot." He was appointed major-general of volunteers in June 1861, and during the Civil War commanded various departments until July, 1865. He was minister to France in 1866–69, and in 1872 was elected by the Republicans governor of New York, but was defeated two years later. He had great energy and administrative ability and served as president of important railways. He died in New York city on April 21, 1879. Among his publications are *A Winter in Madeira and a Summer in Spain and Florence* (1850), and *Speeches and Occasional Addresses* (1864). He wrote English versions of the *Dies irae* and the *Stabat mater.*

His son, MORGAN DIX (1827–1908), graduated at Columbia in 1848 and at the General Theological seminary in 1852, and was ordained deacon (1852) and priest (1853) in the Protestant Episcopal Church. In 1855–59 he was assistant minister, and in 1859–62 assistant rector, of Trinity Church, New York city, of which he was rector from 1862 until his death. He published sermons and lectures; *A History of the Parish of Trinity Church,*

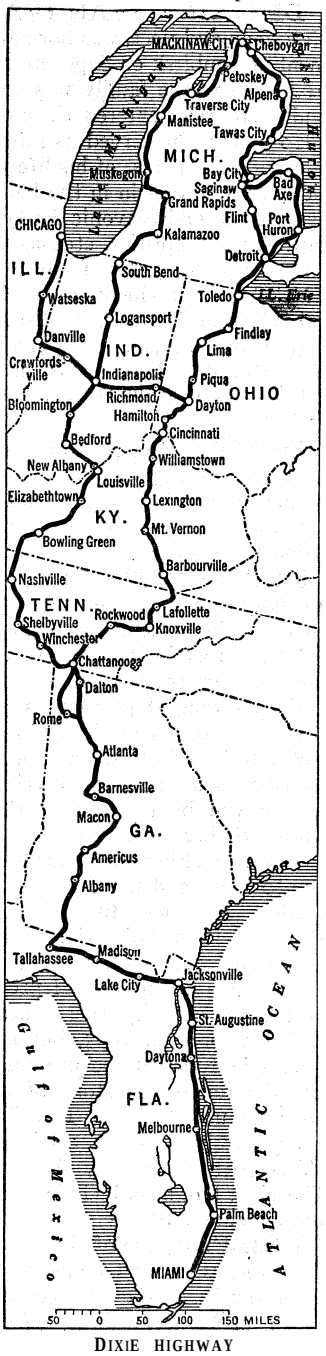


DIXIE OVERLAND HIGHWAY

New York City (1898–1905); and a biography of his father, *Memoirs of John Adams Dix* (1883).

DIXIE, a popular name given to the Southern States of the United States which lie south of the Mason and Dixon line. There are various reasons given for the name, one of the most plausible being that it had its origin in money issued by a bank in New Orleans before the Civil War On the back of the ten dollar bills was printed the French word *Dix,* with other lettering in French, hence the South, particularly Louisiana, became known as the land of Dixies and thereupon Dixie land It was about this time that Daniel Emmett, Negro minstrel and song writer, while looking out on the cold dreary streets of New York and wishing he were in Dixie, picked up his violin and composed that rollicking song, which has been called the national anthem of the South, "Away down South in Dixie."

DIXIE HIGHWAY, a former American thoroughfare from Lake Michigan and Lake Huron to Tallahassee, Jacksonville and Miami, Fla. A branch running through Nashville, Tenn., was called the "Dixie B Line." Paved or improved throughout, it had a length of 3,989 mi., 1,930 mi. in its western and 2,169 mi. in its eastern division. The Dixie highway represented one of the earliest attempts in the United States at modern long-distance road improvement and comprised in its course the scenic charm of the Great Lakes, the Appalachian mountains and the shores of the Gulf of Mexico and the Atlantic ocean.



DIXIE HIGHWAY

DIXON, GEORGE (*c.* 1755–1800), English navigator. He served under Capt. Cook in his third expedition, and after his return became a captain in the royal navy. In the autumn of 1785 he sailed in the "Queen Charlotte," in the service of the King George's Sound Company of London, to explore the shores of the present British Columbia, with the special object of developing the fur trade. His chief discoveries were those of Queen Charlotte's islands and sound (the latter only partial), Port Mulgrave, Norfolk bay and Dixon's Entrance and archipelago. He disposed of his cargo in China and returned in 1788, and published *A Voyage round the World, but more particularly to tfze North-West Coast of America* (1799), the bulk of which consists of descriptive letters by William Beresford, his supercargo His own contribution to the work included valuable charts and appendices He is usually identified with the author of *The Navigator's Assistant* (1791), who was teacher of navigation at Gosport. It is believed that he died *c.* 1800

DIXON, HENRY HALL (1822–1870), English sporting writer over the *nom de plume* "The Druid," was born at Warwick Bridge, Cumberland, and educated at Rugby and at Trinity college, Cambridge, where he graduated in 1846 Three of his novels, *Post and Paddock* (1856), *Silk and Scarlet* (1859), and *Scott and Sebright* (1862) appeared in the *Sporting Magazine* He also published a legal compendium entitled *The Law of the Farm* (1858); *Field and Fern* (1865), giving an account of the herds and flocks of Scotland; and *Saddle and Sirloin* (1870), treating in the same manner those of England

See Hon. Francis Lawley, *Life* and *Times of "The Druid"* (1895).

DIXON, RICHARD WATSON (1833–1900), English poet and divine, son of Dr. James Dixon, a Wesleyan minister, was born on May 5, 1833. He was educated at King Edward's school, Birmingham, and on proceeding to Pembroke college, Oxford, became one of the famous "Birmingham group" there who shared with William Morris and Burne-Jones in the pre-Raphaelite movement. He became minor canon and honorary librarian of Carlisle in 1868, and honorary canon in 1874; he was proctor in convocation (1890–94), and received the honorary degree of D D. from Oxford in 1899 He died at Warkworth, of which parish he was vicar, on Jan. 23, 1900. His principal work is *History of the Church of England from the Abolition of the Roman Jurisdiction* (1878–1902). At the time of his death he had completed six volumes, covering the period 1529 to 1570, two of which were published posthumously

Dixon's ***Selected Poems*** were published in 1909 with a memoir of the author by Robert Bridges.

DIXON, a city of northern Illinois, U S A , on the Rock river and the Lincoln highway, 98m W of Chicago; the county seat of Lee county It is served by the Chicago and North Western and the Illinois Central railways.

The population mas 8,191 in 1920 (91% native white), and was 10,671 in 1940 by the federal census Dixon is the centre of a rich farming region, and has a number of manufacturing industries, for which the river supplies power

It was laid out in 1835 by John Dixon (1784–1876), the first white settler in the county, and was chartered as a city in 1859. In 1832, at the close of the Black Hawk War, Jefferson Davis, Zachary Taylor and Abraham Lincoln were comrades in the old block-house chat stood near the northern end of the present bridge across the river

DIZFUL, a town and district in the province of Khuzistan, Persia, in 32° 25′ N., and 48° 35′ E , anciently known as Andamish It is 6jo ft above sea-level on the left bank of the Ab-i-

Diz, tributary of the river Karun, here crossed by an imposing bridge 430 yards in length in large part dating from Sasanian times and recently repaired under British auspices, the central span now being of the suspension type. The population is estimated at 15,000 and includes Persians, Lurs and Arabs. The roads to Shushtar. 35 m. to the south-east and Ahwaz 85 m. to the south are passable t y motor cars and a motor road to Khurramabad and Burujird is under construction (1928).

The town is on conglomerate cliffs some 70 ft. above river level, in which cool and dry underground chambers are extensively cut for use in the hot weather. The ruins of *Susa* (*q.v.*) are distant about 1 j m. to the south-west. The industries peculiar to Dizful are the preparation of icdigo, the dyeing of cloths and the making of felts. It is the principal southern market town of the nomad population of Luristan. Indigo was first introduced here in the early 19th century, but has since been almost entirely displaced by imported dyes. Dizful reed pens are celebrated in the East and extensively exported. The streets are narrow and crooked and the sanitary conditions bad. In the river bed above the bridge are several flour mills worked by water power. Several canals take off below the bridge and irrigate some 20,000 acres on either bank, but a far greater area was once served by similar canals and could be again fertilized if the dam, on which the original bridge stood, were reconstructed.

DJAKOVO (DAKOVO), a city of Croatia-Slavonia, Yugoslavia, occupied by Italy in April, 1941, after the axis invasion of the Balkans. Pop. 7,987. Djakovo is a Roman Catholic Episcopal see. Bishop Strossmayer (1815–1905), did much to foster the sense of racial kinship among the Yugoslavs, and the town became a centre of religious and political activity. The cathedral, a basilica with a central dome and two lofty spires, was founded in 1866. Its style is Romanesque, chosen by Strossmayer as symbolical of the position of his country, midway between east and west. Djakovo has a thriving trade in agricultural produce. Many Roman remains have been discovered.

For a full description of the cathedral, in Serbo-Croatian and French, *see* the illustrated folio *Stolna Crkva Djakovu,* published by the South Slavonic Academy, 1900.

DJEMAL PASHA, AHMED (1861–1922), Turkish politician, was born at Constantinople on May 1, 1861. He entered the army, and later became a member of the Committee of Union and Progress. He was appointed military governor of Adana (1908), governor-general of Baghdad (1911) and commanded a division during the Balkan wars. In 1913 he commanded the I. Army Corps, and was made Minister of Public Works. In 1914 he became Minister of Marine; in the same year he took over the II. Army, and was afterwards sent to Syria in command of the IV. Army. Owing to dissensions with Enver Pasha and von Falkenhayn he returned to Constantinople in 1917, where he retained the portfolio of the Marine until the Armistice. On the downfall of the Ministry in Oct. 1918 Djemal, with other members of the Committee of Union and Progress, sought refuge in Germany and Switzerland. Later he visited Russia, and thence proceeded to Afghanistan, where he exercised a powerful influence. He was assassinated at Tiflis on July 22, 1922. Djemal did much to awaken the spirit of nationalism in the Mohammedan countries of central Asia.

His writings include a volume in French, *Le Carnet de route du Colonel Djemal Bey,* and works in Turkish on Plevna and the Crimean Campaign. Another work, *Memories of a Turkish Statesman, 1913–19* (1922) appeared in English and in German.

D LINES, in spectroscopy (*q.v.*), the pair of lines, characteristic of sodium, in the yellow region of the spectrum. Their separation is too small to be detected with a spectroscope of low resolving power, hence to Fraunhofer (*q.v.*) they appeared as a single line This line was the fourth prominent absorption line in the sun's spectrum, starting from the red end, and he accordingly designated it by the letter D. It was subsequently resolved into two components D_1 and D_2 corresponding to wave-lengths 5895.93 and 5895.97 Å.U. (10^{-8} cm.) respectively. An emission line appearing in the chromosphere, D_3 λ 5875.62, has since been discovered. This line is due to helium.

DLUGOSZ, JAN (JOHANNES LONGINUS) (1415–1480), Polish historian, was the son of the burgrave of Bozeznica. He became the secretary of Bishop (afterwards Cardinal) Zbygniew Olesnicki (1389–1455), and was employed by him on many important missions. In spite of his connection with Olesnicki he nevertheless supported King Casimir IV. in his Prussian policy in opposition to his patron. After the Cardinal's death in 1455 he began his *Historia polonica* (13 vols., 1st impression, 1614; 1st complete impression, 1711). This great book, the first and still one of the best historical works on Poland, was based on an exhaustive study of the archives of Poland and Hungary. It was completed in 1479. Dlugosz became archbishop of Lemberg in 1478 He died on May 19, 1480, at Piatek.

See Semkowicz, *Critical Considerations of the Polish Works of Dlugosz* (Cracow, 1874); Michael Bobrzynski and Stanislaw Smolka, *Life of Dlugosz and his Position in Literature* (Cracow, 1893); both of these are in Polish.

DMITRIEV, IVAN IVANOVICH (1760–1837), Russian statesman and poet, was born at his father's estate in the Government of Simbirsk on Sept. 20, 1760. In consequence of the revolt of Pugachev the family was compelled to flee to St. Petersburg, and there Ivan entered the army. During the four years from 1810 to 1814 he served as minister of justice under the emperor Alexander. The rest of his life was devoted to literature. He took sides with Karamsin in the battle for a natural Russian language against the Old Slavonic Party. His poems include songs, odes, satires, tales, epistles, etc., as well as the fables—partly original and partly translated from Fontaine, Florian and Arnault—on which his fame chiefly rests. He also wrote a short dramatico-epic poem on Yermak, the Cossack conqueror of Siberia.

His writings occupy three volumes in the first five editions; in the sixth (St. Petersburg, 1823) there are only two. His memoirs, to which he devoted the last years of his life, were published at Moscow in 1866.

DMITRIEVSK, a town in the Stalin district of the Ukrainian S.S.R. long. 38° 48′ E. lat. 47° 56′ N. In 1897 it was a village with a population of 512, but in 1917 its coal mines were developed and metal and chemical industries established. Its population is 51,436.

DNEPROPETROVSK, formerly Ekaterinoslav, a town in a county of the same name, in the Ukrainian S.S.R. It is situated on the right bank of the Dnieper river above the rapids in 48° 21′ N. and 35° 4′ E., alt. 210 ft. In 1927 under American direction, the construction of a ferro-concrete dam, with sluices and docks allowing ships to pass, and turbines for generating electricity was commenced. The proximity of manganese, nitre, coal and iron deposits to the station, and of the Zaporozhny aluminum industry is a great commercial asset. Pressure on the railway system will be relieved by the opening of river transport for wheat, timber, coal, iron and other heavy products. The town has iron-smelting, and metal industries employing more than 50,000 men, and there are also breweries, flour-mills and other smaller industries. In 1895 it became the centre of numerous Franco-Belgian industrial enterprises, and its population has increased from 18,881 in 1861 to 500,662 in 1939. It is a trading centre for the agricultural products of the district. On the site of the present city there formerly stood the Polish castle of Koindak, built in 163 j, but it was destroyed by the Cossacks. Potemkin founded the city in 1786, and Catherine II. in 1787 laid the foundation stone of its cathedral, which however, was not built until 1830–5. Paul I. changed the name of the city to Novo Rossiysk, but its original name was restored in 1802. The oldest part of the city lies very low and is subject to floods The civic buildings include a mining academy, an archaeological museum and a library.

DNIEPER, one of the most important rivers of Europe (the *Borysthenes* of the Greeks, *Danapris* of the Romans, *Uzi* or *Uzu* of the Turks, *Eksi* of the Tartars, *Elice* of Visconti's map [1381], *Lerene* of Contarini [1437], *Luosen* of Baptista of Genoa [1514], and *Lussem* in the same century). It belongs entirely to Russia, and rises in the Smolensk province, in a swampy district (alt. 930 ft.) at the foot of the Valdai hills, not far from the sources

of the Volga and the Dvina, in 55° 52' N. and 33" 41' E. Its length is about 1,410 m. and it drains an area of 202,140 sq.m. In the first part of its course, which may be said to end at Dorogobuzh, it flows through an undulating country of Carboniferous formation; in the second it passes west to Orsha and south through the White Russian S.S.R. to the Ukrainian S.S.R., where it passes south through the fertile plain of Chernigov and Kiev, and then south-east across the rocky steppe to Dnepropetrovsk (Ekaterinoslav). About 45 m. south of this town it has to force its way across the same granitic offshoot of the Carpathian mountains which interrupts the course of the Dniester and the Bug, and for a distance of about 25 m. rapid succeeds rapid. The fall of the river in that distance is 1jj ft. The Dnieper, having got clear of the rocks, continues south-west through the grassy plains of Kherson and Taurida, and enters the Black sea by a considerable estuary in 46° 30' N. and 32° 20' E. with the town of Kherson on its right bank. On this ramifying *liman,* into which the Bug also pours its waters, stands Nikolaiev. Navigation extends as far up as Dorogobuzh, where the depth is about 12 ft., and rafts are floated down from the higher reaches. The banks are generally high, more particularly the left bank. About the town of Smolensk the breadth is 455 ft., at the confluence of the Pripet 1,400, and in some parts of the Dnepropetrovsk district more than $1\frac{1}{4}$ m. In the course above the rapids the channel varies very greatly in nature and depth, and it is not infrequently interrupted by shallows. The rapids form a serious obstacle to navigation; it is only for a few weeks when the river is in flood that they are passable, and even then the venture is not without risk and can be undertaken only with the assistance of special pilots. As early as 1732 an attempt was made to improve the channel. A canal, which ultimately proved too small for use, was constructed at Nenasitets in 1780 at private expense; blastings were carried out in 1798 and 1799 at various parts; in 1805 a canal was formed at Kaindatski, and the channel straightened at Sursk; by 1807 a new canal was completed at Nenasitets; in 1833 a passage was cleared through the Staro-Kaindatski rapid; and in the period 1843 to 1853 numerous ameliorations were effected. The result has been not only to diminish greatly the dangers of the natural channel, but also to furnish a series of artificial canals by which vessels can make their way when the river is low. A ferro-concrete dam was constructed in 1927 across the falls, under American direction, with sluices and docks for letting ships pass, and a station and turbines for the production of electric power. Of the tributaries of the Dnieper the following are navigable—the Berezina and the Pripet from the right, and the Sozh and the Desna from the left. By means of the Dnieper-Bug (King's) canal, and the Berezina and Oginski canals, this river has water connection with the Baltic sea. In the estuary the fisheries give employment to large numbers of people. At Kiev the river is free from ice on an average for 234 days in the year, at Dnepropetrovsk 270 and at Kherson 277.

DNIESTER, a river of south-eastern Europe belonging to the basin of the Black sea. It rises on the northern slope of the Carpathian mountains in Poland. and for 150 miles from Zaleszczyky to Karmassy, where it forms a broad estuary as it flows into the Black sea, is the boundary between Rumanian Bessarabia and the Ukrainian S.S.R. During the 1918 Russo-Rumanian retreat, all the bridges across the Dniester were destroyed, and as diplomatic relations between Rumania and the U S.S R. have not been opened (1928) these bridges have not been re-built, and no traffic is allowed up and down the river. Both banks of the river are watched by armed guards and trade across or along it has completely ceased. The Dniester drains an area of 29,670 sq m. It is excessively meandering, and the current in most parts even during low water is decidedly rapid as compared with Russian rivers generally, the mean rate being calculated at $1\frac{7}{11}$ m. per hour. The average width of the channel is from 500 to 750 ft., but in some places it attains as much as 1,400 ft.; the depth is various and changeable. The navigable portion of the river is interrupted by a granitic spur from the Carpathians which gives rise to the Yampol rapids. For ordinary river craft the passage of these rapids is rendered possible, but not free from danger, by a natural channel on the left side, and by a larger and deeper artificial channel on the right, for steamboats they form an insuperable barrier. The river falls into the sea by several arms, passing through a shallow lagoon, a few miles south west of Odessa. There are two periodical floods—the earlier and larger caused by the breaking up of the ice, and occurring in the latter part of February or in March; and the latter due to the melting of the snows in the Carpathians, and taking place about June. The spring flood raises the level of the water 20 ft., and towards the mouth of the river submerges the gardens and vineyards of the adjacent country. In some years the general state of the water is so low that navigation is possible only for three or four weeks, while in other years it is so high that navigation continues without interruption; but considerable improvements were effected before the World War at government expense. In consequence the traffic increased; the Dniester used to tap regions of great productiveness, especially in cereals and timber. Steamboat traffic was introduced in the lower reaches in 1840. The fisheries of the lower course and of the estuary are of considerable importance; and these, together with those of the lakes which are formed by the inundations, furnish a valuable addition to the diet of the people in the shape of carp, pike, tench, salmon, sturgeon and eels. Its tributaries are numerous, but not of individual importance.

DO, in music, the first of the sol-fa syllables, or sound names for the notes of the scale, this syllable having been substituted, as being more sonorous, for *Ut,* which was originally the first of these syllables—*ut,* re, *mi,* etc.—as chosen in the 11th century by Guido d'Arezzo when he devised his system of solmization. Hence in the Tonic Sol-fa system, based on what is called the "movable *do,*" **do** is the tonic of whatever key may be employed, whereas in the systems employing the "fixed do" it is invariably C.

BOAB, a name appiied in India, according to its derivation (do, two, and ab, river), to the stretch of country lying between any two rivers, as the Bari Doab between the Sutlej and the Ravi, the Rechna Doab between the Ravi and the Chenab, the Jech Doab between the Chenab and Jhelum, and the Sind Sagar Doab between the Jheium and the Indus, but frequently employed, without any distinctive adjunct, as the proper name for the region between the Ganges and its great tributary the Jumna.

DOBBIE, SIR JAMES JOHNSTONE (1852–1924), British chemist, was born at Glasgow on Aug. 4, 1852, and educated at Edinburgh, Glasgow and Leipzig. At Glasgow he became closely associated with Ramsay's work, and they collaborated in a series of papers on the cinchona alkaloids (Trans. *Chem. Soc.,* 1878–1879). He held various posts at University college, Bangor (1884), the Royal Scottish Museum (1903–1909), and the Government Laboratory in London, becoming Government chemist (1911–1920) when the laboratory was created a separate department. He was a Fellow of the Royal Society, and was knighted in 1915. He died on the Ayrshire coast on June 19, 1924.

At Bangor where he helped to establish an agricultural department, Dobbie collaborated with Dr. A. Lauder, and they succeeded in isolating three of the five alkaloids of *Corydalis* cava. As Government chemist he used the absorption spectra method of studying the constitution of organic compounds (with W. N. Hartly, J. J. Fox and others). After the World War he applied the absorption spectra methods to gases. The results of his researches were published in a series of papers from 1893–1921.

DOBBS FERRY, a village of Westchester county, New York, on the east bank of the Hudson river, opposite the northern end of the Palisades, 20 mi. N. of New York city. It is served by the New York Central railroad. The population was 5,883 in 1940. The Masters' corporation, St. Christopher's school, Missionary Sisters of the Sacred Heart are operated as private girls' schools there, together with the Children's Village. The principal industry is the printing plant of the Methodist Book concern, employing 600 workers. It is a typical commuters' neighbourhood. with fine country homes. In 1775 Jeremiah Dobbs, a Swede (probably from Delaware) began operating a skiff ferry there, which was kept up by his family for a century. During the Revolution fortifications were erected, and the village was a rendezvous for the British army after the battle of White Plains and for an American division in Jan. 1777. Washington's army encamped

near by on July 4, 1781, and started thence for Yorktowh the following month. In the Van Brugh Livingston house, on May 6, 1783, Washington and Governor Clinton met General Sir Guy Carleton to negotiate for the evacuation of the posts still held by the British. The village was incorporated in 1873, as Greenburgh, but the original name was soon resumed.

DOBELL, BERTRAM (1842–1914), English bookseller and man of letters, the discoverer of the poet Thomas Traherne, was born at Battle, Sussex, the son of a tailor; he died at Hampstead on Dec. 14, 1914. The father moved to London, and there fell ill; the son became an errand-boy and began to collect old books from the stalls. In 1869 he set up business as a bookseller on a capital of £10, and in 1887 moved to Charing Cross road, where his shop became famous and his catalogues interesting for their literary gossip. Dobell met James Thomson in 1876, and helped him from that time to his death; in 1895 he edited the *Poetical Works* of his friend, with a memoir. His literary work also included the publication of much useful work on Shelley and Charles Lamb. After his death some volumes of his verse containing some admirable sonnets were issued by his son. But his reputation rests chiefly on the identification of Thomas Traherne, whose *Poetical Works* he edited in 1903. For the story of that identification *see* TRAHERNE, THOMAS.

See S. Bradbury, *Bertram Dobell* (1909).

DOBELL, SYDNEY THOMPSON (1824–1874), English poet and critic, was born at Cranbrook, Kent. His father was a wine merchant, his mother a daughter of Samuel Thompson (1766–1837), a London political reformer. The family moved to Cheltenham when Dobell was 12 years old. He was educated privately, and never attended either school or university. He refers to this in some lines on Cheltenham college in imitation of Chaucer, written in his 18th year. An acquaintance with Mr. (subsequently Sir James) Stansfeld and with the Birmingham preacher-politician, George Dawson (1821–76), which afterwards led to the foundation of the Society of the Friends of Italy, fed the young enthusiast's ardour for the Liberalism of the day. Meanwhile, Dobell wrote a number of minor poems, instinct with a passionate desire for political reform. *The Roman* appeared in 1850, under the *nom de plume* of "Sydney Yendys." His second long poem, *Balder,* appeared in 1854. The three following years were spent in Scotland. Perhaps his closest friend at this time was Alexander Smith, in company with whom he published, in 1855, a number of sonnets on the Crimean War, which were followed by a volume on *England in Time of War.* He died on Aug. 22, 1874.

As a poet Dobell belongs to the "spasmodic school," as it was named by Prof. Aytoun, who parodied its style in *Firmilian.* The epithet, however, was first applied by Carlyle to Byron. The school includes George Gilfillan, Philip James Bailey, John Stanyan Bigg (1826-65), Dobell, Alexander Smith, and according to some critics, Gerald Massey. It was characterized by an under-current of discontent with the mystery of existence, by vain effort, unrewarded struggle, sceptical unrest, and an uneasy straining after the unattainable. It thus faithfully reflected a certain phase of 19th century thought.

The standard edition of his *Poems* (1875) includes a memoir by Prof. Nichol, who also edited a collection of his prose writings under the title *Thoughts on Art, Philosophy and Religion (1870).*

DOBELN, a town of Germany, in the *Land* of Saxony, on the (Freiberg) Mulde, two arms of which embrace the town as an island, 35 mi. S.E. from Leipzig by rail, and at the iunction of lines to Dresden, Chemnitz, Riesa and Oschatz. Pop. (1939) 25,048. The Nikolai-kirche, dating in its present form from 1485, a mediaeval town hall, a former Benedictine nunnery and a monument to Luther are notable. The industries includewool-spinning, iron-founding, carriage, agricultural implement, and metal-printing and stamping work.

DOBERAN, a town and watering-place in the *Land* of Mecklenburg, Germany, lying about 2 mi. from the shores of the Baltic and 7 W. of Rostock by rail. Population 5,570. Besides the ruins of a Cistercian abbey founded by Pribislaus, prince of Mecklenburg, in 1173, and secularized in 1552, it possesses an Evangelical Gothic church of the 14th century, one of the finest in north Germany, a palace, a theatre, an exchange and a concert hall. Owing to its delightful situation amid beech forests and to its chalybeate waters, Doberan has become a favourite summer resort. In 1793 Duke Frederick Francis caused the first seaside watering-place in Germany to be established on the neighbouring coast, 4 m. distant, at the spot where the Heiligen-Damm, a great bank of rocks about 1,000 ft. broad and 15 ft. high, stretches out into the sea and forms an excellent bathing ground.

DÖBEREINER, JOHANN WOLFGANG (1780–1849), German chemist, was born near Hof in Bavaria on Dec. 15, 1780. After studying pharmacy at Miinchberg, he started a chemical manufactory in 1803, and in 1810 was appointed professor of chemistry, pharmacy and technology at Jena, where he died on March 24, 1849. The Royal Society's *Catalogue* enumerates 171 papers by him on various chemical topics, but he is best known for his experiments on platinum in a minute state of division and on the oxidation products of alcohol. He studied the formation of aldehyde from alcohol by various methods, also obtaining its crystalline compound with ammonia, and he was the discoverer of furfural. An early observation of the diffusion of gases was recorded by him in 1823 when he noticed the escape of hydrogen from a cracked jar, attributing it to the capillary action of fissures. His works included treatises on pneumatic chemistry (1821–25) and the chemistry of fermentation (1822).

A correspondence which he carried on with Goethe and Charles August, grand-duke of Saxe-Weimar, was collected and published at Weimar by Schade in 1856.

DÖBLIN, ALFRED (1878–), was born at Stettin on Aug. 10, 1878. After studying in Berlin and Freiburg, he settled in Berlin as a practising doctor. His principal works are *Der schwarze Vorhang* (written 1902–03; pub. 1919); *Die drei Sprünge des Wang-lun* (a romance of China, 1916); *Wallenstein* (historical novel, 1919) and *Berge, Meere, Giganten* (a tale of primitive life, 1924). In these works he combines an epic force of expression with an extremely vivid narrative style. Less important are *Wadzek's Kamtpf mit der Dampfturbine* (1918); *Der deutsche Maskenball* (essays, 1921); *Reise in Polen* (an appreciative travel book, 1926); *Manas* (poem, 1927); *Das Ich über die Natur* (1928).

In 1928 Doblin was elected a member of the German Academy of letters.

DÖBRENTEI, GABOR (GABRIEL) (1786–1851), Hungarian philologist and antiquary. was born at Nagyszollos. He completed his studies at the Universities of Wittenberg and Leipzig. and became a tutor in Transylvania. In 1820 Dobrentei settled at Budapest, where he held various official posts, and there he spent the rest of his life. His great work is the *Ancient Monuments of the Magyar Language* (*Régi Magyar Nyelvemlékek,* 1838 *seq.*), the editing of which was entrusted to him by the Hungarian Academy.

Döbrentei was one of the organizers, under the presidency of Count Teleki, of the Hungarian Academy.

He died at his country house, near Budapest, on March 28, 1851.

DOBRICI (or BAZARGIC), capital of the department of Caliacra, southern Dobruja, Rumania. Population 29,938. Dobrici is the centre of a postal district, and has a large annual fair for cattle, horses and sheep.

The small ports of Balcik and Cavarna are situated some 15 m. away, on the Black sea. The population of the district is very mixed, including Turks, Bulgars, Circassians and Tatars. Gagauz and many gypsies.

DOBRIZHOFFER, MARTIN (1717–1791), Austrian Roman Catholic missionary, was born at Gratz, in Styria. He joined the Jesuits in 1736, and in 1749 proceeded to Paraguay, where for 18 years he worked among the Guaranis and the Abipones. Returning to Europe on the expulsion of the Jesuits from South America, he settled at Vienna, obtained the friendship of Maria Theresa, and composed the history of his mission

entitled *Historia de Abiponibus, Equestri Bellicosaque Paraguariae Natione,* etc., 3 vols. (Vienna, 1783). In 1822 there appeared in London an anonymous translation really by Sara Coleridge. Dobrizhoffer died on July 17, 1791.

DOBROVSKY, JOSEPH (1753–1829), Hungarian philologist, was born of Bohemian parentage at Gjermet, near Raab, Hungary, and studied at Prague. In 1772 he joined the Jesuits at Briinn; but on the dissolution of the order in 1773 returned to Prague to study theology, and became tutor in the family of Count Nostitz. In 1792 he was commissioned by the Bohemian Academy of Sciences to visit Stockholm, Abo, Petersburg and Moscow in search of the manuscripts which had been scattered by the Thirty Years' War; and on his return he accompanied Count Nostitz to Switzerland and Italy. Dobrovsky was the real founder of modern Slavonic studies, and the originator of the revival of Czech as a literary language. His grammar and dictionary provided the basis for modern Czech philology, and modern Czech speech. *(See* CZECH LANGUAGE: CZECH LITERATURE.)

The following is a list of his more important works, *Fragmentum Pragense evangelii S. Marci, vulgo autographi* (1778); *Scriptores rerum Bohemicarum* (a vols., 1783); *Geschichte der bohm. Sprache und altern Literatur* (1792); *Die Bildsamkeit der slaw. Sprache* (1799); *Institutiones linguae slavicae dialecti veteris* (1822); *Entwurf zu einem allgemeinen Etymologikon der slaw. Sprachen* (1813); and a critical edition of Jordanes, *De rebus Geticis,* for Pertz's *Monumenta Germaniae historica. See* Palacky, *J. Dobrowskys Leben und gelehrtes Wirken (1833).*

DOBRUJA (DOBROGEA), a region of southeast Rumania and northeast Bulgaria, bounded north and west by the Danube, east by the Black sea, and south by Bulgaria. Its area is 23,262 sq.km., the population (1937) approximately 900,000. It comprises the four districts of Tulcea, Constanţa, Durostor and Bazargic. It consists of low mountains, fens and sandy steppes, wind-swept and drought-ridden, but remarkably fertile when the lack of irrigation is considered. Its main port, Constanţa, is Rumania's principal seaport, connected by a pipe line with the Rumanian oil-fields.

HISTORY

The district was known to the Greeks in the 6th century B.C. and included the Greek colonies of Istros, Tomi and Dionysopolis. In the 5th and 4th centuries B.C. invading Scythians subjugated and later submerged the Thracian population, whence the later names of Scythia Minor and Scythia Pontica. The Romans first invaded it 75–72 B.C., definitely subjecting it in A.D. 46. They and their successors the Byzantine emperors Romanized the population and erected walls for its defence; but it was repeatedly overrun by Goths, Alans and Huns.

In A.D. 678 Asparuch, Khan of the Bulgarians, settled with his horde, by permission of the Byzantine empire, near the present Nicoliţel; but soon repudiated his allegiance and founded the first Bulgarian empire, which included the Dobruja, with its mixed population of Slavs, Bulgars and the remnants of the old Roman colonies. It was recovered for Byzantium in 1018, but in 1186 reverted to the second Bulgarian empire, established by the alliance of Bulgars, Vlachs and Cumans. Magyars, Petchenegs and Cumans had repeatedly ravaged it, the two last named settling there in such numbers that it was known as Petchengia. In the 13th century the Tatars frequently raided it. With the decline of the Bulgarian empire, one Dobrotitich, a condottiere of Wallachian origin, founded here an independent, or at least semi-autonomous depotate; the name Dobruja derives either from Dobrotitich or from the Topruch Tatars. In 1390 it passed under the suzerainty of Mircea-Voda, Voivode of Wallachia; but after his several capitulations to the Turks (1391, 1393, finally in 1411) it came under Turkish domination for nearly 500 years. These years brought a further ethnical change, numbers of Turks, Tatars and Circassians being settled in the steppes.

The Treaty of Berlin (July 13, 1878) assigned the Dobruja to Rumania, in compensation for Bessarabia, annexed by Russia. The Treaty of Bucharest (Aug. 10, 1913) advanced the frontier 30m. southward, the two districts of Bazargic and Durostor being ceded to Rumania by Bulgaria. The Central Powers annexed the entire province under the Treaty of Bucharest (May 7, 1918); the southern half was ceded immediately to Bulgaria, the northern administered provisionally by the Central Powers in condominium, while Rumania was allowed to retain the port of Constanţa (Kustenje) as an outlet to the Black sea. The Treaty of Neuilly (Nov. 27, 1919), restored the 1913 frontier, leaving the entire province to Rumania. The treaty of Crayova in Sept. 1940, restored southern Dobruja to Bulgaria. The territory ceded was about 7,600 sq.km. or a third of the whole area (population, 350,000), made up largely of the districts of Durostor and Bazargic. This fertile quadrilateral contains the important port of Silistra on the Danube and of Balchich on the Black sea. The territory ceded was occupied by Bulgarian troops on Sept. 20. The Rumanians living in the region were to be exchanged for Bulgarians living in the northern Dobruja. Thus the frontier of 1912 was restored. (N. L. F.; H. KO.)

DOBŠINÁ, a small town of central Slovakia in the Triassic limestone "karst" zone of the Carpathians near the Gollnitz valley. Founded by German miners in the 14th century as a result of the wealth of the surrounding mountains in iron, cobalt, copper and mercury, it is now mainly famous for the existence about 3¾ m. N.W. of the town of a cavern containing an icefield, nearly 2 acres in area, with which are associated remarkable and beautiful formations.

DOBSON, FRANK (1887–), British sculptor, was born in London on Nov. 18, 1887. He received his early training with the sculptor W. Reynolds-Stephens, and later obtained a scholarship at Hospitalfield, Arbroath, New Brunswick. After further study in the City and Guilds Schools at Kennington, London, he lived in Cornwall and worked with the granite cutters. He was thus technically well equipped for a sculptor's career. His early works, both in painting and sculpture—few of which now exist—show definitely the attraction of the first Post-Impressionist exhibition held in London in 1909. After war service he exhibited his first important work in stone "The Concertina Man" (1919), which was followed in 1921 by "Two Heads" in red Mansfield stone and the more complex Portland stone group "The Man Child." In 1923 he competed unsuccessfully for the Welsh National Memorial at Cardiff with his recumbent figure, "Cambria." To the next two years belong the white marble figure of a woman (1924), the seated nude "Susanna" and "Morning" (1925). His portraits include the bronze bust of the Earl of Oxford and Asquith (1921), the polished brass head of Osbert Sitwell (1923) and the plaster head of a young girl (1925)—the two last named in the National Gallery of British Art—the bronze half-length of Lydia Lopokova (1924) and heads of L. H. Myers (1925), Robert McAlmond and Robin Sinclair. He was a founder of the X Group, and in 1923 became president of the London Group.

See Roger Fry in *The Burlington Magazine,* vol. *46,* p. 171 (1925); Clive Bell in *The Architectural Review,* vol. 59. p. 41 (1926).

DOBSON, HENRY AUSTIN (1840–1921), English poet and man of letters, was born at Plymouth and educated at Beaumaris, Coventry, and the Strasbourg gymnase. In Dec. 1856 he entered the board of trade, and from 1884 to 1901, when he retired, was a principal clerk in the marine department of that office. In 1873 he collected the poems which had appeared in various periodicals in a volume entitled *Vignettes in Rhyme.* In 1875 appeared *At the Sign of the Lyre,* which contained "The Ladies of St. James's," "The Old Sedan Chair," "My Books," and the delightful "Fables of Literature and Art." The book has the flavour of the 18th century which Dobson loved so well, and of which he has left exquisite pictures in prose as well as in verse. Dobson led the movement in the late '70s for the introduction of French forms, the ballade, the triolet, and the rondeau, forms which he used in his *Proverbs in Porcelain* (1877). *Vignettes in Rhyme* and *Proverbs in Porcelain,* combined in one volume, were printed in the United States as *Vignettes in Rhyme* (1880), and with some additions as *Old World Idylls* (1883) in England. After 1885 Dobson was engaged principally upon critical and biographical prose. His biographies of *Fielding* (1883), *Bewick* (1884), *Steele* (1886), *Goldsmith* (1888), *Walpole* (1890), *Hogarth* (1879–98), *Samuel Richardson* (1902), and *Fanny Burney* (1903) are studies marked

alike by assiduous research, sympathetic presentation and sound criticism. Dobson always added something, and often a great deal, to our positive knowledge of the subject in question, his work as a critic never being solely aesthetic. *Four Frenchwomen* (1890), the three series of Eighteenth-Century Vignettes (1892–94–96), and *The Paladin* of Philanthropy (1899), contain unquestionably his most delicate prose work. In 1901 he collected his hitherto unpublished poems in a volume entitled *Carmina Votiva.*

See Alban Dobson, Austin Dobson, Some Notes (1928).

DOBSON, WILLIAM (1610–1646), English portrait and historical painter, was born in London. Excellent examples of Dobson's portraits are to be seen at Blenheim, Chatsworth, and other country seats throughout England, and there are several examples at Hampton Court and in the National Portrait Gallery, London, including a very fine portrait of Endymion Porter. The head in the '(Decollation of St. John the Baptist' at Wilton is said to be a portrait of Prince Rupert.

See Collins Baker, *Lely* and *the* Stuart Portrait Painters (1912).

DOBSON-FLY, the name given to large flies of the genus Corydalis, allied to the alder-fly (*q.v.*), and inhabiting North and South America and northern India. The males are remarkable for their large jaws. Scientifically, dobson-flies are placed in the family *Sialidae,* order Neuroptera (*q.v.*). The larvae are aquatic.

DOCETAE, a name applied to those thinkers in the early Christian Church who held that Christ, during his life, had not a real or natural, but only an apparent (δοκεῖν, to appear) or phantom body. The name is first used by Theodoret (*Ep.* 82) as a general description, and by Hippolytus (*Philosophumena,* viii. 8–11), Clement of Alexandria and others, as the name of a distinct sect. It must, however, be regarded as a type of Christology. The origin of the heresy is to be sought in Greek, Alexandrine and Oriental speculations about the imperfection or rather the essential impurity of matter. Traces of a Jewish Docetism are to be found in Philo; and in the Christian form it is generally supposed to be combated in the Johannine Epistles (I. ii. 22, iv. 2, v. 6, 20; II. 7) and more formally in the epistles of Ignatius (*Ad* Trall. 9 f., *Ad Smyrn.* 2, 4, *Ad Ephes.* 7; cf. Polycarp, Ad Phil. 7). It differed much in its complexion according to the points of view adopted by the different authors. Among the Gnostics and Manichaeans it existed in its most developed type, and in a milder form is to be found even in the writings of the orthodox teachers.

The more thoroughgoing Docetae assumed the position that Christ was born without any participation of matter; and that all the acts and sufferings of his human life, including the crucifixion, were only apparent. They denied, accordingly, the resurrection and the ascent into heaven. To this class belonged Dositheus, Saturninus, Cerdo, Marcion and their followers, the Ophites, Manichaeans and others. Marcion, for example, regarded the body of Christ merely as an "umbra," a "phantasma." His denial (due to his abhorrence of the world) that Jesus was born or subjected to human development, is in striking contrast to the value which he sets on Christ's death on the cross. The other, or milder school of Docetae, attributed to Christ an ethereal and heavenly instead of a truly human body. Amongst these were Valentinus, Bardesanes, Basilides, Tatian and their followers. They varied considerably in their estimation of the share which this body had in the real actions and sufferings of Christ. Docetism springs from the same roots as Gnosticism (*q.v.*).

DOCHMIAC [Gr. δοχμή, "a hand's breadth"], a form of verse, consisting of *dochmii* or pentasyllabic feet (usually ∪ – – ∪ –), in English, "rĕbēl, slāves, rĕbēl."

'DOCK, in botany, the name applied to the plants constituting a section of the genus *Rumex,* family Polygonaceae. They are biennial or perennial herbs with a stout rootstock, and glabrous linear-lanceolate or oblong-lanceolate leaves with a rounded, obtuse or hollowed base and a more or less wavy or crisped margin The flowers are arranged in more or less crowded whorls the whole forming a panicle; they are generally perfect, with six sepals, six stamens and a three-sided ovary bearing three styles with much-divided stigmas The fruit is a triangular nut enveloped in the three enlarged leathery inner sepals, one or all of which bear a tubercle. In the common or broad-leaved dock, *Rumex* obtusifolius, the flower-stem is erect, branching, and 18 in. to 3 ft. high, with large radical leaves, heart-shaped at the base, and more or less blunt; the other leaves are more pointed, and have shorter stalks. The whorls are many-flowered, close to the stem and mostly leafless. The flowers appear from June to August. In autumn the whole plant may become of a bright red colour. It is a troublesome weed, common by roadsides and in waste places, fields and pastures, where it is often accidentally introduced with clover and grass seeds. The great water dock, *R. hydrolapathum,* is a tall-growing species. Other British species are R. *crispus;* R. conglomeratus, the root of which has been employed in dyeing; R. *sanguineus* (bloody dock, or bloodwort); R. *pulcher* (fiddle dock), with fiddle-shaped leaves; *R. maritimus.* The naturalized species, R. *alpinus,* or "monk's rhubarb," was early cultivated in Great Britain, and was accounted an excellent remedy for ague.

Some 30 or more species occur in North America, widely distributed in the United States and Canada, about one-third of which are naturalized from the Old World. The roots of the canaigre (*R. hymenosepalus*), native to the south-western United States and Mexico, have been used for tanning.

The fleshy, solid part of an animal's tail is also known as "dock" (cf, Icel. docke, stumpy tail; Ger. *Docke,* bundle, skein). The verb "to dock," especially in reference to horses and dogs, is used of the shortening of an animal's tail by severing one or more of the vertebrae. The English Kennel Club (Rules, 1927) disqualifies from prize-winning dogs whose tails have been docked, with the exception of varieties of terriers, spaniels, etc., and such other breeds as may be determined by the committee.

The prisoners' dock, a railed-in enclosure in which prisoners are placed during trial, is apparently derived from Flem *dok,* pen or hutch. It occurs in 1610 as "bail-dock," a room at the Old Bailey left open at the top.

DOCKET, in law, a brief summary of a case, or a memorandum of legal decisions; also the alphabetical list of cases down for trial, or of suits pending. Such cases are said to be "on the docket." In commerce a docket is a warrant from the custom-house, stating that the duty on goods entered has been paid, or the label fastened to goods, showing their destination, value, etc., and, generally. any endorsement on the back of a document, briefly stating its contents.

DOCKS. The principal function of a commercial port is to provide means whereby cargoes may be discharged from and loaded into vessels frequenting it for the purpose. The transfer of goods may be from ship to quay warehouses and other storage places; or to wagons on the quays; or to river and canal craft lying alongside the ship; and vice versa. The facilities provided must be in sheltered positions and suitable appliances are necessary for the convenient and expeditious handling of cargoes. A basin constructed for these purposes, surrounded by quay walls, is known as a dock. The term is specially applied to basins, at places with a large range of tide, usually more than 15ft., in which the water is maintained at a fairly uniform level by gates, which are closed when the tide begins to fall as at the docks of Liverpool. England. and Havre, France. (The word "dock" should, strictly speaking, be applied only to wet-docks closed by gates, and to dry-docks and floating docks used for the repair of vessels. It is. however, commonly and popularly employed in a wider sense and is so used in this article.) Sometimes, however, at both river and sea-coast ports with lesser range of tide such as Glasgow, Hamburg, Rouen, Southampton and New York, dock gates are dispensed with, and open basins and river quays serve for the accommodation of vessels. In tideless seas, such as the Mediterranean, the rivers are usually barred by deltas at their outlets, like the Rhone and Tiber, and thus rendered inaccessible. Ports have often been established on the coasts of such seas by constructing open basins protected by breakwaters, as at Marseilles. Genoa and Naples. Open basins, however, are precisely the same as closed docks, except for the absence of dock gates.

The accommodation for shipping in basins in river ports is so

frequently supplemented by river quays, that closed docks, open basins and river quays and wharves are all naturally included in the general consideration of dock works. The present article therefore comprehends brief descriptions of wet-docks and basins and their approaches; locks and entrances; quay walls, piers and wharves; dry docks and slipways; dock and lock gates and caissons; the equipment and machinery of docks; and the methods of handling cargo in them. Reference is made to Naval docks but

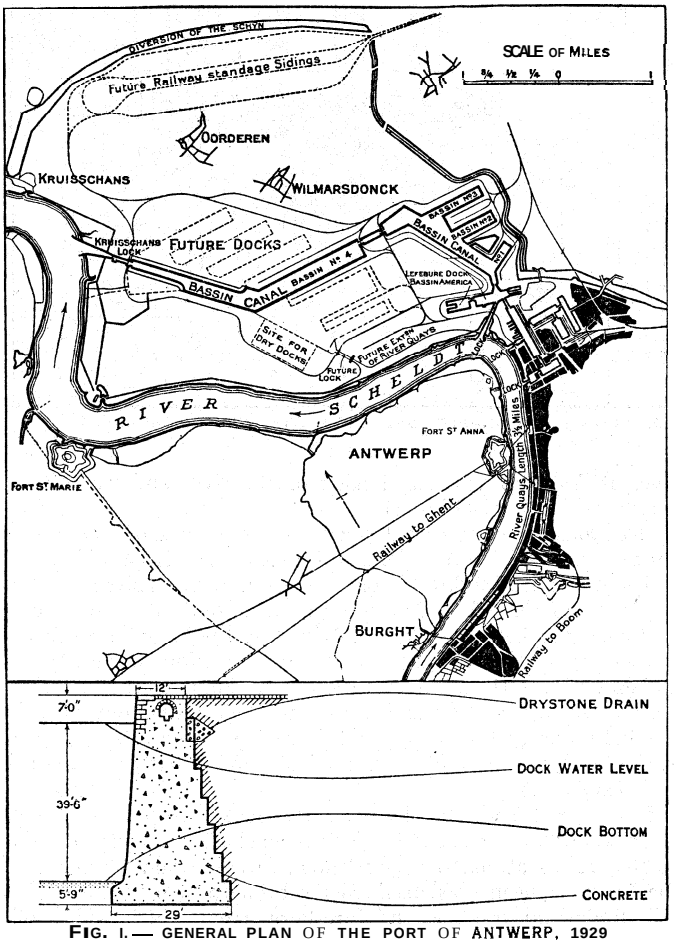


FIG. 1.— GENERAL PLAN OF THE PORT OF ANTWERP, 1929

for these *see* the article DOCKYARDS AND NAVAL BASES. *See* also HARBOURS; BREAKWATER; RIVER AND RIVER ENGINEERING; JETTY; CANALS AND CANALIZED RIVERS; PORT OPERATION.

Early Dock Construction.—Some account of ancient harbour works will be found in the article HARBOURS. The earliest quays or wharves in the Port of London were probably the "hithes" of Saxon times. These were small cuts formed in the bank of the river, their sides being protected by rude piling. The word is still preserved in place names, such as Queenhithe. Dowgate dock and Puddle dock were ancient hithes but the word dock was not used in the sense of a closed dock until the 15th century.

There are records in 1434 of an elementary form of dry-dock at Southampton which seems to have been a narrow embayment in which a ship was placed at high tide and then, as the tide fell, enclosed by a temporary wall of clay, timber and brushwood built across the mouth. The first permanent dry dock, with primitive gates staunched with clay, was built at Portsmouth in 1496. This dock was large enough to take in the "Sovereign," the biggest warship of the time. Later the dock was enlarged and in 1523, the "Henri Grace à Dieu" of 1,000 tons was docked in it. In the Port of London no dry docks, other than those of the ly temporary kind, were constructed until the middle of the century when there were dry docks with gates at Deptford, wall and Woolwich, as well as at Chatham. One such was made at Bristol as early as 1626 and remained in use until 1687; and in 1656 a larger dry dock was built at Portsmouth.

Open tidal basins formed by excavating in the banks of a river, such as the Thames, and surrounded by wharves or primitive timber faced quays, had been in use since the 11th century, and these were sometimes known as docks. But the first closed wet dock was one at Blackwall, which is mentioned by Pepys in 1661; and at Dunkirli a wet dock of 49 acres with closing gates was made in 1686. An Act of Parliament was obtained in 1696 for the building of the Howland dock at Rotherhithe on the Thames, which was later absorbed in the Surrey Commercial docks.

The earliest wet dock at Liverpool, the Old Dock, was built about 1708–10—the exact date is uncertain—and was the pioneer of the great series of docks since constructed in the river Mersey. Bristol followed with a wet dock, begun in 1712; but at that port, the "Trench," an artificial cut forming a new channel for the river Frome into the Avon, with quays and wharves along its bank, was made as far back as 1247. This cut became the harbour of Bristol and from its quay Cabot sailed in 1497, on the voyage which resulted in his discovery of the mainland of North America. (For details of early history see *The Development of Harbour and Dock Engineering*, Sir C. R. S. Kirkpatrick's Vernon-Harcourt Lecture, Inst. C.E. 1926; and Bélidor's *Architecture Hydraulique*, Paris, 1737–53.)

It was not until the beginning of the 19th century that the era of systematic dock construction began which kept pace with the steady development of shipbuilding and maritime transport throughout the past century, and still continues to do so.

Dimensions **of** Shipping.— In designing new port works, it is essential to look forward to the possible future requirements of vessels. The necessity for such forethought is shown by the progressive increase in the size, not only of the largest ocean liners but, also, of cargo carrying ships. The "City of Rome," launched in 1881, was 560ft. long, 52½ft. beam and had a maximum draught of 27½ft.; the "Campania" and "Lucania," of 1893, measured 600 by 65ft. At the close of the 19th century a cargo vessel of over 500ft. in length did not exist: the limiting draught of the Suez canal was 27½ft., and the largest merchant ship afloat, excepting those in the Atlantic trade, was 530 by 61ft. and 28ft. draught.

The period of 15 years which preceded the World War was marked by great advances. In 1910 the largest merchant ship afloat was the "Mauretania" of 30,696 gross tons, 762ft. long and 88ft. beam; but, excluding transatlantic liners, the largest cargo carrying ship did not exceed 13,000 tons. In 1914 merchant ships far exceeding the dimensions of the "Mauretania" were either afloat or building. Harbour authorities, not only of those ports which accommodated the great transatlantic liners but in many other parts of the world, were engaged in increasing their facilities to serve shipping of far larger dimensions than any which had hitherto used their navigable waters. During the war period harbour development throughout the world was arrested and confined. in the main, to works of a belligerent nature.

Until 1930 no ships of greater dimensions than the largest of those building in 1914 were laid down. The dimensions of the "Majestic" (ex "Bismarck"), laid down before the war but not completed until 1921, were 56,551 gross tons, 915·5ft. length, 100·1 ft. beam, and maximum draught 38.9 feet. The "Leviathan" (ex "Vaterland") has been loaded to 41ft. draught. The "Queen Mary" laid down in 1930, but not completed until 1936 was the first ship to exceed 1,000ft. in length (over all) and was followed by the "Normandie," completed in 1935, and the "Queen Elizabeth." These vessels slightly exceed the "Queen Mary" in tonnage and dimensions, the "Queen Elizabeth" being of about 84,000 gross tons. In 1899 the largest general cargo vessel afloat had a gross tonnage of under 8,000 and was 470ft. in length. In 1928 cargo ships over 600ft. long and of 18,000 to 20,000 tons gross were in service, in 1939 there were no less than 82 vessels entered in Lloyd's Register whose gross tonnage exceeded 20.000; 496 ships within the range of 10,000–20,000 tons were in regular service.

Depth of Water.—The deepening and widening of the Suez canal in recent years has enabled ships of the largest class to trade with eastern ports. By 1928 it mas practicable for ships draw-

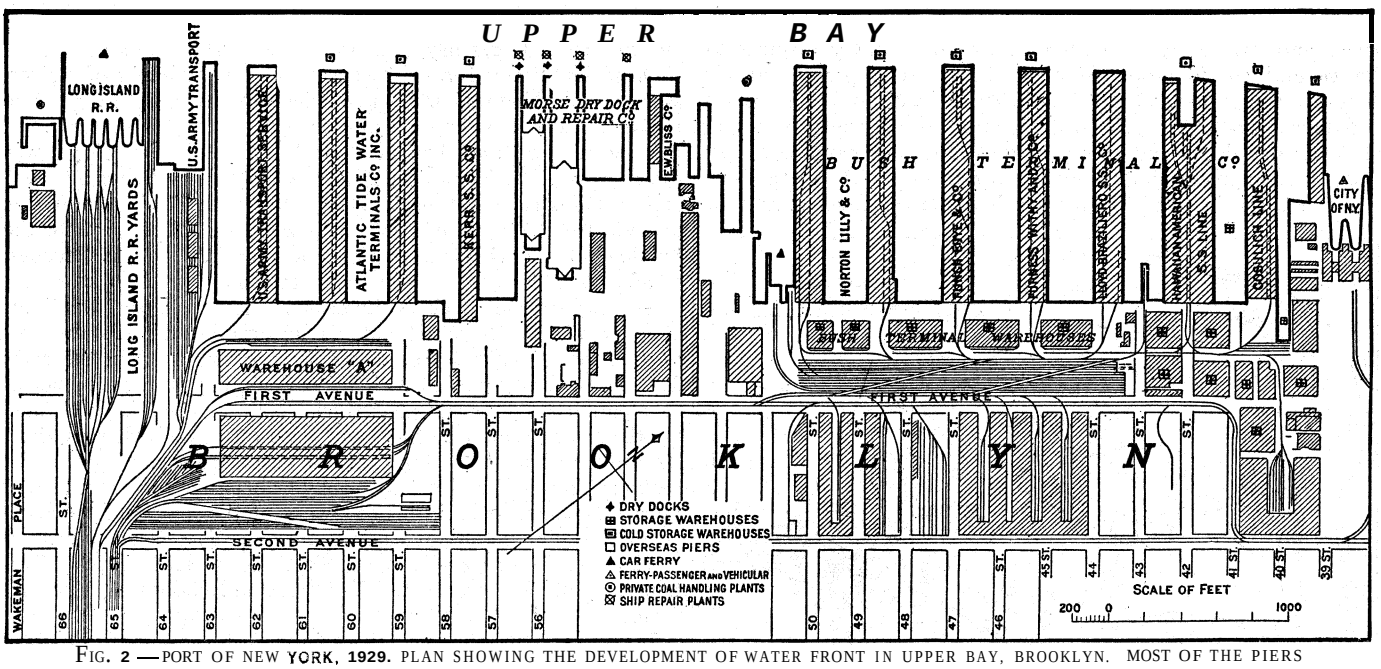

FIG. 2 — PORT OF NEW YORK, 1929. PLAN SHOWING THE DEVELOPMENT OF WATER FRONT IN UPPER BAY, BROOKLYN. MOST OF THE PIERS ARE OPEN PILED STRUCTURES WITH 30 FT. DEPTH OF WATER AT LOW TIDE

ing 33ft. to pass through it. Further improvements in progress in 1940 were to provide for a draught of 35ft. and there is no reasonable limitation to the capacity of the canal. The more important ports of the Far East have been developed concurrently. The opening in 1914 of the Panama canal, having a navigable depth of 40ft., has also had an important bearing on the development of harbours in the Far East and on the Pacific coast of America. Work was begun in 1940 on the construction of a third and larger set of locks in the Panama canal. The internal dimensions of these locks will be approximately 1,200ft. length, 135ft. width and 45ft. depth of water. The general result is that, whereas in 1900 a navigable depth of 30ft. was considered ample, at least 3jft. is now regarded as essential in harbours of the first class and, in special cases, including the ports used by transatlantic liners. depths exceeding 40ft. and even up to 45ft. are required.

Effect of Depth on Cost of Works.—The cost of constructing port works in general shows an increase approximately proportional to the ratios of the cubes of the draughts of the largest ships for which they are designed. (*See* L. H. Savile, 13th International Congress of Navigation, London, 1923.) It is thus obvious that the problem of providing port accommodation for shipping of the largest class is one of considerable importance from the point of view of finance, and may become one of balance between the relative economy of ships of large draught and cargo capacity, and the capital cost of port construction.

Sites for Docks.—Low-lying land adjoining a tidal river or estuary frequently provides suitable sites for docks. The position, being more or less inland, is sheltered; the low level reduces the excavation required for forming the docks, and enables the excavated materials to be utilized in raising the ground at the sides for quays; and the river furnishes a sheltered approach channel. Notable instances are the docks of the ports of London, Liverpool, South Wales, Southampton, Hull, Belfast, St. Nazaire, Rotterdam, Antwerp and Hamburg. Sometimes docks are partially formed on foreshores reclaimed from estuaries, as at Hull, Grimsby, Cardiff, Rosyth Dockyard, Liverpool, Leith and Havre; while at Bristol, a curved portion of the river Avon was appropriated for a dock, and a straight cut made for the river. By carrying docks across sharp bends of tidal rivers, upper and lower entrances can be provided; and of this the London, Surrey Commercial, West India, and Victoria and Albert docks are examples on the Thames, and Chatham dockyard on the Medway. The enlargement of the port of Antwerp is another instance. A series of enclosed docks, extending from Kruisschans, on the Scheldt 7m. below the city, to the old dock system higher up the river at Antwerp, cuts off a bend of the river and was opened for traffic in 1927. (Fig. 1.)

Occasionally, when a tidal river has a shallow entrance, docks, formed on its foreshore adjoining the sea-coast, are provided with a sheltered entrance direct from the sea as in the Havre docks at the outlet of the Seine. Many old ports were first established on sandy coasts where a creek, maintained by the influx and efflux of the tide from low-lying spaces near the shore, afforded some shelter and an outlet to the sea across the beach. Some of these, such as Calais, Dunkirk and Ostend, have had their access improved by parallel jetties and dredging; and docks have been readily formed in the low-lying land only separated by sand dunes from the sea. (*See* HARBOURS.)

In sheltered places on the sea-coast, docks are sometimes constructed on low-lying land bordering the shore, with direct access to the sea, as at Barrow, Hartlepool, Swansea and Bombay. In the Mediterranean open basins have been formed in the sea, by establishing quays along the foreshore, from which wide, solid jetties, lined with quay walls, are carried into the sea at intervals at right angles to the shore. Such basins are sheltered by an outlying breakwater parallel to the coast, and are reached at each end through the openings left between the projecting jetties and the breakwater, as at Marseilles and Trieste, and at the extensions at Genoa (*see* HARBOURS). In some of these ports additional accommodation has been obtained by constructing wide quays along the inner face of the breakwater (*q.v.*). Where, however, the basins are formed within the partial protection of a bay, as in the old ports of Genoa and Naples, the requisite additional shelter has been provided by converging breakwaters across the opening of the bay, and an entrance to the port is left between the breakwaters.

The two deep arms of the sea at New York, known as the Hudson and East rivers, are so protected by Staten Island and Long Island that it has been only necessary to form open basins by projecting jetties or piers into them from the west and east shores of Manhattan island, and from the New Jersey and Brooklyn shores, at intervals, to provide adequate accommodation for Atlantic liners and the sea-going trade of New York. Somewhat similar conditions obtain in many of the great natural harbours in other parts of the world, as, for instance, in Sydney harbour and at San Francisco.

Dock Extensions. — In designing dock works, it is expedien to make provision, as far as possible, for future extensions as trade of the port increases. Generally this can be effected a side tidal rivers and estuaries by utilizing sites lower don

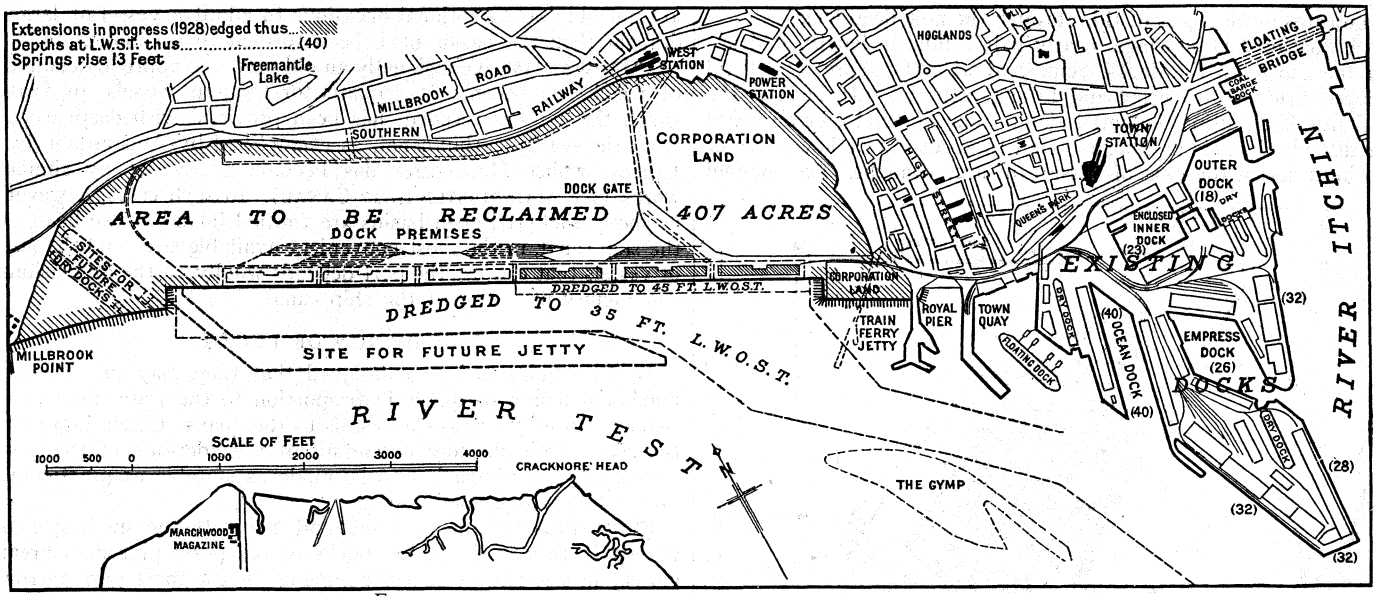

FIG. 8.— DIAGRAM SHOWING THE PLAN OF SOUTHAMPTON DOCKS, 1928

river, or reclaiming unoccupied foreshores of an estuary, as adopted for extensions of the ports of Liverpool, Hull and Havre. At ports on the sea-coast of tideless seas, it is only necessary to extend the outlying breakwater parallel to the shore line, and form additional basins under its shelter, as at Marseilles and Genoa (for plans *see* HARBOURS). Quays also along rivers furnish valuable opportunities of extending the accommodation of ports. Ports, however, established inland, like Manchester, though extremely serviceable in converting an inland city into a seaport, are at the disadvantage of having to acquire very valuable land for any extensions that may be required; but, nevertheless, some compensation is afforded by the complete shelter in which the extensions can be carried out, when compared with Liverpool, where the additions to the docks can only be effected by costly reclamation works along the foreshore to the north, in increasingly exposed situations.

Venice being situated upon an island of limited area in a lagoon has secured the extension of its dock facilities by the construction of an entirely new port on the adjoining mainland. New York, in view of the congestion of traffic at the piers in the upper areas of the harbour, is developing large districts such as Staten island and Jamaica bay nearer the sea entrance.

APPROACH CHANNELS

The accessibility of a port depends upon several factors, such as the depth of its approach channel, which also determines the depth of the docks or basins to which it leads, for it is useless to give a depth to a dock much in excess of the depth down to which there is a prospect of carrying the channel by which it is reached. The great augmentation, however, in the power and capacity of modern dredgers, and especially of suction dredgers not only in sand but also in soft clay, together with the increasing draught of vessels, has resulted in a considerable increase being made in the available depth of rivers and channels leading to docks.

It is therefore necessary to make due allowance for the possibility of a reasonable improvement in determining the depth to be given to a new dock. On the other hand, there is a limit to the deepening of an approach channel, depending upon its length, the local conditions as regards silting, and the resources and prospects of trade of the port, for every addition to the depth generally involves a corresponding increase in the cost of maintenance.

In Tidal Ports.—At tidal ports the maximum available depth for vessels should be reckoned from high water of the lowest neap ides, as the standard which is certain to be reached at high tide. `e period during which docks can be entered at each tide depends the nature of the approach channel, the extent of the tidal and the manner in which the entrance to the docks is effected. Thus, where the tidal range is very large, as in the Severn estuary, the approach channels to some of the South Wales ports are nearly dry at low water of spring tides. It would be impracticable to make these ports accessible near low tide, except for small craft, whereas at high water, even of neap tides, vessels of large draught can enter the docks. Nevertheless, in recent years, it has become increasingly important to provide in tidal ports channels of sufficient depth to permit the access of large ships to the closed docks at all states of the tide and this has been effected at many ports such as Liverpool, London and Havre.

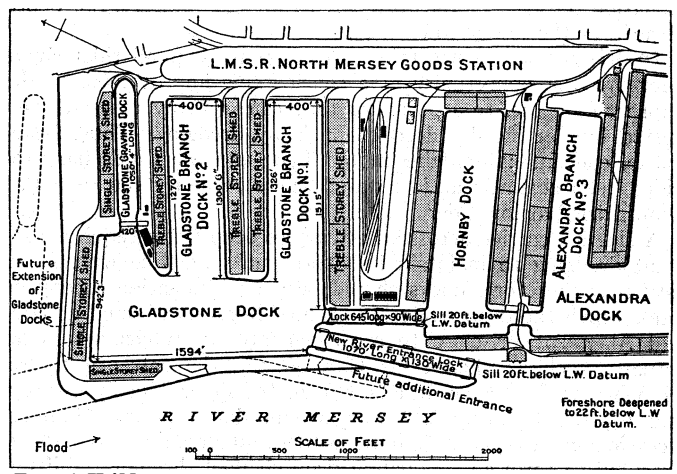

FIG. 4.—PLAN OF NORTHERN END OF DOCKS SYSTEM AT LIVERPOOL INCLUDING THE GLADSTONE DOCK OPENED IN 1927

Liverpool.—In the Mersey, with a rise of 31ft. at equinoctial spring tides, the deep channel between Liverpool and Birkenhead and into the outer estuary of the river in Liverpool bay is maintained by the powerful tidal scour resulting from the filling and emptying of the large inner estuary. Access to the river has been rendered possible, at any state of the tide (except in the case of the largest vessels at and near low water) by dredging a channel through the Mersey bar; minimum depth in bar channels is about 27ft. at mean low water spring tides (*see* RIVER AND RIVER ENGINEERING; HARBOURS) but the docks, with the exception of those communicating with the new Gladstone dock, cannot be entered by large vessels till the water has risen above half-tide level, and the gates are closed directly after high water. Vessels of light draught are, however, able to pass in and out of the older docks from about 3 hours before to 3 hours after high water by using the locks. The opening of the Gladstone dock in 1927 allows ships of moderate size to enter it and the docks with which it com-

municates at all states of tide through the new deep lock.

A floating landing-stage, nearly half a mile in length, in front of the centre of the docks, connected with the shore by several hinged bridges and rising and falling with the tide, enables the Atlantic liners using the port to come alongside and take on board or disembark their passengers at all times except at low water of spring tides in the case of vessels of large draught. The channel

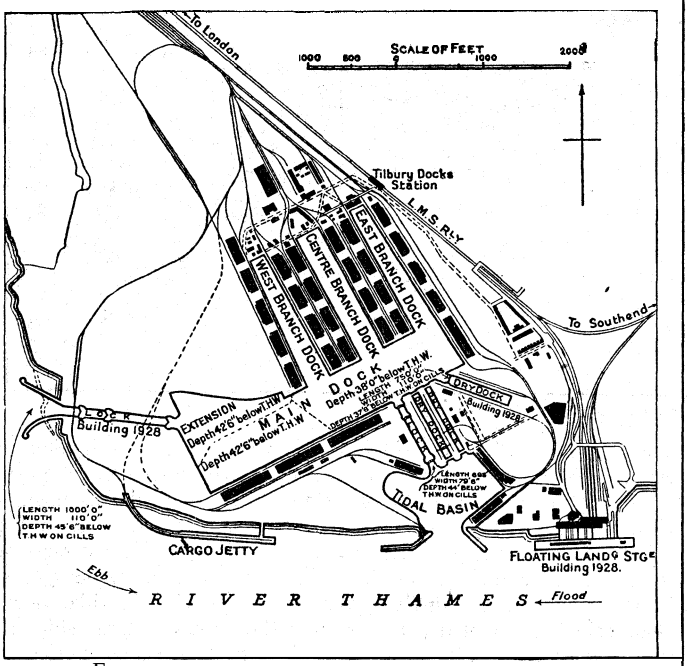

FIG. 5.—TILBURY DOCKS. THE PORT OF LONDON, 1929

alongside the part of the stage used by large vessels has a depth of 32ft. at the lowest low water.

In Rivers and Estuaries.— Comparatively small tidal rivers offer the best opportunity of a considerable improvement in the approach channel to a port; for they can in many cases be converted into artificially deep channels by dredging. Thus, systematic, continuous dredging in the Tyne and the Clyde has provided deep channels at low water where formerly the river bed almost dried at low tide.

A channel carried across an estuary to deep water requires constant dredging to maintain its depth. In large tidal rivers and estuaries, therefore, docks should be placed alongside a concave bank which the deep navigable channel hugs, as effected at Hull and Antwerp; or close to a permanently deep channel in an estuary, such as chosen for Garston and the entrance to the Manchester ship canal at Eastham in the inner Mersey estuary, and for the Grimsby and Immingham docks in the Humber. Occasionally, extensive training works and dredging have to be executed to form an adequately deep channel through a shifting estuary and shallow river, as, for instance, on the Weser to Bremerhaven and Bremen; on the Seine to Honfleur and Rouen; and on the Tees to Middlesborough and Stockton (see RIVER AND RIVER ENGINEERING).

Southampton.— Southampton possesses the very rare combination of advantages of a well-sheltered and fairly deep estuary, a rise of only 13ft. at spring tides, a double high water, and a position at the head of Southampton Water at the confluence of two rivers; so that, with a moderate amount of dredging and the construction of quays, some with a depth of 45ft. in front of them at low water, it is possible for vessels of the largest draught to come alongside or leave the quays at any state of the tide. This circumstance has enabled Southampton to attract many of the Atlantic steamships formerly running to Liverpool.

In Tideless Seas.—Ports on tideless seas have to be placed where deep water approaches the shore and, if possible, where there is an absence of littoral drift. The basins of such ports are always accessible for vessels of the draught they provide for, but they require most efficient protection and, unlike tidal ports, they are not able on exceptional occasions to admit a vessel of larger draught than the basins have been formed to accommodate.

Inland Ports.—Occasionally an old port, the approach channel of which has become inadequate for modern vessels, or from which the sea has receded, has been provided with deep access from the sea by a ship-canal, as exemplified by Amsterdam and Bruges; whilst Manchester has become a sea-port by similar works (see MANCHESTER SHIP CANAL). In such cases, however, perfectly sheltered open basins are formed inland at the head of the ship canal, in the most convenient available site; and the size of vessels that can use the port depends wholly on the dimensions and facility of access of the ship canal.

THE DESIGN OF DOCKS

Docks require to be so designed that they may provide the maximum length of quays in proportion to the water area consistent with easy access for vessels to the quays. Often, however, the space available does not admit of the adoption of the best forms, and the design has to be made as suitable as practicable under the existing conditions.

Planning.— On this account, and owing to the small size of vessels in former times, the docks of old ports present a great variety in size and arrangement, being for the most part narrow and small, forming a sort of string of docks communicating with one another, and provided with locks or entrances at suitable points for their common use. Such conditions are noticeable in the older London and Liverpool docks.

Where the conditions of site permit, the ideal plan for a commercial dock comprises an ample vestibule or turning basin and a series of wide parallel piers or quays with intervening water spaces or branch docks arranged like the teeth of a comb, but inclined slightly towards the approach channel. Vestibule planning has been embodied in the lay-out of many large modern docks including those of Manchester, Dunkirk, Hull and the open basins at Glasgow. It is also the characteristic feature of mohern ports in tideless seas enclosed by protection works as at Marseilles.

Liverpool.— The later Liverpool docks at the northern end of the series, including the Gladstone dock (fig. 4) have been constructed on the vestibule plan with branches. Some of the older docks adjoining them to the south have been remodelled so as to form series of branch docks opening into vestibule docks alongside the river wall. The Gladstone dock includes a vestibule or turning dock, a graving dock, also usable as a wet dock, two branch docks and a large deep water lock giving access from the river. The water area is 58¼ acres and the quayage about 3m. in

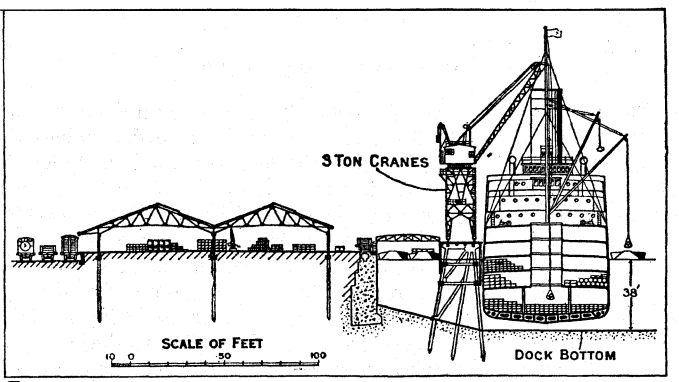

FIG. 6.— CROSS SECTION OF SOUTH QUAY AND ISLAND JETTIES OF KING GEORGE V. DOCK. LONDON, OPENED IN 1921

length. A lock between the adjoining Hornby dock and the new dock makes it possible for ships to enter and leave some of the older docks by way of the deep river lock.

Port of London.— Though narrow timber jetties were introduced long ago in some of the wider London docks for increasing the quay space, no definite planning arrangement was adopted in building the large Victoria and Albert docks between 1850 and 1880. The Victoria dock was made wide, with solid jetties provided with warehouses projecting from the northern quay thereby affording accommodation for vessels lying end on

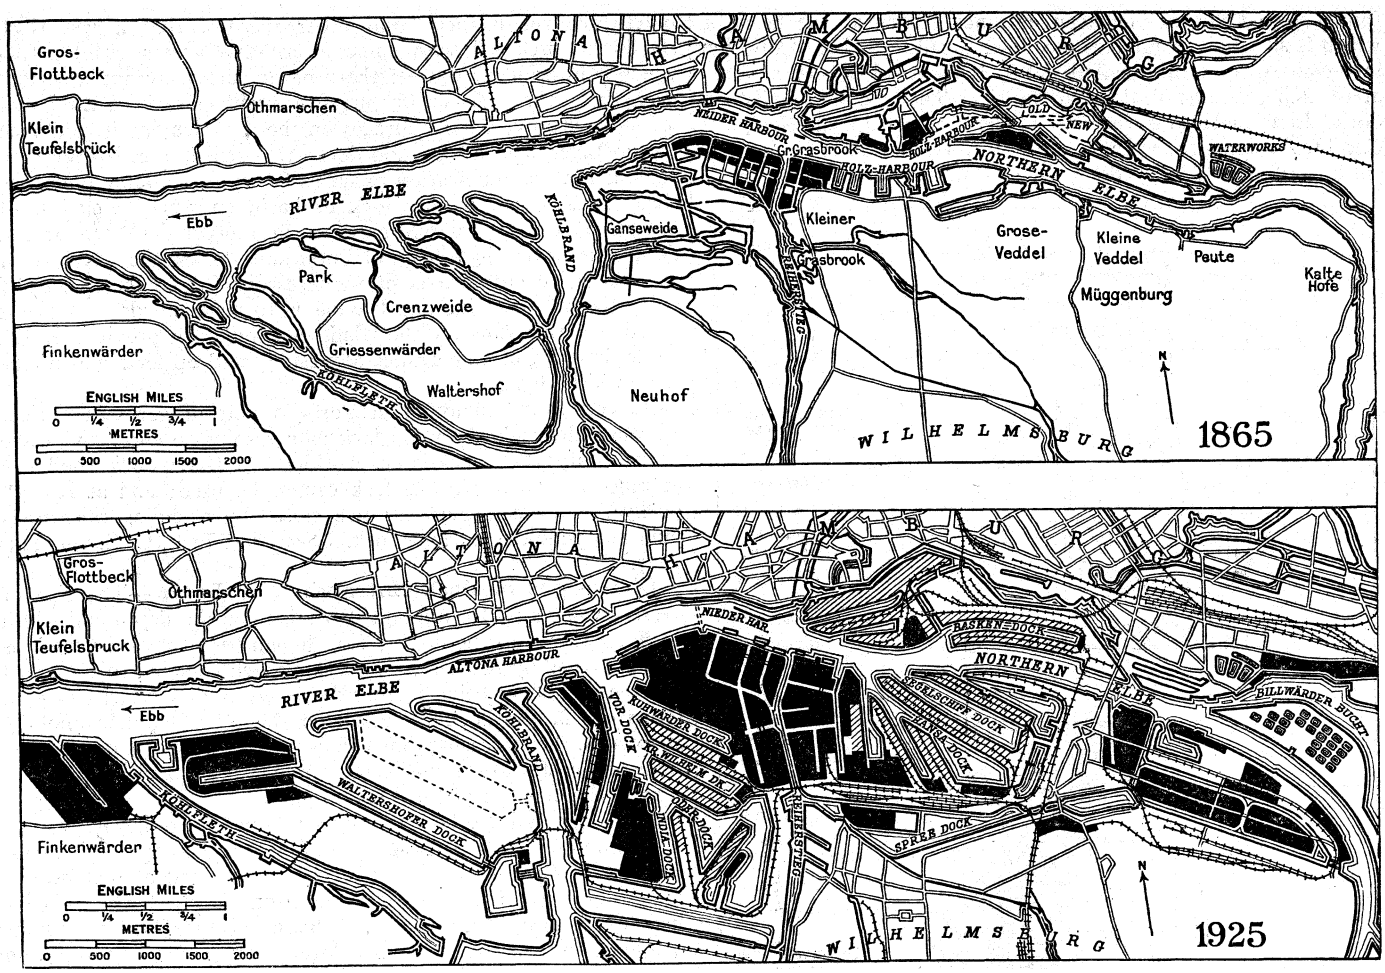

FIG. 7.— PORT OF HAMBURG IN 1865 AND 1925 THE BLACK AND CROSS-HATCHED AREAS ARE COVERED WITH PORT BUILDINGS, THE BLACK AREAS BEING OCCUPIED BY THE PORT OF HAMBURG AUTHORITY

north quay. The Albert dock was given about half the width but made much longer, so that vessels lie alongside the north and south quays in a long line, stretching across the remainder of the wide river bend, in order to obtain a second entrance in a lower reach of the river. Between 1937 and 1940 the Victoria Dock was completely remodelled and deepened, a continuous quay wall taking the place of the old jetties. *(See* Jl Inst. C.E., Jan. 1939).

The Tilbury docks east of London (1886) consist of a series of branch docks separated by wide, solid quays. and opening straight into a vestibule dock in which vessels can turn on entering or leaving. An extension of the main dock at its western end to form a larger branch dock was made in 1912–17, adding about 17ac. to the previously existing 54¾ac. of dock water area. *(See* Proc. Inst C.E. 1923.) A further enlargement 1926–29 provides an additional entrance higher up the river, and a water area sufficient for turning the largest ships.

The latest of the docks in the port of London, the King George V. dock opened in 1921 *(see* Proc. Inst. C.E., ccxvi., 1923) occupies a site lying between the river and the Royal Albert dock with which it is connected by a communication passage. It has a separate entrance from the river by means of a deep lock. The wet dock has an area of about 64 acres and is constructed on the single water-area plan without branches. The two long quays which form its sides are not parallel, the width between them at the entrance end being sufficient to allow of ships turning. An interesting feature of the design is the provision of 7 reinforced concrete island jetties arranged in a line parallel with the south quay-wall with a barge passage between the jetties and the quay (fig. 6). Cranes on the jetties work the ship's cargo either into barges or to the quay as may be required. This system was introduced with the object of affording better facilities for lighter-borne traffic which forms a large proportion of the trade of the port of London.

Tidal and Half-tide Basins.—Tidal basins, as they are termed, were interposed in many old docks between the entrance locks or tidal gates and the dock proper, with the object of facilitating the passage of vessels out of and into the docks before and after high water. This is effected by lowering the water in the basin to meet the rising tide and opening the outer gates directly a level has been formed. The outgoing vessels which have collected in the basin, when level with the dock water, are then passed successively through the outer gates. The incoming vessels are next brought into the basin, the outer gates are closed, and the water in the basin raised to the level in the dock, when the vessels are admitted to the latter. This arrangement, which in effect serves the purpose of a large lock, is still in use at a few of the older docks in the Port of London and also at the Bute and Roath docks at Cardiff, and at Sunderland and other docks. The locks, where they exist, are used (as locks) only for the smaller vessels leaving early or coming in late on the tide.

The large half-tide locks at many of the Liverpool docks serve a similar purpose as tidal basins, but, being much larger, the gates are closed at high water to prevent the lowering of the water level in the dock, and to avoid closing them against a strong issuing current. All entrances on the Mersey have duplicate pairs of gates in case of any accident occurring to one pair. This practice has been followed at some other ports

The so-called tidal basins outside the locks at Tilbury and Barry *(see* Proc. Inst. C.E., ci., 1890) are open water spaces provided to give a sheltered approach to the lock or entrance with comparatively deep water available at or near low water for vessels waiting to enter.

Dock Entrance Channels and **Locks.**—The more modern practice in planning the approach to a large wet dock is to form a

funnel-shaped channel between entrance jetties at the head of which is situated a large entrance lock usually capable of division into two parts by intermediate gates. This plan has been adopted at the King George V. dock in the river Thames; the Gladstone dock, Liverpool; and for the modern entrances at Newport, Cardiff, Avonmouth, Immingham and other docks. The modern entrance at the Tilbury docks is also of this type. When large

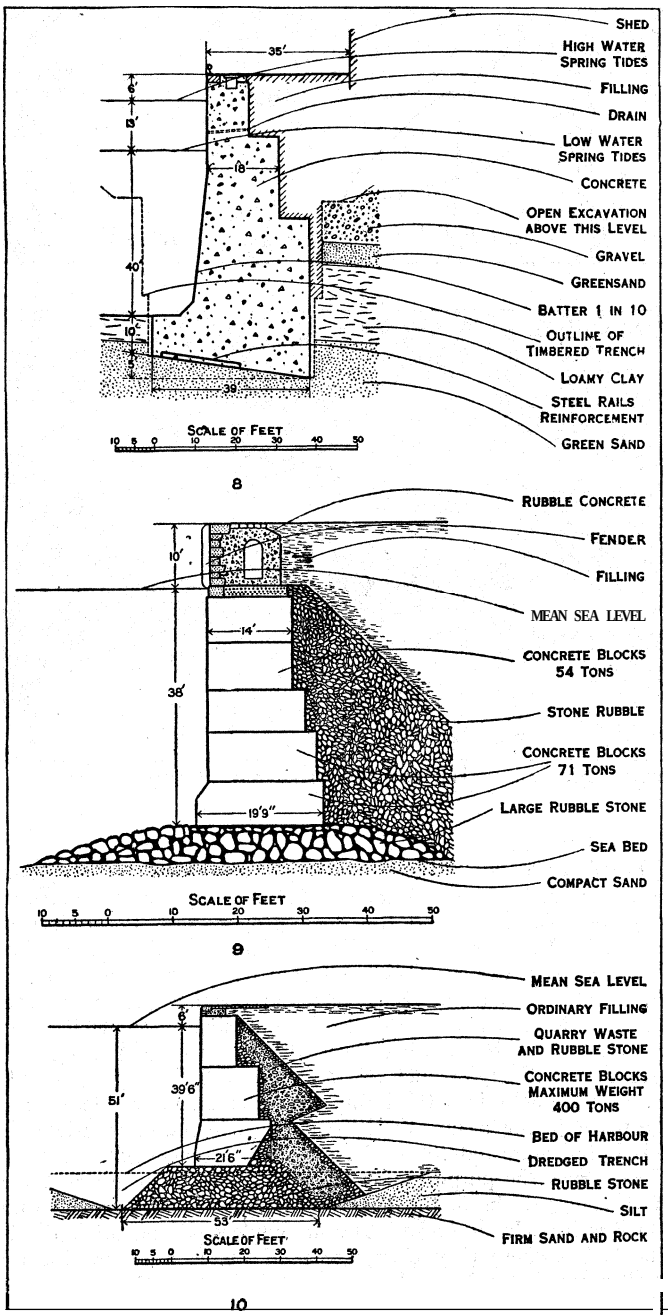

FIG. 8.— SOUTHAMPTON-OCEAN DOCK. SECTION OF QUAY WALL BUILT IN THE DRY IN TIMBERED TRENCH. FIG. 9. GENOA—VITTORIO EMANUELE III BASIN QUAY WALLS OF SUPERIMPOSED CONCRETE BLOCKS. lock entrances are constructed in a river whose current is at times swift it is now the practice to align the lock and entrance channel at a small angle with the direction of the current, and not at right angles to the river, in order to avoid the necessity of large ships getting athwart the tide in entering or leaving the dock. The latest Liverpool, Tilbury and Antwerp entrances are planned in this way.

Emergency Entrances. — It is desirable, although not always practicable for financial and other reasons, that a wet dock should be provided with some alternative access besides that which is in ordinary use. If there be no such provision a serious accident to the one lock or entrance might close it to traffic for a time and prevent ships already in the dock leaving it. In most of the Liverpool and London docks this risk is met by the construction of communication passages between adjoining docks, so that, in the event of any lock or basin entrance being out of operation, some alternative entrance in another dock can be utilized. Moreover, in busy and important docks, the building of an alternative entrance is often necessary for traffic reasons if delay to ships entering and leaving is to be avoided. It may be noted that the plans for the Gladstone wet dock provide for the future building of an entrance alongside the deep lock, and of the same width (fig. 4).

At Havre and many other ports, a pair of gates in a tidal entrance alongside the main lock allows ships to enter and leave at high water if the lock is not working. At Barry dock, the basin entrance is available if the lock cannot be used; and at Rosyth dockyard an emergency entrance closed by a sliding caisson, is built alongside the entrance lock. (See Proc. Inst., C. E. vol. 223, 1927.)

Dimensions of Dock Entrances and Locks. — The size of vessels which a port can admit depends upon the depth and width of the entrance to the docks; for, though the access of vessels is also governed by the depth of the approach channel, this channel is often capable of being further deepened by dredging. The solid structures of the dock entrance, on the other hand, cannot be adapted to the increasing dimensions of vessels except by troublesome and costly works sometimes amounting to reconstruction as carried out at some of the London docks.

The width and depth of access to wet docks are in one way of more importance than the length of locks: for gate entrances, and also locks if both pairs of gates are opened at high water, impose no limitation as regards length on ships entering or leaving. (The terms "entrance" and "gate entrance," used without qualification in connection with a wet dock, commonly imply an entrance closed by a single pair of gates or by a caisson as distinct from a lock.) This factor is of importance in the working of some old docks whose locks are of limited length but of ample width. It is, however, usual in modern dock construction to make a lock amply long enough for any ship whose beam or draught is not too large for the limiting dimensions of its entrance.

Open basins are generally given an ample width of entrance and river quays are also always accessible to the longest and broadest ships which can navigate the channel leading to them. In a tidal port or river, however, the available depth in the berths has to be reckoned from the lowest low water of spring tides, instead of from the lowest high water of neap tides, if the vessels in the open basins and alongside river quays have to be always afloat.

Many years ago the Canada lock (1857) at Liverpool, the Alfred lock at Birkenhead, the Ramsden lock and entrance at Barrow-in-Furness, and the Eure entrance at Havre, were all given a width of about 100 ft. This was no doubt done with the view of admitting the paddle steamers of large overall width in use at the time. With these exceptions the widest lock entrance in the world, until the beginning of the present century, was at the Alexandra dock, Hull, opened in 1885, which was made 85ft., the length being 550ft. The wide entrances to the deepened Brunswick dock and the Sandon dock at Liverpool, completed in 1906, were made 100ft. wide, with sills more than 30ft. below high water of low neap tides. The Gladstone graving dock, which is also usable as a wet dock, opened in 1913, has an entrance 120 ft. in width. The latest addition to the Liverpool docks, the Gladstone wet dock, has a lock 1070×130ft. internally.

The depths of the sills of locks and entrances at large ports have increased in much the same ratio as their other dimensions. Thus, in the port of London, the old lock of the Albert dock, opened in 1880, has a depth of 26½ft. at high water of neap tides and 10ft. at low water of spring tides: the Tilbury lock (1886) has corresponding depths of 393 and 23½ft. over the outer and intermediate sills, but 6ft. less over the inner sill. All the sills

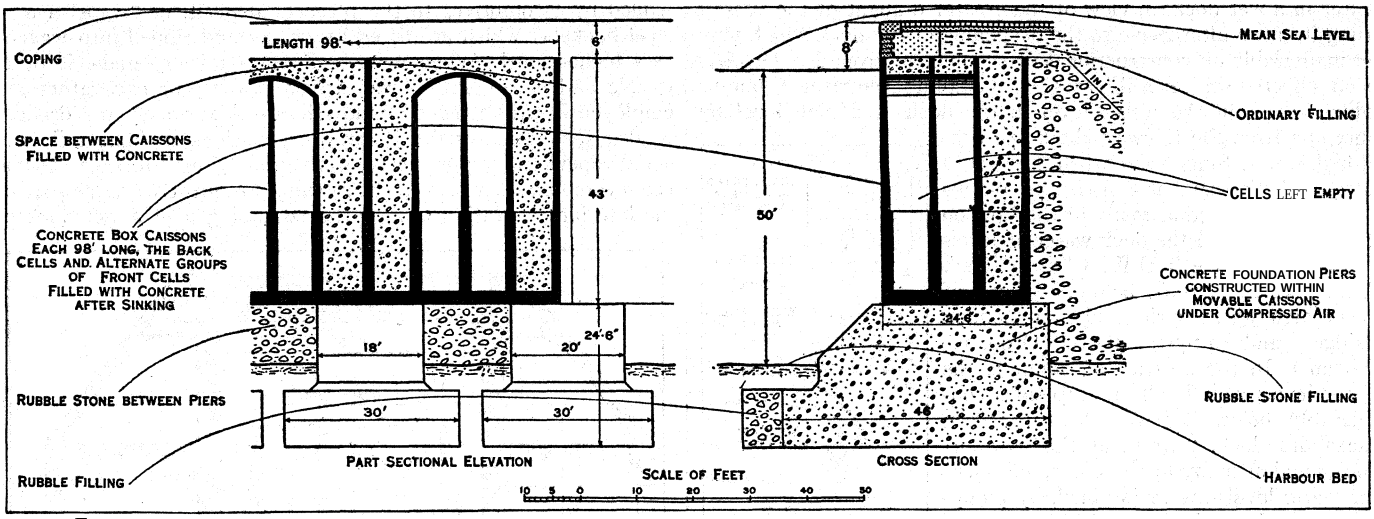

FIG. 11.—PRESIDENT WILSON BASIN. MARSEILLES. QUAY WALL OF CONCRETE CAISSONS ON DISCONTINUOUS CONCRETE FOUNDATIONS IN DEEP WATER

of the King George V. lock are 41½ft., and those of the new Tilbury lock are 41ft. below the level of high water neap tides.

The following table shows the dimensions of some of the largest locks in use or building in 1940:

*At level of H.W.N.T.
†Can be increased to 910ft. if necessary by use of caisson at inner end.

The only other locks in the world having usable dimensions of 1,000×100ft. or more are those of the Panama and Kiel canals respectively 1,000×110ft. and 1,083×147⅔ft. and the No. 2 combined dry dock and lock at Bremerhaven. (*See* CANALS AND CANALIZED RIVERS.)

Open Wharves and Quays.—Where the range of tide is moderate, closed docks, if they exist, or open basins are usefully supplemented by quays or wharves in the river or harbour in positions where the shelter is sufficient for vessels to lie alongside in safety and the currents are not too strong to make this impracticable. Generally a range of 14 or 15ft. at spring tides is the limit above which it becomes more convenient to provide closed docks. On the river Tyne, where the range is 14½ft., the open water quays and coal staiths about equal the closed dock accommodation in extent. On the Clyde, with a tidal range of from 10 to 13ft., and at Hamburg (fig. 7), with a range of 7ft., there are no closed wet docks. Pit Antwerp, a port possessing a very large closed dock system, and having a tidal rise of 15ft., a long line of quays has been constructed along the right bank of the Scheldt at which large ocean-going ships are berthed. Even in the Thames, with a spring range of 21ft., deep water jetties and wharves have been built in the river.

On the Atlantic and Pacific coasts of North America, where the tidal range, except in the Bay of Fundy, is generally small and most of the larger ports are in situations possessing ample natural protection, accommodation is provided for shipping at long piers or jetties projecting from the shore into deep water. Many of these piers, or "docks" as they are termed in New York, have berths upwards of 1,000ft. in length with 30 to 45ft. depth at low water. Timber and reinforced concrete piles are commonly employed for these structures, but sometimes cylinders are used in place of piles for carrying the superstructure of the jetty. The same type of construction has become usual in the natural harbours of Australia and New Zealand where, except in the northern parts of Australia, the tidal range is also small.

The following table (II.) gives particulars of the depth at low water alongside typical deep water tidal quays built since 1910.

Pumping for Impounding in Wet Docks.—It is sometimes desirable to make provision for increasing the minimum depth of

water in a wet dock, in view of the greater draught of the vessels using it, as an alternative to the deepening of the dock which may be inadvisable on constructional or economical grounds. This has been effected in several cases by installing centrifugal pumps which maintain the water level in the dock at a high level by pumping from the tideway about the time of high water Since 1909, when the Port of London Authority was constituted, pumps have been installed at many of the London docks to maintain the dock water at levels 1½ to 3½ft above T H W (Trinity High Water, which is 1·5ft. below the level of mean high water spring tides at London Bridge, and 12 gft above Ordnance Datum) In the absence of pumping the water levels would fall at neap tides considerably below T H W. At the Queen Alexandra dock, Cardiff, at the Newport docks, and at many of the Liverpool docks the water levels are maintained, by pumping, at or about the level of high water of spring tides The British Admiralty practice is to utilize the pumping plant, which is installed for unwatering dry docks, for raising water levels of wet docks when necessary.

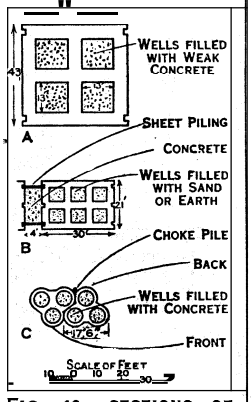

FIG. 12.—SECTIONS OF TYPICAL WELL MONOLITHS A. Rosyth, 1910; B. Clyde, Rothesay Dock, 1901–7; C. Clyde, Queens Dock, 1877.

THE CONSTRUCTION OF DOCKS

Up to the last quarter of the 19th century masonry construction was adopted for the large majority of dock works such as quay walls and locks, and hydraulic limes to a limited extent took the place now occupied by Portland cement. The use of Portland cement concrete for all kinds of port construction is now almost universal, and its cheapness in comparison with the cost of dressed stone in the large majority of situations has restricted the employment of the latter to such purposes as copings and sills, altar courses in dry docks, etc. As an example of this change in practice, the Rosyth dockyard (1909–18) may be mentioned Practically all British naval docks built prior to 1905 are faced throughout, or at any rate on all important surfaces, with dressed stone, usually granite. In the case of Rosyth, however, the quay and dock walls are built of and faced with concrete, dressed granite being used only for copings, quoins, sills and similar work

Reinforced concrete has been used in building jetties, wharves and other dock works since about 1895, and its employment is extending In a considerable measure it has superseded timber in the building of openwork jetties and wharves, particularly in

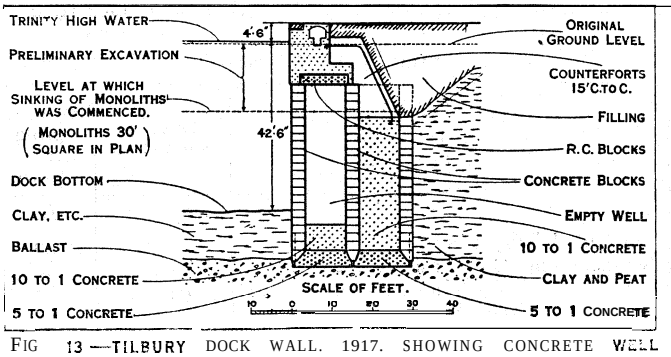

FIG 13.—TILBURY DOCK WALL. 1917. SHOWING CONCRETE WELL MONOLITH

waters where marine borers such as the Teredo (*q.v.*) and *Limnoria* are present. Rapid setting aluminous cement came into use on the continent of Europe about 1920, and its employment in the United Kingdom became rapidly extended; but its suitability for use in sea water had not been fully tested by the lapse of time. Pozzuolana and trass cements (see CEMENT) are largely employed on the continent of Europe, usually in combination with Portland cement.

Excavations for Docks.—When a dock has to be made on land the excavation is performed by men filling wagons, which are hauled by locomotives to the place of deposit, or "skips" (large steel buckets) which are lifted by cranes and tipped into wagons at a higher level. When, however, the conditions make it practicable and economical power driven navvies or excavators are employed in preference to hand labour. A form of land dredger is also sometimes used for large excavations in light soil, and aerial ropeways, dragline excavators and various forms of electric conveyors find their uses in excavation. Frequently a large part of the interior excavation (called the "dumping") of a wet dock or

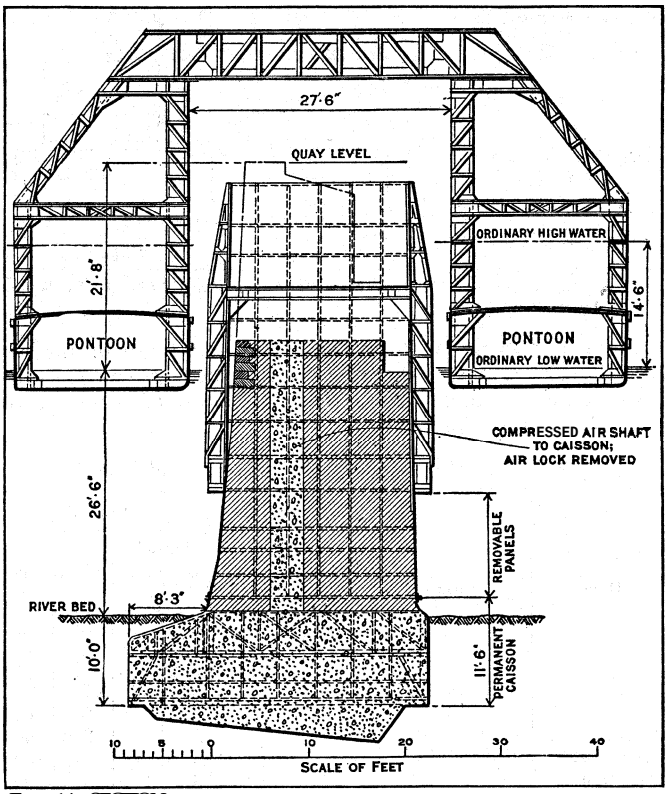

FIG. 14.—SECTION OF QUAY WALL IN THE RIVER SCHELDT. ANTWERP. 1903. FOUNDED ON CAISSONS SUNK BY COMPRESSED AIR

basin is left to be dredged away by floating dredgers after the walls of the dock have been completed and water has been admitted to the area.

When the standing water level in the soil is reached, the water has to be removed from the excavation by pumps drawing from sumps sunk down below the foundations in suitable positions so that the lowest portions of the dock walls and other structures may be built out of water. A method of draining the working area first adopted in Holland and Belgium and successfully applied in the construction of the King George V. dry-dock at Southampton (1931–33) where the pressure of artesian water in sandy beds beneath the foundations was relieved by pumping from wells, is to sink filter wells at intervals round the dock area outside the lines of the permanent works. The suction pipes in the wells, nhich are sunk to a depth below the deepest foundation, are connected up to one or more pumps which, working continuously, lower the standing water level in the ground to be excavated to the required amount.

In many cases of dock building a cofferdam has to be constructed cutting off the entrance works from the river or harbour water. This cofferdam is removed when the works built within it have been completed. When a dock is to be constructed, partially or wholly, on reclaimed land, a reclamation bank for enclosing the site and excluding the tide may be necessary, as in the construction of the King's Dock, Swansea. In some cases, however, the wall forming the outer boundary of the dock has been built by sinking concrete monoliths from temporary staging erected on the foreshore or sea bed. This plan was adopted to a partial extent in building the enclosing wall of the Rosyth Dockyard

basin (1909–15).

Dock Walls.—Docks and open basins are generally surrounded by upright walls retaining the quays alongside which vessels lie for discharging and taking in cargoes. In some cases the dock sides are, either wholly or in part, formed by stone pitched and even natural soil slopes over which openwork wharves of timber or reinforced concrete are built out to the toe of the under water

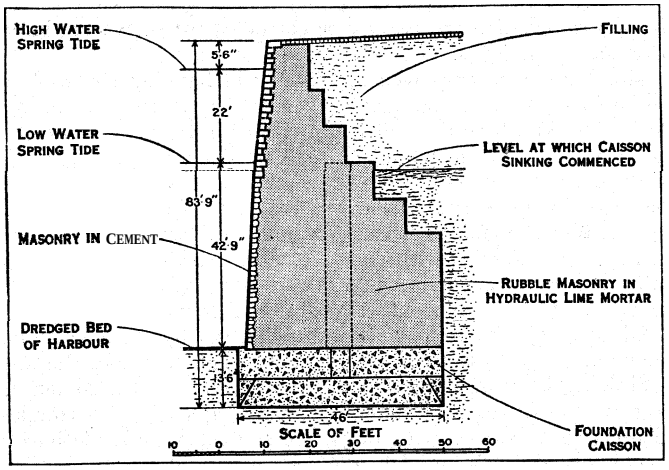

FIG. 15.—SECTION OF THE TIDAL QUAY AT HAVRE. BUILT 1915–23
Foundations were constructed within permanent caissons each 141 feet long, and the upper part of the caisson removed

slope. The solid upright wall, is, however, the usual practice in large and deep modern docks.

The nature of the strata to be excavated and on which the walls are to be founded is ascertained by trial borings and, when practicable, by sinking trial pits. The nature of the foundation has an important bearing on the design of the wall and its method of construction. Ordinarily, hard clay (such as boulder clay), compact gravel and sand, as well as most rocks form excellent foundations. It is, in these cases, usually unnecessary to carry the base of the wall more than a few feet below the dock bottom. In less satisfactory ground, however, such as slippery clay and alluvial material, and sand charged with water, the foundations may have to be carried down to a considerable depth and the base width increased. Timber bearing piles are sometimes driven to form a

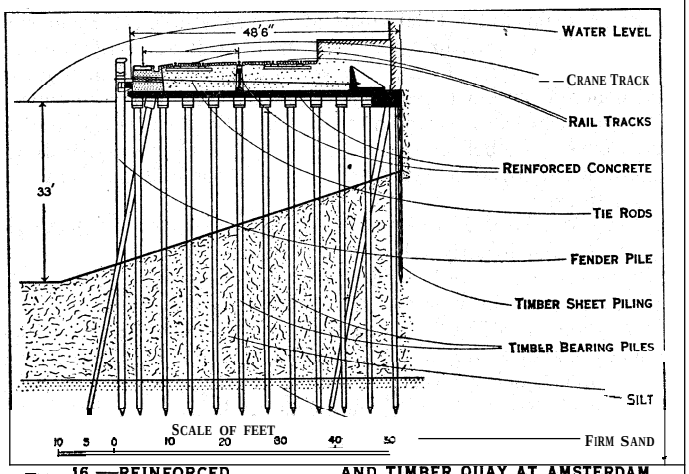

FIG. 16.—REINFORCED CONCRETE AND TIMBER QUAY AT AMSTERDAM

foundation for a wall. In other cases a trench has been dredged in the soft material along the line of wall and filled with ballast or stone or even coarse sand to provide a sound foundation.

The walls round a dock serve as retaining walls; and, though they have the support of the water in front of them when the docks are in use, they have, when built and before the water is admitted, to sustain the full pressure of the filling at the back, as well as any surcharge due to erections on the quay. The completion of the filling behind the wall is on this account sometimes deferred until after the dock is filled with water.

The thickness of solid dock walls is increased downwards to support the pressure which increases with the depth. This pressure depends on the nature and angle of repose or natural slope of the ground and filling material behind the wall. But the pressure is often increased by the accumulation of water at the back, which with fine silty material, is liable to exert a sort of fluid pressure against the wall proportionate to the density of the mixture of silt and water. The increase of thickness towards the base used formerly to be effected by a batter on the face, as well as by stepping the back. The vertical form now given to the sides of ships necessitates, however, a corresponding vertical, or nearly vertical, face for the wall.

The height of a dock wall above the dock bottom depends upon the minimum depth of water always available for vessels, and the rise of the tide. In tideless sea-ports and inland ports removed from tidal influence, the height is represented by the minimum depth of water plus a margin of from 6 to 10ft. from the water level to the quay surface. At tidal ports, however, an addition has to be made equal to the difference in height between

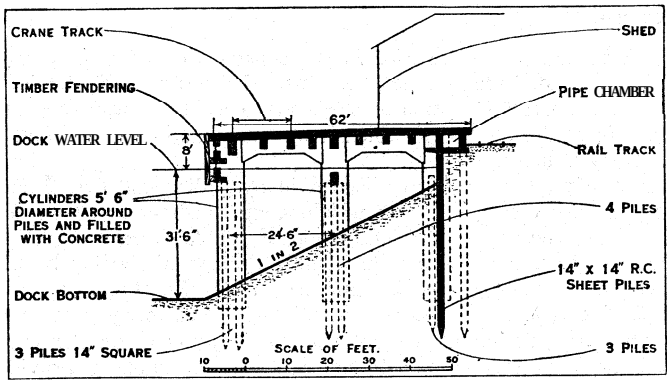

FIG. 17.—CROSS SECTION OF REINFORCED CONCRETE QUAY ON PILES AND CYLINDERS, VICTORIA DOCK, LONDON, BUILT 1925

the highest and lowest water levels in the dock or in the open basin as the case may be. At some ports, *e.g.*, Montreal, provision against river floods, etc., necessitates especially high coping levels.

Under normal conditions, a solid or gravity dock wall should be given a width at a height halfway between dock-bottom and quay level, not less than $\frac{1}{3}$ of its height above dock bottom, and a width of about half this height at dock bottom. Conditions, however, are so largely governed by the nature of the strata that every case has to be dealt with on its merits.

Dock walls are constructed of masonry, brickwork or concrete, or of concrete with a facing of masonry or brick. The bulk of recent dock wall building has been in concrete and, when suitable materials are available at or near the site of the works, concrete construction is usually cheaper than any other form. Where no extraordinary difficulty is to be apprehended the foundations for dock walls, below the level at which open excavation is practicable and economical, are excavated in a trench. The trench is lined with timbering for the support of the sides during excavation and, in bad ground and very deep trenches, timber sheet-piling or interlocked steel sheet piles are driven to form the sides. Examples of dock walls built in trenches are shown in figs. 6 and 8.

The walls of open basins are often constructed in the dry precisely like dock walls as in the case of some of the basins at Glasgow. They differ only from dock walls in being exposed to variations in the pressure at the back resulting from the lowering of the water-level in front. This feature is, indeed, shared to some extent by the walls round closed docks where the difference in the high water levels of springs and neaps is considerable. The walls, however, round basins in tideless seas, such as Marseilles, occasionally those inside harbours and docks, and especially quay walls along rivers, have to be constructed under water. If mass concrete walls are to be built in the dry some form of cofferdam is necessary when the site is covered by water and steel sheet piling is now commonly employed for the purpose of enclosing the area to be excavated.

Concrete Block Walls.—The simple expedient was adopted

long ago of constructing the quay walls, lining the basins formed in the sea at Marseilles, by depositing tiers of large concrete blocks on a rubble foundation, one on top of the other, till they reached sea level, and then building a solid masonry wall out of water on the top. This practice has been widely followed, particularly in Mediterranean ports (fig. 9) and the size of blocks employed has progressively increased. As far back as 1871, blocks

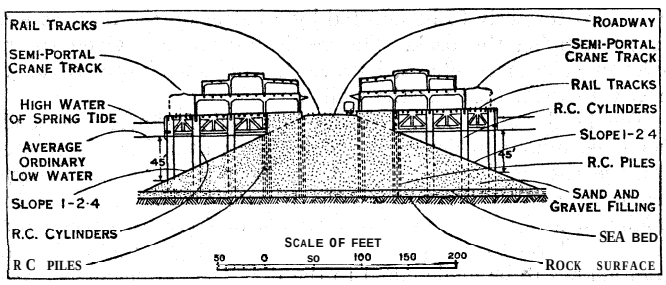

FIG. 18.— CROSS SECTION OF OUTER BERTHS. BALLANTYNE PIER, VANCOUVER

weighing 360 tons were used in the construction of a quay wall in the port of Dublin (see *Proc.* Inst. C E., 1876). Each block formed a complete section of the lower part of the wall and was lifted from the staging on which it was made and deposited under water by a floating derrick.

Recently quay walls have been built by Italian and French engineers with concrete blocks weighing up to about 400 tons set one above the other on a foundation of rubble or on a prepared rock bed (fig. 10). Both cellular and "cyclopean" (solid) blocks have been employed for this purpose. (See also BREAKWATER.)

Sloping blocks (see BREAKWATER) were used many years ago in the construction of a quay wall at Marmagoa, on the west coast of India, erected on a foundation layer of rubble, to provide against unequal settlement on the soft bottom. The system has often been employed since. Recent examples are the quay walls of Valparaiso and Kilindini (Mombassa) harbours.

Reinforced Concrete **Caissons.**—Since about 1905 reinforced concrete caissons with closed bottoms have been frequently used in the construction of quay walls (fig. 11). The caissons are constructed on shore, in a dry dock or in some position from which they can be launched into the water or lifted by a goliath crane and put afloat. When floated they are towed to the required position and sunk on a prepared bed of rubble stone or concrete. The cells of the caissons are then filled, usually with concrete, but in some cases stone or sand filling is used in the rear cells. Notable examples are the more recent quay walls at Marseilles In some cases caissons have been sunk on a prepared and levelled natural bottom, as at Heligoland and Dublin. Reinforced concrete caissons have also been used for quay wall construction at Rotterdam, where, in one case, the soft alluvial material on the site of the wall was dredged away down to a firm stratum of sand and the trench thus formed was filled with sand upon which, after it had been consolidated, the caissons, 138ft.x37ft. in plan, were founded. The depth of water in the berths in front of the wall is 33ft. at low water.

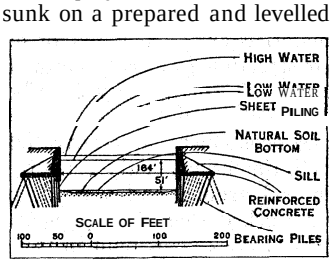

FIG. 19.—CROSS SECTION OF LOCK CHAMBER. YMUIDEN LOCK AT ENTRANCE TO AMSTERDAM SHIP CANAL

Well Monoliths.— It is sometimes necessary, even in positions where the whole of the dock walls are constructed in ground above water level or within an enclosing embankment or cofferdam, to have recourse to monolith sinking on account of the treacherous nature of the strata to be passed through. Monolith foundations are derived from the ancient Indian system of well sinking. They are built up generally on steel framed "curbs" provided with a cutting edge and gradually sunk by excavating inside, usually by grabbing. (See also CAISSON.)

Cylindrical well foundations were used for the construction of quay walls in the Clyde about 1870. Originally built of brick, but in later work of concrete, single cylinders were first employed placed side by side. Subsequently monoliths with three wells planned like a trefoil (fig. 12) were introduced on the Clyde and afterwards at other ports. Still later, monoliths rectangular in plan came into general use and some of these have as many as six wells. The rectangular multiple well monolith possesses the advantage over other forms in that any tendency to tilt from the vertical position can usually be corrected by excavating in one or other of the wells.

Monoliths were employed at Tilbury in building the walls of the main dock extension (fig. 13) and at Calcutta for the new docks (1928) where the soil is alluvial of a very soft character. At Rosyth some of the monoliths sunk for forming the outer walls of the dock were carried down to a depth of 121ft. below the coping before a sound foundation was reached (see *Proc.* Inst. C.E. 1927). When monoliths have been sunk to the required level the well spaces are sealed with concrete. In some cases the wells are entirely filled with concrete, in others sand filling is used above the concrete seal at the bottom. At Tilbury, Karachi and Southampton (1933–34), the front wells are only partially filled to reduce the intensity of pressure on the foundations at the toe of the wall.

Sinking by Compressed Air.— Compressed air has sometimes been used in sinking well monoliths, and frequently in bottomless caissons (*q.v.*) for carrying down the subaqueous foundations of quay walls, through alluvial deposits, to a solid stratum. About 1880 the building of a long line of river quays, extending out into the Scheldt, was commenced at Antwerp with the object of regulating the width of the river simultaneously with the provision of deep-water quays. The wall was built, out of water, on the flat tops of a series of wrought iron caissons, 82ft. long and 29½ft. wide, constructed on shore. These were floated out, one by one, between two barges and gradually lowered as the wall was built up inside a plate iron enclosure erected round the roof of the caisson. Each caisson was eventually sunk by aid of compressed air through the bed of the river to a compact stratum. An extension of the wall carried out in a somewhat similar manner was completed in 1903 (fig. 14).

A dry dock and quay walls constructed in the old harbour at Genoa about 1888, were founded under water in a similar manner by the aid of compressed air. Part of the Broomielaw quay at Glasgow was reconstructed about 1902 on steel caissons carried down by means of compressed air from 54 to 70ft. below quay level. A deep water tidal quay at Havre was built upon steel caissons about 141ft. long and 45ft. wide sunk by compressed air through about 57ft. of soil. The wall was constructed of masonry and concrete within temporary caissons raised upon the tops of the permanent caissons which terminate at the level of the dredged berth over 40ft. below low water (fig. 15). Compressed air has also been employed at Marseilles (fig. 11) for building quay wall foundations.

Quay Walls of Timber Crib Work.— In some North American ports, particularly where firm under water foundations are obtainable, walls have been built up to low water level of timber crib work, sunk in a previously dredged trench or on to a hard bottom, and then filled with rubble stone. Above low water mass concrete or masonry walls are raised in the dry on the crib foundation. Such quay walls are still being built at Montreal, St. John (N.B.), in some of the ports of the Great Lakes and at other places.

Quay Walls, Wharves and Piers on Piled Foundations.— In many cases where soft strata extend to considerable depths, river and basin quays have been constructed by building a comparatively light wall upon a series of bearing and raking piles driven into, and if possible through, the soft alluvium. Thus the older quay walls at Rouen were built upon bearing piles carried down through the alluvial bed of the river to the chalk. The lower portion of the wall was built of concrete and brickwork within water-tight timber caissons resting on the piles at a depth of 8 to 10ft. below low water.

The pier and wharf walls in the port of New York and other North American harbours are frequently built on bearing and

raking piles. These are some cases where the soft silt into which piles have been driven is so deep that no firm stratum could be reached and the supporting power of the piles has been increased by tipping large quantities of stone rubble and gravel around them before and after they were driven.

Many of the basin and quay walls at Bremen, Hamburg and other German ports are also built on bearing and raking piles, the wall being begun a few feet below low water. At Rotterdam timber piling in combination with fascine work was used for many of the older quay walls.

Reinforced concrete piles have been used in substitution of timber piles to an increasing extent since about 1900 for foundation piling under solid superstructure walls, but in waters where marine borers are not present as, for instance, at Amsterdam and Hamburg, timber is still employed and has a long life in positions where it is always submerged. Reinforced concrete is also widely used for building the superstructures of wharves (figs. 16–17) as well as for the piles on which they are built. At Madras piles 25in. square and over 7jft. in length were employed in building a deep water wharf completed in 1928. Substantial piers and wharves have been built by driving clusters of reinforced concrete piles inside cylinders of that material sunk below the dredged level of the berth. The spaces between the piles and the surrounding cylinders are filled in solid with concrete. In some cases cylinder foundations are sunk without piles. An example of this construction applied to the typical North American wide pier or jetty is seen in the Ballantyne pier at Vancouver (fig. 18), completed in 1923. It is 1,200ft. long, 341ft. wide, with a depth of water in the berths of 45ft. at low water. The hearting of the pier is formed of sand and gravel filling; the outer rows of columns are 7ft. diameter reinforced concrete cylinders and the inner rows clusters of piles. Economy in construction is sometimes obtained by forming sloping sides to part of a dock or river frontage in place of vertical quay walls. Jetties or open wharves of timber or reinforced concrete can be carried out across the slope, as at many coal-shipping ports; and the length of the slope projection into the dock is sometimes reduced by substituting sheet piling for a portion of the slope at the toe or at the upper part.

A type of open-work quay wall much used in Dutch and Scandinavian ports is shown in fig. 16. The example shown is built on timber piles, but in some cases reinforced concrete piles are used.

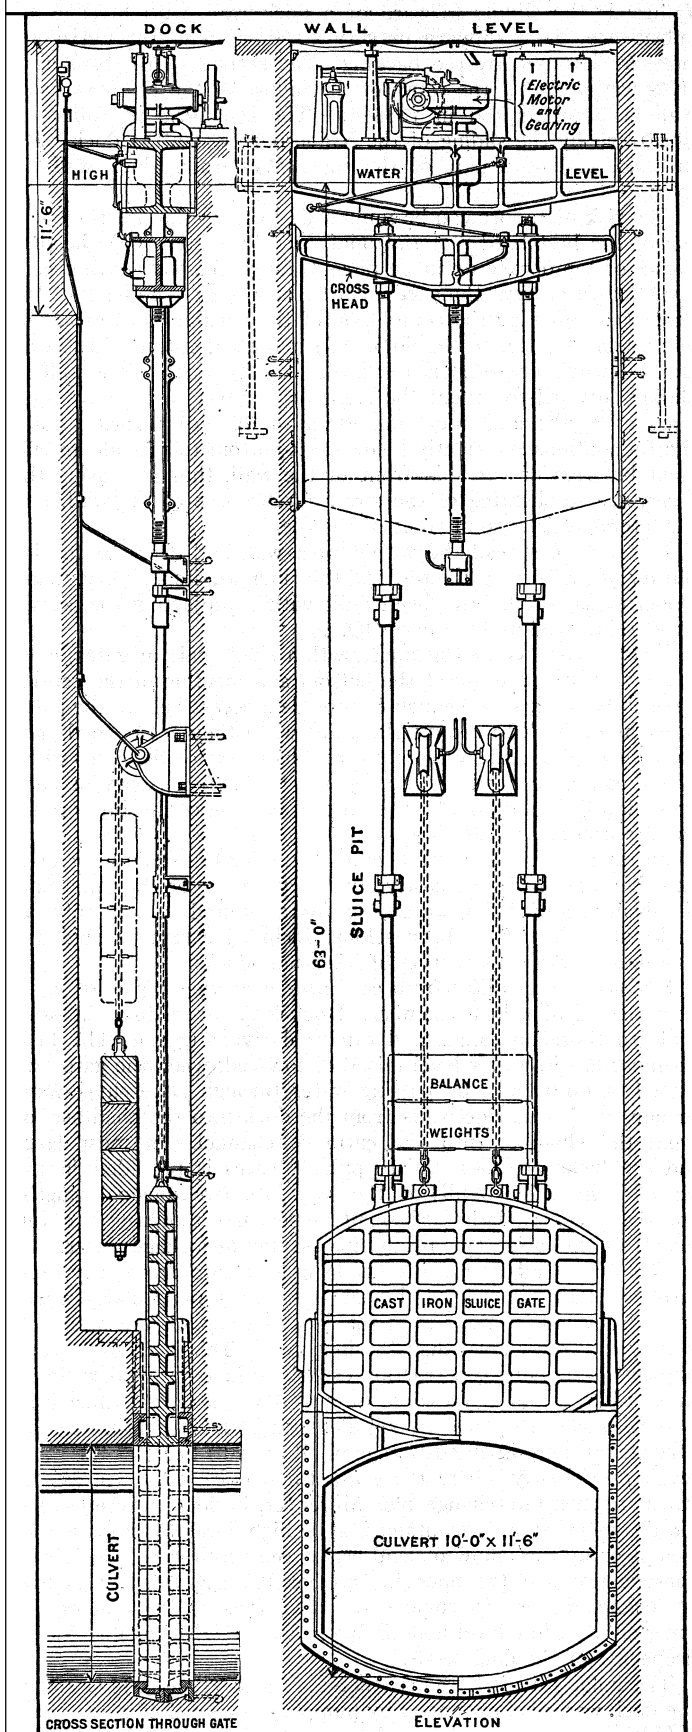
The Tilbury river jetty (fig. 5), completed in 1921, is an example of a cargo wharf in tidal waters where the spring tide range is 21ft. The design of this jetty is hardly typical as it is intended to deal with special conditions of part-cargo traffic.

In tropical ports materials for concrete construction, as well as skilled labour, are occasionally difficult to obtain and the use of timber for wharf construction may be unsuitable on account of the ravages of marine borers. These conditions exist, for instance, in some ports of East and West Africa and in them open work wharves and jetties have been built of mild steel completely fabricated in European or American works and sent overseas ready for erection. Screw piles are frequently used where the foundations are suitable, and timber is employed for the decking.

Reinforced concrete in wharves and jetties is liable to damage by vessels, and such damage is often more difficult and costly to repair than timber construction in similar positions. It is, therefore, important to provide substantial timber fendering on the face of such works.

Failure of **Dock** Walls.—Dock walls, especially before the admission of water into the dock, constitute high retaining walls. not infrequently founded upon soft or slippery strata, and backed up with excavated materials into which water is liable to percolate. Furthermore, when water is admitted to the dock there is always present the possibility of a large part of the mass of the wall being partially waterborne owing to the upward pressure of water under the base of the wall reducing the weight of the wall acting vertically. Thus dock walls may be exposed under unfavourable circumstances to the danger of failure (see Proc. Inst. C.E. cxxi., cxcv. and ccxiii.).

A dock wall founded on a soft bottom is liable to settle down at its toe, where the intensity of pressure is greatest, and to fall



BY COURTESY OF MESSRS. GLENFIELD AND KENNEDY, LTD.

FIG. 20.— SLUICE GATE AT CONGELLA DRY DOCK (DURBAN) OPERATED BY A 25 HORSE-POWER ELECTRIC MOTOR. THE TOTAL WATER PRESSURE ON THE SLUICE DOOR (EITHER SIDE) IS 170 TONS

forward. It is found, however, that the most common form of failure is the sliding forward of a dock wall, with little or no subsidence, on a slippery or silty stratum under the horizontal pressure imposed by the backing. The second of these alternatives was probably the cause of the failure of the Empress basin wall at Southampton in 1888–89 The last form of failure is illustrated by the sliding of the Kidderpur (Calcutta) dock walls in 1890, and of a part of the south West-India dock walls in 1870.

The risk of failure can be minimized by: (a) the use for backing of the best hard material unaffected by water; (b) the provision of temporary drainage pipes through the wall during construction to prevent the accumulation of water at the back of the wall; (c) deferring the completion of the backing until after the admission of water to the dock; (d) making the base of the wall slope downwards towards the back, thereby forcing the wall in sliding forward to mount the slope or to push forward a larger mass of earth; and, most important of all, (e) carrying down the foundations sufficiently below dock-bottom to provide an efficient buttress of earth in front of the wall, thus increasing the resistance to shearing of the strata at the base of the wall, and the lateral resistance in front of the toe.

In order to spread the weight of a wall and decrease the intensity of pressure at the toe. and thus increase its stability, many modern quay walls have been built with a projecting toe, sometimes reinforced by steel bars (fig. 8).

Gate Entrances. — Entrances with a single pair of gates, closing against a raised sill at the bottom and meeting in the centre, have to be made long enough to provide a recess behind the gates in each side wall to receive the gates when they are opened, and to form an abutment in front to bear the thrust of the gates when closed against a head of water in the dock. A masonry or concrete floor is laid on the bottom in continuation of the sill, serving as an apron against erosion.

Entrances have the advantage of occupying less room than locks and they are much less costly; but they are under the important disadvantage of being accessible for a limited period only on each tide. They have been seldom included except as auxiliary passages, in the construction of large new docks.

Locks. — Locks differ from entrances in having a pair of gates at each end of a lock chamber. Dock locks are similar in principle to those on canals and canalized rivers (*q.v.*). The lock chamber has its water level raised or lowered, when the gates are closed at both ends, by passing water through large sluice-ways or culverts in the side walls from the dock into the chamber, or from the chamber into the entrance channel. In most large modern locks an intermediate pair of gates is provided in the chamber in order to divide the lock into two unequal lengths for the accommodation of small vessels not requiring the full length of the lock. This results in a saving of lockage water.

The inner and outer sills of dock locks are frequently constructed at the same level; but at some ports, particularly where the tidal range is large, as in the Bristol Channel, the outer sill is laid at a lower level than the inner one. This effects an economy in the cost of construction especially in large modern locks designed to admit a vessel at or near low water, in which case it is necessary to place the sill at a considerable depth. On the other hand there is an advantage in all the sills being at the same level, particularly where there are three pairs of gates, as the gates are then interchangeable. Moreover, in docks where the enclosed water is not maintained at a high level by impounding pumps or by the inflow of land water, the depth in the dock, and consequently over the inner sill, is reduced at neap tides by the loss of lockage water. In some cases, also. the construction of the inner sill at a low level is desirable in view of the possible future deepening of the dock itself.

The inner sill of the King George V. lock (London), although the dock water is impounded by pumping at a level of $2\frac{1}{2}$ ft. above T.H.W., was constructed at the same level as the outer sill and about 10ft. deeper than the general surface of the dock bottom. The impounding at the King George V. dock is consequent on its being connected by a passage with the Albert dock. where the necessary increase in depth had been effected by this means. The Gladstone (Liverpool) lock sills are also all at the same level but. in this case, the level of the dock bottom is approximately the same as that of the sills and no provision is made for impounding. On the other hand, the inner sill at Rosyth is laid at dock bottom level or $13\frac{1}{3}$ ft. above the outer sill. The sills of intermediate gates are always placed at the same level as the outer sills.

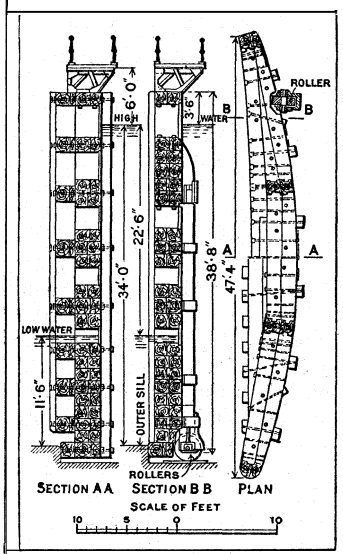


FIG. 21.—TIMBER DOCK GATES. ALEXANDRA DOCK. HULL

The foundations for the sills, side walls and invert or floor of a lock are generally constructed under shelter of a cofferdam across the entrance channel, and the excavations are kept dry by pumping. Under sills and the adjacent walls the foundations are usually carried down to a lower level than the rest and, if possible, to an impervious stratum, to prevent infiltration of water under them owing to the water pressure on the upper sides of the gates. Sometimes permanent sheet piling is driven across the lock site under the sills, and occasionally under the side walls also, to cut off the flow of water.

The sills, projecting about 2 or $2\frac{1}{2}$ ft. above the gate floor, and the hollow quoins are almost always constructed of granite, carefully dressed to a smooth and true surface. The hollow quoin is the vertical concave recess formed in the wall, in which the heelpost of the gate turns, and is exposed to considerable wear. Other parts of the lock structure are ordinarily built of concrete except the coping courses which also are frequently of granite.

The side walls of a lock chamber are very similar in construction to dock walls; but they are strengthened against the loss of water pressure in front of them, when the water is lowered in the chamber, by the floor or "invert" of the lock, usually built of concrete and sometimes constructed in the form of an inverted arch. This invert prevents any forward movement of a sidewall, the toe of which abuts against it. In some cases too it acts as an inverted arch and assists to resist any upward hydrostatic pressure under the floor when the lock water is run down. The side walls alongside the gates also abut against a thick level gate floor and apron and, moreover, are widened to provide space for the culverts, sluice pits and gate machinery.

A feature in the design of all modern locks and entrances, including those of dry docks, is the rectangular form of the entrance, approximating to the shape of the midship section of modern steamships. Most old entrances were constructed with inverted arch floors, the depth being greater in the centre than at the sides.

In situations where a lock has to be built in waterlogged alluvial strata of a soft nature it is sometimes necessary to sink concrete well monoliths in constructing the foundations: this has been done in building the locks at the King George dock, Calcutta and Tilbury (1928). Large caissons were employed for constructing, under compressed air, the foundations of the gate chambers, lock heads and portions of the side walls and floor of the Florida lock at Havre; *V. The Engineer*, 1908, *et* seq. A large lock at New Orleans, built in fine quicksand, is supported on 24,000 piles (see CANALS AND CASALIZED RIVERS.)

The entrance lock at Ymuiden, opened in 1930, is the largest in the world (see Table 1). It is a remarkable structure of reinforced concrete resting on piles of the same material. The lock has a floor of reinforced concrete under and near the caisson sills but in the main chamber the natural bed is left uncovered between the side walls the foundations of which are, however, sheet piled (fig. 19). The lock was built on fine waterlogged sand, the excavations being kept dry by rneans of the ring-well system of pumping In a few other instances, including one of the large locks at

Bremerhaven, an artificial floor has been dispensed with except at the ends of the lock chamber.

DOCK GATES, CAISSONS, ETC.

Sluice **Valves, etc.**—Valves or sluice gates in various forms are used for controlling the water levels in locks and docks. Valves were formerly, in some cases, built into the gates, but, as the volume of water to be dealt with grew larger it became usual to build culverts with controliing gates in the side walls of the lock or entrance. Gate sluices are, however, still used in some docks for the purpose of sluicing silt deposits from the sill apron. An oid form of sluice gate or "paddle," still largely employed, is constructed of timber, usually greenheart, and is raised and lowered over the culvert mouth in the sluice chamber by hand power or hydraulic gear. Cast iron gates faced with gun-metal and working against cast iron frames are often employed and these are usually operated by hydraulic or electric machines. A double faced sluice gate at the Congella dry dock, Durban, is illustrated in fig. 20 Balanced cylindrical sluice valves, in which the water flows between the bottom edge of a steel cylinder and its annular seating when the cylinder is raised, are used in some cases. Roller gate sluices of the Stoney pattern are frequently employed in large culverts as at the locks of the Panama canal; and "butterfly" or balanced flap sluice valves turning about a horizontal axis are occasionally used in culverts of moderate dimensions. Cylindrical and "butterfly" valves both possess the advantage, in that they are balanced, or in equilibrium so far as water pressure is concerned, of eliminating friction at the meeting surfaces. In roller sluices the friction is reduced to insignificant dimensions. All dock sluices operated by electric motors or hydraulic rams should be fitted with means for hand working when necessary Stop paddles for emergency use are often provided in secondary sluice pits

Dock Gates.—The entrances and locks at wet docks, and the entrances at dry docks are closed by either gates or caissons. Gates were formerly built of timber, greenheart being used very generally for that purpose in England. Until about 1915 practically all the gates at Liverpool were so constructed, even for such wide openings as 100ft. at the Canada lock. The difficulty of obtaining very large greenheart timbers, its high cost since the war, and the convenience and economy of steel construction have resulted in the almost universal use of mild steel for gate building. During the second half of the last century many gates were built of wrought iron until the general adoption of mild steel for structural purposes superseded it. In steel gates the heel post, *i.e.*, the vertical closing piece at the hinge end, the mitre post at the meeting end, and the sill piece or "clapping sill" which closes against the fixed sill of the gate chamber, are all usually built of greenheart or faced with it.

Wooden gates consist of a series of horizontal framed beams, made thicker and placed closer together towards the bottom to resist the water-pressure which increases with the depth. The beams are framed and fastened to the heel post and mitre post at the ends and there are usually intermediate uprights. On the inner face watertight planking is fixed (fig. 21).

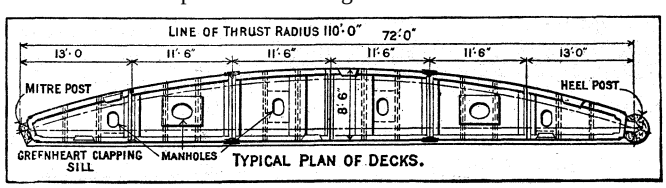

FIG 22A — ENTRANCE GATES OF GLADSTONE DOCK, LIVERPOOL

Steel gates have generally an outer as well as an inner skin of plating braced vertically and horizontally by steel plate ribs and girders. Steel gates have the important advantage over those built of timber in that they can be made with buoyancy chambers which relieve the gate anchorage at the head of the heel post of a great part of the horizontal stress, due to the weight of the gate, and the pivot support, at its foot, of all weight except so much as is necessary to prevent the gate floating out of its seating They are thus much easier to move in the water than wooden gates. On the other hand the latter are less likely to be seriously damaged if run into by a vessel. All anchorages and supports of a steel gate should, however, be made strong enough to sustain its weight in the event of the buoyancy chambers becoming waterlogged.

The adoption of the semi-buoyant type of steel gate, now generally employed in modern docks, has made it possible to dispense with the roller and roller path under the gate near the mitre post formerly provided to sustain the weight. These were always a source of trouble and anxiety and their use is now practically abandoned in new construction. The buoyancy of the gate is maintained at a practically constant value by constructing the watertight air or buoyancy chamber in the lower part of the gate, all the chambers formed by the skin plating above the watertight compartments being open on the outside face to the free flow of the tide. Thus, so long as the buoyancy chambers are submerged, the unbalanced weight remains practically unchanged whatever the depth of water may be. In this way the unfloated weight of the gate can be reduced to a few tons.

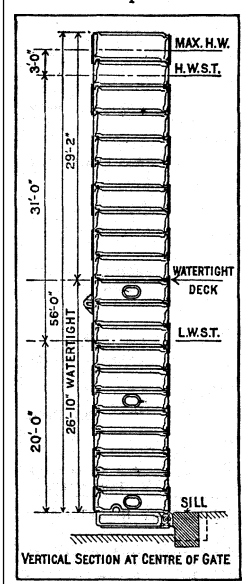

FIG. 22B.—VERTICAL SECTION OF ENTRANCE GATES, GLADSTONE DOCK

Formerly dock gates were sometimes made segmental in plan on both faces with the inner faces forming a continuous circular arc. It is now usual to make gates with perfectly straight faces on the sill side, the pressure or inside faces being either curved or polygonal. Fig. 22 illustrates one of the Gladstone lock gates with curved inner face which weighs 496 tons. The width of a gate leaf at its centre is usually made about $\frac{1}{8}$ of its length.

The pressures produced by a head of water against gates when closed depend not only on the form of the gates but also upon the projection given to the mitre of the sill in proportion to the width of the opening. This projection is called the "rise" of the gate and is usually about $\frac{1}{5}$ (more or less) the width of the opening. In straight gates, the stresses consist: first, of a transverse stress due to the water pressure against the gate; and, secondly, of a compressive stress along the gate, resulting from the pressure of the other gate against its meeting post. This pressure varies inversely with the rise. Though an increase in the rise reduces this stress, it increases the length of the gate and the transverse stress, and also the length of the chamber. By curving the gates, the transverse stress is reduced and the longitudinal compressive stress is augmented, till at last, when the gates form a horizontal segmental arch, the stresses become wholly compressive. The straight fronted and curved or straight backed gate now usually adopted is a compromise mainly dictated by practical considerations. Gates are, however, always designed so that the horizontal line of thrust falls within the skin plating.

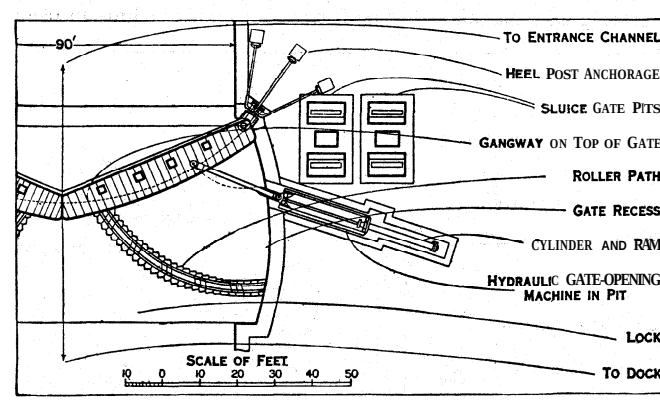

FIG. 23.— HALFPLAN OF GATES OF 90 FT. ENTRANCE LOCK AT CARDIFF DOCKS, SHOWING ROLLER PATH AND GATE OPENING MACHINE

Storm gates, pointing in the reverse direction to the impounding gates and placed outside them, are occasionally employed in entrances which are subjected at times to extraordinarily high tides, floods or strong wave action. Strut gates are auxiliary hinged and framed shores, housed at the back of the gate recess. They can be swung into position at the back of the impounding gates to support them against the pressure of waves at or about high

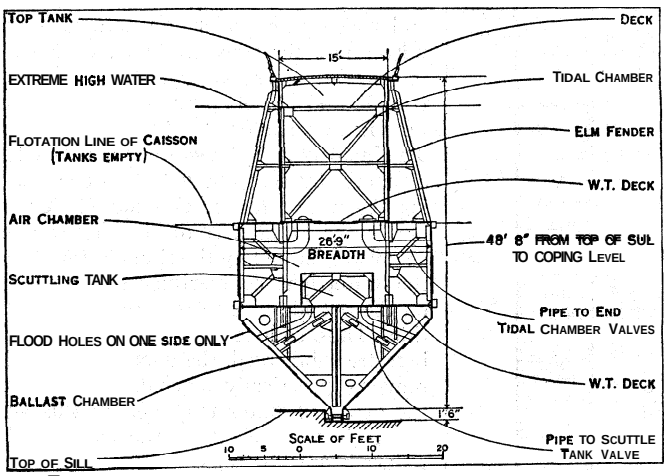

FIG. 24.— FLOATING CAISSON FOR EMERGENCY USE AT ROSYTH

water in exposed situations. Single leaf semi-buoyant gates, hinged on a horizontal axis below the level of the sill, have been used in some dry dock entrances. The gate is lowered into the water to open the entrance until it lies flat on a platform or apron outside and below the level of the sill. The train-ferry dock at Dover, opened in 1936, is provided with horizontally-hinged gates. As this is a wet dock and is designed to maintain the water surface inside the gates at a level which may be either higher or lower than the tidal water outside, there are two gates. one behind the other, capable of being lowered in opposite directions.

Gate Machinery.— The old practice was to attach two chains to each gate, hauled by hand winches or some form of power machine. Direct acting hydraulic rams, placed in covered pits just below the coping level of the lock, were first introduced about 1889 at the Barry docks. This system, in an improved form (fig. 23), has been widely adopted, particularly in Great Britain, and is still in general use. On the continent of Europe and in America electric power has been generally employed in recent years for operating gate machinery. One form of electric machine in use on the Panama canal consists of a large horizontal spur wheel linked, at one point on its circumference, to the gate by a connecting rod and rotated by an electric motor through gearing. In opening the gate the spur wheel turns through about a half circle. Another type used both in America and on the continent of Europe employs a connecting rod in the form of a rack which is engaged by worm gearing driven by an electric motor. In all these cases the operating machinery is placed in pits at the side of the lock.

Dock Caissons.—Caissons for closing the entrances of wet docks, dry docks and locks are constructed with buoyancy and ballast tanks so that, by means of valves and a pump or ejector fitted in the caisson, the weight of the contained water ballast can be varied at will for the purpose of floating or sinking the caisson or adjusting the unbalanced weight. Caissons are fitted with greenheart sill pieces and meeting faces which close against the granite faced sills and stops provided in the dock or lock entrance. They are of three general types: (a) floating caissons

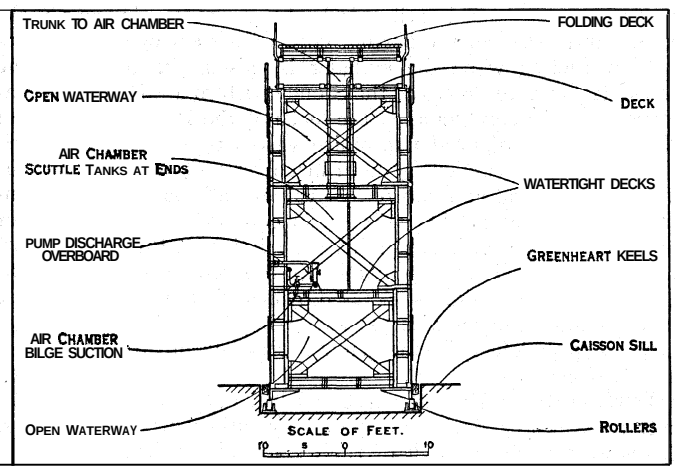

FIG. 25.— CROSS SECTION OF ROLLING CAISSON AT OUTER SILL, CONGELLA DRY DOCK, DURBAN

which are either ship form or rectangular and are moved without guides or rollers; (b) sliding caissons, provided with greenheart or other keel pieces which rest on sliding ways of smooth granite over which the caisson is drawn; and (c) rolling caissons, having wheels fixed to the under side on which they travel over rails laid on the floor of the entrance. In some cases the wheels or rollers are attached to the floor and the rails to the caisson.

The second and third types require a long recess or "camber"

to be formed in the side of the entrance into which the caisson may be withdrawn when the passage is to be opened. In a few cases, *e.g.*, a dry dock at Dundee, floating caissons have been hinged at one end and arranged to swing out into a recess in the dock wall. Floating caissons are in use for closing many dry docks. They are often provided at wet docks for emergency use (fig. 24). A rolling caisson was used at the Garvel dry dock, Greenock, in 1874. Qthers are at the entrance lock of the Bruges ship canal, the Congella dry dock, Durban (1925) (fig. 25); the Kruisschans lock, Antwerp (1927); and the Ymuiden lock (1930). The caissons which close the combined lock and dry dock at St. Nazaire (1932) and the new locks at Bremerhaven (1931) and Dunkirk (building 1940), are supported on a submerged roller carriage at one end and slung at the camber end from an overhead roller carriage travelling on the side walls of the camber chamber.

For closing large dry docks sliding caissons have been adopted in many recent instances (see Table III.). They are employed less frequently in the case of wet docks and locks, but of this use there are, however, important examples. Thus, most of the recent naval wet dock entrances in Great Britain, including Rosyth and Portsmouth, are closed by sliding caissons as is also the 140ft. entrance, made in 1917, at Cammell Laird & Co.'s fitting out dock at Tranmere on the Mersey. Among commercial docks they are in use at Bremen and Bremerhaven, and at the Ramsden dock, Barrow. A recent example is the Calcutta lock (completed, 1929).

A floating caisson is occasionally made to draw back into a camber and in this form differs but slightly from a sliding caisson. The large dry dock at Havre (1927) is closed by a caisson of this type. Sliding or rolling caissons, although more costly than simple floating caissons, are more easily and rapidly moved.

In situations where it is necessary to provide for carrying a road or railway over a sliding or rolling caisson, one or other of two methods is usually adopted for effecting this. In the first the camber is covered by a fixed roof carrying the rail tracks, and a lower-

ing platform forms the deck of the caisson and is depressed before the latter is hauled into the recess (fig. 25). In the alternative arrangement the roof of the camber itself is carried on elevating jacks which raise it sufficiently to allow the caisson to be run in under it, only the guard railings at the sides of the caisson deck being lowered. A modification of this arrangement is used in British naval docks. The ways on which the caisson slides are

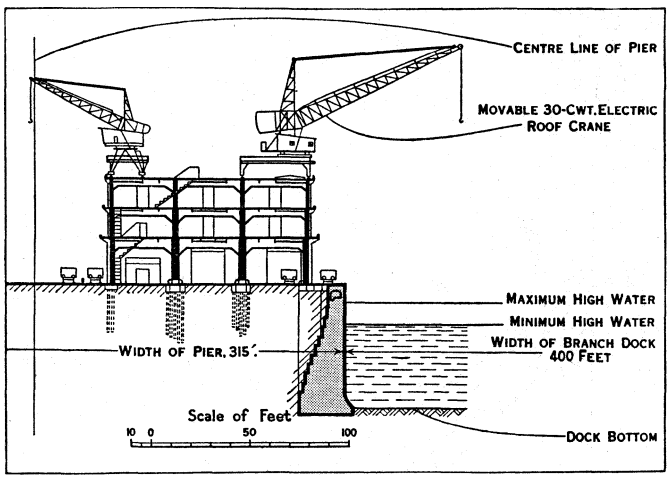

FIG. 28.— GLADSTONE DOCK. LIVERPOOL. HALF SECTION THROUGH THE BRANCH DOCK AND QUAY SHED SHOWING MOVABLE ROOF CRANES

formed on a gradient sloping downwards into the camber and the movable deck is hinged at the inner end and raised at the outer end to allow the caisson to pass under it. The caisson when in the camber is at a level which will allow the deck to be again lowered into its normal position flush with the coping.

Sliding and rolling caissons are hauled in and out of the cambers by means of wire ropes or chains or gearing usually operated electrically.

The caissons at Rosyth, in Scotland, the Gladstone dry dock, Liverpool and the Congella dock, Durban, in South Africa, are examples of electrical operation.

Relative Advantages of Gates and Caissons.--On the whole gates are easier to move and work than caissons and occupy less time in opening and closing. They necessitate a longer lock or entrance passage than caissons because of the space required for the gate recesses; but, on the other hand, a sliding or rolling caisson requires a long camber at the side of the entrance. Caissons are somewhat more costly than gates, but they can conveniently be made to afford accommodation for rail and road traffic across an entrance and thus obviate the necessity of a swing bridge in some cases. Moreover, they can be constructed to take water pressure on both sides, thus doing the work of two pairs of gates. An instance of this is the lock at Ymuiden. Where these two conditions have to be provided for the advantages are decidedly in favour of the caisson.

DRY DOCKS, ETC.

Provision has often to be made at ports for the repairs of vessels frequenting them. The primitive method of effecting repairs and cleaning was by careening the vessel or by beaching.

The simplest structure designed for the purpose of effecting minor under-water repairs and cleaning is the gridiron, still employed in some ports, where the tidal rise is suitable, for vessels of moderate size. It is a level platform of timber beams, constructed on a firm foundation, on which the ship settles with a falling tide and can then be inspected at low water.

Slipways.— Inclined slipways, up which a vessel of moderate size, resting in a cradle on wheels, can be drawn out of the water above the reach of the tide for cleaning or repairs, are used in many ports in all parts of the world. The foundations for the rails on which the cradle travels must be firm and unyielding. The rails are laid at gradients which vary from 1 in 15 to 1 in 25, the usual slope being about 1 in 20. The contrivance was patented by Thomas Morton of Leith, in 1818. He constructed many "patent slips," as they are often called, in European ports. Hydraulic hauling machines were first used for slipways about 1850. Previous to that time horses or steam engines and gearing were used. In modern examples electric hauling gear is frequently employed. A few slipways have been constructed to haul up ships broadside on, the cradle being borne on a series of transverse rails instead of on rails laid parallel with the centre line of the ship which is the usual practice. Slipways have been built in Europe to take vessels displacing up to about 4,500 tons; but in North American waters there are examples having a still larger capacity.

Slip-docks.— When the vessel is partially withdrawn from the water by means of a cradle on ways and the tide is excluded from the upper part of the slipway by a pair of gates and side walls, thus effecting an economy in its length, the arrangement is called a slip-dock. They are, however, rare in modern ports.

Dry Docks.—A dry dock is the usual means provided for enabling the cleaning and repairing of vessels to be carried out (v. supra for early examples). Dry docks are sometimes known as graving docks but the former term is now more often used in British ports. The word "graving" originally denoted the cleaning

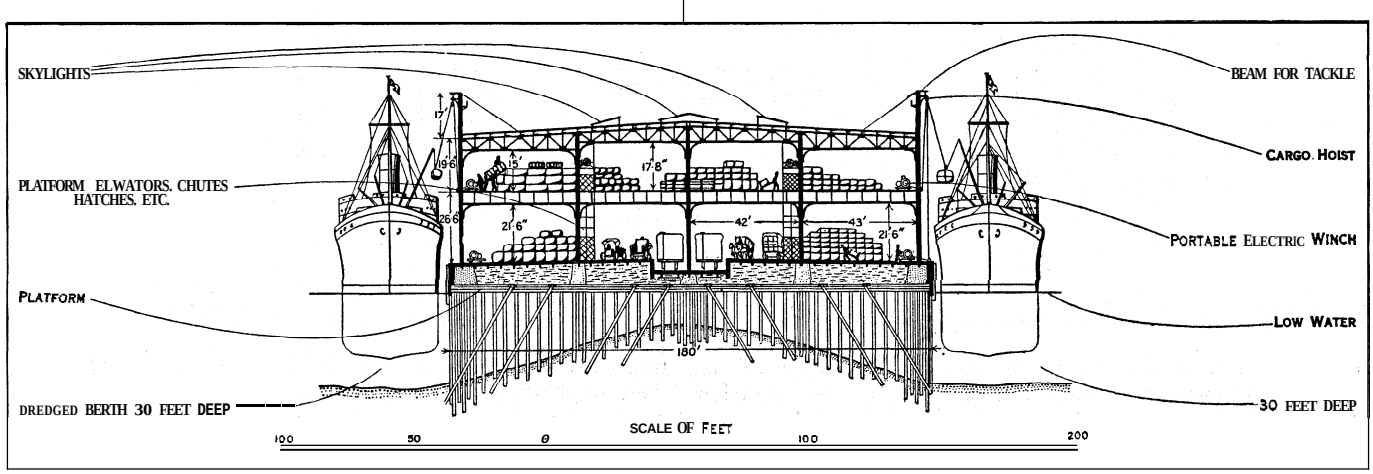

FIG. 29.— PLAN OF CARGO PIER, PHILADELPHIA, U.S.A. (1915), A TYPICAL PIER IN ATLANTIC PORTS OF THE U.S.A., SHOWING ARRANGEMENTS FOR "BURTONING" CARGO

of a ship's bottom by scraping or burning, and coating with tar.

A dry dock is a narrow basin, closed by gates or by a caisson, in which a vessel may be placed and from which the water may be pumped or let out, leaving the vessel dry and supported on blocks. A dry dock is sometimes used, especially in naval dockyards, for building ships. Many old dry docks were built of timber, and there are several such still in use in the port of London. In the United States timber dry docks are in common use even for large vessels. The typical modern dry dock, however, consists of concrete side walls, resembling those of a lock, but

stepped back towards the top, with a substantial concrete floor upon which the keel blocks, and sometimes bilge blocks also, rest (figs. 26 and 27). The floor usually has a slight fall from back to front, and from the centre to the sides, to facilitate drainage.

Dry docks should, for preierence, be founded on a solid impervious stratum, but this is not always possible. It is often impracticable to obviate the presence under the dock bottom of water which may exert a hydrostatic upward pressure when the dock is pumped out. Such conditions are usually met in one or other of two ways. The floor may be made comparatively thin with vents formed in it or low down in the side walls to relieve the pressure of the water which is allowed to leak into the dock and is dealt with by drainage pumps. The alternative is to make the dock floor and walls of sufficient weight and dimensions to resist the maximum pressure due to saturation of the surrounding soil. That is to say, the floor must act as an inverted arch and the whole body of the dock when empty must be of sufficient weight to resist the tendency to flotation. In bad ground and when the floor is thin, bearing piles are often driven under the dock floor in way of the keel blocks, and, in some cases, under the whole of the floor and side walls also. In any case the floor must be of sufficient strength to bear the weight of the heaviest ship which the dock can take in, concentrated on the lines of the supporting blocks. Thus far very few dry docks have been built of reinforced concrete, forming a rigid box, usually supported on piling.

A dry dock at Havre (see table III.), opened in 1927, is of particular interest on account of the method adopted for its construction on a deep stratum of sand and silt. The entire dock structure was built in and upon a huge steel caisson framework 1,132 x 197ft. which was floated into position over the site of the dock, previously dredged to the required depth, and there sunk in place. The caisson was constructed on levelled ground within a containing embankment and portions of the floor and side walls were built in it before it was floated out to the permanent site.

The stepped courses provided in the upper parts of the side walls of a dry dock are called "altars" and are used for the support of side shorks between them and the ship. Culverts, controlled by sluice gates (fig. 20), are built in the side walls of the entrance for flooding the dock when it is necessary to let a ship out. Centrifugal pumps—usually electrically driven in modern docks—are employed for pumping out the dock and maintaining effective drainage. The water flows to the pump sump chamber and from the pumps to the outside of the dry dock through culverts. (See figs. 26 and 27). In many old docks, in positions where the tidal range is suitable, water is run out as the tide falls; but in modern practice it is customary to provide for pumping out the whole of the water in about 3 hours—more or less.

In ports where the tidal rise is considerable and there are wet docks, it is preferable, when practicable, to construct a dry dock with its entrance from within the wet dock and not from the tideway. There are many advantages attending this arrangement: still water for manoeuvring the ship; availability for use at all states of the tide; and comparative freedom from siltation may be instanced. In situations where a dry dock is entered from tidal water of considerable range, it is desirable to provide for holding up the water inside the dock above the level of the falling tide in order that ample time shall always be available for shoring and other dock operations.

Equipment of Dry Docks.—The machinery employed at dry docks for working gates, caissons, sluices and capstans is generally on the same lines as for entrance locks. It is necessary, however, to equip a dry dock, in addition to the pumps already referred to, with powerful cranes, travelling along the dock side, to deal with the heavy lifts sometimes necessary in effecting ship repairs (see fig. 27). As an example of such provision the Trafalgar dry dock at Southampton has an electric travelling portal crane lifting 50 tons at a radius of 87ft. Most of the modern dry docks thus far constructed are also well equipped for working electric and compressed air tools.

Examples of Dry Docks.—The following table (III.) gives particulars of some typical large modern dry docks:—

TABLE 111.—Dry Docks

Port, name and date of opening	Available			Method of closing
	Length	Breadth	Depth over sills or blocks at H. W. O. S. T. or maximum dock level	
	ft.	ft.	ft.	
London, Tilbury, 1929	750	110	376	Floating ship-type caisson
Rosyth, H. M. Dockyard, 1915	890	105	40	Sliding caisson
Bombay, Hughes, 1914	1000	100	36¼	Floating calsson
Liverpool, Gladstone, 1913	1050	120	436	Sliding caisson
Boston, U.S.A., Navy, 1920	1170	120	43	Floating ship-type caisson
Esquimalt (Victoria), 1926	1150	125	40	do.
St. John (N. B.), 1923	1165	125	42	do.
Durban, Congella, 1925	1150	110	41	Rolling calsson
Havre, 1927	1023	125	52½	Floating box caisson
Panama Canal, Balboa, 1916	1044	110	41½	Gates
Singapore, King George VI., 1937	1000	130	44	Sliding caisson
Southampton, King George V. dock, 1933	1200	135	48½	Sliding calsson
St. Nazaire (combined lock and dry dock), 1932	1148	164	43½	Rolling caisson
Genoa (No. 4 dock), 1940	919	131	423	Floating caisson

Floating Docks.—Floating dry docks are used in some situations where there is no site available for an ordinary dry dock or where special conditions render the floating structure more convenient or economical. They possess the advantage of mobility and, during the World War, large floating docks were moved from ports where they were not urgently needed to places such as the Tyne and Cromarty firth where they could be more usefully employed. It is only necessary to find a sheltered site, with a sufficient depth of water, for conducting the operations of a floating dock. But, although a floating dock may be self-contained with workshops in its walls, or be served by a separate floating workshop, experience shows that to obtain the full advantage it is advisable to have an establishment on shore. This tends to restrict the choice of site. Furthermore, a floating dock can often be built and placed in service in a fraction of the time which would be necessary to construct an ordinary dry dock. The largest floating dock in the world (1940) is that at Southampton completed in 1924. It has an overall length of 860ft.; clear inside width of 130⅔ft.; and a total lifting power of 60,000 tons. The dock can be submerged to take in ships drawing 38ft., and the berth where it is moored is dredged to a depth of 61ft. at L W.O S T. It has docked some of the largest ships afloat (see *Proc.*, Inst.C.E. 192j).

Unfortunately the dredging of such deep pits below the general level of the harbour bed as are required in some situations for a floating dock of very large dimensions is sometimes followed by rapid silting and this has occurred at Southampton where redredging has been necessary at intervals of less than 2 years.

Another large floating dock of 50,000 tons lifting capacity was built on the Tyne in 1927–28 for the Singapore naval base. (See also section in this article Floating ***Docks.)***

NAVAL DOCKS

The dockyard at Rosyth, on the north side of the Firth of Forth, is the most modern example of naval dock construction in Great Britain. The works had been commenced in 1909 and,

although a large part of the accommodation was made available for the fleet by the summer of 1915, construction continued until 1921. The dockyard occupies a site on the foreshore of the Firth above the Forth bridge and comprises a closed basin or dock of 56½ac., an entrance lock, three dry docks, and tidal basins and in addition, there is a tidal entrance to the basin 115ft. wide at sill level (see Proc., Inst. C.E. 1927).

To meet the growing needs of the navy new locks and a dry dock with dimensions practically identical with those at Rosyth, were constructed at Portsmouth shortly before the war of 1914–18.

In the years following the war, many of the locks, dry docks and basin entrances at the naval dockyards of Devonport, Portsmouth and Chatham were enlarged. The naval base at Singapore, begun in 1928 and in its main features completed in 1938, includes over 6,000 lin.ft. of deep-water quayage in a tidal basin most of which has a depth of water alongside the walls of 40ft. at low water. The dry dock (see Table III.) has an entrance width of 130 feet. The dockyard also comprises a floating-dock and power stations, together with all the workshops, etc., necessary in a naval repair base. Occupying a site on the southern shore of the Johore Strait, it cost upwards of £11,000,000 excluding fortificationsand air defences.

THE EQUIPMENT OF DOCKS

Railways and Roads.—In order to deal expeditiously with the cargoes and goods brought into and despatched from docks, numerous sidings communicating with the railways of the district are arranged along the quays. In ports where a large railway traffic is dealt with it is necessary to provide, within or near the dock area, marshalling yards and standage sidings if congestion of traffic on the quays is to be avoided.

The "lay-out" of the railways in a dock area calls for much skill and ingenuity, both in planning and in the arrangement of gradients, to secure economical and rapid working. Moreover, in busy ports of modern construction it is usual to provide at least three lines of rails on those quays where goods are worked direct from ship to railway truck, or vice versa, and not through transit sheds. This arrangement allows two roads to be used for standing wagons while one is a running road. The growth of motor road transport has made it necessary to afford liberal accommodation for heavy lorries both on quays and at the side of transit sheds and warehouses, and the provision of adequate road access has become a matter of primary importance. The tendency in all modern dock construction is, in fact, to provide much wider quay spaces than was formerly the practice. Even in the port of New York where the old long, narrow pier is the characteristic feature of the quay accommodation, wide piers are now being built.

Warehouses, etc.—The arrangement and nature of store and transit sheds, warehouses, etc., varies at every port, depending largely on the local trade and traffic conditions. At Liverpool three-storey sheds with roof cranes have been built at the new Gladstone docks (fig. 28). At the Manchester docks there are large quay-side warehouses of five floors and in some North American ports transit sheds with as many as 8 and 9 floors. Where double sided piers and quays are constructed, widths of from 300 to over 500ft. are usual in order to provide ample space for sheds and warehouses which frequently have rail and road tracks on both sides. A typical example of such construction in northern Pacific ports is the Ballantyne pier at Vancouver (fig. 18). The piers at New York and in some of the other Atlantic ports of the United States are, however, usually built without open quay spaces on the water fronts. Often the transit sheds cover practically the whole surface, and roadways and rail tracks, when provided, are constructed inside the building. Piers with open quay-side spaces and rail tracks are, however, becoming more common in the Atlantic ports.

Appliances for Special Trades.—Elaborate and costly plants for loading, discharging and storing special classes of cargo have been established at ports in all parts of the world where such cargoes are dealt with in large quantities. Among them may be instanced coal, grain, ores and oil in bulk; and chilled meat and fruit. With the exception of coal all these classes of traffic may be said to be modern developments of transport, at any rate in regard to the working of bulk cargoes. The bulk shipment of wheat at such ports as Montreal, New York, Vancouver and Port Arthur has necessitated the building of vast granaries (*q.v.*) and elevators, some of them holding over 110,000 tons and capable of loading into ships at a rate of 3,000 tons per hour. For the discharge of grain pneumatic and bucket elevators and electric conveyors and large storage warehouses, the working of which is almost entirely automatic, are provided at many ports. Floating pneumatic elevators for discharging grain from ships into lighters or to shore granaries are largely employed. Appliances for the shipment and discharge of ores have been developed to a high standard of efficiency in some of the ports of the United States. Both in America and in European ports grabs and transporters are used for discharging ore cargoes. Mechanical handling is employed at docks where chilled and frozen meat is imported on a large scale, as in the port of London. Electric conveyors, runways and hoists carry the carcasses from the ship to the cold rooms in large stores at or near the quays with a minimum of manual labour (see REFRIGERATION AND ITS APPLICATION).

Oil Export and Import.—The transport of oil in bulk (see PETROLEUM) is a product of the 20th century. At all ports where tank steamers discharge, the oil berths are isolated and the arrangements for storage on shore must be such as to minimize the risk of fire and its spreading. The sea transport of petroleum in barrels is on a very small scale compared with bulk cargoes. The latter are loaded by being pumped from large storage tanks to the ship through mains.

Ports such as Los Angeles in California, Corpus Christi in Texas and Abadan in the Persian Gulf have been created since the beginning of the century for the shipment of bulk oil cargoes. Los Angeles has been made, as a port, since the opening of the Panama canal, and the bulk of its seaborne trade of over 21 million tons annually is the export of oil. According to official statistics it is the second port of the United States in point of tonnage.

Continuous quayage being unnecessary, the berths at which tankers load and discharge are usually alongside isolated jetties or dolphins connected with the shore by light piled structures on which the pipe mains are carried. Provision for the bunkering of ships using oil fuel is made at many ports, special oil jetties being set apart for this purpose.

In ports such as London, situated at a considerable distance from the mouth of a tidal river, oil berths are usually isolated in the lower reaches seaward of the dock areas. In some ports, however, this is not possible and at Stanlow, near Ellesmere, on the Manchester ship canal, a special petroleum dock, provided with a floating isolating gate or boom across the entrance, has been constructed with the object of preventing the flow of oil beyond the limits of the dock. Similar provision is made in other ports, *e.g.* at Amsterdam.

Coal Shipping Ports.—At docks whose principal export trade is coal, the arrangement of quays and berths is planned with special reference to the running of coal wagons to and from the shipping points. (For bunkering of ships see BUNKERING OF SHIPS.) In the ports of north-east. England high level coal "staiths" are much used, mainly on account of the high elevation of the ground in the neighbourhood of the shipping berths, as, for instance, on the river Tyne. At many high-level staiths such as those at Dunston on the Tyne and at Blyth, which are built parallel to the river bank, trains of wagons are brought on to the staith and discharged successively by means of shoots into vessels lying alongside. In situations where the elevation of the surrounding ground is insufficient to provide for gravity discharge from staiths to the hatchways of large modern vessels, hydraulic hoists (electric hoists are sometimes used in American and continental ports, but in Great Britain hydraulic hoists are very generally employed) are often provided, as in the docks of South Wales and Scotland as well as at north-east coast ports. Wagons are brought to the shipping points at quay level, or over a graded gantry structure raised sufficiently high above the quay t o avoid obstruction of the quay space,

The coal hoist is contained in a steel latticework tower erected on the dock side. The tower may be either fixed in position or capable of limited movement along the quay so as to suit the position of a ship's hatchway. The loaded wagon is raised on a cradle or platform to the required height for the discharge of the coal through adjustable steel shoots into the ship's hold. In some ports the practice is for wagons to discharge through bottom doors; in others the wagons are fitted with end doors and are tipped on a cradle in the hoist. The running of wagons to and from the staith or hoist is, wherever possible, assisted by suitable grading of the tracks. Empty wagons are sometimes run off from the hoist at a higher level than the loaded wagon roads and run by gravity to the empty sidings. Electric and hydraulic capstans are also used for working the wagons at shipping places.

Electric conveyors are much used in the shipment of coal, in some cases raising it from quay-level, as at Hull and Manchester. They are also used at some coal staiths in order to increase the height of the point of delivery of the coal. In this way they are employed at Dunston and other Tyne shipping places. Some of the modern coal shipping appliances in British ports, as at Newport, are capable of loading coal into a ship at the rate of 850 tons per hour and at elevations of over 75ft. above high water.

In a few English ports, including Liverpool and Cardiff, some coal is shipped by means of cranes lifting wagons or containers and emptying them over the ship's hatchway. At Goole *(see* CANALS AND CANALIZED RIVERS) small compartment boats containing coal are raised by hoists and discharged into the waiting ships.

The wharf or jetty on which the coaling staith or hoist is erected is frequently constructed over and in front of a stone pitched slope in order to avoid the necessity of building a continuous deep uater wall. This plan has been adopted at Swansea. Barry Dock, Newport and at many of the Tyne staiths. At the King's dock, Swansea, and at the King George dock, Hull, some of the coaling jetties are arranged en echelon; thus, in effect, increasing the length of available berthing space by permitting one vessel partially to overlap that of another in the adjoining berth.

Up to about 1910 the use in the United Kingdom of high capacity coal wagons carrying 20 tons was uncommon, the usual maximum load being 10 tons. The large wagon is, however, steadily replacing the older, uneconomical, small wagon at coal shipping ports. Practically all coal hoists, conveyors and other coal shipping appliances constructed in Great Britain since 1918 have been designed for the 20-ton wagon and a few wagons of 40-ton capacity are in use. Appliances to minimize the breakage of coal in falling from the shoot into the ship's hold, are commonly used at ports where grades, the value of which is seriously deteriorated by breakage, are shipped.

In America railway freight cars are of much larger capacity than in Europe and coal cars carrying up to 120 tons are in use. The shipment of coal is effected both by hoists and conveyor belts as in the United Kingdom, but the tipping arrangements provided for the cars are on a much larger scale; and it is customary to discharge them by means of revolving "tipplers" or "dumpers" into large hoppers whence the coal is delivered to the ship, either direct or over conveyor belts, through shoots as required. The large hoppers serve as reservoirs to equalize the rate of supply. In some cases the coal is dumped from railroad cars on the low level into very large pier cars which are raised by hoists and are tipped over hoppers at a high level. **A** coal shipping installation on the belt system, put into service at Baltimore in 1918 by the Baltimore and Ohio Railway, employs self-trimming loaders which shoot the coal at high velocity in any desired direction between decks. Somewhat similar mechanical trimmers are in daily use at the several other coal ports of the American continent.

By these means, in conjunction with highly developed arrangements for dumping cars and belt feeding, the rate of shipment of coal has been largely augmented. The Baltimore pier is double-sided, 700ft. long and has four main coal loading towers. Over 40.000 tons have been loaded at it in one day. The use of the American type of large coal cars and mechanical trimming enables ships to be loaded with coal at some of the best equipped U. S. A. ports more rapidly than in British ports where the time rate for a complete cargo does not often exceed 600 tons per hour and is usually less on account of delays in trimming the coal between decks. The best American shipping plants have, in this respect, an advantage of at least 50% over the Tyne and South Wales ports.

Power for Dock Machinery, **etc.**—Though different sources of power are sometimes made use of at different parts of the same port, it is generally most convenient to work the various installations by one form of power from a central station. This applies in particular to installations of dock-side cranes. The adaptability and flexibility of electric power has led to its general adoption, and its use for cranes and other mechanical appliances at docks has become almost universal. Even at numerous other important ports where hydraulic power is available at the docks, electric appliances are now being installed side by side with hydraulic equipment.

Hydraulic power for dock appliances is more commonly used in Great Britain than in American ports and on the continent of Europe. It possesses undoubted advantages for operating gate-opening machinery, large sluices, coal hoists, capstans, swing bridges and some other forms of dock equipment.

Appliances for Loading and Unloading Ships.—In addition to the provision of high speed electric cranes or cargo hoists on quays and wharves in most European and North American ports, the equipment of warehouses and transit sheds with electric "run about" and overhead cranes, runways, loaders, conveyors and hoists is becoming general.

In the Far East, however, even at ports handling a large volume of trade, this equipment is not general and cargo is still generally discharged by means of ships' derricks and dealt with on shore by manual labour. Again, in some ports, notably those of London, Rotterdam and Amsterdam, a large proportion of the cargoes is loaded or discharged overside from or into lighters and barges, and at Rotterdam sea-going ships lying at moorings in the river or basins frequently take in or discharge the whole of their cargo from or to large Rhine river barges without going alongside a quay.

The rapid loading and discharge of ships, thus enabling a quick "turn round" of the ship to be made, is of the utmost importance both to the ship owner and the dock authority. The capital sum represented by a modern cargo ship and a dock berth is very large, and if the average time of loading or discharge of a ship can be reduced from, say 4 to 2 days, by the installation of appropriate mechanical appliances, the revenue earning capacity of the berth is increased theoretically by 100%, and that of the ship in proportion to the reduction effected in the time required for the voyage.

' At quays working general cargo in busy ports a liberal but not extravagant provision of cranes is one for every 100 or 120 feet of quay. The traffic capacity of docks varies within very wide limits and depends largely on the nature of the principal exports and imports and on seasonal variations of traffic. In a well equipped port through which a large volume of mixed traffic passes, it is not too much to aim at a traffic intensity of 300 tons of cargo per foot of quay per annum. During the last 18 months of the war of 1914–18 the ports in northern France operated by the British army passed an import tonnage of well over 1 ton per day per foot of quay frontage.

Cranes.—Dockside cranes for general cargo purposes are frequently of the portal type, travelling on rails laid upon the quay with space between the legs (which carry the crane platform) for railway wagons to pass under. In some docks where warehouses are near to the face of the dock wall, travelling cranes of semi-portal type are employed: one pair of the crane legs travels on rails laid near the quay edge and the other pair on elevated rails fixed to the wall of the building. As a result this leaves nearly the whole quay space free for the passage of transport.

Cargo cranes must be raised high enough above the quay sur-

face to enable their jibs to command the hatchways of ships rising high above the water level. For general purposes cranes of 1½-, 3- and 5-ton lifting capacity are most commonly used, but for special purposes much more powerful travelling cranes are provided. Floating and fixed cranes of great capacity are employed for dealing with exceptional loads. Some floating cranes lifting 250 tons are in use and at least one fixed crane, that at the Philadelphia navy yard, is capable of lifting 350 tons.

Some modern dockside warehouses have been equipped with electric cranes travelling on the flat roof of the building and arranged to work cargo to and from the several floors of the warehouse through hatchways formed in them and in the roof as at the Gladstone docks, Liverpool.

In New York and some other ports of the United States, particularly on the Atlantic coast, quay-side cranes are in use to a limited extent only. The bulk of the working of general cargo is effected by a process called "Burtoning." This consists of the joint working of the load by means of a ship's derrick and a fixed cargo mast or hoist attached to the wall of the pier shed which is built out close to the water front.

Electric current for dockside cranes is taken either from conductors in conduits laid below the quay surface or fixed to the walls of quay-side buildings, or by means of flexible cables from plug boxes at points on the quay. (*See* also CRANES.)

Brief modern surveys of cargo handling at ports are the *Vernon-Harcourt Lectures,* Inst.C.E., 1928; H. A. Reed's *Cargo Handling;* and N. G. Gedye's *The Mechanical Handling of Coal at Ports* (1931).

Colson, *Docks & Dock Constructign* (1894); Quinnette de Rochemont, *Cours de Travaux Maritzmes,* 3 vols. (1900); C. de Cordemoy, *Les Ports Modernes,* 2 vols. (1900); *Ports Maritimes de l'Italie* (Rome, 1931), Fr. & Ital. editions. More recent works of general engineering description are.—de Joly, Laroche, Watier and De Rouville, *Travaux Maritimes,* 4 vols. (Paris, 1930–39); Brysson Cunningham, *Dock Engineering* (1922); A. C. Gardner's *Vernon-Harcourt Lecture* (1940), "The Construction of Deep-Water Quays." Several volumes of the series *Handbuch der Ingenier Wissenschaften* (Engelmann) Leipzig, 1912 *et seq.,* deal with docks and dock equipment and are well illustrated. For U S.A. ports the series of reports and plans issued 1921 *et seq.* by the War Department should be consulted. C. Greene, *Wharves & Piers* (New York, 1917), contains good descriptions of American practice. W. H. Hunter's *Dock & Lock Machinery* (London, 1921), is an excellent work on the mechanical operation of gates, caissons, sluices, etc. For cargo handling *see* B. Cunningham. *Cargo Handling at Ports* (1923) and *Port Administration and Operation* (1925); and R. S. MacElwee, *Port Development* (1925) and *Ports & Terminal Facilities* (1926). The *Reports* of the Committee of the Inst. of Civil Engineers on the *Deterioration of Structures* exposed to the action of sea water (1920 *et seq.*) are valuable and authentic. The best American work on the subject is *Marine Structures,* Report of Committee, National Research Council (1924). The Port of London and its history are well described in works by Sir J. Broodbank, 2 vols. (1921), and D. J. Owen (1927). The *Proceedings* of the International Navigation Congresses contain many important papers. Exhaustive bibliographic lists are issued periodically (since 1908) by the International Association of Navigation Congresses, Brussels. *See* also *passim,* the *Proceedings* of the Inst C.E. and of similar American and European Institutions and Societies and British technical journals such as *The Engineer, Engineerzng* and *The Dock and Harbour Authority. Lloyds Register* (annually) contains world lists of wet docks, basins, dry docks, etc., with dimensions. *Gvaving Docks, Floating Docks and Patent Slips in the British Empire,* London, H M. Stationery office, is compiled under Admiralty-authority. Revised editions are issued at intervals. Also F. M. Du-Plat-Taylor, *Docks, Wharves and Piers* (1928). (N. G. G.)

PIERS, WHARVES, AND DOCKS OF THE UNITED STATES

Waterborne commerce of the U S., which exceeds 500,000,000 short tons annually, is handled at ports on the Atlantic, Gulf, and Pacific coasts and on the Great Lakes, and at terminals on the rivers, canals, and connecting channels. A detailed description of port and harbour facilities at the principal ports of the United States is contained in Government publications called *Port Series,* which are prepared jointly by the Board of Engineers for Rivers and Harbors War Department, and the Division of Research, United States Maritime Commission. The piers wharves, and docks at typical United States ports, each having a combined foreign and domestic commerce exceeding 15,000,000 tons annually, are described in the following paragraphs:

The Port of New York.—New York, the most important seaport of the United States and among the foremost of the world, is on the Atlantic coast at the mouth of the Hudson river. The water front of the port of New York is extensively developed along the Hudson and East rivers, the Harlem river, Newtown creek, Gowanus bay and canal, and Upper New York bay. The west side of Arthur Kill, the Kill van Kull, and the Passaic river have also a considerable number of water terminal facilities. The port has a total of approximately 1,900 water terminal facilities, including piers, bulkhead wharves, ferry slips and railroad-car ferry transfer bridges.

The Hudson river on the New York side is the most intensely developed water front in the port area, being devoted almost entirely to shipping, with no large industrial sites. A great part of the passenger and express freight business of the port is handled in this section. The large express liners of the European trade, with turn-arounds as short as two days, cause considerable congestion on the marginal ways and on piers. The greater part of the Hudson river water front on the New Jersey side is devoted to railroad use. The East river has terminal facilities used in the West Indies and Mexican passenger and freight trade and in the coastwise trade It is the centre of the fish and shellfish business of the harbour. The Brooklyn navy yard, with four dry docks and extensive shipbuilding and repair facilities, is located on the Long Island side of East river. A large number of industries, including oil and sugar refineries, are established in this section Passenger and freight steamship lines from all ports of the world use the Long Island terminals. The city of New York has provided 12 piers, known as the Stapleton piers, which are modern in every respect. Five of these piers are included within the area occupied by the Foreign Trade zone. Other portions of the port of New York, such as the Kill van Kull, Passaic river. and Upper New York bay, have terminal facilities for the needs of oil companies, refineries, copper refining works, lumber yards, coal yards, and chemical, fertilizer, and asphalt plants and various other commercial establishments The State of New York has eight modern barge terminals conveniently located for shippers using the State Barge Canal system. The piers and wharves of the port are in general owned or used under lease by operators.

The Port of Boston.—Boston, Mass., is on the North Atlantic coast of the United States. There are 223 commercial piers or wharves in Boston harbour, providing 26 mi. of berthing space. The piers are mainly of open-pile construction and many have rail connections. Practically all of the terminals fronting on the main ship channel are in close proximity to storage warehouses, both cold and dry, which greatly facilitates the transfer of cargo. The water front of Boston harbour proper comprises 28 piers and wharves, with a total berthing space of nearly 20,000 linear feet. Eight of its more important terminals afford facilities for handling cargoes of the inland waterway carriers, and six are used in the foreign and coastwise trade. Many of the wharves have rail facilities.

At East Boston, five terminals are used for handling miscellaneous cargo in foreign and coastwise trade and six provide for the transfer of coal. There are also wharves and piers for handling lumber and fish and for marine repair activities. Chelsea creek. a branch of the harbour, is used primarily for the handling of petroleum products, several large oil plants having been established along this waterway. Among the 18 wharves on Mystic river one, owned by a railroad, consists of a large coal-handling plant having six steam travelling tower cranes and in the rear of the wharf a steam travelling bridge crane. The United States Navy yard, comprising 11 piers, is situated on the Charlestown water front. This section of the harbour has various commercial wharves used for handling miscellaneous cargo in foreign anc coastwise trade, and is equipped for handling grain. At South Boston the Commonwealth of Massachusetts has provided severa piers, one of which, constructed of steel and concrete is equippec with cargo beams and electric winches for thr handling of cargo

The Port of Philadelphia.— The water front of the port of Philadelphia, which is on the Delaware river 100mi. from the Atlantic ocean, covers a distance of 38mi. on the west side of the river between Hog island on the south and Poquessing creek on the north, and on both sides of the Schuylkill river, a tributary stream.

Within this area are 191 piers, wharves, and bulkheads, excluding those of the Navy yard, with a total berthing capacity of about 159,000 linear feet.

The wharfage facilities at the port vary from simple timber bulkheads with solid earth fill to the large piers constructed of timber piles supporting timber or concrete relieving platforms, at low water, which in turn carry timber or concrete retaining walls and solid fill. The ownership of terminal facilities at the port is divided as follows: city owned, 34; United States, 7; the several railroads own or control 66; while the remainder, or 84, are privately owned or operated. Of the total number, 39 facilities are open to all water carriers on equal terms and 152 are used for the private purposes of their occupants. Over one-half of the facilities have rail connections.

The Port of Baltimore.— At the port of Baltimore, which is on the middle Atlantic coast near the head of Chesapeake bay, there are 289 piers, wharves, and bulkheads having a combined berthing capacity of 211,000 linear feet. Facilities are available for accommodating all classes of vessels from the smallest to ships of 35-foot draught.

Practically all of the terminals used for general cargo shipping in overseas, coastwise, and bay traffic are on the Northwest branch of the Patapsco river, and within convenient access to the centre of the city. Piers for overseas traffic are generally of open-pile and timber construction, while a few have timber bearing platforms on timber piles to low water, covered by concrete retaining walls and earth fill.

Rail service is generally available, either on the aprons or within and in the rear of the transit sheds. Overseas freight is usually handled by means of cargo beams on transit sheds and ships' gear, though in some instances gantry cranes and other mechanical devices are utilized. Some of the large industrial plants, together with their terminals, are located in outlying sections of the water front, principally at Sparrows Point, at Fairfield, and on Curtis bay.

Ports in the Hampton Roads Area.— Norfolk, Portsmouth, Newport News, Hampton, and Old Point Comfort comprise the principal ports in the Hampton Roads area, which is on the middle Atlantic coast, at the entrance to Chesapeake bay. These ports have a combined total of 293 piers and wharves, with space of 175,000 linear feet for berthing vessels and transit shed areas of 4,458,000 square feet. Of this number the several railroads entering these ports own 74 facilities with 72,500 linear feet of berthing space. The United States own 28 piers and wharves with 27,000 linear feet of berthing space, steamship lines own 7 piers and wharves, the municipalities own 24, and private corporations and individuals own 159.

At Norfolk and Berkley, Va., there are 176 terminals having a combined berthing space of 107,000 linear feet. Privately owned terminals are used for shipbuilding and ship repair, by fertilizer plants, by sea food packing plants, and for the handling of petroleum products and farm produce. Portsmouth, including Pinners Point and West Norfolk, has a total of 54 piers, wharves, and docks with a total berthing space of 33,000 linear feet, owned by railroad companies, the United States, the municipality, and private concerns. There are 41 piers, wharves, and docks in Newport News.

The Port of Los Angeles.—Los Angeles harbour, Calif., is on the west coast of the United States. It consists of an outer harbour and an inner harbour, with a total water frontage of 25½mi., 55% of which is improved. Approximately 95% of the wharves, sheds, and port facilities open to the public are owned by the city of Los Angeles.

Of total wharfage, the city owns 44,582ft., three-fourths of which is of timber deck construction supported by creosoted timber piles, and the remainder is of composite concrete and timber construction, or has concrete decks supported by reinforced concrete piles. Private wharfage totals 21,900ft., nearly all of which is of timber construction. The city owns and operates 22 one-story and 2 two-story transit sheds totalling 16,000ft. in length.

All facilities are easily accessible by motor trucks over well-paved highways, and the majority are served by a belt line railroad which connects with the main railroad system and the electric interurban railway serving the port.

The Port of New Orleans.— New Orleans, La., is situated on both banks of the Mississippi river, 110mi. from the Gulf of Mexico. There are 100 piers, wharves, or docks at the port, practically all of which lie on the east bank of the Mississippi river. They are parallel to the river bank and form a continuous quay for a distance of approximately 10 miles.

Of the port facilities, 25 are used for handling general cargo in foreign trade. Various wharves are used for receiving molasses in bulk, for handling fuel oil, coal, cotton, and tropical fruit, or for miscellaneous and private purposes. The public wharves, which are controlled by a local port commission, cover 62% of the improved water front. These wharves are generally of open pile with timber and concrete deck construction, and the greater portion of the wharf area is covered by transit sheds of steel framework with corrugated metal walls. The aprons extending along the front of the wharves average from 20 to 30ft. in width. In the rear of the transit sheds a roadway built at car floor level furnishes a platform over which cargo is conveyed to the various rail lines either directly or by means of a public belt railroad.

Port Arthur.— The city of Port Arthur, Texas, is on Sabine lake at the head of Port Arthur canal, 20mi. from the Gulf of Mexico. The port has 11 wharves, all are of creosoted pile and timber construction except one which is of concrete. Five are used almost exclusively for handling petroleum products and the remainder is used for handling coal, lumber, general merchandise, grain, and cotton. A case oil dock, 600ft. long, has sheds constructed of concrete and tile, with two movable link-belt conveyors and gravity spiral chutes for loading cases directly into ships. One of the wharves used for handling fuel oil and products is of concrete construction, 3,000ft. long, with a depth alongside of 32 feet. At a terminal located at Sabine Pass, oil for storage is obtained by inland pipe lines and by vessels, and is loaded into tankers through pipe lines located on the wharf

The Port of Beaumont.— The harbour of Beaumont, Texas, which extends along the Neches river, 50mi. from the gulf, has 12 terminal facilities, and in addition the Neches river below Beaumont has nine facilities. The principal terminal development at the port is the municipal enterprise which comes under the jurisdiction of the local port commission. It has a total berthing space of 2,900ft. and handles practically all of the general shipping of the port. The terminal is made up of several wharves; some are of pile and timber construction, while others are of concrete bulkhead construction. There are transit sheds served by surface tracks on the wharf proper and additional tracks immediately in the rear of the sheds.

A terminal used for handling cargo oil and petroleum products, and as a fuel oil bunkering station, has a wharf 1,500ft. long of concrete quay wall construction. Terminal facilities below Beaumont harbour are all owned and operated by oil companies and are used principally for the receipt and shipment of crude and refined oil, and petroleum products.

The Port of Houston.— The port of Houston, Texas, is at the head of the Houston Ship channel, a deep-draught waterway extending 50mi. inland from the Gulf of Mexico. The port has 48 wharves, bulkheads and moorings used for commercial purposes, which provide berthing space for 58 seagoing vessels, 18 at the public wharves and 40 at private plants. Of the total number of terminals 19 are used for the handling of general merchandise and cotton, 14 for oil, and the remainder for steel, grain, bulk freight, miscellaneous commodities, and private purposes.

The principal terminal facilities are located at the turning basin within the city of Houston. Surrounding the basin are 13 public wharves, nine of which are of reinforced concrete construc-

tion and four of pile and timber, all but two having transit sheds and modern mechanical handling equipment. A public belt railroad with track scales serves all these facilities.

Below the turning basin the city of Houston has public wharves which are used for handling bulk cargoes of grain, coal, ore, sulphur, and oils. Additional terminals, operated by private corporations, are located along the ship channel and handle a considerable volume of the business of the port, especially in the shipping of cotton. A number of oil docks for the loading or discharge of tank vessels and barges or bunkering of vessels exist along the upper 2 j-mile reach of the ship channel.

The Port of Duluth-Superior.—Duluth-Superior harbour, Minnesota and Wisconsin, is a Great Lakes port at the head of Lake Superior. Terminal facilities at the port include 98 wharves. Of this number 10 are used for general merchandise, 21 for handling coal, 11 for handling grain, seven for handling ore, and four for sand and gravel. The remainder provide for the handling of forest products, rails, structural steel, salt, lime, cement, and other products, or for miscellaneous or private purposes. There are eight railroads and two switching lines connecting with the water terminals. Eight package freight wharves are railroad terminals and two are owned by individual companies, the latter having cold storage facilities for perishable goods.

The first ore-shipping docks on the Great Lakes were built in the early '70s, and the present docks in Duluth-Superior have been developed since then. The facilities for handling ore are most extensive. The total length of the seven ore docks, which are of modern concrete and steel construction, is 15,000ft., and the total storage capacity is over 800.000 tons. One of these modern ore docks is 2,438 ft. long, has a structural steel frame, and contains four tracks with necessary trestle approach. It is 84ft. high and has 384 pockets arranged in pairs. Operation is by electricity throughout. There are 21 coal docks at this port, all equipped with efficient mechanical means for handling coal. At the most modern docks, the unloading, stocking, repairing, reclaiming, and loading operations are performed with the electrically operated man-trolley type of travelling bridge crane.

The Port of Toledo.—The city of Toledo, situated at the mouth of the Maumee river at the westerly extremity of Lake Erie, is one of the most important bulk commodity ports of the Great Lakes. It has 46 piers, wharves, and docks operated mainly for the receipt of ore, for the shipment of coal, and for handling sand, gravel, grain, oil, and fish. A publicly owned wharf, leased as a general cargo and terminal warehouse, has mechanical handling facilities consisting of electric conveyors, and steam and electric cranes. Railroad companies own a number of wharves, many of which have modern equipment for the expeditious handling of cargo. One wharf, 900ft. long, is constructed of wooden piles with riprap fill. Privately owned wharves are used for handling iron ore, coal, oil, grain, cement, automobiles, and package freight. (J. L. S.)

FLOATING DOCKS

A floating dock is a steel, iron or timber floating construction designed to raise ships out of the water, that their under-water portions may be inspected and, if need be, painted or repaired. The earliest known form was evolved by an English captain during the reign of Peter the Great in the harbour of Cronstadt. His ship being in need of repairs, and no facilities being available, he bought an old hulk which he gutted completely, and fitted with a watertight gate at the stern. He then berthed his ship inside the hollow shell thus formed and, after closing the gate, pumped out the water remaining inside. He was thus able to repair his own ship in the dry. This type of dock continued in use for the next 150 years, and is known as a "camel" dock, from the name of the Cronstadt hulk.

The first obvious improvement was to construct a dock specially for the purpose instead of utilizing a hulk. A dock of essentially this type was built by Christopher Watson in 1785 at Rotherhithe. The useful life of timber docks is surprisingly long. An engraving of this dock was made, dated 1829, or no less than 44 years after the dock was built, and it is not known how many years of life the dock had after it was first built and used.

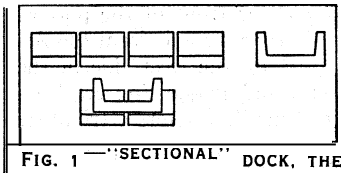

FIG. 1.—"SECTIONAL" DOCK, THE EARLIEST OF THE SELF-DOCKING TYPE. MADE UP OF INDIVIDUAL SECTIONS. CHAINED TOGETHER

The next step in the evolution of the modern floating dock was to make the walls and bottom hollow, and thus buoyant. As early as 1809 a patent was taken out for a hollow iron dock, but there the matter rested for many years. The first hollow docks were constructed of timber in the United States, the earliest of any note being that in the navy yard at Portsmouth, Maine, which was built in 1848. These early timber docks suffered from the fact that they would not readily sink low enough to allow a ship to enter them. The walls therefore were fitted with a deck inside them above the normal water line forming chambers into which water could be pumped in addition to the amount which could flow in by gravity, thus overcoming the natural buoyancy of the timber. This drawback ceased to exist when iron was substituted for wood in the construction of the hull, but the same system of pumping water into the walls was followed for some years.

In 1866 iron docks began to be freely built from the designs of George Banks Rennie, James Campbell and others, which were worked at Cartagena, Saigon, Callao, Bermuda and other places. The most notable of these was Campbell's dock at Bermuda, then and for many years the largest floating dock in the world. It had a length of 381ft. and a lifting power of 10.000 tons, and was in use up to the year 1905. In addition to the buoyancy due to the fact that the structure of the dock was hollow, further lifting power was obtained by means of gates, which could be put in place at each end when the ship was partly lifted, water being pumped out from the space between them exactly as was done in the very earliest type of floating dock.

In 1876 a new problem in docking ships was presented by the construction of Admiral Popoff's circular ironclads in the Black sea. The diameter of the largest of these was 120ft., and no dock in the world had a width of entrance enough to admit a vessel of such beam. This problem was solved by Clark and Standfield, who devised a floating dock with only one side, the loss of stability entailed by the absence of the other side being compensated for by a floating outrigger attached to the dock by two sets of hinged parallel arms This was called a "depositing" dock. The pontoon or horizontal portion of the dock, upon which the ship rested, instead of being a continuous platform, consisted of a series of fingers with a space of jft. between them, each finger being 72ft. long. By detaching some of these from the wall of the dock and attaching them to the ends of others, a platform 144ft. wide could be made, and upon this the circular ironclads were lifted. A staging had been built along the shore, with the spacing of the grids corresponding to the distance between the fingers of the dock, so that by towing the dock with the ship on it sideways to the staging the fingers and the grids were interlaced. If then the dock was lowered, the ship mas deposited on the staging, and the dock was free to be towed away to lift another ship and deposit it on a further length of staging. Examples of these depositing docks are still to be found at Nicolaieff, Vladivostok, Barcelona and Kobe. The dock at Kobe was built principally for dealing with immense monoliths of reinforced concrete. which were built on the staging, lifted off by the dock, and towed away to the site of the quay wall, where they were sunk in position, thus allowing the quay wall to be built of blocks weighing upwards of 6.000 tons. An outcome of the depositing dock was the "off-shore." This is also a single-sided dock, but the pontoon is a continuous structure, and the floating outrigger is replaced by braced vertical columns on shore. Many of these docks have been built, most of them being very rapid in operation.

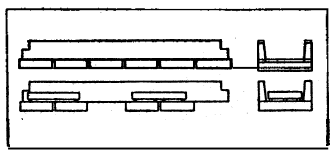

FIG. 2.—SECTIONAL PONTOON DOCK WHICH HAS THE WALLS, DOCK AND PONTOON CONTINUOUS. THUS LESSENING POSSIBILITY OF BREAKAGE

The most common type of floating dock is the double-sided dock, of which there are many kinds distinguished by the means

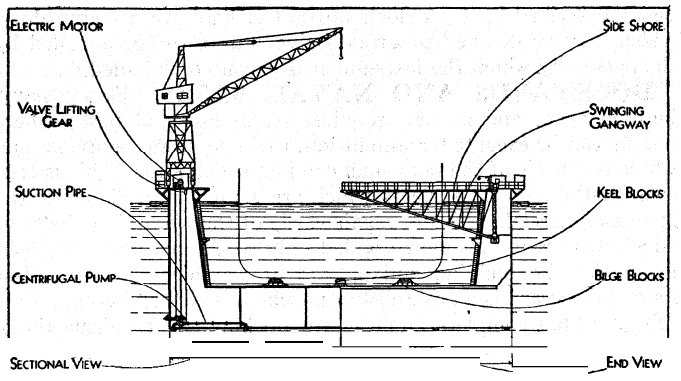

FIG. 3.—END AND SECTIONAL VIEWS OF THE SOUTHAMPTON DOCK. SHOWING MACHINERY, BOOMS, ONE OF TWO CRANES AND GANGWAYS

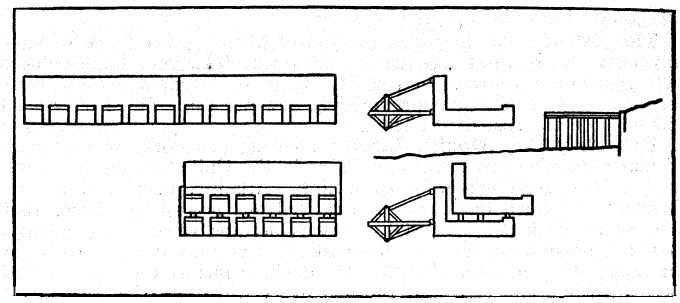

FIG. 4.— DEPOSITING DOCK OR "SECTIONAL BOX," THE STRONGEST TYPE OF DOCK. ABLE TO WITHSTAND GREAT FORCE AND STRAIN BY MEANS OF THE BOLTED AND RIVETED JOINTS WHICH JOIN THE SECTIONS

employed to arrange them for self-docking. It is obvious that a floating iron or steel structure must from time to time be got out of the water for repainting if its life is to be prolonged. As a rule a floating dock is too wide to go into any other dock, even if such be available, so all but the very smallest are designed to be able to lift each portion of themselves out of the water in turn.

Self-docking Docks.—The earliest of the self-docking docks was the "sectional." In this case the dock was built of a number of separate and independent sections which were held together generally by chains, the length of each section being such that it could be turned sideways and lifted by two other sections. This system has the drawback that it has no longitudinal strength, and the risk of straining the ship by uneven pumping is considerable. Accidents have occurred due to the breaking of the connections between the different sections.

A much better form, generally known by the name of its inventor as the "Rennie" or "sectional pontoon" dock, has the walls continuous, thus forming a stiff girder the whole length of the dock, and the pontoon divided up as in the case of the "sectional" dock, the joint between the walls and pontoons being horizontal. This type of dock has been built to take ships up to 25,000 tons, but it is better adapted for smaller sizes, more particularly if they have to be towed across the ocean to their final destination.

The strongest and at the same time the lightest form of self-docking dock is known as the "sectional box." This was evolved also by Clark and Standfield, and is the type used by them for the 60,000-ton dock at Southampton, which was built to take the largest Atlantic liners as well as battleships. It is similar to the "sectional" dock, but the sections are attached together all round their complete profile by bolted joints below the water line and riveted joints with butt covers above it. Thus the dock forms one continuous whole, with very great longitudinal strength to withstand the stresses set up in the structure during the operation of docking a ship, or the much greater stresses which may occur during an ocean voyage. When it is required to self-dock, the joints between the sections are unmade, and the sections successively lifted upon the rest of the dock.

The self-docking of a single-sided dock is very simple. There is a transverse joint at the centre of its length which when unmade enables one half to be lifted, so to speak, onto the lap of the other.

General **Description.**—A typical modern floating dock may be said to be a large rectangular hollow steel trough. The principal functions of the vertical sides of the trough, which form the walls of the dock, are to give stability to the dock when it is being worked without a ship on it, to contain the machinery required to lift the ship, to form platforms from which to berth the ship, and to give longitudinal strength. The horizontal portion of the trough, or pontoon, forms the platform upon which the ship rests, and provides the buoyancy which lifts the ship out of the water. The pontoon is extensively subdivided by watertight bulkheads to ensure stability, and the walls are also divided, but to a lesser extent.

The underlying principle upon which the working of a floating dock depends is that if, say, a ton is removed from a floating structure, that structure exerts an upward pressure of one ton. The main machinery of a floating dock, therefore, consists of a number of centrifugal pumps placed as low down as possible in the pontoon, and worked by steam, electric or other prime movers, situated on the top of the walls; and it is the throwing out of the water by these pumps which causes the ship gradually to emerge from the sea. In order that the ship may be kept level, each subdivision of the dock has separate suction pipes and valves, all the rods actuating the valves being brought together in the valve-house.

Fig. 3 represents two views of the Southampton floating dock, one seen from the end and the other as the dock would appear if cut in two. The arrangement of the machinery can be clearly seen in the left-hand view. In the motor house on the top deck is shown an electric motor, which by means of a vertical shaft drives a centrifugal pump seated on a cast-iron pipe running the full length of the dock. Branching from this pipe are other pipes leading to different watertight compartments. The water flowing through these branch pipes is, as shown in the drawing, regulated by a valve, the rod actuating this being carried nearly to the top of the wall, where it is attached to a pneumatic press by which it is worked. The admission of air to these presses is electrically controlled from the valve-house. In the Southampton dock there are 56 of these compartment valves, and 14 electrically driven pumps. On the top of one of the motor houses is the valve-house, from which all the machinery of the dock—valves and motors—is operated, so that the dockmaster can perform the whole operation of lifting a ship without leaving his post. The side-shores are shown touching the sides of the vessel; they consist of lattice girders which can be moved in and out electrically, and are geared together across the dock. When they are pushed home as shown in the drawing it is known that the ship is accurately in the centre of the dock. In order to lift materials on and off the dock or ship, there is an electrically driven travelling crane on the top of each wall, only one being shown in the drawing for the sake of clearness. This dock is moored to the shore by means of a series of booms hinged at each end, attached at intervals to the back of the dock and to dolphins respectively, end-long movement being prevented by fore and aft chain cables. The top of one of these booms is decked and fitted with hand-rails, to serve as a means of communication between the shore and deck of the dock.

The following operations are performed in lifting of a ship on a floating dock:—(I) Water is admitted to the interior of the dock until it is sufficiently deeply sunk to allow the ship to be brought in; (2) the ship is brought in and centred; (3) water is pumped out of the dock until it is bearing firmly on the keel of the ship; (4) the bilge-blocks or side supports are put in place under the bottom of the ship to keep her steady; (5) water is pumped out of the dock until the deck is above sea level.

The life of a floating dock depends very largely upon the amount of care which is bestowed upon it, but in general a life of from 40 to 50 years may be looked for.

Floating docks are constructed of all sizes according to the requirements of the port where they are to be worked; from 300 tons lifting power up to 60,000 tons were the limits in 1928, but if ships increase in size there is no physical or economic reason why floating docks should not do likewise. At the beginning of 1928 nine floating docks were in existence capable of lifting ships

of 30,000 tons and upwards.

The cost of a floating dock per ton of lifting power tends to vary inversely as the total capacity of the dock. The very largest docks will cost about £6–10s. per ton of ship to be lifted, whereas a dock of 1,000 tons will cost approximately £22 per ton. These figures do not include the cost of dredging. (S. F. S.)

Floating **Dry Docks, U.S.A.** Floating dry docks present particular advantages to naval operations in the United States and territories. The great extent of coast lines—Atlantic, Pacific, Gulf, and insular—on which operations are carried out necessitates docks that can be conveniently located for vessels needing repairs. Frequently, it is not possible or desirable to construct a graving dock in a distant harbour. Also, it is possible that the docking facilities are not needed permanently. The ease and rapidity with which floating dry docks can be constructed, the ability to transfer them from port to port, and their adaptability to localities where graving docks cannot be constructed give them an importance that cannot be disregarded.

American experience with floating dry docks began in 1816 when a patent was granted to J. Adamson. This Adamson dock consisted simply of a float with vertical sides. Such docks were built of wood and in one piece until 1837 when J. Thomas began building them in sections. The Thomas patent shows the first conception of distinctly separate sponsons and coupling logs, which are the essential features of a sectional dry dock. Side wings were added by W. Thomas in 1854. These wings made the dock independent of guides on the shore, and produced the general appearance of the floating dry dock that is kno n today.

Although floating docks had been in use since J. Adamson obtained his patent, it was not until 1899 that construction was started on the first large dock for the U.S. Navy. This dock was built by the Maryland Steel Company at Sparrows Point, Md.. for the Naval Station at Algiers, Louisiana. The overall length is 52jft. and the breadth between fenders on walls is 100 feet. The lifting capacity is 15,000 tons when the deck is 2ft. out of water, and 18,000 tons when the deck is awash. The maximum draught of vessels that can be handled by the dock is 30 feet. Upon completion of the structure, it was towed to Algiers, La., where acceptance tests were made.

An outstanding example of the movability of floating docks occurred in the transport of the dry dock "Dewey" to its home station. The "Dewey," completed by the Maryland Steel Company at Sparrows Point, Md., in 1905, is jooft. long with a breadth between fenders on walls of 100 feet It is capable of handling vessels of 30ft. draught and has a total lifting capacity of 16,000 tons, with 2ft. free-board. Upon completion of acceptance tests, in 1906 the dock was towed across the Atlantic ocean, through the Mediterranean sea, Suez canal, Red sea, Indian ocean, and South China sea to its home station at Olongapo, Subig bay, Philippine islands. The total time required for the journey was 150 days.

Floating dry docks are common equipment for shipbuilders' yards. One of the earlier large docks was constructed in 1915 by the Bethlehem Shipbuilding Corporation at Sparrows Point, Maryland. The dock is 480ft. long with 90ft. between fenders on walls and has a lifting capacity of 20,000 tons. This same company, in 1920, had a fleet of four floating docks at the Potrero Works on the Pacific coast.

Sizes and capacities of these docks were:

No. 2 270ft. long, 66ft. inside width, 2,000 ton capacity;
No. 3 301ft. long, 68ft. inside width, 2,500 ton capacity;
No. 4 450ft. long, Soft. inside width, 6,500 ton capacity;
No. 5 420ft. long, 90ft. inside width, 12,000 ton capacity;

A typical modern floating dry dock is that of the Todd Seattle Drydocks, Inc., which went into operation about 1937. This new 16,000 ton dock is equipped with dual control stations which permit the operator to raise or lower any section of the dock from a commanding position on the wharf, or from a control house located on one side of the wharf out of the way of cranes and locomotives.

The new dock is 531ft. long and 128ft. wide, with a width of 85ft. at the coping. It is comprised of five equal sections, each of which is a complete dry dock.

Each unit is constructed of northwest fir timber. The interior is arranged with a set of three watertight compartments on each side. Each compartment has a pump to discharge the water, while flooding of compartments is controlled by valves.

DOCK WARRANT, in law, a document by which the owner of a marine or river dock certifies that the holder is entitled to goods imported and warehoused in the docks. In the Factors Act 1889, it is included in the phrase "document of title" and is defined as any document or writing, being evidence of the title of any person therein named . . . to the property in any goods or merchandise lying in any warehouse or wharf and signed or certified by the person having the custody of the goods. It passes by indorsement and delivery, and transfers the absolute right to the goods described in it. A dock warrant is liable to a stamp duty, which may be denoted by an adhesive stamp, to be cancelled by the person by whom the instrument is executed or issued.

DOCKYARDS AND NAVAL BASES. Every navy, both in peace and in war, requires dockyards and bases where repairs can be executed, ammunition, fuel and stores supplied, and where the needs of the personnel can be provided for. This is true also for the mercantile fleets which are served impartially by the great commercial ports and repair yards of the world, but the term "dockyard" is usually now applied only to the national establishments for the building and upkeep of warships. In its fullest sense a dockyard is an establishment which builds and equips warships, and has complete facilities for docking and repairing them. It supplies and perhaps manufactures armaments and ammunition, provides general and victualling stores and fuel and also contains training, medical and other establishments for the service of the personnel. It is however, only the few large home dockyards in each country which are so completely equipped, and even in these only a small proportion of warships are now actually built. Government dockyards are now mainly used for fitting out and commissioning new ships and for the upkeep of the fleets. In most countries, private firms manufacture guns and armour, engines and boilers and often carry the building of ships to the final stages before delivering them to the Government establishments for completion. Other dockyards (*e.g.,* Malta) have no special facilities for building ships but are very completely equipped for the maintenance of a large fleet. Others again, though maintaining the status of dockyards, are capable only of minor repairs and of supplying stores, ammunition and fuel; these smaller establishments are really fortified naval bases or fuelling stations (*q.v.*).

Every Government dockyard is a naval base, but the converse is not true. A modern fleet must have a base from which to operate: and the first requirements of a base are a safe harbour for the auxiliary craft attendant upon the fleet, and a protected fleet anchorage where the ships can, without molestation, replenish with fuel, stores and ammunition and give rest and recreation to the crews. Every dockyard or naval base must be defended by sufficient fixed and mobile local defences to protect it from attack by submarines or torpedo craft, from predatory raids by a few cruisers and from attack from the air. The security of any dockyard or base, however, must depend, ultimately, upon the ability of the fleet which it serves to maintain the command of the sea.

Great Britain.— Until the beginning of the 16th century England had no regular establishment for the Navy and possessed neither arsenals nor dockyards. The fleet was composed of a few "King's ships" supplemented by ships provided by the seaport towns. These towns were charged with the maintenance of the fighting ships when they were laid up and there are evidences of dockyards, or of something answering thereto. at the Cinque Ports as early as the 13th century. In 1238 the keepers of the King's galleys were ordered to build a house at Winchelsea for the safe custody of the vessels. In 1243 the Sheriff of Sussex was ordered to enlarge a house at Rye in which the King's galleys were kept and ten years later the bailiffs of Rye and Winchelsea were ordered to repair these buildings. As the fighting ships developed from the galley to the larger sailing ships there appear to have been depots for both ships and stores maintained at Southampton and Portsmouth, and Henry VII., who laid the foundations of Britain's sea power, built the first dry dock at the latter place in 1495. Henry VIII., in 1509, purchased land at Woolwich and Deptford upon which the building of the first royal dockyards was started and in 1540 the Royal Dockyard at Portsmouth was founded around the site of the dry dock of Henry VII. Queen Elizabeth started the dockyards at Chatham and Sheerness and both were considerably extended by Charles II. after the Restoration. Plymouth, although its ships played so great a part in Elizabethan times, did not become a royal dockyard until 1689, when William III. commenced the Plymouth dock at Devonport. The small dockyard at Pembroke was founded in 1814 and was followed by the establishment at Haulbowline (Queenstown)

Until 1832 the royal dockyards remained under the control of the Navy Board. which had been founded in 1546 by King Henry

VIII. The Admiralty were responsible only for the fleet at sea and this dual control of the Navy had many disadvantages. It led to extravagance and allowed mismanagement and corruption which, several times in the history of the country, came near to bringing about national disaster. With the Reform Bill in 1832, the Admiralty and the Navy Office were amalgamated and the present system of dockyard administration came into being. During the 19th century a gradual change came over the dockyards with the transition from sail to steam and many additions were made to meet the needs of the modern fleet. The most important improvements at any one period were brought about by the Naval Works Act of 1895, which sanctioned a large number of new works. Defensive harbours were commenced at Portland, Dover and Gibraltar and also dockyard extensions at the latter place. At Devonport dockyard the great Keyham extension was started and new works were put in hand at Hongkong and Simon's Town. At the same time the building of naval barracks at the three home ports began, together with new hospitals at Chatham, Haslar and Haulbowline and colleges at Dartmouth and Keyham.

The growing German menace in the North sea, in the opening years of the present century, compelled the Admiralty to seek a new base on the east coast, farther north and easier of approach than Chatham. In 1903 the Government approved the creation of a new naval dockyard at Rosyth on the Firth of Forth. The outbreak of the World War found this base far from complete and the defence of the anchorage against submarines, in common with other naval anchorages, had been almost entirely neglected. The work was pressed on and before the end of the war, a very fine dockyard had been completed. Its 'facilities were such that the biggest ships of the Grand Fleet could be docked and refitted there whilst a large fleet could lie in safety behind boom defences.

In 1914 Great Britain possessed large dockyards at Portsmouth, Plymouth, Chatham and Malta, as well as the uncompleted works at Rosyth, at all of which the largest ships could be docked. Smaller establishments existed, in home waters, at Sheerness, Portland, Haulbowline and Pembroke. At Gibraltar, Hongkong, Bermuda, Simon's Town (Cape of Good Hope) and Sydney (N.S.W.) were dockyards of old standing with dry docks for the largest ships and there were minor establishments at Ascension, Wei-Hai-Wei, Colombo, Bombay and Calcutta, the two last mentioned belonging to the Indian Government. Yet, with all this array of permanent dockyards, the World War made necessary the establishment of other naval bases. Scapa Flow became the main base of the Grand Fleet equipped only for storing, ammunitioning and "running repairs." Cromarty Firth became the second base of the fleet and with the aid of a large floating dock was able to complete the repairs of the biggest ships badly damaged in battle. Harwich, Dover and Immingham acted as bases for light forces and Mudros, Alexandria and other places became bases during particular operations. With the surrender of the German fleet and the changes brought about by post war conditions, Rosyth lost its importance. The great dockyard was reduced to a condition of care and maintenance and so remains. In the interests of economy and the general reduction of armaments the dockyards at Haulbowline and Pembroke were closed down and a reduction in establishment was made at other places.

The result of the World War brought about a re-orientation in British sea power and the growth in the size of capital ships has necessitated the provision of a base in the Far East, capable of maintaining a modern fleet. Hongkong, the only base in those waters for British naval forces, is quite inadequate and, moreover, under the Washington Treaty, no additions or improvements can be made there. The agreement, however, prescribed certain exact limits which definitely excluded Singapore from any prohibitions. That port has been selected for the new dockyard because it lies upon the flank of the sea route to Australia and New Zealand, while behind it are the waters of the Indian ocean and the great British possessions that lie around them. Singapore threatens no one, for it is as far from Japan as Gibraltar is from New York and it is very nearly antipodal to the latter place. But it ensures that, if need be, a battle fleet with all its attendant auxiliaries can be moved into such a position as to afford security to that part of the British empire that lies east of Suez. Without such a base there would be a grave risk in sending heavy ships so far from docking and repairing facilities, for Malta, the nearest large dockyard, is 6,000m. from Singapore. The importance of this dockyard to the sea security of the empire is perhaps not yet fully understood in England, but in Australia and New Zealand and the British possessions in the Far East its necessity is fully appreciated. The work of creating it was put in hand in 1923, checked for a year in 1924 and restarted in the following year. The estimated cost of the new base is £9,000,000.

Dockyard Administration. — The system under which British dockyards are administered is uniform for all, whether the yards are large or small, at home or abroad. The control of all dockyards is vested in the controller of the navy (the third sea lord). At the Admiralty, working under the controller are the director of naval construction, by whom all ships are designed, and the engineering, ordnance, torpedo, electrical and other technical departments, each responsible for the design of its own material. The director of dockyards, also working under the controller, is the Admiralty official under whose instructions the work in the dockyards goes on, involving the control of an army of artisans and labourers and the keeping of costing accounts. Instructions emanate from the Admiralty, the details are left to the dockyard officials and in practice there is considerable decentralization.

Each dockyard is under the charge of an admiral or a captain superintendent, according to its size. His deputy as a rule acts as King's harbour master and is responsible for the berthing and moving of ships in the port. The chief dockyard officers are the constructive manager, the engineer manager, the naval store officer, the electrical engineer, whose names explain their duties, the civil engineer, in charge of all buildings, docks, basins, etc., the cashier, expense accounts officer and medical officers. Technical matters regarding guns and torpedoes are supervised by the captains of the local gunnery and torpedo schools. There being close personal communication between responsible officers, rapid decisions can be taken in matters arising between the departments as the work progresses and operations are thus conducted with ease and efficiency.

France. — The French coast is divided into five arrondissements having the headquarters at the naval ports of Cherbourg, Brest, Toulon, Lorient and Rochefort. All these are building and fitting-out yards. Corsica has naval bases at Ajaccio, Porto Vecchio and Bonifacio. On the African coast there are docking facilities at Algiers and fortified bases at Oran and Bizerta. There are naval establishments at Saigon and Hai-phong in the Far East and at Diego Suarez in Madagascar. There is a gun foundry at Ruelle: steel works at Guerigny, where anchors, cables and armour plates are made: machinery works are at Indret, an island in the River Loire, and there are many private shipbuilding establishments.

In each arrondissement the vice-admiral, who is the naval prefect, is the representative of the minister of marine and has full direction and command of the arsenal. He is commander-in-chief and governor designate in time of war, but his authority does not extend to ships belonging to organized squadrons. The naval prefect is assisted by a rear-admiral as chief of the staff whose special functions are the efficiency of the personnel of the fleet, whilst the "major-general," who is usually another rear-admiral, is concerned with the material. There are also directors of stores, of naval construction, of the medical service, of naval ordnance and of works as well as of the submarine defences which include torpedoes, mines and torpedo-boats. The prefect directs the operation of the whole dockyard and port and is responsible for the efficiency of ships there in reserve.

Germany. — In the first years of the present century, during the expansion of the German fleet, two great modern dockyards were built at Wilhelmshaven on the North sea and at Kiel in the Baltic with a ship canal connecting the two. Smaller establishments were maintained at Cuxhaven, Bremerhaven, Flensburg, Swinemünde, Danzig and at Kiaochow in the Far East. The last-named two were lost to Germany as the result of the World War, and with the disappearance of the German fleet as an important one, all the dockyards have been much reduced.

The chief official at each German dockyard is the superintendent, who is a rear-admiral or captain directly responsible to the naval secretary of State. Under the superintendent's orders are the captain of the fleet reserve, the directors of ordnance, torpedoes, navigation, naval construction, engineering and harbour works, besides other officers. Considerable progress is being made in the re-organization of the German Navy, within the limits of the Versailles Treaty. Important private shipyards exist at Elbing in East Prussia, at Bredow, near Stettin, at Bremen and at Hamburg, which though primarily commercial are all capable of building warships.

Italy. — The Italian Navy is particularly well equipped with modern dockyards. The chief establishment is at Spezia, where there are four large docks and two large building slips in a very completely equipped dockyard. At Naples there are small dry docks with building slips at the subsidiary establishment at Castellamare, across the bay. Taranto and Venice both possess large docks and building slips. A small naval base exists at Maddalena in Sardinia and, as the result of the World War, the valuable Austrian dockyards at Trieste and Pola became Italian property. The Italian Government has no gun or torpedo factories, most of the ordnance being made by the Armstrong firm at Pozzuoli and torpedoes by Schwarzkopf at Venice, whilst armour plates are supplied by the important steel works at Terni. Machinery is supplied by private firms of which there are large numbers.

Japan. — The first dockyard was established in Japan in 1866 at Yokosuka, and this still remains the principal establishment in the country. At first, French naval constructors and engineers were employed but, in 1875, the Japanese took the administration into their own hands. At that time the largest ship that could be constructed in Japan was 5,000 tons, but the dockyard expanded rapidly and is now able to build and dock the largest and most modern ships. Until after the close of the Russo-Japanese War, in 1905, all the important ships of the Japanese fleet were built in Great Britain, France, Germany or the United States. In that year a large first-class cruiser was launched at the new dockyard at Kure and since then the Japanese have only gone abroad for the first ship of each new type. These have been copied in their own establishments, which are thoroughly equipped for producing ships and material second to none, in spite of the fact that a large proportion of the raw material has to come from abroad. Besides Yokosuka, there are now large modern dockyards at Kure, where an armour plate factory has been established; at Sasebo and at Maizuru. Ryojun (Port Arthur) became Japanese after the war with Russia, and there are other naval establishments at Masampo, Takeshiki (Tsushima Is.), Ōminato and at Bako in the Pescadores. Docking facilities for large ships also exist at Tokyo, Yokohama and Uraga.

Soviet Russia. — Of the present state of the Russian dockyards very little is known. Before the break up of Russia, important dockyards existed at Kronstadt and Petrograd and at Nikolayev in the Black sea, with lesser establishments at Archangel, Sevastopol, Batum, Baku, Vladivostock, Reval, Libau and Sveaborg. The World War removed the last-named three from Russian possession and the naval effectiveness of the remainder is now probably negligible. Ordnance and steel works exist at Obukhov and Putilov but their output is at present unimportant.

Spain. — The Spanish dockyards at Ferrol, Cartagena and Cadiz are old establishments which, of recent years, have not kept pace with the times. The fleet is, however, now being steadily modernized and will, in the not far distant future, become a factor in the balance of sea power amongst the States with a Mediterranean littoral. At both Ferrol and Cartagena there are large dry docks. The larger ships are built at Ferrol, Cartagena dealing only with torpedo craft and gunboats; both dockyards are being brought up to date. The dockyard at La Carraca (Cadiz) has four dry docks but no building slips and is used chiefly as a base for gunboats and torpedo craft. There is a small naval establishment at Port Mahon in the Balearic Islands and considerable commercial building and repair yards belonging to private firms at Barcelona, Gijon, Santander and Bilbao.

Minor Naval Powers. — Naval dockyards are maintained by all the Powers who possess fleets, but those in European waters which have not been mentioned above are of secondary importance and are only capable of serving the small navies that they maintain. In South America, although the dockyards themselves are small, the largest capital ships can be docked at Buenos Aires and Puerto Belgrano in Argentina, at Rio de Janeiro in Brazil and at Talcuhuano in Chile. (S. T. H. W.)

UNITED STATES

The shore establishments under control of the navy department are known as navy yards and naval stations. The navy yards are equipped with dry-docks, and shops for general repairs and alterations to vessels of the fleet. They are also provided with building ways for the construction of new vessels. Each yard is equipped for the manufacture of certain equipment used in the naval service and has a supply department for supplying stores and equipment to vessels in active commission and for outfitting new vessels. There are several important naval stations established for special purposes.

Navy Yards. — There are nine navy yards within and two navy yards without the continental limits of the United States. Those in the United States on the Atlantic coast are situated at Portsmouth, N.H. (Kittery, Me.); Boston, Mass.; New York (Brooklyn), N.Y.; Philadelphia. Pa.; Washington, D.C.; Norfolk (Portsmouth), Va.; and Charleston, S.C. Those on the Pacific coast are situated at Bremerton, Wash., and Mare Island, Calif. The two yards outside the United States are Pearl Harbor, Hawaii, and Cavite, P.I. The latter yard includes Olongapo where the Dewey dry dock is located.

Naval Stations are at Key West, Fla., Guantanamo Bay, Cuba, W.I. and Guam, Marianas Islands. Two inoperative stations are at New Orleans, La. and Culebra, an island east of Puerto Rico.

Submarine Bases are at New London, Conn; Coco Solo, Canal Zone and Pearl Harbor, Hawaii. Two inoperative stations are located at Norfolk, Va. and Key West, Fla. These bases are fitted with small machine shops and barracks for officers and enlisted men, and bear the same relation to submarines as a mother ship. The station at New London has a school for the instruction of officers and enlisted men in submarine work.

Naval Operating Bases are at Norfolk, Va.; Balboa, Canal Zone; San Diego, Calif.; San Francisco, Calif. Men-of-war can operate and be maintained from these centres in time of peace or war, and they afford anchorage space for a large number of vessels.

Naval Air Stations are at Alameda, Calif.; Anacostia, D.C.; Cape May, N.J.; Coco Solo, Canal Zone; Jacksonville, Fla.; Miami, Fla.; Kanoehe, Hawaii; Kodiak, Alaska; Lakehurst, N.J.; Midway Island; Norfolk, Va.; Pearl Harbor, Hawaii; Pensacola, Fla.; San Diego, Calif.; San Juan, P.R.; San Pedro, Calif.; Seattle, Wash.; Sitka, Alaska; Tongue Point, Ore. These stations are fitted with machine shops and landing fields for the general repair and the operations of shore base aircraft. Beside the above stations there are maintained a number of reserve aviation bases and aviation facilities for the purpose of training personnel and servicing aircraft from other bases.

Training Stations, for newly enlisted men. are at Newport, R.I.; Hampton Roads, Va.; San Diego, Calif.; and Great Lakes, Ill.

Naval Hospitals are maintained at all major navy yards, naval stations and where there are other naval activities.

Other Special Stations are: the Naval War college at Newport, for the instruction of officers; Naval academy at Annapolis. Md., for the training and education of midshipmen prior to commissioning as officers; Engineering Experimental station at Annapolis, Md.; and Experimental Laboratory at Bellevue, D.C., ior experimental work in engineering; Aircraft factory, Philadelphia, Pa., for building and testing of aircraft; Torpedo stations at Newport, R.I., Alexandria, Va., and Keyport, Wash., for building, repairing and testing of torpedoes, and torpedo parts; Naval Gun factory, Washington, D.C., for construction of naval ordnance;

Naval Ordnance plant, South Charleston, W.Va., for the manufacture of armour and gun forgings; powder factory, Indian Head, Md., for the manufacture of powder; Naval Proving ground, Dahlgren, Va., for testing of naval ordnance; Naval Mine depot, Yorktown, Va., for the storage of mines and explosives; Helium plant, Fort Worth, Texas, for the production of helium gas used in lighter-than-air craft; Naval observatory, Washington, D.C., for the purpose of furnishing astronomical data and nautical instruments to naval vessels and aircraft and furnishing time signals. Fueling depots have been established at Melville, R.I.; Yorktown, Va.; La Playa, Calif.; Tiburon, California.

The officer ordered to command a navy yard or naval station is the commandant. He is usually a rear admiral and is the representative of the navy department in all matters within the limits of his command and is responsible for business transacted therein. The principal aids to the commandant are the captain of the yard and the manager. The captain of the yard, who is next in succession to command, has general charge of the water-front, yard craft and ships moored there, the police force, fire department and other purely military activities as distinct from industrial activities. The manager is the officer in charge of the industrial activities, including the labour force, productive shops and offices. He is directly responsible to the commandant for all industrial work performed at the yard. Under the manager are the inside superintendent, outside superintendent, plant superintendent and accounting superintendent. The other yard heads of departments are known as supply officer, public works officer, medical officer.

With few exceptions, the entire working force of the yards and stations is employed under the rules of the civil service. All are graded under a uniform efficiency-marking system. The employment is continuous as long as funds and work are available. Upon decrease of funds or work the force is reduced by discharging those having lowest efficiency ratings. Veterans are given a preference in case of discharge when their efficiency rating is good or better. The wages are, by law, required to be based upon the wages paid for corresponding trades in the vicinity of the local yards and stations. The wage scale is revised each year by a local wage board and a departmental wage board. In addition to all national and executive order holidays, each yard employee is granted 30 days' leave each year with full pay. Eight hours constitute a day's work and employees are paid 50% additional for all overtime and holiday work. Overtime is only authorized in case of extraordinary emergencies when necessary to save life or Government property.

The nature and extent of repair work necessary upon naval vessels is submitted by commanding officers to the commandant of the yard who approves those that can be accomplished with the funds allotted by the various bureaus of the navy department. Alterations must be approved by the department and funds allotted before being undertaken by yards.

Navy yards are permitted to do work for other Government departments when such work does not interfere with naval work. They are not permitted to compete with private plants for private work and can only undertake private work with departmental approval when such work is in the nature of an emergency and can not be performed by any private plants in the vicinity.

The department has under its control 64 radio stations and 57 radio compass stations. The radio stations are for naval communications and do not compete with private stations. The compass stations are available to merchant as well as naval vessels, upon request direct to station, furnishing bearings and position.

(Y. S. W.)

DOCTOR (Lat. for "teacher"), the title conferred by the highest university degree. Originally there were only two degrees, those of bachelor and master, and the title doctor was given to certain masters as a merely honorary appellation. At Bologna it seems to have been conferred in the faculty of law as early as the 12th century. Paris conferred the degree in the faculty of divinity, according to Antony Wood, some time after 1150. In England it was introduced in the 13th century; and both in England and on the Continent it was long confined to the faculties of law and divinity. It was not until the 14th century that the doctor's degree began to be conferred in medicine. The tendency since has been to extend it to all faculties in French and English universities; while in Germany, in the faculty of arts, it has replaced the old title of *magister*.

Doctors of *the Church* are certain saints whose doctrinal writings have obtained, by the universal consent of the Church or by papal decree, a special authority. In the case of the great schoolmen a characteristic qualification was added to the title doctor; *e.g.*, "angelicus" (Aquinas), "mellifluus" (Bernard). The doctors of the Church are: for the East, SS. Athanasius, Gregory of Nazianzus, Basil the Great, John Chrysostom; for the West, SS. Hilary, Ambrose, Jerome, Augustine, Gregory the Great, Anselm, Bernard, Bonaventura and Thomas Aquinas. To these St. Alphonso dei Liguori was added by Pope Pius IX.

DOCTORS' COMMONS, the name formerly applied to a society of ecclesiastical lawyers in London, forming a distinct profession for the practice of the civil and canon laws. Some members of the profession purchased in 1567 a site near St. Paul's, on which at their own expense they erected houses (destroyed in the Great Fire, but rebuilt in 1672) for the residence of the judges and advocates, and proper buildings for holding the ecclesiastical and admiralty courts. In 1768 a royal charter was obtained by virtue of which the then members of the society and their successors were incorporated under the name and title of "The College of Doctors of Law exercent in the Ecclesiastical and Admiralty Courts." The college consisted of a president (the dean of Arches for the time being) and of those doctors of law of the Universities of Oxford or Cambridge, who had been admitted advocates in pursuance of the rescript of the archbishop of Canterbury, and elected fellows in the manner prescribed by the charter. There were also attached to the college 34 proctors, whose duties were analogous to those of solicitors. The judges of the archiepiscopal courts were always selected from this college. By the Court of Probate Act, 1857, the college was empowered to sell its real and personal estate and to surrender its charter, and it was enacted that on such surrender the college should be dissolved and its property distributed among the members. The college was accordingly dissolved, and the various ecclesiastical courts which sat at Doctors' Commons are now open to the whole bar.

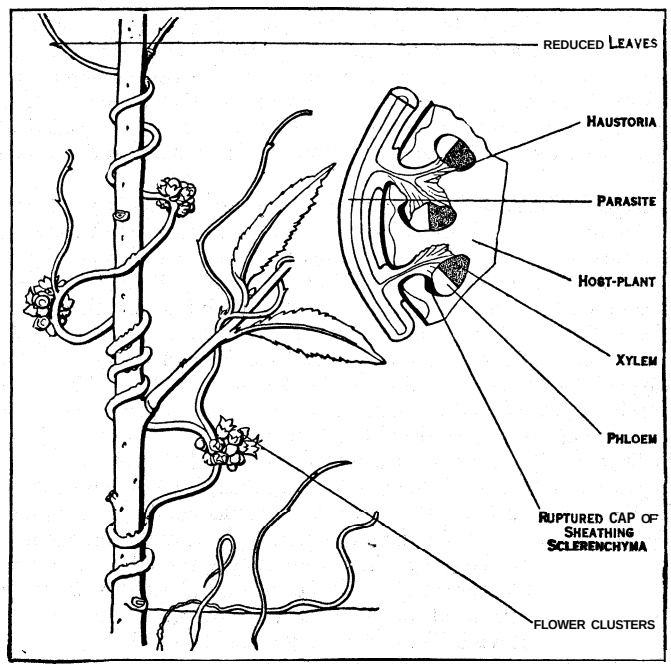
DOCTRINAIRES, the name given to the leaders of the moderate and constitutional Royalists in France after the second restoration of Louis XVIII. in 1815. In 1816 the *Nain jaune réfugié*, a French paper published at Brussels by Bonapartist and Liberal exiles, began to speak of Royer-Collard as the "doctrinaire." The "doctrinaires" was a popular name for a religious order founded in 1592 by César de Bus. The nickname for M. Royer-Collard was well chosen, for he made it his business to preach a doctrine and an orthodoxy. The rapid extension of the name to his colleagues proves that it had more than a personal application. The duc de Richelieu and M. de Serre had been Royalist émigrés; MM. Royer-Collard himself, Lainé, and Maine de Biran had sat in the revolutionary assemblies; Pasquier Beugnot, de Barante, Cuvier, Mounier, Guizot, and Decazes had been imperial officials; but they were closely united by political principle, and all were noted for the dialectical rigidity of their arguments. Their ideal was a king who frankly accepted the results of the Revolution, and who governed in a liberal spirit, with the advice of a chamber elected by a very limited constituency. Their views were set forth by Guizot in 1816 in his treatise Du gouvernement *représentatif* et de *l'état* actuel de la France. The history of the Doctrinaires as a separate political party began in 1816 and ended in 1830. In 1816 they obtained the co-operation of Louis XVIII., who had been frightened by the violence of the reactionary majority in the chamber of 1815. In 1830 they were destroyed by Charles X. when he took the reactionary prince de Polignac as his minister and entered on the conflict with Liberalism which ended in his overthrow. During the revolution of 1830 the Doctrinaires became absorbed in the Orleanists. (See FRANCE: History.) The word "doctrinaire" has become naturalized in English as applied, in a slightly contemptuous sense, to a theorist, as distinguished from a practical man

DOCUMENT, strictly, in law, that which can serve as evidence or proof, and is written or printed, or has an inscription or any significance that can be "read"; thus a picture, authenticated photograph, seal or the like would furnish "documentary evidence." More generally the word is used for written or printed papers that provide information or evidence on a subject. (See DIPLOMATIC; and EVIDENCE.)

DODD, WILLIAM (1729–1777), English divine, was born at Bourne, Lincs., in May 1729. He was admitted a sizar of Clare hall, Cambridge, in 1745, and took the degree of B.A. in 1750, being 15th wrangler. He entered the church, received rapid preferment, and was also tutor to Philip Stanhope, earl of Chesterfield. An effort by his wife to bribe the wife of the lord chancellor drove him from England for some time. He returned in 1776, and, being in financial straits, forged a bond for £4,200 on his former pupil, Lord Chesterfield. He was sentenced to death, and was executed at Tyburn on June 27, 1777. Samuel Johnson was very zealous in pleading for a pardon, and a petition from the City of London received 23,000 signatures. Dr. Dodd wrote one or two comedies and a popular book, the Beauties of Shakespeare (1752). A list of his 55 writings and an account of the writer is included in the *Thoughts* in *Prison*, a poem written in prison before his execution.

See P. Fitzgerald, ***A Famous Forgery (1865).***

DODDER, the popular name of the annual, rootless, leafless, twining, parasitic plants forming the genus Cuscuta, formerly regarded as representing a distinct family Cuscutaceae, but now included in the Convolvulaceae. The genus contains nearly 100 species and is widely distributed in the temperate and warmer parts of the earth. The slender thread-like stem is white, yellow, or red in colour, bears no leaves, and in the seedling stage attaches itself by suckers to the stem or leaves of some other



BY COURTESY OF MESSRS. GUSTAV FISCHER, FROM STRASBURGER, "LEHRBUCH DER BOTANIK"

DODDER (CUSCUTA EUROPAEA). A PARASITIC PLANT ON A WILLOW **TWIG**
In the small figure is seen a transverse section of the host-plant, showing the contact of the dodder with the tissues of the host, which it finally destroys

plant round which it twines and from which it derives its nourishment. It bears clusters of small flowers with a four- or five-toothed calyx, a cup-shaped corolla with four or five stamens inserted on its tube, and sometimes a ring of scales below the stamens; the two-celled ovary becomes when ripe a capsule splitting by a ring just above the base. The seeds are angular and contain a thread-like spirally coiled embryo which bears no cotyledons. On coming in contact with the living stem of some other plant the seedling dodder throws out a sucker, which penetrates the host, its tissues establishing organic union with the tissues of the host. By this means water is drawn from the wood and nutriment from the bast of the host. The dodder then soon ceases to have any connection with the ground. As it grows, it throws out fresh suckers, establishing itself very firmly on the host-plant. After making a few turns round one shoot the dodder finds its way to another, and thus it continues twining and branching till it resembles "fine, closely-tangled, wet catgut." The injury done to flax, clover, hop and bean crops by species of dodder is often very great. C. *europaea,* the greater dodder (see fig.) is parasitic on nettles, thistles, vetches and the hop; C. *epilinum,* on flax; *C. epithymum,* on furze, ling and thyme. *C. trifolii,* the clover dodder, is probably a sub-species of the last mentioned.

In the United States and Canada about 30 species occur, a few of which have been naturalized from the Old World. Among the native species are the love-vine (C. Gronovii), common on herbs and low shrubs in the Eastern States and adjacent Canada; the glomerate dodder (C. paradoxa), which forms dense ropes of flowers on tall herbs in the Central States; and the marsh dodder (C. *salina*), abundant in salt marshes of the Pacific coast, forming golden patches on various saline herbs.

DODDS, ALFRED AMÉDEE (1842–1922), French general, was born at St. Louis, Senegal, on Feb. 6, 1842, of Anglo-French origin. He was educated at Carcassonne and at St. Cyr, and in 1864 joined the marine infantry as a sub-lieutenant. He served as a company commander in the Franco-German War, was taken prisoner at Sedan but escaped, and took part in the campaigns of the Loire and of the east. In 1872 he was sent to west Africa, and except when on active service in Cochin-China (1878) and Tong-king (1883), he remained on duty in Senegal for the next 20 years, taking a prominent part in the operations which brought the countries of the upper Senegal and Upper Niger under French rule. He led the expeditions against the Boal and Kayor (1889), the Serreres (1890) and the Futa (1891), and from 1888 to 1891 was colonel commanding the troops in Senegal. At the close of 1891 he returned to France to command the eighth marine infantry at Toulon. In April 1892 Dodds was selected to command the expeditionary force in Dahomey; he occupied Abomey, the hostile capital, in November, and in a second campaign (1894) he completed the subjugation of the country. He was then appointed inspector-general of the marine infantry, and after a tour of the French colonies was given the command of the XX (Colonial) Army corps, becoming inspector-general of colonial troops. From 1904 to 1914 he was a member of the Conseil Supérieur de Guerre. He died in Paris on July 18, 1922.

DODECAHEDRON: see SOLIDS, GEOMETRIC.

DODECANESE (twelve islands), in the Aegean sea are near the coast of Asia Minor, inhabited by Greeks, and formed before the Italian occupation part of the Ottoman empire. The term first appears in the 9th century and was used in the middle ages for the Cyclades. After the Italian occupation it was applied to "the 13 southern Sporades," consisting of the 13 (not 12) islands of Rhodes, Cos, Kalymnos, Leros, Nisyros, Tēlos, Symē, Khalkē, Astypalaia, Karpathos, Kasos, Patmos and Lipsos. The two first and the last were not included in the mediaeval "dodecanese," which, however, comprised Nikaria and Castellorizo. Turkish firmans from 1652 to 1833 conferred or confirmed their fiscal privileges, and local Greek authorities collected a lump annual sum as tribute to the Porte. These privileges, despite occasional infringements in 1869, 1886 and 1893, continued down to the Turkish Revolution. The Young Turks, in 1909, abolished them, but in 1912, when the islands ceased to belong to Turkey, this decision had not yet been carried out. In that year the Italians, then at war with Turkey and meeting with difficulties in Libya, occupied the 13 islands after a single battle at Psinthos in Rhodes, in which they were aided by the islanders, believing in the promises of General Ameglio and Admiral Presbitero, that "autonomy" would follow the abolition of Turkish rule. Indeed. an Insular assembly met at Patmos, and proclaimed the "Autonomous State of the Aegean" with its own flag. The first Treaty of Lausanne, in Oct. 1912, pledged Italy to evacuate the islands as soon as the Turks had evacuated Libya.

Signor Giolitti, when premier, sincerely repudiated the idea of "annexing territories of Greek nationality" and Sir Edward

Grey, in 1913, declared that their fate "interested all the Great Powers." Nevertheless, the 8th article of the secret Treaty of London of 1915, which secured Italy's entrance into World War I, gave her full sovereignty over the islands. A convention was, however, made between M. Venizelos and Senator Tittoni (then foreign minister) on July 29, 1919, which was to have simultaneous effect with the subsequent Treaty of Sèvres, and which ceded 12 of the islands to Greece, and provided that Rhodes, the thirteenth, should have "a wide local autonomy." A further treaty was signed on Aug. 10, 1920, by M. Venizelos and Count Bonin at Sèvres. It confirmed the above, and added that Rhodes should, 15 years later, become Greek also if Great Britain should have ceded Cyprus to Greece, and a Rhodian plebiscite, held under the supervision of the League of Nations, should have decided for union. Meanwhile Italy pledged herself to give to the islands within two months a "wide local autonomy." In 1922, however, Senator Tittoni's successor, Count Sforza, denounced these agreements on the ground that circumstances had changed, and the fall of M. Venizelos strengthened the determination of the Italians to remain, despite Lord Curzon's stiff note of Oct. 15, 1922, intimating that the cession of Jubaland by Great Britain to Italy was conditional upon the Italian settlement of the question of the Dodecanese nith Greece. This position, however, was abandoned by Ramsay MacDonald. Meanwhile the Treaty of Sèvres formally assigned the Dodecanese to Italy, which by article 15 of the second Treaty of Lausanne not only obtained the recognition by Turkey of her full sovereignty over "the 13 islands," but also the ratification of her occupation (during World War I) of Castellorizo.

The metropolitan of Rhodes was expelled in 1921, and, after an exile of three years, was allowed to return and remain only on condition that he sever his connection with the Oecumenical patriarch. The Italian plan was to create an autocephalous church for the Dodecanese on the mistaken precedent of Cyprus, which nas ecclesiastically autocephalous many centuries before the British occupation. The death of the patriarch, however, prevented the execution of this arrangement, which would have been uncanonical without his consent and contrary to the example of Protestant England in the Ionian Islands and of Catholic Austria in Bosnia and Hercegovina. Another regulation in 1925 compelled all inhabitants of the Dodecanese to take Italian nationality, although, with the exceptions of the Muslims and Jews in Xhodes, they are all practically of Greek race. The fortification of Leros as a naval base and the establishment of a university at Rhodes pointed to the permanence of the Italian occupation, which was the chief obstacle to Graeco-Italian friendship. The islands, with the exception of the sponge-fishing industry of Kalymnos and Symē, have small economic value, and the prohibition of sponge-fishing off the north coast of Africa by the Italians in 1916, later withdrawn, not only injured the islands economically but also diminished their population. only about 80,000, by emigration.

The islands, officially known as Isole Italiane dell' Egeo, are under a governor who resides in Rhodes and is subordinated to the ministry of foreign affairs. Under him serve the regent of Cos and the delegates of Leros, Kalymnos, Symē, Karpathos and Castelrosso. The area of the islands is 1,035 sqmi.; the population on April 21, 1936, amounted to 140,848, of whom 85% were Greek. The capital is Rhodes, with 27,466 inhabitants. The fourteen islands, with their Greek and Italian names, their area and population figures in 1936, are: Rhodes (Rodi) 545 sqmi., pop. 61,886; Cos (Coo) 111 sq mi., pop. 19,731 (capital of same name, 9,852); Kalymnos (Calino) 49 sq.mi., pop. 15,247 Leros (Lero) 28 sq.mi., pop. 13,657; Karpathos (Scarpanto) 118 sq.mi., pop. 7,770; Symē (Simi) 25 sq.mi., pop. 6,195; Nisyros (Nisiro) 18 sq.mi., pop. 3,391; Patmos (Patmo) 22 sq.mi., pop. 3,184; Castelrosso (Castellorizo) 4 sq.mi., pop. 2,238; Astppalaia (Stampalia) 44 sq.mi., pop. 2,006; Kasos (Caso) 27 sq.mi., pop. 1,890; Khalkē (Calchi) 12 sq mi., pop. 1,461; Tēlos (Piscopi) 25 sq.mi., pop. 1,215; Lipsos (Lisso) 7 sq.mi., pop. 977.

The main islands are fertile and famous for their vineyards, their olives and tobacco. Some of the smaller islands are famous for their sponge-fishing. The commerce ordinarily is conducted mainly with Italy, Egypt and Turkey. The development of trade can be seen from the following table in thousands of lire:

	1930	1934	1938
Imports	88,000	56,000	157,421
Exports	17,000	18,000	21,851

The budget for 1938–39 amounted to 32,000,000 lire. The islands were connected by air with Italy and Greece, and by steamship with Italy, Egypt, Syria and Turkey. There are no railroads on the islands; but good motor roads were built by the Italian government, which also tried to promote tourist traffic and the establishment of resorts on Rhodes. A number of representative official buildings were built in the typical fascist style, but behind this façade the life of the native population remained unchanged in its Greek traditions.

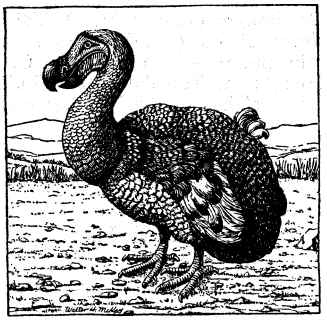
DODGE CITY, a city of south-western Kansas, U.S.A., on the Arkansas river, at an altitude of 2,478 ft; the county seat of Ford county. It is on federal highways 50S and 154, and is served by the Rock Island and the Santa Fe rail ays. The population in 1930 was 10,059; in 1940 by federal census 8,487. It has railroad shops, flour-mills, a dressed poultry plant and creameries, and is the supply centre for a large agricultural and stock-raising area. The meridian separating "central" from "mountain" time passes through the city. Dodge City was settled about 1872 and incorporated in 1875. It was a famous frontier town on the old Santa Fe trail, the rendezvous of picturesque characters, the centre of important freighting lines and headquarters of the cattle business. At the peak, in 1884, herds aggregating 8,000,000 head of cattle passed through from Texas, in charge of 3.000 men. There were immense herds of buffalo in this region. Hunting parties often killed 250 in a day, and the first trains often had to wait hours while a herd crossed the track. The first winter after the Santa Fe came through, 200,000 buffalo hides were shipped from Dodge City. At some stations in the vicinity shipments of buffalo bones in 1875 averaged a car load. a day. On the river 5 mi. E. of the city is old Ft. Dodge, an important frontier garrison, now the State home for disabled volunteer soldiers.

DODGSON, CHARLES LUTWIDGE ("LEWIS CARROLL") (1832–1898), English mathematician and author, son of the Rev. Charles Dodgson, vicar of Daresbury, Cheshire, was born in that village. The literary life of "Lewis Carroll" became familiar to a wide circle of readers, but the private life of Charles Lutwidge Dodgson was retired and practically uneventful. After four years at Rugby, Dodgson matriculated at Christ Church, Oxford, in May 1850. He took a first class in the final mathematical school in 1854, and the following year was appointed mathematical lecturer at Christ Church, a post he continued to fill till 1881. His earliest publications, beginning with *A Syllabus of Plane Algebraical Geometry* (1860), and *Tlze Formulae of Plane Trigonometry* (1861), were exclusively mathematical; but late in the year 1865 he published, under the pseudonym of "Lewis Carroll," *Alice's Adventures in Wonderland*, which has become an English classic. It was an open secret that the original of "Alice" was a daughter of Dean Liddell. *Alice* was followed (in the "Lewis Carroll" series) by *Phantasmagoria* (1869); *Through the Looking-Glass* (1871); *The Hunting of the Snark* (1876); *Rhyme and Reason* (1883); A *Tangled Tale* (1885); and *Sylvie and Bruno* (in two parts, 1889 and 1893). He wrote skits on Oxford subjects from time to time. *The Dynamics of a Particle* was aritten on the occasion of the contest between Gladstone and Mr. Gathorne Hardy (afterwards earl of Cranbrook); and *Tlze New Belfry* in ridicule of the erection put up at Christ Church for the bells that were removed from the cathedral tower. While "Lewis Carroll" was delighting children of all ages, C. L. Dodgson periodically published mathematical works—An *Elementary Treatise on Determinants* (1867); *Euclid, Book V., proved Algebraically* (1874); *Euclid and his Modern Rivals* (1879), the work on which his reputation as a mathematician largely rests; and *Curiosa Mathematica* (1888). Though the fact of his authorship of the "Alice" books was well known, he invariably stated, when occasion called for such a pronouncement, that "Mr. Dodgson neither claimed nor acknowledged any connection with the books not published under his name." His memory is appro-

priately kept green by a cot in the Children's Hospital, Great Ormond street, London, which was endowed perpetually by a public subscription. The beautifully written ms. of *Alice in Wonderland* was sold by Dean Liddell's daughter in April 1928 for £15,400.

See S. D. Collingwood, *Life and Letters of Lewis Carroll* (1898).

DODO, a large bird formerly inhabiting the island of Mauritius, but now extinct—the *Didus ineptus* of Linnaeus. The Dutch called them *Walgvögels, i.e.,* nauseous birds, because no cooking made them palatable. A compendious bibliography of notices of the bird up to the year 1848, will be found in the classical work, *The Dodo and its Kindred,* by H. E. Strickland and A. G. Melville (London, 1848), and the list was continued by G. R. von Frauenfeld *Neu aufgefundene Abbildung des Dronte* (Wien, 1868) for 20 years later. The last evidence we have of the dodo's existence is furnished by a journal kept by Beni. Harry and now in the British Museum (mss. *Addit.* 3,668, 11 D). This shows its survival till 1681, but the writer's sole remark upon it is that its "flesh is very hard." Professor Reinhardt was the first to suggest the affinity of the dodo to the pigeons (Columbidae) and Sir R. Owen's examination of the material discovered in a mud pool by G. Clark in 1865 confirmed this.



FROM WILLIAM SCLATTER, "THE IBIS"

DODO (DIDUS INEPTUS)

Native to Mauritius, the Dodo was exterminated about 1681. It was nearly the size of a swan, and flightless, living in the island forests

In 1889 Th. Sauzier, acting for the Government of Mauritius, sent a great number of bones from the same swamp to Sir Edward Newton. From these the first correctly restored and properly mounted skeleton was prepared and sent to Paris, to be forwarded to the museum of Mauritius. Good specimens are in the British Museum, at Paris and at Cambridge, England.

The huge blackish bill of the dodo terminated in a large, horny hook; the cheeks were partly bare, the stout, short legs yellow. The plumage was dark ash-coloured, with whitish breast and tail, yellowish white wings (incapable of flight). The short tail formed a curly tuft.

The dodo inhabited forests and laid one large white egg on a mass of grass. Man and the hogs and other animals he imported effected its extermination.

The nearest ally of the dodo was the solitaire (*q.v.*) of Rodriguez, also now extinct.

DODONA, in Epirus, the seat of the most ancient and venerable of all Hellenic sanctuaries. Its ruins are at Dramisos, near Tsacharovista. Though the Greeks of the south looked on the inhabitants of Epirus as barbarians nevertheless for Dodona they maintained a certain reverence. Its temple was dedicated to Zeus, and connected with it was an oracle which would seem to date from early times; for the method of gathering responses was by listening to the rustling of an old oak tree: perhaps a remnant of very ancient tree-worship. Sometimes, however, auguries were taken from doves in the branches, the murmur of a fountain, or the clanging of brazen caldrons hung round the tree or temple. Croesus proposed to this oracle his well-known question; Lysander sought from it sanction for his ambitions; Athens frequently appealed to its authority. But the most frequent votaries were the Acarnanians and Aetolians, with the Boeotians, who claimed a special connection with the district.

Dodona is spoken of in the *Iliad* as the abode of Selli who sleep on the ground and wash not their feet, and the *Odyssey* has an imaginary visit of Odysseus to the oracle. A Hesiodic fragment describes Dodonaea or Hellopia as a district full of cornfields, of herds and flocks and of shepherds, where is built on an extremity (*ha' ἐσχατίῃ*) Dodona, where Zeus dwells in the stem of an oak (*φηγός*). The priestesses were called doves (*πέλειαι*) and Herodotus tells a story which he learned at Egyptian Thebes, that the oracle of Dodona was founded by an Egyptian priestess who was carried away by the Phoenicians, out says that the local legend substitutes a black dove, in which he tries to find a rational meaning. In historical times there was worshipped, together with Zeus, a consort named Dione *(see* further ZEUS; ORACLE; DIONE).

The ruins, a theatre, town walls and other buildings were identified by Wordsworth in 1832, and excavated by Constantin Carapanos after 1875. The topographical and architectural results are disappointing; either the site always retained its simplicity, or else its buildings have been very completely destroyed.

South of the hill, on which are the town walls east of the theatre, and towards the eastern end of a plateau about 200 yd. long and 50 yd. wide are the remains of the temple of Zeus; pronaos, cella and opisthodomus, about 130 ft. by 80 ft. over all. Some lower drums of internal columns of the cella still rest on their foundations. No trace of external colonnade was found. It had been converted into a church. In and around it were found statuettes and decorative bronzes, many bearing dedications to Zeus Naïus and Dione, many small tablets of lead which contained questions put to the oracle.

Below the terrace was a precinct, flanked with porticoes over 100 yd. in length and breadth, of irregular shape. One of the buildings on the south-western side contained a pedestal or altar, and is described by Carapanos as a temple of Aphrodite. In front of the porticoes are rows of pedestals, which once bore statues and other dedications. At the southern corner is a gate, flanked with two towers, between which are placed two coarse limestone drums. If these belong to the original gateway, it must have been of a very rough character.

The smaller antiquities are now in the National Museum in Athens. Among the dedications are weapons dedicated by King Pyrrhus from the spoils of the Romans.

The temple of Dodona was destroyed by the Aetolians in 219 B.C., but the oracle survived to the times of Pausanias and the emperor Julian.

See C. Wordsworth, *Greece* (1839), p. 247; Constantin Carapanos, *Dodone et ses ruines* (Paris, 1878). For the oracle inscriptions, *see* E. S. Roberts in *Journal of Hellenic Studies,* vol. i., p. 228.

DODS, MARCUS (1834–1909), Scottish divine and biblical scholar, was born at Belford, Northumberland, on April 11, 1834. He studied at Edinburgh and was licensed in 1858. In 1864 he became minister of Renfield Free Church, Glasgow, where he worked for 25 years and in 1889 was appointed professor of New Testament exegesis in New college, Edinburgh, of which he became principal on the death of Dr. Rainy in 1907. He died in Edinburgh on April 26, 1909. His views on inspiration brought on him a charge of unorthodoxy which was preferred against him by the General Assembly in 1890, a year after his election to the professorship; the charge was soon dropped by a large majority, and in 1891 he received the honorary degree of D.D. from Edinburgh university. He edited Lange's *Life of Christ* in English (Edinburgh, 1864, 6 vols.), Augustine's works (1872–76), and, with Dr. Alexander Whyte, Clark's "Handbooks for Bible Classes" series. In the Expositor's Bible series he edited Genesis and I Corinthians, and he was also a contributor to the ninth edition of the *Encyclopædia Britannica* and Hastings' *Dictionary of the Bible.*

Among other important works are: *The Epistle to the Seven Churches* (1865); *Israel's Iron Age* (1874); *Mohammed, Buddha and Christ* (1877); *Handbook on Haggai, Zechariah and Malachi* (1879); *The Gospel according to St. John* (1897), in the Expositor's Greek Testament; *The Bible, its Origin and Nature* (1904). *See* his *Early Letters* (1910) and *Later Letters* (1911).

DODSLEY, ROBERT (1703–1764), English bookseller and miscellaneous writer, was born near Mansfield, Nottinghamshire, where his father was master of the free school. He is said to have been apprenticed to a stocking-weaver in Mansfield, from whom he ran away, taking service as a footman. In 1729 Dodsley published his first work, *Servitude, a Poem . . . written by a Footman,* with a preface and postscript ascribed to Daniel Defoe; and a collection of short poems, *A Muse in Livery, or the Footman's Miscellany,* was published by subscription in 1732, Dodsley's patrons comprising many persons of high rank. This was followed by a satirical farce called *The Toyshop* (Covent Garden, 1735).

With the help of his friends—Pope lent him £100—Dodsley set up as a publisher at the "Tully's Head" in Pall Mall in 1735. One of his first publications was Dr. Johnson's *London,* for which he gave 10 guineas in 1738. He published many of Johnson's works, and he suggested and helped to finance the *English Dictionary.* Pope also made over to Dodsley his interest in his letters. In 1738 the publication of Paul Whitehead's *Manners,* voted scandalous by the lords, led to a short imprisonment. Dodsleg also founded several literary periodicals: *The Museum* (1746–67, 3 vols.); *The Preceptor containing a general course of education* (1748, 2 vols.), with an introduction by Dr. Johnson; *The World* (1753–56, 4 vols.); and *The Annual Register,* founded in 1758 with Edmund Burke as editor. Dodsley is, however, best known as the editor of two collections: *Select Collection of Old Plays* (12 vols., 1744; and edition with notes by Isaac Reed, 12 vols., 1780; 4th edition, by W. C. Hazlitt, 1874–76, 15 vols.); and *A Collection of Poems by Several Hands* (1748, 3 vols.), which passed through many editions. In 1737 his *King and the Miller of Mansfield,* a "dramatic tale" of King Henry II, was produced at Drury Lane; the sequel, *Sir John Cockle at Court,* a farce, appeared in 1738. In 1745 he published a collection of his dramatic works, and some poems which had been issued separately, in one volume under the modest title of *Trifles;* and this was followed by other poems and plays. His tragedy of *Cleone* (1758) had *a* long run at Covent Garden, 2.000 copies being sold on the day of publication and it passed through four editions within the year. In 1759 Dodsley retired, leaving the conduct of the business to his brother James (1724–97), with whom he had been many years in partnership. He died at Durham while on a visit to his friend, the Rev. Joseph Spence.

Dodsley's poems are reprinted with a memoir in A. Chalmers's *Works of English Poets,* vol. xv (1810). *See* also Charles Knight, *Shadows of the Old Booksellers* (1865) pp. 189–216; E. Solly, in *The Bibliographer,* v (1884) *pp.* 57–61; Austin Dobson, "At Tully's Head" in *Eighteenth Century Vignettes* (2nd series, 1894); R. Straus, *Robert Dodsley, Poet, Publisher and Playwright* (1910).

DODSWORTH, ROGER (1585–1654), English antiquary, was born near Oswaldkirk, Yorkshire, the son of Matthew Dodsworth, registrar of York cathedral. He collected a vast store of materials for a history of Yorkshire, a *Monasticon Anglicanum,* and an English baronage. The second of these was published with considerable additions by Sir William Dugdale (2 vols.. 1655 and 1661). The mss. were left to Thomas, third Lord Fairfax, who by his will bequeathed them (160 volumes in all) to the Bodleian library at Oxford. Portions have been printed by the Yorkshire Archaeological society (*Dodsworth's Yorkshire Notes,* 1884) and the Chetham society (copies of Lancashlre post-mortem inquisitions, 1875–1876).

DODWELL, HENRY (1641–1711), scholar, theologian and controversial writer, was born at Dublin. He became a fellow of Trinity college, Dublin, but having conscientious objections to taking orders he relinquished his fellowship in 1666. In 1688 he was elected Camden professor of history at Oxford, but in 1691 was deprived of his professorship for refusing to take the oath of allegiance to William and Mary. He retired to Shottesbrooke to study chronology and ecclesiastical polity.

His chief works on classical chronology are: *A Discourse concerning Sanchoniathon's Phoenician History* (1681); *Annales Thucydidei* el *Xenophontei* (1702); *Chronologia Graeco-Romana pro hypothesibus Dion. Halicarnassei* (1692); *Annales Velleiani, Quintilianei, Statiani* (1698); and a larger treatise entitled *De veteribus Graecorum Romanorumque Cyclis* (1701).

DOG. Although the word "dog" is believed to have been originally applied to a particular English breed, it is now used in a general sense to connote all the domesticated varieties of the zoological genus *Canis,* of which the wolf (*Canis lupus*) and the northern jackal (*Canis aureus*) of Europe and Asia are familiar wild species. The accepted zoological name is *Canis familiaris.*

Origin and Antiquity.— The time that prehistoric man first domesticated a wild canine to serve as his hunting aid or cave guardian is unknown. The aboriginal peoples of Switzerland and Ireland used dogs for hunting and undoubtedly ate dog flesh long before they learned to till the soil. Cave drawings of the palaeolithic era include hunting scenes in which the rough form of a canine appears alongside the huntsmen. One of these drawings is estimated to be 50,000 yrs. old.

The question which naturally arises relative to such old drawings is whether the canines pictured can rightfully be called dogs. They undoubtedly were wild animals, probably wolves, which were taken into the caveman's abode as cubs and nourished by bones and entrails of the animals eaten by the family. The domesticated canine probably learned that it was easier to procure food by accompanying the huntsman than by chasing and killing its own prey, thus becoming a hunting assistant and probably a guardian of its master.

The most commonly accepted theory of canine development is that the wolf was the main progenitor, with subsequent crossings with other wild canines such as the Eskimo and the dingo. It is unlikely that the jackal was a contributor to the strain in view of the fact that the jackal's dental structure is different from that of the dog, whereas the teeth of the wolf are identical in every detail with those of the dog.

From the investigations of caves, middens and lake dwellings, it is known that Europeans of the new stone age possessed a wolf-like breed of dogs; and a similar breed has been traced through the successive ages of bronze and iron. But accurate information of the external form of domesticated dogs prior to historic times is not available. From the oldest records supplied by Chaldean and Egyptian monuments, it is manifest that several distinct varieties had been developed 4.000–5,000 yrs. ago. Slender dogs of the greyhound type, and a short-legged breed of a terrier type are depicted in Egypt; and the Assyrians of about 600 B.C. had mastiff-like hounds.

The early Greeks and Romans had dogs and mentioned them often in their literature. The Romans' canine classifications were similar to our modern groups. Both made distinctions between those which hunted by scent and those which hunted by sight, just as we divide hounds from hunting breeds. The Romans also had *Canes villatici* (housedogs) and *Canes pastorales* (sheep dogs) which compare to modern working dogs.

MODERN BREEDS OF DOGS

There are five main classes of dogs in addition to a miscellaneous sixth group. This division is based on the uses of the dogs—sporting dogs for hunting by air scent; hounds for hunting primarily by ground scent; terriers which hunt by going to earth; working dogs to serve as guards, guides, and herders; toy dogs to serve as companions; and the miscellaneous or non-sporting group of dogs for a great variety of uses. This general classification applies to modern dogs all over the world. In 1943 there were 112 breeds in these 6 groups recognized in the United States.

The Sporting Group.—(Wire-haired pointing griffon, pointer, German short-haired pointer, Chesapeake Bay retriever, curly-coated retriever, flat-coated retriever, golden retriever, Labrador retriever, English setter, Gordon setter, Irish setter, American water spaniel, Brittany spaniel, clumber spaniel, cocker spaniel, cocker spaniel [English type], English springer spaniel, field spaniel, Irish water spaniel, Sussex spaniel, Welsh springer spaniel and Weimaraner).

The dogs in this group serve as hunters' assistants, mainly as finders and retrievers of small furbearers and fowl. The spaniels are the largest class of hunting breeds. The Irish were among the first users of spaniels, and the name indicates that they probably procured their original stock from Spain. The word spaniel was first printed in the Irish laws of 17 A.D. in a statement that water spaniels had been given as tribute to the king. Three hundred years later, during the period when Wales was overrun by the Irish, spaniels are mentioned in Welsh statutes.

English literature of the 14th century mentions "spanyells," and they were used in falconry during the 16th century, probably to retrieve game killed or injured by the falcons. From the reign of Henry VIII there are records of payments made to "Robin, the King's spaniel keeper."

The spaniel family is divided into those breeds which hunt and retrieve, those which retrieve only and toy spaniels which do not hunt (see *Toy Dogs,* below). Most of the sporting spaniels, in-

cluding the cocker, springer and clumber, range the hunting ground just ahead of the gunner. Their task is to range back and forth over terrain selected by the hunter, but always close enough to the gunner that the charge from his shotgun can kill the game which the dogs flush. Thus the spaniel may be as close as 20 yds. to the hunter, rarely more than 75 yds. away. The reason that spaniels must hunt close is that they give no warning upon finding game, as do the pointing dogs, but immediately rout the game from cover. A well-trained spaniel of this type hunts until he finds game, flushes the game, then immediately sits. For such a dog to chase flushed game is a serious hunting fault. If the game is killed, the spaniel is ordered to find the dead bird or animal and return it to the gunner. Hunting spaniels of this type are trained to flush both furred and feathered game. They also can be trained to retrieve waterfowl from a hunting blind, the springer spaniel being especially adaptable for this work.

The Irish water spaniel, despite its name, is usually classed with the retrievers rather than the spaniels. It competes with the Labrador, Chesapeake Bay and other retrievers in usage.

A second group of gun dogs includes the pointers and setters, which hunt upland game birds by pointing. Unlike the spaniels, which hunt close to the gunner, the pointing breeds range far ahead of the huntsman — often out of sight. When they scent game they do not immediately flush the birds into the air, but stand immobile within a few feet of the game, their sensitive noses pointing toward the single bird or covey. They remain in this position until the hunter flushes and shoots the birds. A well-trained pointing dog will hold such a point for a minute to two hours, stand staunchly while the game is shot and wait for the hunter's command to find and retrieve the killed game.

Pointing dogs are of comparatively recent origin, their development paralleling the development of sporting firearms Wing shooting came into popularity during the first decade of the 18th century, and from that period the rise of the "bird dogs" was marked. The dogs of the pointing group include the German short-haired pointer, the pointer, English setter, Irish setter, Gordon setter and Weimaraner.

Most of the pointing breeds were developed in the British Isles. The first of record were those used in England about 1650 for pointing hares. The English setter probably was developed from crosses of the Spanish pointer, the large water spaniel and the springer spaniel; and there is evidence that a distinct breed of the English setter type was used as early as 1582. It was not until about 1825, however, that the breed came into real prominence through the English sportsman, Edward Laverack, whose breeding practices standardized the appearance of the English setter.

The Gordon setter often is called the black and tan setter because of its coat colours. The breed never has approached the English or Irish setter or the pointer in popularity.

The mahogany-red Irish setter, as distinguished from an earlier red and white breed, first appeared in Ireland early in the 19th century. In addition to being one of the most handsome of all breeds, the Irish setter is a capable field dog.

The retriever breeds are hunting specialists. Their job in the field is that of finding game which has been killed or wounded by the hunter and returning that game to their masters. During the hunting of upland game, retrievers often are worked with spaniels. The spaniels quarter the ground and "spring" the game while the retrievers are kept at the hunter's side. When game is downed the retrievers are sent out to do their specialized job.

The most common use of retrievers is in the hunting of waterfowl. In this type of sport the retrievers remain in the shooting blind until birds are killed, when they are ordered after the downed game. They retrieve equally well on land or water, being strong swimmers. The most popular retriever breeds are the Labrador, Chesapeake Bay, and golden retrievers and the Irish water spaniel. Other breeds used in this hunting work are the curly-coated and flat-coated retrievers.

The Hound Group. — (Afghan hound, bassethound, beagle. bloodhound, borzoi. dachshund, Scottish deerhound, American foxhound, English foxhound, greyhound, harrier, Norwegian elkhound, otterhound, saluki, whippet and Irish wolfhound).

Most of the dogs of this group were developed for sporting uses, primarily to trail game by ground scents. The exceptions to this rule are the Irish wolfhound, borzoi and Scottish deerhound, all of which hunt large game primarily by sight.

The typical breeds of the hound group are powerfully built dogs with strong legs, long heads and muzzles, pendulous ears and pendulous upper lips or "flews." There was at least one hound type, called the St. Hubert, in France before the Conquest; and there are good reasons for the belief that English breeds of the present day are traceable to the importation of these dogs by King William I. From them were derived the talbot and the old English staghound, both now extinct, and the bloodhound which still survives. The bloodhound, which exhibits the hound characteristics of the head in the most exaggerated form, has the keenest scent of all dogs but is heavily built and lacking in speed. For these reasons the bloodhound has been weaned away from its original use as a sporting dog and now is used as a police aid in the trailing of criminals and lost persons.

There seem to have been other breeds in England in the middle ages known as the southern and northern hounds, and in addition there mas a large hound used for trailing deer and smaller hounds, principally harriers and beagles, used for hares. Harriers and beagles are miniature foxhounds in appearance, the beagle being the smallest of the true hounds.

The English country gentlemen of the middle ages were the prime developers of hound breeds, and the development of the breeds paralleled the hunting fancies of the times. Staghunting and hare hunting were popular long before fox hunting became the vogue; thus harriers and beagles, which were followed on foot, are older breeds than the foxhound. The latter breed probably was developed by crossing one of the old English hounds of the bloodhound type with the greyhound to give speed in the pursuit of the fox in open country.

In the United States, the two most popular hounds are the beagle and the dachshund. Basically they are hunting dogs, and the beagle's popularity is due to its ownership by thousands of rural sportsmen for the hunting of rabbits. Single beagles commonly are used for this type of hunting, but they may be hunted in braces or in packs.

Short-legged and long-bodied hounds of the dachshund type were recorded in carvings in Egyptian monuments of the 15th century B.C.; and there is evidence that Englishmen, as well as Germans and Italians, had a similar breed used in hunting during the 15th and 16th centuries, but it was in Germany that the breed was standardized in its modern conformation. The dachshund's popularity in the United States springs from the fact that it is a small, intelligent and friendly house pet. The breed is only occasionally used for hunting. Another of the hound breeds, the greyhound, is distinguished as one of the oldest of all established dog types.

The Working Group. — (Alaskan Malamute, Belgian sheep dog, Bernese Mountain dog, Bouvier de Flandre, boxer, briard, bull-mastiff, collie [rough], collie [smooth], Doberman pinscher. Eskimo, German shepherd, great Dane, Great Pyrenees, komondor, Kuvasz, mastiff, Newfoundland, old English sheep dog, puli, Rottweiler, Samoyede, schnauzer [giant], Shetland sheep dog, Siberian husky, St. Bernard, Welsh corgi [Cardigan] and Welsh corgi [Pembroke]).

There is no doubt that the dogs of the working group have the greatest utilitarian value of all the modern canine classifications. Except in rare cases they are not used in sporting capacities. Instead, they work as police aids, draft animals, herders of livestock and guides for the blind.

In the police group are the boxer, Doberman pinscher, Rottweiler, German shepherd, great Dane, and giant schnauzer, all of which are commonly trained to serve as sentry aids and guard dogs. In addition, the Airedale and standard schnauzer from the terrier group are similarly trained, and the bloodhound from the hound group serves often as a police aid for trailing duty. Thus all of these breeds may be considered "police dogs," a term often

mistakenly used to denote the German shepherd.

Other breeds in the working division were developed as farmers' aids. This group includes the collie, puli, old English sheep dog, Shetland sheep dog, Belgian sheep dog, German shepherd and the corgi, all of which are herders. The Norwegian elkhound, from the hound group, also is used for herding duties. Almost every nation has its dog breed used for herding purposes. Thus we have the collie from Scotland, the puli from Hungary, the corgi from Wales and other imported breeds. The dog most commonly used on U.S. farms for herding work is an unrecognized breed unofficially called the American shepherd, English shepherd or border collie. It is a collie type, but has a shorter muzzle and smaller body, and usually is black and white in colour

Sure-footed draft animals also are included in the utilitarian group of working dogs. Arctic explorations would have been impossible but for the Eskimo and Alaskan Malamutes which pulled long sleds filled with necessary foods and supplies. Draft dogs also are commonly used in Belgium and the Netherlands.

A further sub-classification of working dogs are the "rescue breeds"—the St. Bernard and Newfoundland. The former breed accompanies the monks of the Hospice of St. Bernard, Switzerland, to find helpless persons overcome during storms. The Newfoundland, a strong swimmer, is used to carry life lines to stricken vessels and to aid in the rescue of shipwreck survivors.

The activities of other working breeds, including guide dogs for the blind and modern war dogs, are included in later paragraphs.

The Terrier Group.—(Airedale terrier, Bedlington terrier, border terrier, bull terrier [white], bull terrier [coloured], Cairn terrier, Dandie Dinmont terrier, fox terrier [smooth-haired], fox terrier [wire-haired], Irish terrier, Kerry blue terrier, Lakeland terrier, Lhasa terrier, Manchester terrier, Norwich terrier, schnauzer [miniature], schnauzer [standard], Scottish terrier, Sealyham terrier, Skye terrier, Staffordshire terrier, Welsh terrier, West Highland white terrier).

The terriers hunt by digging into the earth to rout furred animals such as badgers, woodchucks, otters and many others. In some cases their duty is merely to force the furbearers from their dens in order that the huntsman can complete the capture. In other cases the terrier's job is to find and destroy the furbearers, either on the surface or underground. The word terrier is from the Latin *terra*, earth.

The terrier group includes breeds which differ so profoundly from each other that the extreme types have hardly a character in common. The terriers are linked with the mastiff group through the bull terrier, which originally was produced by crossing the bulldog with the white English terrier, a breed now extinct. With the hound group the terriers are connected through the Airedale, which resulted from a cross between the otterhound and a terrier of the Aire valley in England. Apart from their size, the original Airedales did not differ greatly from rough-coated Welsh or Irish terriers.

England, Ireland and Scotland produced most of the terrier breeds. Among the breeds developed in England were the aforementioned Airedale, Bedlington, bull terrier, fox terrier, Manchester and Staffordshire. Scottish breeders developed the popular Scottish terrier in addition to the Cairn, Skye, and West Highland white. Ireland's contributions to the terrier family include the Irish terrier and the distinctive Kerry blue terrier, whose coat ranges from light steel blue to very dark blue. The Sealyham and the Welsh terriers came from Wales. The standard and miniature schnauzers were developed in Germany, and the Lhasa terrier is of Tibetan origin.

The Toy Group.—(Affenpinscher, Chihuahua, English toy spaniel, Brussels griffon, Italian greyhound, Japanese spaniel, Maltese, Mexican hairless, Papillon, Pekingese, miniature pinscher, Pomeranian, pug, toy Manchester terrier, toy poodle, Yorkshire terrier).

All of the dogs in the first four groups; *i.e.*, the sporting dogs, hounds, working dogs and terriers, originally mere bred for a specific purpose—to hunt, trail, rout vermin, serve as protectors of livestock or humans or fill some other need. In most cases, however, the dogs kept in modern homes are kept primarily as pets, secondly for the utilitarian purpose they can fulfill. Thousands of setters never are taken into the hunting field; thousands of sheep dogs never are used for herding stock, and only a comparatively few of the breeds developed as police aids are used for that work. These breeds are capable of such work if trained for it, but the modern dog serves mankind mainly as a companion and pet.

The dogs of the toy group make little claim to any value except as ideal house pets. Like most breeds, they develop a protective instinct which causes them to warn members of their masters' families upon the approach of a stranger, but aside from the performance of that valuable service they earn their keep by providing friendly companionship.

All of the dogs of the toy group are small, ranging from Chihuahuas, which may weigh as little as 1 lb., to pugs which may range up to 18 lbs. Most of the toy breeds are miniature counterparts of larger breeds. The English toy spaniels and Japanese spaniels, for example, are similar in conformation and physiognomy to the hunting spaniels. The Italian greyhound is a dwarfed specimen of the larger gazehound of the ancients. The Pomeranian is the smallest representative of the northern group, which includes the chowchow, Siberian husky, Eskimo, Norwegian elkhound, keeshond and schipperke. The toy Manchester terrier is the toy counterpart of the standard Manchester terrier.

It should not be assumed that toy breeds are new breeds. The Chinese are known to have kept "lion dogs" almost identical to the modern Pekingese as early as 2000 B.C. "Lap dogs" were popular during Caesar's reign. The forest laws written by Canute in the early years of the 11th century contained the provision that any dogs kept within 10 mi. of any of the king's forests must have their knee joints cut to prevent them from chasing game. An exception was made in the case of small dogs which could pass through a dog gauge, an oval ring 7 in. wide and 5 in. high.

Neither must it be assumed that all toy dogs are useless except as companions. As mentioned above, most dogs of the toy group develop a protective instinct after being in a home for a few months, thereafter serving effectively as sentries to warn of the approach of strangers. In many cases this instinct becomes so completely developed that toy dogs will attack intruders.

The Nonsporting Group.—(Boston terrier, bulldog, chowchow, Dalmatian, French bulldog, keeshond, poodle, schipperke)

In this miscellaneous sixth class of dogs are some of the most interesting of all canine types. Three of the eight breeds are of the bulldog family. These are the bulldog, Boston terrier and French bulldog. The distinguishing features of this family are the muscular neck and the strong jaws and teeth. The English-type bulldog was the first of the three modern bulldogs. This massive breed was mentioned in a book published in England in 1500, and probably was used at least two centuries before that in the sport of bullbaiting. In this activity, an English forerunner of bullfighting, a dog with strong jaws was needed to seize the bull by the nose and hold the animal close to the floor of the arena. This cruel sport was outlawed, but the massive and courageous bulldog was retained.

The French bulldog is a comparatively new breed, having been developed by the French from small bulldog stock imported from England. The Boston terrier is one of the few breeds developed in the United States, crossbred by Robert C. Hooper, of Boston, in the mid-19th century.

The chowchow probably is the oldest of the breeds in the nonsporting group. A bas relief dated to the Han dynasty of about 150 B.C. pictures a chow in a hunting capacity. The modern chow is popular in England and the United States as a companion and guard dog.

Wild Dogs.—A number of the best known of the undomesticated dogs deserve mention. The Australian dingo is somewhat like a fox in appearance. Although having a shorter coat, the dingo is both cunning and savage. The animal probably comes from wild stock native to Australia, but it is possible that it derived from crossbreedings of wild canines and dogs brought by

early settlers of the continent. Like the wolf, the dingo in its wild state is nocturnal in habit and hunts in packs. It is somewhat destructive of livestock, and the Australian settlers made attempts to exterminate it. The dingo can be domesticated, and when befriended becomes very much attached to Its master.

The wild dog of Turkey is a pariah, a medium-sized canine which varies greatly in colour and coat. They remain in packs, and are countenanced in Eastern cities to serve as scavengers.

India's native wild dog is the dhole. The same canine also inhabits Tibet. The dhole avoids human habitats but attacks such animals as tigers and leopards.

The licaone is a wild dog of the African continent. It belongs to the family of hairless dogs and has bell-shaped ears. The usual colour is black with white spots. These canines hunt in packs and have a keen sense of smell.

THE DOG'S SENSES

In most respects the dog's senses are considerably keener than man's. In hearing tests conducted by W. A. Engelmann, a German scientist, a German shepherd responded from a distance of 26 yds. to a command which could not be heard by a man 6½ yds. away. The so-called "silent whistles" used by many trainers of hunting dogs demonstrate the great range of a dog's hearing powers. A man standing only a few feet away cannot hear the sound which emanates from these instruments, yet a dog will respond to the same sound from a distance of more than 75 yds. The reason for this is that the sound range of the human ear is restricted, whereas the dog can hear extremely high-pitched tones from a considerable distance. These same tones are above the auditory range of the human ear.

The dog's nose is so sensitive that we are unable to conceive the great range of odours which canines detect. A piece of wood touched only by the tip of a master's finger can be selected by a trained dog from 20 other identical pieces. Bloodhounds have been known to follow perfectly the trail of a stranger 48 hrs. after the path was traversed. There is no known method of measuring this sensitivity of the dog's olfactory powers, but it is among his strongest and most often utilized senses.

The dog's sight, on the other hand, is considerably weaker than man's, forcing the dog to use his keen senses of smell and hearing to make identifications. In one scientific test it was found that dogs could not distinguish between a a-in. delta triangle and a a-in. inverted triangle at a distance of 20 in. On the other hand, dogs have great sensitivity to movements, however slight. This ability to detect very slight motions explains the ability of stage dogs to solve problems in arithmetic. Such trained dogs bark the answers to addition and multiplication problems by following movements of the trainer's hand or jaw which cannot be detected by the human eye.

In another respect dogs' sight is inferior, in that they are colour blind. Their world is one of white, black, and shades of gray, and most tests indicate that their ability to differentiate between gray shades is inferior to that of man.

Guide **Dogs for** the Blind.--One of the most concentrated efforts to turn dogs to the use of man has been the training of thousands of guide dogs for the blind. The Germans led this movement by training several thousand dogs to guide soldiers who returned sightless from World War **I.** Nearly all other countries which participated in that war started similar training programs. In the United States the Seeing Eye foundation, Morristown, N.J., became the leading school for training guide dogs; several others were established in the middle west and western states.

The German shepherd is the breed most often used for this work, about 90% of all U.S. guide dogs being of this breed. Other breeds sometimes used are the boxer, Doberman pinscher and Labrador retriever. Bitches are preferred for guide service, but temperament is the guiding factor in selecting individual canines for the work.

Guide dogs wear a leather harness to which is attached a leather-covered metal hoop which extends to the master's palm. The blind person holds this hoop lightly as the dog walks close to his legs, and is guided according to the pressure exerted by the dog's movements as transmitted through the harness. The dogs guide their masters at about the same speed as that of the normal walker. They proceed largely without commands except for "right," "left," "forward" and "halt." They guide their masters around all holes and barriers and stop before going down or up a curb stone. After making such a stop the dog waits until the master determines the height of the curb and orders "forward." In addition to serving as a guide animal, the dogs perform such other services as picking up articles which the master may have dropped unintentionally. Such services are rendered without command.

A question commonly asked about guide dogs relates to their ability to follow red, green and yellow traffic signals. Inasmuch as dogs are colour blind, they obviously cannot interpret such signals. In fact, trained dogs do not watch traffic signals. They are trained to watch the flow of traffic and to guide their masters across streets when traffic permits safe movement.

The training of guide dogs is complicated for many reasons. These canines must be taught to judge, for example, the speed of approaching vehicles to determine if there is time to cross the street before the vehicle reaches the blind person's path. Similarly, they must be trained to judge heights to determine if the blind person can pass under a barrier, or must walk around it.

Institutions which train guide dogs believe, with good reason, that the work of these canines provides psychological as well as economic benefits. Not only do the dogs give their masters almost complete independence of human aid, but in many cases have changed their masters' entire temperament and approach to life.

Dogs in World War 11.—All of the major powers engaged in World War II used trained dogs in numerous capacities. The United States army organized a K-9 corps as a branch of the quartermaster department for the sole purpose of training dogs for war use. It is known that Germany had 40,000–50,000 trained dogs available for service at the start of the war and later gave Japan 10,000 of these. Russia and England also adopted dogs for military purposes.

American military dogs were put to use by all branches of the service—army, navy, marines and coast guard. The breeds wanted and approved by the armed forces for war dog training. as of 1943, were as follows: Airedale terriers, Alaskan Malamutes, Belgian sheep dogs, Bouviers de Flandre, boxers, briards, buil mastiffs, Chesapeake Bay retrievers, collies (both rough and smooth), curly-coated retrievers, Dalmatians, Doberman pinschers, English springer spaniels, Eskimos, flat-coated retrievers, German shepherds, German short-haired pointers, giant schnauzers, Great Pyrenees, Irish water spaniels, Labrador retrievers, Newfoundlands, Norwegian elkhounds, pointers, Rottweilers, Samoyedes, Siberian huskies, St. Bernards, standard poodles, wire-haired pointing griffons, and crossbred dogs of any of the above breeds.

The major use of dogs trained for the military is that of aiding sentries. The canines are taught to accompany guard soldiers, either inside supply depots or outside military buildings or encampments. Under such conditions the dog is expected to range away from its handler, using its nose to find and rout any intruders. Other uses for which war dogs are trained are as messengers, detectors of machine gun nests, pack dogs, sledge dogs and first aid assistants.

FEEDING THE DOG

The basis of canine health is a proper diet. A well-fed dog has the resistance to throw off minor diseases and resist major ailments. Similarly, a well-fed dog is most likely to be active and alert, with clear eyes and a healthy skin and coat. Conversely, a poor diet may be the forerunner of many troubles, including diseases of the heart, intestines, lungs and skin.

In their natural state dogs are carnivorous animals. Wild canines live almost entirely on the flesh, skins and bones of animals which they catch. It therefore follows that meat is the prime requisite in the dog's diet, although the variations in the mode of existence between wild dogs and modern house pels

naturally requires that there be variations in their diet.

Wild dogs, for example, require more food and a higher ratio of protein foods than do domesticated house pets, for the obvious reason that a wild dog utilizes considerable energy for chasing and killing the game which he eats, whereas the pet kept in a home gets his meals without effort.

The meat which forms the backlog of the dog's diet may be supplied in one of several forms. It may be fresh meat, commercially-packed dog meat or dehydrated meat in biscuit form. Many large kennels which keep dogs in almost perfect condition for exhibition in shows feed almost no fresh meat, but depend upon commercially manufactured biscuit focds which contain dehydrated meat in addition to bone meal, corn and wheat products, soybean meal, dried milk, yeast, bran, cheese meal, fish meal, molasses arid cod liver oil. Pet owners who keep only one dog in the house can economically follow the example set by the large kennels by feeding biscuit foods in conjunction with table scraps, milk and other beneficial dog foods. These prepared cereal foods may be fed dry, but are more palatable if softened with milk, hot water or broth.

Since the dog is primarily a carnivorous animal, vegetables must be considered as a subsidiary food in his diet. Vegetables may be fed to dogs in small portions and mixed with other foods. In almost every case they should be cooked and mashed, since the dog cannot digest vegetable chunks. Among the vegetables which, in small quantities, are beneficial to the dog are spinach, carrots, asparagus, beans, tomatoes and potatoes. Milk can be given to dogs of any age and is particularly beneficial to puppies just past the weaning stage. Among the foods which should be avoided are pork, uncooked fish and fowl.

A common query relates to the quantity of food to be given to a dog and the number of meals each day. Most veterinarians recommend that a puppy from 6 to 10 weeks old be given 4 meals a day at 4 hr. intervals. Between the ages of 10 weeks and 6 months the dog can be fed 3 times a day at 5 hr. intervals. After 6 months most dogs thrive on a light meal in the morning and a major meal in the evening.

There is no fast rule on the amount of food a dog should be given each day. Roughly, toy breeds require about ½ lb. of food per day; breeds weighing 10–20 lbs. require about 1 lb. of food; dogs weighing 20–50 lbs., about 1½ lbs. of food, and those weighing more than 50 lbs. may consume 2–4 lbs. of food per day. This schedule varies greatly, however, according to the temperament of the individual dogs. A very active terrier weighing only 20 lbs., for example, may eat as much as a 50 lb. dog that has a placid temperament. The best rule is to watch the dog's actions to determine the amount of food he can assimilate. The owner should feed no more than the dog eats readily at each meal and naturally change or reduce the diet if the dog becomes overweight or underweight.

DOG AILMENTS

Distemper. — Sometimes called "canine plague" because of its widespread occurrence and virulence, distemper is one of the most serious of all the diseases of dogs. The virus causing distemper is air-borne, and can affect dogs of any age, although it is most serious in puppies under a year of age because these young dogs often do not have the strength to combat the disease.

The most common symptoms of distemper are discharges from the nose and eyes; an offensive odour of the skin, caused by slight skin eruptions; sneezing and coughing; loss of appetite and a general indication of waning strength.

Distemper is more easily prevented than cured. A series of three inoculations, given to puppies over three months of age by a veterinarian, provides dogs with almost complete protection.

Rabies. — Rabies is an infectious disease affecting many warm-blooded animals, including man, in which case it is termed hydrophobia. It is more common in dogs than in any other animal because of their roving nature, but it can affect and be transmitted by rodents, cattle, horses, cats, monkeys and other animals. The usual method of transmission of the rabies virus is through the bite of an infected animal, in which case the rabies bodies in the saliva of the infected animal are injected into the nervous system of the animal attacked. In rare cases the disease can be transmitted without biting taking place. This occurs if saliva from an infected animal enters the nervous system of another animal through a skin abrasion.

There are two types of true rabies in dogs. The first is dumb rabies, so-called because the lower jaw of a dog thus affected becomes paralyzed, preventing barking and biting. The second type is violent rabies, the symptoms including extreme nervousness and biting of other animals without reason.

Veterinarians and scientists disagree as to the value of preventive rabies inoculations. Many U.S. states require annual anti-rabies inoculations. England has almost eliminated rabies by a strict quarantine law which bans dogs from the country until after six months of observation. The most certain method of protecting a family dog against rabies is to keep it under strict control, either on its home property or otherwise on leash, since the only manner by which it can contract the disease is through the bite of an infected animal.

There is no cure for rabies or hydrophobia, but it can be prevented by the Pasteur treatment, provided this treatment is started while the disease is in the incubative stage.

Internal Parasites. — Several types of worms may be internally harboured by dogs. They can be inherited, but more commonly the worm larvae is taken into the dog's organs through its food. The most common internal parasites are roundworms, tapeworms, hookworms, whipworm and heartworm. The latter type is most common in the southern United States and usually is fatal.

Worms sometimes can be detected in the dog's bowel excretions, but a microscopic examination usually is necessary to determine the type of worms present. External indications of the presence of worms include excessive appetite, or almost complete lack of appetite, laziness, loss of weight, eve excretions and vomiting. These same symptoms also are present in other dog ailments. however. and therefore are not wositive guides. The aforementioned microscopic examination of the dog's stool is the only definite proof of worm presence Treatment for worms varies according to the types present, and should not be undertaken in the home without veterinary recommendations.

INDIVIDUAL BREEDS

Sporting Breeds. — Griffon (Wire-Haired Pointing). — A medium-sized dog developed in the last quarter of the 19th century. Primarily a pointing breed.

Pointer.--One of the leading sporting breeds, and the first type of dog developed to stand game as we understand the term today. Originally used in England to point hares. The pointer probably was developed from foxhound, greyhound, bloodhound and spaniel blood. Common colours are white and black, white and liver, white and orange and white and lemon.

Pointer (German Short-Haired). — A versatile breed developed in Germany about 1895 for pointing upland game and coursing furbearers and large game.

Retriever (Chesapeake Bay). — Hunters' retriever used for finding and delivering upland game and waterfowl. Developed in America.

Retriever (Curly-Coated), — First breed developed exclusively for retrieving game in the hunting field. First exhibited publicly in England in 1859.

Retriever (Flat-Coated). — Similar to the curly-coated retriever and developed at about the same time for the same uses.

Retriever (Golden). — Developed in England about 1870 from the Russian tracker breed, with bloodhound crosses.

Retriever (Labrador). — An all-black, short-haired retrieving breed developed in England from stock imported from Newfoundland.

Setter (English). — One of the most popular game pointing breeds in the British Isles and the United States. Developed in England in the 15th century for pointing upland game birds.

Setter (Gordon). — Similar to the English setter and Irish setter, but black and tan in colour. Developed in Scotland, and

takes its name from the Duke of Gordon, a Scotch breeder of the late 18th century.

Setter (Irish).—A red- or chestnut-coated pointing breed developed in Ireland early in the 18th century.

Spaniel (American Water).—Smaller than the Irish water spaniel, and used both for flushing and retrieving game.

Spaniel *(Brittany)*.—Developed in France, this is the only member of the spaniel family which points game.

Spaniel *(Clumber)*.—A large and deliberate sporting dog, the clumber was developed in England from spaniel and bassethound bloodlines.

Spaniel (Cocker).—In the 1940s the most popular breed in America, being kept primarily as a house pet and hunting dog. Originally developed in England for hunting woodcock, hence its name. Specimens of this breed weigh 18-24 lbs. and may be either solid-coloured or two-coloured.

Spaniel (Cocker—Englislz Type).—Similar to the American-type cocker spaniel in conformation, colour and temperament, but slightly larger in size.

Spaniel (English Springer).—One of the most popular of the sporting dogs of general usage, the springer flushes and retrieves upland game and also retrieves in water. Dogs of this breed weigh 42-50 lbs. and have the typical spaniel head and body conformation.

Spaniel (Field).—Dark-coated hunting spaniel developed in England; weighs 35-50 lbs.

Spaniel *(Irish* Wafer).—Developed in Ireland in the first half of the 19th century. Tallest of the spaniels, the breed is used primarily as a retriever on land and water.

Spaniel (Sussex).—A determined and valuable hunter of upland game, the Sussex works more slowly and deliberately in the field than does the cocker or springer. Weighs 35-45 lbs.

Spaniel (Welsh Springer).—A red and white spaniel developed in Wales and used primarily in the British Isles for upland game.

Weimaraner.—A German breed similar in appearance to the short-haired pointer. An all-around hunting breed, but most commonly used for pointing upland game.

Hound Breeds.—Afghan Hound.—One of the oldest of all breeds, there being evidence that it was kept in Egypt 5,000 to 6,000 yrs. ago. Later bred in northern Afghanistan, the breed hunts by sight.

Basset Hound.—Developed in France, the basset weighs 25-40 lbs. and is used in the United States for trailing foxes, rabbits, pheasants and raccoons.

Beagle.—One of the five most popular breeds in America, the beagle is primarily a rabbit hunter and companion dog. Became popular during the Elizabethan period for hunting hares. May be hunted singly, in braces or in packs.

Bloodhound.—One of the oldest of the scent-hunting hounds, having been known in Italy as early as the 3rd century. The breed name is derived from the fact that it was one of the first of the "blooded" or purebred hounds, and its main modern use is that of trailing criminals or lost persons.

Borzoi.—Used as coursing hounds since the 13th century, the borzoi also is called the Russian wolfhound. Large, angular canines, the borzois stand from 26-31 in. at the shoulder and weigh 55-105 lbs.

Dachshund.—One of the most popular of the hounds, the dachshund has the temperament, size and intelligence to qualify it as an ideal house pet. Developed in Germany to enter badger dens, hence its long body and short, powerful legs. The short-haired variety is most common, but there also are long-haired and wire-haired types.

Deerhound (Scottish).—As its name implies, this breed was used most extensively in Scotland and England for coursing deer. Completely established as a distinct breed in the 16th century.

Foxhound (American).—A variation of the English foxhound, and well established in the United States in colonial days. George Washington was one of the first U.S. enthusiasts of the breed.

Foxhound (English).—Somewhat larger than the American foxhound, and hunted in packs for trailing the fox. The most common colour combination for both the American and English foxhound is black, white and tan.

Greyhound.—One of the oldest established breeds, having been established in Egypt between 4000 and 3500 B.C. and later favoured by the Greeks. Used for tracking all types of game, but most commonly used in hunting hares.

Harrier.—One of the early hounds used in pack hunting, the harrier probably was introduced into England by the Normans. Similar to but smaller than the foxhound.

Norwegian *Elkhound*.—Another of the ancient hound breeds, having been used by the Vikings as early as 4000 B.C. Has a thick, grey coat, and stands 18-20½ in. tall at the shoulder.

Otterhound.—Hounds were used for killing otter in England as early as A.D. 1200, and this breed was established for this type of hunting as early as A.D. 1300. A large, rough-coated dog weighing up to 6j lbs.

Saluki.—Perhaps the oldest known breed of domesticated dog; excavations of the Sumarian empire of 7000 to 6000 B.C. show canines of the saluki type. Similar to the greyhound in conformation, but with silky feathering on the ears and tail.

Whippet.—The fastest of all the small, domesticated animals, the whippet is similar to but smaller than the greyhound, weighing 10-28 lbs.

Wolfhound (Irish).—The tallest of all dogs, having a greyhound conformation. The Irish wolfhound was kept by Celts as early as 273 B.C.

Working Breeds.—Alaskan *Malamute*.—One of the oldest of the Arctic sled dogs. A heavy-coated, compact dog weighing 50-85 lbs.

Belgian *Sheep* Dog.—There are six varieties of Belgian sheep dogs, the Groenendael, a long-coated black type, being the most popular. This variety weighs 50-55 lbs. and is used mainly for herding.

Bernese Mountain Dog.--One of the four varieties of Swiss mountain dogs, used mainly as a draught animal. Stands 21-27½ in. high at the shoulder.

Bouvier de Flandre.—A Belgian breed used as police and army aids. Usually fawn or black in colour, and stands 22¾-27½ in. at the shoulder.

Boxer.—Related to other breeds of the bulldog type, having some terrier blood. The boxer is smooth-coated, of medium size and handsome conformation. Excellent as a police aid and home protector.

Briard.—A French breed known as early as the 12th century. A dark-coloured dog standing 22-27 in. at the shoulder. Used primarily as a sheep herder, guard dog and police aid.

Bull-Mastiff.—A massive, short-haired breed developed in England in the latter half of the 19th century by crossbreeding the mastiff and the bulldog.

Collie.—The smooth-coated collie and the more common rough-coated collie are recognized as separate breeds. Both developed in Scotland in the 18th century, the former for driving sheep and the latter for guarding sheep.

Dobernzan *Pinscher*.—A medium-sized guard dog and companion developed by Louis Dobermann, a German breeder, around 1890. Usually black and rust or rust in colour, short-haired and weighing 60-75 lbs.

Eskimo.—One of the northern breeds, famed as a sledge dog. Has long hair and weighs 50-85 lbs.

German *Shepherd*.—A leading working breed, having been used in herding, guard work, battlefield rescue missions, guiding the blind and police assistance. Has long hair, of almost all colours, and stands 22-26 in. at the shoulder.

Great Dane.—One of the largest of the modern breeds, having been developed in Germany to hunt boars. Probably has Irish wolfhound and old English mastiff blood. May be brindle, fawn, blue, black or black and white. Females measure more than 28 in. at the shoulder, males 30 in.

Great Pyrenees.—A large dog, usually white, most commonly used as a watch dog, companion and pack dog. Known in Europe more than 3,000 yrs. ago, and became a favourite of French royalty in the 17th century.

Komondor.—One of the three breeds of Hungarian working

dogs, kept mainly by shepherds of that country for protecting the flocks. An all white breed, with long hair, standing at least 23½ in. at the shoulder.

Kuvasz.—Developed in Hungary in the 15th century from forbears brought from Tibet, the Kuvasz was used for hunting big game, for guard duties and for herding purposes. All specimens are pure white, long-haired and stand 25-27 in at the shoulder.

Mastiff.—A giant, short-haired dog, with heavy head and short muzzle, which has been used in England for more than 2,000 yrs. as a watch dog. A representative of the mastiff family known in Egypt as early as 3000 B.C.

Newfoundland—Originated in Newfoundland from forbears brought there by fishermen from Europe. A large, strong, active dog, black in colour and weighing 110-150 lbs. Landseer Newfoundlands may be almost any colour, but usually are white with black or bronze markings.

Old English *Sheep* Dog.—Developed in England early in the 19th century for driving cattle and sheep. Usually white with markings of grey, grizzle or blue; with long hair over entire body, including the head.

Puli.—The third of the Hungarian working breeds, the puli is an alert, medium-sized dog used primarily for herding sheep. Has a long coat, usually black, grey or white in colour.

Rottweiler—A large, mastiff-type working dog developed by German breeders from stock known to the Romans. Primarily a guard dog and cattle driver, the Rottweiler is black with tan markings and stands 21¾-27 in. at the shoulder.

Samoyede.—An Arctic sledge dog, white in colour and weighing 36-55 lbs.

Schnauzer (Giant).—See Schnauzer under Terrier Breeds, below.

Shetland Sheep Dog.—A miniature collie in appearance, this breed was developed in the Shetland Islands. Stands 12-15 in. at the shoulder, and is usually sable, black or blue with markings of white and tan.

Siberian Husky.—A sled dog developed in Siberia and commonly used in Alaska. Usually grey with white and black markings and weighing 40-65 lbs.

St. Bernard.—This breed has been kept by monks at the Hospice of St. Bernard in the Swiss Alps since the latter part of the 17th century. It is massive, stands 25½-27½ in. at the shoulder, and has red or brindle markings.

Welsh Corgi (Cardigan Type).—This breed was introduced to Wales by the Celts at about 1200 B.C. It is similar to the dachshund in conformation, but has a medium-length coat and erect ears. Used for driving cattle.

Welsh Corgi (Pembroke).—Similar to the Cardigan type corgi in conformation, but having a short tail. Introduced into Wales by Flemish immigrants in A.D. 1107.

Terrier Breeds.—Airedale *Terrier.*—Developed by cross-breeding the now extinct old English terrier with the otterhound. One of the largest of the terriers, black and tan in colour and weighing 38-45 lbs.

Bedlington Terrier.—Developed about 182; in Bedlington, Northumberland, England. Distinctive because of its sheep-like appearance, it weighs 22-24 lbs. and has a thick coat of light blue, liver or sandy hue.

Border Terrier.—An active, game terrier weighing 11½-15½ lbs., with a head akin to that of an otter.

Bull Terrier.—Developed early in the 19th century by cross-breeding of the white English terrier, bulldog and Spanish pointer. There are two varieties—one all-white and rhe other any colour other than white or coloured with white markings. The weight of the standard varieties is 25-60 lbs.

Cairn Terrier.—One of the Scottish breeds, developed for routing otter, foxes and other furbearers. Females weigh 13 lbs., males 14 lbs., and may be any colour except white.

Dandie Dinmont Terrier.—A native of the borderlands between England and Scotland, first recorded as a distinct breed about 1700. Mustard or pepper in colour, dogs of this breed weigh 14-24 lbs.

Fox Terrier.---One of tile best known of the terriers, being popular in the United States, Britain and most of the nations of continental Europe. Developed by the English for routing vermin, the fox terrier may have either a smooth- or wire-haired coat. White is the predominating colour, with dark markings. The fox terrier weight is 16-18 lbs.

Irish Terrier.—An all-red terrier with a wire-haired coat, this breed was developed in Ireland. Similar to the fox terrier in conformation, but somewhat larger, weighing 25-27 lbs.

Kerry *Blue* Terrier.—Ireland's national dog, having been developed in County Kerry before 1835. A distinctive breed, having a light or dark blue coat and weighing 32-38 lbs.

Lakeland Terrier.—Similar to the Irish terrier in conformation, but weighing only 16-17 lbs. Developed in the lake districts of England for routing fox and otter, dogs of this breed may be black and tan, grizzle and tan or blue and tan in colour.

Lhasa Terrier.—Developed in Tibet more than Soo years ago. the Lhasa terrier has a long, straight coat, usually of golden hue.

Manchester Terrier.—The standard Manchester terrier weighs 14-22 lbs., whereas the toy Manchester weighs 7-12 lbs. Both are black and tan in colour, short-haired, with somewhat roached backs. Developed in the Manchester district of England.

Norwich Terrier.—A small, short-legged, wiry-coated dog used for routing foxes, the Norwich usually weighs about 11 lbs. and is red, black and tan or grizzled in colour.

Schnauzer.—There are three size varieties of this breed, the giant standing 21½-25½ in. at the shoulder, the standard type measuring 17-20 in. at the withers, and the miniature type 11½-13½ in. at the shoulder. All are similar in conformation, with hard, wiry coats, rectangular heads and short tails.

Scottish Terrier.—One of the earliest of the terriers indigenous to Scotland, this popular breed usually is black in colour, but may be wheaten, grey or grizzled. An active, short-legged breed weighing 18-20 lbs. and used for routing foxes, rodents and other furbearers.

Sealyham Terrier.—A white terrier having conformation and size similar to that of the more common Scottish terrier. Developed in Wales between 1850 and 1890.

Skye Terrier.—A short-legged and long-bodied Scotch breed, being about 9 in. high at the shoulder, about 40 in. long and weighing 16-18 lbs. The breed's coat is about 5½ in. long and is blue, grey or fawn in colour.

Staffordshire *Terrier.*—Similar to and related to the white bull terrier, but dark in colour, the Staffordshire weighs 35-50 lbs. and was developed from bulldog and terrier blood.

Welsh Terrier.—A squarely-built black and tan terrier standing 15 in. high at the shoulder and weighing about 20 lbs., this breed was developed in Wales for hunting the otter, fox and badger.

West Highland White Terrier.—Of the Scottish family of terriers, this breed is all white and weighs 13-19 lbs. It has the conformation of most of the Scottish terrier breeds, with short legs and a short, cobby body.

Toy Breeds.—*Affenpinscher.*—A rare breed in America, somewhat similar to the more common Brussels griffon in appearance, the affenpinscher has a red or grey wiry coat, a distinctive "beard" and never exceeds 10¼ in. in height.

Chihuahua.—The smallest of all breeds, weighing only 1-6 lbs., the Chihuahua is a native of Mexico. This breed should not be confused with the Mexican hairless, since it may be either short-haired or long-haired.

English Toy Spaniel.—A breed weighing 9-12 lbs., the English toy spaniel has a long silky coat and a head formation somewhat like that of the Pekingese. There are several varieties of this breed, including the Prince Charles, King Charles, Ruby and Blenheim, the main variations being in colour.

Griffon (Brussels).—Developed prior to the 17th century from the affenpinscher, the now extinct Belgian street dog, the Chinese pug and the Ruby spaniel, the Brussels griffon has a wiry, reddish-brown coat and weighs 7-12 lbs.

Italian Greyhound.—A small, short-haired breed of typical greyhound conformation, the Italian greyhound has existed in its present form for more than 2,000 yrs. The average dog of this

breed weighs about 8 lbs.

Japanese Spaniel.—This breed is similar to the English toy spaniel in appearance, but is always black and white or red and white in colour. This spaniel has a head somewhat similar to that of the Pekingese, its coat may be profuse or short and its average weight is about 7 lbs.

Maltese.—This breed, somewhat like the Skye terrier in conformation and type of coat, was developed on the island of Malta more than 2,800 yrs. ago. Its coat is white and long, and it weighs 2-7 lbs.

Mexican Hairless.—A rare breed, probably having descended from the hairless dogs of China, these dogs were established in Mexico by the Aztecs. Not to be confused with the Chihuahua, which is a distinct breed.

Papillon.—A member of the toy spaniel group of dogs which probably was developed in Spain but attained its greatest popularity in France during the reign of Louis XIV. A small breed, predominantly white with patches of other colours.

Pekingese.--One of the most popular of the toy breeds, the Pekingese originated in China before the 8th century. It has a pug type head, including a very short, flat nose. The profuse Pekingese coat may be any colour, and specimens of the breed weigh under 14 lbs.

Pinscher (Miniature).—Similar to the more common Doberman pinscher in conformation and coat, but weighing only 6-10 lbs., this breed was developed in Germany.

Pomeranian.—One of the northern breeds, being related to the chowchow, Alaskan malamute and Norwegian elkhound, the Pomeranian was developed in Pomerania. Germany. Ideal specimens of the breed are compact, short-coupled, weigh about 7 lbs. and have profuse coats and plume tails of varying colours.

Pug.—A short-faced dog which probably originated in China, the pug is a square, cobby breed which weighs 14-18 lbs. and has a short coat which is silver or apricot-fawn in colour.

Toy *Manchester* Terrier.—See Manchester Terrier under Terrier Breeds, above.

Toy Poodle.—See Poodle under *Non-Sporting* Breeds, below.

Yorkshire Terrier.—Probably a descendant of the Skye terrier, having been developed in the Lancashire and Yorkshire areas of England, this small terrier type has a long, straight coat which often touches the ground and usually is dark blue mingled with fawn or bronze.

Nonsporting Breeds.—Boston Terrier.—One of the few breeds developed in America, the Boston terrier became one of the most popular of U.S. dogs. It was developed in Boston in the middle of the 19th century by crossbreeding the English bulldog and the white English terrier. The breed is compactly built, with a square skull, bulldog-type face, brindle and white or black and white in colour, short coat and a weight of about 12-25 lbs.

Bulldog.—An English breed originally used in baiting and fighting bulls. Like other members of the bulldog family, this breed has a short, broad face with protruding lower jaw, a deep-set nose, massive neck and body and rather short, strong legs. Females of this breed weigh around 40 lbs., males 10 lbs. more.

Chowchow.—One of the oldest dog breeds, the chow was standardized in China as early as 150 B.C. It has a large, massive head, flat skull, short nose, deep-set eyes and erect ears. Its coat is abundant, outstanding and may be any solid colour.

Dalmatian.—A medium-sized, short-haired dog, white spotted with black or liver, this breed gets its name from Dalmatia, on the eastern shore of the coast of Venice. The Dalmatian weighs 35-50 lbs.

French Bulldog.—This breed probably was developed of miniature bulldog stock sent to France from England. Specimens are similar to the more common English bulldog in conformation, but are smaller, weighing less than 28 lbs., and have erect ears.

Keeshond.—One of the northern breeds, related to the Samoyede, chowchow, and Pomeranian, the keeshond is considered the national dog of Holland. It has a short, compact body; small, erect ears; fox-like head and a dense grey coat. The breed height is 17-18 in, at the shoulder.

Poodle.—Although the poodle probably was originated by the Germans, it attained its greatest popularity in France and sometimes is called the "French poodle." The standard poodle stands more than 15 in. at the shoulder; the miniature poodle less than 15 in., and the toy poodle never exceeds 12 lbs. All three types may be any solid colour.

Schipperke.—A native of the Flemish provinces of Belgium, the schipperke is all black, tailless and weighs up to 18 lbs. It has a small, foxlike head and is alert and active.

DOG-BANE (*Apocynum androsaemifolium*), **N.** American plant of the dog-bane family (Apocynaceae), called also spreading dog-bane, honey-bloom, wild ipecac and American fly-trap, native to fields and thickets from Quebec to British Columbia and southward to Georgia, Missouri, Arizona and California. It is a rather slender, herbaceous perennial, 1 ft. to 4 ft. high, with widely branching stems, opposite, oval, slightly pointed leaves, and numerous, small, bell-shaped pink flowers, with darker stripes inside, borne in clusters at the ends of the branches. When in blossom from late June to August it is a beautiful wild flower. (*See* APOCYNACEAE; HEMP.)

BY COURTESY OF WILD FLOWER PRESERVATION SOCIETY

NORTH AMERICAN DOG-BANE, AN HERBACEOUS PLANT VALUED FOR THE TONIC PROPERTIES OF ITS ROOT

DOG DAYS, hot summer days, when Sirius, the dog-star, rises in conjunction with the sun.

DOGE, the title of the chief magistrate in the extinct republics of Venice and Genoa. For the character of the office at Venice see the articles COMMUNE: Mediaeval; BUCENTAUR. In Genoa the institution of the doge dates from 1339. At first he was elected without restriction and by popular suffrage, holding office for life; but after the reform effected by Andrea Doria (*q.v.*) in 1528 the term of his office was reduced to two years. At the same time plebeians were declared ineligible, and the appointment of the doge was entrusted to the members of the great and the little councils, who employed for this purpose a machinery almost as complex as that of the later Venetians.

See B. Cecchetti, *Il Doge* di Venezia (1864); E. Musatti, *Storia* della *promissione* ducale (Padua, 1888); and H. F. Brown, Venice: a Historical Sketch (1893).

DOG-FISH, a name applied to several species of the smaller sharks, and given owing to the habit these fishes have of pursuing or hunting their prey in packs. The small-spotted dog-fish or rough hound (*Scyllium* canicula) and the large-spotted or nurse hound (*Scyllium catulus*) are also known as ground-sharks. They keep near the sea bottom, feeding chiefly on the smaller fishes and crustacea. They differ from the majority of sharks in being oviparous. The eggs are enclosed in semi-transparent horny cases, often called "mermaids' purses" and these have tendril-like prolongations from each of the four corners, by means of which they are moored to sea-weeds or other fixed objects, until the young dog-fish is ready to make its exit. The larger of these species attains a length of 4 to 5 ft., the smaller rarely more than 30 in. The picked dog-fish (Acanthias *vulgaris*) is abundant in the temperate seas of both hemispheres, and on both sides of the Atlantic. It attains a length of 4 ft., but the usual length is 2 to 3 ft., the female, as in most sharks, being larger than the male. The body is round and tapering, and the mouth is placed ventrally some distance from the end of the snout. There are two dorsal fins, each armed anteriorly with a sharp spine. This species is viviparous, the female producing five to nine young at a birth; the young when born are 9 to 10 in. long and similar to the parents, except in size. The picked dog-fish is gregarious, and is abundant at all seasons everywhere on the British coasts. They, even more than other dog-fish, are the special enemies of the fisherman, injuring his nets, removing the hooks from his lines, and

CHART OF STEAMING TRACKS OF BRITISH AND GERMAN BATTLE CRUISERS IN ACTION

Admiral Beatty, with the 1st and 2nd battle-cruiser squadrons, surprised Admiral Hipper, commanding the German 1st scouting group, near the Dogger Bank, in the North Sea, on Jan. 24, 1915. A running fight ensued, the German squadron making for port under full steam as soon as they sighted Beatty's ships. The "Blücher" was finally sunk by two torpedoes from the "Arethusa," and the "Seydlitz" was seriously damaged. The approach of the German High-Sea Fleet enabled Hipper to escape without further loss. German casualties were 954 killed, 90 wounded, and 189 taken prisoners; the British, 15 killed and 32 wounded

spoiling his fish. They are eaten, both fresh and salted, on the west coast of England, and are sold regularly in the French markets. Of recent years an attempt has been made to sell them in London under the name of "flake." (*See* SELACHIANS; FISHES.)

DOGGER BANK, an extensive shoal in the North Sea, about 60 m. E. of the coast of Northumberland, England. The depth of water, in some parts only 6 fathoms, is generally from 10 to 20 fathoms. It is well known as a fishing ground. The origin of the name is obscure; but the middle Dutch *dogger* signifies a trawling vessel, and was formerly applied to two-masted vessels employed in the North Sea fisheries, and also to their crews (doggermen) and the fish taken (dogger-fish). Off the south end of the bank an engagement took place between English and Dutch fleets in 1781. Here on Oct. 21, 1904, during the Russo-Japanese War, some British trawlers were fired on by the Russian Baltic fleet. An acute crisis between Britain and Russia followed. The affair was settled by an international commission which reported on Feb. 25, 1905. Compensation was paid by the Russian government.

BATTLE OF THE DOGGER BANK

This naval action was fought during the World War on Jan. 24, 1915, near the Dogger Bank in the North Sea between British and German battle-cruisers and light forces.

Reports from America at this time had led the Germans to think that a plan for blocking their harbours was afoot and Rear-Admiral Hipper was despatched at nightfall on Jan. 23 to reconnoitre off the Dogger Bank. His force consisted of four battle-cruisers of the 1st scouting group, "Seydlitz" (flag), "Derfflinger," "Moltke" and "Bliicher," with four light cruisers and 19 destroyers. Before the ships left the Jade, their strength and intentions had been revealed by their own wireless and Vice-Admiral Beatty left the Forth to intercept them at 6 P.M. on the 23rd. With him were the five battle-cruisers of the 1st and 2nd Battle Cruiser Squadrons, the "Lion" (flag), "Tiger," "Princess Royal," "New Zealand" and "Indomitable," and the four light cruisers of the 1st Light Cruiser Squadron under Commodore W. E. Goodenough in the "Southampton." He was to proceed to a rendezvous in lat. 55deg. 12min. north, long. 3deg. 12min. east, 180m. from Heligoland, where he was to meet Commodore Tyrwhitt with three light cruisers and 30 destroyers of the Harwich force. The 3rd Battle Squadron, of seven "King Edwards," left Rosyth and Admiral Jellicae put to sea from Scapa with the battle-fleet at 9 P.M. In heavy guns Beatty's force was decidedly superior, mounting 24 13.5-in. and 16 12-in. against Hipper's 8 12-in., 20 11-in. and 16 8.2-in.

The Fight **Begins.**—Beatty reached the rendezvous at 7 A.M. It was a crisp winter morning with a calm sea and good visibility. The battle cruisers were in single line ahead with Goodenough's light cruisers two miles on the port bow. Course was then altered to south by west at 18 knots. Ten minutes later "Arethusa," Tyrwhitt's flagship, was sighted southeast about seven miles on the port bow. She had hardly been identified when the flash of guns was seen to the south-south-east. "Aurora," some 15m. behind Tyrwhitt, had met and engaged the German light cruiser "Kolberg," on the port bow of Hipper's squadron coming from the southeast. Each received a couple of hits and "Kolberg" retired at 7:25 A.M.

At the sound of the guns, Beatty ordered the light cruisers to chase to south. "Southampton" had barely gone two miles when she sighted "Aurora" on her starboard bow and, a few minutes later, German battle-cruisers on the port bow to the south-east. Dense clouds of smoke were pouring from their funnels and they were evidently raising steam for full speed. It was then 7:50 A.M. Beatty's appearance had come on Hipper as a surprise snd, turning to the southeast, the latter ran for home.

Pursuit **of** the Germans.—At 8:30 A.M. Beatty's position was lat. 54deg. 50min. north, long. 3deg. 40min. east, and the two had settled down to a long rush towards Heligoland, 140m. away. The British battle-cruisers were in single line ahead on a south-east by south course, working up to full speed. Hipper was 11m. sharp on "Lion's" port bow, in full flight on a south-south-east course. In speed Beatty's squadron bad a decided superiority. It was

able to maintain a seagoing speed of 26 knots, while Hipper was limited at first to 23 or 24. At 8:52, when the range of "Blucher" had come down to 22,000yd., "Lion" opened fire and at 9:05 hoisted the signal to engage. The German battle-cruisers were then forming on a line of bearing to port. At 9:09 Hipper opened fire as "Lion" scored her first hit on "Bliicher."

The action ran on to the southeast with the range gradually decreasing, but it was not till 9:28 that the Germans scored their first hit on "Lion," sending an 11-in. shell through her waterline aft. At 9:43 a 13.5-in. shell crashed through the quarter deck of "Seydlitz," penetrated the after turret and, exploding inside, set fire to the charges in the working chamber. The flames went roaring through the turret, passed through a small door into the adjoining one, set fire to the charges there and, wrapping both turrets in a sheet of flame, slew as one every man inside. "Bliicher" was having trouble with her engines at this time and about 10 A.M. drew out of the line, labouring heavily.

At 10:22 Beatty, to bring the rear of his line into action, ordered the battle-cruisers to form on a line of bearing north-north-west and to proceed at utmost speed. "Lion" had eased to 24 knots to let the ships in the rear come up, and, as the enemy had turned slightly away, the range was increasing. At 10:30 a salvo fell on "Blücher"; a shell penetrated the central ammunition passage, set fire to the cartridges and sent a flash of flame through the fore turrets. The main steam pipe was damaged, her speed came down to 17 knots and she gradually dropped behind, enveloped in smoke.

The Action Broken Off.—The remainder of the enemy were, clearly, bent on escape and, to this end, concentrated their fire chiefly on the leading British ship, the "Lion," which between 10:35 and 10:50 was repeatedly hit with heavy shell, with the result that she started to drop astern, while the other battle-cruisers raced past her. At 11 A.M. the flagship received such heavy injuries that she was thrown definitely out of the fight. Beatty, however, still retained control. Just before this the periscope of an enemy submarine was reported on the starboard bow, and at 10:54 he had made a signal to alter course 8 points (90°) to port to a course north by east. This was the initial cause of the action being broken off. The usual submarine warning was not made by the "Lion," thereby mystifying the other ships and Rear-Admiral Sir A. G. H. W. Moore, the second in command, as to the reason for the manoeuvre, and making it doubly difficult for the signals intended to convey Beatty's subsequent wishes to be interpreted. These, made at 11:02, were an endeavour by the latter to get the squadron to turn back again three points to the north-east, followed by a signal "Attack the enemy's rear." The form in which the signals were displayed, however, was such that they were understood to mean that the ships were to attack the enemy bearing north-east, which was the "Blucher." This ship was by now disabled and rapidly drifting astern of her companions.

Beatty made a final effort to turn the squadron back on to the course of pursuit by signalling "Keep closer to the enemy," but which enemy was not specified. By now, however, the "Lion" was so far astern that Moore, in the "New Zealand," could not read the flagship's signal. Fire was therefore concentrated on the unfortunate "Blucher," while Hipper, with the remainder of the German force, having turned to the east-south-east, drew rapidly out of range. At 11:38 the "Arethusa" came up and fired two torpedoes into the "Bliicher." She ceased firing and, listing heavily, ablaze fore and aft, she sank at 12:13. Hipper was out of sight some fifteen miles off, so Moore formed the battle-cruisers into line ahead and steered to the westward.

Beatty by this time had transferred his flag to the destroyer "Attack" and was racing after his squadron. He reached "Princess Royal" at 12:30 and hoisted his flag, but pursuit was then hopeless and a warning had been received of the approach of the High Sea Fleet. He therefore gave up all idea of renewing the action. Hipper made for home and got in touch with the High Sea Fleet about 2:30 P.M. "Blücher" had been lost, "Seydlitz" seriously damaged and "Derfflinger" hit. On the British side "Lion" had been put out of action and "Tiger" damaged.

Admiral Jellicoe with the battle-fleet met Beatty at 4:30 P.M. "Lion" was taken in tow by "Indomitable" and, screened by light cruisers and destroyers, reached Rosyth safely the next morning. On the British side the result was regarded as disappointing, but it must be remembered that, with the exception of "Blücher," the enemy's speed was not seriously diminished when the action was broken off.

The forces engaged were as follows:

BRITISH

1st Battle Cruiser Squadron.

"Lion" (flag), Vice-Admiral Sir David Beatty, Captain Alfred Chatfield, 28 knots.

"Princess Royal," Captain Osmond de B. Brock, 28 knots.

"Tiger," Captain Henry B. Pelly, 30 knots.

Armament of each ship 8 13.5-in., 16 4-in. ("Tiger" 16 6-inch).

2nd Battle Cruiser Squadron.

"New Zealand" (flag), Rear-Admiral Sir Archibald Moore, Captain Lionel Halsey, 25 knots.

"Indomitable," Captain Francis W. Kennedy, 25 knots.

Armament of each ship 8 12-in., 16 4-inch.

1st Light *Cruiser Squadron.*

"Southampton," Commodore W. E. Goodenough, Commander E. A. Rushton.

"Birmingham," Captain Arthur A. Duff.

"Nottingham," Captain Charles B. Miller.

"Lowestoft," Captain Theobald W. Kennedy.

Armament of each ship g 6-in., "Southampton" 8 6-in.; 25·5 knots.

Harwich Flotillas.

"Arethusa," Commodore Reginald Tyrwhitt.

10th Flotilla: "Meteor" (Commodore Hon. Herbert Mead), "Miranda," "Milne," "Mentor," "Mastiff," "Minos," "Morris"; speed 34 knots.

3rd Flotilla: "Undaunted" (Captain Francis St. John), "Lookout," "Lysander," "Landrail," "Laurel," "Liberty," "Laertes," "Lucifer," "Lawford," "Lydia," "Louis," "Legion," "Lark; speed 29 knots.

1st Flotilla: "Aurora" (Captain Wilmot S. Nicholson), "Acheron," "Attack," "Hydra," "Ariel," "Forester," "Defender," "Druid," "Hornet," "Tigress," "Sandfly," "Jackal," "Goshawk," "Phoenix," "Lapwing"; speed 27 knots.

GERMAN

1st Scouting Group (battle-cruisers).

"Seydlitz," Rear-Admiral Hipper, 10 11-in., 12 5.9-in., 26.5 knots.

"Derfflinger," 8 12-in., 12 5.9-in., 26.5 knots.

"Moltke," 10 11-in., 12 5.9-in., 25 knots.

"Blucher," 12 8.2-in., 8 5.9-in., 24 knots.

2nd Scouting Group (*light cruisers*).

"Graudenz," "Stralsund," "Kolberg," "Rostock."

Casualties.—"Blücher," which sank, received about 40 hits and 2 torpedoes, had 792 of her crew killed, 45 wounded and 189 taken prisoner. "Seydlitz" sustained 3 hits, had 159 killed and 33 wounded. "Derfflinger" was only hit once, and "Kolberg" twice, the latter having 3 killed and 2 wounded.

On the British side "Lion" was put out of action with 12 hits; 1 killed and 20 wounded. "Tiger" received 7 hits, having 10 killed and 11 wounded: "Aurora" received 2 hits and "Meteor" sustained 1 hit, with 4 killed and 1 wounded. The British fired 1,154 rounds of heavy gun ammunition, of which 708 were armour-piercing shell, 77 common, g6j high explosive and 4 shrapnel. The Germans fired 976 rounds from their heavy guns.

BIBLIOGRAPHY.—Sir J. S. Corbett, History *of the* Great War: Naval Operations, vol. a (1921); A. B. Filson Young, With the Battle Cruisers (1921); see also the German official publication, Krieg *zur See: Nordsee,* vol. 3.

DOGGETT or **DOGGET, THOMAS** (d. 1721), English actor, was born in Dublin, and made his first appearance in London in 1691 as Nincompoop in D'Urfey's *Love* for *Money.* He followed Betterton to Lincoln's Inn Fields, creating the part of

Ben, especially written for him, in Congreve's *Love for Love*, with which the theatre opened (1695); and next year played Young Hobb in his own *The Country Wake*. He was associated with Cibber and others in the management of the Haymarket and Drury Lane, and he continued to play comedy parts at the former until his retirement in 1713. In 1715 he founded the prize of "Doggett's Coat and Badge," "in commemoration of his Majesty King George's happy Accession to the Brittish Throne." The prize was a red coat with a large silver badge on the arm, bearing the white horse of Hanover, and the race had to be rowed annually on Aug. 1 on the Thames, by six young watermen who were not to have exceeded the time of their apprenticeship by twelve months. The names of the winners have only been preserved since 1791. The race is still rowed each year, but under modified conditions. The date of his death is variously given as Sept. and Oct. 1721.

See Thomas Doggett, Deceased (1908).

DOG LICENCES. The great growth of dog-keeping is revealed by the record of the dog licence duties, which show that the dog populations have become enormous. In Great Britain dogs over six months old must have a licence which costs 7s. 6d. a year. Dogs used as guides by blind persons, sheep and cattle dogs, and hounds under 12 months old which have not hunted, are exempt. In 1936, 2,932,612 dog licences were taken out, but it is probable that there are about four million dogs in Great Britain. The penalty for non-compliance with the law is a fine up to £5. The licences are issued at post offices, and their revenue goes to the local authorities in whose areas the receiving post office is situated. The law requires also that dog collars should be engraved with their owners' names and addresses, but it is not strictly enforced. In Great Britain there is no way of telling if a particular dog is licensed or not.

In the Irish Free State dogs must be licensed when one month old and in Northern Ireland when six months old; in each case the licence costs 5s.

In the British oversea Dominions dog licensing is general. In Canada each province by statute empowers its municipalities to impose a dog tax. Thus in Ontario the licence costs $2 for a dog and $4 for a bitch, a higher duty being imposed when more than one animal is kept. In Australia licences vary little; in Victoria all dogs are taxed at 5s. a year; in South Australia a dog is licensed at 5s., a bitch at 7s. 6d. All dogs must wear a collar or tab unless kept for hunting or coursing. In South Africa the tax is high, being 12s. 6d. in Natal and 10s. in the Transvaal, where there is a £5 tax on all dogs with a greyhound strain that can be used for hunting.

In Germany all dogs are taxed, the amounts varying in the different districts, being usually small in villages and high in the big towns, and the law is strictly enforced. In Berlin the dog tax is £3 in English money. Sheep dogs on German farms go free of tax. A metal disc bearing the number of the licence must be attached to each dog's collar.

In the United States licences are issued variously by a State, county or municipality. Enforcement of the ordinances requiring registration of dogs is usually within the police powers conferred upon local corporations, but some States, such as Pennsylvania and Connecticut, have general laws on the subject. Registration of dogs above the age of six months, except those in kennels, for which there are special regulations, is usually required annually. A stated fee is paid to the city, county or State officer for the licence, the applicant receiving a tag which must be attached to the animal's collar as evidence of such registration. In case the tag is lost, a duplicate may be obtained, but failure to register a dog, under most ordinances, authorizes the officers to kill it.

DOGMA, DOGMATIC THEOLOGY. Theology, like political economy, has no technical terminology, but seeks to use the language of ordinary life in a specialized sense. Colloquially, to assert dogmatically is contrasted with speaking tentatively. But also, dogmatism is contrasted with proof. "I'm not arguing with you, I'm telling you"—he who so speaks is, reasonably or unreasonably, dogmatic. The claim of accuracy akin to that of science and of authoritativeness akin to that of law, are the two poles of the universe of dogma. In the New Testament the word means decree, although the Greek fathers early misunderstood it. The older philosophical use, for the leading and inviolate principles of any system, is best illustrated by the *Ipse dixit* of the Pythagoreans; whatever their master had said was final. German theologians have sought to define the word for their own purpose by drawing a line round those doctrines which deserve to be called dogmas and by separating them from the region of open questions. According to W. Herrmann (opening p. of *Dogmatik* in *Die Kultur der Gegenwart*), "We must not mainly understand by a 'Dogma' a definition upon Church authority. Such a definition is only the last stage in a long process, which has all along been actuated by the thought of a *revealed doctrine*. And that conception is the main element in 'Dogma.' .. In contrast with this F. Loofs (*Leitfaden zum Studium der Dogmengeschichte*, ed. 4. p. 9) holds that "Dogmas are those affirmations of religious faith whose acknowledgment a Church expressly requires from its members or at least from its teachers." Harnack in his great *History of Dogma* prefers a more historical definition. Dogma is (1) a creation of Greek thought on the soil of the gospel and (2) kindred mediaeval findings, but (3) it is transformed or disappears in Protestantism through deepening religious insight, in Socinianism and the Enlightenment through the dominance of rationalism, in the post-Tridentine church through more sweeping exercise of authority. Each of these definitions has its merits. Something is to be said also for the view that, in the modern Church of Rome, we have dogmatism superlatively developed—partly just because that Church forbids one to draw a hard and fast line separating dogmas from pious opinions, or formulated dogmas from unformulated; all the Church's teaching being infallibly and dogmatically true. The choice of a definition can only be made by balancing advantages against disadvantages.

As to dogmatic theology, all that need be said is that it is the most widely accepted name for the systematic statement of Christian doctrines—and not merely of dogmas, if dogmas are to be separated off from the floating mass of theories.

When the Church inherited the Jewish scriptures, it took over an instalment of dogma, and one beset for it by special difficulties too little recognized by theologians—a book holy and divine, and yet not the perfect revelation of God! When, in controversy with Gnosticism, a collection of New Testament writings was added to the "Old Testament," the inheritance grew; and the dogmatic postulate, that all scriptures contain the same teaching, became no easier to vindicate. One cannot deny that Calvinism in the past or that Fundamentalism in the present is in a very high degree dogmatic. For each of these, the corpus of scripture is the sum total of dogma; and to the scripture every thought of man is to bow. The Catholic ethos adds other things—an emphasis on sacraments; a gathering up of the contents of the Bible (with unconfessed modifications) into creeds; a franker announcement of church authority. In these features of Catholicism there appears to be a fuller realization of the dogmatic temper than where appeal is made to the Bible alone.

Harnack has good reason for insisting on the fundamental importance of the great Eastern dogmas, Trinity and Incarnation. These expressed the piety of Eastern Catholicism; and they passed into the mediaeval West and even into historic Protestantism as presuppositions—only presuppositions, but as such indispensable. And yet, in their original shaping, the West had played no small part, when curiously hard questions were raised by the East. It has been felicitously observed that "the East thought that everything could be explained; and the West, that nothing needed to be explained." Even at the first General Council (Nicaea, 325) it appears certain that Western minds brushed aside Eastern scruples in imposing the watchword "homoousios"—a term with questionable associations, but a term which not even the slipperiness of the Arians could evade. So again, at Chalcedon (451) and at the First Trullan Council (680), the West threw in the dogmatic watchword round which crystallization ensued The Councils of Constantinople (381) and Ephesus (431) were more Eastern. The adoption of a non-Biblical phrase at Nicea. constituted a landmark in the growth of dogma; it is true, since

the Church—the universal Church speaking by its bishops—says so; though the Bible does not! Even at Nicea there was a small obstinate minority. Oliver Wendell Holmes draws the inference that Catholic unanimity means "a majority vote" (followed by excommunication of the few). Similarly, from Nicea onwards, formulated dogma is-accompanied by anathemas. We have good reason for including in our definition of dogma this mark—dogma (for all who receive it) is an affirmation which it is sinful to deny, or to challenge, or to ignore. It is a singularly ominous claim.

Another landmark is established for us by the so-called Athanasian creed—a (probably later) Western summary and elaboration of Eastern results, with two well-marked divisions concerning the Trinity and concerning the Person of Christ. It is "before all things" necessary to be accurate in minute detail regarding these doctrines. Sacraments are not so much as named. Indeed, except in the "one baptism for the remission of sins" of the "Nicene-Constantinopolitan" creed, the great early creeds are strangely silent concerning sacraments; although no Catholic mind could ever doubt that it is "he that believeth and is baptized" who shall be saved. In one sense, then, the Athanasian creed marks a climax. It puts the claim of dogma amazingly high. Though it has not forgotten that Christ is "to judge . . . all men . . . according to their own works," orthodoxy is "before all things necessary."

Yet the mediaeval West goes on to alter the balance of emphasis in several ways. First, it works out the theory of sacraments in fuller detail—numbers them as seven; specifies them one by one; includes in its findings the staggering miracle of transubstantiation. And in all these points the East accepts results from the West. Sacraments will not save if an obex or hindrance is wilfully interposed (*e.g.,* by deliberate purpose of mortal sin); and the doctrine of reception in voto—heaven taking the will for the deed—seems to shake the theory to its foundation. But the emphasis is laid upon the necessity of sacraments, even at the expense of doctrine. For, secondly, implicit faith may suffice lay Christians—may possibly suffice many of the clergy. It is a popular error, though shared by some well educated persons, to speak of implicit "obedience." Fides *implicita* is the correct phrase. By assenting in general terms to Church teaching, while believing explicitly the minimum creed of Heb. xi. 6, one believes by *implication* whatever else is de *fide*. We even meet with the position that there is merit before God in believing heretically, if one honestly supposes that one's heretical view is taught by the Church. All this is a notable counter-stroke to the detailed dogmatism of the Athanasian creed. One understands the motives at work; but it is not with God that "we have to do," still less with conscience, but with—the Church. There is no shadow of excuse in the theory for dissent from Church teaching. Ignorance is encouraged; bad mistakes are excused; but submission is exacted to the uttermost.

The third mediaeval innovation is the Thomist doctrine of mystery. While reason and conscience warrant theistic belief, revelation includes things which reason cannot grasp. Again one comprehends the motive; but again one observes how the significance of the Church is aggrandized by the new doctrine. An enemy might say that doctrines which are "mysterious" in the technical sense are the fossilized remains of what once was living thought. We have a formula; true; but what does the formula contain? No child of the Church dare seek to answer. If the progress of dogmatic definition means the condemnation of views which in the past were innocent, the goal of the dogmatic progress seems to lie altogether beyond the region of knowledge.

Genius in Protestant theology was confined almost entirely to Luther; and even he in later life stiffened and hardened. When he proclaims that justification by faith is in itself the *articulus stantis* vel cadentis *ecclesiae*—"article" is a frequent synonym for dogma—he is seeking to gather up a multitude of authoritative dicta in one thrilling personal experience. So too when he graduates the books of the New Testament he is claiming to go beyond the letter even of scriptural authority in the strength of his knowledge of the gospel of salvation. In words of his. which are written on his monument at Worms, and which might be called the undying charter of evangelical Protestantism, Those who truly know Christ cannot be caught in the snare of any human authority. While Luther was incomparably the most daring, all the early reformers hesitated over the great Greek dogmas—but all alike brushed their hesitations aside, and reimposed upon the modern time the presuppositions of their fathers. Similarly, the Protestant doctrine of inspiration grew steadily harder. An imperfect but valuable attempt to construe Christianity as a thing of experience was made by Schleiermacher; and the school of Ritschl has even more carefully sought after "Anschluss an Luther." Historically it is a fair question whether Protestant evangelicalism ought to speak of dogmas at all. This means that doctrine is for it a less thing than Christian life, and that "we know in part."

The Council of Trent (1545–63) for the first time dogmatically places unwritten tradition side by side with scripture; it also subordinates scripture text and interpretation to the Church's authority. After the period of general relaxation in the 18th century, movements of reaction everywhere set in. In the Church of Rome Pius IX. (1854) proclaimed de suo the Immaculate Conception of the Virgin, and the Council of the Vatican (1870) recognized the Pope's personal authority as equal to that of any council. In quaint technical language, his formal pronouncements are "irreformable." Thus dogma makes quite clear that the "development" of which J. H. Kewman and others speak is purely one of accretion. Nothing can be cancelled. Nothing can be bettered—it is divinely perfect. Alike in 1854 and in 1870, the decreta claim to reiterate a "divinely revealed doctrine" or "dogma." The Vatican council also makes Thomist apologetic de *fide*. (1) Theism is demonstrable. But (2) there are unintelligible mysteries in revealed faith. The former position seems highly complicated. It is now a dogma that, dogmatic revelation apart, reason itself proves the being of God, if you hesitate over this, anathema *sis*. The highroad of reason is prescribed to you. authoritatively; and the goal is also prescribed. If your reason does not lead you to the goal, anathema sis. And if you fail to recognize mysteries above "though not contrary to" reason, anathema *sis*.

When for the first time a closure was introduced into the House of Commons, Lord Salisbury "did not believe the Liberals were sharpening a scimitar in order to cut bread and butter." The Church of Rome since 1871 has possessed the keenest possible cutting weapon, but has cut with it—nothing. The dogmatic impulse seems to have temporarily exhausted itself in placing the Pope upon his pinnacle.

At the opposite theological extreme from Roman Catholicism, radical Protestantism shows a germ or a vestige of dogma, or at any rate a real parallel to dogma, if it asserts (with G. B. Foster) the Finality of the Christian Religion.

It has been proposed by an eminent scientific writer, Dr. Whitehead, that we should speak of the "dogmas" of science, and should recognize that these must from time to time be "changed." Apparently, the first principles underlying scientific theory are working hypotheses. Such things of course are endlessly modifiable. But a student of theology must hold that it will not tend to clearness of thought if working hypotheses are called "dogmas."

LITERATURE.—Matthew Arnold's Literature and Dogma (1873) is important for literary usage: cf. A. B. Bruce, Chief End of Revelation. Classical and early Christian usages, E. Hatch, Hibbert *Lect.* (1888), pp, 119, 120; J. B. Lightfoot on Colossians ii. 14 (20); W. Schmidt, *Dogmatik,* vol. i. (1895)—many quotations in *extenso;* C. Stange, *Das* Dogma und seine Beurteilung in der neueren Dogmengeschichte (1898)—a pamphlet protesting against what Loofs terms the "generally accepted view." Articles in the (Roman Catholic) Kirchenlexikovz of Wetzer and Welte, 2nd ed. (by Hergenröther and Kaulen), 1882–1901. Arts. "Dogmatik" (J. Köstlin), "Dogmengeschichte" (F. Loofs) in Herzog-Hauck's Encykl. *f. prot. Theol.* (vol. iv., 1898). Art. "Glaubensartikel" in previous ed. (Herzog-Plitt, vol. v., 1879) by C. F. Kling and L. F. Schoeberlein. Along with Foster, Troeltsch should be studied; English summaries in R. S. Sleigh's *Sufficiency* of Christianity and *Ernst* Troeltsch, and briefly in a paper on Troeltsch by the present writer, Congregational *Quarterly* (April, 1925). J. M. E. McTaggart's Some *Dogmas* of Religion interprets dogma as claiming ultimate absolute truth. (See also THEOLOGY.) (R. MA.)

DOGMATISM is the uncritical acceptance and application of any belief, especially of those ultimate or fundamental beliefs

known as principles. In philosophy the term has been applied by Kant (*q.v.*) rather sweepingly to most preceding systems of philosophy on account of their alleged neglect to examine "critically" the nature and bounds of human knowledge as a preliminary step to their construction.

DOGON, a light-skinned patrilineal people of medium stature (also known as Habe) in the Bandiagara highland and Hombori hills districts of the French Sudan. Their language. with many dialects, is related to Mandinga. The villages are independent and ruled by an elected sacerdotal headman (*Hogon*), assisted by a council of elders and dignitaries (*seru*). In certain groups girls belong to their maternal uncle. The family estate is first inherited by the brother of the deceased who succeeds to the family headship. Personal property (according to its male or female character) passes to the son or daughter. They are excellent husbandmen, do some cattle raising, are animists and offer seasonal sacrifices, with, quite recently, human victims. Each village is protected by a sacred animal. There are traces of totemism and the dead are placed in cliff caverns.

See Arnaud, "Notes sur les montagnards Habe des Cercles de Bandiagara et de Hombori (Soudan Français)," ***Revue*** *d'Ethnogr. et Trad. pop.* (1921).

DOGRA, an inhabitant of the Duggar tract in the foothills. now mostly comprised in the Jammu territory of Kashmir, India. Duggar appears to mean the-"land between two lakes." as the original home of the Dogra people was situated between the lakes of Siroensar and Mansar. Sanskritized as Drigarh-desh, it is unknown to literature.

The Duggar is inhabited by a number of castes, including Brahmans, about five classes of Rājpūts with numerous septs and the usual under castes. The Dogra who enlists in the Indian army is or should be a Rājpūt of some degree from this or the adjacent sub-Himalayan tracts.

He is an excellent soldier. The Dogra regiments acquired their high reputation in the first Sikh war.

DOGS, ISLE OF, a district of east London, England, on the north bank of the Thames, forming the southern extremity of the metropolitan borough of Poplar (*q.v.*). It is enclosed on three sides by a bend of the Thames formed by Limehouse. Greenwich and Blackwall reaches, and includes Millwall (with Millwall dock) on the west and Cubitt Town on the east; the West India docks across its northern end make of it almost an island. Greenwich tunnel (1902) for pedestrians and vehicles passes under the river here. The whole district is occupied by docks, riverside works and poorhouses. The origin of the name is not certainly known. The suggestion that it is corrupted from the Isle of Docks falls to the ground on the question of chronology; another, that there were royal kennels here, is improbable.

DOG STAR: *see* SIRIUS.

DOG'S-TOOTH VIOLET, any plant of the genus *Erythronium* of the lily family (Liliaceae) comprising about 1*j* species. all, except one, North American. They are low herbs with unbranched stems which spring from deep corms and bear near the surface of the ground a pair of unequal leaves, often mottled with dark splotches, and large, nodding, lily-like, mostly solitary flowers on slender stalks. The European dog's-tooth violet (E. *denscanis*), the only old world species, a delicate spring-bloomer, with rose-purple flowers, is planted in borders and rockeries. The best known representative in eastern North America is the yellow dog's-tooth violet (E. *americanum*), known also as yellow adder's-tongue and trout-lily, with yellow flowers, $ in. to 1½ in. long, on stalks 6 in. to *8* in. high. This handsome spring wild flower is native to moist woods from Nova Scotia to Minnesota and southward to Florida and Arkansas. The similar but smaller white dog's-tooth violet (E. *albidum*), called also fawn lily, with white flowers, occurs in low woodlands from Ontario to Minnesota and southward to Georgia and Texas. A conspicuous species in the Rocky mountain region is the large-flowered (E. *grandiflorum*), variously called Adam-and-Eve and glacier lily with flower stalks *8* in. to *16* in. tall, bearing 1 to 5 yellow flowers *1* in. to 2 in. long. The avalanche lily (E. *montanum*), common in alpine meadows in Washington and Oregon, is a smaller plant with white flowers

DOG-TOOTH. in architecture, a band decoration of adjoining, projecting triangles, called, from its saw-tooth shape, in French, *dent de scie.* Early examples of this decoration are found in Syria and in the Mesopotamian valley, *e.g.*, in the palace front at Rabbath-Ammon (built either in the last years of the Sassanian dynasty or in the early part of the Mohammedan rule), where it is used on arch mouldings; and in a highly decorative form, in the palace of Machitta of the 8th century. It is found widely during the Romanesque period throughout Europe, where it is thought to have been introduced by the Crusaders from the east, and is particularly common in Norman work in France and England, appearing as the chevron (*q.v.*) and zig-zag. It often appears in arch mouldings as a series of projecting pyramids, the sides decorated with foliage. To its supposed resemblance, in this form, to a dog's-tooth violet, some people incorrectly attribute the origin of its name.

DOGWOOD, the name applied to shrubs and small trees of the genus *Cornus,* of the family Cornaceae, comprising some 60 species which, except for a single Peruvian species, are found in north temperate regions. They are mostly hardy shrubs, usually with handsome foliage and attractive flowers and fruits. Several are widely cultivated as summer and autumn ornamentals and also for the winter effect of their brightly coloured branches. The common European dogwood, prickwood, skewerwood, cornel or dogberry (*C. sanguinea*), is a shrub reaching a height of 8 ft. or 9 ft., and is commonly found in hedges, thickets and plantations in Great Britain. Its branches are dark red; the leaves, egg-shaped, pointed, about 2 in. long by 1½ in. broad, turn red in the autumn; the flowers are dull white, borne in terminal clusters. The berries are small, of a black-purple colour, bitter and one-seeded, and contain a considerable percentage of oil. The white wood is very hard, and, like that of various other dogwoods, is used for making ladder-spokes, wheelwork, skewers, forks and other implements.

About 20 species are native to North America, mostly found east of the Rocky mountains, only 6 occurring on the Pacific coast. Of these the most striking are the flowering dogwood (*C. j'iorida),* of the eastern and southern United States, one of the most beautiful of American flouering trees, and its very similar counterpart, the western dogwood (*C. nuttallii*), of the Pacific coast. The wood of the former is used for shuttles. Both are usually small trees 10 ft. to 1; ft. high, but occasionally 40 ft. or more, bearing in early spring a profusion of flower heads each surrounded by four flowering bracts (involucre) *1* in. to *3* in. long, usually white but varying to rose-red. giving the head the appearance of a flower *2* in. to 5 in. across. The red-flowered forms of *C. florida* are extensively propagated for ornament. Other well-known North American species are the red-osier dogwood or kinnikinnick (*C. stolonifera),* found across the continent, the silky dogwood (*C. amomum*), the panicled dogwood (*C. paniculata*), and the alternate-leaved or pagoda dogwood (*C. alternifolia*), natives of the eastern states and adjacent Canada. There are also two low, almost herbaceous, species—the dwarf cornel or bunchberry (*C. canadensis),* found from Newfoundland to Alaska south to Virginia and California, and the northern or Lapland cornel (*C. suecica),* native across Canada and northward of the Arctic zone, also in Scotland, northern Europe and Asia. Both bear clusters of brilliant red fruits; those of the latter are eaten by the Eskimos.

The widely planted Cornelian cherry (C. *mas),* a native of Europe and northern Asia. is a handsome shrub with glossy foliage, clusters of yellow flowers, and shining scarlet edible fruits which are made into preserves. The Japanese Kousa (*C. kousa*), native to eastern Asia, with creamy-white flowering bracts *3* in. across and fruits united in a globular head, is also grown as an ornamental shrub. The Jamaica dogwood, the root-bark of which is poisonous, is *Ichthyomethia piscipula,* of the family Leguminosae. (E. S. HR.)

DOHERTY, CHARLES JOSEPH (1855–1931), Canadian politician, was born at Montreal on May 11, *1855,* and educated at McGill university. Called to the Quebec bar in 1877, he became a Q C. in *188;* and was *a* puisne judge of the superior court of Quebec from 1891 to 1906. He was first elected to the

House of Commons as a Conservative member for the St. Anne's Division of Montreal in 1908 and became Minister of Justice in Sir Robert Borden's Government in 1911, a post which he held until 1921. He joined the Unionist Government in Dec. 1917 and, as acting Prime Minister and Minister of Justice, he had the difficult task of administering the Military Service Act. In 1918 he accompanied the prime minister to the Peace Conference at Paris, and in 1920 was one of the Canadian representatives at the League of Nations. He was appointed to the Privy Council, London, in the same year.

DOHERTY, HUGH LAWRENCE (1875–1919), English lawn-tennis player, was born at Clapham, London, on Oct. 5, 1875. He was educated at Westminster school and Trinity college, Cambridge. At Cambridge he and his brother, Reginald F. Doherty (1872–1911), made their names as tennis players. They were undoubtedly among the greatest and most artistic players of their day, and their joint work On *Lawn Tennis* (1903) is a classic of the game. The elder brother held the All England singles championship at Wimbledon from 1897–1900, and the younger from 1902–06, when he resigned the title. Playing in doubles, the brothers were champions from 1897 to 1905, being only once defeated, by S. H. Smith and F. L. Riseley, in 1902. H. L. Doherty won the American national championship in 1903. During the war he was in the anti-aircraft service, and the hard work entailed probably hastened his death, which took place on Aug. 11, 1919.

DOHNÁNYI, ERNST VON (1877–), Hungarian composer, pianist and conductor, was born at Bratislava (Pressburg) on July 27, 1877. He studied at the Budapest Royal Academy, and was for a short time a pupil of Eugen d'Albert. He attracted notice by his first pianoforte quintet as early as 1895. He was appointed professor of the pianoforte at the Berlin Hochschule (1908) and director of the Academy at Budapest in 1919. He became conductor of the Philharmonic orchestra of Budapest, and conducted with notable success in the United States. The style of his compositions is conservative and individual and carries on the romantic traditions of the 19th century. Among his principal works may be mentioned *Die Schleier der Pierrette* (ballet pantomime); Tante Simona (comic opera, 1912); *Der Turmder Woijwoden* (opera, 1922); also orchestral and chamber music and songs, all of a high order and giving him a place among the first composers of his day. As a pianist he also takes high rank.

DOHRN, ANTON (1840–1909), German zoologist, was born on Dec. 29, 1840, at Stettin, the son of Karl Dohrn, coleopterist, and editor of *Linnae Entomologia* (16 vols., 1846–66). After studying at Jena, under Haeckel, he devoted himself to the investigation of marine animals, and in 1870 founded the famous zoological station at Naples. He died on Sept. 26, 1909, at Munich. His publications are *Untersuchungen über Bau u. Entwicklung der Arthropoden* (18 jo); *Der Ursprung der Wirbelthiere* (1875); and *Studien zur Urgeschichte des Wirbeltlzierkorpers* (1882).

DOIRAN, BATTLE OF, 1917. This abortive offensive by the British on the Doiran sector on April 24, 1917, and the subsequent attempts is described under SALONIKA CAMPAIGNS. The British forces were here launched against the most formidable positions with the idea of easing the way, by attracting enemy reserves, for a decisive Allied stroke elsewhere—which was suspended almost before it began.

DOL, a town of north-western France, in the department of Ille-et-Vilaine, *36* m. N. of Rennes on the Ouest-État railway. Pop. (1936), 3,720. The town was unsuccessfully besieged by William the Conqueror, taken by Henry II. in 1164 and by Guy de Thouars in 1204. In 1793 the Vendeans there defeated the republican forces who had taken refuge within its walls. The bishopric was suppressed in 1790. Dol is situated to the south-west of the rich agricultural district known as the marsh of Dol, where market-gardening is especially flourishing. Picturesque houses of the 14th and 1 jth centuries still stand with projecting upper storeys. The grey granite cathedral, mainly 13th century. dedicated to St Samson, is interesting for the English character of its design, for its stained-glass windows of the 13th century and for the finely sculptured tomb of Bishop Thomas James (d. 1504). About 1½ m. from the town is the *pierre du Champ Dolent,* a menhir some 30 ft. in height; not far off stands the great granite rock of Mont Dol, over 200 ft. in height, surmounted by the statue and chapel of Notre-Dame de l'Espérance. Dol has trade in grain, vegetables and fruit, and there are salt-marshes. Tanning and leather-currying are carried on.

DOLABELLA, PUBLIUS CORNELIUS, Roman general and son-in-law of Cicero, was born about 70 B C. In the civil wars he at first took the side of Pompey, but afterwards went over to Caesar and was present at Pharsalus. To escape the demands of his creditors he introduced (as tribune) a bill proposing that all debts should be cancelled. This was resisted by his colleagues and led to disturbances in Rome. Caesar, on his return from Alexandria, seeing the expediency of removing Dolabella from Rome, took him as one of his generals in the expedition to Africa and Spain. On Caesar's death Dolabella seized the consulship (which had already been conditionally promised him), and, by making friends with Brutus and the other assassins, was confirmed in his office. When, however, M. Antonius offered him the command of the expedition against the Parthians and the province of Syria he changed sides at once. His journey to the province was marked by plundering, extortion, and the murder of C. Trebonius, proconsul of Asia, who refused to allow him to enter Smyrna. He was thereupon declared a public enemy and superseded by C. Cassius (the murderer of Caesar), who attacked him in Laodicea. On the capture of the place, Dolabella ordered one of his soldiers to kill him (43). Throughout his life he was a profligate and a spendthrift.

See Cicero's *Letters* (ed. Tyrrell and Purser); *G.* Boissier, *Cicero and his Friends* (Eng. trans. 1897); Orelli, *Onomasticon Tullianum;* Dio Cassius xli. 40, xlii. 29, xliii. 51, xliv. 22, xlvi. 40, xlvii. 30; Appian, *Bell. civ.* iii. 7, iv. 60.

DOLCE, LUDOVICO or **LUIGI** (1508–1568 or 1569), Italian writer, was a native of Venice. He wrote some 70 works, but is remembered chiefly for his *Marianna,* a tragedy from the life of Herod, which was recast in French by Tristan and by Voltaire, and still keeps a place on the stage. Four licentious comedies, *Il Ragazzo* (1541), *Il Capitano* (154j), *Il Marito* (1560), *11 Ruffian* (1560), and seven of Seneca's tragedies complete the list of his dramatic efforts.

See A. Salza, *Delle commedie di Ludovico Dolce* (1899).

DOLCI, CARLO or **CARLINO** (16 16–1686), Italian painter, was born in Florence on May 25, 1616, and died there on Jan. 17, 1686. He was a disciple of Jacopo Vignali; and when only 11 years of age he attempted a whole figure of St. John, and a head of the infant Christ. His portrait of his mother displayed a new and delicate style which brought him extensive employment at Florence and in other parts of Italy.

Carlo Dolci holds somewhat the same rank in the Florentine that Sassoferrato does in the Roman school. Without the possession of much genius, invention or elevation of type, both these artists produced highly wrought pictures, extremely attractive to some tastes. Many of his pictures represent the patient suffering of Christ, or the sorrows of the Mater Dolorosa. Dolci was, in fact, from early youth, exceedingly pious; it is said that during Passion week every year he painted a half-figure of the Saviour. Among his best works are the "St. Sebastian"; the "Four Evangelists," at Florence; "Christ Breaking the Bread," in the marquess of Exeter's collection at Burleigh; the "St. Cecilia" in Dresden; an "Adoration of the Magi"; and in especial "St. Andrew praying before his Crucifixion," in Florence, his most important composition, painted in 1646. There are examples also in the National gallery and Dulwich gallery, London; and at Rome. Vienna, Munich, Berlin and Leningrad.

DOLDRUMS, the shifting zone of equatorial calms or variable airs between the trade winds. The weather is hot, moist and extremely dispiriting with heavy and frequent rainfall usually accompanied by thunderstorms In the old days, sailing vessels sometimes lay helplessly becalmed for weeks with the crew "in the doldrums" ("in the dumps").

DOLE, SANFORD BALLARD (1844–1926), jurist and statesman of the Hawaiian Islands, was born in Honolulu on April 23, 1844, the son of American missionaries. After studying law in Boston he returned to Hawaii to become one of its leading lawyers, a member of the legislature from 1884 to 1887, and a leader in the reform movement which secured the Constitution of 1887. Also in 1887 he was appointed an associate justice of the supreme court, which office he held until the monarchy was overthrown in 1893 by a revolution of which Dole was himself a leader. In May, 1893, he was elected by the Constitutional Convention as the first president of the Republic of Hawaii. With firmness and wisdom he guided the Republic through a difficult period, suppressing revolutions and stabilizing the governmental machinery. When President Cleveland demanded the restoration of Queen Liliuokalani to the throne Dole refused to yield, claiming that Cleveland was without authority to act. In 1898 he went to Washington in the interests of annexation, and when that event took place in 1900 Dole was appointed by President McKinley as the first territorial governor. In 1903 he became United States district judge of Hawaii and in 1909 was reappointed to a second term. At its expiration in 1915 he retired to private life in Honolulu, where he died on June g, 1926.

DÔLE, a town of eastern France, capital of an arrondissement in the department of Jura, 29 mi. S.E of Dijon on the Paris-Lyon railway. Pop. (1936), 22,885. Dôle, the ancient *Dola,* was in Roman times the meeting place of several roads, and considerable remains have been found there; in the later middle ages, till 1648, it was the capital of Eranche Comté and seat of a parlement and a university; but in 1479 the town was taken and destroyed by Louis XI. It subsequently came into the hands of Maximilian of Austria, and in 1530 was fortified by Charles V. In 1668 and 1674 it was captured by the French and lost its parlement and university, both of which were transferred by Louis XIV. to Besançon. Dôle occupies the slope of a hill overlooking the forest of Chaux, on the right bank of the Doubs, and of the canal from the Rhone to the Rhine which accompanies that river. The steep, narrow streets contain many old houses recalling, in their architecture, the Spanish occupation of the town. The church of Notre Dame is Gothic of the 16th century. The college, once a Jesuit establishment, contains the library and a museum of paintings and has a chapel of the Renaissance period; the Hôtel-Dieu and hôtel de ville are both 17th century buildings; and the law court occupies an old convent of the Cordeliers. In the courtyard of the hôtel de ville stands an old tower dating from the 15th century. The birth of Louis Pasteur (1822) in the town is commemorated by a monument, and there is also a monument to Jules Grévy. Dôle is the seat of a sub-prefect and has tribunals of first instance and of commerce. Metal-founding and the manufacture of pumps. kitchen-ranges and other iron goods, chemical products, machinery, blue and blacking, and pastry are among the industries. There is a good trade in agricultural produce and live stock, and in wood, iron, coal and the stone of the vicinity. Wine is largely produced in the district.

DOLE, a portion, a distribution of gifts, especially of food and money, given in charity (O E. dal, *cf.* mod. "deal"). The distribution of alms to the local poor at funerals was a universal custom in the middle ages. Thus in 1399 Eleanor, duchess of Gloucester, ordered in her will that 15 poor men should carry torches at her funeral, "each having a gown and hood lined with white, breeches of blue cloth, shoes and a shirt, and £20 amongst them." Later, doles usually took the form of bequests of land or money, the interest or rent of which was to be annually employed in charity. Often the distribution took place at the grave of the donor. Lenten doles were also formerly common. A will of 1537 bade a barrel of white herrings and a case of red herrings be given yearly to the poor of Clavering, Essex, to help them tide over the fast. A pilgrim's dole of bread and ale can be claimed by all wayfarers at the Hospital of St. Cross, Winchester. This is said to have been founded by William of Wykeham. Emerson, when visiting Winchester, claimed and received the dole. What were known as scrambling doles, so called because the meat and bread distributed were thrown among the poor to be scrambled for, were not uncommon in England. At Wath, near Ripon, a testator in 1810 ordered that 40 penny loaves should be thrown from the church leads at midnight on every Christmas eve. The best known dole in the Cnited States is the "Leake dole of bread." John Leake, a millionaire, dying in 1792, left £1,000 to Trinity church, New York, the income to be laid out in wheaten loaves and distributed every Sabbath morning after service. (X.)

Dole in Unemployment. — While, as explained above, a dole is strictly a charitable gift, usually of food, the term came in Great Britain after the World War to be applied loosely to the various kinds of weekly payments to the unemployed.

These payments were first made on a national scale under the out-of-work donation scheme which was instituted immediately after the Armistice in 1918, and inasmuch as the scheme was entirely non-contributory, the term "dole" might be regarded as not inappropriate. The expression "dole" in relation to donation payments obtained currency soon after the scheme began.

The scheme applied not only to unemployed ex-members of the Forces who had served during the World War, but to civilian unemployed workers also. The payments came wholly from the Exchequer and amounted to £62,448,000 (£40,723,000 to ex-members of the Forces and £21,725,000 to civilians). The scheme for civilians was in existence for the year Nov. 1918 to Nov. 1919. For ex-members of the Forces it continued until March 1921.

By what may be described as a natural, or at least an easy, transition the term "dole" was afterwards applied to the weekly payments made under the National Unemployment Insurance scheme (see UNEMPLOYMENT INSURANCE). This general scheme of insurance against unemployment was, however, on a contributory basis from its inception. The contributing parties were the employer, the employed person, and the Exchequer, the share of the contribution borne on national funds being only one-fifth of the whole. (The Exchequer share was later increased and in the year 1930 amounted to one-third of the whole.)

From 1920 to Dec. 1929, over £284,000,000 were contributed by employers and workers and over £110,000,000 by the Exchequer.

Unemployment Benefits **Subscribed** For. — The unemployment insurance scheme was launched on what may be called a strictly insurance basis, persons who contributed to it being entitled when unemployed to receive benefit in proportion to their contributions, subject to a maximum period in each year. Owing, however, to the scheme coming into operation just when the severe industrial depression began, it became necessary to graft on to it a supplementary scheme under which benefit might be drawn by persons who would normally have contributed to the scheme but who, owing to the slump, either had not paid a sufficient number of contributions or had exhausted their benefit rights. The term "dole" was soon commonly applied to this extra or uncovenanted benefit, and it almost inevitably became associated with the insurance scheme as a whole, to which, however, as an insurance scheme it is quite inappropriate.

The term has also been applied to payments by the Poor Law authorities for relief of the able-bodied unemployed — an application which, having regard to the nature of the payments, is more justified than one referring to the unemployment insurance scheme.

Generally, it may be said that from the year 1919 the term "dole" has been loosely applied to payment made from national or local funds to the unemployed and even to benefits paid from insurance funds to which the recipients themselves contribute heavily. (J. F. G. P.)

DOLERITE is a word which has carried more than one meaning. It was originally applied by Haüy (from Gr. *δολερός* deceptive) to coarse-grained basalts with little or no glass, but it is now usually taken to indicate intrusive rocks, of basic composition belonging to the hypabyssal group, and therefore intrusions and not lavas. It is, however, sometimes difficult to ascertain whether a particular sheet is an intrusion or a lava-flow, because in the later stages of volcanicity the lava does not always reach the surface, but may be injected among the earlier flows.

The dolerite group includes both cale-alkaline and alkaline

varieties, of which the former are by far the commoner. Their essential minerals are a basic plagioclase felspar (usually ranging from andesine to anorthite, the most typical being labradorite) and augite; the more basic varieties contain olivine, while in more acid types a little alkali-felspar and quartz may be present, often as micropegmatite (*q.v.*). Original hornblende is not very common, though the augite is often more or less converted to hornblende by secondary changes. In some varieties enstatite or hypersthene are found, often with quartz. The commonest accessories are ilmenite and apatite. In the alkaline dolerites, often called teschenites, there is rather more alkali-felspar and either nepheline or more commonly analcite.

The dolerites are dark-coloured, heavy rocks, most commonly of even grain, though sometimes carrying phenocrysts of felspar, augite or olivine. The structure is typically ophitic; *i.e.,* the crystals of felspar of prismatic form are enclosed in large plates of augite, giving a sort of shimmery appearance. The centre of a comparatively large mass may approach a gabbro in texture, while the margins are often of very fine grain, or even glassy, owing to chilling during intrusion by the cold country rock.

Dolerites may form small bosses and laccoliths, thus merging into the gabbros, but the most typical manner of occurrence is as sills and dikes, varying in thickness or width from a mere film to hundreds of feet. Often there is to be observed a considerable variation in composition from the centre to the margins of a large intrusion, owing to differentiation of the magma during cooling, the basic minerals concentrating near the margin, while felspar, including orthoclase or albite and even quartz may be found at the centre. Again it is not infrequent to find an injection of some acid rock in the same dike-fissure, or forming a parallel sheet or sill. This phenomenon is due to differentiation before crystallization.

The ordinary dolerites, poor in alkalis and correspondingly rich in lime, are undoubtedly the most abundant of all basic intrusive~.They occur in great quantity along with surface flows of basalt in innumerable localities. In Britain dolerites, mostly carrying olivine, are abundant in the Tertiary volcanic province of western Scotland and north-eastern Ireland, as well as among the carboniferous eruptives of the central valley of Scotland. Well-known examples of enstatite-dolerite (with quartz) are the Great Whin Sill of northern England, and Penmaenmawr in north Wales. By far the greatest known development of dolerite, however, is that of the Karroo region, Natal, etc., in South Africa, where individual sheets may be thousands of feet thick.

Alkaline dolerites (teschenites) are less common; the type example is that of Teschen in Moravia, while a good many occurrences are known in Scotland, of both carboniferous and Tertiary age, and in the English midlands (Clee hills, etc.).

The dolerites are of considerable economic value, as when fresh the stone is hard, heavy and tough, being well-suited for paving setts and road metal.

In America and in mining literature generally the dolerites are often called *diabase,* but this name is not to be recommended, owing to the different-senses in which it has been used in past times. (R. H. RA.)

DOLET, ETIENNE (1509–1546), French scholar and printer, was born at Orleans. After studying at Paris and Padua, he became secretary in 1530 to the bishop of Limoges, who was French ambassador to the republic of Venice. He then studied law at Toulouse. In 1535 he entered the lists against Erasmus in the famous Ciceronian controversy, by publishing a *Dialogus de imitatione Ciceroniana;* and the following year saw his *Commentariolum linguae Latinae.* This work was dedicated to Francis I., who gave him the privilege of printing during ten years any works in Latin, Greek, Italian or French, which were the product of his own pen or had received his supervision; and accordingly, on his release from an imprisonment occasioned by his justifiable homicide of a painter named Compaing, he began at Lyons his typographical and editorial labours. He started by publishing a *Cato christianus,* or Christian moralist, in which he made profession of his creed. The catholicity of his literary appreciation, in spite of his ultra-Ciceronianism, was soon displayed by the works which proceeded from his press—ancient and modern, sacred and secular, from the New Testament in Latin to Rabelais in French. After being thrice imprisoned for atheism, he was tortured and burnt at Paris on Aug. 3, 1546. On his way to the stake, he is said to have composed the punning pentameter—Non *dolet ipse Dolet, sed pia turba dolet.*

Whether Dolet was a Protestant or an anti-Christian rationalist is debatable. He was condemned by Calvin but many of his books were of a religious character, and he repeatedly advocated the reading of the Scriptures in the vulgar tongue.

See A. F. Didot, *Essai sur la typographie* (1852); L. Michel, *Dolet* (1889); R. C. Christie, *Étienne Dolet, the Martyr of the Renaissance* (2nd ed. 1889, bibl.); O. Galtier, *Étienne Dolet* (1908), and pt. 3 of J. C. Dawson's *Toulouse in the Renaissance* (New York, 1923).

DOLGEELY, a market and county town of Merionethshire, Wales, situated on the streams Wnion and Aran, at the north base of Cador Idris, on the G.W. railway. Pop. of urban district (est. 1938) 2,461. It consists of small squares and narrow streets, with a grammar school (1665), market hall and assize hall. There is a little manufacture of flannel and coarse woollens. An ancient house has associations with Owain Glyn Dwr, who established relations with the Continent from here in 1404. Hengwrt, a mansion near the ruins of Cymmer Abbey, has given its name to a famous collection of Welch mss. once housed there, and now in the National Library of Wales, Aberystwyth.

DOLGORUKI, VASSILI LUKICH, COUNT (1672–1739), Russian diplomatist and minister, was one of the first group of young Russians whom Peter the Great sent abroad to be educated. On his return home he entered the diplomatic service, and served on a series of important missions. During the reign of Peter II. (1727–30) Dolgoruki was appointed a member of the supreme privy council, and, after procuring the banishment of Menshikov, he took charge of the young emperor, whom he would have forced to marry his niece Catherine but for Peter's sudden death. He then drew up a letter purporting to be the last will of the emperor, appointing Catherine Dolgoruki his successor, but had to abandon the scheme as impracticable. He supported the election of Anne of Courland to the throne on condition that she first signed nine "articles of limitation" which left the supreme power in the hands of the Russian council. Anne, who repudiated the "articles" on the first opportunity, never forgave Dolgoruki. He was banished first to his country seat and then to the Solovetsky monastery. Nine years later the charge of forging the will of Peter II. was revived, and he was tortured and then beheaded at Novgorod on Nov. 8, 1739.

See Robert Nisbet Bain, *The Pupils of Peter the Great* (1895).

DOLHAIN, the most eastern town of Belgium, situated on the Vesdre, north-east of Verviers and close to the German frontier. It is quite a modern town, occupying the site of the lower town of the ancient city of Limburg, which was destroyed by Louis XIV. in 1675 On a rocky eminence above Dolhain are still to be seen the fine ruins of the old castle of Limburg, the cradle of the ancient family of that name from which sprang the Luxemburg family and several emperors of Germany. At a short distance from Dolhain is the famous dam of the Gileppe, the vast reservoir constructed to supply Verviers with water free from lime for its cloth manufactures.

DOLICHOCEPHALIC (long-headed), a term denoting skulls the diameter of which from side to side, or the transverse diameter, is 75% or less of the longitudinal diameter or that from front to back taken as 100.

DOLLAR, burgh and parish, Clackmannanshire, Scotland, 6 m. N.E. of Alloa by the L.N.E.R., not far from the Devon. Pop. (1938) 1,428. The village is beautifully situated. It has a well known school, the academy, housed in a fine mass of buildings of the Grecian order (opened about 1819).

DOLLAR, a silver coin at one time current in many European countries, and adopted under varying forms of the name elsewhere. The word "dollar" is a modified form of *thaler,* which, with the variant forms (daler, dalar, daalder, tallero, etc.), is said to be a shortened form of *Joachimsthaler.* This *Joachimsthaler* was the name given to a coin intended to be the silver equivalent

of the gold gulden, a coin current in Germany from the 14th century. In 1516 a rich silver mine was discovered in Joachimsthal (Joachim's dale), a mining district of Bohemia, and the count of Schlick, by whom it was appropriated, caused a great number of silver coins to be struck (the first having the date 1518), bearing an effigy of St. Joachim, hence the name. The *Joachimsthaler* was also sometimes known as the *Schlickenthaler*. The first use of the word dollar in English was as applied to this silver coin, the thaler, which was current in Germany at various values from the 16th century onwards, as well as, more particularly, to the unit of the Germany monetary union from 1857 to 1873, when the mark was substituted for the thaler. The Spanish piece-of-eight (real) was also commonly referred to as a dollar; it was used both in the Spanish-American and in the English colonies.

On July 6, 1785, the dollar was adopted by the Continental Congress as the monetary unit of the United States. Actual coinage was not begun until after the enactment of the law, April 2, 1792, providing for a dollar of $371\frac{1}{4}$ grains of pure silver or 416 grains of standard silver. An act of March 3, 1849, directed the coinage of gold dollars of $25\frac{8}{10}$ grains, of which 23.22 grains were to be fine gold, and by act of Feb. 12, 1873 this became the American unit of currency. According to the Constitution, Congress has the power to regulate the currency, and under that power Congress by act of May 12, 1933, provided that the weight of gold in the dollar might be fixed by the President but not below 60% of its then weight. By proclamation of the President, Jan. 31, 1934, the gold in the dollar was fixed at $15\frac{5}{21}$ grains, nine-tenths fine, a reduction of approximately 41 per cent. The silver dollar contains $412\frac{1}{2}$ grains, nine-tenths fine. No gold is now coined, having been withdrawn from circulation in 1934. The present subsidiary coins are the half-dollar or so-cent piece, the quarter-dollar or 25-cent piece, the dime or 10-cent piece, all in silver; the 5-cent piece in nickel; and the 1-cent piece in copper.

The Spanish piece-of-eight was the ancestor of the Mexican, the Newfoundland. and the Spanish-American dollar.

DOLLAR STABILIZATION. Under the existing currency system, the so-called "level of prices" is largely at the mercy of monetary and credit conditions. The purchasing power of money has. in the past, always been unstable, because a unit of money was not determined as a unit of purchasing power but only as a unit containing a certain weight of gold or silver. Other units—the yard, pound, bushel, etc.—were once as unstable as monetary units, but, one after another, they have all been stabilized or standardized. Short weights and measures cheat the buyer; long weights, the seller. So a unit of money which changes in value or purchasing power is always playing havoc between contracting parties. The following table shows how the level of prices and the purchasing power of the dollar have fluctuated, according to Prof. Irving Fisher's index number of wholesale prices.

	Index number of prices in % of 1926, *i.e.*, 1926 = 100%	Purchasing power of the dollar in 1926 cents, *i.e.*, 1926 = 100 cents
1860	67	151
1865 (high)	143	70
1896 (low)	46	218
1913	70	143
1920 May (high)	167	60
1922 Jan. (low)	96	104
1926	100	100
1929	96	104
1931	71	140
1932	62	162
1933	65	157
1934	77	131
1935	83	121
1936	84	120
1937	91	110
1938	81	123

An Unsatisfactory System.—When prices are rising, *i.e.*, when the purchasing power of the dollar is falling, creditors and recipients of fixed incomes suffer injustice. The sufferers include savings-bank depositors, bondholders and salaried classes. On the other hand, when prices fall, it is other classes, such as debtors, stockholders, farmers and independent business men generally, who suffer. The indirect effects of falling or rising prices, *i.e.*, of a rising or falling dollar, are equally bad. These indirect effects include industrial discontent, due either to the high cost of living or to unemployment and economic crises.

Hitherto there was ample excuse for the unstable monetary units of various countries, in that no instrument for measuring their aberrations had been devised. Likewise, until weighing scales were invented weights could not be standardized, and until instruments for measuring electrical magnitudes were invented, electrical units could not be standardized. But for some years the index number of prices has provided a fairly accurate instrument for measuring the value of money in terms of its power to purchase goods. An index number of prices is a figure which shows, for a specific period of time or on a specific date, the average percentage increase or decrease of prices. This instrument for measuring changes in the purchasing power of money has been utilized, beginning in the 1920s, in adjusting wages and salaries to the cost of living, and a number of industrial and financial concerns, and some private agencies, have amended wages on the basis of an index number of the prices of commodities. A number of countries had also officially adopted the principle of adjusting a basic rate of the wages of labour in accordance with changes in the purchasing power of the monetary unit as expressed in an index number of the cost of living.

However, this method of offsetting fluctuations in the purchasing power of money has proved entirely inadequate; for it merely intended to prevent some of the symptoms of monetary instability, without attacking its cause. Since 1931 efforts have been made to incorporate the necessary corrections in the monetary unit itself by keeping it stable in purchasing power.

Trend Since 1931.—In 1929–30, as prices began to decline, practically all currencies were linked to one another by the fact that they could, either directly or indirectly, be exchanged into fixed weights of gold. The fall of prices, therefore, indicated not only that national currencies were increasing in purchasing power, but that the value of gold was changing correspondingly. Countries whose currencies were not thus linked to gold, as for instance China which was on a silver basis, experienced no corresponding change in purchasing power and consequently no depression. In Sept, 1931, England, followed by the countries belonging to the sterling area, cut loose from gold and thus prevented any further appreciation of purchasing power. The fact that these currencies were no longer exchangeable into fixed weights of gold, caused fears of a repetition of post-war experiences with paper money, namely, a chaotic rise of prices indicating complete collapse of purchasing power. In order to mitigate such fears and give direction to their monetary policies, the Scandinavian countries, notably Sweden, announced their determination to maintain the stability of purchasing power of their currencies as measured by an official price index. On July 3, 1933, President Roosevelt, in a message to the World Economic Conference then meeting in London, proclaimed a similar policy of dollar stabilization, saying that "the United States seeks the kind of dollar which a generation hence will have the same purchasing and debt-paying power as the dollar value we hope to attain in the near future."

Requirements of a Stabilization Policy.—Experience has shown that the declaration of a policy of stable money, or the construction of an official index number for measuring purchasing power, are not sufficient to actually maintain stability. Once a country has decided on purchasing power stability as the objective of monetary policy, it is essential that this goal be defined as narrowly as possible to eliminate the need for wide discretion on the part of the monetary authority—usually the central bank. Among the powers the monetary authority should possess is that of issue and control of the nation's money. This implies the need for banking reform so as to prevent commercial banks from arbitrarily changing the volume of money when lending their customers not actual currency but the bank's credit. The practice

of banks to issue their own credit when making loans, and destroying this credit when calling loans, has been one of the chief factors responsible for violent fluctuations in the purchasing power of money. In the United States, such bank-created-and-destroyed credit (called demand bank deposits) transacts more than nine-tenths of the nation's business. The monetary authority should also be required to change foreign exchange rates and the prices of gold and silver whenever necessary to maintain the stability of purchasing power of the monetary unit.

DOLLFUSS, ENGELBERT (1892–1934), Austrian statesman, born in Texing, Lower Austria, in 1892, was educated at the universities of Vienna and Berlin. During the world war he served as an officer in the Austrian army. In October 1931 he became president of the Austrian Federal Railways, in March 1932 minister of Agriculture and Forestry, and in May 1932 was appointed Chancellor. On March 4, 1933, feeling the need of a strong government in face of the growing menace to Austria from German Nazis, he dispensed with further meetings of the *Nation*alrat. He was wounded in an attempt upon his life on Oct. 3, 1933; and on July 25, 1934, he was assassinated by a group of Austrian Nazis who, disguised as members of the Heimwehr, seized the Chancellery in Vienna.

DÖLLINGER, JOHANN JOSEPH IGNAZ VON (1799–1890), German theologian and church historian, was born at Bamberg, Bavaria, on Feb. 28, 1799, and was educated at the Würzburg gymnasium and at Bamberg. On April 5, 1822 he was ordained priest. In 1823 he became professor of ecclesiastical history and canon law in the lyceum at Aschaffenburg, and in 1826 professor of theology at Munich, where he spent the rest of his life. He entered into relations with the well-known French Liberal Catholic, Lamennais, whose views on the reconciliation of the Roman Catholic Church with the principles of modern society had aroused much suspicion in ultramontane circles. In 1832 Lamennais, with his friends Lacordaire and Montalembert, visited Germany, with a view to bringing about a modification of the Roman Catholic attitude to modern problems. In 1838 he published a treatise against mixed marriages, and in his works on The Reformation (3 vols. Regensburg, 1846–48) and on Luther (1851, Eng. tr., 1853) he is very severe on the Protestant leaders. In 1842 he entered into correspondence with the leaders of the Tractarian movement in England, notably with Pusey, Gladstone and Hope Scott; and two years later was made representative of his university in the second chamber of the Bavarian legislature. In 1847, in consequence of the fall from power of the Abel ministry in Bavaria, with which he had been in close relations, he was removed from his professorship at Munich, but in 1849 was invited to occupy the chair of ecclesiastical history. He was a delegate to the national German assembly at Frankfort in 1848.

It has been said that his change of relations to the Papacy dated from the Italian war in 1859, but no sufficient reason has been given for this statement. He was unfavourably impressed by the promulgation (1854) of the dogma of the Immaculate Conception of the Blessed Virgin, and he disliked the attitude of the zealots for the restoration of the temporal sovereignty of the pope. In 1863 he invited 100 theologians to discuss at Malines the question which Lamennais and Lacordaire had already raised in France, namely, the attitude that should be assumed by the Roman Catholic Church towards modern problems and modern science. His strong liberalism and the anti-ultramontane and anti-Jesuit attitude which he displayed at this conference led the pope to suppress it after four days session. On Dec. 8, 1864 Pius IX. issued the Syllabus (*q.v.*), in the 13th thesis of which he condemned certain of Dollinger's views. It was in connection with the problems raised at the conference that Dollinger published his Past and Present of Catholic Theology (1863) and his Universities Past and Present (Munich, 1867).

We now approach the critical period of Dollinger's life. The headquarters of the opposition to the movement for the declaration of papal infallibility which was now mooted in many quarters was Germany, and its leader was Dollinger. Among the group were his intimate friends Johann Friedrich (*q.v.*) and J. N. Huber, in Bavaria. In the rest of Germany he found many supporters, chiefly professors in the Catholic faculty of theology at Bonn, among whom were the famous canonist von Schulte, Franz Heinrich Reusch, the ecclesiastical historian Joseph Langen, as well as J. H. Reinkens, afterwards bishop of the Old Catholic Church in Germany, Knoodt, and other distinguished scholars; and, in Switzerland, Prof. Edward Herzog, who became Old (or, as it is sometimes called, Christ-) Catholic bishop in Switzerland Early in 1869 the famous Letters of *Janus,* written by Dollinger in conjunction with Huber and Friedrich (which were at once translated into English; 2nd ed. Das Papsttum, 1891), began to appear. The Letters pointed out the tendency of the *Syllabus* towards obscurantism and papal despotism, and marshalled the evidence against papal infallibility, a subject which had been placed on the agenda of the Vatican Council fixed for Dec. 8, 1869. During its session the world was kept informed of what was going on in the Letters of *Quirinus,* by Dollinger and Huber, who were supplied with information by Augustin Theiner, the librarian at the Vatican, then in disgrace with the pope for his outspoken Liberalism. The dogma was carried by an overwhelming ,majority, and the dissentient bishops, one by one submitted (see VATICAN COUNCIL). Dollinger, understanding infallibility to apply to all official exercise of the supreme magisterium, including encyclicals, headed a protest by 44 Munich professors, and convened a congress at Nuremberg, which met in Aug. 1870 and issued a declaration adverse to the Vatican decrees. The archbishop of Munich called upon Dollinger to submit. Dollinger answered (Nov. 28, 1871) that the decrees were opposed to Holy Scripture, to the traditions of the Church for the first 1,000 years, to historical evidence, to the decrees of the general councils, and to the existing relations of the Roman Catholic Church to the state in every country in the world. "As a Christian, as a theologian, as an historian, and as a citizen," he added, "I cannot accept this doctrine."

The archbishop replied (April, 1871) by excommunicating Döllinger (see VATICAN COUNCIL and INFALLIBILITY), who was thereupon almost unanimously elected rector-magnificus of the university of Munich while Oxford, Edinburgh and Marburg universities conferred upon him the honorary degree of doctor of laws and Vienna that of philosophy. The Bavarian clergy invited Bishop Loos of the Jansenist Church in Holland, which for more than 150 years had existed independent of the Papacy and had adopted the name of "Old Catholic," to hold confirmations in Bavaria. The offer was accepted, and the three Dutch Old Catholic bishops declared themselves ready to consecrate a bishop, if it were desired. The momentous question was discussed at a meeting of the opponents of the Vatican decrees, when Dollinger voted against the proposition, and withdrew from any further steps towards the promotion of the movement. He declined to initiate a schism (see OLD CATHOLICS).

Dollinger's attitude to the new community was not very clearly defined. His addresses on the reunion of the Churches, delivered at the Bonn Conference of 1872, show that he was not hostile to the newly formed communion, in whose interest the conference was held; in 1874 and again in 1875, he presided over the Reunion Conferences held there and attended by leading ecclesiastics from the British Isles and from the Orthodox Church. At the latter of these two conferences, when Dollinger was seventy-six years of age, he delivered a series of addresses in German and English, in which he discussed the state of theology on the continent, the reunion question, and the religious condition of the various countries of Europe in which the Roman Catholic Church held sway, and he succeeded in inducing the Orientals, Anglicans and Old Catholics present to accept a formula of concord, drawn

from the writings of the leading theologians of the Greek Church, on the question of the Procession of the Holy Spirit. During his last years of retirement he wrote, in conjunction with his friend Reusch, *Geschichte der Moralstreitigkeiten in der römisch-katholischen Kirche seit dem sechzehnten Jahrhundert mit Beiträgen zur Geschichte und Charakteristik des Jesuitenordens* (Nordlingen, 1889). Döllinger died in Munich on Jan. 14, 1890, at nearly ninety-one. He declined to receive the sacraments from the parish priest at the cost of submission, but the last offices were performed by his friend Professor Friedrich.

In addition to the works referred to in the foregoing sketch, we may mention *The Eucharist in the First Three Centuries* (Mainz, 1826); a *Church History* (1836, Eng. trans, 1840); *Hippolytus and Callistus* (1854, Eng. trans., 1876); *First Age of Christianity* (1860); *The Church and the Churches* (Munich, 1861); *Lectures on the Reunion of the Churches; The Vatican Decrees; Studies in European History* (tr. *M.* Warre, 1890); *Miscellaneous Addresses* (tr. *M.* Warre, 1894).

See L. von Kobell, *Conversations of Dr. Döllinger* (tr. by *K.* Gould, 1892); and J. Friedrich, *Ignaz von Dollinger* (Munich, 1899–1901).

DOLLOND, JOHN (1706–1761), F.R.S. (1761), English optician, was the son of a Huguenot refugee, a silk-weaver at Spitalfields, London, where he was born on June 10, 1706. He followed his father's trade, but found time to acquire a knowledge of Latin, Greek, mathematics, physics, anatomy and other subjects. In 1752 he abandoned silk-weaving and joined his eldest son, Peter Dollond (1730–1820), who in 1750 had started in business as a maker of optical instruments. His reputation grew rapidly, and in 1761 he was appointed optician to the king. In 1758 he published an "Account of some experiments concerning the different refrangibility of light" (*Phil. Trans.*, 1758), describing the experiments that led him to the discovery of a means of constructing achromatic lenses by the combination of crown and flint glasses. Following the suggestion of Leonhard Euler and the experiments of Samuel Klingenstjerna (1698–1765) Dollond commenced a series of tests on achromatism. Early in 1757 he succeeded in producing refraction without colour by the aid of glass and water lenses, and a few months later he obtained the same result by a combination of glasses of different refrangibilities (*see* TELESCOPE). Dollond also published two papers on apparatus for measuring small angles (*Phil. Trans.*, 1753, 1754). He died in London on Nov. 30, 1761.

DOLLS. The doll, the familiar toy puppet of childhood, is one of the oldest of human institutions. Common among both savage and civilized people, its antiquity is attested by Egyptian, Greek and Roman remains, among which small figures of clay, wood, bone and ivory are identified as dolls from being found in children's graves.

Dolls are among the first inventions of children, having been doubtless improvised in the earliest instances from natural objects such as sticks and stones. Aboriginal America and Japan are the chief sources of information. The child's doll occurs among the American Indians as the image of a deity, made of wood, regarded as sacred and entrusted to the child in its religious instruction. Such dolls, carved to represent the masked dancers who personate the gods, are used to-day throughout the Pueblo area of the United States in New Mexico and Arizona, and in a derived form among the Pomo in California. They are also treated with great respect by the Pueblos, their sale being forbidden. The dolls of the Keres Indians of Laguna and Cochiti are not elaborately carved or dressed, being flat or rounded billets, identical in form with the prayer sticks employed as ceremonial offerings. The Navajo who occupy the adjacent territory look with superstitious fear upon the Pueblo doll and use a wooden effigy representing a Hopi doll to work evil upon an enemy. Indian mothers among the Chippewa put feathers in the form of a child in the cradle of a dead infant, carrying this about with them and treating it as though living. The Eskimo and northern Indians make children's dolls of bone, ivory and mammoth teeth, and dress them in fur and hide. Small clothed clay dolls are found in ancient Peruvian graves. The beaded buckskin dolls of the Plains and other Indians appear to have been inspired by white influence.

In Japan a primitive type of child's doll consists of a shaved willow stick with shavings or strings for hair, and paper clothes, an obvious adaptation of the shaved willow sticks formerly set up on the banks of streams as scapegoats at the annual purification ceremony. An actual scapegoat doll, which was dressed and fed and generally treated as though alive, was given to mothers in old Japan to ward off evil from their children. Women desiring children presented dolls essentially emblems of maternity, at a certain shrine. Apart from these "magical" dolls, Japanese girl children have ordinary dolls as well as ceremonial dolls symbolizing the imperial court, which are not played with but exhibited formally at the girls' festival on May 3. Japanese boys have similar toy images of warriors, which are displayed at their festivals on the fifth of March.

PRIMITIVE TYPES OF DOLLS OF THE CARAJA INDIANS, BRAZIL

In Korea little girls make their own dolls and cut a bamboo pipe stem about 5 in. long, in the top of which they put long grass, salted and made fine like hair. They never give these a face but sometimes paste a little white powder in its place. They dress the stick in clothes like those worn by women and sometimes put a pin, made by themselves, in the hair. The children's festival in Korea occurs on April 8, celebrated in Japan as the birthday of Buddha. On this occasion, the Koreans make an image of a woman of paper with a rounded base made of clay so that it stands erect. In Japan the corresponding toy is identified as the Buddhist *Daruma* and is purchased by boys at the festival of a certain temple. One which rises quickly to a vertical position is selected. The face is painted, but instead of eyes, two white paper discs are pasted. This doll is carried home, placed on the "god shelf" and a prayer is said. The god is promised eyes if he answers the prayer, and, this accomplished, black dots are made with ink on the vacant eye discs. In China this toy is made to represent an actor and described as a drunken man.

Among the Hindus and Mohammedans in India, where infant marriage prevails, elaborately dressed dolls with belongings are among the presents given to a girl at marriage. Their use is general throughout the Mohammedan East in spite of the laws of Islam which forbid the representation of the human figure. The nine year old wife of Mohammed, Aischa, brought her dolls when she entered his harem and the Prophet himself is said to have played with them. Mohammedan women in Baghdad are said to see a spirit in every doll that may bring harm to their children. Dolls, therefore, are not given to children as toys, but little girls, following their instincts, make dolls of pillows and blocks of wood. In Persia girls make their dolls of pieces of folded cotton which they clothe and mark with features. Here, too, an image of a doll is, it is said, sometimes placed in a temple at the time of its erection to secure its continued welfare.

Dolls are common in Africa, where certain forms are peculiar to certain regions and their use by children as toys is complicated by magical observances. Their general appearance is similar to the carved wooden fetishes to which they seem genetically related. Among the Fingo of the Orange Free State, a girl is given a doll when she becomes of age, which she keeps until she has a child. Then her mother gives her another doll which she keeps until she has a second child. Analogous to the scapegoat dolls of old Japan, these dolls are considered sacred and not parted with.

As regards Christian Europe there is little direct information, although dolls are known to have existed, as has been previously indicated, from Roman time.

It is known also that in earlier centuries those used as playthings were connected with images of the saints and were associated with the Christmas festival. A structure representing the scene of the Nativity was erected in churches and private houses, where the Christ child was displayed in its cradle with more or less elaborately costumed figures of the Holy Family, the Magi

and their retainers. These reached a poinr of great elaboration in the 17th and 18th centuries, as shown in the collection in the Bavarian National museum in Munich. And this custom still survives in France, Spain, Italy and all other Catholic countries. Toy fairs are held in the streets and purely secular dolls are sold side by side with toy images representing the Holy Infant, the Virgin Mary, St. Joseph, St. Nicholas and St. Christopher and other saints associated with this season.

In Protestant Europe the doll's house seems to have replaced the *crèche,* the *krippe* and the *nacimiento* of France, Germany and Spain and is highly developed, as may be seen in the Germanic National museum in Niirnberg, the South Kensington museum in London and in museums of Holland and Belgium.

As regards manufacture of dolls the Netherlands and the Tyrol have long been leading centres of the industry in Europe, while it may be noted further that dolls intended to illustrate seasonal fashions constitute a branch of the industry which came into existence much earlier than might be generally supposed. During the World War elaborately costumed dolls of the latter type, made very often by women artists as a means of livelihood in the period of distress, and bought by adults for ornamental purposes, if not as playthings, were produced in large numbers and acquired great popularity as gifts and keepsakes among the well-to-do.

DOLMAN, originally a long, loose garment left unfastened in front, and with narrow sleeves. It is worn generally by the Turks, and is not unlike a cassock in shape. The name was given to the uniform jacket, worn by hussars, and slung from the shoulders with the sleeves hanging loose.

DOLMEN, the term used of a certain type of prehistoric monuments, which usually consists of several great stone slabs set edgewise in the earth to support a flat stone which serves as a roof. The structure was designed as a burial chamber and is typical of the Neolithic period in Europe. The word is Celtic in origin but probably is not Breton; the Welsh equivalent of the word is Cromlech. Dolmens, although found in covered form as far East as Japan are mainly confined to Europe and Northern Africa. There are many examples in the British Isles. *See* BARROW and Borlase, *The Dolmens of Ireland* (1897).

DOLMETSCH, ARNOLD (1858–1940), French musician, was born at Le Mans in 1858. He studied under Vieuxtemps in Brussels and later at the Royal College of Music in London. His keen interest in old music and obsolete instruments took the practical form of research among the manuscripts in the British Museum and other collections on the one hand and of collecting and repairing the instruments themselves on the other. To reconstruct new instruments on the lines of the old was the next step, and to this end he worked from 1902 to 1909 at the Chickering factory in Boston, U.S.A., and from 1911 to 1914 at the Gavaud factory in Paris. In 1914 he returned to London, where he became a familiar figure in the musical world by virtue of his interesting revivals of early English music and his ingenious reconstructions of harpsichords and clavichords. He maintained a workshop at Haslemere in Surrey, where he also organized annual festivals of old chamber music of the 16th, 17th and 18th centuries. On these occasions the fortnight's programmes were carried through, with but little outside assistance, by Dolmetsch and his family, the members of which he had trained to take their parts in a concert of viols or recorders or in any combination of instruments. These concerts continued until his death

Among Dolmetsch's published works are: *Select English Songs and Dialogues of the XVI. and XVII. Centuries* and *The Interpretation of the Music of the XVI. and XVII. Centuries* (1915).

DOLOMIEU, DÉODAT GUY SILVAIN TANCREDE GRATET DE (1750–1801), French geologist and mineralogist, was born at Dolomieu, near Tour-du-Pin, Isère, on June 24, 1750. He was admitted in his infancy a member of the Order or Malta. In his nineteenth year hc quarrelled with a knight of the galley on which he was serving, and in the duel that ensued killed him. He was condemned to death, but in consideration of his youth was pardoned, after nine months' imprisonment. In 1775 he published his *Recherches sur la pesanteur des corps à differentes distances du centre de la terre,* and soon after threw up his commission in the carabineers, and in 1777 accompanied the *bailli* (afterwards Cardinal L. R. E.) de Rohan to Portugal. In the following years he visited Spain, Sicily, the Pyrenees and Calabria, the scientific results being given in a series of important works. In 1789 and 1790 he studied the Alps, and the mineral *dolomite* (named after him) was described by Dolomieu in 1791. He returned to France in that year, bringing with him rich collections of minerals. On Sept. 14, 1792, his friend, the duc de la Rochefoucauld was assassinated at Forges, and Dolomieu retired with the widow and daughter of the duke to their estate of Roche Guyon. In 1798 he accompanied Bonaparte's expedition to Egypt, but ill health compelled his return. On the way home he was captured, and imprisoned at Naples in a pestilential dungeon, where he remained 21 months. Deprived of writing materials, he made a piece of wood his pen, and with the smoke of his lamp for ink he wrote upon the margins of a Bible, the only book he still possessed, his treatise *Sur la philosophie minéralogique et sur l'espèce minérale* (1801). He died at Château-Neuf, Saône-et-Loire, on Nov. 26, 1801.

See Lacépède, "Éloge historique de Dolomieu," in *Mtmoires de la classe des sciences de l'Institut* (1806); Thomson, in *Annals of Philosophy,* vol. xii. p. 161 (1808).

DOLOMITE, a mineral species consisting of calcium and magnesium carbonate, $CaMg(CO_3)_2$, and occurring as rhombohedral crystals or large rock-masses. Analyses of most well-crystallized specimens correspond closely with the above formula, the two carbonates being present in equal molecular proportions ($CaCO_3$,54·35; $MgCO_3$,45·65%). Normal dolomite is thus not an isomorphous mixture of calcium and magnesium carbonates, but a double salt. In crystalline form it is very similar to calcite, belonging to the same group of rhombohedral carbonates; the primitive rhombohedron, parallel to the faces of which there are perfect cleavages, has interfacial angles of 73° 45'. A specially characteristic feature is that this rhombohedron is frequently the only form present on the crystals (in calcite it is rare except in combination with other forms); the faces are also usually curved, sometimes to an extraordinary degree, giving rise to saddle-shaped crystals. In the degree of symmetry possessed by the crystals there is, however, an important difference between calcite and dolomite; the latter is hemihedral with parallel faces, having only an axis of triad symmetry and a centre of symmetry.

Dolomite is both harder (H=3·5–4) and denser (sp. gr. 2.85) than calcite. The two minerals may also be readily distinguished by the fact that dolomite is not acted upon by cold, dilute acids. Crystals of dolomite vary from transparent to translucent, and often exhibit a pearly lustre, especially when the faces are curved; the colour is usually white or yellowish.

The crystallized mineral was first examined chemically by P. Woulfe in 1779, and was named compound-spar by R. Kirwan in 1784; other early names are bitter-spar, rhomb-spar and pearl-spar (but these included other rhombohedral carbonates). The name dolomite (*dolomie* of N. *T.* de Saussure, 1792) is in honour of the French geologist, D. G. Dolomieu; this name was originally applied to the rock only, but was later extended to the crystallized mineral, first in the form dolomite-spar.

In the white crystalline dolomite-rock of the Binnenthal near Brieg in Switzerland beautiful water-clear crystals of dolomite are found; and crystallized masses occur embedded in serpentine, talc-schist and other magnesian silicate rocks. The best crystallized specimens are, however, usually found in metalliferous deposits; for example, in the iron mines of Traversella near Ivrea, Piedmont (as large twinned rhombohedra) and Cleator Moor, Cumberland; in the deposits of lead and zinc ores at Alston, Cumberland, Laxey in the Isle of Man and Joplin in Missouri. (L. J. S.)

DOLOMITES, THE, a mountain district in the South Tirolese Alps, and a subdivision of the Alps. The mountains are

ASIATIC AND EGYPTIAN DOLLS

1. Wooden Japanese puppet doll mounted on a staff
2. Japanese court dolls
3. Satsuma standing dolls of Japan, made of papel
4. Indian dolls, sometimes used as wedding presents to child brides
5. Coptic doll of bone, seven and one half inches high
6. Chinese "tilting" dolls, made to represent actors

formed of dolomite (magnesian limestone), which rises in peaks of a singular degree of sharpness and streaked by veins of startling colours. It is well known to tourists. Most of the more striking peaks were first ascended in the late sixties and early seventies of the 19th century by English mountaineers. Roughly speaking (from west to east) the Dolomite region lies between the Brenner railway from Franzensfeste to Trent and the road over the Monte Croce Pass from Innichen in the Drave valley by way of the Sexten glen and the Piave valley to Belluno and Feltre. On the north it is limited by the railway line from Innichen to Franzensfeste, and on the south by the railway and road from Trent to Feltre. The highest summit is the Marmolata (10,972 ft.), but far more typical are the Sorapis, the Cimone della Pala, the Langkofel, the Pelmo, the Drei Zinnen, the Sass Maor and the Rosengarten (see ALPS). Among the chief tourist resorts are St. Ulrich (in the Groden valley), San Martino di Castrozza (near Primiero), Caprile and Cortina d'Ampezzo.

Besides the Dolomites included in the above region there are several other Dolomite groups (though less extensive) in the Alps. North-west of Trent rises the Tosa group, while in Switzerland there are the Piz d'Aela group, south-west of Bergiin on the Albula Pass route, and the curious little group north of the village of Spliigen, besides other isolated peaks between the St. Gotthard and Lukmanier Passes. In Dauphin6 itself (the home of the geologist Dolomieu) the mountain districts of the Royannais, of the Vercors, and of the Dévoluy (all south-west of Grenoble) are more or less Dolomitic in character.

DOLPHIN, a name for the cetacean *Delphinus delphis,* and extended to include its allies. The dolphins or porpoises inhabit seas and large rivers. They rarely exceed 11ft. in length. They feed chiefly on fish and are mostly gregarious. They show great agility and grace in the water, and often play round ships. The common dolphin of the Mediterranean and Atlantic measures some 6-8ft. in length, with a back fin of 9 or 10in. The "forehead" descends abruptly to the base of the flattened beak, which is about 6in. long. The sharp teeth number some 160 to 200 in all. The eyes are of moderate size, the ear aperture minute, and the blow-hole crescentic. Dolphins are black above, white below. The female brings forth a single young and is a devoted parent.

There are many other genera in the family *Delphinidae,* while the *Platanistidae* include the blind susu (*Platanista* gangetica) of the Ganges, Brahmaputra, and Indus, and two other species inhabiting the Amazon (*Inia geoffroyensis*) and an estuary of the La Plata respectively. (See CETACEA.)

DOMAIN. EMINENT: see EMINENT DOMAIN.

DOMAT or **DAUMAT, JEAN** (1625–1696), French jurisconsult, was born at Clermont in Auvergne. He was closely in sympathy with the Port-Royalists, and was intimate with Pascal, at whose death he was entrusted with his private papers. He is principally known from his legal digest entitled Lois civiles *dans leur ordre naturel* (1689), for which Louis XIV. settled on him a pension of 2,000 livres. A fourth volume, Le Droit public, was published in 1697, a year after his death. This is one of the most important works on the science of law that France has produced. Domat endeavoured to found all law upon ethical or religious principles, his motto being *L'homme* est *fait* par *Dieu* et *pour* Dieu. Besides the Lois *Civiles,* Domat made in Latin a selection of the most common laws in the collections of Justinian, under the title of Legunt delectus (Paris, 1700; Amsterdam, 1703); it was subsequently appended to the Lois civiles. His works have been translated into English.

In the Journal des savants for **1843** are several papers on Domat by Victor Cousin, giving much information not otherwise accessible.

DOMBES, a district of eastern France, formerly part of the province of Burgundy, now comprised in the department of Ain, and bounded on the west by the Saône, south by the Rhone, east by the Ain and north by the district of Bresse. The region forms an undulating plateau with a slight slope towards the north-west, the higher ground bordering the Ain and the Rhone attaining an average height of about 1,000ft. The Dombes once formed part of the kingdom of Arles. In the 11th century, when the kingdom began to break up, the northern part of the Dombes came under the power of the lords of Baugé, and in 1218, by the marriage of Marguerite de Baugé with Humbert IV. of Beaujeu, passed to the lords of Beaujeu. The southern portion was held in succession by the lords of Villars and of Thoire. In 1400, Louis II., duke of Bourbon, acquired the northern part of the Dombes, together with the lordship of Beaujeu, and two years later bought the southern part from the sires de Thoire, forming the whole into a new sovereign principality of the Dombes, with Trévoux as its capital. The principality was confiscated by King Francis I. in 1523, along with the other possessions of the Constable de Bourbon, was granted in 1527 to the queen-mother, Louise of Savoy, and after her death was held successively by kings Francis I., Henry II. and Francis II., and by Catherine de'Medici. In 1561 it was granted to Louis, duke of Bourbon-Montpensier, by whose descendants it was held till, in 1682, "Mademoiselle," the duchess of Montpensier, gave it to Louis XIV.'s bastard, the duke of Maine, as part of the price for the release of her lover Lauzun. The eldest son of the duke of Maine, Louis Auguste de Bourbon (1700–5j), prince of Dombes, was made colonel-general of the Swiss regiment, governor of Languedoc and master of the hounds of France. He was succeeded, as prince of Dombes, by his brother the count of Eu (*q.v.*), who in 1762 surrendered the principality to the Crown.

See Guichenon, *Histoire* de Dombes **(1863,** 1872); **A. M.** H. J. Stokvis, Manuel d'histoire (Leyden, **1889);** and various works by M. C. Guigue, including Bibliotheca Dumbensis (with Valentin Smith) (1856–85).

DOMBROWSKI, JAN HENRYK (1755–1818), Polish general, was born at Pierszowice in the palatinate of Cracow, on Aug. 29, 17jj. Under Poniatowski, he took part in the campaign of 1792 against the Russians. In 1794 he distinguished himself under Kosciusko in the defence of Warsaw. He then went to Paris, and in Jan. 1797 was authorized by the Government of the Cisalpine republic to organize a Polish legion. This task he executed at Milan. In command of his legion he played an important part in the war in Italy, entered Rome in May 1798, and distinguished himself at the Trebbia (June 19, 1799), where his legion was annihilated, and in other battles and combats of 1799–1801. After the peace of Amiens he passed, as general of division, into the service of the Italian republic. Summoned by Napoleon in 1806 to promote a rising in Poland, he organized several divisions of Poles, and distinguished himself at Danzig and Friedland. In 1809 he served in the Polish campaign and in 1812 he commanded a Polish division in the Grande *Armée,* being wounded at the passage of the Beresina. He fought under Marmont at the battle of Leipzig, and in 1813 returned to Poland. He was one of the generals entrusted by the tsar with the reorganization of the Polish army, and was named in 1815 general of cavalry and senator palatine of the new kingdom of Poland. Gen. Dombrowski died at his seat of Wina-Gora in Posen on June 26, 1818.

DOME, in architecture, an ovoidal or hemispherical vault; also any vault of polygonal plan that approaches the true dome in shape. The origin of the term lies in the fact that such a vault was a common feature of the Italian cathedrals—duomo,

The dome is an obvious type of covering for the primitive circular hut in countries where building materials are only in small units, such as bricks, and where timber is lacking. In the Mesopotamian valley, where these conditions existed, domes, probably of sun-dried brick, were built from an early period; many representations of them are shown in Assyrian stone bas reliefs of the 7th and 8th centuries B.C.; in these the domes are of a high elliptical form, and certain authorities find their origin in tents. With the growing use of square and rectangular rooms, this early form of dome, because of the difficulties of building a circular vault over such structures, largely disappeared, although it persisted in tomb design, where circular chambers remained in use. In such primitive tomb chambers, however, the form may be that of a true vault, but the construction is usually by corbelling, or building the whole covering of horizontal courses, each one of which projects slightly in beyond the one below, until the opening at the top is small enough to be covered by a single slab of stone. Such an arrangement may be seen on a grand scale in

the famous so-called Tholos or tomb of Atreus at Mycenae (*c.* 1200 B.C.), and in such Etruscan tombs as that from Volterra (6th century B.C.), now in the Archaeological museum at Florence. A rock-cut tomb at Viterbo, of approximately the same date, shows exactly the form of domical covering that appears on Assyrian reliefs.

Roman.—The Romans transformed this primitive idea into one of the most fruitful architectural forms. It first appeared as a half dome over niches, and was commonly so used throughout the early empire. In the Tabularium, Rome, 78 B.C., the square bays of the gallery, still existing, are roofed with vaults of ovoid section, rising equaily from all four sides—a type of vault known as the cloister vault, which in reality is a square dome. With the development of many buildings of circular plan, during the empire, such as *nymphaea*, or round garden buildings, and the *calidaria*, or hot rooms of the baths, the dome naturally came into use. An early example is the scalloped domical vault at the *nymphaeum* of the Garden of Sallust, Rome (*c.* A.D. 70–80). Hadrian, however, was the first to realize the tremendous opportunities of the simple dome form; he applied it on enormous scale to the circular Pantheon, built between A.D. 110 and 12;. This dome, 144 ft. in diameter, is constructed of brick, with the lower portion stiffened by a series of relieving arches. It is decorated on the inside with coffers, or deeply sunk panels, which seem to have been cut into the brick at a later period, and it is lighted by an enormous eye, or circular opening, at the top. Another interesting dome of the same period occurs in the villa of Hadrian at Tivoli, in the vestibule of the so-called Piazza d'Oro. Here, again, the scalloped type is used.

From the time of Hadrian, the dome became more and more common. In the baths of Caracalla, the *calidarium*, an immense, circular room, 116 ft. in diameter, was roofed with a dome, but still more interesting was the attempt to put a dome over an octagonal room in one of the side buildings. The problem thus presented, of supporting the in-curving parts of the dome, had puzzled the Romans for many years, and all sorts of attempts, by means of corbelling, and diagonal arches and niches, had been made. It was never thoroughly solved until the Byzantine period. Roman domes, except on a very small scale in late tomb chambers, are therefore limited to buildings of polygonal or circular plan. The most remarkable of the late Roman dome-roofs is that of the so-called temple of Minerva Medica, in reality, the *nymphaeum* of the Licinian gardens (*c.* 250), noteworthy because of the daring lightness of its construction and its use of a structural framework of brick ribs.

Byzantine.—The Byzantine perfection of the pendentive (*q.v.*) made possible the use of the dome over a plan of any shape. This style became pre-eminently a domed style, and its achievements, in building light but substantial domes, coloured not only all Renaissance church architecture, but also almost all Mohammedan building. A possible source for Byzantine skill in dome building was in the facility of the Sassanian vault constructors of Persia, who, in the palace at Firouzabad, probably end of the 5th century, used ovoid domes, about 50 ft. wide, supported on diagonal, arched squinches (*q.v.*).

The greatest of the Byzantine domes was that by Anthemius and Isidorus for the church of S. Sophia at Constantinople, consecrated 561, remarkable for the fact that 40 windows are pierced through its base, not only lessening its weight, but admirably lighting the great interior. This dome is 100 ft. in diameter, with a crown 180 ft. above the floor. S. Mark's at Venice, begun 1063, and modelled on the church of the Holy Apostles, Constantinople, exerted great influence on northern Italian Romanesque work (S. Antonio, Padua, 13th century). Later Byzantine domes are almost universally raised on drums, pierced with windows, as in the church of S. Theodore, at Athens. Another interesting offshoot of Byzantine dome design is a group of French domed churches, largely in Aquitania. Most of these date from the last half of the 11th and the first half of the 12th centuries, and are remarkable for their almost universal use of the pointed arch. These churches are without drums, and in some cases the curve of dome and pendentive is continuous, with, however, a projecting moulding at the dome base. Windows are occasionally pierced in the dome, as in early Byzantine examples. Cahors cathedral, 1119, and Angoulême, 1136, are outstanding instances, but the finest of the group is S. Front, Perigueux, begun 1120, whose plan is almost a replica of that of S. Mark's. These French domes are usually pointed in section, and decorated on the outside with

stone, carefully cut in scalloped patterns, and crowned with decorative finials. Smaller conical dome shapes, with similar details, are used frequently for spire tops and for ornamental pinnacles.

The Mohammedan builders were strongly under Byzantine influence; they adopted the dome as one of their favourite motives, using it in a lavish form, on a small scale, in Spain and northern Africa, but developing it as an important structural feature along Byzantine lines in the later architecture of Egypt, and in Persia, India and especially Turkey. Smaller domes and half domes were usually greatly enriched with fantastic stalactite ornaments, and sometimes elaborate systems of ribs, or transverse and diagonal arches replaced the pendentive. Particularly noteworthy is the Mohammedan work of India, especially the Djumma Musjid in Delhi (1560), and the Gol Gumbaz at Bijapur (1630). In certain examples, as the exquisite Taj Mahal at Agra (1630), the domes possibly follow Mohammedan Persian examples in their bulbous or onion form which appeared in Persia in about the 15th century and later, as in the tomb mosque of Tamerlane in Samarkand (1405), or the great mosque of Baghdad. Earlier Persian domes are of simple pointed outline, like the tomb at Sultanieh (1320). These domes are frequently double, the exterior surface raised high above the interior dome. The Muslim Turks carried out the Byzantine idea most directly and simply, making of the combination of domes and half domes, which they adopted from S. Sophia, compositions of the most powerful exterior, and airy interior effect. The mosque of Suleiman, designed by the famous Turkish architect Sinan, completed 1556, at Constantinople; that of Selim at Adrianople, finished 1574; and that of Yeni Djami, by Kassim, 1650, in Constantinople, are characteristic examples (see MOSQUE).

Renaissance.— The dome of the Pantheon at Rome exercised an enormous influence on the imagination of the Italian Renaissance (see RENAISSANCE ARCHITECTURE). Brunelleschi's so-called dome of the cathedral at Florence, completed 1431, lantern 1471, is, however, not a true dome, but a vast octagonal cloistered vault, with double shells, supported and connected by great stone ribs, which carry the weight of the stone lantern more than 300 ft. in the air. As this vault was supported on a high drum, no buttressing to withstand its thrust was possible, and although this was minimized by the shape chosen, it was, nevertheless, necessary to build in great bands of wooden beams tied together, in a chain, to prevent the base from spreading. Later designers combined the Byzantine pendentive with the idea of the drum, the dome and the lantern, and this combination became the governing motive of Renaissance dome design. Moreover, in order to get the requisite exterior effect without unduly raising the interior dome, the custom grew of building church domes with two or more shells, although such examples as the church of the Gesù at Rome (16th century, 57 ft. in diameter) are single. In some cases the exterior dome was merely a curved timber roof above the interior dome of masonry, as in the magnificent dome of S. Maria della Salute, in Venice, designed by Longhena (1631, 80 ft. in diameter). In the dome of S. Peter's, at Rome, designed by Michelangelo, and completed in 1590, after his death, both shells are of brick, but connected and strengthened, as in the cathedral at Florence, by stone ribs. The domes of S. Peter's and of the Florence cathedral are nearly of the same size, between 136 and 138 ft. in internal diameter. The support of such a heavy masonry construction as a Renaissance lantern, high in the air, caused great difficulties, tremendously increasing a tendency of the dome to spread. The original construction of the dome of S. Peter's embraced three chains to counteract this, but since its completion it has been necessary to add six more chains. In prder to diminish such thrusts Sir Christopher Wren, in the magnificent dome of S. Paul's, in London, used three shells, the inner one almost a hemisphere (102 ft. in diameter), the middle one a cone shaped structure carrying the stone lantern and the outer one merely a protecting roof of timber, whose weight is largely carried on the cone, thus helping to diminish its own thrust. In the dome of the chapel of Les Invalides, in Paris, by J. H. Mansard (1706, 92 ft. in diameter) there are also three shells, but in this case the lantern is of timber construction.

Modern.— The most daring of more recent domes is that of the Pantheon at Paris, 1735, by Soufflot (internal diameter 74 ft.). In this example, all three shells are of stone, with the lantern supported, as usual, on the central one, cut away with great arched openings so as almost to form four great hyperbolic legs. The outer dome is thinned to the last degree compatible with safety, being only 19 in. thick at the base, and further lightened by a series of arched recesses. In the United States the dome form has become common for State capitol buildings, due to the influence of the national capitol, whose enormous outer dome, of cast iron, was completed in 1865 by Thomas U. Walter. Notable examples are those at Madison, Wis.; St. Paul, Minn ; Jefferson City, Mo. Most of such domes are built with steel construction, and are, therefore, not true vaults. The domical form is also used in glass and steel construction for exposition buildings, and large conservatories. A notable example was the horticultural hall of the Panama Pacific Exposition in San Francisco, 191j, by Bakewell and Brown.

(T. F. H.)

DOMENICHINO (or DOMENICO), **ZAMPIERI** (1581–1641), Italian painter, was born at Bologna, on Oct. 21, 1581, and died at Naples on April 1j, 1641. He was a pupil in the Academy of the Caracci, under Agostino. Towards the beginning of the 17th century he went to Rome to study under Annibale Caracci, and there obtained employment from Cardinals Borghese, Farnese, and Aldobrandini, for all of whom he painted works in fresco. His success excited the envy of some of his contemporaries, who accused him of plagiarism. Disgusted with these cabals, he left Rome for Bologna, where he remained until he was recalled by Pope Gregory XV., who appointed him principal painter and architect to the pontifical palace. He designed in great part the Villa di Belvedere at Frascati, and the whole of the Villa Ludovisi, and some other edifices. From 1630 onwards Domenichino was engaged in Naples, chiefly on a series of frescoes (never wholly completed) of the life of St. Januarius in the Cappella del Tesoro. He settled in that city with his family, and opened a school. There the so-called "Cabal of Naples"— the painters Corenzio, Ribera and Caracciolo—leagued together as they were to exclude all alien competition, annoyed the Bolognese artist in all possible ways; for instance, on returning in the morning to his fresco work, he would find not infrequently that someone had rubbed out the performance of the previous day. He died in Naples, after two days' illness, on April 15, 1641.

Domenichino is esteemed the most distinguished disciple of the Caracci, or second only to Guido Reni. Algarotti preferred him to the greatest masters; and Nicolas Poussin considered the painter of the "Communion of St. Jerome" to be the first after Raphael. His pictures of "Adam and Eve," and the "Martyrdom of St. Agnes," in the Gallery of Bologna, are amongst his leading works. Others of interest are his first known picture, a fresco of the "Death of Adonis," in the Loggia of the Giardino Farnese, Rome; the "Martyrdom of St. Sebastian," in Santa Maria degli Angeli; the "Four Evangelists," in Sant' Andrea della Valle; "Diana and her Nymphs," in the Borghese gallery; the "Assumption of the Virgin," in Santa Maria in Trastevere; and frescoes in the neighbouring abbey of Grotta Ferrata, lives of SS. Nilus and Bartholomew. His portraits are also highly reputed. It is admitted that in his compositions he often borrowed figures and arrangements from previous painters. Domenichino also excelled in landscape painting.

See C. Landon, *Works of Domenichino, with a Memoir* (1823); Bolognini, *Life of Domenichino* (1839).

DOMENICO VENEZIANO, Italian painter of the Florentine school (working 1438–61), probably Venetian by birth Very little is known about him. He may have acquired rhe rudiments

of art in Venice; his style was formed under the influence of Donatello, Masaccio and Fra Angelico. He is first heard of in a letter written to Pietro di Cosimo de Medici from Perugia on April 1, 1438, in which he asks for a recommendation. From 1439–45 he was working in Santa Maria Nuova in Florence in association with Piero della Francesca, who was his assistant, on frescoes no longer extant. He died in Florence on May 15, 1461. The story told by Vasari that he was murdered by Andrea del Castagno, who wished to monopolize the secret of oil-painting, which Domenico Veneziano is said to have received from Antonello da Messina, is now completely disproved, since Castagno is known to have died four years earlier than his alleged victim. There are only two authentic works by the master extant. The most important of these is an altarpiece painted for the church of Santa Lucia de Bardi. The central panel, representing the "Virgin and Child Enthroned with Four Saints," is in the Uffizi gallery. It is signed "Opus Dominici De Venetiis." A fragment of the predella of the same altarpiece with the "Martyrdom of St. Lucy" is in the Berlin museum. Two more fragments, representing the "Annunciation" and the "Miracle of St. Zenobius," were recently discovered in the Fitzwilliam museum at Cambridge. (Bequest of Prof. Fred. Fuller.) The other signed work by the artist is in the National Gallery, London, a "Madonna and Child Enthroned" on canvas transferred from fresco. The work is mentioned by Vasari as having been painted in the angle of two roads, the Canto de Carnesecchi. The painting has suffered much and is not in its original condition. A fresco representing John the Baptist and St. Francis in Santa Croce, Florence, is attributed to Domenico on stylistic evidence. All other attributions are problematical. Thus the series of women's profiles in the Berlin museum, the Mond collection, London, and the Poldi Pezzoli collection, Milan. (See J. P. Richter, Mond Collection II.)

Domenico Veneziano was in Florence at the time when Uccello and Castagno were working on the solution of problems involved in the pictorial representation of form. His contribution lay in the sphere of colour. Coming from Venice, it was natural that he should be a colourist. His tones are silvery and luminous, and his shadows are lit up by the play of numerous reflections. According to Vasari he was an innovator in Florence as regards the oil medium which he is supposed to have used in his paints.

See Vasari, Vite (ed. Milanesi); Crowe and Cavalcaselle, History of Painting in Italy (edit. Douglas); B. Berenson, Florentine Painters (1909); Schmarsow, *Repert. f. Kunst w. XVI.* (1893); *L'Arte* XV. (1912).

DOMESDAY BOOK, or simply DOMESDAY, the record of the great survey of England executed for William the Conqueror. We learn from the English Chronicle that the scheme of this survey was discussed and determined in the Christmas assembly of 1085, and from the colophon of Domesday Book that the survey (*descriptio*) was completed in 1086. But Domesday Book (liber), although compiled from the returns of that survey, must be carefully distinguished from them; nor is it certain that it was compiled in the year in which the survey was made. For the making of the survey each county was visited by a group of royal officers (legati), who held a public enquiry, probably in the great assembly known as the county court, which mas attended by representatives of every township, as well as of the local lords. The unit of enquiry was the Hundred, and the return for each Hundred was sworn to by 12 local jurors, half of them English and half Normans. What is believed to be a full transcript of these original returns is preserved for several of the Cambridgeshire Hundreds, and is of great illustrative importance. The Inquisitio *Eliensis,* the "Exon Domesday" (so called from the preservation of the volume at Exeter), and the second volume of Domesday Book, also contain the full details which the original returns supplied.

The original ms. of Domesday Book consists of two volumes, of which the second is devoted to the three eastern counties, while the first, which is of much larger size, comprises the rest of England except the most northerly counties. Of these the north-westerly portion, which had Carlisle for its head, was not conquered till some years after the survey was made; but the omission of Northumberland and Durham has not been satisfactorily explained. There are also no surveys of London, Winchester and some other towns. For both volumes the contents of the returns were entirely rearranged and classified according to fiefs. Instead of appearing under the Hundreds and townships they now appeared under the names of the local "barons," *i.e.,* those who held the lands directly of the crown in fee. In each county the list opened with the holding of the king himself (which had possibly formed the subject of separate enquiry); then came those of the churchmen and religious houses; next those of the lay tenants-in-chief (barones); and last those of women, of the king's serjeants (servientes), of the few English "thegns" who retained land, and so forth. The two volumes are distinguished even more sharply by the exclusion from the larger one of certain details such as the enumeration of the live stock, which would have added greatly to its size. It has been suggested that the eastern counties' volume represents a first attempt, and that it was found impossible, or at least inconvenient, to complete the work on the same scale.

For the object of the survey we have three sources of information: (1) the passage in the English Chronicle, which tells us why it was ordered, (2) the list of questions which the jurors were asked, as preserved in the Inquisitio *Eliensis,* (3) the contents of Domesday Book and the allied records mentioned above. Although these can by no means be reconciled in every detail, it is now generally recognized that the primary object of the survey was to ascertain and record the fiscal rights of the king. These were mainly (1) the national land-tax (*geldum*), paid on a fixed assessment, (2) certain miscellaneous dues, (3) the proceeds of the crown lands. After a great political convulsion such as the Norman Conquest, and the wholesale confiscation of landed estates which followed it, it was William's interest to make sure that the rights of the crown, which he claimed to have inherited, had not suffered in the process. The Domesday survey therefore recorded the names of the new holders of lands and the assessments on which their tax was to be paid. But it did more than this; by the king's instructions it endeavoured to make a national valuation list, estimating the annual value of all the land in the country, (1) at the time of King Edward's death, (2) when the new owners received it, (3) at the time of the survey, and further, it reckoned, by command, the potential value as well. It is evident that William desired to know the financial resources of his kingdom, and probable that he wished to compare them with the existing assessment, which was one of considerable antiquity, though there are traces that it had been occasionally modified. The great bulk of Domesday Book is devoted to the somewhat arid details of the assessment and valuation of rural estates which were as yet the only important source of national wealth. After stating the assessment of the manor, the record sets forth the amount of arable land, and the number of plough-teams (each reckoned at eight oxen) available for working it, with the additional number (if any) that might be employed; then the river-meadows, woodland, pasture, fisheries (*i.e.,* weirs in the streams), water-mills, saltpans (if by the sea) and other subsidiary sources of revenue; the peasants are enumerated in their several classes; and finally the annual value of the whole, past and present, is roughly estimated. Both in its values and measurements, the survey's reckoning is crude.

Apart from the wholly rural portions, which constitute its bulk, Domesday contains entries of interest concerning most of the towns, which were probably made because of their bearing on the fiscal rights of the crown therein. These include fragments of custumals, records of the military service due, of markets, mints, and so forth. From the towns, from the counties as wholes, and from many of its ancient lordships, the crown was entitled to archaic dues in kind, such as honey. The information of most general interest is that on political, personal, ecclesiastical and social history, which only occurs sporadically and, as it were, by accident. Much of this was used by E. A. Freeman for his work on the Norman Conquest. Although unique in character and of priceless value to the student, Domesday will be found disappointing and largely unintelligible to any but the specialist. Even scholars are unable to explain portions of its language and of its system. This is partly due to its very early date, which has placed

between it and later records a gulf that is hard to bridge.

But in the *Dialogus de scaccario (temp.* Hen. II.) it is spoken of as a record from the arbitrament of which there was no appeal (from which its popular name of "Domesday" is said to be derived). In the middle ages its evidence was frequently invoked in the law-courts; and even now there are certain cases in which appeal is made to its testimony. To the topographer, as to the genealogist, its evidence is of primary importance; for it not only contains the earliest survey of a township or manor, but affords in most cases the clue to its subsequent descent. The rearrangement on a feudal basis, of the original returns (as described above) enabled the Conqueror and his officers to see with ease the extent of a baron's possessions; but it also showed how far he had enfeoffed "under-tenants," and who those under-tenants were. This was of great importance to William, not only for military reasons, but also because of his resolve to make the under-tenants (though the "men" of their lords) swear allegiance directly to himself. As Domesday normally records only the Christian name of an under-tenant, it is vain to seek for the surnames of families claiming a Norman origin; but much has been done to identify the under-tenants, the great bulk of whom bear foreign names.

Domesday Book was originally preserved in the royal treasury at Winchester (the Norman kings' capital), whence it speaks of itself (in one later addition) as *Liber de Wintonia.* When the treasury was removed to Westminster (probably under Henry II.) the book went with it. Here it remained until the days of Queen Victoria, being preserved from 1696 onwards in the Chapter House, and only removed in special circumstances, as when it was sent to Southampton for photozincographic reproduction. It was eventually placed in the Public Record Office, London, where it can be seen in a glass case in the museum. In 1869 it received a modern binding. The ancient Domesday chest, in which it used to be kept, is also preserved in the building.

The printing of Domesday, in "record type," was begun by Government in 1773, and the book was published, in two volumes fol. in 1783; in 1811 a volume of indexes was added, and in 1816 a supplementary volume, separately indexed, containing (1) the "Exon Domesday" (for the south-western counties), (2) the *Inquisitio Eliensis,* (3) the *Liber Winton* (surveys of Winchester early in the 12th century), and (4) the *Boldon Book*—a survey of the bishopric of Durham a century later than Domesday. Photographic facsimiles of Domesday Book, for each county separately, were published in 1861–63, also by Government.

DOMESTIC SERVICE, employment in household service. In this branch of employment in Great Britain, females outnumber males by about five to one. At the census of 1921, this group was included under the heading "personal service" in the occupational classification, the figures being as follows:—

Occupational group	Males	Females	Total	Percentage of grand total
1. Domestic servants (indoor)	64,443	1,270,946	1,335,389	60·3
2. Game keepers and game watchers	13,334	[2]	13.336	0·6
3. Restaurant keepers	20,643	16,081	36,724	1·7
4. Lodging and boarding house keepers	7,840	115,919	123,759	5·6
5. Matrons and stewards in schools and other private institutions	1,057	6,786	7,843	0·4
6. Inn, hotel-keepers; publicans; beersellers	74,385	37,151	111,136	5·0
7. Barmen	23,822	25,550	49,372	2·2
8. Waiters . . .	16,861	56,854	73,715	3·3
9. Hall and hotel porters; doorkeepers and carriage attendants	11,750	326	12,076	0·5
10. Laundry workers, washers, ironers, manglers	9,700	117,331	127,031	5.7
11. Managers, attendants of baths and wash houses	2,754	1,604	4,358	0·2
12. Hairdressers, manicurists, chiropodists	41,573	6,287	47,860	2·1
13. Caretakers and office keepers	27,221	20,983	48,204	2·2
14. Charwomen, office cleaners . .	3,153	133,470	136,623	6·2
15. Carpet beaters, vacuum cleaners, window cleaners . . .	14,928	741	15,669	0·7
16. Chimney sweeps .	5,537	25	5,562	0·3
17. Undertakers .	2,786	159	2,945	0·1
18. Others in personal service	29,895	34,359	64,254	2·9
Total . .	371,682	1,844,574	2,216,256	100·0

Nearly one-third of all female workers and about 10% of all females aged 12 and upwards enumerated were found to be employed in personal service. These proportions would, of course, be immensely increased if account could also be taken of those females not working for payment or profit who were occupied with the domestic duties of the home, of which the occupations within this classification may be regarded as an extension.

Between 1881 and 1901 the number of females engaged in indoor domestic service (including service in hotels, lodging houses and eating houses, as well as in private families) increased from 1,230,106 to 1,339,283, or by about 8%. This rate of increase was much below that of the population as a whole. In 1881 there were in England and Wales approximately 123 female domestic indoor servants to every 1,000 of the population aged ten years and upwards, 47 per 1,000 of the total population and 218 per 1,000 families. By 1901 the ratio had declined to 101 per 1,000 of the population aged ten years and upwards, 41 per 1,000 of the total population and 189 per 1,000 families. In Scotland the ratio of the population aged ten years and upwards fell during the same period from 91 per 1,000 to 80 per 1,000.

Changes introduced in 1921 into the basis of classification prevent comparison of the foregoing occupational statistics to the results of the census of 1921. The figures already quoted include all domestic servants, whether employed in private families or in establishments which were carried on for purposes of gain. It is possible, however, to make a rough comparison between the results of the censuses of 1911 and 1921 so far as they relate to private personal service and to service in hotels, boarding houses, etc.

In England and Wales, between 1911 and 1921, the number of females in private personal service declined from about 1,261,000 to about 1,005,000, or by over 20%. This represents a decline from 159 per 1,000 families in 1911 to 115 in 1921. In the same period the number of males in private personal service decreased from 266 000 to 227,000, or by 14·6%.

The tendencies in the various branches of the personal service

group outlined above, when looked at as a whole, may also reflect in some degree changes which are occurring in the social habits, of a section of the population. There has been a growth in the number and size of commercial establishments which cater for personal needs, together with a marked increase in the number of labour-saving devices for use in the home, and consequently much of the work formerly required in private households is being steadily eliminated. (X.)

United States,——Domestic service in the United States has always been the leading field of gainful employment for women. In colonial times, the servants were chiefly Indian and negro slaves and transported white convicts and "redemptioners." Girls were frequently apprenticed to domestic service until of age or married; and women probably "hired out" as "help" before they engaged in any handicraft for pay. The number of women in manufacturing increased rapidly, however, and, later, many entered clerical and professional pursuits. But in 1870 over half of the gainfully employed females were in domestic service; and even in 1920 this remained one of the principal fields of employment for women.

The relative importance of domestic service as a field of employment for women has declined steadily for many years, the decline being especially rapid during the decade 1910 to 1920. Regardless of colour or race, women are abandoning domestic service to seek employment in stores, factories and offices. The inducements are probably regular and shorter hours in other employments, greater standardization, more congenial companionship and pleasanter surroundings, and also a better social status. Other causes are: The high wages and the great demand for women workers outside the home during the World War; practical cessation of immigration between 1915 and 1920, which greatly reduced the number of foreign-born women available as servants; increased wages for servants, making them luxuries which only the well-to-do can afford; simplified housekeeping, resulting from the fact that much work formerly done in the home is now done outside, from increased use of electrical and other household appliances, and from the increase in apartment homes with the growing custom of taking meals in cafes and restaurants. Servants are less necessary than formerly, and people are doing without them. The number of servants per 1,000 of the population decreased from 19.1 in 1900 to 13 in 1920. During the half century from 1870 to 1920, the proportion of non-agricultural female workers of all ages employed as servants or in similar pursuits declined from 60.7 to 18·2%, while the proportion in clerical and similar pursuits increased from 0·8 to 25·6%, the proportion in factory occupations increased from 17.6 to 23·8%, and the proportion in the principal professions increased from 6.4 to 13·3%. Notwithstanding the marked decline in the relative importance of domestic service for female gainful workers, 1,358,665 of them were employed as servants or in similar pursuits in 1920. Of these, native whites formed 46·9%, foreign-born whites 20·7%, negroes 32·1% and others 0·3%. The native whites were rather widely distributed, the foreign-born whites were largely in the north-east, and the negroes mostly in the South. (A. M. E.)

DOMETT, ALFRED (1811–1887), British colonial statesman and poet, was born at Camberwell Grove, Surrey, on May 20, 1811. He became the intimate friend of Robert Browning, of whose poem "Waring" he was the subject. An interesting account of the friendship between the two men appeared in *The* Contemporary Review for Jan. 1905, by W. H. Griffin. (See also Robert Browning and Alfred Domett, edited by F. G. Kenyon, 1906.) In 1842 Domett emigrated to New Zealand, where he filled many important administrative posts, being colonial secretary for New Munster in 1848, secretary for the colony in 1851, and prime minister in 1862. He returned to England in 1871, was created C.M.G. in 1880, and died on Nov. 2, 1887. Among his volumes of verse, Ranolf and Amohia, a South Sea Day Dream, is the best known (1872), and Flotsam and Jetsam (1877) is dedicated to Browning.

DOMETTE. A term applied to a loosely-woven fabric of light texture of the plain calico weave and finished with a nap on both sides, similar to flannelette (q v). It is sometimes woven either plain or striped as an all-cotton fabric; and sometimes with a cotton warp and woollen weft, and employed for various purposes as, for example, a light wadding for use by dressmakers; waist-bands for hosiery pants, pyjamas, shirts and shrouds. One quality of domette contains 36 warp threads per inch, of 32's cotton, and 22 picks per inch, of 10's uoollen weft.

DOMFRONT, a town of northwestern France in the arrondissement of Alençon, in the department of Orne, 43 mi. W.N.W. of Alençon by rail. Pop. (1936) 2,803. The town, situated on a bluff overlooking the Varenne, has a church, Notre-Dame-sur-l'Eau, dating from the 11th century. Domfront is said to have grown up in the 6th century round the oratory of the hermit St. Front, and played an important part in the wars against the English and the religious wars. In 1574 it was occupied by the Protestant leader Gabriel de Montgomery, who after a stubborn siege was forced to yield it to Jacques Goyon, count of Matignon. In the middle ages it was one of the chief strongholds in Normandy, and there still remain several towers of its ramparts, and ruins of the keep of its castle built in 1011, rebuilt in the 12th century by Henry II., king of England, and dismantled at the end of the 16th century. The town is the seat of a sub-prefect, and has a tribunal of first instance. There are quarries in the vicinity. Domfront is known for its horse breeding.

DOMICILE, or DOMICIL, a residence; in law, the place where a person has his or her principal residence. In French law it is only a step to naturalization. In English law it implies something more than mere residence. A person has either a domicile of origin or a domicile of choice. The former is the place of his parents' home—and the latter is the place where he intends to reside. In the United States, it is the place where a person exercises his political rights.

Since the beginning of the 19th century most of the leading European States have unified their internal laws; and attachment to a province by domicile having thus become an unnecessary consideration, they have adopted political nationality as the criterion of the law to be applied in most of the questions which used to depend on domicile. Thus as between themselves they have greatly simplified the determination of those questions, but a similar elimination of domicile is impossible in what concerns British subjects, because the British empire continues to include a great variety of laws, as those of England, Scotland, the province of Quebec, the Cape Colony, etc. Within the British dominions domicile is the only available criterion of the legal character of a British subject, and all British courts continue to apply the same criterion to British subjects outside those dominions and to foreigners.

The Roman jurists defined domicile to be the place "*ubi* quis *larem rerumque* ac fortunarrrm *summam constituit;* unde *rursus non* sit *discessurus si* nihil avocet; *unde cum* profectus est, *peregrinari videtur:* quo *si* rediit *peregrinari* iam destitit." This makes that place the domicile which may be described as the headquarters of the person concerned; but a man's habits of life may point to no place, or may point equally to two places, as his headquarters, and the connection of domicile with law requires that a man shall always have a domicile, and never more than one. The former of these difficulties is met in the manner described by Lord Westbury in Udny v. Udny. (L.R., 1 H L. Sc.A.) "It is," he said, "a settled principle that no man shall be without a domicile, and to secure this end the law attributes to every individual as soon as he is born the domicile of his father, if the child be legitimate, and the domicile of his mother, if the child be illegitimate. This is called the domicile of origin, and is involuntary. It is the creation of the law, not of the party. It may be extinguished by act of law, as for example by sentence of death or exile for life, which destroys the *status civilis* of the criminal; but it cannot be destroyed by the will and act of the party. Domicile of choice is the creation of the party. When a domicile of choice is acquired, the domicile of origin is in abeyance, but is not absolutely extinguished or obliterated. When a domicile of choice is abandoned, the doinicile of origin revives, a special intention to revert to it not being necessary. A natural-born Englishman may domicile himself in Holland, but if he breaks up his establishment there and quits Holland, declaring that he will never return, it is absurd to suppose that

his Dutch domicil clings to him until he has set up his tabernacle elsewhere." If to this we add that legitimate minors follow the change's of the father's domicil and a married woman follows the domicil of her husband, also that compulsory detention will not create a domicil, the outlines of involuntary domicil will have been sufficiently sketched.

For the establishment of a domicil of choice there must be both *animus* and *factum,* intention and fact. The fact need not be more than arrival in the territory of the new domicil if there be the necessary intention, while any number of years' continuance there will not found a domicil if the necessary intention is absent. As the result of the most recent English and Scottish cases it may be laid down that the necessary intention is incompatible with the contemplation by the person in question of any event on the occurrence of which his residence in the territory in question would cease, and that if he has not formed a fixed and settled purpose of settling in that territory, at least his conduct and declarations must lead to the belief that he would have declared such a purpose if the necessity of making an election between that territory and his former one had arisen. The word territory, meaning a country having a certain legal system, is used advisedly, for neither the intention nor the fact need refer to a locality. It is possible that a Scotsman or a foreigner may have clearly established a domicil of choice in England, although it may be impossible to say whether London, Brighton or a house in the country is his true or principal residence. What is here laid down has been gradually attained. In the older English cases an intention to return to the former domicil was not excluded, if the event on which the return depended was highly uncertain and regarded by the person in question as remote. Afterwards a tendency towards the opposite extreme was manifested by requiring for a domicil of choice the intention to associate oneself with the ideas and habits of the new territory—*Quatenus* in *illo* exuere *patriam,* not in the political sense, which it was never attempted to connect with change of domicil, but in the social and legal sense. At present it is agreed that the only intention to be considered is that of residence, but that, if the intention to reside in the territory be proved to amount to what has been above stated, a domicil will be acquired from which the legal consequences will follow, even defeating intentions about them so clearly expressed as, for instance, by making a will which by reason of the change of domicil is invalid. The two most important cases are Douglas v. Douglas (1871), L.R., 12 Eq. 617, before Vice-chancellor Wickens, and *Winans* v. Att. Gen. (1904), A.C. 287, before the House of Lords.

When the circumstances of a person's life point to two territories as domicils, the selection of the one which alone can fill that character often leads to appeals even up to the highest court. The residence of a man's wife and family as contrasted with his place of business, his exercise of political or municipal functions, and any conduct which tends to connect his children with a given country, as by their education, or the start given them in life, as well as other indications, are often cited as important; but none of them is in itself decisive. The situation must be considered as a whole. When the question is between the domicil of origin and an alleged one of choice, its solution is rendered a little easier than it is when the question is between two alleged domicils of choice, the burden of proof lying on the party which contends that the domicil of origin has been abandoned.

In the state of the law which has been described it will not be found surprising that an act of parliament, 24 and 25 Vict. c. 121, recites that by the operation of the law of domicil the expectation and belief of British subjects dying abroad with regard to the distribution of their property are often defeated, and enacts that when a convention to that effect has been made with any foreign country, no British subject dying in such country shall be deemed to have acquired a domicil therein, unless he has been resident in such country for one year previous to death and has made a declaration in writing of his intention to become domiciled; and that British subjects so dying without having so resided and made such declaration shall be deemed for all purposes of testate or intestate succession as to movables to retain the domicil they possessed at the time of going to reside in such foreign country. Similar exemptions are conferred on the subjects of the foreign State dying in Great Britain or Ireland. But the act does not apply to foreigners who have obtained letters of naturalization in any part of the British dominions. It has not been availed of, and is indeed an anachronism, ignoring as it does the fact that domicil has no longer a world-wide importance, owing to the substitution for it of political nationality as a test of private law in so many important countries. The United States of America is not one of those countries, but there the importance of domicil suffers from the habit of referring questions of capacity to the law of the place of contract instead of to any personal law. (J. W.)

DOMINANT, in music, the fifth degree of the diatonic scale, *e.g.,* G in the key of C; A in that of D, and so on; so called from its exceptional influence and importance in relation to the tonic, or key-note, and the harmony in general.

Dominant was used by Mendel to describe a biological character which manifests itself, as opposed to a recessive character, which remains latent (see MENDELISM).

DOMINIC, SAINT (1170–1221), founder of the Dominican Order of Preaching Friars, was born in 1170 at Calaroga in Old Castile. He spent ten or twelve years in study, chiefly theological, at Palencia, and then, about 1195, he was ordained and became a canon in the cathedral chapter of Osma, his native diocese. The bishop induced his canons to follow the Rule of St. Augustine and thus make themselves Augustinian Canons (*q.v.*); and so Dominic became a canon regular and soon the prior or provost of the cathedral community. The years from 1195 to 1203 have been filled up with fabulous stories of missions to the Moors; but Dominic stayed at Osma, preaching much in the cathedral, until 1203, when he accompanied the bishop on an embassy in behalf of the king of Castile to "The Marches." This has commonly been taken as Denmark, but more probably it was the French or Italian Marches. When the embassy was over, the bishop and Dominic repaired to Rome, and Innocent III. charged them to preach among the Albigensian heretics in Languedoc, upon which work Dominic was engaged for ten years (1205–15).

The Albigenses (*q.v.*) have received much sympathy, as being a kind of pre-Reformation Protestants; but it is now recognized that their tenets were an extreme form of Manichaeism. They believed in the existence of two gods, a good (whose son was Christ) and an evil (whose son was Satan); matter is the creation of the evil principle, and therefore essentially evil, and the greatest of all sins is sexual intercourse, even in marriage; sinful also is the possession of material goods, the eating of flesh and many other things. So great was the abhorrence of matter that some even thought it an act of religion to commit suicide by voluntary starvation, or to starve children to death (see article "Neu-Manichäer" by Otto Zockler in ed. 3 of Herzog's Realencyklopadie fur *protestantische* Theologie [1903]; or c. iii. of Paul Sabatier's Life of St. Francis). Such tenets were destructive not only of Catholicism but of Christianity of any kind and of civil society itself; and for this reason so unecclesiastical a person as the emperor Frederick II. tried to suppress the kindred sects in Italy. In 1208, after the murder of a papal legate, Innocent III. called on the Christian princes to suppress the Albigensian heresy by force of arms, and for seven years southern France was devastated by one of the most bloodthirsty wars in history, the Albigenses being slaughtered by thousands and their property confiscated wholesale.

In the opinion of Grützmacher, one of the most recent Protestant writers on him, St. Dominic, though keeping on good terms with Simon de Montfort, the leader, and praying for the success of the crusaders' arms during the battle of Muret, "took no part in the crusade, but endeavoured to carry on his spiritual activity on the same lines as before. The oldest trustworthy sources know nothing of his having exercised the office of Inquisitor during the Albigensian war." This verdict of a fair-minded and highly competent Protestant church historian on the most controverted point of Dominic's career is of great value. His method was to travel over the country on foot and barefooted, in extreme poverty, simplicity and austerity, preaching and instructing in high-

ways and villages and towns, and in the castles of the nobility, controverting and discussing with the heretics. He used often to organize formal disputations with Albigensian leaders, lasting a number of days. Many times plots were laid against his life. Though in his ten years of preaching a large number of converts were made, it has to be said that the results were not such as had been hoped for, and after it all, and after the crusade, the population still remained at heart Albigensian. A sense of failure appears in Dominic's last sermon in Languedoc: "For many years I have exhorted you in vain, with gentleness, preaching, praying and weeping. But according to the proverb of my country, 'where blessing can accomplish nothing, blows may avail.' We shall rouse against you princes and prelates, who, alas, will arm nations and kingdoms against this land . . . and thus blows will avail where blessings and gentleness have been powerless." The threat that seems to be conveyed in these words, of trying to promote a new crusade, was never carried out; the remaining years of Dominic's life were wholly given up to the founding of his order.

The Order of Dominicans grew out of the little band of volunteers that had joined Dominic in his mission among the Albigenses. He had become possessed with the idea of addressing wider circles and of forming an order whose vocation should be to preach and missionize throughout the whole world. By 1214 the nucleus of such an institute was formed round Dominic and was known as the "Holy Preaching." In 1215 the bishop of Toulouse, Dominic's great friend, established them in a church and house of the city, and Dominic went to Rome to obtain the permission of Innocent III. to found his order of preachers *(see* DOMINICANS). After three years, in 1218, the full permission he desired was given by Honorius III. These last years of his life were spent in journeying backwards and forwards between Toulouse and Rome, where his abode was at the basilica of Santa Sabina on the Aventine, given to him by the pope; and then in extended journeys all over Italy, and to Paris, and into Spain, establishing friaries and organizing the order wherever he went. It propagated and spread with extraordinary rapidity, so that by Dominic's death in 1221, only five or six years after the first practical steps towards the execution of the idea, there were over 500 friars and *60* friaries, divided into *3* provinces embracing the whole of western Europe. Thus Dominic was at his death able to contemplate his great creation solidly established, and well launched on its career to preach to the whole world.

It appears that at the end of his life Dominic had the idea of going himself to preach to the heathen Kuman Tatars on the Dnieper and the Volga. But this was not to be; he was worn out by the incessant toils and fatigues and austerities of his laborious life, and he died at his monastery at Bologna, on Aug. 6, *1221.* He was canonized in 1234 by Gregory IX., who, as Cardinal Ugolino, had been the great friend and supporter both of Dominic and of Francis of Assisi.

As St. Dominic's character and work do not receive the same general recognition as do St. Francis of Assisi's, it will be worth while to quote from the appreciation by Prof. Griitzmacher of Heidelberg:—"It is certain that Dominic was a noble personality of genuine and true piety. . . . Only by the preaching of pure doctrine would he overcome heretics. . . . He was by nature soft-hearted, so that he often shed tears through warm sympathy. . . . In the purity of his intention and the earnestness with which he strove to carry out his ideal, he was not inferior to Francis."

The chief sources for St. Dominic's life are the account by Jordan of Saxony, his successor as master-general of the order, and the evidence of the witnesses at the Process of Canonization,—all in the Bollandists' *Acta sanctorum,* Aug. 4. Probably the best modern Life is that by Jean Guiraud, in the series *Les Saints* (Eng. trans. by Katharine de Mattos, 1901); the bibliography contains a useful list of the chief sources for the history of St. Dominic and the order, and of the best modern works thereon. *See* also the article "Dominicus" in ed. 2 of Wetzer and Welte, *Kirchenlexicon;* Grdtzmacher's excellent article "Dominikus," in ed. 3 of Herzog, *Realencyklopadie* fur *protestantische Theologie,* already referred to; also Bede Jarrett, O.P., *The Life of St. Dominic* (1924), and *H.* Petitot, O.P., *Vie de S. Dominique* (1925). (E. C. B.)

DOMINICA, the largest of the five presidencies in the colony of the Windward Islands, British West Indies. It lies in 15° 30′ N. and 61° 20′ W., between the French islands of Martinique and Guadeloupe, at a distance of about *25* m. from each, is 29 m. long, has a maximum breadth of *16* m. and an area of 304 sq.m. *A* range of lofty forest-clad mountains traverses the island from north to south, broken in the centre by a narrow plain drained by the rivers Layou and Pagoua, flowing west and east respectively. The highest point is Morne Diablotin (5,314 ft.), in the north. Signs of volcanic activity include solfataras, subterranean vapours and hot springs; while in the south the so-called Boiling Lake lies on the mountain side, 2,300 ft. above the sea; its banks are steep and its depth unknown. Its waters are often forced *3* ft. above the normal level by the pressure of the escaping gases; and the fumes are occasionally poisonous. The island is of extraordinary beauty and botanically remarkable for its great number of peculiar species. The hills produce valuable timber, while coffee, limes, oranges, india-rubber trees, spices and many tropical fruits grow luxuriantly in the rich lowlands. There are some thirty streams of considerable size, besides numerous mountain torrents. The fisheries are productive, and honey and wax are furnished by wild bees, originally introduced from Europe. The temperature varies from 78° to 86° F in the hot season from August to October, and from 72° to 84° in the cooler months; the rainfall varies in different parts from 50 to 162 in. per annum, but the porous soil soon absorbs the rain, and keeps the atmosphere clear and invigorating.

The manufactures include Sugar, lime-juice and essential oils; the exports are cocoa, coconuts, limes and lime products, oranges and bananas The inhabitants in 1939 numbered 51,951. The majority are negroes; the whites are of French and British descent. There are also a few Caribs, the remnant of the aboriginal population. A French *patois* is the language of the peasantry, but English is generally understood. The capital, Roseau (6,803), is a fortified town and a port; Portsmouth, the only other town, possesses the better harbour in Prince Rupert's Bay on the north-west. In religion Roman Catholics predominate, and a bishop resides at Roseau, but there is no established church. Education is free and compulsory.

History.—Dominica was thus named by Columbus in 1493, in commemoration of the date, Sunday (*Dies Dominica*) Nov. 3. The first European settlers (1632) were French. In 1660 a treaty appears to have been made between the French, British and the natives, assigning St. Vincent and Dominica to the Caribs, and in 1748 it was once more agreed that Dominica should be left in the undisturbed possession of the natives. Nevertheless the French settlers increased, and the island came under the rule of a French governor. It was captured by the British and recaptured by the French frequently in the wars from 1761 onwards, and in 1805 the French general, La Grange, at the head of 4,000 troops, took Roseau and pillaged the island. The French were, however, unable to make good their hold, and Dominica has since remained undisturbed in British possession.

After 1872 Dominica formed part of the colony of the Leeward islands. In 1898 the local legislature, in consideration of pecuniary assistance from Great Britain, abrogated the semi-elective constitution and provided for a nominated legislative council, but in 1925 the island reverted to the elective system. In Jan. 1940, Dominica was transferred from the Leeward to the Windward Islands group.

DOMINICAL LETTERS or **SUNDAY LETTERS,** letters employed in the construction of the calendar to mark the Sundays throughout the year. The first seven letters of the alphabet are taken to mark the first seven days of the year, the following sets of seven following on according to this marking. As the year consists of *52* weeks and one day the dominical letters go backward one day every year, the same order of letters recurring every 28 years, making the solar circle. *See* also CALENDAR.

DOMINICAN REPUBLIC: *see* SANTO DOMINGO.

DOMINICANS, otherwise called Friars Preachers, and in England Black Friars, from the black mantle worn over a white habit, an order of friars founded by St. Dominic (*q.v.*). Their first house was in Toulouse, where the bishop established them at the church of St. Romain, *1215.* Dominic at once went to Rome

to obtain permission to found an order of preachers whose sphere of activity should be the whole world, but Innocent III. said they must adopt one of the existing rules. Dominic returned to Toulouse and it was resolved to take the Rule of St. Augustine, Dominic himself having been an Augustinian canon at Osma (see AUGUSTINIAN CANONS). Dominic went again to Rome, and in 1216 obtained from Honorius III. a series of confirmations of the

ST. THOMAS TRIUMPHS OVER AVERROËS, THE MOORISH PHILOSOPHER
After an altar-piece by Traini in Santa Caterina at Pisa. Holding a bible in his hand and four of his own works on his knee, St. Thomas is the recipient of rays of wisdom from Christ (above), four apostles, Moses and St. Paul; Aristotle (at his right) and Plato (at his left). At his feet, between groups of faithful, lies the prostrate Averroës, with a ray of refutation piercing his "Commentary"

community at Toulouse as a congregation following the Rule of St. Augustine with a special mission to preach. Early in 1218 an encyclical bull was issued to the bishops of the whole Catholic world recommending to them the "Order of Friars Preachers," followed in 1221 by another ordering them to give to the friars faculties to preach and hear confessions in their dioceses. By this date the friars had penetrated into some parts of Italy, France, Spain, Poland and Bohemia, and some were on their way to England.

The order took definite shape at the two general chapters held at Bologna in 1220 and 1221. The manner of life was very austere —midnight office, perpetual abstinence from meat, frequent disciplines, prolonged fasts and silence. At St. Dominic's suggestion, and under his strong pressure, but not without considerable opposition, the general chapter determined that the poverty practised in the order should be not merely individual, as in the monastic orders, but corporate, as among the Franciscans; so that the order should have no possessions, except the monastic buildings and churches, no property, no fixed income, but should live on chsrity and by begging. Thus, doubtless in imitation of the Franciscans, the Dominicans became a mendicant order.

The extraordinarily rapid propagation of the institute suffered no diminution through the founder's death in 1221, for his four immediate successors in the generalate were men of conspicuous ability and high character. In a few years the Dominicans penetrated into Denmark, Sweden, Russia, Prussia and Poland, preaching and missionizing in the still pagan districts of these countries; and soon they made their way to Greece and Palestine and thence to central Asia. From the 14th century until the middle of the 17th the Dominicans had numerous missions in Persia, India and China, and in the northern parts of Africa. They followed the Spanish and Portuguese explorers and conquerors to both East and West, converting, protecting and civilizing the aborigines. Many suffered martyrdom.

Another conspicuous field of work of the Dominicans lay in the universities. It had been St. Dominic's policy to aim at founding houses first of all in the great university towns—at Paris, Bologna, Palencia, Oxford. This policy was adhered to, and the Dominicans soon became a power in the universities, occupying chairs in those just named and in Padua, Cologne, Vienna, Prague and Salamanca. The scholastic doctors Albert the Great and Thomas Aquinas mere the leaders in this side of Dominican activity, and the order's influence on the course of mediaeval theological development was exercised mainly by these doctors and by the Dominican school of theology, which to this day has maintained the principles and methods elaborated by St. Thomas.

The Dominican name is in a special way associated with the Inquisition, the office of Inquisitor in all countries, including Spain, having usually been held by Dominicans. The vicissitudes of the order have been much like those of other orders—periods of relaxation being followed by periods of revival and reform; but there were not any reforms of the same historical importance as in most other orders, the policy having been to keep all such movements strictly within the organization of the order. In 1425 Martin V. relaxed for some houses the law of corporate poverty, allowing them to hold property, and to have fixed sources of income; and 50 years later Sixtus IV. extended this mitigation to the entire order, which thereby ceased to be mendicant. This change caused no troubles, as among the Franciscans, for it was felt that it did not touch the fundamental Dominican ideal.

The Friars Preachers came to England and were established at Oxford in 1221, and by the end of the century 50 friaries were in existence in England, usually in the towns, and several in Ireland and Scotland. In London they were first on the site of Lincoln's Inn, but in 1275 migrated to that now occupied by Printing-house Square, their name, "Blackiriars," surviving as that of the adjacent district. The only nunnery was at Dartford. In Mary's reign some of the scattered friars were brought together and established in Smithfield, and the remnant of the nuns were restored to Dartford. In 1559 these houses were suppressed and the nuns and friars expatriated, and for a hundred years there was no English Dominican community. In 1658 Friar Thomas Howard (afterwards Cardinal) succeeded in establishing at Bornhem near Antwerp a house for the English friars. From that time there has always been an organized body of English Dominicans, again and again reduced almost to extinction, but ever surviving; it now has half a dozen thriving friaries. The Irish province also survived the days of persecution and possesses a dozen friaries. In 1840 Lacordaire restored the French province. Missionary work still holds a prominent place in Dominican life; there are missions in Annam, Tongking and China, and in Mesopotamia, Mosul and Kurdistan. They have also a remarkable school for Biblical studies and research at Jerusalem, and the theological faculty in the Roman Catholic university at Fribourg in Switzerland is in their hands. There have been four Dominican popes: Innocent V. (d. 1276), Benedict XI. (d. 1304), Pius V, (d. 1572), Benedict XIII. (d. 1730).

The friars form the "First Order"; the nuns, or Dominicanesses, the "Second Order." The latter may claim to have chronological precedence over the friars, for the first nunnery was established by St. Dominic in 1206 at Prouille in the diocese of Toulouse. as a refuge for women converted from the Albigensian heresy. The second convent was at San Sisto in Rome, also

founded by Dominic. From that time the institute spread widely. The rule resembled that of the friars, except that the nuns were to be strictly enclosed and purely contemplative; in course of time, however, they undertook educational work. They have schools and orphanages in South Africa, especially in the Transvaal.

DOMINIONS OFFICE: see GOVERNMENT DEPARTMENTS.

DOMINIS, MARCO ANTONIO DE (1566–1624), Italian theologian, was born on the island of Arbe, off the Dalmatian coast. He was educated by the Jesuits, and became professor of mathematics at Padua, and professor of rhetoric and philosophy at Brescia. In 1596 he was appointed to the bishopric of Segnia (Zengg) in Dalmatia, and in 1600 was raised to the archbishopric of Spalato and primacy of Dalmatia and Croatia. His attempts at reform brought him into conflict with his suffragans; and he also became involved in the quarrel between the papacy and Venice. He resigned his see in Sept. 1616, and wrote at Venice his *Consilium profectionis,* criticizing the papacy. In the same year, he crossed to England, and being regarded as a convert to Anglicanism, was appointed master of the Savoy (1618) and dean of Windsor (1619); he subsequently presented himself to the living of West Ilsley, Berkshire. His published attacks on the papacy include the *Papatus Romanus,* issued anonymously (London, 1617; Frankfurt, 1618), the *Scogli* del *naufragio Christiano* (London [?] 1618), and a Sermon preached in Italian, etc. before the king. But his principal work was the De *republica ecclesiastica,* of which the first part — after revision by Anglican theologians — was published under royal patronage in London (1617), in which he ably set forth his theory of the church. In 1619 Dominis published without the author's consent Paolo Sarpi's *Historia* del *Concilio Tridentino,* the ms. of which he had brought with him from Venice.

Three years later the ex-archbishop was back again in Rome, doing penance for his heresies. He may have been enticed back by the elevation of his kinsman, Alessandro Ludovisi, to the papal throne as Gregory XV. (1621), but if so, he had barely time to publish at Rome (1623) his *Sui reditus* ex Angliae *consilium,* a repudiation of his anti-papal works, when Gregory died (July 1623). The proceedings of the Inquisition against the archbishop were revived, but before they were concluded, Dominis died in prison, on Sept. 8, 1624. Judgment was pronounced over his corpse, which was publicly burnt in the Campo di Fiore. By a strange irony of fate the publication of his *Reditus* consilium was subsequently forbidden in Venice because of its uncompromising advocacy of the supremacy of the pope over the temporal powers.

See Herzog-Hauck, Realencyklopadie, where a full bibliography is given; G. Goodman, *The* Court of James *I.* ed. Brewer (London, 1839); H. Newland, *Life* and Contemporaneous Church *History of* Antonio de *Dominis* (Oxford, 1859).

DOMINOES, a game unknown until the 18th century, and probably invented in Italy, played by two or more persons, usually with 28 oblong pieces, or dominoes, known also as cards or stones (called pieces or *men* in America), having ivory faces backed with ebony; from this backing, as resembling the cloak (usually black) called a domino (see MASKS), the name is said to be derived. Cardboard dominoes to be held in the hand are also in use. The face of each card is divided into two squares by a black line, and in each square half the value of the card is indicated by its being either a blank or marked with one or more black pips, generally up to six, but some sets run as high as double-nine.

The Block and Draw Games. — The dominoes are shuffled face downwards on the table. The lead is usually decided by drawing for the highest card, but it is sometimes held that any doublet takes precedence. The cards are then reshuffled, and each player draws at random the number of cards required for the particular form of the game, usually seven. The cards left behind are called the stock. To play a card is known technically as to pose. The leader poses first, generally playing his highest domino, since at the end the player loses according to the number of pips in the cards he has left in his hand. By some rules, a player after playing a double may play another card which matches it; *e.g.,* if he plays double-six he may play another card which has a six at one end. The second player has to match the leader's pose by putting one of his cards in juxtaposition at one end; *i.e.,* if the leader plays four-five, the second player has to play a card which contains either a four or a five, the five being applied to the five or the four to the four. Doublets are placed *à* cheval (*crosswise*). If a player cannot match, he says "go," and his opponent plays, unless the Draw game — the usual game — is being played, in which case the player who cannot match draws from the stock (two cards must always be left in stock) till he takes a card that matches. If a player succeeds in posing all his cards, he calls "Domino!" and wins the hand, scoring as many points as there are pips on the cards still held by his opponent. If neither player can match, that player wins who has the fewest pips left in his hand and he scores as many points as are left in the two hands combined (sometimes only the excess held by his opponent); but when a player has called "Go!" his adversary must match if he can, in which case the other player may be able to match in turn. A game is generally 100 points.

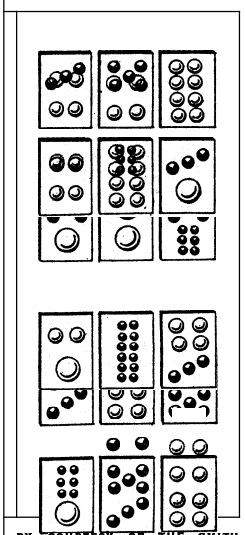
ESKIMO DOMINOES, USED BY THE INNUIT TRIBE

The number of pieces varies from 60 to 148, and a set is called A ma zu lat

All Fives (or Muggins). — Each player takes five cards. If the leader poses either double-five, six-four, five-blank, or three-two, he scores the number of pips that are on the card. If in the course of play a player can play such a card as makes the sum of the end pips 5, 10, 15 or 20, he scores that number; *e.g.,* if to two-four he can play double-four (h cheval) he scores 10; if to six-one he plays six-four he scores 5. He must pose if he can match; if he cannot, he draws till he can. Scores are called and taken immediately. At the point of the domino, the winner scores in points the multiple of five which is nearest to the number of pips in his adversary's hand; *e.g.,* he scores 25 if his adversary has 27 pips, 30 if he has 28. If neither hand can match, the lowest number of pips wins, and the score is taken as before, without addition or subtraction, according to the adversary's pips.



BY COURTESY OF THE SMITHSONIAN INSTITUTION

KOREAN DOMINO PIECES

The set consists of 32 pieces, made of wood, bone or ivory. There are no blanks

All Threes is played in the same manner as Muggins, save that three or some multiple of three are aimed at.

Threes and Fives is similar, but only one point is scored for each five or three made at the two ends, though they can be scored in combination. Thus A plays six-five; B six-one; B scores 2 points for five-one (two threes). A plays one-five; B double-five; B now scores 8 more. 5 for five threes and 3 for three fives.

Domino Whist is played by four players. Partners are drawn for as at whist; the player drawing the highest domino leads. Each player takes seven cards. There are no tricks, trumps or honours. The cards are played as in ordinary dominoes, a hand being finished when one of the players plays his last card, or when both ends are blocked. Pips are then counted, and the holder or holders of the highest number score to their debit the aggregate number of points. The side that is first debited with 100 points loses the game. Strength in a suit is indicated by the lead.

Matador.—This is a favourite and is perhaps also the most scientific form of the game. It is played on a different principle from the preceding variations, the object being not to match the end number, but to pose such a number, as, added to the end, will make seven; *e.g.*, to a five a two must be played, to a three a four, etc. Seven dominoes are drawn and the highest double begins. When a player cannot make a seven on either end he must draw from stock until he secures a card that will enable him to make seven, two cards remaining in the stock. As Matador is played with dominoes no higher than six, a blank means blocking of that end. In this case no further play can take place at that end excepting by posing a matador, which may be played at any time. There are four matadors, the 6-1, 5-2, 4-3, and double-blank. It is often better to draw one or more fresh cards than to play one's last matador, as it may save the game at a critical juncture. In posing a double counts as a single number only, but in scoring the full number of pips is counted. When the game has been definitely blocked the player whose pips aggregate the lower number scores the number of the combined hands (sometimes only the excess in his opponent's hand), the game being usually 100. Matador can be played by three persons, in which case the two having the lowest scores usually combine against the threatening winner; and also by four, either each for himself or two on a side.

Other varieties of the game not often played are the Bergen game, Sebastopol, Domino Loo, Bingo, Tiddle-a-Wink, the Game of Four, Malakoff, Cyprus, Round the Clock and others.

See Hoffman, *Card and Table Games;* F. *W*. Lewis, *Dominoes.*

DOMINUS, the Latin word for master or owner. As a title of sovereignty the term under the republic at Rome had all the associations of the Greek *τύραννος*; refused during the early principate, it finally became an official title of the Roman emperors under Diocletian. *Dominus,* the French equivalent being *sieur,* was the Latin title of the feudal (superior and mesne) lords, and also an ecclesiastical and academical title. The ecclesiastical title was rendered in English "sir," which was a common prefix before the Reformation for parsons, as in "Sir Hugh Evans" in Shakespeare's Merry Wives of *Windsor.* The academical use was for a bachelor of arts, and so is still used at Cambridge and other universities. The shortened form "dom" is used as a prefix of honour for ecclesiastics of the Roman Church, and especially for members of the Benedictine and other religious orders. The same form is also a title of honour in Portugal, as formerly in Brazil, used by members of the blood royal and others on whom it has been conferred by the sovereign. The Spanish form "don" is also a title, formerly applicable only to the nobility, and now one of courtesy and respect applied to any member of the better classes. The feminine form "doña" is similarly applied to a lady. The English colloquial use of "don" for a fellow or tutor of a college at a university is derived either from an application of the Spanish title to one having authority or position, or from the academical use of *dominus.* The earliest use of the word in this sense appears, according to the New English Dictionary, in South's Sermons (1660). An English corruption "dan" was in early use as a title of respect, equivalent to "master." The literary application to poets is due to Spenser's use of "Dan Chaucer, well of English undefyled" (*Faëry Queen,* IV. ii. 32).

DOMITIAN (TITUS FLAVIUS DOMITIANUS), Roman emperor A.D. 81–96, the second son of Vespasian, was born at Rome on Oct. 24, A.D. 51. When Vespasian was proclaimed emperor at Alexandria, Domitian escaped with difficulty from the temple of the Capitol, which had been set on fire by the Vitellians, and remained in hiding till his father's party proved victorious. After the fall of Vitellius he was saluted as Caesar by the troops, obtained the city praetorship, and was entrusted with the administration of Italy till his father's return from the East. But although in his father's lifetime he was several times consul, and after his death was nominally the partner in the empire with his brother Titus, he took no part in public business, but lived in great retirement, devoting himself to a life of pleasure and of literary pursuits till he succeeded to the throne. The death of Titus, if not hastened by foul means. was at least eagerly welcomed by his brother. Domitian's succession (on Sept. 13, 81) was unquestioned, and it would seem that he had intended, so far as his weak volition and mean abilities would allow, to govern well. Like Augustus, he attempted a reformation of morals and religion. He erected many temples and public buildings (amongst them the Odeum, a kind of theatre for musical performances) and restored the temple of the Capitol. He passed many sumptuary laws, and issued an edict forbidding the over-cultivation of vines to the neglect of corn-growing. Finally, he took a personal share in the administration of justice at Rome, checked the activity of the informers (*delatores*), and exercised a jealous supervision over the governors of provinces. Even when Rome and Italy smarted beneath his proscriptions and extortions, the provinces were undisturbed.

Though he took the title of imperator more than 20 times, and enjoyed at least one triumph, Domitian's military achievements were insignificant. He defeated the Chatti, annexed the district of the Taunus, and established the *Limes* as a line of defence; but he suffered defeats at the hands of the Quadi, Sarmatae and Marcomanni; in Dacia he received a severe check, and was obliged to purchase peace (90) from Decebalus by the payment of a large sum of money and by guaranteeing a yearly tribute—the first instance in Roman history. His jealousy was provoked by the successes of Agricola in Britain, who was recalled to Rome (85) in the midst of his conquests, condemned to retirement, and perhaps removed by poison. The revolt of Antonius Saturninus, the commander of the Roman forces in upper Germany (88 or 89), marks the turning-point in his reign (on the date see H. Schiller, Geschichte der romischen kaiserzeit, i. pt. 2, p. 524, note 2). It was speedily crushed; but from that moment Domitian's character changed. He got rid of all whom he disliked on the charge of having taken part in the conspiracy, and no man of eminence was safe against him. He was in constant fear of assassination and distrusted all around him. During the last three years of his life his behaviour was that of a madman. He sentenced to death his own cousin and nephew by marriage, Flavius Clemens, whose wife he banished for her supposed leaning towards Judaism (Christianity). He was stabbed in his bedroom by a freedman of Clemens named Stephanus on Sept. 18, 96.

DOMREMY-LA-PUGELLE, a village of eastern France, in the department of Vosges, on the left bank of the Meuse, 7 m. N of Neufchâteau by road. Pop. (1936) 248. Domrémy was the birthplace of Joan of Arc, and the cottage in which she was born still stands. Above the door are the arms of France and of Joan of Arc and an inscription of 1481 reading Vive labeur; vivc le *roi Louys.* There are several monuments to the heroine, and a modern basilica has been erected in her honour on a neighbouring hill, where she is said to have heard the voices in obedience to which she took up the sword. The story of the heroine is annually celebrated by a play in which the villagers take part.

DON, river, south Aberdeenshire, Scotland, rising in peat-moss to the east of Glen Avon on the borders of Banffshire, at a height of nearly 2,000 ft. It follows a generally easterly course, roughly parallel with that of the Dee, and a few miles north of it, falling into the North Sea close to Old Aberdeen, after a run of 82 m. At the mouth the two rivers are only $2\frac{1}{3}$ m. apart. Dee and Don are excellent salmon streams.

DON, a river of European Russia (anc. *Tanais*), called *Tuna* or Duna by the Tatars, rising in Lake Ivan (580 ft. above sea-

level) in the province of Tula, where it has communication with the Volga by means of the Yepifan canal, which links it with the Upa, a tributary of the Oka, which itself enters the Volga. The Don, after curving east through Ryazan, flows generally south through Tambov, Orel, Voronezh and the North Caucasian Area, describing in the last-named a sweeping loop to the east, in the course of which it approaches within 48 m. of the Volga in 49° N. In the province of Stalingrad it turns definitely south-west, and finally enters the north-east extremity of the Sea of Azov, forming a delta 130 sq m. in extent. Its total length is 1,325 m., and its drainage area is calculated at 166,000 sq.m. The average fall of the river is about 5¼ in. to the mile. In its upper course, which may be regarded as extending to the confluence of the Voronezh in 51° 40′, the Don flows for the most part through a low-lying, fertile country, though in Ryazan its banks are rocky and steep, and in some places even precipitous. In the middle division, or from the mouth of the Voronezh to the point where it makes its nearest approach to the Volga, the stream cuts its way for the most part through Cretaceous rocks, which in many places rise on either side in steep and elevated banks, and at intervals encroach on the river-bed. A short distance below the town of Rostov it breaks up into several channels, of which the largest and most southern retains the name of the river. Before it receives the Voronezh the Don has a breadth of 500 to 700, or even in a few places 1,000 ft., while its depth varies from 4 to 20 ft.; by the time it reaches its most eastern point the depth has increased to 8–50 ft., and the ordinary breadth to 700–1,000 ft., with an occasional maximum of 1,400 ft.; in the lowest division the depth is frequently 70 ft., and the breadth in many places 1,870 ft. Generally speaking, the right bank is high and the left flat and low. Shallow reaches are not uncommon, and there are at least seven considerable shoals in the south-western part of the course; partly owing to this cause, and partly to the scarcity of ship-timber in the Voronezh province, the Don, although navigable as far up as Voronezh, does not attain any great importance as a means of communication till it reaches Kalach, where the railway (built in 1862) from the Volga has its western terminus. Of the tributaries of the river, the Voronezh, the Khoper, the Medvyeditsa and the Donets are navigable—the Donets having a course of 680 m., and during high water affording access to the government of Kharkov. The Manych, another large affluent on the left, marks the ancient line of water connection between the Sea of Azov and the Caspian sea. The lower section of the Don is subject to two annual floods, of which the earlier, known as the "cold water," is caused by the melting of the snow in the North Caucasian Area, and the later, or the "warm water," is due to the same process taking place in the region drained by the upper parts of the stream. About the beginning of June the river begins to subside with great rapidity; in August the water is very low and navigation almost ceases; but occasionally after the September rains the traffic with small craft is again practicable. Since the middle of the 18th century there have been five floods of extraordinary magnitude—namely, in 1748, 1786, 1805, 1820 and 1845. The river is usually closed by ice from November or December to March or April, and at rare intervals it freezes in October. At Aksai, in the delta, it remains open on the average for 250 days in the year, at the mouth of the Medvyeditsa for 239, and at Novocherkassk, on another arm of the delta, for 246. This river supports a considerable fishing population, who despatch salt fish and caviare all over Russia. Salmon and herrings are taken in large numbers. The areas of calcareous soil on its banks are favourable to vine cultivation and "Don Champagne" is in great demand.

DONAGHADEE, a market town of Co. Down, Ireland, near the south of Belfast Lough, 25 m. E. by N. of Belfast by rail. Pop. (1926), 2,534. It is 214 m. S.W. of Portpatrick in Wigtownshire, with which it is connected by telegraph and telephone cables. To the north-east is a rath or encampment 70 ft. high. The parish church dates from 1626. There are two holy wells, and the town is a seaside resort.

DONALDSON, SIR JAMES (1831–1915), Scottish classical scholar, educational and theological writer, was born at Aberdeen on April 26, 1831, and died on March 9, 1915. In 1854 he was appointed rector of the Stirling high school, in 1866 rector of that of Edinburgh, in 1881 professor of humanity in the University of Aberdeen, and in 1890 principal of the University of St. Andrews. He was knighted in 1907.

His chief works are *Modern Greek Grammar* (1853); *Lyra Graeca* (1854), specimens of Greek lyric poetry from Callinus to Soutsos; *A Critical History of Christian Literature and Doctrine from the Death of the Apostles to the Nicene Council* (i. iii., 1864–66; new ed. of i. as *The Apostolical Fathers,* 1874), a book unique of its kind in England at the time of its appearance and one which adds materially to the knowledge of Christian antiquities as deduced from the Apostolic fathers; *Lectures on the History of Education in Prussia and England* (1874); *The Westminster Confession of Faith and the Thirty-Nine Articles of the Church of England* (1905); *Woman, her position and influence in ancient Greece and Rome* (1907).

DONALDSON, JOHN WILLIAM (1811–1861), English philologist and biblical critic, was born in London on June 7, 1811. He was educated at University College, London, and Trinity College, Cambridge, of which he became fellow. Headmaster of King Edward's school, Bury St. Edmunds from 1841 to 1855, he spent the last years of his life at Cambridge; and died on Feb. 10, 1861. The *New Cratylus* (1839), the book on which his fame mainly rests, was an attempt to apply to Greek the principles of comparative philology; it was founded mainly on the comparative grammar of Bopp, but a large part of it was original, Bopp's grammar not being completed till ten years after the first edition of the *Cratylus.* In the *Varronianus* (1844) the same method was applied to Latin, Umbrian and Oscan.

DONATELLO (diminutive of Donato) (*c.* 1386–1466), Italian sculptor, was the son of Niccolò di Betto Bardi, a member of the Florentine Woolcombers' Gild, and was born in Florence probably in 1386. It is certain that Donatello received his first training in a goldsmith's workshop, and that he worked for a short time in Ghiberti's studio. He was too young to enter the competition for the baptistery gates in 1402, from which Ghiberti issued victorious against Brunelleschi, Jacopo della Quercia, Niccolò d'Arezzo and other rivals. But when Brunelleschi in his disappointment left Florence and went to Rome to study the remains of classic art he was accompanied by young Donatello. This Roman sojourn was decisive for the entire development of Italian art in the 15th century, for it was during this period that Brunelleschi undertook his measurements of the Pantheon dome and of other Roman buildings, which enabled him to construct the noble cupola of S. Maria del Fiore in Florence, while Donatello acquired his knowledge of classic forms and ornamentation. The two masters, each in his own sphere, were to become the leading spirits in the art movement of the 15th century. Brunelleschi's buildings and Donatello's monuments are the supreme expression of the spirit of the early Renaissance in architecture and sculpture and exercised a potent influence upon the painters of that age.

Donatello probably did not return to Florence before 1405, since the earliest works in that city that can be traced to his chisel are two small statues of "prophets" for the north door of the cathedral, for which he received payment in Nov. 1406 and 1408. In the latter year he was entrusted with the important commissions for the marble "David," now at the Bargello, and for the colossal seated figure of "St. John the Evangelist," which until 1588 occupied a niche of the old cathedral façade, and is now placed in a dark chapel of the Duomo. He was next employed at Or San Michele, where between 1340 and 1406 only four of the 14 niches had been filled. As the result of a reminder sent by the Signory to the gilds who had undertaken to furnish the statues, the services of Ciuffagni, Nanni di Banco, Ghiberti and Donatello were enlisted, and Donatello completed between 1412 and 1415 the "St. Peter," the "St. George" (the original, now in the Bargello, has been replaced by a copy) and the "St. Mark." He probably also assisted Nanni di Banco in his group of four saints. To this early period belongs the wooden crucifix in S. Croce, the most striking instance of Donatello's realism in rendering the human form and his first attempt at carving the nude. It is said that this crucifix was executed in rivalry with Brunelleschi's noble work at S. Maria Novella, and that Donatello, at the sight of his friend's work, exclaimed, "It has been left to you to shape a real Christ, whilst I have made a peasant." In

this early group of statues, from the prophets for the cathedral door to the "St. George," can be followed the gradual advance from Gothic stiffness of attitude and draping to a forceful rendering of the human form and of movement, which is a distinct approach to the classic ideal. All these figures were carved in marble and are admirably conceived in relation to their architectural setting. In fact, so strong is this tendency that the "St. Mark," when inspected at the master's workshop, was disapproved of by the heads of the Gild of Linen-weavers, but aroused public enthusiasm when placed in *situ.*

Between the completion of the niches for Or San Michele and his second journey to Rome in 1433, Donatello was chiefly occupied with statuary work for the campanile and the cathedral, though from this period dates the bronze figure of the Baptist for the christening font of Orvieto cathedral, which was never delivered and is now among the treasures of the Berlin museum. This, and the "St. Louis of Toulouse," which originally occupied a niche at Or San Michele and is now badly placed at S. Croce, were the first works in bronze which owed their origin to the partnership of Donatello with Michelozzo, who undertook the casting of the models supplied by his senior. The marble statues for the campanile, which are either proved to be Donatello's by documentary evidence or can be recognized as his work from their–style, are the "Abraham," wrought by the master in conjunction with Giovanni di Bartolo (il Rosso); the "St. John the Baptist"; the so-called "Zuccone" (Jonah?); "Jeremiah"; "Habakkuk" (?); the unknown "prophet" who is supposed to bear the features of the humanist Poggio Bracciolini; and possibly he may have had a share in the completion of the "Joshua" commenced by Ciuffagni in 1415. All these statues, and the "St. John" at the Bargello, mark a bold departure from the statuesque balance of the "St. Mark" and "St. George" to an almost instantaneous impression of life. The fall of the draperies is no longer arranged in harmonious lines, but is treated in an accidental, massive, bold manner. At the same time the heads are no longer, as it were, impersonal, but almost cruelly realistic character portraits of actual people, just as the arms and legs and necks are faithfully copied from life with all their angularities and deviations from the lines of beauty. During this period Donatello executed some work for the baptismal font at S. Giovanni in Siena, which Jacopo della Quercia and his assistants had begun in 1416. Though the Florentine's share in it is confined to a relief which may have been designed, or even begun, by Jacopo, and a few statuettes, it is of considerable importance in Donatello's life-work, as it includes his first attempt at relief sculpture — except the marble relief on the socle of the "St. George" — his first female figures, — "Faith" and "Hope," and his first *putti.* The relief, "Herod's Feast," shows already that power of dramatic narration and the skill of expressing the depth of space by varying the treatment from plastic roundness to the finest *stiacciato,* which was to find its mature expression in the panels of the altar of S. Antonio in Padua and of the pulpit of S. Lorenzo in Florence. The casting of the pieces for the Siena font was probably done by Michelozzo, who is also credited with an important share in the next two monumental works, in the designing of which Donatello had to face a new problem — the tomb of John XXIII. in the baptistery (begun about 1425), and that of Cardinal Brancacci at S. Angelo a Nilo in Naples (executed in Pisa, 1427). The noble recumbent figure of the defunct on the former, the relief on the sarcophagus, and the whole architectural design, are unquestionably due to Donatello; the figure of the pope is the most beautiful tomb figure of the 15th century, and served as the model on which Rossellino, Desiderio and other sculptors of the following period based their treatment of similar problems. Donatello's share in the Naples monument is probably confined to the characteristic low relief of the "Ascension." The baptistery tomb shows how completely Donatello had mastered the forms of Renaissance architecture, even before his second visit to Rome. An earlier proof of his knowledge of classic art is his niche for the "St. Louis" at Or S. Michele, now occupied by Verrocchio's "Christ and St. Thomas." Similar in treatment to the "Ascension" relief is the "Charge to St. Peter" at South Kensington, which is almost impressionistic in its suggestion of distance and intervening atmosphere expressed by the extreme slightness of the relief.

When Cosimo was exiled from Florence in 1433, Michelozzo accompanied him to Venice, whilst Donatello went to Rome to drink once more at the source of classic art. The two works which still testify to his presence in this city, the "Tomb of Giovanni Crivelli" at S. Maria in Aracoeli, and the "Ciborium" at St. Peter's, bear the stamp of classic influence. Donatello's return to Florence in the following year almost coincides with Cosimo's. Almost immediately, in May 1434, he signed a contract for the marble pulpit on the façade of Prato cathedral, the last work executed in collaboration with Michelozzo, a veritable' bacchanalian dance of half-nude *putti,* pagan in spirit, passionate in its wonderful rhythmic movement — the forerunner of the "singing tribune" for Florence cathedral, at which he worked intermittently from 1433 to 1440, and which is now restored to its original complete form at the museum of the Opera del Duomo. But Donatello's greatest achievement of his "classic period" is the bronze "David" at the Bargello, the first nude statue of the Renaissance, the first figure conceived in the round, independent of any architectural surroundings — graceful, well-proportioned, superbly balanced, suggestive of Greek art in the simplification of form, and yet realistic, without any striving after ideal proportions. The same tendencies are to be noted in the bronze *putto* at the Bargello.

In 1443 Donatello was invited to Padua to undertake the decoration of the high altar of S. Antonio, but in the period preceding his departure he not only assisted Brunelleschi in the decoration of the sacristy of S. Lorenzo, towards which the bronze doors are his chief contribution, but found time to chisel, or model in wax or terra-cotta, for Cosimo and other private patrons, most of the portrait busts and small reliefs, which are now distributed over the museums of the world. His first work in Padua was the bronze crucifix for the high altar, a work immeasurably superior to the early wooden crucifix at S. Croce, both as regards nobility of expression and subtlety of form. In the very year when Donatello arrived in Padua the famous Condottiere Erasmo de' Narni, called Gattamelata, had died, and when it was decided to honour his memory with an equestrian statue, it was only natural that this master should be chosen to undertake a task from the difficulties of which all others may well have shrunk. This commission, and the reliefs and figures for the high altar, kept Donatello in Padua for ten years, though during that time he visited Venice (where he carved the wooden "St. John" at the Frari) and probably Mantua, Ferrara and Modena. In his workshop in Padua he gathered around him quite a small army of assistants, stone-carvers, metal-workers, painters, gilders and bronze-casters. The Gattamelata was finished and set up in 1453—a work powerful and majestic in its very repose; there is no striving for dramatic effect, no exaggerated muscular action, but the whole thing is dominated by the strong, energetic head, which is modelled with the searching realism of the Zuccone and the Poggio heads. The high altar, for which Donatello executed 22 reliefs, seven statues and the crucifix, was completed in 1450, but had subsequently to undergo many changes, in the course of which the original disposition of the sculptures was entirely lost sight of, the present arrangement being due to Camillo Boito (1895). The chief features of the altar are the wonderfully animated and dramatic bronze reliefs, four in number, of the "Miracles of St. Anthony."

With the exception of another visit to Siena in 1457, of which the bronze "St. John" in the cathedral is a reminder, Donatello spent the remaining years of his life in Florence. Closely akin to the rugged "St. John" at Siena and therefore probably contemporaneous, is the repulsively ugly, emaciated "Magdalen" at the baptistery in Florence. The dramatic intensity of the "Judith" group in the Loggia de' Lanzi, which was originally placed in the court of the Medici Palace, marks it as belonging to the post-Paduan period of the master's life. His last work of importance was the bronze reliefs for the pulpit of S. Lorenzo, commissioned about 1460, and finished after Donatello's death by his pupil

Bertoldo. The reliefs of the "Flagellation" and "Crucifixion" at the Victoria and Albert Museum are typical examples of the master's style at this closing period of his life. He died on Dec. 13, 1366.

Donatello, whose supreme mastery had been acknowledged by Michelangelo, Raphael and the other giants of the late Renaissance, almost sank into oblivion during the 18th and early 19th centuries, and only in comparatively recent times has he been restored to the eminent position which is his due in the history of art. The full power of his genius was only revealed to the world when, at the quincentenary celebration of his birth, the greater part of his life-work was brought together in Florence. The large hall at the Bargello has ever since been devoted to the display of his works, the numerous original bronzes and marbles and terra-cottas being supplemented by casts of works at other places.

DONATI, GIOVANNI BATTISTA (1826–1873), Italian astronomer, was born at Pisa on Dec. 16, 1826. In 1854–64 he discovered six comets, one of which, first seen on June 2, 1858, bears his name (*see* COMET). On Aug. 5, 1864, he discovered the gaseous composition of comets by submitting to spectroscopic analysis the light of one then visible.

DONATIO MORTIS CAUSA (grant in case of death), in law, a gift of personal property made in contemplation of death and intended either expressly or impliedly to take complete effect only if the donor dies of the illness affecting him at the time of the gift. The conception as well as the name is borrowed from Roman law, and the definition given by Justinian (*Inst.* ii. 7. 1) applies equally to a *donatio ntortis causa* in Roman and English law. A distinction, however, has arisen between the English and civil codes; by English law delivery either actual or (when from the nature of the thing actual delivery is impossible) constructive is essential, and this delivery must pass not only the possession but the dominion of the thing given; by the civil law, delivery of possession was not essential. A *donatio mortis causa* is halfway between a gift *intcr vivos* and a legacy, and has some of the characteristics of each form of disposition. It resembles a legacy in that (1) it is revocable during the donor's life, (2) it is subject to death duties, (3) it is liable to satisfy debts of the testator in default of other assets. On the other hand, it resembles a gift *inter vivos* in that it takes effect from delivery; therefore the consent of the executor is not necessary. Anything may be the subject of a *donatio ntortis causa*, the absolute property in which can be made to pass by delivery after the donor's death either in law or equity; this will cover bankers' deposit notes, bills of exchange and notes and cheques of a third person, but not promissory notes and cheques of the donor in favour of the donee, for the donor's signature is merely an authority for his banker to pay, which is revoked by his death.

DONATION OF CONSTANTINE (*Donatio Constantini*), the supposed grant by the emperor Constantine, in gratitude for his conversion by Pope Silvester, to that pope and his successors for ever, not only of spiritual supremacy over the other great patriarchates and over all matters of faith and worship, but also of temporal dominion over Rome, Italy and "the provinces, places and *civitates* of the western regions."

The famous document, known as the *Constitutum Constantini* and compounded of various elements (notably the apocryphal *Vita* S. *Silvestri*),, now universally admitted to be a gross forgery, was fabricated at Rome between the middle and the end of the 8th century, was included in the 9th century in the collection known as the False Decretals, and two centuries later was incorporated in the *Decretum* by a pupil of Gratian. It was regarded as genuine both by the friends and the enemies of the papal pretensions throughout the middle ages, though at the close of the 10th century Leo of Vercelli, Otto III.'s chancellor, proclaimed its true character, as, in 1452, did the heretical followers of Arnold of Brescia. Though little use of it was made by the popes during the 9th and 10th centuries, from this time forward it was increasingly employed by popes and canonists in support of the papal claims, and from the 12th century onward became a powerful weapon of the spiritual against the temporal powers. It is, however, as Cardinal Hergenrother points out, possible to exaggerate its importance in this respect. By the partisans of the Empire the Donation was looked upon as the *fons et origo malorum*, and Constantine was regarded as having, in his new-born zeal, betrayed his imperial trust.

The genuineness of the *Constitutum* was first critically assailed by Laurentius Valla in 1440, whose De *falso credita et ementita Constantini donatione declamatio* opened a controversy that lasted until, at the close of the 18th century, the defence was silenced. In modern times the controversy as to the genuineness of the document has been succeeded by a debate scarcely less lively as to its date, its authorship and place of origin. The efforts of Roman Catholic scholars have been directed (since Baronius ascribed the forgery to the Greeks) to proving that the fraud was not committed at Rome. Thus Cardinal Hergenrother holds that it was written by a Frank in the 9th century, in order to prove that the Greeks had been rightiully expelled from Italy and that Charlemagne was legitimate emperor. The evidence now available, however, confirms those who ascribe an earlier date to the forgery and place it at Rome. The view held by Gibbon, Dollinger (*Papstfabeln des Mittelalters*, Eng. tr. 1871) and others, that the *Constitutum* is referred to in the letter of Adrian I. to Charlemagne (778), is now largely rejected; and the same must be said of Friedrich's attempt to find such reference in the letter addressed in 785 by the same pope to Constantine VI., emperor of the East, and his mother Irene. Still less safe is it to ascribe the authorship of the forgery to any particular pope on the ground of its style; for papal letters were drawn up in the papal chancery and the style employed tliere was apt to persist through several pontificates.

On one point, however, agreement seems now to have been reached, a result due to the labours of Scheffer-Boichorst (*Mitteilungen des Instituts fur osterr. Geschichtsforschung*, x., 1889, xi., 1890), namely; that the style of the *Constitutum* is generally that of the papal chancery in the latter half of the 8th century. This being granted, there is room for plentiful speculation as to where and why it was concocted. We may still hold the opinion of Dollinger that it was intended to impress the barbarian Pippin and justify in his eyes the Frank intervention in favour of the pope in Italy; or we may share the view of Loening that the forgery was a pious fraud on the part of a cleric of the Curia, committed under Adrian I., with the idea of giving a legal basis to territorial dominion which that pope had succeeded in establishing in Italy. The donations of Pippin and Charlemagne established him as sovereign *de facto;* the donation of Constantine was to proclaim him as sovereign *de jure*. It is significant in this connection that it was under Adrian (*c*. 774) that the papal chancery ceased to date by the regnal years of the Eastern emperor and substituted that of the pontificate. Dollinger's view is supported and carried a step further by G. H. Bohmer (art. "Konstantinische Schenkung." Herzog-Hauck, *Realencyclopädie*), who by an ingenious argument endeavours to prove that the *Constitutum* was forged in 753, probably by the notary Christophorus, and was carried with him by Pope Stephen II. to the court of Pippin, in 754, with an eye to the acquisition of the Exarchate. In support of this argument it is to be noted that the forged document first appears at the abbey of St. Denis, where Stephen spent the winter of 754. E. Mayer

("Die Schenkungen Konstantins und Pippins," *Deutsche Zeitschrift fur Kirchenrecht,* 1904), on the other hand, denies that the *Constitutum* can have been forged before the news of the iconoclastic decrees of the council of Constantinople of 754 had reached Rome. He lays stress on the relation of the supposed confession of faith of Constantine, embodied in the forgery, to that issued by Constantine V., pointing out the efforts made by the Byzantines between 7j6 and the synod of Gentilly in 767 to detach Pippin from the cause of Rome and the holy images. The forgery thus had a double object: as a weapon against Byzantine heresy and as a defence of the papal patrimony. As the result of an exhaustive analysis of the text and of the political and religious events of the time, Mayer comes to the conclusion that the document was forged about 775, *i.e.,* at the time when Charlemagne was beginning to reverse the policy by which in 774 he had confirmed the possession of the duchies of Spoleto and Benevento to the pope.

In addition to works already mentioned, *see* Hergenrother, *Catholic Church and Christian State* (Freiburg im Breisgau, 1872; Eng. trans. 2 vols. 1876); W. Martens, *Die romische Frage unter Pippin u. Karl d. Grossen* (Stuttgart, 1881), with text; L. Weiland, "Die Konst. Schenkung" in *Zeitschr. f. Kirchenrecht,* xxii. (1887–1888), maintaining that the *Constitutum* was forged at Rome between 813 and 875, in connection with the papal claim to crown the emperors; with text; Friedrich, *Die Konst. Schenkung* (Nordlingen, 1889), with text; W. Martens, *Die falsche Generalkonzession Konstantins des Grossen* (Munich, 1889); G. Kriiger, "Die Frage der Entstehungszeit der Konst. Schenkung," in *Theologische Literaturzeitung,* xiv. (1889); Laurentius Valla's treatise was issued in a new edition, with French translation and historical introduction, by *A.* Bonneau, La *Donation de Constantin* (Lisieux, 1879).

DONATISTS, a powerful sect which arose in the Christian church of northern Africa at the beginning of the 4th century. In its doctrine it sprang from the same roots, and in its history it had in many things the same character, as the earlier Novatians. The predisposing causes of the Donatist schism were the belief, early introduced into the African church, that the validity of all sacerdotal acts depended upon the personal character of the agent, and the question, arising out of that belief, as to the eligibility for sacerdotal office of the *traditores,* or those who had delivered up their copies of the Scriptures under the compulsion of the Diocletian persecution; the exciting cause was the election of a successor to Mensurius, bishop of Carthage (d. 311). Mensurius had held moderate views as to the treatment of the *traditores,* and accordingly a strong fanatical party, supported by Secundus, bishop of Tigisis and primate of Numidia, had formed itself in Carthage in opposition to him. There were thus two parties, each anxious to secure the succession to the vacant see. The friends of the late bishop fixed their choice on Caecilian, the archdeacon, and secured his election and his consecration by Felix, bishop of Aptunga, before the other party were ready for action. It had been customary for the Numidian bishops to be present at the election and consecration of the bishop of Carthage, who as metropolitan of proconsular Africa occupied a position of primacy towards all the African provinces. Caecilian's party, however, had not waited for them, knowing them to be in sympathy with their opponents. Soon after Caecilian's consecration Secundus himself with 70 of the Numidian bishops arrived at Carthage. A synod of Africa was formed, before which Caecilian was summoned; his consecration was declared invalid, on the ground that Felix had been a traditor; and finally, having refused to obey the summons to appear, he was excommunicated, and the "reader" Majorinus consecrated in his stead.

To investigate the dispute Constantine issued a commission to five Gallic bishops, under the presidency of Melchiades, bishop of Rome. Ten bishops appeared on each side, the leading representative of the Donatists being Donatus of Casae Nigrae. The decision was entirely in favour of Caecilian, and Donatus was found guilty of various ecclesiastical offences. An appeal was taken and allowed; but the decision of the synod of Arles in 314 not only confirmed the position of Caecilian, but greatly strengthened it by passing a canon that ordination was not invalid because performed by a traditor, if otherwise regular. Felix had previously been declared innocent after an examination of records and witnesses at Carthage. A further appeal to the emperor in person was heard at Milan in 316, when all points were finally decided in favour of Caecilian, probably on the advice of Hosius, bishop of Cordova. Henceforward the power of the state was directed to the suppression of the defeated party. Persistent Donatists were no longer merely heretics; they were rebels and incurred the confiscation of their church property and the forfeiture of civil rights.

The attempt to destroy the sect by force had the result of intensifying its fanaticism. Majorinus, the Donatist bishop of Carthage, died in 315, and was succeeded by Donatus, surnamed Magnus, a man of great force of character after whom the movement was named, and under whose influence it gained fresh strength from the opposition it encountered. In 321 Constantine, seeing probably that he had been wrong in abandoning his usual policy of toleration, sought to retrace his steps by granting the Donatists liberty to act according to their consciences, and declaring that the points in dispute between them and the orthodox should be left to the judgment of God. This wise policy, to which he consistently adhered to the close of his reign, was not followed by his son and successor Constans, who, after repeated attempts to win over the sect by bribes, resorted again to persecution, many of their bishops falling victims and Donatus and others being banished. The power which they had been the first to invoke having thus declared so emphatically and persistently against them, the Donatists revived the old world-alien Christianity of the days of persecution, and repeated Tertullian's question, "What has the emperor to do with the church?" *(Quid est imperatori cum ecclesia?)*

With the accession of Julian (361) an entire change took place; their churches were restored to the Donatists and their bishops reinstated, with the natural result of greatly increasing both the numbers and the enthusiasm of the party. A return to the earlier policy of repression was made under Valentinian I. and Gratian, by whom the churches were again closed, and all assemblies forbidden. It was not, however, until the commencement of the 5th century that the sect began to decline, owing largely to the rise among them of a group of moderate and scholarly men like the grammarian Tychonius, who vainly strove to overcome the more fanatical section. Against the house thus divided against itself both state and church directed not unsuccessful assaults. In 405 an edict was issued by the emperor Honorius commanding the Donatists, under the severest penalties, to return to the Catholic church. On the other hand, Augustine, bishop of Hippo, after several years' negotiation, arranged a great conference between the Donatists and the orthodox, which was held under the authority of the emperor at Carthage in 411. There were present 286 Catholics and 279 Donatist bishops. Before entering on the proceedings the Catholics pledged themselves, if defeated, to give up their sees, while in the other event they promised to recognize the Donatists as bishops on their simply declaring their adherence to the Catholic church. The latter proposal, though it was received with scorn at the time, had perhaps ultimately as much influence as the logic of Augustine in breaking the strength of the schism. The discussion, which lasted for three days, turned exclusively upon the two questions that had given rise to the schism —first, the question of fact, whether Felix of Aptunga who consecrated Caecilian had been a traditor; and secondly, the question of doctrine, whether a church by tolerance of unworthy members within its pale lost the essential attributes of purity and catholicity. The Donatist position, like that of the Novatians and, earlier, of the Montanists (*q.v.*) was that the church is a society of holy persons, and that the mark of the true church is to guard the essential predicate of holiness by excluding all who have committed mortal sin; the Catholic standpoint was that such holiness is not destroyed by the presence of unworthy members in the church but rests upon the divine foundation of the church and upon the gift of the Holy Spirit and the communication of grace through the priesthood. In the words of Optatus of Milevi, *sanctitas de sacramentis colligitur, non de superbia personarum pondera.* And the much wider diffusion of the orthodox church was also taken as practical confirmation that it alone possessed what was regarded as the equally essential predicate of catholicity.

The decision of Marcellinus, the imperial commissioner, was in favour of the Catholic party on both questions, and it was at once confirmed on an appeal to the emperor. The severest penal measures were enforced against the schismatics; in 414 they were denied all civil rights, in 415 the holding of assemblies was forbidden on pain of death. But they lived on, suffering with their orthodox brethren in the Vandal invasions of the 5th century, and like them finally disappearing before the Saracen onslaught two centuries later.

BIBLIOGRAPHY.—For contemporary sources *see* Optatus Milevitanus *De Schismate Donatistarum adversus Parmenianum,* written *c. 368* (Migne, *Patrologia Latina,* vol. xi.), and several of the works of Augustine. Chapman, *Donatus the Great and Donatus of Casae* in Revue Bénédictine 26 (1909) 13–23; P. Monceaux, *Histoire littéraire de l'Afrique chrétienne,* IV and VI (1913 and 1923); H. von Soden, *Urkunden zur Entstehunggeschichte des Donatismus* (1913).

DONATUS, AELIUS, Roman grammarian and teacher of rhetoric, flourished in the middle of the 4th century A.D. He was the tutor of St. Jerome. Of his numerous works, the following are extant: the *Ars grammatica;* most of his commentary on Terence (a compilation from other commentaries), but probably not in its original form; and a few fragments of his notes en Virgil, preserved and severely criticized by Servius, together with the preface and introduction, and life of Virgil. The *Ars,* though having little claim to originality, and based on the authorities used by Charisius and Diomedes, became so popular as a school-book that in the middle ages the writer's name became a common metonymy (in the form *donet*) for any rudimentary treatise. It is extant in the form of an *Ars Minor,* which only treats of the parts of speech, and an *Ars Maior,* which deals with grammar in general at greater length.

Aelius Donatus is to be distinguished from Tiberius Claudius Donatus, the author of a commentary (*Interpretationes*) on the Aeneid (of far less value than that of Servius), who lived about 50 years later.

The best text of the *Ars* and the commentaries upon it by Servius and others is in H. Keil, *Grammatici Latini,* iv.; of the commentary on Terence there is an edition by P. Wessner (1902, Teubner series), with bibliography and full account of mss. *See* generally E. A. Grafenhan, *Geschichte der klassischen Philologie im Altertum,* iv. (1850); P. Rosenstock, *De Donato, Terrenti . . . explicatore* (1886); *H.* T. Karsten, *De Comm. Don. ad Terenti fabulas origine et compositione* (Leyden, 1907). For the commentary of Tiberius Donatus see O. Ribbeck, Prolegomena to Virgil, Grafenhan (as above), and V. Burkas, *De Tiberii Claudii Donati in Aeneidem commentario* (1889). The text will be found in *G.* Fabricius's edition ot Virgil (1561), ed by H. George, i. (1905 foll.). *Sre* also R. Sabbadini, *Storia e Critica di Test. Latini* (Catania, 1914), dealing with the mss. of the commentaries of Aelius and Tiberius.

DONAUWÖRTH, a town of Germany in the *Land* of Bavaria, on the left bank cf the Danube, at the confluence of the Wörnitz, 25 m. N. of Augsburg by rail and at the junction of lines to Ulm and Ingolstadt. Pop. (1939) 6,041. It grew up during the 11th and 12th centuries under the protection of the castle of hlangoldstein, and became for a time in the 13th a seat of the duke of Upper Bavaria. The town received the freedom of the Empire in 1308, and resisted the encroachments of Bavaria till 1607, when the duke of Bavaria was authorized to punish the Protestant inhabitants for their interference with the abbot of the Heilig-Kreuz. In the Thirty Years' War it was stormed by Gustavus Adolphus (1632), and captured by King Ferdinand (1634). Important battles were fought in the neighbourhood in 1704 and in 1805. The imperial freedom restored to the town by Joseph I. in 1705 was again lost by reincorporation with Bavaria in 1714. The Kloster-Kirche (monasterial), a Gothic edifice, the church of the former Benedictine abbey, Heilig-Kreuz, the Gothic town hall and the so-called Tanz-haus, which now includes both a theatre and a school are notable. The industries include machinery, brewing and saw-milling; the place is a river port, and trade is in agricultural produce

DON BENITO, a town of western Spain, in the province of Badajoz; near the left bank of the river Guadiana, on the Madrid-Badajoz-Lisbon railway. Pop. (1930) 21,196. Don Benito, centre of a fertile district, dates from the 15th century, when it was founded by refugees from Don Llorente, driven out of their own town by floods from the Guadiana. Besides manufactures o oil, soap, flour, linen, lace and cloth, it has an active trade in wheat, cattle, wine and fruit, especially melons.

DONCASTER, market town, county borough, Doncaster parliamentary division, West Riding, Yorkshire, England, 156 mi. N. of London. Pop. (est. 1938) 71,600. Area 12.2 sq.mi. It lies astride the ridge dividing the watershed of the rivers Don and Trent. It is the centre of a large coal-mining area and an important station on the L.N.E. railway, whose principal locomotive and carriage works are here. It is also served by the L.M.S. railway, stands on the Great North road, and the river Don affords water communication with the Humber and Goole. The parish church of St. George (architect Sir G. G. Scott) occupies the site of an older structure, destroyed by fire in 1853. It is a fine cruciform structure of Decorated character, with a central tower 170 ft. high, and contains a fine organ. St. James's church was erected by the same architect and Lord Grimthorpe. Other important buildings are the guildhall, mansion house, public library, school of art, technical college, corn exchange and market hall. The grammar school was founded in 1553 and has been greatly enlarged. There is a large high school for girls and a school of art, while some of the elementary schools are the finest in the country.

The Doncaster racecourse lies 1 mi. S.E. of the town and is owned and managed by the corporation. The old course is 1 mi. 7 fur. 70 yd. long; the Sandall mile was added in 1892 and the straight mile in 1912. Race-meetings are normally held in September, October and May. In September the St. Leger race, which originated in 1776, is run. The grandstand was erected in 1777 but there are several other stands. Systems of electric tramways, trolley vehicles and motor omnibuses connect the borough with the coal-mining towns in the neighbourhood, there being about two dozen coal mines within a 10-mile radius. Agricultural trade is extensive, though coal working is the principal industry, and there are iron, brass, wagon, wire and agricultural machine works, toffee and chocolate works, wall-paper works and a woollen mill. Adjoining the borough are the Saxon and Norman ruins of Conisbrough castle and the remains of the Norman Tickhill castle. The town contains free libraries, a museum and art gallery, six public parks and a municipal swimming bath.

History.—There was a Roman station here, and numerous remains of the Roman period have been found. In the reign of Edward the Confessor, Doncaster belonged to Earl Tostig; but before 1086 it had been granted to Robert, earl of Mortain, nhose successor William was attainted for treason in the time of Henry I. The overlordship then fell to the crown, and the families of Fossard, Mauley and Salvin successively held the manor as underlords. Doncaster was evidently a borough held of the crown for a fee farm rent before 1194, when Richard I granted and confirmed to the burgesses their soke and town to hold by the ancient rent and by 2j marks yearly. The town was incorporated in 1467 by Edward IV. In 1623 Ralph Salvin tried to regain the manor of Doncaster from the mayor and burgesses who, fearing that the case would go against them, agreed to pay about £3,000, in return for which he gave up his claim. Charles II in 1664 gave the town a new charter, but since this was not enrolled, the burgesses obtained another charter from James II in 1684 by which the town was governed until the Municipal Corporation act. It was created a county borough in 1927. In 1200 a fair at Doncaster on the vigil and day of St. James the Apostle was confirmed, and by the charter of 1194 the burgesses received licence to hold a fair on the vigil, feast and morrow of the Annunciation. These fairs were confirmed by Henry VII in 1505. The fairs and markets are still held under these charters.

DONDERS, FRANZ CORNELIUS (1818–1889), Dutch ophthalmologist, was born on May 27, 1818, in Tilburg, and studied at Utrecht where, after being an army surgeon, he became professor of physiology in 1847. From 1852 onwards he specialized in ophthalmology to which belong his studies of the *muscae volitantes* (1847), the relation between convergence of visual axes and accommodation (1848), regeneration of the cornea

(1848), hypermetropia (1858), ametropia (1860), astigmatism (1862). His *lhe Anomalies of Refraction and Accommodation* was published in England in 1864. Donders died in Utrecht on March 24, 1889.

See: E. Clarke, *A Brief* Review *of the Work of Donders* (1914).

DONEGAL, a county in the extreme north-west of Eire, bounded north and west by the Atlantic ocean, east by Lough Foyle and the counties Londonderry and Tyrone, and south by Donegal bay and the counties Fermanagh and Leitrim. The area is 1,865 sq.mi. Pop. (1936) 142,310.

Geology.—The rocks of the county are chiefly igneous or archaean and, structurally, it is a continuation of the Scottish Highlands, the same north-east-south-west structural lines dominating both, as a result, probably, of post-Silurian ("Caledonian") earth movements. The archaean area usually forms the highest land, with quartzite standing out in white summits at Errigal (2,466 ft.) in the western or Derryveagh mountains, to the south of which is lower land towards Gweebarra bay, mostly formed by igneous rock which stretches north-eastwards along a valley with long lakes, and separates the Derryveagh from the Glendowan mountains, the latter again archaean. An important syncline of carboniferous sandstone and limestone forms the north-east shores of Donegal bay, and another one, or another part of the same one, forms the shores of Lough Foyle in Co. Londonderry and is continued south. Beyond the Donegal bay syncline, to the north-east, is a high igneous mass (Bluestack, 2,219 ft.). Much of the drainage is carried to the Foyle by the Derg and Finn rivers. Donegal includes the high Inishowen peninsula between Lough Swilly and Lough Foyle, formed mainly of archaean rocks (Slieve Snaght, 2,019 ft.), with some carboniferous along Lough Foyle. Lough Swilly is a marked feature; its upper part is related to the synclinal lines of Donegal bay and runs south-west-north-east; its lower part turns out of this direction, and is a feature related to the unequal denudation of igneous and archaean rocks and the general coastal sinking which has contributed so much to the complexity of Donegal's coast-line.

History.—The greater part of Donegal was anciently called Tyrconnell (*q.v.*) or the country of Conall; and it was sometimes called O'Donnell's country, after the head chieftains of the district. This district was formed into the county of Donegal in the reign of Queen Elizabeth, in 1585, by the lord-deputy, Sir John Perrot. At the head of Lough Swilly, on the summit of a hill 802 ft. high, are some remains of a fortress or palace of the northern Irish kings. These are known as the Grianan of Aileach, and evidently date from a period prior to the 12th century. On Tory island there are one of the best specimens of a round tower and other remains. Numerous ruins of castles along the coast prove that much attention was formerly paid to the defence of the country from invasion. The principal are Kilbarron castle, near Ballyshannon; Donegal castle and Burt castle. Traces of religious houses, some only in traditionary or documental records, are numerous; the ruins of that of Donegal, founded in 1474, may still be seen. At Raphoe, 5 m. N.W. of Lifford, is the cathedral of a former diocese united to that of Derry in 1835.

Industries.—The soil of the greater portion of the county, *i.e.*, the granite, quartz and mica slate districts, is thin and cold, while that on the carboniferous limestone is warm and friable. In most parts of the West the patches of glacial drift form the only agricultural land. Owing to the boggy nature of the soil, agriculture has not made much progress, although in certain districts (Gweedore, for instance) much land has been brought under cultivation through the enterprise of the proprietors. Wheat and barley are quite an inconsiderable crop, and in this, as well as in other respects, Donegal is much behind the rest of Ulster. It bears, however, a more favourable comparison as regards its live stock, as cattle, sheep and poultry are extensively kept.

The linen manufacture affords employment to a number of inhabitants, especially at Raphoe, while the manufacture of excellent homespun, woollen stockings and worked muslin is carried on fairly extensively. The trade in these manufactures and in the domestic produce of the county finds its principal outlets through the port of Londonderry and the inland town of Strabane, Co. Tyrone. The deep-sea fisheries are important, and are centred at Killybegs, Gweedore and Rathmullen. The salmon fishery is also prosecuted to a considerable extent, the principal seats of the trade being at Ballyshannon and Letterkenny. Bog iron-ore is raised as a gas-purifier; and talc-schist has been worked for steatite at Crohy Head. The fine-grained sandstone of Mt. Charles, near Donegal, is a well known building stone, and the granites of the north-west have attracted much attention.

Most of the railway lines are owned jointly by the G N. railway (Ireland) and the L.M S. railway, and are controlled by the Co. Donegal joint committee. The chief branch leaves the Great Northern line from Londonderry to Omagh at Strabane. From Stranorlar one line follows the upper Finn valley and serves Glenties, whilst another line utilizes a gap to the south-west and communicates with Donegal. From here local lines serve the fishing villages and resorts around Donegal bay. Letterkenny is also connected with Strabane by rail. The county town is Lifford, practically a suburb of Strabane in Co. Tyrone. Other important towns are Letterkenny (2,649), Ballyshannon (2,223) and Buncrana (2,295). The Revision of Constituencies Act (1935) assigned to East Donegal four members and to West Donegal three members in Dáil Eireann.

DONEGAL, a small seaport and market town of Co. Donegal, Eire, at the head of Donegal bay and the mouth of the river Eask. Pop. (1936) 1,315. There are ruins of a Jacobean castle (1610) on the site of a fortress of the O'Donnells of Tyrconnell, and of a Franciscan monastery (founded in 1474), at which were compiled the famous *Annals of tlze Four Masters*, a record of Irish history, completed in 1636. Donegal received a charter from James I. The name is said to allude to a settlement of the Northmen. Trade is hindered by shoals, which render difficult the approach to the harbour.

DONELSON, FORT, an entrenched camp at Dover, Tenn., U.S.A., erected by the Confederates in the Civil War to guard the lower Cumberland river, and taken by the Federals on Feb. 16, 1862. It consisted of two continuous lines of entrenchments on the land side, and water batteries commanding the river. After the capture (Feb. 6) of Fort Henry on the lower Tennessee the Union army under Brig.-gen. U. S. Grant moved to invest Donelson, two divisions marching overland while the third went by water, and the gunboat flotilla (Commodore A. H. Foote) descended the Tennessee and ascended the Cumberland to meet him. Albert Sidney Johnston, the Confederate commander in Kentucky, dividing his army, had retired himself to Nashville and had thrown a large garrison under Gen. Floyd into Donelson, and Grant was at first outnumbered; though continually reinforced, the latter had at no time more than three men to the Confederates' two. The troops of both sides were untrained but eager.

On Feb. 12 and 13, 1862, the Union divisions, skirmishing heavily during the second day, took up their positions investing the fort, and on the 14th Foote's gunboats attacked the water batteries. The latter received a severe repulse, Foote himself being amongst the wounded, and soon afterwards the Confederates determined to cut their way through Grant's lines. On the 1 jth Gen. Pillow attacked the Federal division of McClernand and drove it off the Nashville road; having done this, however, he halted, and even retired. Grant ordered Gen. C. F. Smith's division to assault a part of the lines which had been denuded of its defenders in order to reinforce Pillow. Smith personally led his young volunteers in the charge and carried all before him. The Confederates returning from the sortie were quite unable to shake his hold on the captured works, and, Grant having reinforced McClernand with Lew Wallace's division, these two generals reoccupied the lost position on the Nashville road. On the 16th, the two senior Confederate generals, Floyd and Pillow, having escaped by steamer, the infantry left in the fort under Gen. S. B. Buckner surrendered unconditionally. The Confederate cavalry under Col. Forrest made its escape by road. The prisoners numbered about 15,000 out of a total of 18,000.

See "Fort Donelson," *Military Historian and Economist,* vol. i, p. 33–62 (Cambridge, Mass, 1916); and "Campaign Against Forts Henry and Donelson," *Coast Artillery Journal,* vol. lxvii, p. 389–404 (Hampton, Va., 1927).

DONGA, a Bantu word for a narrow watercourse or eroded gully. Adopted by Europeans in S. Africa from the Kaffirs, it was applied to similar ravines or watercourses elsewhere. It is almost equivalent to the Arabic khor, which also means the dry bed of a stream and to the Indian *nullah* (properly a watercourse).

DONGAN, THOMAS: see LIMERICK, THOMAS DONGAN.

DONGOLA, a *mudiria* (province) of the Anglo-Egyptian Sudan. It lies wholly within the region known as Nubia and extends along both banks of the Nile from about 18° N. to 20° N. The rainfall is very slight, and the area of fertility is mainly confined to the lands watered by the Nile, and to the Wadi el Kab (Gab), west of and parallel to the Nile. Farther west is the extensive plateau of Jebel Abiad, and beyond, some 250 m. due west of Debba, is Bir Natron, or Bir Sultan, a valley whence natron is obtained. In this desert region is found the addax, the rarest of Sudan antelopes. The province is noted for a breed of strong, hardy horses. The largest town is Dongola, but the administrative headquarters of the mudiria are at New Merawi (Merowe, Meroe), on the left bank of the Nile, below the 4th cataract. Other towns, also on the Nile, are Debba and Korti, whence start caravan routes to Kordofan and Omdurman. Old Merawi, on the right bank of the Nile, and Sanam Abu Dom, on the left bank, indicate the site of the Ethiopian city of Napata. From Kareima, on the right or northern bank of the Nile, 6 m. above New Merawi, a railway (opened in March 1906) runs to join the main Sudan Government line at Abu Hamed. From Kareima downstream the Nile is navigable to Kerma, just above the 3rd cataract.

The Dongolese (Dongolawi, Danaglas, Danagalehs) are Nubas in type and language, but have a large admixture of Arab, Turk and other blood. They are great agriculturists and keen traders, and were notorious slave-dealers. South of Old Dongola the inhabitants are not Nubians but Shagia (*q.v.*), and the Nubian tongue is replaced by Arabic. Of the nomad desert tribes the chief are the Hawawir and Kabbabish.

History.—Dongola was once part of the empire of Ethiopia (*q.v.*), Napata being one of its capital cities. From about the beginning of the Christian era the chief tribes were the Blemmyes and the Nobatae. The latter became converted to Christianity about the middle of the 6th century. A chieftain of the Nobatae, named Silko, before the close of that century, conquered the Blemmyes, founded a new state, made Christianity the official religion of the country, and fixed his capital at (Old) Dongola. This state, generally known as the Christian kingdom of Dongola, lasted for eight or nine hundred years. Christianity, after the wars of Silko, spread rapidly, and when the Arab conquerors of Egypt sought to subdue Nubia they met with stout resistance. Dongola, however, was captured by the Muslims in 652, and the country laid under tribute (*bakt*)—400 men having to be sent yearly to Egypt. This tribute was paid when it could be enforced; sometimes the Nubians gained the upper hand, as in 737 when their king Cyriacus, marched into Egypt to redress the grievances of the Copts. By the close of the 10th century the Nubians seem to have regained almost complete independence. They did not, however, possess any part of the Red Sea coast, which was held by the Egyptians, who, during the 9th and 10th centuries, worked the emerald and gold mines between the Nile and the Red sea. The kingdom, according to the Armenian historian Abu Salih, was in a very flourishing condition in the 12th century. It then extended from Aswan southward to the 4th cataract, and contained several large cities. Gold and copper mines mere worked. The liturgy used was in Greek. In 1173 Shams ed Daula, a brother of Saladin, attacked the Nubians and captured the city of Ibrim (Primis). The Egyptians retired, and for about 100 years the country was at peace. In 1275 the Mameluke sultan Bibars aided a rebel prince to oust his uncle from the throne of Nubia; the sultans Kalaun and Nasir also sent expeditions to Dongola, which was several times captured. Though willing to pay tribute to the Muslims, the Nubians clung tenaciously to Christianity, and, despite Arab raids, the country appears during the 12th and 13th centuries to have been fairly prosperous. It is not certain how far south the authority of the Dongola kingdom (sometimes known as Mukarra) extended Another Christian state, Aloa (Alwa), with its capital Soba on the Blue Nile, was its near neighbour on the south.

Cut off from free intercourse with the Copts in Egypt, the Nubian Christians at length began to embrace Jewish and Mohammedan doctrines. The decay of the State was hastened by dissensions between Mukarra and Aloa, but the Nubians were strong enough to invade upper Egypt during the reign of Nawaya Krestos (1342–72), because the governor of Cairo had imprisoned the patriarch of Alexandria. The date usually assigned for the overthrow of the Christian kingdom is 1351. Only the northern part of the country (as far as the 3rd cataract) came under the rule of Egypt. Nevertheless, according to Leo Africanus, at the close of the 15th century Christianity and native states still survived in Nubia, and in the 16th century the Nubians sent messengers to Abyssinia to Father Alvarez, begging him to appoint priests to administer the sacraments to them—a request he was unable to grant. Thereafter the Nubian Church is without records. The region between Dongola and Shendi appears to have been depopulated. In the north the Turks introduced in the 16th century numbers of Bosnians, whose descendants ruled the district, paying a nominal allegiance to the Porte. At Ibrim, Mahass, and elsewhere along the banks and on the islands of the Nile, they built castles, now in ruins. South of Hannek the kings of Sennar became overlords of the country. As the power of the Sennari declined, the nomad Shaggia (or Shaikiyeh) attained pre-eminence in the Dongola district.

About 1812 Mamelukes fleeing from Mohammed Ali, the pasha of Egypt, made themselves masters of part of the country, destroying the old capital and building a new one lower down the Nile. In 1820 both Mamelukes and Shaggia were conquered by the Egyptians, and the Dongola province annexed to Egypt.

After the failure of the British relief expedition of 1884–85 and the Mahdist capture of Khartum it was decided to withdraw to the region of the 2nd cataract, and the Dongola Province was evacuated. The British rearguard left Dongola town in June 1885 and the Mahdists occupied it at the end of August. They held the province for 11 years, during which its northern villages were depopulated and their riverside lands laid waste. It was reoccupied by Kitchener's forces in 1896, Dongola being recaptured on Sept. 23. As a province of the reorganized Anglo-Egyptian Sudan, the country has been prosperous, and there is an increasing annual production of cotton.

Dugmore, *The Vast Sudan* (1924); also the annual Government Reports and the official *Sudan Handbook.*

DONGOLA, a town of the Anglo-Egyptian Sudan, which gives its name to a *mudiria.* It is situated on the west bank of the Nile, about 45 m. above the third cataract, in 19° 10′ N., 30° 29′ E. It is 1,083 m. S. of Cairo by river and 638 m. N. of Khartum by the same route. It is a thriving, well-built town; an important agricultural and trading centre. Lignite is found on the east bank of the Nile opposite the town. Founded *c.* 1812 by Mamelukes who fled to Nubia from the persecutions of Mohammed Ali, the town is called Dongola Makara (New Dongola) to distinguish it from Dongola Agusa (Old Dongola), which it supplanted. The Mahdi Mohammed Ahmed was a native of Dongola. In 1884–1885 the town was the base of the British troops in their advance on Khartum.

Dongola Agusa, 75 m. upstream from New Dongola, now a heap of ruins, was the capital of the Nubian state usually called the Christian kingdom of Dongola. An Arab historian of the 11th century describes it as a large city with many churches, fine houses and wide streets. It is said to have been finally destroyed by the Mamelukes.

DONIZETTI, GAETANO (1797–1848), Italian musical composer, was born at Bergamo on Nov. 29, 1797. He studied at Naples under Simon Mayr, the operatic composer, and then under Mattei at Bologna. After his return to Bergamo, his father

insisted upon his giving lessons in order to earn his living. Donizetti revolted, and enlisted in the army. His regiment was quartered at Venice, and here the young composer's first opera, *Enrico comte di Borgogna,* saw the light in 1818.

The success of this work, and of a second opera brought out in the following year, established Donizetti's reputation. He obtained his discharge from the army, and henceforth his operas followed each other in rapid and uninterrupted succession at the rate of three or four a year. Although he had to contend successively with two such dangerous rivals as Rossini and Bellini he succeeded in taking firm hold of the public, and the brilliant reception accorded to his *Anna Bolena* at Milan, where Pasta and Rubini appeared in it, carried his name beyond the limits of his own country. In 1835 Donizetti went for the first time to Paris, where, however, his *Marino Faliero* failed to hold its own against Bellini's *Puritani,* then recently produced at the Théâtre Italien. The disappointed composer went to Naples, where the enormous success of his *Lucia di Lammermoor* (1835) consoled him far his failure in Paris. Returning to Paris he produced at the Opéra Comique what proved eventually his most popular opera, *La Fille du régiment,* but it was not till after the work had made the round of the theatres of Germany and Italy that it found favour with the French. A revival in Paris of his *Lucrezia Borgia,* produced at Milan in 1833, was interrupted by Victor Hugo's claim for infringement of copyright, and the libretto was altered. *La Favorita,* generally considered Donizetti's masterpiece, was produced in 1840. His next important work, *Linda di Chamounix,* was written for Vienna, where it was received most favourably in 1842, and the same success attended the production of *Don Pasquale* in Paris in 1843. Soon after this event the first signs of a fatal disease, caused to a great extent by overwork, began to show themselves. The utter failure of *Don Sebastian,* a large opera produced soon after *Don Pasquale,* is said to have hastened the catastrophe. A paralytic stroke in 1844 deprived Donizetti of his reason, and for four years he lingered on in a state of mental and physical prostration. A visit to his country was proposed as a last resource, but he reached his native place only to die there on April 1, 1848.

The sum total of his operas amounts to sixty-four. The large number of his works accounts for many of their chief defects. His rapidity of working made all revision impossible. It is said that he once wrote the instrumentation of a whole opera within thirty hours. And yet it may be doubted whether more elaboration would have essentially improved his work, for the dramatic last act of the *Favorita,* infinitely superior to the preceding ones, is also said to have been the product of a single night.

Without boasting the sweetness of Bellini or the sparkle of Rossini, Donizetti won the popular ear by his flow of melody and by his rare skill in writing for the voice, to which qualities may be added his power of humorous delineation, as evinced in *Don Pasquale* and *L'Elisir d'amore,* which works will probably last as long as anything he ever wrote.

See F. Cicconetti, *Vita di G. Donizetti* (1864); *Lettere inedite di Gaetano Donizetti* (ed. Eisner-Eiscnhoff, 1897); Ch. Malherbe, *Le centenaire de Donizetti* (1897); and *A.* Cametta, *Donizetti* (1907).

DONJON, the French term for the keep (*q.v.*) of a mediaeval castle, used in contradistinction to *dungeon* (*q.v.*), the prison, an anglicized spelling of the same word.

DON JUAN, a legendary character, whose story has found currency in various European countries. He was introduced into formal literature in the Spanish *El Burlador de Sevilla y convidado de piedra,* a play which was first printed at Barcelona in 1630, and is usually attributed to Tirso de Molina; but the story of a profligate inviting a dead man to supper, and finding his invitation accepted, was current before 1630, and is not peculiar to Spain. The available evidence goes to show that Don Juan is a universal type, the subject of local myths in many countries, that he received his name in Spain, and that the Spanish version of his legend has absorbed certain elements from the French story of Robert the Devil. The character of Don Juan as the incarnation of perverse sensuality and arrogant blasphemy, may be considered as the creation of the author of El *Burlador.* The drama was apparently more popular in Italy than in Spain, and was frequently given in pantomime by Italian actors, a company of whom took the story into France in 1657. It was dramatized by Dorimond in 1659 and by De Villiers in 1661; their attempts suggested *Le Festin de Pierre* (1665) to Molitre, who substituted prose for verse, reduced the supernatural element, and interpolated new comic effects. The story was introduced into England by Sir Aston Cokain in his unreadable *Tragedy of Ovid* (1669), and was the theme of *The Libertine* (1676) by Shadwell. *El Burlador* was recast, but not improved, by Antonio de Zamora early in the 18th century, and a hundred years later the character was endowed with a new name in Espronceda's *Estudiante de Salamanca.* But the most curious resuscitation of the type in Spain is the protagonist in Zorrilla's *Don Juan Tenorio,* which is usually played in all large cities during the first week in November, and has come to be regarded as an essentially national work. It is in fact little more than an adaptation of the elder Dumas' *Don Juan de Marana,* which, in its turn, derives chiefly from Mérimée's novel, *Les Ames du Purgatoire.* Byron's *Don Juan* resembles Ulloa's murderer in nothing but his name.

The sustained popularity of the Don Juan legend is undoubtedly due in great measure to Mozart's incomparable setting of Da Ponte's mediocre libretto. In this pale version of *El Burlador de Sevilla* the French romantic school made acquaintance with Don Juan, and hence, no doubt, the works of Mérimée and Dumas already mentioned, Balzac's *Élixir d'une longue vie,* and Alfred de Musset's *Une Matinée de Don Juan* and *Namouna.* The legend has been treated subsequently by Flaubert and Barbey d'Aurevilly in France, by Landau and Heyse in Germany, by Sacher-Masoch in Austria and in a highly modernized form by G. B. Shaw *(Man and Superman).* It has always fascinated composers. Mozart's *Don Giovanni* has annihilated the earlier operas of Le Tellier, Righini, Tritto, Gardi and Gazzaniga; but Gluck's ballet-music still survives, and Henry Purcell's setting—the oldest of all—has saved some of Shadwell's insipid lyrics from oblivion.

DONKEY: *see* Ass.

DONKEY-ENGINE. A steam-engine of small or moderate power which works a crane or hoist, chiefly on board ship, to handle cargo and luggage. The steam is supplied by a donkey-boiler, instead of being taken from the main boilers. A donkey-pump is of very compact design, and suitable for being bolted to a ship's side, a column or wall, or a boiler. It is used for feeding boilers, tanks, vats, etc., and works by the direct action of a steam driven piston on a plunger in the pump cylinder. A flywheel helps to maintain a steady action of the pump. The smallest pumps, of the type shown *(see* p. 530), deliver about 90gal. per hour, and the largest 4,000.

DONKIN, SIR RUFANE SHAW (1773–1841), British soldier, son of Robert Donkin (d. 1821), joined the army at the age of 14. He was divisional commander in Hastings' operations against the Mahrattas (1817–18), receiving the K.C.B. as his reward. From 1820 to 1821 he administered the Cape of Good Hope with success, and named the rising seaport of Algoa bay Port Elizabeth in memory of his wife. In 1821 he became lieutenant-general and G.C.B.

See Jerdan, *National Portraits,* vol. iii.; *Gentleman's Magazine,* xcii. i. 273.

DONNAY, CHARLES MAURICE (1859–), French dramatist, was born of middle-class parents in Paris in 1859. He made his serious début as a dramatist on the little stage of the Chat Noir with *Phryné* (1891), a series of Greek scenes. *Lysistrata,* a four-act comedy, was produced at the Grand Théâtre in 1892 with Mme. Réjane in the title part. Later plays include *Folle Entreprise* (1894); *Pension de famille* (1894); *Amants* (1895), produced at the Renaissance theatre with Mme. Jeanne Granier as Claudine Rozeray; *La Douloureuse* (1897); *L'Affranchie* (1898); *Georgette Lemeunier* (1898); *Le Torrent* (1899), at the Comédie Française; *Education de prince* (1900), and *Oiseaux*

de Passage (1904), in collaboration with L. Descaves; *La Bascule* (1901); *L'Autre danger,* at the *Comédie Française* (1902); *Le Retour de Jérusalem* (1903); *L'escalade* (1904); and *Paraître* (1906). With *Amants* he won a great success, and the play was hailed by Jules Lemaître as the *Bérénice* of contemporary French drama. The whole series of plays reflect the various questions agitating society at the time, and the witty dialogue is written with an apparent carelessness that approximates very closely to the language of every day.

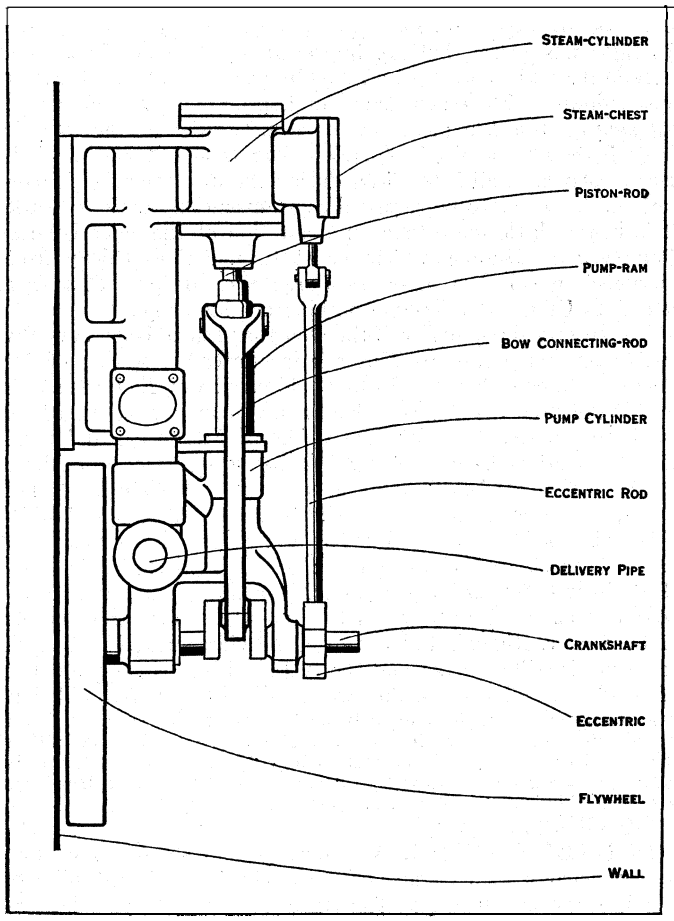

DIAGRAM OF A DONKEY PUMP. THE PUMP-RAM IS WORKED DIRECT BY THE PISTON ROD OF THE STEAM CYLINDER, AND THE FLYWHEEL PROVIDES A STEADY ACTION. (SEE P. 529)

DONNE, JOHN (1573–1631), English poet and divine of the reigns of James I., and Charles I., was born in 1573 in the parish St. Nicholas Olave, in the city of London. His father was a wealthy merchant, who next year became warden of the Company of Pronmongers, but died early in 1576. Donne's parents were Catholics, and his mother, Elizabeth Heywood, was directly descended from the sister of the great Sir Thomas More; she was the daughter of John Heywood the epigrammatist. As a child, Donne's precocity was such that it was said of him that "this age hath brought forth another Pico della Mirandola." He entered Hart Hall, Oxford, Oct. 1584, and left it in 1587, proceeding, according to Walton, to Cambridge, where he remained three years. At Oxford began his friendship with Henry Wotton, and at Cambridge, probably, with Christopher Brooke. Donne was "removed to London" about 1590 and in 1592 he entered Lincoln's Inn with the intention of studying the law.

When he came of age, he found himself in possession of a considerable fortune, and about the same time rejected the Catholic doctrine in favour of the Anglican communion. He began to produce *Satires,* which were not printed, but eagerly passed from hand to hand; the first three are known to belong to 1593, the fourth to 1594, while the other three are probably some years later. In 1596 Donne engaged himself for foreign service under the earl of Essex, and "waited upon his lordship" on board the "Repulse," in the magnificent victory of the 11th of June. We possess several poems written by Donne during this expedition, and during the Islands Voyage of 1597, in which he accompanied Essex to the Azores. According to Walton, Donne spent some time in Italy and Spain, and intended to proceed to Palestine, "but at his being in the farthest parts of Italy, the disappointment of company, or of a safe convoy or the uncertainty of returns of money into those remote parts, denied him that happiness." There is some reason to suppose that he was on the Continent at intervals between 1595 and the winter of 1597. His lyrical poetry was mainly the result of these years, if we are to believe Ben Jonson, who told Drummond of Hawthornden that Donne "wrote all his best pieces ere he was 25 years old." At his return to England he became private secretary to Sir Thomas Egerton, the lord keeper (afterwards Lord Chancellor Ellesmere), in whose family he remained four years. In 1600 he found himself in love with his master's niece, Anne More, whom he married secretly in Dec. 1601. As soon as this act was discovered, Donne was dismissed, and then thrown into the Fleet prison (Feb. 1602), from which he was soon released. His circumstances, however, were now very much straitened. His own fortune had all been spent and "troubles did still multiply upon him." Mrs. Donne's cousin, Sir Francis Wooley, offered the young couple an asylum at his country house of Pyrford, where they resided until the end of 1604.

During the latter part of his residence in Sir Thomas Egerton's house, Donne had composed the longest of his existing poems, *Of the Progress of the Soul,* not published until 1633. In the spring of 1605 we find the Donnes living at Camberwell, and a little later in a small house at Mitcham. He had by this time "acquired such a perfection" in civil and common law that he was able to take up professional work, and he now acted as a helper to Thomas Morton in his controversies with the Catholics. Donne is believed to have had a considerable share in writing the pamphlets against the papists which Morton issued between 1604 and 1607. In the latter year, Morton offered the poet certain preferment in the Church, if he would only consent to take holy orders. Donne, however, although he was at this time become deeply serious on religious matters, did not think himself fitted for the clerical life. In 1607 he started a correspondence with Mrs. Magdalen Herbert of Montgomery castle, the mother of George Herbert. Some of these pious epistles were printed by Izaak Walton. These exercises were not of a nature to add to his income, which was extremely small. His uncomfortable little house he speaks of as his "hospital" and his "prison"; his wife's health was broken and he was bowed down by the number of his children, who often lacked even clothes and food. In the autumn of 1608, however, his father-in-law, Sir George More, became reconciled with them, and agreed to make them a generous allowance. Donne soon after formed part of the brilliant assemblage which Lucy, countess of Bedford, gathered around her at Twickenham; we possess several of the verse epistles he addressed to this lady. In 1609 Donne was engaged in composing his great controversial prose treatise, *Pseudo-Martyr,* printed in 1610; this was an attempt to convince Roman Catholics in England that they might, without any inconsistency, take the oath of allegiance to James I. In 1611 Donne wrote a curious and bitter prose squib against the Jesuits, entitled *Conclave Ignati.* To the period between 1602 and 1609, belongs the apology for the principle of suicide, which was not published until 1644, long after Donne's death. This work. *Biathanatos,* is an attempt to show that "the scandalous disease of headlong dying," to which Donne himself in his unhappy moods had "often such a sickly inclination," was not necessarily and essentially sinful.

In 1610 Donne formed the acquaintance of a wealthy gentleman, Sir Robert Drury of Hawsted, who offered him and his wife an apartment in his large house in Drury lane. Drury lost his only daughter, and in 1611 Donne published anonymously an extravagant elegy on her, entitled *An Anatomy of the World,* to which he added in 1612 a *Progress of the Soul* on the same subject; he threatened to celebrate the "blessèd Maid," Elizabeth

Drury, in a fresh elegy on each anniversary of her death, but he happily refrained from the third occasion onwards. At the close of 1611 Sir Robert Drury determined to visit Paris (but not, as Walton supposed, on an embassy of any kind), and he took Donne with him. When he left London, his wife was expecting an eighth child. It seems almost certain that her fear to have him absent led him to compose one of his loveliest poems:

Sweetest Love, I do not go
For weariness of thee.

He is said to have had a vision, while he was at Amiens, of his wife, with her hair over her shoulders, bearing a dead child in her arms, on the very night that Mrs. Donne, in London (or more probably in the Isle of Wight), was delivered of a still-born infant. He suffered, accordingly, a great anxiety, which was not removed until he reached Paris, where he received reassuring accounts of his wife's health. The Drurys and Donne left Paris for Spa in May 1612, and travelled in the Low Countries and Germany until September, when they returned to London. In 1613 Donne contributed to the Lachrymae *lachrymarum* of Sylvester an obscure and frigid elegy on the death of the prince of Wales, and wrote his famous Marriage Song for St. Valentine's Day to celebrate the nuptials of the elector palatine with the princess Elizabeth. About this time Donne became intimate with Robert Ker, then Viscount Rochester and afterwards the infamous earl of Somerset, from whom he had hopes of preferment at court. Donne was now in weak health, and in a highly neurotic condition. It is probable that at this time he went through a spiritual crisis which, after many misgivings on his part, ended in a determination to enter the ministry—a course which some of his friends had been urging him to adopt for no little time. At the close of 1614 the king sent for Donne to Theobald's, and "descended to a persuasion, almost to a solicitation of him, to enter into sacred orders," but Donne asked for a few days to consider. Finally, early in 1615, King, bishop of London, "proceeded with all convenient speed to ordain him, first deacon, then priest." He was, perhaps, a curate first at Paddington, and presently was appointed royal chaplain.

His earliest sermon before the king at Whitehall carried his audience "to heaven, in holy raptures." In April, not without much bad grace, the University of Cambridge consented to make the new divine a D.D. In the spring of 1616, Donne was presented to the living of Keyston, in Hunts, and a little later he became rector of Sevenoaks; the latter preferment he held until his death. In October he was appointed reader in divinity to the benchers of Lincoln's Inn. His anxieties about money now ceased, but in Aug. 1617 his wife died, leaving seven young children in his charge. Perhaps in consequence of his bereavement, Donne seems to have been inspired with a peculiar fervour of devotion. In 1618 he wrote a cycle of Holy Sonnets, which was not printed in complete form until by Sir Edmund Gosse in 1899. Of the very numerous sermons preached by Donne at Lincoln's Inn, 14 have come down to us. His health suffered from the austerity of his life, and it was probably in connection with this fact that he allowed himself to be persuaded in May 1619 to accompany Lord Doncaster as his chaplain on an embassy to Germany. Having visited Heidelberg, Frankfurt and other German cities, the embassy returned to England at the opening of 1620.

In Nov. 1621, James I., knowing that London was "a dish" which Donne "loved well," "carved" for him the deanery of St. Paul's. He resigned Keyston, and his preachership in Lincoln's Inn (Feb. 1622). In Oct. 1623 he suffered from a dangerous attack of illness, and during a long convalescence wrote his Devotions, a volume published in 1624. He was now appointed to the vicarage of St. Dunstan's in the West. In April 1625 Donne preached before the new king, Charles I., a sermon which was immediately printed, and he now published his Four Sermons upon Special Occasions, the earliest collection of his discourses. When the plague broke out he retired with his children to the house of Sir John Danvers in Chelsea, and for a time he disappeared so completely that a rumour arose that he was dead. Sir John had married Donne's old friend, Mrs. Magdalen Herbert, for whom Donne wrote two of his most ingenious poems, "The Primrose" and "The Autumnal." The popuiarity of Donne as a preacher rose to its zenith when he returned to his pulpit, and it continued there until his death. Walton, who seems to have known him first in 1624, now became an intimate and adoring friend. In 1630 Donne's health, always feeble, broke down completely, so that, although in August of that year he was to have been made a bishop, the entire collapse of his health made it worse than useless to promote him. The greater part of that winter he spent at Abury Hatch, in Epping Forest, with his widowed daughter, Constance Alleyn, and was too ill to preach before the king at Christmas. It is believed that his disease was a malarial form of recurrent quinsy acting upon an extremely neurotic system. He came back to London, and was able to preach at Whitehall on Feb. 12, 1631. This, his latest sermon, was published, soon after his demise, as *Death's* Duel. He now stood for his statue to the sculptor, Nicholas Stone, standing before a fire in his study at the deanery, with his winding-sheet wrapped and tied round him, his eyes shut, and his feet resting on a funeral urn. This lugubrious work of art was set up in white marble after his death in St. Paul's cathedral, where it may still be seen. Donne died on March 31, 1631, after he had lain "15 days earnestly expecting his hourly change." His aged mother, who had lived in the deanery, survived him, dying in 1632.

Donne's poems were first collected in 1633, and afterwards in 1635, 1639, 1649, 1650, 1654 and 1669. Of his prose works, Pseudomartyr appeared in 1610; *Ignatius,* both in Latin and in English, in 1611; the Devotions, in 1624; the Juvenilia in 1633; the *LXXX* Sermons in 1640; Biathanatos in 1644; Fifty Sermons in 1649; Essays in Divinity 1651; his Letters to Several Persons of Honour; 1651; Paradoxes, Problems and Essays (a reprint of *Ignatius* and the *Juvenilia* with some new, and some spurious, matter), 1652; and Six and Twenty Sermons, 1661. Izaak Walton's Life of Donne, an admirably written but not entirely correct biography, preceded the Sermons of 1640. The principal editor of his posthumous writings was his son, John Donne the younger (1604–62), a man of eccentric and scandalous character, but of considerable talent.

The influence of Donne upon the literature of England was singularly wide and deep, although almost wholly malign. His originality and the fervour of his imaginative passion made him extremely attractive to the younger generation of poets, who saw that he had broken through the old tradition, and were ready to follow him implicitly into new fields. In the 18th century his reputation almost disappeared, to return, with many vicissitudes in the course of the 19th. The first impression of an unbiassed reader who dips into the poems of Donne is unfavourable. He is repulsed by the intolerably harsh and crabbed versification, by the recondite choice of theme and expression, and by the oddity of the thought. In time, however, he perceives that behind the fantastic garb of language there is an earnest and vigorous mind, an imagination that harbours fire within its cloudy folds, and an insight into the mysteries of spiritual life which is often startling. Donne excels in brief flashes of wit and beauty, and in sudden daring phrases that have the full perfume of poetry in them. Some of his lyrics and one or two of his elegies excepted, the Satires are his most important contribution to literature. They are probably the earliest poems of their kind in the language, and they are full of force and picturesqueness. Their obscure and knotty language only serves to give peculiar brilliancy to the not uncommon passages of noble perspicacity.

BIBLIOGRAPHY.—Izaak Walton's Life, first published in **1640,** and entirely recast in **1658,** has been constantly reprinted. Donne's prose works have not been collected. In **1899** Edmund Gosse published in two volumes Tke Life and Letters of Jokn Donne, for the first time revised and collected. The standard edition of Donne's Poems is that published in two volumes, by Professor Herbert J. C. Grierson (Oxford **1912**); A Study of Donne's Prose Works by Evelyn M. Simpson (Oxford 1924) deals with the rest of his work and prints new letters. A full Bibliography by G. L. Keynes was published at the Cambridge Press in 1915. (E. G.)

DONNER, RAPHAEL GEORG (1693–1741), Austrian sculptor, born on May 24, 1693, at Esslingen in Lower Austria, went to Heiligenkreuz intending to take holy orders, but he was there encouraged to follow his artistic bent by the sculptor Giul-

iano, and, after working in his studio, entered the Vienna academy. His fine work brought him to the notice of the court and he found employment in Salzburg for some years, afterwards returning to Vienna, where he died on Feb. 15, 1741. His masterpiece is the fountain on the Neumarkt in Vienna, which he executed in the years 1738 and 1739. The figures originally cast in lead, a technique favoured by the artist, were replaced by exact copies in bronze in 1873. Other works are the fountain with Perseus and Andromeda in the courtyard of the Vienna Rathaus and a statue of Charles VI. in the Belvedere, Vienna. Donner's refined plastic form and clear outline contrasted with the art of his contemporaries and predecessors, who tended towards exaggerating the restlessness of Bernini's baroque style, and influenced his followers to adopt a more classic conception of form.

DONNYBROOK, part of Dublin, Eire. The former village of the name was famous for a fair held under licence from King John in 1204, but discontinued in 1855.

DONO, PAOLQ DI: see UCCELLO.

DONORA, a borough of Washington county, Pa., U.S.A., on the Monongahela river and the Pennsylvania railroad, 20 mi. S. by E. of Pittsburgh. The population in 1920 was 14,131; in 1930 it was 13,905; in 1940, 13,180 by federal census. It is an important manufacturing centre of the Pittsburgh district, producing steel, nails, wire, zinc and chemicals.

DONOSO CORTÉS, JUAN, marquis de Valdegamas (1809–1853), Spanish author and diplomatist. After entering politics as an advanced liberal, he made a complete volte-face after 1848, and in his Ensayo *sobre* el *catolicismo,* el *liberalismo,* y el socialismo, *considerados* en *sus principios fundamentales* (1851), denounced reason as the enemy of truth and liberalism as leading to social ruin. With all its rhetorical excesses, the Ensayo remains one of the finest specimens of impassioned prose published in Spain during the 19th century.

DOOM, originally a law or enactment, the legal decision of a judge, and particularly an adverse sentence on a criminal (O.E. *dóm,* a word common to Teut. languages for that which is set up or ordered). The word is thus applicable to the adverse decrees of Fate, and particularly to the day of judgment. The verb "deem," to deliver a judgment, is seen in "deemster," the name of the two judges of the Isle of Man (*q.v.*).

DOON DE MAYENCE, a hero of romance, who gives his name to the third cycle of the Charlemagne romances, those dealing with the feudal revolts. There is no real unity in the geste of Doon de Mayence. The rebellious barons are connected by the *trouvères* with Doon by imaginary genealogical ties, and all are represented as in opposition to Charlemagne, though their adventures, in so far as they possess a historical basis, must generally be referred to earlier or later periods. The general insolence of their attitude to the sovereign suggests that Charlemagne is here only a name for his weaker successors. The tradition of a traitorous family of Mayence, which was developed in Italy into a series of stories of criminals, was, however, anterior to the Carolingian cycle, for an interpolator in the chronicle of Fredegarius states (iv. 87) that the army of Sigebert was betrayed from within its own ranks by men of Mayence in a battle fought with Radulf on the banks of the Unstrut in Thuringia. The chief heroes of the poems which make up the geste of Doon de Mayence are Ogier the Dane (*q.v.*), the four sons of Aymon (see RENAUD), and Huon of Bordeaux (*q.v.*). It is probable that Doon himself was one of the last personages to be clearly defined, and that the chanson de geste relating his exploits was drawn up partly with the view of supplying a suitable ancestor for the other heroes. The latter half of the poem, the story of Doon's wars in Saxony, is perhaps based on historical events, but the earlier half is obviously pure fiction and dates from the 13th century.

See *Hist. litt.* de la France, vols. xxii. and xxvi. (1852 and 1873), for analyses of these poems by Paulin Paris; also J. Barrois, *Éléments* rarolingiens (1846); W. Niederstadt, Alter und Heimat der altfr. *Doon* (Greifswald, 1889). The prose romance, La *Fleur des batailles* Doolin de Mayence, was printed by Antoine Vérard (1501), by Alain Lotrian and Denis Janot (c. 1530), by N. Bonfons (no date), by J. Waesbergue (Rotterdam, 1604), etc. The chief poems of the cycle are available in the series of Anciens *Poètes* de la France (1859, etc.).

DOOR, a single piece, or assemblage of pieces, of wood, metal, stone or other material, supported movably in an opening, so as to allow or prevent passage through that opening. In door openings of primitive huts sheets of hide or textiles were hung as doors. These were either hung as flaps or else arranged to roll up. In the tomb of Ti, in Egypt, of the 5th dynasty, there are elaborate wall-painting representations of doors of richly decorated matting which were rolled up to the top, like an awning, to admit entrance, and in certain Italian churches to the present day similar flaps of leather are used as secondary doors. Doors of more rigid materials came into use early and consisted, apparently, of single heavy wooden boards, with pivots at the top and bottom of one side, fitted into sockets in the sill and head. This seems to have been the common practice in Egypt; when the doorway was wide, two such doors were used, pivoted on opposite sides.

In countries where wood was scarce, stone doors were used. This is notably the case in Syria, where many stone doors dating from the 4th to the 6th century have been found. Similar doors of stone or marble were frequent in tombs. There is a famous marble door from a tomb in Pompeii, probably of the Augustan era. These stone doors were always panelled, very likely to lessen the weight without reducing the strength.

In countries with damp climates, where single pieces of wood would warp, wooden doors are built up of several pieces, either by forming them of a series of vertical planks, tied together by tenons, dowels or horizontal braces known as battens, or else by forming a framework of uprights called stiles, and horizontal members called rails, with thinner panels placed between them and held in by grooves or additional mouldings. In Syria, Palestine and Mesopotamia wooden doors were frequently sheathed in sheets of metal richly *repoussé.* In the British Museum there are numerous examples of the bronze bands decorated with processions of figures and battle scenes and also the bronze pivots from the gates at Balawat (895–825 B.C.). These gates were of two leaves, each about 8ft. 4in. wide and 27ft. high, and the bands which decorated them are 10in. high. Solomon's temple is described (I Kings vi.) as having doors of carved wood covered with gold leaf.

Classic doors were usually of wood, panelled. Representations in Pompeiian wall paintings and contemporary reliefs show that they greatly resembled the doors of the present day, and a plaster cast of an original charred door confirms this. These ancient doors seem to have been frequently in two, three or four leaves, and hinges connecting the leaves of such a door have been found. The doors for monumental buildings were largely of bronze (see BRONZE) and the beautifully designed example in the Pantheon (A.D. 110–125) is famous. Several similar Roman examples remain, especially those of the basilica of SS. Coamas and Damian, in Rome, taken from an earlier building dating from the best Roman imperial period, and those of the Lateran basilica. The most important Byzantine examples extant are those of S. Sophia, Constantinople. They are heavily panelled with deep mouldings and further enriched by rows of rosettes and decorative bolt heads. The influence of Roman precedent is obvious in the design. Many Romanesque bronze doors exist in south Italy. In these the panels are small, shallow and usually square. The richness is obtained through low relief that is sometimes scarcely more than engraving. The finest examples are those at Amalfi (1060), two at Troja (1119 and 1124), that at Ravello (1179) and the doors of Trani cathedral (late 12th century).

Late in the 12th century the pivoting of the doors at top and bottom gave way, generally, to the use of hinges; this change offered great opportunities for door decoration which was represented in most of the important Gothic cathedrals. Here the doors are usually simple planked doors of wood, the decoration consisting of the elaborate wrought iron hinge plates (see IRON IN ART) hammered into intricate foliated scrolls; occasionally, as in the famous doors of Notre Dame at Paris (early 13th century), additional cross braces of similar foliated wrought iron are introduced among the three hinges. In the late Gothic period this usage died out. Decoration was obtained in the wood of the door itself by forming the panels with tracery, occasionally very

intricately, and sometimes adding miniature buttresses and carved figures. In the smaller doors the use of the linen fold (simulating folded cloth) decoration is common. With the coming of the early Renaissance a similar kind of decoration was carried out with even greater richness, and wooden doors, in which panels crowded with figures, buttresses, simulated architectural forms and decorated mouldings give an impression of extraordinary richness. arc characteristic: *e.g.,* the doors of S. Maclou at Rouen, by Jean Goujon, 1540. The later Renaissance returned to more classic and simple forms. Typical are the bronze doors of the Baptistery at Florence designed by Ghiberti (1402–52). Although in the north doors he followed the Gothic scheme of Andrea Pisano's south door, in the east, despite the complexity and beauty of the figure decoration, the scheme is rigidly rectangular. The use of rectangular or square panels remained constant throughout the Italian Renaissance, but in France, from the time of Henry IV. on, doors became more and more fantastic, culminating in those of the time of Louis XIV. and Louis XV., with their curved headed panels and double or triple mouldings.

In Muslim doors the enormous skill in elaborate wood framing possessed by Mohammedan carpenters finds congenial expression and the most intricate panelled types, with star-shaped and polygonal panels, are common. Frequently additional decoration is given by complicated pierced and cut out metal mountings; somewhat similar mountings ornament the corners of the temple doors of China and Japan. These doors are usually of two panels, the lower solid, the upper filled with elaborate grill work in wood, either based on hexagonal patterns and triangles or an intricate network of straight lines of varying angles and lengths, over which paper is pasted in lieu of glass. In Japanese houses doors are usually sliding and may have the same pattern as the walls.

Modern wooden doors continue the traditional panel type. In construction, however, solid doors are more and more giving place to those in which a core of small pieces of soft wood is covered by sheets of veneers, enabling the occasional abandonment of panels and the making of flush doors which are commonly used in hospitals. Another characteristic modern development has been the tremendous increase in the number and variety of metal doors in connection with fire-proof construction. These are of two types: metal covered or kalamein, in which a core of wood is covered with metal sheets, carefully soldered and locked together; and hollow metal, in which a frame of structural metal sections is encased with metal plates. In both of these types, for structural reasons, the panel design is usually perpetuated, but flush pattern hollow metal doors are becoming more and more common. The use of top and bottom pivots instead of hinges is frequent in exterior doors, particularly where there are several doors in a row, in order to avoid vertical bars or mullions between them. Elaborate mechanical development of all types of locks, hinges, pivots, door checks and door closers is noteworthy. *(See* DOORWAY.) (T. F. H.)

DOORWAY, in architecture, the entrance of a building, room or enclosure, especially the framing of such an opening. In primitive construction with brick or rubble, opening frames were usually of wood, and consisted of uprights or jambs on each side, and lintels or heads at the top. Such doorways occurred in the archaic work in Greece, and evidences of wooden frames exist in Tiryns from about the 12th century B.C. and in the Heraeum at Olympia, where the early, crude arrangement was preserved all through. In wooden framed buildings the lintel is usually framed between the uprights which continue up beyond it. Examples of this arrangement are represented in certain Egyptian mastaba tombs of the second, third and fourth dynasties. Where building is all in cut stone, no separate door frame is necessary, but decorative lines are, nevertheless, frequently carried around the opening, as a legacy from other and earlier types of building.

In Egyptian work, although the doorway jambs are not indicated, and the banding of the cut stone wall is frequently carried, unbroken, straight to the opening, the head was expressed by means of a projecting cornice This cornice was of the usual *cavetto* or concave type, and often carried a decoration in the centre, formed of the winged globe symbolizing the sun. In some of the doorways in the stone screen walls of later Egyptian temples it was necessary for the door opening to be carried up higher than the height of the screen, to allow banners and the sacred boats to be carried through in processions. In order to accomplish this and still. preserve the doorway form, the head was not complete and was formed merely by stones with small projections inward from the jambs, ornamented, however, like the complete lintels, as in the famous Ptolemaic temple at Edfu (237 to 57 B.C.).

In archaic Etruria as well as in Greece doorways were frequently smaller at the top than at the bottom, in order to lessen the length of the lintel, and apparently in both countries, at nearly the same time, the idea occurred of decorating the jambs and lintel by means of a continuous moulding, running up the sides and across the top. As the lintel was frequently longer than the combined width of opening and jamb stones, and the moulding was cut round the outside, projections in the architrave or moulding were formed at the level of the lintel. These are called keys or *croisettes.* Examples of this occur in the Beule gateway of the Acropolis at Athens, in many Etruscan tombs from the 7th to the 5th century B.C., and in the temple of Hercules at Cori (72 B.C.). In the Etruscan examples the lintel keys are sometimes further decorated by down-curving pendants. In the developed classic treatment the moulding around the jamb and heads is treated as an architrave, usually with two or three bands and a raised moulding on the outside. Frequently a frieze and cornice are added, sometimes with consoles (*q.v.*), which are always set on the outside of the architrave moulding, as in the doorway of the Erechtheum (*q.v.*) at Athens, completed 408 B.C., and in the colossal doorway of the temple of Jupiter at Baalbek (C. A.D. 120) which is zoft. wide and 45ft. high. The doorway of the Pantheon at Rome (A.D. 110–125), of the same width, still possesses the original Roman bronze door frame, door and transom screen.

In both the Romanesque and Gothic periods church doorways were among the most characteristic features of the styles. They were formed by means of an elaborate series of recesses in the thickness of the wall, usually in steps or orders, which ran not only up the sides, but also in an arch over the top, leaving a lunette (*q.v.*) or *tympanum* (a section of vertical wall) between the under side of the arch and the horizontal head of the door opening. These steps or orders were ornamented with mouldings, carvings and sculpture; occasionally columns were placed at the side. In Gothic work statues often take the place of columns, and bands of angels, under little canopies (*q.v.*), encircle the arch between the mouldings. The *tympanum* and door lintel are also richly sculptured, and there is often a central pier dividing the door opening in two, frequently carrying a statue, especially in the Gothic. A moulding projecting from the wall surface and called a drip or hood mould frequently surrounds the entire arch.

In the Renaissance period doorway design returned to generally classic lines. In the early Renaissance, however, classic motives of great complexity were used for doorway decoration in a manner far different from the usual Roman or Greek precedent. Colonnettes, gaines (half figures used as supports), pediments and arches with decorated lunettes are common; especially fantastic are the examples found in the transitional Renaissance of Germany, France and England. With increasing knowledge of classic detail more sober treatments prevailed. The use of columns and pilasters with pediments remained general. During the baroque period these basically classic motives received the typical fantastic and imaginary treatment. Noteworthy among these later Renaissance doorways are those of England and America in the late 18th and early 19th centuries, in which side-lights at each side of the door and a fanlight above, often with rich decorative leading, are all enclosed in a single doorway frame.

In Muslim countries doorways achieve enormous importance, the door itself being often merely an incident in a rich composition running the entire height of the wall. This usually takes the form of an arched niche or recess, sometimes crowned with a stalactite vault, sometimes simply a high pointed arch, as in the magnificent tile-lined mosque doorways of Persia.

Chinese and Japanese doorways are commonly simple, their type of timber framing allowing little decorative treatment. Occa-

sional arched doorways with ornamented lunettes are found in city gates, temples or palaces, especially in northern China.

Although the *art nouveau* movement of the '90s gave rise to many fantastic doorway schemes, the general modernist treatment is a return to simplicity. Exceptions are, however, frequent, and certain modernist doorways, particularly of commercial buildings, are rich with carved ornament. *(See* ARCHITRAVE, BYZANTINE AND ROMANESQUE ARCHITECTURE, CONSOLE, DOOR and articles on architecture.) (T. F. H.)

DOPOLAVORO (literally "Afterwork") is a state-controlled Italian organization which takes care of the recreation of the workers during their leisure hours.

Since 1910, there has existed in Rome an "Afterwork Office" to promote and assist the development of welfare and recreational efforts organized by employers for their dependents. Before fascism came into power (1922), the "Afterwork Office" had only a limited scope. The majority of workers preferred their own organizations established by the trade unions.

Pursuing its policy of acquiring control over individuals and the masses through a complete hold on their organizations, the fascist party annexed the *Dopolavoro* in 1922 with the aim of expanding it and absorbing other organizations. At the close of 1923, the *Dopolavoro* passed under the control of the Confederation of Fascist Trade Unions.

In 1925, all Italian athletic and sport societies, choral societies, bands, University extension groups, night schools, circulating libraries and pleasure clubs which were not already under fascist administration, were submitted to the control of commissars appointed by the fascist government. The buildings of the democratic sport and cultural organizations like the Spreti Palace in Ravenna and the People's House in Rome were confiscated and donated by the government to the *Dopolavoro.*

On May 1, 1925, the *Dopolavoro* received its charter of incorporation under the name of *Opera Nazionale Dopolavoro* and became officially one of the institutions of the fascist state. The government granted the *Opera* an endowment of 1,000,000 lire and an annual grant of 400,000 lire. Besides this, it received annual contributions from local authorities and from various associations, the annual dues paid by the affiliated societies, etc. As a result of its "fascistization" the *Dopolavoro* devoted itself not only to the organization of sport and welfare, but also to fascist political propaganda.

With the consolidation of the fascist dictatorship (1926) the *Dopolavoro* grew rapidly. It extended from factory workers to other large groups, including the employees of the state railways, of the postal, telegraph and telephone services, of the central and local state administration, of the banks and trade corporations, etc.

Members of families of workers and of employees were also organized in the *Dopolavoro.* Special sections were established for women. At the beginning of 1936, the *Dopolavoro* included in Italy over 20.000 societies and a total membership of 2,108,227. At the end of 1926. the Italian preparation for the Olympic games was entrusted—by order of the secretary general of the fascist party—to the *Dopolavoro,* which had to supervise all activities concerning physical education and sport. Later the members of the largest trade unions, which had already been put under the control of the fascist party, were officially obliged to join the *Dopolavoro.* Even those who were not interested in sports or recreations had to pay dues to the *Dopolavoro.*

Besides sports, an important activity of the *Dopolavoro* was the organization of popular shows. This was done through the "carri di Tespi" (Thespis' chariots), which toured the country putting on plays in open-air theatres.

Italian sport champions, trained and maintained at public expense, were for a while successful in international sport contests. In the Olympic games held in Los Angeles in 1932, Italy came second only to the United States.

The *Opera Nazionale Dopolavoro* has its headquarters in Rome. From 1927 on its directors, appointed by the prime minister, were placed under the direct control of the secretary general of the fascist party. The central directorate acts in each province through a local *Dopolavoro* office which is presided over by the provincial secretary of the fascist party.

Societies affiliated with the *Opera* obtain for their members, who pay an annual fee of a few lire, free entrance to museums, excavations, etc , considerable reductions on 3rd class railway rates for week-ends, holidays and excursions, reductions also on theatre and cinema tickets, discounts from booksellers, etc. Furthermore they enjoy the benefits of a special insurance which covers all risks in leisure hours and another insurance covering risks during matches.

The *Dopolavoro* occupies an important place within the frame of Italian Fascist institutions. It is a political and military weapon at the orders of Fascism. It facilitates the policing of millions of workers and employees, whose activities can be controlled by trusted members of the fascist party even after they have left the factories and the offices. Already in 1932, the leaders of important sections of the *Dopolavoro* inaugurated the practice of giving a reward in cash to the members of the organization who collaborated with the party in uncovering antifascist plots. After the introduction of racial laws in Italy (1938), the political tasks of the *Dopolavoro* (from which all Jewish members had been expelled) were even more important.

Outside Italy, *Dopolavoro* centres had been established in most localities containing a large number of emigrants. These centres were under the orders of the fascist consuls and represented an important element for the spreading of fascist influences among the emigrants. (M. W. S.)

DOPPLER, CHRISTIAN JOHANN (1803–1853), Austrian physicist, was born at Salzburg, on Nov. 29, 1803. He was educated at Salzburg and Vienna, and became, in 1850, director of the Physical Institute and professor of experimental physics at Vienna. He died at Venice on March 17, 1853. Doppler's earliest writings were on mathematics, but his name is associated with his work in physics. In 1842 he published a paper "über das farbige Licht der Doppelsterne," which contained what is now known as Doppler's principle *(see* LIGHT: *Waves and Interference).* He drew the analogy between the sound coming from a moving source and the light coming from a moving star; as the pitch of sound from a moving source varies, so Doppler thought the colour of the light from a star would be altered.

The principle was verified experimentally for sound by Buys-Ballot in 1845, but the correct explanatiop in the optical case was given by Fizeau in 1848.

Doppler's principle is applied to the motion of stars in the line of sight, and is used for the discovery of double stars (*see* STAR).

DOPPLER EFFECT, the change in the observed frequency of a vibration owing to relative motion between the observer and the source of the vibration. In sound (*q.v.*) this effect is an everyday experience; *e.g.,* on passing a ringing bell at any speed above about 10 m.p.h. the pitch of the note suddenly sounds lower.

The Doppler effect for light waves is evident in spectroscopy (*q.v.; see* also LIGHT: *Waves and Interference).*

DOPPLERITE, a naturally occurring organic substance found in amorphous, elastic or jelly-like masses, of brownish-black colour, in peat beds in Styria and in Switzerland. It is tasteless, insoluble in alcohol and ether, and is described by Dana as an acid substance, or mixture of different acids, related to humic acid.

DORAN, JOHN (1807–1878), English author, was born in London of Irish parentage. He succeeded Hepworth Dixon as editor of *The Athenaeum* for a short time in 1869, until he became editor of *Notes and Queries* in 1870. His most elaborate work, *Their Majesties' Servants, a* history of the English stage from Betterton to Kean, was published in 1860, and was supplemented by *In and About Drury Lane,* which was written for *Temple Bar* and was not published in book form till 1885. Among his other works may be mentioned *The History of Court Fools* (1858), *The Last Journals of Horace Walpole* (1859), *London in Jacobite Times* (1877), and *Memories of our Great Towns* (1878).

DORAT, CLAUDE JOSEPH (1734–1780), French man of letters, was born in Paris. He obtained a great vogue by his *Réponse d' Abailard à Héloïse,* and followed up this first success with a number of heroic epistles, *Les Victimes de l'amour, ou lettres de quelques amants célèbres* (1776). Besides light verse he wrote comedies, fables and novels. He was maladroit enough to draw down on himself the hatred both of the *philosophe* party and of their arch-enemy, Charles Palissot, and thus cut himself off from the possibility of academic honours. *Le Tartufe littéraire* (1777) attacked La Harpe and Palissot, and at the same time D'Alembert and Mlle. de Lespinasse. Dorat died in Paris on April 29, 1780.

See his Oeuvres complètes (20 vols., 1764–80); G. Desnoireterres, *Le Chevalier Dorat et les poètes légers au XVIIIe siècle* (1887). For the bibliographical value of his works, *see* Henry Cohen, *Guide de l'amateur de livres à figures et à vignettes du XVIIIe siècle* (editions of Ch. Mehl, 1876, and R. Portalis, 1887).

DORCHESTER, DUDLEY CARLETON, VISCOUNT (1573–1632), English diplomatist, son of Antony Carleton of Baldwin Brightwell, Oxfordshire, was born on March 10, 1573, and educated at Westminster school and Christ Church, Oxford, where he graduated M.A. in 1600. As secretary to the earl of Northumberland his name was associated with the Gunpowder Plot, but he succeeded in clearing himself. In 1610 he was knighted and was sent as ambassador to Venice, where he concluded the Treaty of Asti. In 1616 he was appointed ambassador to Holland. In his house at The Hague the unfortunate Elector Frederick and the princess Elizabeth took refuge in 1621. Carleton returned to England in 1625 with the duke of Buckingham, and was made vice-chamberlain of the household and a privy councillor. After an abortive mission to France he returned in 1626 and sought in the House of Commons (he had been a member since 1604) to defend his patron, the duke of Buckingham. Created Baron Carleton of Imbercourt, and, after another mission to The Hague, Viscount Dorchester (1628), he supported the conferences between Buckingham and Contarini for a peace with France on the eve of the duke's intended departure for La Rochelle, which was prevented by Buckingham's assassination. In December 1628 he was made principal secretary of State, and died on Feb. 15, 1632.

His voluminous correspondence, remarkable for its clear, easy and effective style and for the writer's grasp of the main points of policy, covers practically the whole history of foreign affairs during the period 1610–1628, and furnishes valuable material for the study of the Thirty Years' War. His letters as ambassador at The Hague, Jan. 1616 to Dec. 1620, were first edited by Philip Yorke, afterwards second earl of Hardwicke, with a biographical and historical preface, in 1757; his correspondence from The Hague in 1627 by Sir Thomas Phillipps in 1841; other letters are printed in the *Cabala* and in *T*. Birch's *Court and Times of James I. and Charles I.,* but by far the greater portion remains in ms. among the State papers.

DORCHESTER, GUY CARLETON, 1ST BARON (1724–1808), British general and administrator, was born at Strabane, Co. Tyrone, Ireland, on Sept. 3, 1724. He served in 1759 in America as quartermaster-general, under his friend Wolfe. He was wounded at the capture of Quebec, and promoted to the rank of brigadier-general. From 1766 to 1778 he was governor-general of Canada. His justice and kindliness greatly endeared him to the recently conquered French-Canadians, and did much to hold them neutral during the War of American Independence. He ordered the first codification of the civil law of the province, and was largely responsible for the passing of the Quebec Act. On the American invasion of Canada in 1775 he was compelled to abandon Montreal and narrowly escaped capture, but defended Quebec (*q.v.*) with skill and success. In October of the same year he destroyed the American flotilla on Lake Champlain. In 1777 he was superseded in his command of the military forces by Maj.-Gen. John Burgoyne, and asked to be recalled. He returned, however, to America in May 1782 as commander-in-chief, remaining till November 1783. In 1786 he was again sent to Canada as governor-general and commander of the forces, with the title of Baron Dorchester. Many important reforms marked his rule; he kept the country loyal to the British crown amid the ferment caused by the French Revolution. In 1791 the province was divided into Upper and Lower Canada by the Constitutional Act. Of this division Carleton disapproved, as he did also of a provision tending to create in the new colony an hereditary aristocracy. In 1796 he insisted on retiring. He died in England on Nov. 10, 1808. On the death in 1897 of the 4th baron (a grandson) the title became extinct, but was revived in 1899 for his cousin and co-heiress Henrietta Anne as Baroness Dorchester.

See J. C. Dent, *Canadian Portrait Gallery* (Toronto 1880); *A.* G. Bradley, *Life* of *Guy Carleton, Lord Dorchester* (1907). Most of his letters and state papers are calendared in Brymner's *Reports on Canadian Archives* (Ottawa, 1885, *seq.*).

DORCHESTER, a market town and municipal borough and the county town of Dorsetshire, England, in the Western parliamentary division, 135¼ mi. W.S.W. from London by the S.R. and also served by the Weymouth section of the G.W. Ry. Pop (est. 1938) 10,230. Area 2.6 sq.mi. It stands on an eminence on the right bank of the river Frome, within a wide open tract of beautiful views, 6 mi. N. of the English channel at Weymouth bay. St. Peter's church is a Perpendicular building with a fine tower. All Saints and Holy Trinity churches were rebuilt in the last century, but St. George's, Fordington, retains Norman and Transitional details. Of public buildings the principal are: the town hall, market house and corn exchange, shire hall, the interesting county museum, the county hospital and the former county, now government, prison. The grammar school, in modern buildings, was founded in 1569. A statue to Thomas Hardy, the poet and novelist, was unveiled in 1931. There is also a statue to William Barnes, the Dorsetshire poet (1801–1886). Hardy was born near Dorchester, which is the "Casterbridge" of the Wessex novels. A room containing part of his study and other memorabilia was opened in the museum in 1939. The town is noted also for its ale. It is a place of considerable agricultural trade, and large sheep and lamb fairs are held annually.

Durnovaria, at the intersection of a number of Roman roads, was a Romano-British country town of considerable size, probably successor to a British tribal centre of the Durotriges. The walls can be traced in part, and many mosaics, remains of houses, etc., have been found The notable remains of a Roman amphitheatre are seen at Maumbury Rings, near the town. Maiden castle, on a hill 2 mi. S.W., is a vast earthwork encircled by gigantic entrenchments and ramparts, the whole occupying 120 ac. Excavations in 1934 indicated that the hill was the site of an important town in Iron Age times. Another smaller encampment is at Poundbury close by, and barrows and numerous other remains have been found in the vicinity. Little mention of Dorchester *(Dornceaster, Dorcestre)* occurs in Saxon annals, but a charter from Aethelstan to Milton abbey in 939 is dated at *villa regalis quae dicitur Doracestria,* and at this period it possessed a mint. According to the Domesday survey it was a royal borough and had contained 172 houses, of which 100 had been totally destroyed since the conquest. Mention is made of a castle at Dorchester in records of the 12th and 13th centuries; and the Franciscan priory, founded some time before 1331, is thought to have been constructed out of its ruins. The latter was suppressed among the lesser monasteries in 1536. Edward II granted the borough to the bailiffs and burgesses at a fee-farm rent of £20 for five years.

The first charter of incorporation, granted by James I in 1610, established a governing council, which Charles I in 1629 enlarged, while also incorporating the freemen of the borough with power to make laws for the regulation of the markets and trade Dorchester returned two members to parliament from 1295 until the Representation of the People act (1868) reduced the number to one; in 1885 the representation was merged in the county. Edward III granted to the burgesses the perquisites from three fairs, and three weekly markets. Elizabeth granted an additional three days' fair at Candlemas. Markets are now held on Wednesdays and Saturdays and fairs in February, May, July, August, October and November. The cloth industry which flourished during the 16th century never recovered from the depression following the Civil War. The malting and brewing industries came into prominence in the 17th century, when there was also a considerable serge manufacture, which has since declined.

DORCHESTER, a large village in the Henley parliamentary division of Oxfordshire, England, 9 mi. S.S.E. of Oxford by road,

on the west bank of the river Thame, 1 mi. from its junction with the Thames. Pop. of civil parish (1931) 774. At Dike hill close to the present village there was a Roman station, and facing, across the Thames, the double isolated mound known as Wittenham Clumps (historically Sinodun), is the site of ancient earthworks. In Dorchester itself the chief point of interest is the abbey church of St. Peter and St. Paul. This consists of a nave of great length, primarily of the transitional Norman period; a choir with arcades of the finest Decorated work; north choir aisle of the close of the 13th century, south choir aisle (c. 1300) and south nave aisle (*c.* 1320). The tower (western) is an erection of the late 17th century. The eastern bay of the choir is considered to have been added as a Lady chapel, and the north window is a magnificent example of a "Jesse window," in which the tracery represents the genealogical tree of Jesse, the complete execution of the design being carried on in the glass. The ancient sedilia and piscina are very fine. The Decorated windows on the south side of the church form a beautiful series, and there are early monuments and brasses of great interest.

Dorchester (Dorcinia, *Dornacestre,* Dorchecestre) was conquered by the West Saxons about 560. It occupied a commanding position at the junction of the Thames and the Thame, and in 635 was made the seat of a bishopric which at its foundation was the largest in England, comprising the whole of Wessex and Mercia, Birinus, apostle of the West Saxons, becoming its first bishop. The witenagemot of Wessex was held at Dorchester three times in the 9th century, and in 958 Aethelstan held a council here. In the 11th century the town is described as small but remarkable for the majesty of its churches, and *c.* 1086 the bishop's stool was removed to Lincoln by Remigius, the 23rd bishop. According to Domesday, Dorchester was held by the bishop of Lincoln. In 1140 Alexander bishop of Lincoln founded the abbey of Black Canons at Dorchester, of which the only remains are the abbey church. The town declined in importance after the removal of the cathedral, but in 1939 it was made a see suffragan to Oxford.

DORCHESTER, a residential and manufacturing district of Bcston, Massachusetts, U.S.A., a separate town until 1870, between the Neponset river on the south and South Boston and Boston proper on the north. A ridge, with an average height of about 100 ft. above the sea, extends through the district from north to south and commands delightful views of Boston bay to the east and of the Blue hills to the south. Franklin field and Franklin park, one of the larger parks of the Boston park system, are in Dorchester. The Robert Pierce house, built in 1640, stands on its original site on Oakton avenue, and is one of Dorchester's landmarks. The Barnard Capen house, built about the same time, has been removed to Milton. The James Blake house (1648) maintained by the Dorchester Historical society, has a library and a museum. Not far away is the old Dorchester burying ground, which dates from 1634; it has many curious epitaphs, and contains the graves of Barnard Capen, who died in 1638 (probably the oldest marked grave in the United States); of William Stoughton (1631–1701), chief justice of the court which tried the Salem "witches" in 1692, and founder of the original Stoughton Hall, Harvard; and of Richard Mather.

Dorchester was founded by about 140 colonists from Dorsetshire, England, with whom the movement for planting the colony in Massachusetts Bay was begun under the leadership of Rev. John White. They organized as a church while at Plymouth, England, in March 1630, then embarked in the ship "Mary and John," arrived in Boston bay two weeks before Governor Winthrop with the rest of the fleet, and in June selected Savin Hill as the site for their settlement. At the time the place was known as Mattapanock, but they named it Dorchester. In Oct. 1633, a town Government was organized, and the example was followed by the neighbouring settlements; this seems to have been the beginning of the town-meeting form of government in America. Up to this time Dorchester was the largest town in the colony, but dissatisfaction arose with the location (Boston had a better one chiefly on account of the deeper water in its harbour), and in 1635–37 many of the original settlers removed to the valley of the Connecticut where they founded Windsor. New settlers, however, arrived at Dorchester and in 1639 that town establishecl a school supported by a public tax; this was the first free school in America supported by direct taxation or assessment on the inhabitants of a town. It was the fortification of Dorchester Heights, under orders from Gen. Washington, on the night of March 4–5, 1776, that forced the British to evacuate Boston.

See W. D. Orcutt, *Good Old Dorchester* (Cambridge, *1893)*; and The Dorchester Book (Boston, 1899).

DBRDOGNE, an inland department of south-western France, formed in 1790 from nearly the whole of Périgord, a part of Agenais, and small portions of Limousin and of Angoumois. Area 3,561 sq.mi. Pop. (1936) 386.963 It is bounded N. by Haute-Vienne, W. by Charente, Charente-Inférieure and Gironde, S. by Lot-et-Garonne, and E. by Lot and Corrèze. Situated on the western slopes of the Massif Central, Dordogne consists in the north-east and centre of sterile plateaus sloping towards the west, where they end in a region of pine forests known as the Double. The greatest altitudes are found in the highlands of the north, where many points exceed 1,300 ft. in height. Many beautiful river valleys, of the Dordogne, the Isle, with the Dronne and Auvézère, and the Vézère converge towards the southwest of the department. The climate is mild, but rather humid, especially in the north-east. Agriculture prospers in the south and south-west of the department, especially in the valleys of the Dordogne and Isle, but the rest of its surface is covered to a great extent by woods and heath. Pasture and forage amply suffice for the raising of large flocks and herds. The vine, cultivated mainly in the neighbourhood of Bergerac, and tobacco are important sources of profit. Wheat and maize are the chief cereals and potatoes are largely grown. The truffles of Périgord are famous for their abundance and quality. The plum and cider-apple yield good crops. In the forests the prevailing trees are the oak and chestnut. The chestnuts are much used as food by the people and for fattening hogs, reared in large numbers. The walnut is extensively grown for its oil. The department has mines of lignite, and produces freestone, lime, cement, mill-stone, peat, potter's clay and fireclay. The leather industry and the preparation of preserved foods are important, and there are brick and tile works, earthenware manufactories and iron works. Exports consist of truffles, wine, chestnuts and other fruit, live stock, poultry and minerals of various kinds. Dordogne is served by the Orléans railway; the Dordogne, the Isle and the Vézère furnish nearly 200 m. of navigable waterway. It is divided into the arrondissements of Périgueux, Bergerac. Nontron and Sarlat, with 47 cantons and 587 communes, and belongs to the ecclesiastical province of Bordeaux, to the académie (educational division) of Bordeaux and to the region of the XII army corps, which has its headquarters at Limoges. Its court of appeal is at Bordeaux

Périgueux, the capital, and the other principal towns are treated in separate articles. Bourdeilles has two finely preserved chbteaux, one of the 14th century, with an imposing keep, the other in 16th century Renaissance. Both buildings are contained within the same fortified enceinte. The chbteau of Biron (11th century and later) has a beautiful chapel of late Gothic and early Renaissance workmanship. The chbteau of Jumilhac-le-Grand is of the 15th century. Dordogne possesses several mediaeval bastides, the most perfect of which is Monpazier. At Cadouin there are the remains of a Cistercian abbey. Its church is a fine Romanesque building, while the cloister is excellent Flamboyant. St. Jean-de-Côle has an interesting Romanesque church and a château of the 15th, 16th and 18th centuries. In the rocks of the valley of the lower Vézère there are prehistoric caves of great importance for the study of Palaeolithic man. Troglodytic dwellings are to be found in many other places in Dordogne.

DORDOGNE, a river of central and south-western France, rising at a height of 5,640 ft. on the Puy-de-Saucy, a section of the volcanic core of the Plateau Central in the department of Puy-de-Dame, and flowing to the Garonne, with which it unites at Bec d'Ambès to form the Gironde estuary. It has a length of 295 m. and the area of its basin is 9,214 sq. miles. The Dordogne is a good example of a consequent stream of the

western section of the Plateau Central. In its course it cuts across a large number of geological formations, as do its two great right-bank tributaries, the Vézère and the Isle. The Dordogne descends rapidly from its source and enters deep gorges as it flows through the Archaean plateau-country, rich in granites, until it reaches Beaulieu (department of Corrèze) where it enters a wide fertile valley and is joined by the Cère. Entering the department of Lot, it abandons a south-westerly course for a westerly course. It now flows through limestone country, often in gorges with the Causses above on both sides. It traverses the department of Dordogne, where it receives the Vézère. The lower course of the latter is through a calcareous country, and its many caves have made it classic ground for the study of Palaeolithic man. Below the town of Bergerac the Dordogne enters the department of Gironde and is joined by the Isle at Libourne. The river is some 3,300 yd. wide at its union with the Garonne, 45 m. from the sea. In its lower course it flows over Tertiary material. There are important bridges at Cubzac-les-Ponts. There is much river traffic after the confluence with the Vézère over the last 112 m. of its course. The estuary of the Gironde is one of the most conspicuous features of the western coast of France, and the highest tides ascend the Dordogne as far as Pessac, a distance of approximately 100 m. from the ocean.

DORDRECHT (abbreviated *Dordt* or *Dort;* old name THUREDRECHT), in the province of South Holland, Holland, and a junction station 12½ mi. S.E. of Rotterdam. It is connected with Papendrecht and Zwijndrecht on the opposite shore. Pop. (1940) 62,007. Dordrecht was founded by Count Dirk III of Holland in 1018, becoming a town about 1200. One of the first towns in the Netherlands to embrace the reformed religion and to throw off the yoke of Spain, it was in 1572 the meeting-place of the deputies who asserted the independence of the United Provinces. In 1618 and 1619 it was the seat of the synod of Dort (*q.v.*). It fell to German troops in 1940.

Dordrecht presents a picturesque appearance with its busy quays and numerous canals and windmills, its quaint streets and curiously gabled houses. The Groote Kerk, of Our Lady, with a massive tower, dates from the 14th century and contains some finely carved stalls (1540) by Jan Terween Aertsz, and a remarkable pulpit (1759). In the town museum is an interesting collection of paintings, including pictures by some of the old masters, some of whom were natives of Dordrecht. Close to the museum is one of the old city gates, rebuilt in 1618, and now containing a collection of antiquities belonging to the Oud-Dordrecht Society. The harbour of Dordrecht still has a large trade, but much has been diverted to Rotterdam. Large quantities of wood are imported from Germany, Scandinavia and America. There are numerous saw-mills, shipbuilding yards, sugar refineries, etc.

DORÉ, PAUL GUSTAVE, (1832–1883), French artist, the son of a civil engineer, was born at Strasbourg on Jan. 6, 1832, and died in Paris on Jan. 23, 1883. In 1848 he came to Paris and secured a three years' engagement on the *Journal* pour *rire.* His facility as a draughtsman was extraordinary, and among the books he illustrated in rapid succession were Balzac's *Contes drolatiques* (1855), Dante's *Inferno* (1861), *Don Quixote* (1863), *The Bible* (1865), *Paradise Lost* (1866), the *Fables* of La Fontaine (1867), and the works of Rabelais (1873). He painted also many large and ambitious compositions of a religious or historical character, and had some success as a sculptor. Doré's illustrations had a great popular success over a long period of years, especially in England and America. *See* W. B. Jerrold, *Life of Gustave Doré* (1891).

DORIA, ANDREA (1466–1560), Genoese *condottiere* and admiral, was born at Oneglia of an ancient Genoese family. Being left an orphan at an early age, he became a soldier of fortune, and served first in the papal guard and then under various Italian princes. But it was as a naval captain that he became famous. For several years he scoured the Mediterranean in command of the Genoese fleet, waging war on the Turks and the Barbary pirates. In the meanwhile Genoa had been recaptured by the French, and in 1522 by the Imperialists. But Doria now veered round to the French or popular faction and entered the service of King Francis I., who made him captain-general; in 1524 he relieved Marseilles, which was besieged by the Imperialists, and helped to place his native city once more under French domination. But Francis was mean about payment, and he resented the king's behaviour in connection with Savona, which he delayed to hand back to the Genoese as he had promised; consequently on the expiry of Doria's contract we find him in the service of the emperor Charles V. (1528). He ordered his nephew Filippino, who was then blockading Naples in concert with a French army, to withdraw, and sailed for Genoa, where he expelled the French once more and re-established the republic under imperial protection. He reformed the constitution in an aristocratic sense, and put an end to the factions which divided the city. He refused the lordship of Genoa and even the dogeship, but exercised predominant influence in the councils of the republic until his death. He was given two palaces, many privileges, and the title of *Liberator et Pater Patriae.* As imperial admiral he commanded several expeditions against the Turks, capturing Corona and Patras, and co-operating with the emperor himself in the capture of Tunis (1535). Charles found him an invaluable ally in the wars with Francis, and through him extended his domination over the whole of Italy. Doria's defeat by the Turks at Preveza in 1538 was said to be not involuntary, and designed to spite the Venetians, whom he detested. He accompanied Charles on the ill-fated Algerian expedition of 1541, of which he disapproved, and by his ability just saved the whole force from complete disaster. For the next five years there was hardly an important event in Europe in which he had not some share. After the peace of Crépy between Francis and Charles in 1544 he hoped to end his days in quiet. But he had many enemies, and in 1547 the Fiesco conspiracy to upset the power of his house took place. His nephew Giannettino was murdered, but the conspirators were defeated, and Andrea showed great vindictiveness in punishing them. He was implicated in the murder of Pier Luigi Farnese, duke of Parma *(see* FARNESE), who had helped Fiesco. Other conspiracies followed, of which the most important was that of Giulio Cibb (1548), but all failed. Doria successfully opposed the emperor Charles's repeated attempts to have a citadel built in Genoa and garrisoned by Spaniards; neither blandishments nor threats could win him over to the scheme. Nor did age lessen his energy, for in 1550, when eighty-four years old, he again put to sea to punish the raids of his old enemies the Barbary pirates, but with no great success. War between France and the Empire having broken out once more, the French seized Corsica, then administered by the Genoese Bank of St. George; Doria was again summoned, and he spent two years (1553–1555) in the island fighting the French with varying fortune. He returned to Genoa for good in 1555, and gave over the command of the galleys to his great-nephew Giovanni Andrea Doria. Andrea Doria died on Nov. 25, 1560, leaving his estates to Giovanni Andrea. The family of Doria-Pamphilii-Landi (*q.v.*) is descended from him and bears his title of prince of Melfi. Doria was a man of indomitable energy and a great admiral. If he appears unscrupulous and even treacherous he did but conform to the standards of 16th century Italy.

See E. Petit, *Andrt Doria* (Paris, 1887) which is an accurate and documented biography, indicating all the chief works on the subject, but the author is perhaps unduly harsh in his judgment of the admiral; F. D. Guerrazzi, *Vita di Andrea Doria* (3rd ed., Milan, 1874). Among the earlier works L. Cappelloni's *Vita di Andrea Doria* (Italian edition, Genoa, 1863) and V. Sigonius's *Vita Andreae Doriae* (1576) may be mentioned; *see* also "Documenti ispano-genovesi del-l'Archivio di Simancas" in the *Atti della Società ligure di Storia patria,* vol. viii.; the *Archivio storico italiano* (serie iii. tome iv. parte i., 1866) contains a bibliography, but a great deal has been published since that date.

DORIANS. In classical times a fourfold division ran through the Greek world, linguistic and partially social. The Dorians represent one section of this division, the remaining three being Aeolians, Ionians and Arcado-Cyprians or Achaeans. They were settled in the Peloponnese where they were the dominant race, in the Sporades and in Crete, in south-western Asia Minor, and in a string of colonies along the eastern and southern coasts of Sicily. Between Mounts Parnassus and Oeta was a small district

called Doris, whose inhabitants in historic times spoke an Aeolic dialect. They were distinguished from other Greeks by their dialect, by a calendar of festivals. and by certain social and political institutions. The worship of Apollo and of Heracles was looked upon by the Greeks as being in some sense more particularly Dorian, though not confined to Dorian peoples.

The Doric dialect, of which there were several varieties, was allied with a group known as North-west Greek, spoken in Phocis, Locris and Elis, as opposed to Aeolic, Ionic, Attic and Arcado-Cyprian, which may be said to have formed loosely an eastern group. Some of its characteristics are the retention of τ where Attic shows σ in verbal endings such as $\delta\acute{\iota}\delta\omega\tau\iota$, in $-\kappa\alpha\tau\iota o\iota$ as the termination in the *hundreds* in place of $-\kappa o\sigma\iota o\iota$ etc.; the formation of the nominative plural of the article in $\tau o\acute{\iota}, \tau\alpha\acute{\iota}$; $\ddot{o}\kappa\alpha, \tau\acute{o}\kappa\alpha, \pi\acute{o}\kappa\alpha$ for $\ddot{o}\tau\epsilon, \tau\acute{o}\tau\epsilon, \pi\acute{o}\tau\epsilon$ etc.; the termination of the first person plural active in $-\mu\epsilon\varsigma$ instead of $-\mu\epsilon\nu$, *e.g.*, $\phi\acute{\epsilon}\rho o\mu\epsilon\varsigma$; the formation of the future in $-\sigma\epsilon\omega$; the lengthening of ϵ and o to η and ω in place of $\epsilon\iota$ and $o\upsilon$; the reduction of intervocalic σ to h and in some cases its complete disappearance. The Cretan dialects showed peculiarities of their own. The Doric dialects continued in use until displaced by the $\kappa o\iota\nu\acute{\eta}$ based upon Attic, which became the common language of Greece in Hellenistic times. The modern Tzakonian dialect spoken in the neighbourhood of Sparta exhibits characteristics which entitle it to be regarded as the descendant of an ancient Doric dialect, possibly Laconian. Within the Doric group Laconian inclined in certain respects to agreement with Aeolic where Corinthian and Argolic show rather more similarity to Ionic.

It is clear that the Dorians were a conquering stratum of the population in the Peloponnese. Beside the fact that a non-Doric dialect survived in Arcadia closely akin to the dialects of Cyprus, the social structure of the Doric cities provides evidence that the Dorians had conquered and were holding in subjection a former population. Sparta was the armed camp of a close aristocracy which alone possessed political rights. The majority of the population, known as Helots, were serfs, hostile to their masters and breaking into rebellion whenever opportunity presented itself. Between the Helots and the Spartiate families was a class known as Perioeci (*q.v.*) who were not slaves but did not enjoy Spartan rights. In the 8th and 7th centuries B.C., Sparta subjugated and annexed Messenia, the district that lay along the west coast of the Peloponnese, but there is no evidence as to whether the Messenians were Dorian or otherwise. They appear to have spoken a Doric dialect, but so probably did the Achaeans along the Peloponnesian shore of the Corinthian gulf, and the latter in other respects were definitely regarded as non-Doric. It is possible that the Doric dialects were the speech of the pre-Dorian inhabitants of the Peloponnese, the Homeric Achaeans, and that this was adopted by the conquerors. There is insufficient evidence to warrant a decision. The other Doric cities of the Peloponnese, notably Argos and Corinth, though their constitutions differed widely from that of Sparta, presented similar strata of population, between whom a social and political compromise had been reached. Sparta was not typical but peculiar. The so-called constitution of Lycurgus, however, under which she was governed, was closely reflected in Dorian Crete. The double kingship suggests prehistorical amalgamation. Owing to Sparta's dominant position in the Dorian world in historical times the rest of Greece was inclined to regard what was peculiarly Spartan as typically Dorian. The rivalry of race between Dorian and Ionian underlay the struggles of the Greek world until at least the 4th century, being prominent in the Peloponnesian War at the close of the 5th century.

When and from what direction did the Dorian invasion of the Peloponnese take place? Homer knew of Dorians only in Crete. The mainland of Greece was inhabited in Homeric times by a people called Achaeans, which was the general name for Greeks, afterwards replaced by the name Hellenes. In the Hesiodic genealogies Dorus appears as a son of Rellen beside Aeolus and Xuthus the father of Ion and Achaeus. It is evident that at that time (7th or 6th century) these four divisions were regarded as comprising together the whole Greek world. The Hellenes of Homer's time were a small Thessalian tribe, and the extension of their name illustrates the possibility of a similar process in the case of that of the Dorians. The inheritance of Dorus was in central Greece between that of Aeolus in Thessaly and of Xuthus in the Peloponnese. Under Aegimius, a descendant of Dorus, the Dorians acquired the country between Mounts Parnassus and Oeta, thenceforward known as Doris. An alliance took place between Aegimius and the Heracleidae, Hyllus son of Heracles being adopted by Aegimius. There followed the expeditions to the Peloponnese to assist the Heracleidae to recover their inheritance there. The route of the invasion was through Aetolia and Elis, the Corinthian Gulf being crossed at Naupactus. After several attempts the conquest of the Peloponnese was achieved. Thucydides dates the invasion 80 years subsequent to the Trojan War, and it was generally regarded as having taken place in the second half of the 12th or early in the 11th century. Megara and Corinth were conquered rather later. From the alliance between Aegimius and the Heracleidae dated the threefold Dorian division into Hylleis, Dymanes and Pamphyli.

A second tradition, current in the 4th century, brought the Argive Dorians to the eastern Peloponnese by sea. Their starting-point is not stated. It is assumed to be the Maliac gulf, which is the nearest sea-coast to Doris in central Greece. The Cretan Dorians were regarded as an offshoot of this expedition from which they were considered to have separated in Histiaeotis.

The facts of the Dorian overlordship in the Peloponnese show the invasion and conquest to have been historical, and light may be thrown upon the whereabouts of the former homes of the invaders by the names of the three Dorian tribes. Hylleis is the name of a large and widespread Illyrian tribe settled upon the Dalmatian coast of the Adriatic and centring around the promontory known anciently as Hyllis, now as Sabbioncello. Indeed the name Illyrii may be identical with that of the Hylleis except for an additional suffix. Again the tribal name Dymanes has a termination frequent in Epirus and exemplified in such names as Atintanes, Athamanes, Akarnanes, etc. Both these names point decisively to the north-west and confirm the tradition of an invasion across the Corinthian gulf from Aetolia to Elis, of an Illyrian or Epirote tribe. What of the Pamphyli? The second tradition, that the Dorian conquerors of Argolis reached the east coast of the Peloponnese by sea, has already been mentioned. Is it possible that it is wrongly assumed that the starting-point of this expedition was the Maliac gulf, and that such an invasion took place, but from Crete and the south-eastern Aegaean? Is it too bold to connect the name Pamphyli with the familiar Anatolian Pamphylia? In Homeric' times Dorians are recorded only in Crete. The constitution of Lycurgus at Sparta was traditionally derived from Crete. We know that the Achaeans were in pre-Homeric times in the eastern Aegaean and later in the Peloponnese and the Greek mainland. Thus a Dorian migration from east to west across the Aegaean would have merely followed in the wake of previous Achaean migrations, while Dorian attacks upon the Peloponnese from Crete would have been no more than repetitions of previous Minoan history. Thus an invasion of the Achaean Peloponnese by northern hordes was coincident with attacks from Crete and the Aegaean. It may well have been designedly coincident, one set of invaders calling in the other as allies, and such an amalgamation may well explain the double kingship at Sparta. If the name Dorian first applied to a small tribe in Crete and later became extended to the new masters of the Peloponnese as a whole, this fact is no stranger than the increase of scope of the name Hellenes, which underwent an even wider development. The Parnassian Doris was never in historical times the home of Dorians. It represents perhaps no more than a coincidence of name, which is not surprising and far from unparalleled, especially if it connects with the root of $\delta\rho\hat{\upsilon}\varsigma, \delta\acute{o}\rho\upsilon$, *tree*, etc. It is possible that the northern invaders occupied it for a time before their irruption into the Peloponnese.

A widely-held view would bring all Greek-speaking peoples by land to Greece from the north in three successive waves, Ionian, Achaean and Dorian, the first two being the promotors of Mycenean civilization. This presupposes an original "Helladic" popula-

tion of Greece, whose language is unknown and whose origin is unexplained. All Greek settlements in the Aegaean, Asia Minor and Cypress were on this view colonized from the mainland of Greece.

Doris was also in historical times the collective name of the Dorian cities in south-western Asia Minor, corresponding with Ionia and Aeolis. Whether or not Dorians had dwelt in this region since Homeric times, that is to say, since a date previous to their occupation of the Peloponnese, these cities had received an influx of population from the Peloponnese and looked to it in historical times as the home of their mother-cities.

See ACHAEANS; IONIANS; GREECE, History.

DORIA-PAMPHILII-LANDI, a princely Roman family of Genoese extraction. The founder of the house was Ansaldo d'Oria, consul of Genoa in the 12th century, but the authentic pedigree is traced no further back than to Paolo d'Oria (1335). The most famous member of the family was Andrea Doria (*q.v.*). The marquisate of Civiez and the county of Cavallamonte were conferred on the family in 1576, the duchy of Tursi in 1594, the principality of Avella in 1607, the duchy of Avigliano in 1613. In 1760 the title of *Reichsfürst* or prince of the Holy Roman Empire was added and attached to the lordship of Torriglia and the marquisate of Borgo San Stefano, together with the qualification of Hochgeboren. That same year the Dorias inherited the fiefs and titles of the house of Pamphilii-Landi of Gubbio, patricians of Rome and princes of San Martino, Valmontano, Val di Toro, Bardi and Corupiano. The Doria-Pamphilii palace in Rome, a splendid edifice, was built in the 17th century, and contains a valuable collection of paintings. The Villa Doria-Pamphilii with its gardens is one of the loveliest round Rome. During the siege of 1849 it was Garibaldi's headquarters.

DORIC ORDER, in architecture, the simplest and earliest perfected of the Greek orders, adopted and developed in a modified form by the Romans, characterized by a simple, moulded capital, and the existence in the frieze of upright, grooved forms, known as triglyphs separated by squares, known as metopes (see ORDER).

DORION, SIR ANTOINE AIME (1816–1891), Canadian lawyer and statesman, was born at Sainte Anne de la Pérade on Jan. 17, 1816 of an old Liberal family. He studied law under Cherrier, was called to the bar in 1842, and rose rapidly in his profession. At the time that Dorion commenced the study of law, Canada was entering upon a new phase of her political life. The rebellion of 1837 had resulted in the suspension of the constitution of 1791 and the union of provinces, effected under the Imperial Act of 1840, was framed to compel the obedience of the refractory population. The elections of 1854 had brought new blood into the ranks of the Liberal party, young men eager to carry out measures of reform, and Dorion was chosen as leader. Under the coalition brought about by McNab between the Tories of Upper Canada and the Liberals of the lower province old abuses were removed, and, after the abolition of seigneurial tenure and clergy reserves, it appeared that the political atmosphere was clear. In 1856 the question of representation by population was again prominent. Upper Canada had increased, and it contributed a larger share to the revenue, and demanded proportionate representation. Macdonald, who became prime minister in 1856, and had formed a new government with Cartier in 1857, maintained that no amendment to the constitution was necessary; that existing conditions were satisfactory. Brown, on the opposite side of the House, declared that representation by population was imperative, with or without constitutional changes; and Dorion appears to have suggested the true remedy, when he gave notice of a motion in 1856:—

That a committee be appointed to inquire into the means that should be adopted to form a new political and legislative organization of the heretofore provinces of Upper and Lower Canada, either by the establishment of their former territorial divisions or by a division of each province, so as to form a federation, having a federal government and a local legislature for each one of the new provinces, and to deliberate as to the course which should be adopted to regulate the affairs of united Canada, in a manner which would be equitable to the different sections of the province.

Dorion was in advance of the time. He understood the true principle of federative union as applicable to Canada. But he did not pursue this idea. On Aug. 2, 1858 he formed an administration with Brown, but was forced to resign after being in office three days. When the question of confederation was discussed a few years later he opposed the scheme, believing there was nothing to justify the union at the time. In 1873 he became minister of justice in the Mackenzie government, and secured the passage of the Electoral Law of 1874 and the Controverted Elections Act. Dorion sat as a member of the assembly for the province of Canada for the city of Montreal from 1854 to 1861, for the county of Hochelaga from 1862 to 1867; as member of the House of Commons for the county of Hochelaga from 1867 to July 1872, and for the county of Napierville from Sept. 1872 to June 1874, when he was appointed chief justice of the province. In 1878 he was created a knight bachelor. He died at Montreal on May 31, 1891.

See Fennings Taylor, *Dorion, a Sketch* (Montreal, 1865); "Sir Antoine Aimé Dorion," by Sir Wilfrid Laurier, in *The Week* (1887).

DORIS, a small district in central Greece, between Mts. Oeta and Parnassus, containing the head-waters of the Cephissus. This little valley, which nowhere exceeds 4 m. in breadth and has but four small townships, owed its importance partly to its command over the road from Heracleia to Amphissa, but chiefly to its prestige as the alleged mother-country of the Dorian conquerors of Peloponnesus (see DORIANS). Its history is mainly made up of petty wars with Oetaeans and Phocians. In 457, the Spartans, admitting their claim to be the Dorian metropolis, sent an army to their aid, and again during the second Sacred War (356–346). Except for mention of its cantonal league in 196, Doris passed early out of history.

See Strabo, pp. 417, 427; Herodotus i. 56, viii. 31; Thucydides i. 107, iii. 92; Diodorus xii. 29, 33; W. M. Leake, *Travels in Northern Greece,* chap. xi. (1835).

DORISLAUS, ISAAC (1595–1649), Anglo-Dutch lawyer and diplomatist, was born at Alkmaar, Holland, the son of a minister of the Dutch Reformed Church. He was educated at Leyden, removed to England about 1627, and was appointed to a lectureship in history at Cambridge, where his attempt to justify the Dutch revolt against Spain led to his early resignation. In 1629 he was admitted a commoner of the College of Advocates. In 1632 he made his peace at court, and on two occasions acted as judge advocate, in the bishops' war of 1640 and in 1642 in the army commanded by Essex. In 1648 he became one of the judges of the admiralty court, and was sent on a diplomatic errand to the States General of Holland. He assisted in preparing the charge of high treason against Charles I., and, while negotiating an alliance between the Commonwealth and the Dutch republic, was murdered at The Hague by royalist refugees on May 10, 1649.

DORKING, a market town and urban district in the Reigate parliamentary division of Surrey, England, with three (including Box Hill, four) railway stations on the Southern railway, about 26 mi. S.S.W. of London. Pop. of urban district (1938) 17,110. Area 1 j sq mi. It lies at the edge of the North Downs in the sheltered valley of the river Mole, near the base of Box Hill. and is noted for the beauty of its countryside. It is the centre of an extensive residential district. The parish church of St. Martin's is a handsome edifice rebuilt in 1873. Lime of exceptionally good quality is burned in the neighbourhood and is derived from the Lower Chalk formation. Dorking gives its name to a well-known breed of fowl distinguished by its having five toes. Several fine mansions are in the vicinity of the town, notably that of Deepdene, containing part of a gallery of sculpture collected by Thomas Hope, the author of *Anastasius.* The Roman road of Stone street, which crossed from the Sussex coast to the Thames, passed near the present churchyard of St. Martin. The district has literary associations, including the names of George Meredith, who lived and is buried here, Fanny Burney, Malthus and others.

DORLEANS, LOUIS (1542–1629), French poet and political pamphleteer, was born in Paris. He studied under Jean Daurat, and after taking his degree in law began to practise at the bar with but slight success. After the League had arrested the royalist members of parliament, he was appointed (1589) advocate-general. His *Avertissement* des catholiques *anglais* aux *Français catholiques* went through several editions, and was translated into English. Dorléans was proscribed when Henry IV. entered Paris. He took refuge in Antwerp, but was amnestied nine years later, and returned to Paris, where he was soon imprisoned for sedition. The king, however, released him after three months in the Conciergerie.

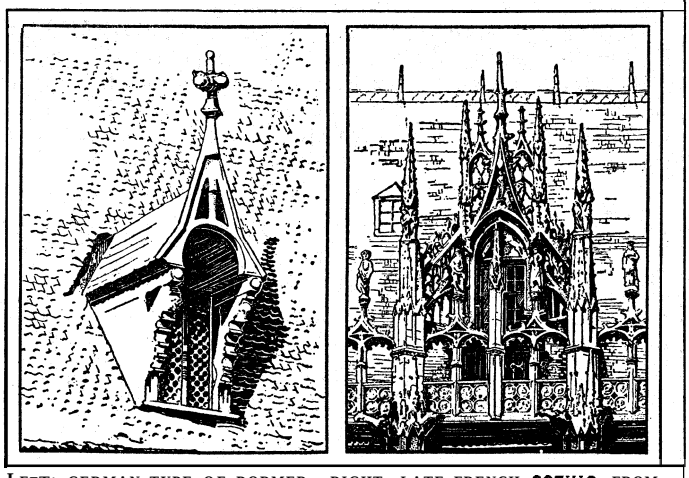
DORMAN, LONG AND COMPANY, LIMITED. This British joint stock company, which in 1928 had an issued share capital of £8,050,000 are manufacturers of iron and steel, constructional engineering and bridge building materials and colliery and mine owners. Founded in 1876 by Mr. (now Sir) Arthur Dorman, in partnership with the late Albert de Lande Long at West Marsh Ironworks, Middlesbrough, Yorkshire, the steel plant, together with the various auxiliary and by-product plants, now cover in the same district a very large area. In 1889 Bell Bros., Limited, ironmasters and colliery owners, became associated with Dorman, Long, and in 1903 the company acquired the ordinary share capital of the adjacent North Eastern Steel company.

In 1916, to meet the urgent needs of the World War, the Redcar steel works was laid down by the company's own department. Further additions were made in 1917 (Sir B. Samuelson and company—collieries and ironstone mines, blast furnaces, coke ovens and by-product plant) and in 1921 (the Carlton Iron company—manufacturers of ferro-manganese), so that in 1923, on the amalgamation of all these firms, Dorman, Long and Co., Ltd., became the largest coal, iron and steel undertaking under one management in Great Britain.

From Middlesbrough the company have extended their organization to London, Melbourne, Sydney, Calcutta, South Africa and Buenos Aires, where they have established shops and associated-companies for fabricating steel constructional work and where they carry large stocks of steel. They have agencies in New Zealand, Kenya Colony, Egypt, the Sudan and elsewhere.

In 1928, Dorman, Long jointly with Baldwins, Ltd., and Hosbins, Ltd., formed an Australian company named "Australian Iron and Steel, Ltd." with a capital of £5,000,000. (L. C. M.)

DORMER, in architecture, a projection from a sloping roof, containing a window. Dormers may occur either on the face of the wall or high up on the roof; their roofs may be gabled, hipped, flat or with one slope. Wherever steep, high roofs are common, dormers are common, in order to light the space within. Simple dormers, frequently in several rows, characterize the steep roofs of Teutonic countries, but in the late Gothic and early Renaissance periods, certain dormers, whose fronts were on the wall line of the building, were built in masonry and richly decorated. Similar elaborate dormers, usually with gabled roofs, are characteristic of the French châteaux from the time of Louis XII. to that of Louis XIV., and of Tudor work in England and Scotland; examples of dormers, ornamented with pinnacles, tracery and buttresses, occur in the Palais de Justice at Rouen (end of the 15th century). Heidelberg castle (1556), and the châteaux of Blois and Chambord (time of Francis I.) show characteristic Renaissance enrichment. The term "dormer" arose from the windows being those of sleeping-rooms. The phrase "dormer beam" is the equivalent of the modern "sleeper."



LEFT: GERMAN TYPE OF DORMER. RIGHT: LATE FRENCH GOTHIC, FROM PALAIS DE JUSTICE. ROUEN

DORMITORY, the name given in monasteries to the monks' sleeping apartment. It sometimes formed one long room, but was more generally subdivided into as many cells or partitions as there were monks. The dormitories were sometimes of great length; that of the monastery of S. Michele in Bosco near Bologna (now suppressed), is said to have been over 400 feet. In some of the larger Elizabethan mansions the space in the roof constitutes a long gallery, which in those days was occasionally utilized as a dormitory. The name "dormitory" is also applied to the large bedrooms with a number of beds, in schools and similar modern institutions, and also to any institutional building whose purpose is to furnish sleeping quarters for pupils or others, irrespective of whether or not they are divided into individual rooms.

DORMONT, a residential borough of Allegheny county, Pa., U.S.A., on the southern edge of Pittsburgh. The population was 13,190 in 1930 and 12,974 in 1940 by federal census.

DORMOUSE, a small rodent, *Muscardinus* avellanarius, is the sole representative of its genus, but belongs to a family—the Gliridae or Myoxidae—containing a small number of Old World species. All the dormice are small rodents, of arboreal habits, and for the most part of squirrel-like appearance; some of their most distinctive features being internal. In the more typical members of the group, forming the sub-family *Glirinae,* there are four pairs of cheek-teeth, which are rooted and have transverse enamel-folds. As the characters of the genera are given in the article RODENTIA it will suffice to state that the typical genus Glis is represented by the large European edible dormouse, G. *vulgaris* (or G. *glis*), a grey species with black markings known in Germany as Siebenschlafer; the genus ranges from continental Europe to Japan. The common dormouse *Muscardinus avellanarius,* ranging from England to Russia and Asia, is of the size of a mouse and mainly chestnut-coloured. The third genus is represented by the continental *lerot,* or garden-dormouse, *Eliomys guercinus,* which is a large parti-coloured species, with several local forms—either species or races. Lastly, *Graphiurus,* of which the species are also large, is solely African. In their arboreal life, and the habit of sitting up on their hind-legs with their food grasped in the fore-paws, dormice are like squirrels, from which they differ in being completely nocturnal. They live either among bushes or in trees, and make a neat nest for the reception of their young, which are born blind. The species inhabiting cold climates construct a winter nest in which they hibernate, waking up at times to feed on an accumulated store of nuts and other food. Before retiring they become very fat, and at such times the edible dormouse is a favourite article of diet on the Continent. The young are generally four in number, and are produced twice a year. They are born blind, but in a marvellously short period are able to cater for themselves; and their hibernation begins later in the season than with the adults. The fur of the dormouse is tawny above and paler beneath, with a white patch on the throat. A second sub-family is represented by the Indian *Platacanthomys* and the Chinese *Typhlomys,* in which there are only three pairs of cheek-teeth; thus connecting the more typical members of the family with the *Muridae.*

DORNBIRN is a township in the Austrian province of Vorarlberg, at the foot of the Bregenzerwald. The name is a collective appellation for four straggling villages—Dornbirn, Hatlerdorf, Oberdorf and Haselstauden—chiefly important as small centres manufacturing textiles and iron goods with motive power from the Dornbirner Ach, a tributary of the Rhine. Pop. (1939) 17,510. Germany annexed the township in 1938.

DORNBURG, a town of Germany, in the *Land* of Thuringia, situated 400 ft. above the Saale. 7 mi. N.E. of Jena. Population 918. Dornburg is chiefly famous for its three grand-ducal castles. The Altes Schloss is built on the site of an imperial stronghold (Kaiserpfalz), once a bulwark against the Slavs, often a residence of the emperors Otto II. and Otto III., and the place where the emperor Henry II. held a diet in 1005. Goethe was often a guest at the Neues Schloss, built (1728–48) in Italian style. The third castle is the so-called Stohmannsches Rittergut, purchased in 1824 and fitted as a modern palace.

DORNER, ISAAC AUGUST (1809–1884), German Lutheran divine, was born at Keuhausen, Württemberg on June 20, 1809. After studying at Tubingen, he travelled in England and Holland, and in 1837 became professor extraordinarius of theology at Tiibingen. His *Entwicklungsgeschichte der Lekre von der Person Christi* (1835–39), an indirect reply to Strauss' *Life* of *Jesus,* led to his being invited in 1839 to Kiel as professor ordinarius. There he wrote, among other works, *Das Princip unserer Kirche nach dem innern Verhältniss seiner zwei Seiten betrachtet* (1841). In 1843 he removed to Konigsberg, in 1847 to Bonn, in 1853 to Gottingen and in 1862 to Berlin. In 1867 appeared his valuable *Geschichte der protestantischen Theologie* (Eng. trans., 1871). His ultimate position as one of the "mediating" theologians is best seen in his *Christliche Glaubenslehre* (1879–81). The companion work *System der christlichen Sittenlehre* was published in 1886. He founded and for many years edited the *Jahrbücher für deutsche Theologie.* He died at Wiesbaden on July 8, 1884.

See Herzog-Hauck, *Realencyklopadie;* Pfleiderer, *The Development of Theology in Germany since Kant* (1890); *F.* Lichtenberger, *History of German Theology in the Nineteenth Century* **(1889)**; Carl Schwarz, *Zur Geschichte der neuesten Theologie* **(1869).**

DORNOCH, royal burgh and county town, Sutherlandshire, Scotland. Pop. (1938) 676. It lies on the north shore of Dornoch firth, an arm of the North sea, $7\frac{3}{4}$ m. S.S.E. of Mound station on the L.M.S.R. by light railway. Its dry and bracing climate and fine golf courses have made it a health resort. Before the Reformation it was the see of the bishopric of Caithness and Sutherland. The cathedral, built by Bishop Gilbert de Moravia (Moray) (d. 1245), the last Scot enrolled in the Calendar of Scottish saints, was damaged by fire in 1570, during a raid, and afterwards neglected till 1837, when it was restored, and has since been used as the parish church. It is the burying-place of the Sutherland family and contains the remains of sixteen earls. The ancient castle was also the bishop's palace; its west tower remains. the rest was destroyed in 1570. Dornoch became a royal burgh in 1628. It was the scene of the last execution for witchcraft in Scotland (1722). At Embo, 2 m. N.N.E., a sculptured stone commemorates the battle with the Danes in the 13th century, in which Richard de Moravia was killed. He was buried in the cathedral, where his effigy was found in the chancel. Skibo castle, about 4 m. W. of Dornoch, once a residence of the bishops of Caithness, was acquired in 1898 by Andrew Carnegie.

DOROHOI or **DOROGOI,** the capital of the department of Dorohol, Rumania; on the right bank of the river Jijia, which broadens into a lake on the north. Dorohoi is a market for the timber and farm produce of the north Moldavian highlands; merchants from the neighbouring States flock to its great fair, held on June 12. There is a church built by Stephen the Great (1458–1504). Population 15,375.

DOROTHEUS, a professor of jurisprudence in the law school of Berytus in Syria, and one of the three commissioners appointed by the emperor Justinian to draw up a book of Institutes to serve as an introduction to the *Digest* already completed. His colleagues mere Tribonian and Theophilus, and their work was accomplished in 533. Dorotheus later wrote a commentary on the *Digest,* which is called the *Index,* and was published by him in 542. Fragments of this commentary have been preserved in the *Scholia* appended to the *Basilica,* from which it seems probable that the commentary of Dorotheus contained the substance of a course of lectures on the *Digest* delivered by him in the law school of Berytus.

D'ORSAY, ALFRED GUILLAUME GABRIEL, COUNT (1801–1852), a famous dandy and wit, was born in Paris on Sept. 4, 1801, and was the son of General D'Orsay, from whom he inherited an exceptionally handsome person. In his youth he entered the French army and served as a *garde du corps* of Louis XVIII. In 1822, while stationed at Valence on the Rhone, he met the earl and countess of Blessington (*q.v.*) whose house he had visited when in London a little earlier. At the invitation of the earl he accompanied the party on their tour through Italy. In the spring of 1823 he met Lord Byron at Genoa. and the published correspondence of the poet at this period contains numerous references to the count's gifts and accomplishments, and to his peculiar relationship to the Blessington family. A diary which D'Orsay had kept during a visit to London in 1821–22 was much praised by Byron for the knowledge of men and manners and the keen faculty of observation it displayed. On Dec. 1, 1827, Count D'Orsay married Lady Harriet Gardiner, a girl of 15, the daughter of Lord Blessington by his previous wife. The union, if it rendered his connection with the Blessington family less ostensibly equivocal than before, was in other respects an unhappy one, and a separation took place almost immediately. After the death of Lord Blessington, which occurred in 1829, Lady Blessington returned to England, accompanied by Count D'Orsay, and her home, first at Seamore Place, then at Gore House, soon became a resort of the fashionable literary and artistic society of London. Count D'Orsay had been from his youth a zealous Bonapartist, and one of the most frequent guests at Gore House was Prince Louis Napoleon. In 1849 he went bankrupt, and the establishment at Gore House being broken up, he went to Paris with Lady Blessington, who died a few weeks after their arrival. His relations with Napoleon were less cordial after the *coup d'état* of 1851 of which he disapproved. His appointment to the post of director of fine arts was announced only a few days before his death which occurred on Aug. 4, 1852.

Count d'Orsay was the supreme dandy, and the list of his accomplishments is surprising. In addition to wit, charm, and taste in dress and furniture, he was a good shot, a good horseman, a good fencer and even a good boxer. He had considerable skill in painting and sculpture as well. It is more surprising, perhaps, to find him in the light of benefactor to distressed compatriots in England, and as the original founder of the *Société de Bienfaisance.*

Much information as to the life and character of Count D'Orsay is to be found in Richard Madden's *Literary Life and Correspondence of the Countess of Blessington* (1855).

DORSET, EARLS, MARQUESSES AND DUKES OF, English titles one or more of which had been borne by the families of Beaufort, Grey and Sackville. About 1070 Osmund, or Osmer, an alleged son of Henry, count of Séez, by a sister of William the Conqueror, is said to have been created earl of Dorset, but the authority is a very late one and Osmund describes himself simply as bishop (of Salisbury). William de Mohun of Dunster, a partisan of the empress Matilda, appears as earl of Dorset or Somerset, these two shires being in early times united under a single sheriff. In 1397 John Beaufort, earl of Somerset (d. 1410), the eldest son of John of Gaunt, duke of Lancaster, and Catherine Swinford, was created marquess of Dorset; two years later, however, he was reduced to his former rank of earl of Somerset. In 1411 his brother Thomas, afterwards duke of Exeter, was created earl of Dorset, and in 1441 his youngest son, Edmund, obtained the same dignity. Two years later Edmund was created marquess of Dorset and still later duke of Somerset. Edmund's son Henry, duke of Somerset and marquess of Dorset, was attainted during the Wars of the Roses, and was beheaded after the battle of Hexham in May 1363, when the titles became extinct. In 1475 Thomas Grey, 8th Lord Ferrers of Groby (1451–1501), a son of Sir John Grey (d. 1461) and a stepson of King Edward IV., having resigned the earldom of Huntingdon, which he had received in 1471, was created marquess of Dorset (*see* below). He was succeeded in this title by his son Thomas (1477–1530), and then by his grandson Henry (1510–54), who was created duke of Suffolk in 1551. When in Feb. 1554 Suffolk was beheaded for sharing in the rising

of Sir Thomas Wyat, the marquessate of Dorset again became extinct; but in 1604 Thomas Sackville (see the account of the family under SACKVILLE, 1ST EARL) was created earl of Dorset (see below), and his descendant, the 7th earl, was created duke in 1720. In 1843 the titles became extinct.

THOMAS GREY, 1ST MARQUESS OF DORSET (1451–1501), was the elder son of Sir John Grey, 7th Lord Ferrers of Groby (1432–61), by his wife, Elizabeth Woodville, afterwards queen of Edward IV. He fought for Edward at Tewkesbury; in 1475 he was created marquess of Dorset. After the death of Edward IV. Dorset and his brother, Richard Grey, supported their half-brother, the young Edward V., thus incurring the enmity of Richard duke of Gloucester, afterwards Richard III. Richard Grey was arrested and beheaded at Pontefract in June 1483, while the marquess saved his life by flight. Dorset was one of the leaders of the duke of Buckingham's insurrection, and when this failed he joined Henry earl of Richmond in Brittany, but he was left in Paris when the future king crossed to England in 1485. After Henry's victory at Bosworth the marquess returned to England and his attainder was reversed, but he was suspected and imprisoned when Lambert Simnel revolted; he had, however, been pardoned, had marched into France and had helped to quell the Cornish rising, when he died on Sept. 20, 1501.

Dorset's sixth son, Lord Leonard Grey (c. 1490–1541), went to Ireland as marshal of the English army in 1535, and in 1536 was appointed lord deputy in succession to Sir William Skeffington. He was accused, probably with truth, of favouring the family of the Geraldines, to whom he was related, and quarrelled fiercely with the rival family of the Butlers. Returning to England in 1540 he was condemned to death for treason. He was beheaded on July 28, 1541. (See R. Bagwell, Ireland under the Tudors, vol. i., 1885.)

THOMAS GREY, 2ND MARQUESS OF DORSET (1477–1530), the eldest son of the 1st marquess, fled to Brittany with his father in 1484. He spent some years in prison under Henry VII., but was highly favoured by Henry VIII., who gave him command in France in 1512, and in 1523 made him warder of the Scottish eastern and middle marches. He was famous for his skill in the tournament. He died on Oct. 10, 1530.

His eldest son, Henry Grey, 3rd marquess of Dorset, was in 1551 created duke of Suffolk (*q.v.*). A younger son, Lord Thomas Grey, was beheaded in 1554 for sharing in the rebellion of Sir Thomas Wyat; another son, Lord John Grey, was also sentenced to death for his share in this rising, but his life was spared by the efforts of his wife, Mary, daughter of Sir Anthony Browne. Under Elizabeth, Lord John, a strong Protestant, was restored to the royal favour. He died on Nov. 19, 1569. In 1603 his son Henry (d. 1614) was created Baron Grey of Groby, and in 1628 his great-grandson Henry was made earl of Stamford. (For the 1st earl of Dorset, see SACKVILLE, THOMAS.)

EDWARD SACKVILLE, 4TH EARL OF DORSET (1591–1652), son of the 2nd earl, succeeded his brother Richard, the 3rd earl (1590–1624), in 1624. He had attained much notoriety by killing Edward Bruce, 2nd Lord Kinloss, in a duel, and in 1620 he fought for James I.'s son-in-law, Frederick V., elector palatine of the Rhine, at White Hill, near Prague. In the House of Commons, where he represented Sussex, Sackville defended Bacon and advocated an aggressive policy for the recovery of the Rhenish Palatinate; twice he was ambassador to France, and he was interested in Virginia, and the Bermuda islands. Under Charles I. he was a privy councillor and lord chamberlain to Henrietta Maria. At the outbreak of the Civil War, he joined the king at York, but he endeavoured to secure peace. At Oxford he was lord chamberlain to the king and lord president of his council, but Charles did not altogether approve of his pacific attitude He died on July 17, 1652. His wife Mary (d. 1645), daughter of Sir George Curzon, was governess to the sons of Charles I., the future Charles II. and James II.

CHARLES SACKVILLE, 6TH EARL OF DORSET (1638–1706), English poet and courtier, son of Richard Sackville, 5th earl (1622–77), was born on Jan. 24, 1638, and succeeded to his father's estates and title in 1677. In Charles II.'s first parliament he sat for East Grinstead, Sussex. He won a reputation as courtier and wit at Whitehall, where he bore his share in the excesses for which Sir Charles Sedley and the earl of Rochester were notorious. In 1662 he and his brother Edward, with three others, were indicted for the robbery and murder of a tanner named Hoppy. The defence was that they were in pursuit of thieves, and mistook Hoppy for a highwayman. In 1665 he volunteered to serve under the duke of York in the Dutch war. His famous song, "To all you Ladies now at Land," was written, according to Prior, on the night before the victory over "foggy Opdam" off Harwich (June 3, 1665). Dr. Johnson, with the remark that "seldom any splendid story is wholly true," says that the earl of Orrery had told him it was only retouched on that occasion. In 1667 Pepys laments that he had lured Nell Gwyn away from the theatre, and that with Sedley the two kept "merry house" at Epsom. Next year the king was paying court to Nell, and her "Charles the First," as she called him, was sent on a "sleeveless errand" into France to be out of the way. His gaiety and wit did not especially recommend him to James II. He retired from court at the beginning of the new reign. Dorset concurred in the invitation to William of Orange, who made him privy councillor, lord chamberlain (1689), and knight of the Garter (1692). During William's absences in 1695–98 he was one of the lord justices of the realm.

He was a generous patron of men of letters. Dryden's "Essay on Satire" and the dedication of the "Essay on Dramatic Poesy" are addressed to him. Walpole (Catalogue of Noble *Authors,* iv.) says that he had as much wit as his first master, or his contemporaries, Buckingham and Rochester, without the royal want of feeling, the duke's want of principle or the earl's want of thought; and Congreve reported of him when he was dying that he "slabbered" more wit than other people had in their best health.

The fourth act of *Pompey the Great, a tragedy translated out of French by certain persons of honour,* is by Dorset. The satires for which Pope classed him with the masters in that kind seem to have been short lampoons, with the exception of *A Faithful Catalogue of o w Most Eminent Ninnies* (reprinted in *Bibliotheca Curiosa,* ed. Goldsmid, **1885**). *The Works of the Earls of Rochester, Roscommon and Dorset, the Dukes of Devonshire, Buckinghamshire, etc., with Memoirs of their Lives* (1731) is catalogued (No. **20,841**) by H. G. Bohn in **1841**. His *Poems* are included in Anderson's and other collections of the British poets.

LIONEL CRANFIELD SACKVILLE, 1ST DUKE OF DORSET (1688–1765), the only son of the 6th earl, was born on Jan. 18, 1688. He succeeded as 7th earl of Dorset in 1706, and was created duke of Dorset in 1720. He was twice lord steward of the household, twice lord-lieutenant of Ireland, and lord president of the council from 1745–51. His second viceroyalty of Ireland (1750–55) was stormy and ended in dismissal. The duke died on Oct. 10, 1765. He left three sons: Charles, the 2nd duke; John Philip (d. 1765); and George, who took the additional name of Germain in 1770, and in 1782 was created Viscount Sackville (*q.v.*).

CHARLES SACKVILLE, 2ND DUKE OF DORSET (1711–1769), an associate of Frederick, prince of Wales, was a member of parliament for many years and a lord of the Treasury under Henry Pelham; he died on Jan. 5, 1769. His nephew, John Frederick (1745–1799), 3rd duke, was ambassador in Paris from 1783 to 1789, and lord steward of the household from 1789 to 1799; he died on July 19, 1799, and was succeeded by his only son, George John Frederick (1793–1815). When the 4th duke died unmarried in Feb. 1815, the titles passed to his kinsman, Charles Sackville Germain (1767–1843), son and heir of the 1st Viscount Sackville, who thus became 5th duke of Dorset. When he died on July 29, 1843, the titles became extinct.

DORSET, a south-western county of England, bounded north-east by Wiltshire, east by Hampshire, south by the English Channel, west by Devon and north-west by Somerset. The area is 973 square miles.

In the centre of the county the chalk hills of the western downs sweep south-west from Cranborne Chase through Blandford, Milton Abbas and Frampton to Dorchester. Here the chalk outcrop narrows and turns south-eastward by Portisham and Bincombe to West Lulworth, whence it is continued eastward as the Purbeck hills. Within this rim of chalk is a fringe of Reading

beds and London clay which may be traced from Cranborne through Wimborne Minster, near Bere Regis and Puddletown, then southeastward through West Knighton, Winfrith and Lulworth, and along the northern side of the Purbeck hills to Studland. Bounded by this arc and occupying the eastern portion of the county is a low-lying region of sands, gravel and clay, probably an extension of the Hampshire basin. Denudation has revealed the Wealden beds in the vale between Lulworth and Swanage, and also near East Chaldon. The town of Shaftesbury stands upon a hill of Greensand, while the Upper Greensand also forms the high ground above Lyme Regis, Golden Cap and Pillesden and Lewesden Pens. It is thought that a stream following the syncline of the Frome valley, the Solent and the Spithead was at one time the chief feature of the drainage. Subsidence, however, has resulted in the tributaries of this stream now finding their way independently to the sea. The Stour rises in Wiltshire and flows with a general southeasterly course to join the Hampshire Avon near its mouth. It receives the Cale and Lidden, which drain the Vale of Blackmore, in its upper course, and breaches the western downs in its middle course between Sturminster Newton and Blandford.

The small river Puddle or Trent and the Frome flow across the eastern plain and almost unite their mouths in Poole harbour.

In the northwest the Yeo flows northward to join the Parret and so sends its waters to the Bristol channel. The Char, the Brit and the Bride drain the southwest. Lulworth Cove is an excellent example of differential marine erosion. Chesil Bank has been formed from debris accumulated there by up-channel currents.

Archaeology and History.—Several beakers indicate early settlement. One handled beaker found 3 mi. from Dorchester, on the Ridgeway hill, may imply influences from eastern England. (See Fox in Arch. *Camb.* vol. lxxx, pt. 1, p. 19.) Numerous interments of cremated bones (yielding many cinerary urns but few incense cups), disc-barrows resembling those of Wiltshire, unchambered barrows and ston circles, testify to the importance of Dorset in the Bronze age. The sheltered waters of Weymouth, with access to the well-drained chalk uplands of the interior, favoured maritime trade. At Wareham was found a palstave of a type largely confined to southern England and northern France, which has been considered as an indication of early intercourse with neighbouring parts of the continent. (See Crawford, in *L'Anthropologie,* tome xxiv, 1913, pp. 641–649.) The numerous earthworks, of which the best known is Maiden Castle, may have been constructed to guard the principal routes from the coast. The finding of La Tène brooches at Woodcuts, Iwerne, Blandford and Maiden Castle (Dorchester) suggests contacts with northwestern France during the Early Iron age. (See Fox, *Arch. Camb.,* vol. lxxxii, pt. 1, pp. 67–112.)

The kingdom of Wessex originated with the settlement of Cedric and his followers in Hampshire in 495. In 705 the West Saxon see was transferred to Sherborne, and many religious houses were founded later. In 787 the Danes landed at Portland, and in 833 they arrived at Charmouth and fought with Egbert. The shire is first mentioned by name in the Saxon Chronicle in 845. During the following $2\frac{1}{2}$ centuries Dorset was constantly ravaged by the Danes.

Several of the West Saxon kings resided in Dorset, and Aethelbald and Aethelbert were buried at Sherborne, and Aethelred at Wimborne. In the reign of Canute Wareham was the shire town. Dorset formed part of Harold's earldom, and its resistance to the Conqueror was punished by the devastation of Dorchester, Wareham, Shaftesbury and Bridport.

No Englishman retained important estates after the conquest, and at the time of the survey the bulk of the land, except 46 manors held by the king, was in the hands of religious houses, the abbeys of Cerne, Milton and Shaftesbury being the most wealthy. There were 272 mills, and nearly 80 men were employed in working salt along the coast. Mints existed at Shaftesbury, Wareham, Dorchester and Bridport, the three former having been founded by Aethelstan. King John frequently hunted in the county. In the time of Egbert, Wessex was divided into definite *pagi,* each under an ealdorman, which no doubt represented the later shires. The *Inquisitio Geldi,* drawn up two years before the Domesday survey, mentions the 39 pre-conquest hundreds of Dorset. The 33 hundreds and 21 liberties of the present day retain some original names, but boundaries have changed. Until the reign of Elizabeth, Dorset and Somerset were united under one sheriff. After the transference of the West Saxon see from Sherborne to Sarum, in 1075. Dorset remained part of that diocese until 1542, when it was included in the newly formed diocese of Bristol. The vast power and wealth monopolized by the Church in Dorsetshire tended to check the rise of any great county families.

The three finest churches are the abbey church of Sherborne (*q.v.*), Wimborne Minster (*q.v.*) and Milton Abbey church, a Decorated and Perpendicular structure erected on the site of a Norman church.

Dorset took no active part in the struggles of the Norman and Plantagenet period. In 1627 the county refused to send men to La Rochelle. On the outbreak of the Civil War the general feeling was in favour of the king, and in 1643 Lyme Regis and Poole were the only garrisons in the county left to the parliament. By 1644, however, parliament had gained the whole county except Sherborne and the Isle of Portland. The remains of Corfe castle (*q.v.*) and of Sherborne castle may still be seen. The general aversion of Dorset people to warlike pursuits is demonstrated at this period by the rise of the "clubmen," so called from their appearance without pikes or firearms at county musters, whose object was peace at all costs. In the 14th century Dorset produced much wheat and wool and had a prosperous clothing trade, which declined after the ravages of the plague in 1626. The hundred of Pimperne produced saltpetre in the 17th century, and the serge manufacture was introduced about this time. Portland freestone was first brought into use in the reign of James I, and after the Great Fire it was extensively used by Sir Christopher Wren. In the 18th century Blandford, Sherborne and Lyme Regis were famous for their lace. The county returned two members to parliament in 1290; in 1572 the county and nine boroughs returned a total of 20 members. Under the Reform Act of 1832 the county returned three members, and Corfe castle was disfranchised. Lyme Regis was disfranchised in 1868 and the remaining boroughs in 1885. Under the Representation of the People act, 1918, the county returns four members.

Agriculture and Industries.—The climate is mild, and in some sheltered spots semi-tropical plants flourish. Much fine timber appears in the richer soils, in some of the sheltered valleys of the chalk district, and more especially upon the Greensand, though many woods have been cleared. In 1939 there were only 97,525 ac. of arable land, but 318,198 ac. (76.5% of the total acreage under crops and grass) of permanent grass, including 69,173 ac. of rough grazing ground, the chalk downs being celebrated as sheep walks. The chief crops were oats (16,282 ac.), wheat (15,561 ac.) and turnips and swedes (11,204 ac.). Barley and mangolds followed, with 8,430 ac. and 3,017 ac. respectively. Devons, Shorthorns and Herefords are the most common breeds of cattle, and dairy farming is extensively carried on. The National Trust owned 9 ac. in the county in 1942.

The quarries of the Isles of Portland and Purbeck are important. The first supplies a much used white freestone. Purbeck marble was used for many of the most famous Gothic churches in England. A valuable product of Purbeck is a white pipeclay, exported to the potteries of Staffordshire from Purbeck. Some shipbuilding is carried on at Poole, and paper is made at several towns. Other small manufactures are those of flax and hemp in the neighbourhood of Bridport and Beaminster, of bricks, tiles and pottery in the Poole district, and of nets (braiding, as the industry is called) in some of the villages. There are silk mills at Sherborne and elsewhere. The chief ports are Poole, Weymouth, Swanage, Bridport and Lyme Regis. The harbour of refuge at Portland, under the admiralty, is an important fortified naval station.

The main line of the Southern railway serves Gillingham and Sherborne, in the north of the county. Branches of this system serve Wimborne, Poole, Swanage, Dorchester, Weymouth and

Portland. The last two towns, with Bridport, are served by the Great Western railway; the Somerset and Dorset line follows the Stour valley by Blandford and Wimborne; and Lyme Regis is the terminus of a light railway from Axminster on the Southern ry.

The population of the administrative county was, in 1938, 252,240. An increase in the county population of 3% between Sept. 1939 and Feb. 1941 was caused by wartime movements. The county contains eight municipal boroughs, and four urban districts. It and Poole each have a court of quarter sessions and there are nine petty sessional divisions. The dialect of the county, distinguishable from those of Wiltshire and Somersetshire, yet bearing many common marks of Saxon origin, is admirably illustrated in some of the poems of William Barnes (*q.v.*). Many towns, villages and localities are readily to be recognized from their descriptions in the "Wessex" novels of Thomas Hardy (*q.v.*).

BIBLIOGRAPHY.—A curious ancient *Survey* of *Dorsetshire* was written by the Rev. Mr. Coker, about the middle of the 17th century, and published from his ms. (1732). *See* also J. Hutchins, *History and Antiquities of the County of Dorset* (1774, 2nd ed. by R. Gough and E. B. Nichols, 1796–1815; 3rd ed. by W. Shipp and J. W. Hodson, 1861–73); C. Warne, *Ancient Dorset* (1865); R. W. Eyton, *A Key to Domesday, Exemplified by an Analysis and Digest of the Dorset Survey* (1878); C. H. Mayo, *Bibliotheca Dorsetiensis* (1885); W. Barnes, *Glossary of Dorset Dialect* (Dorchester, 1886); H. J. Moule, *Old Dorset* (1893); *Victoria County History, Dorsetshire; The Land of Britain* (Report of Land Utilisation Survey, pt. 88), (London, 1940).

DORT, SYNOD OF. An assembly of the Reformed Dutch Church, with deputies from Switzerland, the Palatinate, Nassau, Hesse, East Friesland, Bremen, Scotland and England, called to decide the theological differences existing between the Arminians (or Remonstrants) and the Calvinists (or Counter-Remonstrants), was held at Dort or Dordrecht (*q.v.*) in 1618 and 1619. The government of Louis XIII. prohibited the attendance of French delegates. During the life of Arminius a bitter controversy had sprung up between his followers and the strict Calvinists, led by Francis Gomar, his fellow-professor at Leyden; and, in order to decide their disputes, a synodical conference was proposed, but Arminius died before it could be held. The essential contentions of the Arminians were the denial of irresistible predestination and the affirmation that Christ died for all men, not only for the "elect." In 1614, at the instance of the Arminian party, an edict was passed by the states general, in which toleration of the opinions of both parties was declared and further controversy forbidden; but this act only served, by rousing the jealousy of the Calvinists, to fan the controversial flame into greater fury. Gradually the dispute pervaded all classes of society, and religious questions became entangled with political issues; the partisans of the house of Orange espoused the cause of the stricter Calvinism, whereas the bourgeois oligarchy of republican tendencies, led by Oldenbarnevelt and Hugo Grotius, stood for Arminianism. In 1617 Prince Maurice of Orange committed himself definitely to the Calvinist party, found an occasion for throwing Oldenbarnevelt and Grotius into prison, and furthermore in 1617 called a synod intended to crush the Arminians. This synod, which assembled at Dort in November 1618, was strictly national — called by the national authority to decide a national dispute, and not intended to have more than a national influence. The foreign deputies were invited to attend, only to assist by their advice in the settlement of a controversy which concerned the Netherland church alone, and which the Netherland church alone could decide. At the fourth sitting it was decided to cite Simon Episcopius (*q.v.*) and other Remonstrants to appear within fourteen days before the synod, to state and justify their doctrines. It was also agreed to allow the Arminian deputies to take part in the deliberations, only on condition that they forebore to consult with, or in any way assist, their cited brethren, but this they refused. When Episcopius and the others cited appeared, the former surprised the deputies by a bold and outspoken defence of his views, and even went so far as to say that the synod, by excluding the Arminian deputies, could now only be regarded as a schismatic assembly. The Remonstrants were asked to file copious explanations of the points in dispute (*Sententia Remonstrantium*), but objecting to the manner in which they were catechized, they were dismissed from the synod. The synod then proceeded in their absence to judge them from their published writings, and came to the conclusion that as ecclesiastical rebels and trespassers they should be deprived of all their offices. The synodical decision in regard to the five points is contained in the canons adopted at the 136th session held on April 23, 1619; the points were: unconditional election, limited atonement, total depravity, irresistibility of grace, final perseverance of the saints. These doctrinal decisions and the sentence against the Remonstrants were, at the 144th sitting, read in Latin before a large audience in the great church. The Remonstrants were required to subscribe the condemnation, and many of them refused and were banished. "The canons of Dort represent the last effort of rigid Calvinistic orthodoxy to meet the difficulties and objections besetting their system, both from a popular and a theological point of view." (See REMONSTRANTS.)

DORTMUND, a town of Germany, in the Prussian province of Westphalia, on the Emscher, in a fertile plain, 50 m. E. from Düsseldorf by rail. Pop. (1939) 537,000.

Dortmund, the Throtmannia of early history, was already a town of some importance in the 9th century. In 1005 the emperor Henry II. held here an ecclesiastical council, and in 1016 an imperial diet. The town was walled in the 12th century, and in 1387–1388 successfully withstood the troops of the archbishop of Cologne for twenty-one months. About the middle of the 13th century it joined the Hanseatic League. In 1803 Dortmund lost its rights as a free town, and was annexed to Nassau. The French occupied it in 1806, and in 1808 it was made over by Napoleon to the grand-duke of Berg, and became the chief town of the department of Ruhr. Through the cession of Westphalia by the king of the Netherlands, on May 31, 1815, Dortmund became a Prussian town.

The old walls were abolished in 1863 but the centre of the town retains a mediaeval aspect. Its ancient buildings include Reinoldikirche, with fine stained-glass windows; Marienkirche, the nave of which dates from the 11th century; and Petrikirche, with a curious altar, and the Dominican church, with beautiful cloisters. The 13th-century town hall was restored in 1899 and now contains the municipal antiquarian museum. Dortmund owes its development to its situation in the centre of the Westphalian coal basin. In the immediate vicinity are also extensive beds of iron ore, and the town competes with Essen, Oberhausen, Duisburg and Hagen in the products of the iron industry. These in Dortmund include steel rails, mining plant, wire ropes, machinery, safes and sewing machines. Its airfield, oil tanks and factories were constant targets for British bombers in World War II. It is a railway centre and is also connected with the river Ems by the Dortmund-Ems canal, 170 mi, in length.

DOSITHEUS MAGISTER, Greek grammarian, flourished at Rome in the 4th century A.D. He was the author of a Greek translation of a Latin grammar, intended to assist the Greek-speaking inhabitants of the empire in learning Latin. The Latin grammar used was based on the same authorities as those of Charisius and Diomedes. Dositheus contributed very little of his own. Some Greek-Latin exercises by an unknown writer of the 3rd century, are of value as illustrating the social life of the period and the history of the Latin language. Of these *Hermeneumata*, the third book, containing a collection of words and phrases from every day conversation has been preserved. A further appendix consisted of anecdotes, letters and rescripts of the emperor Hadrian; fables of Aesop; extracts from Hyginus; a history of the Trojan War, and a legal fragment, De *manumissionibus*.

EDITIONS.—*Grammatica* in H. Keil, *Grammatici Latini*, vii. and separately (1871); J. Tolkiehn (Lips. 1913); *Hermeneumata* by G. Götz (1892) (in G. Löwe's *Corpus glossariorum Latinorum*, iii.) and E. Böcking (1832), which contains the appendix (including the legal fragment). *See* also C. Lachmann, *Versuch über Dositkeus* (1837); *H.* Hagen, *De Dositkei magistri quae feruntur glossis* (1877).

DOSSAL (dorsal; Lat. dorsum, Fr. dos, back), an embroidered curtain hung behind the altar.

DOSSERET, or impost block, in architecture, the block of stone sometimes used in the Byzantine style above the capital (*q.v.*) of a column. It has the form of a truncated pyramid, with the large side up, and therefore furnishes ample bearing for carrying the arches and vaults above it.

DOSSO DOSSI, GIOVANNI (1479–1542), Italian painter, the head of the Ferrarese school in the 16th century. His real name was Giovanni de Lutero. His father, Niccolo de Lutero, a native of Trent, settled at Ferrara, and Giovanni and his brother Battista (d. 1549) were probably born at Dosso, a village near Mantua. Vasari does not mention the name of their master, but according to Scannelli they studied under Lorenzo Costa, while Morelli suggests that their first teacher was G. Panetti. We know by documentary evidence that Battista was in Rome in 1519; there is, however, no proof that Dosso studied in Rome. His work is Ferrarese, though his colour is under Venetian influence. From 1514 Dosso was in the service of Alfonso d'Este. He painted portraits of the Este family, he decorated the ducal palaces and executed designs for tapestries and majolica. The two brothers Dossi, though not always on good terms with one another, often co-operated, as in the decoration of the ducal palace of Ferrara, of the palace of the Gonzagas at Mantua (1512), of the Villa Imperiale near Pesaro, and of the bishop's palace at Trent (1532). Dosso died at Ferrara shortly before Aug. 27, 1542. He was a friend of his compatriot Ludovico Ariosto, and, like this great poet, loved to depict romantic scenes from pagan myths or from legends of Christian chivalry. His fantastic "Circe" in the Galleria Borghese might be an illustration of Ariosto's poetry. The admiration was reciprocal, for in the Orlando *Furioso* (xxxiii., 2) Dosso ranks with Leonardo, Michelangelo, Raphael, Titian, Bellini and Mantegna. Dosso was a poet in his colour schemes. His shadows are saturated with colour, his lights sparkling and strong. He was an innovator in landscape painting, for he made the scenery take part in the drama enacted by the figures. Thus the background in the "Adoration of the Magi" (National Gallery, London) is illuminated by a supernatural light. Nearly all the frescoes of Dosso are much damaged or have perished. However, a number of oil paintings have survived. Besides those mentioned above the following are his chief works: the altarpiece in the cathedral of Modena representing the "Madonna and Saints"; the altarpiece of the cathedral of Ferrara representing '(St. Bartholomew and John the Baptist" which has passed into the Chigi collection; the "Four Fathers of the Church" in the Dresden gallery; that gallery also contains several pictures from the ducal palace of Ferrara, some by Dosso and others designed by him and completed by his brother and Girolamo Carpi. The gallery at Modena contains some fine examples and several of his works are at Hampton Court Palace.

(I. A. R.)

DOST MOHAMMED KHAN (1793–1863), founder of the dynasty of the Barakzai in Afghanistan, was born in 1793. His elder brother, the chief of the Barakzai, Fateh Khan, took an important part in raising Mahmud to the sovereignty of Afghanistan in 1800 and in restoring him to the throne in 1809. But Mahmud secured his assassination in 1818, and thus incurred the enmity of his tribe. After a bloody conflict. Mahmud was deprived of all his possessions but Herat, the rest of his dominions being divided among Fateh Khan's brothers. Of these Dost Mohammed received Ghazni, to which in 1826 he added Kabul; he at once found himself involved in disputes with Ranjit Singh, the Sikh ruler of the Punjab, who used the dethroned Saduzai prince, Shuja-ul-Mulk, as his instrument. In 1834 Shuja made a last attempt to recover his kingdom. He was defeated by Dost Mohammed under the walls of Kandahar, but Ranjit Singh seized the opportunity to annex Peshawar. The recovery of this fortress became the Afghan amir's great concern. Rejecting overtures from Russia, he sought alliance with England, and welcomed Alexander Burnes to Kabul in 1837. But the governor general, Lord Auckland, did not respond to the amir's advances. Dost Mohammed was enjoined to abandon the attempt to recover Peshawar, and to place his foreign policy under British guidance. In return he was only promised protection from Ranjit Singh, of whom he had no fear. He replied by renewing his relations with Russia, and in March 1839 a British force under Sir Willoughby Cotton advanced through the Bolan Pass, and on April 26, it reached Kandahar. Shah Shuja was proclaimed amir, and entered Kabul on Aug. 7, while Dost Mohammed sought refuge in the Hindu Kush. On Nov. 4, 1840, he surrendered. He remained in captivity during the British occupation, during the disastrous retreat of the army of occupation in Jan. 1842, and until the recapture of Kabul in the autumn of 1842. (See INDIA: History.) He was then freed.

On his return from India Dost Mohammed was received in triumph at Kabul. From 1846 he renewed his policy of hostility to the British and allied himself with the Sikhs; but after the defeat of his allies at Gujrat on Feb. 21, 1849 he led his troops back into Afghanistan. In 1850 he conquered Balkh, and in 1854 he acquired control over the southern Afghan tribes by the capture of Kandahar. On March 30, 1855, Dost Mohammed concluded an offensive and defensive alliance with the British government. In 1857 he declared war on Persia in conjunction with the British, and in July a treaty was concluded by which the province of Herat was placed under a Barakzai prince. During the Indian Mutiny Dost Mohammed punctiliously refrained from assisting the insurgents. His later years were disturbed by troubles at Herat and in Bukhārā. These he composed for a time, but in 1862 a Persian army, acting in concert with Ahmad Khan, advanced against Kandahar. The old amir called the British to his aid, and, putting himself at the head of his warriors, drove the enemy from his frontiers. On May 26, 1863, he captured Herat, but on June 9 he died suddenly in the midst of victory, after playing a great rôle in the history of Central Asia for forty years. He named as his successor his son, Shere Ali Khan.

DOSTOIEVSKI, TKEODORE (FYODOR) MIKHAYLOVICH (1821–81), Russian writer, b. Moscow Oct. 30 (o.s.), 1821, his father of Ukrainian extraction, his mother of Moscow merchant stock. He was educated in Moscow, and at the School of Military Engineers in St. Petersburg (Leningrad). In 1841 he obtained a commission in the army, but three years later he left the service to devote himself to literature. In 1845 he completed his first novel, Poor Folk. Its publication, in the following year, was one of the great events which marked the coming of a new literary age in Russia. Dostoievski came to be regarded as the most promising of the young novelists. But his second novel, The Double, published before the end of the same year (18463 disappointed the critics, and his success began to wane. He continued, however, to work with great productivity for the next three years, producing a great number of novels and stories, among which the most important are Mr. *Prokharchin,* The Landlady and *Netochka Nezvanova.* These early works display the strong influence of Gogol, and to a less extent of Balzac. Unlike the later work they betray intense interest in problems of form, and a great variety and conscious originality of verbal expression. Passionate sympathy with the humiliated and the downtrodden, and intense interest in morbid psychology (*The* Double) are already very apparent. In Netochka Nezvanova (1849) appears for the first time that type of "proud girl" which was to play such a prominent part in the great novels of his maturity. Though Dostoievski had quarrelled with the liberal littérateurs owing to their failure to appreciate The Double and to their constant pinpricks, and his morbid self-consciousness suffered from the systematic teasing of some of them (especially Turgenev), he continued to be intimate with another circle of advanced young men who, under the guidance of Petrashevski, met to study the French socialists and discuss social and political reform in Russia.

The reactionary wave that followed 1848 brought with it the arrest (April 23, 1849) and trial of the Petrashevski circle.

Dostoievski and the other "conspirators" were condemned to deportation, but a bogus sentence of death was read to them and mock preparations for the execution were gone through, the real sentence being communicated to them only at the last moment before the expected volley (Dec. 21, 1849). These moments produced a fatal impression on Dostoievski and he alludes to them more than once in his later work. His epilepsy, the first traces of which go back to before the sentence, was greatly aggravated by it. For four years Dostoievski was a convict in the penal settlement of Omsk. These years profoundly changed his mind, and it was then that he evolved his new Christianity, which was essentially based on worshipping Christ *because* he was worshipped by the Russian people. Early in *1854* he was released from prison and transferred as a private to a unit stationed in Siberia. In *18*jj he had his commission restored to him, and in 1859 he was finally amnestied and allowed to live in the capitals. In Siberia he fell in love and married Marie Isaeva, a sensual and crude woman, who brought him no happiness. From *1856* onwards he was able to resume his literary work. His first novel after these seven years of enforced silence was the *Manor of Stepanchikovo* (English version—Tlze *Family Friend) (1859*), written in Siberia. Its central figure of Foma Opiskin is one of the greatest, and most repulsive, satirical character-creations in Russian literature. After his return to St. Petersburg he published *The House of Death* (1861), in which he embodied his prison impressions, and which remained till after his death the most generally popular of his works; and *The Insulted and the Injured* (1862), in which the influence of the more sentimental aspects of Dickens are plainly apparent.

At the same time he engaged in journalism, trying to steer an independent course between the conservatives and the freethinking radicals. His programme was a democratic and Christian nationalism, equally hostile to reaction and to atheistic radicalism, and inspired by a faith in the Russian peasant people, as the depositary of supreme spiritual values. With his brother Michael and several other valuable allies, he started a review, *Vremya (The Times*) which, in spite of hostility from both right and left, succeeded in winning the public ear and was financially a success. In *1863* it was, h'owever, suppressed by the Government on what soon proved a misunderstanding. The Dostoievskis were allowed to revive the review under a new name *(Epokha),* but the new publication failed to revive the success of its predecessor. Michael Dostoievski died (1864), and after a year and more of struggle against adverse circumstances Dostoievski succumbed, discontinued the review and found himself burdened with debts he was unable to pay, besides the obligation of keeping his brother's family.

This crisis coincided with a profound crisis of his inner life. His first wife died. Before her death he had already become intimate with Pauline Suslova, a young woman of sensual, proud and "demoniac" character. His brief intimacy with her appears to have been one of the crucial experiences of his life. In 1863 he travelled with Pauline abroad, strengthening his aversion from bourgeois civilization and contracting the gambling habit. In *1864* he published *Letters from the Underworld* which marks a turning-point in his work and from which we must date the final maturity of his genius. After the failure of *The Epoch* Dostoievski became a victim to the callous exploitation of publishers, for whom he had to work by writing with superhuman speed such works as *Crime and Punishment (1866)* and *The Gambler (1867).* While writing them he employed as secretary Anna Grigorievna Snitkina, whom in *1867* he married. This coincided with a complete financial collapse. He went abroad to escape his creditors, and for four years lived there, passing much of his time at the gambling house of Baden-Baden. Only gradually, by dint of hard work at the series of novels that have since made his name famous in the world was he able once again to support himself.

In 1871 he returned to Russia, and soon obtained a situation as editor of a conservative weekly (1873–74). After *1876* he published and edited a journal of his own, *An Author's Diary,* in which he continued the line of national and democratic Christianity started by the *Vremya.* He became influential as a journalist and his last years were spent in comparatively favourable circumstances. His contemporary fame reached its culminating point in 1880, after his address on the unveiling of the Purhkin memorial, the most characteristic and impassioned of his non-imaginative work. He died on Jan. *28, 1881.* His funeral was accompanied by an inspiring public demonstration.

The work that has made Dostoievski a world classic belongs to the last *17* years of his life. The series of his great novels is ushered in by *Letters from the Underworld* (1864) which may be considered as the central work of Dostoievski. It marks the crisis which changed him, from the humanitarian idealist and dreamer of his early years, into the tragic creator of his full maturity. As in his great novels, the main subject is the problem of human liberty and of the justification of God and the World Order. The great novels that followed were: *Crime and Punishment (1866); The Idiot* (1868–69); *The Demons (1871;* Eng. version *The Possessed)* and *The Brothers Karamazov* (1880); to which must be added *Tlze Gambler* (1867), *The Eternal Husband* (1870); *A Raw Youth* (1875) and some shorter pieces included in *An Autlzor's Diary.* These last, though much shorter, are sometimes of first-rate importance for the understanding of Dostoievski (especially *Bobok* and *The Dream of a Queer Fellow).* In these works Dostoievski gave his full measure as one of the greatest novelists of all times, and as a personality of exceptionally deep significance. For psychological imagination, for power of dramatic construction, for the convincingness and reality of his characters he has no equals. As a thinker, we have to distinguish between the "Christian and national" element of his journalistic writings and of the less inspired parts of his novels (viz., the preachings of Father Zosima in *The Brotlzers Karamazov*), and the profound Jobean and Promethean questioner of the main great novels, whose only peers in modern times are Pascal and Nietzsche. His influence on .Russian literature was greatest between 1895 and *1915.* His ideas always loomed larger than his imaginative creation. Europe began to show a passionate interest in him from about 1905. His influence on French, German and English literature within the last 20 years has been considerable.

DOTHAN, a city in the extreme south-eastern part of Alabama, U.S.A.; the county seat of Houston county. It is on Federal highways *84* and 231, and is served by the Atlanta and St Andrews Bay, the Atlantic Coast Line, and the Central of Georgia railways. The population was 10,034 in 1920 (43% negroes) and was 17,194 in 1940 by the federal census Dothan is the centre of a fertile farming and stock-raising region, and has a large number of diversified manufacturing industries. The city was founded in 1884 and incorporated in 1885.

DOUAI, a town of northern France, capital of an arrondissement in the department of Nord, 20 m. S. of Lille on the Northern railway between that city and Cambrai. Pop. (1936), *33* 201 Douai, the site of which was occupied by a castle (*Castrum Duacense)* as early as the 7th century, belonged in the middle ages to the counts of Flanders, passed in *1384* to the dukes of Burgundy, and so in 1477 with the rest of the Netherlands to Spain. In *1667* it was captured by Louis XIV., and was ceded to France by the treaty of Ctrecht in 1713. Historically Douai is

important as the centre of the political and religious propaganda of the exiled English Roman Catholics. In 1562 Philip II. of Spain founded a university here, in which several English scholars were given chairs; and in connection with this William Allen (*q.v.*) in 1568 founded the celebrated English college. It was here that the "Douai Bible" was prepared. There were also an Irish and a Scots college and houses of English Benedictines and Franciscans. All these survived till 1793, when the university was suppressed. The modern university is at Lille. Douai stands in a marshy plain on the banks of the Scarpe which supplies water to a canal on the west. The old fortifications, of which the Porte de Valenciennes (15th century) survives are now boulevards and gardens. The industrial towns of Dorignies, Sin-le-Noble and Aniche are practically suburbs of Douai. The church of Notre Dame (12th and 14th centuries) possesses a fine altar-piece (early 16th century) of wooden panels painted by Jean Bellegambe of Douai. The handsome hôtel de ville, partly of the 15th century, has a lofty belfry. The Palais de Justice (18th century) was formerly the town house *(refuge)* of the abbey of Marchiennes. Houses of the 16th, 17th and 18th centuries are numerous. The municipal museum contains a good library, and a fine collection of sculpture and paintings but was damaged in World War I.

Douai is the seat of a court of appeal, a court of assizes and of a subprefect and has a tribunal of first instance, a board of trade-arbitrators, an exchange, a chamber of commerce and a branch of the Bank of France. There is an airfield. The educational institutions include a lycée, training colleges, a school of mines, an artillery school, schools of music, agriculture, drawing, architecture, etc. and a national school for instruction in brewing and other industries connected with agriculture. In addition to other iron and engineering works, Douai has a large cannon foundry and an arsenal; coal-mining and the manufacture of glass bottles and chemicals are carried on on a large scale in the environs; among the other industries are flax-spinning, ropemaking and the manufacture of farm implements, oil and sugar. Trade. which is largely water-borne, is in grain and agricultural products, coal and building material.

See F. Brassart, *Hist. du chciteau et de la chcitellenie de Douai* (Douai, 1877–87); C. Mine. *Hist. pop. de Douai (ib.* **1861**); *B.* Ward, *Dawn of the Catholic Revival* (London, 1909); Handecoeur, *Hist. du Collège anglais, Douai* (Reims, **1898**); Daucoisne, *Établissements britanniques à Douai* (Douai, **1881**).

DOUARNENEZ, a fishing-port of western France, in the department of Finistère, on the southern shore of the Bay of Douarnenez, 15 mi. N.W. of Quimper by rail. Pop. (1936), 10,556. About 800 boats, and between 3,000 and 4,000 men, carry on the sardine fishery from June to December, and the preserving of the fish is an important industry. Mackerel and tunny fishing, boat-building and rope and net making also occupy the inhabitants. There is a lighthouse on the small island of Tristan off Douarnenez.

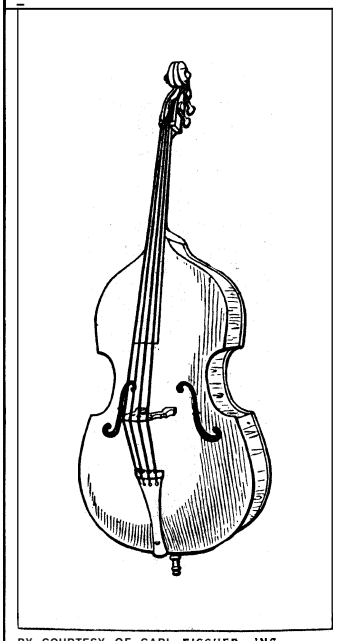
DOUBLE, twice as much, or large, having two parts, having a part repeated (from the Mid. Eng. *duble,* through the Old Fr. *duble,* from Lat. *duplus,* twice as much). The word appears as a substantive with the special meaning of the appearance to a person of his own apparition, generally regarded as a warning, or of such an apparition of one living person to another, the German *Doppelganger (see* APPARITIONS). "Double" is also used of a person whose resemblance to another is peculiarly striking or remarkable, so that confusion between them may easily arise.

Double or doubles, in music, is an old and now obsolete term for instrumental variations, derived possibly from the fact that more often than not each succeeding variation "doubled" the notes of the preceding one, two quavers taking the place of one crotchet, and so on. The word "doubles" is also applied in bell-ringing terminology to a "change" in which two pairs of bells change places.

DOUBLE BASS, the largest member of the violin family and the lowest in pitch. (Fr. *contrebasse;* Ger. *Kontrabass, Gross Bass Geige;* Ital. *contrabasso, violone.*) The double bass differs slightly in construction from the other members of the family in that it has more slanting shoulders (one of the features of the *viola* da *gamba, see* VIOLIN) Formerly, too, the double bass was made with a flat back—another characteristic of the viol family—whereas now the back is as often found arched as flat.

The technique of the double bass presents certain difficulties inherent in an instrument of such large proportions. The stretches for the fingers are very great, almost double those required for the violoncello, and owing to the thickness of the strings great force is required to press them against the finger-board when they are vibrating.

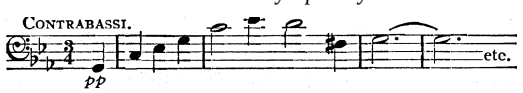
The double bass sometimes has three strings tuned, in England and Italy in fourths:  ; in France and Germany in fifths:  the real sounds being an octave lower. Owing to the scoring of modern composers, however, it was focnd necessary to adopt an accordance of four strings in order to obtain the additional lower notes required, although this entailed the sacrifice of some beauty of tone, the three-stringed instrument being more sonorous. The four strings are tuned in fourths:  . The practical compass of the double bass extends from 
(real sounds) with all chromatic intervals. In order to avoid using numerous ledger lines the music is written an octave higher.



BY COURTESY OF CARL FISCHER, INC.
DOUBLE BASS, LAST SURVIVING REPRESENTATIVE OF THE EARLIER VIOLS

The quality of tone is very powerful .but somewhat rough, and varies greatly in its gradations. The tone of the *pizzicato* is full and rich owing to the slowness of the vibrations. Both natural and artificial harmonics are possible on the double bass, the former being best; but they are seldom used in orchestral works.

The technical capabilities of the double bass are necessarily somewhat more limited than those of the violoncello, but it is the foundation of the whole orchestra and therefore of great importance; it plays the lowest part, often, as its name indicates, only doubling the 'cello part an octave lower. It is only since the beginning of the 19th century that an independent voice has occasionally been allotted to it, as in the Scherzo of Beethoven's *Fifth Symphony:*—



These opening bars are played *soli* by 'cellos and double basses, a daring innovation of Beethoven's which caused quite a consternation at first in musical circles. Still more striking is the famous passage, suggesting the gambols of an elephant, which the double basses are called on to play at the opening of the trio of the same movement.

The remote origin of the double bass is the same as that of the violin. It was evolved from the bass viols, though whether the transformation took place simultaneously with that of the violin from the treble viol, or preceded it, has not been definitely proved.

Giovanni Bottesini (1822–89) was the greatest virtuoso on the double bass that the world has ever known. Before him, Domenico Dragonetti (1763–1846) also enjoyed great fame, while more recently Kussevitsky, who later exchanged the bow for the bbton and became a world-renowned conductor, was for some years a leading exponent of the instrument.

DOUBLE ENTRY: *see* BOOKKEEPING.

DOUBLE FUGUE, in music, a fugue with two subjects, norked together or interwoven (*See* FUGUE.)

DOUBLE JEOPARDY. The 5th Amendment to the U.S. Constitution provides no one shall be "twice put in jeopardy": no one punished or acquitted of an offense may be re-tried.

DOUBLE LIABILITY, in the United States, applies to the stockholders' liability in certain corporations, signifying that, in case of insolvency, the stockholders may not only lose the amount which they invested in their stock but may also be called upon ratably for the concern's indebtedness up to an additional amount equal to the full par value of the stock. This double liability does not apply to stocks of ordinary business corporations but to banking corporations. The laws of most States make State-chartered banks subject to double liability, and the national banking laws make double liability apply to the stock of national banks. The national bank act in providing for double liability on national bank stock provides: "except that shareholders of any banking association now existing under state laws having not less than five million dollars of capital actually paid in and a surplus of twenty per centum on hand, both to be determined by the Comptroller of the Currency, shall be liable only to the amount invested in their shares." At the time of the passage of the act, the National Bank of Commerce of New York city met the above requirements and so its stock became the exception to the double liability for national banks.

DOUBLE-NAME PAPER, notes, bills of exchange or acceptances bearing two names, each of which represents a separate interest and each of which is responsible for the payment. The names may represent a signature and an endorsement, or two signatures. The former class is often known as endorsed paper, and both classes are commonly known as two-name paper. Trade acceptances and bankers' acceptances necessarily have two or more names and both the drawer and the acceptor are liable for the payment. (See ACCEPTANCE; BILL OF EXCHANGE; NOTE; DRAFTS.)

DOUBLE REFRACTION, the resolution, on entering a non-isotropic medium, of light into two rays travelling with different velocities. (See LIGHT.)

DOUBLE STAR: see BINARY SYSTEM and STAR.

DOUBLE-STOPPING, a musical term signifying the playing of two notes simultaneously on a stringed instrument of the violin family. In strictness the term should not be applied when one of the notes is an "open" one and has therefore not entailed any "stopping," *i.e.,* pressing down of the string against the fingerboard by the finger, whereby its vibrating length is shortened; but in practice the distinction is not observed.

DOUBLET, a close-fitting garment, with or without sleeves, extending from the neck to a little below the waist, worn from the 14th century to the time of Charles II., when it began to be superseded by coat and waistcoat. The doublet was introduced into England from France, and was originally padded for defence or warmth. "Doublet" is also used of a pair or couple, as in philology, one of two words differing in form, but represented by an identical root, *e.g.* "alarm" or "alarum"; in optics, of a pair of lenses, combined to correct aberration. In the work of the lapidary a doublet is a counterfeit gem, made by cementing two pieces of plain glass or crystal on each side of a layer of glass (coloured to represent the stone counterfeited); a thin portion of a genuine stone may be cemented upon an inferior one, as a layer of diamond upon a topaz, or ruby on a garnet. In electricity, doublet is a term for two equal and opposite electrical charges situated extremely close together (see ELECTRICITY).

DOUBS, a frontier department of eastern France, formed in 1790 of the ancient principality of Montbéliard and of part of the province of Franche-Comté. It is bounded E. and S.E. by Switzerland, N. by the territory of Belfort and by Haute Saône, and W. and S.W. by Jura. Pop. (1936) 304.812. Area 2,031 sq.mi. The river Doubs traverses the department. Between the Ognon, which forms the north-western limit of the department, and the Doubs, runs a range of low hills known as "the plain." The rest of Doubs is mountainous, four parallel chains of the Jura crossing it from N.E. to S.W. The Lomont range, the lowest of these chains, dominates the left bank of the Doubs. The central region is occupied by hilly plateaux covered with pasturage and forests, while the rest of the department is traversed by the remaining three mountain ranges, the highest and most easterly of which contains the Mont d'Or (4.800 ft.). Besides the Doubs the chief rivers are its tributaries, the Dessoubre, watering the east of the department, and the Loue its south-western portion. The climate is in general cold and rainy, and the winters are severe. The soil is stony and loamy, and at the higher levels there are many peat-bogs. In its agricultural aspect the department may be divided into three regions. The highest, on which the snow usually lies from six to eight months in the year, is in part barren, but on its less exposed slopes is occupied by forests of fir trees, and affords good pasturage for cattle. In the second or lower region the oak, beech, walnut and sycamore flourish; and the valleys are capable of cultivation. The region of the plain is the most fertile, and produces all kinds of cereals as well as hemp, vegetables, vines and fruit. Cattle-rearing and dairy-farming receive much attention; large quantities of cheese, of the nature of Gruyère, are produced, mainly by the co-operative cheese factories or *fruitières*. The rivers of the department abound in gorges and falls of great beauty. The most important manufactures are watches, made chiefly at Besançon and Morteau, hardware (Hérimoncourt and Valentigney), and machinery. Large iron foundries are found at Audincourt (pop. 9,308) and other towns. Distilling and the manufacture of cotton and woollen goods, automobiles and paper are also carried on. Exports include watches, live-stock, mine, vegetables, iron and hardware; cattle, hides, timber, coal, wine and machinery are imported. Large quantities of goods, in transit between France and Switzerland, pass through the department. Among its mineral products are building stone, rock-salt and lime, and there are peat workings. Doubs is served by the Paris-Lyon railway, the line from Dôle to Switzerland passing, via Pontarlier, through the south of the department. The canal from the Rhône to the Rhine traverses it for 84 miles.

The department of Doubs is divided into the three arrondissements of Besanqon, Montbéliard and Pontarlier, with 27 cantons and 636 communes. It belongs to the *académie* (educational circumscription) and the diocese of Besancon, which is the capital, the seat of an archbishop and of a court of appeal, and headquarters of the VII. army corps. Besides Besançon the chief towns are Montbéliard and Pontarlier (*qq.v.*). Ornans, a town on the Loue, has a church of the 16th century and ruins of a feudal castle. Montbenoit on the Doubs near Pontarlier has the remains of an Augustine abbey (13th to 16th centuries), the cloisters are of the 15th century, and the church contains fine 16th century stalls. Morteau has the Maison Pertuisier, of the Renaissance period. Baume-les-Dames owes the affix of its name to a Benedictine convent founded in 763, to which only noble ladies were admitted. Numerous antiquities have been found at Mandeure (near Montbéliard), on the site of the Roman town of *Epomanduodurum*.

DOUBS, a river of eastern France, rising in the Jura at the foot of the Noirmont ridge, at a height of 3,074 ft., and flowing into the Saône. It is 269 m. long, though, owing to the fact that it doubles back upon itself, the distance from source to mouth in a direct line is only 56 miles. Its basin has an area of 3,020 sq. miles. The river begins by flowing north-east and traverses the Lake of St. Point and passes Pontarlier. Thenceforth its course lies chiefly through wooded limestone gorges of great grandeur. After skirting the town of Morteau, below which it expands into the Lake of Chaillexon and descends over the Fall of the Doubs (88 ft.), the river for about 28 m. forms the frontier between France and Switzerland. It flows in the latter country for some distance and then turns abruptly westward. Thus far the Doubs has been flowing between the folds of the Jura, but when it comes against the shattered southern face of the old block of the Vosges its course is rapidly altered. After turning westward it finds its way through this complicated country by turning north, and finally, at Voujeaucourt, south-west. Below that town the river is joined by the canal from the Rhone to the Rhine, to accommodate which its course has been canalized as far as Dôle. The Doubs passes Clerval and Baume-les-Dames to Besanqon. The lower section of its course is in the great

structural depression between the Côte d'or and the Jura. After passing Dôle it leaves the high ground and enters the plain of the Saône. Here it receives the waters of the Loue, which also has a complicated structural history, finding its way, like the Doubs, between the outer folds of the Jura—sometimes parallel with them and sometimes cutting across them, and finally falling into the great structural depression with the lower Doubs and Saône. The Doubs reaches the Saône at Verdun-sur-le-Doubs. The river is navigable only for approximately 8 miles above its mouth.

DOUCE, FRANCIS (1757–1834), English antiquary, was born in London. He interested himself in antiquities, and was for a short time keeper of manuscripts in the British Museum. He left his books, illuminated manuscripts, coins, etc., to the Bodleian library; his own manuscript works to the British Museum, but they were returned; and his paintings, carvings and miscellaneous antiquities to Sir Samuel Meyrick, who published an account of them, entitled *The Doucean Museum.* His published works are *Illustrations of Shakespeare and Ancient Manners* (2 vols., 1807), and *Dissertation on the Various Designs of the Dance of Death* (1833), the substance of which had appeared forty years before. He also contributed a considerable number of papers to the *Archaelogia* and *The Gentleman's Magazine.*

DOUGHBOY, in the 17th century, signified "dumpling." During the American Civil War it was applied to the mass buttons on uniforms and thence to infantrymen. At a period not exactly ascertained the word was supposed to come from the dough-like appearance of a uniform soiled by moistened pipe-clay. Again, infantrymen were said to march in "dough" during wet weather. "Adobe" furnishes a similar derivation, although it may be a "popular etymology," or wholesale transference of a foreign word to an English meaning and spelling. "Doughboys" was a favourite designation for the United States soldiers during the World War.

See J. H. Moss, *Officers' Manual* (1909); G. P. Krapp, The *English Language in America* (2 vols., 1925).

DOUGHERTY, PAUL (1877–), American painter, was born at Brooklyn (N.Y.), on Sept. 6, 1877. He was educated at the Brooklyn Polytechnic Institute and the New York Law school, where he took the degree of LL.B. in 1898. He then spent five years in Europe, devoting himself to the study of art. His first picture was exhibited at the Paris Salon in 1901. He was chiefly concerned with marine subjects, in which he achieved great success, being awarded the Osborne Prize (1905), the Inness Gold Medal and the Carnegie Prize, National Academy of Design (1913), the gold medal at the San Francisco exposition (1915), and the Altman Prize (1918). Among his more important pictures are "October Seas," "The Road to Cayey," and "Lake Louise," in the Metropolitan Museum, New York city; "The Land and the Sea," in the Corcoran gallery, Washington; "Flood Tide," in the Carnegie Institute, Pittsburgh; "Moonlight Cove," in the Toledo museum; "Sun and Storm," in the National gallery, Washington; and "A Freshening Gale," in the Albright Art gallery, Buffalo.

DOUGHTY, SIR ARTHUR GEORGE (1860–1936), Canadian historian and archivist, was born March 22. 1860, at Maidenhead, England; educated at Oxford, and Dickinson college, Carlisle, Pa. He went to Montreal as a journalist and private secretary, becoming in 1901 joint librarian of the provincial legislature, and in 1904 Dominion archivist and keeper of the records. He was appointed deputy minister in 1912, in which year he also became joint editor, with Adam Shortt, of the series, *Canada and its Provinces.* His chief works are *Tennyson* (1893); *Siege of Quebec* (6 vols., 1901); *Documents Relating to the Constitutional History of Canada* (1907–18); *The Cradle of New France* (1908); *The Acadian Exiles* (1915); and *The Canadian Archives and its Activities* (1924).

DOUGHTY, CHARLES MONTAGU (1843–1926), British traveller and writer, younger son of the Rev. C. M. Doughty of Theberton Hall, Suffolk, was born on Aug. 19, 1843. He was prevented by an impediment in speech from entering the navy, and his education was continued at King's college, London, and at Caius and Downing colleges, Cambridge, where he graduated in natural science in 186;. He turned then to independent travel and study, freely adventuring in his chosen fields of geology, archaeology and philology. And he did so in no half-hearted way: in Norway, Oxford, Leyden, Louvain, Italy, Spain, North Africa and Greece he served a long novitiate in wandering and scholarship which led him at last to Syria, Palestine and his adventures in Arabia.

In Nov. 1876 Doughty set out from Damascus with a pilgrim caravan. At Madâin Sâlih he left the Haj, and surveyed the Al Hajar monuments and inscriptions. He then decided to reach independently the aasis of Khaibar, and to this end attached himself to wandering Bedouins. Dependent on their movements, his dangers were now multiplied and his life was repeatedly endangered by the inevitable suspicion, fanaticism and treachery which on occasion broke through the respect and hospitality which Doughty's courageous personality compelled. He reached Khaibar from Taima in the summer of 1877, was sent back to Hail, thence to Al Qasim, Buraida and 'Anaiza. From there, after some months, he travelled southwards towards Mecca and reached safety at Jidda in Aug. 1878. The story of this great journey, which threw many fresh lights on the geology, hydrography and ethnology of Arabia, Doughty told in *Travels in Arabia Deserta* (1888, abridged edition 1926). Doughty was less concerned to produce a chronicle or work of information than to create, out of his unique experience, an unique monument of what he considered pure English prose. To him, this meant the achievement of an Elizabethan directness of utterance and the renunciation of all post-Elizabethan growths in syntax and vocabulary. He succeeded. His profound literary sense had told him aright when it inspired him to treat his remote and lonely adventuring in this bare, majestic styie.

The later years of Doughty's life, mostly spent in England, were given over to poetry. Essentially, indeed, he was always a poet, in his deep comprehension of the values of words no less than in his power of penetrating into the living past, whether of a country's physical structure or of its people and their life. Fourteen years' labour produced his epic, *The Dawn in Britain* (1906), his other long poems and poetic dramas including *The Cliffs* (1909), *The Clouds* (1912), *The Titans* (1916) and *Man-soul* (1920, new edition 1923). Like *Arabia Deserta,* the poems he wrote reflect his Elizabethan predilections. He died at Sissinghurst, Kent, on Jan. 20, 1926. (J. H. M.)

DOUGHTY-WYLIE, CHARLES HOTHAM MONTAGU (1868–1915), British soldier and consul, was born at Leiston, Suffolk, on July 23, 1868, and was educated at Winchester and Sandhurst, from which he passed into the Royal Welch Fusiliers in 1889. He was on active service in India in the Hazara (1891) and Chitral (1895) campaigns. He also served with great distinction in the Egyptian campaign of 1898, in the Boer War, in the China Field Force (1901), and as special service officer in Somaliland. But the field in which his remarkable force of character was most clearly shown was in the Near East. In Sept. 1906 Doughty-Wylie was appointed military consul at Konieh, in Anatolia, and in 1909 Cilicia was added to his area. In that year an attempted inassacre of the Christian population of Adana was stopped by his courage and quickness, when he collected a small group of Turkish regulars, and saved the Armenian quarter. The next four years were spent as consul at Addīs Ababa, Abyssinia, but the outbreak of war brought him back to England. He was attached to Sir Ian Hamilton's staff for the Gallipoli expedition, and went ashore with the first batch of troops on the "River Clyde." His gallant exploit on V. Beach on April 26, 1915, when he captured Hill 141 in hand-to-hand fighting, cost him his life. Doughty-Wylie was buried on the spot.

See an article, based on personal knowledge, by D. G. Hogarth, in the *Dict. Nat. Biog. Supp. 1912–21* (1927).

DOUGLAS, the name of a Scottish noble family, now represented by the dukes of Hamilton (Douglas-Hamilton, heirs-male), the earls of Home (Douglas-Home) who also bear the title of Baron Douglas of Douglas, the dukes of Buccleuch and Queensberry (Montagu-Douglas-Scott), the earls of Morton (Douglas), the earls of Wemyss (Wemyss-Charteris-Douglas),

and the baronets Douglas of Carr, of Springwood, of Glenbervie, etc. The marquessate of Douglas and the earldom of Angus, the historic dignities held by the two chief branches of the family, the Black and the Red Douglas, are merged in the Hamilton peerage. The name represented the Gaelic dubh glas, dark water, and Douglasdale, the home of the family in Lanarkshire, is still in the possession of the earls of Home. The first member of the family to emerge with any distinctness was William de Douglas, or Dufglas, whose name frequently appears on charters from 1175 to 1213. He is said to have been brother, or brother-in-law, of Freskin of Murray, the founder of the house of Murray. His second son, Brice (d. 1222), became bishop of Moray, while the estate fell to the eldest, Sir Archibald (died c. 1240).

SIR WILLIAM OF DOCGLAS (d. 1298), called *"le hardi,"* Archibald's grandson, first formally assumed the title of lord of Douglas. He gave a grudging allegiance to John de Baliol, and swore fealty to Edward I. in 1291; but when the Scottish barons induced Baliol to break his bond with Edward I. he commanded at Berwick Castle, which he surrendered after the sack of the town by the English in 1296. After a short imprisonment Douglas was restored to his Scottish estates on renewing his homage to Edward I., but his English possessions were forfeited. He joined Wallace's rising in 1297, and died in 1298, a prisoner in the Tower of London.

His son, SIR JAMES OF DOUGLAS (1286–1330), lord of Douglas, called the "Good," was educated in Paris. On his return he found an Englishman, Robert de Clifford, in possession of his estates. His offer of allegiance to Edward I. being refused, he cast in his lot with Robert Bruce, whom he joined before his coronation at Scone in 1306. From the battle of Methven he escaped with Bruce and the remnant of his followers, and accompanied him in his wanderings in the Highlands. In the next year they returned to the south of Scotland. He twice outwitted the English garrison of Douglas and destroyed the castle. One of these exploits, carried out on Palm Sunday, March 19, 1307, with barbarities excessive even in those days, is known as the "Douglas Larder." Douglas routed Sir John de Mowbray at Ederford Bridge, near Kilmarnock, and was entrusted with the conduct of the war in the south, while Bruce turned to the Highlands. He made many successful raids on the English border, which won for him the dreaded name of tbe "Black Douglas" in English households. Through the capture of Roxburgh Castle in 1314 by stratagem, the assailants being disguised as black oxen, he secured Teviotdale; and at Bannockburn, where he was knighted on the battlefield, he commanded the left wing with Walter the Steward. During the 13 years of intermittent warfare that followed he repeatedly raided England. He slew Sir Robert de Kevill, the "Peacock of the North," in single combat in 1316, and in 1319 he invaded Yorkshire, in company with Randolph, defeating an army assembled by William de Melton, archbishop of York, at Mitton-on-Swale (Sept. zo), in a fight known as "The Chapter of Myton." In 1322 he captured the pass of Byland in Yorkshire, and forced the English army to retreat. He was rewarded by the "Emerald Charter," granted by Bruce, which gave him criminal jurisdiction over the family estates, and released the lords of Douglas from various feudal obligations. In a daring night attack on the English camp in Weardale in 1327 Douglas came near capturing Edward III. himself. After laying waste the northern counties he retreated, without giving battle to the English. Before his death in 1329 Bruce desired Douglas to carry his heart to Palestine in redemption of his unfulfilled vow to go on crusade. Douglas set out in 1330, bearing with him a silver casket containing the embalmed heart of Bruce, but he fell fighting with the Moors in Spain on Aug. 25 of that year, and was buried in St. Bride's church, Douglas. Since his day the Douglases have borne a human heart in their coat of arms. Sir James was said to have fought in 70 battles and to have conquered in 57. His exploits, as told in Froissart's Chronicles and in John Barbour's *Bruce,* are familiar from Scott's Tales *of* a *Grandfather* and Castle Dangerous. His half-brother, Sir Archibald, defeated Edward Baliol at Annsn in 1332, and had just been appointed regent of Scotland for David II when he risked a pitched battle at Halidon Hill, where he was defeated and killed (1333), with his nephew William, lord of Douglas. The inheritance fell to his brother, a churchman, Hugh the "Dull" (b. 1294), who surrendered his lands to David II.; and a re-grant was made to William Douglas, next referred to.

WILLIAM DOUGLAS, 1ST EARL OF DOUGLAS (c. 1327–1384) had been educated in France, and returned to Scotland in 1348. In 1353 he killed in Ettrick forest his kinsman, William, the knight of Liddesdale (c. 1300–1353), known as the "Flower of Chivalry," a descendant of a younger son of the original William de Douglas. Some of the Liddesdale lands fell to his kinsman and murderer, who was created earl of Douglas in 1358. In 1357 his marriage with Margaret, sister and heiress of Thomas, 13th earl of Mar, eventually brought him the estates and the earldom of Mar. He was one of the securities for the payment of David II.'s ransom, and in consequence of the royal misappropriation of some moneys raised for this purpose, Douglas was for a short time in rebellion in 1363. In 1364 he joined David II. in seeking a treaty with England which should deprive Robert the Steward, formerly an ally of Douglas, of the succession by putting an English prince on the Scottish throne. The independence of Scotland was to be guaranteed, and a special clause provided for the restoration of the English estates of the Douglas family. On the accession of Robert II. he was nevertheless reconciled, becoming justiciar of southern Scotland, and the last years of his life were spent in making and repelling border raids. He died at Douglas in May 1384, and was succeeded by his son James. By his wife's sister-in-law, Margaret Stewart, countess of Angus in her own right, and widow of the 13th earl of Mar, he had a son George, afterwards 1st earl of Angus.

JAMES, 2ND EARL OF DOUGLAS AND MAR (c. 1358–1388), married Lady Isabel Stewart, daughter of Robert II. In 1385 he made war on the English with the assistance of a French contingent under John de Vienne. He allowed the English to advance to Edinburgh, wisely refusing battle. and contented himself with a destructive counter-raid on Carlisle. In 1388 Douglas captured Hotspur Percy's pennon in a skirmish near Newcastle. Percy sought revenge in the battle of Otterburn (Aug. 1388), which ended in a victory for the Scots and the capture of Hotspur and his brother, though Douglas fell in the fight. The struggle, narrated by Froissart, is celebrated in the English and Scottish ballads called "Chevy Chase" and "The Battle of Otterburn." The 2nd earl left no legitimate male issue. His natural sons William and Archibald became the ancestors of the families of Douglas of Drumlanrig (see QUEENSBERRY) and Douglas of Cavers. His sister Isabel became countess of Mar, inheriting the lands of Mar and his unentailed estates.

The earldom and entailed estates of Douglas reverted by the patent of 1358 to ARCHIBALD DOUGLAS, 3RD EARL OF DOUGLAS, called "The Grim" (c. 1328–*c.* 1400), a natural son of the "good" Sir James. He was warden of the western marches, lord of Galloway in 1369, increased his estates by his marriage with Joanna Moray, heiress of Bothwell, and by his purchase of the earldom of Wigtown in 1372. During the intervals of war with the English he imposed feudal law on the border chieftains, drawing up a special code for the marches. He was twice sent on missions to the French court. The power of the Black Douglas overshadowed the Crown under the weak rule of Robert III., and in 1399 he arranged a marriage between David, duke of Rothesay, the king's son and heir, and his own daughter, Marjory Douglas. A natural son of Archibald, Sir William of Douglas, lord of Nithisdale (d. 1392), married Egidia, daughter of Robert III.

Archibald the Grim was succeeded by his eldest son, ARCHIBALD, 4TH EARL OF DOUGLAS, 1st duke of Touraine, lord of Galloway and Annandale (1369?–1424), who married in 1390 Lady Margaret Stewart, eldest daughter of John, earl of Carrick, afterwards King Robert III. In 1400 March and Hotspur Percy had laid waste eastern Scotland as far as Lothian when they were defeated by Douglas (then master of Douglas) near Preston. With the regent, Robert, duke of Albany, he was suspected of complicity in the murder (March 1402) of David, duke of Rothesay, who was in their custody at Falkland Castle, but both were officially declared guiltless by the parliament. In that year Douglas raided England and was taken prisoner at Homildon Hill by the Percys. He

fought on the side of his captors at Shrewsbury (1403), and was taken prisoner by the English king, Henry IV. He became reconciled, during his captivity, with the earl of March, whose lands had been conferred on Douglas, but were now, with the exception of Annandale, restored. He returned to Scotland in 1409, but was in constant communication with the English court for the release of the captive king, James I. In 1412 he had visited Paris, when he entered into a personal alliance with John the Fearless, duke of Burgundy, and in 1423 he commanded a contingent of 10,000 Scots sent to the help of Charles VII. against the English. He was made lieutenant-general in the French army, and received the peerage-duchy of Touraine with remainder to his heirs-male. The new duke was defeated and slain at Verneuil (1424) with his second son, James; his persistent ill-luck earned him the title of the Tyneman (the loser).

ARCHIBALD, 5TH EARL OF DOUGLAS (*c.* 1391–1439), succeeded to his father's English and Scottish honours, though he never touched the revenues of Touraine. He fought at Baugé in 1421, and was made count of Longueville in Normandy.

His two sons, WILLIAM, 6TH EARL (1423?–1440), and David, though they were little more than boys at the time of their father's death in 1439, were summoned to court by Sir William Crichton, lord chancellor of Scotland, on Nov. 24, 1440, and, after a mock trial in the young king's presence, were beheaded forthwith in the courtyard of Edinburgh Castle. This murder broke up the dangerous power wielded by the Douglases. The lordships of Annandale and Bothwell fell to the Crown; Galloway to the earl's sister Margaret, the "Fair Maid of Galloway"; while the Douglas lands passed to his great-uncle JAMES DOUGLAS, 7TH EARL OF DOUGLAS, called the "Gross," of Balvany (1371–1444), lord of Abercorn and Aberdour, earl of Avondale (cr. 1437), younger son of the 3rd earl.

The latter's sons, WILLIAM (*c.* 1425–1452) and JAMES (1426–1488), became 8th and 9th earls respectively; Archibald became earl of Moray by marriage with Elizabeth Dunbar, daughter and co-heiress of James, earl of Moray; Hugh was created earl of Ormond in 1445; John was lord of Balvany; Henry became bishop of Dunkeld.

The power of the Black Douglases was restored by the 8th earl, who recovered Wigtown, Galloway and Bothwell by marriage (by papal dispensation) with his cousin, the Fair Maid of Galloway. He was soon high in favour with James II., and procured the disgrace of Crichton, his kinsmen's murderer, by an alliance with his rival, Sir Alexander Livingstone. In 1450 James raided the earl's lands during his absence on a pilgrimage to Rome; but their relations seemed outwardly friendly until, in 1452, the king invited Douglas to Stirling Castle under a safe-conduct, in itself, however, a proof of strained relations. There James demanded the dissolution of a league into which Douglas had entered with Alexander Lindsay, the "Tiger" earl (4th) of Crawford. On Douglas's refusal the king murdered him (Feb. 22) with his own hands, the courtiers helping to despatch him. The tales of the hanging of Sir Herbert Herries of Terregles and the murder of McLellan of Bombie by Douglas rest on no sure evidence.

JAMES DOUGLAS, 9TH EARL (and last), denounced his brother's murderers and took up arms, but was obliged by the desertion of his allies to submit. He obtained a papal dispensation to marry his brother's widow, in order to keep the family estates together. He intrigued with the English court, and in 1455 rebelled once more. Meanwhile another branch of the Douglas family, known as the Red Douglas, had risen into importance (*see* ANGUS, EARLS OF), and George Douglas, 4th earl of Angus (d. 1463), greatgrandson of the 1st earl of Douglas, took sides with the king against his kinsmen. James Douglas, again deserted by his chief allies, fled to England, and his three brothers, Ormond, Moray and Balvany, were defeated by Angus at Arkinholm on the Esk. Moray was killed, Ormond taken prisoner and executed, while Balvany escaped to England. Their last stronghold, the Thrieve in Galloway, fell, and the lands of the Douglases were declared forfeit, and were divided among their rivals, the lordship of Douglas falling to the Red Douglas, 4th earl of Angus. In England the earl of Douglas was employed by Edward IV. in 1461 to negotiate a league with the western highlanders against the Scottish kingdom. In 1484 he was taken prisoner while raiding southern Scotland, and was relegated to the abbey of Lindores, where he died in 1488.

The title of Douglas was restored in 1633 when WILLIAM, 11th earl of Angus (1589–1660), was created 1ST MARQUESS OF DOUGLAS by Charles I. In 1645 he joined Montrose at Philiphaugh and was imprisoned in 1646 at Edinburgh Castle, only obtaining his release by signing the Covenant. His eldest son, Archibald, created earl of Ormond, Lord Bothwell and Hartside, in 1651, predeceased his father; Lord James Douglas (c. 1617–1645) and his half-brother, Lord George Douglas (c. 1636–1692), created earl of Dumbarton in 1675, successively commanded a Scots regiment in the French service. William (1635–1694), created earl of Selkirk in 1646, became 3rd duke of Hamilton after his marriage (1656) with Anne, duchess of Hamilton in her own right. By the failure of heirs in the elder branches of the family the dukes of Hamilton (*q.v.*) became heirs-male of the house of Douglas.

JAMES DOUGLAS, 2ND MARQUESS OF DOUGLAS (1646-1700), succeeded his grandfather in 1660. His eldest son, John, by courtesy earl of Angus, raised a regiment of 1,200 men, first known as the Angus regiment, later as the Cameronians (26th Foot). He was killed at its head at Steinkirk in 1692. The younger son, ARCHIBALD, 3RD MARQUESS (1694–1761), was created duke of Douglas in 1703, but the dukedom became extinct on his death, without heirs, in 1761. He was a consistent supporter of the Hanoverian cause, and fought at Sheriffmuir. The heir-presumptive to the Douglas estates was his sister, Lady Jane Douglas (1698–1753), who in 1746 secretly married Colonel, afterwards Sir, John Steuart of Grandtully, by whom she had twin sons, born in Paris in 1748. These children were alleged to be spurious, and when Lady Jane and the younger of the two boys died in 1753, the duke refused to acknowledge the survivor as his nephew; but in 1760 he was induced, under the influence of his wife, to revoke a will devising the estates to the Hamiltons in favour of Lady Jane's son, Archibald James Edward Steuart (1748–1827), 1st baron Douglas of Douglas (cr. 1790) in the British peerage. The inheritance of the estates was disputed by the Hamiltons, representing the male line, but the House of Lords decided in favour of Douglas in 1769. Three of his sons succeeded Archibald Douglas as Baron Douglas, but as they left no male issue the title passed to the earls of Home, Cospatrick Alexander, 11th earl of Home, having married a granddaughter of Archibald, 1st Baron Douglas. Their descendants, the earls of Home, represent the main line of Douglas on the female side.

BIBLIOGRAPHY.—David Hume of Godscroft (1560?–1630), who was secretary to Archibald Douglas, 8th earl of Angus, wrote a *History of the House and Race of Douglas and Angus*, printed under his daughter's superintendence (Edinburgh, 1644). He was a partial historian, and his account can only be accepted with caution. Modern authorities are Sir William Eraser, *The Douglas Book* (4 vols., Edinburgh, 1885), and Sir H. Maxwell, *History of the House of Douglas* (2 vols., 1902). *See* also G. *E.* C(okayne)'s *Peerage*, and Douglas's *Scots Peerage; Calendar of State Papers, Scottish Series, The Hamilton Papers*, etc.

DOUGLAS, SIR CHARLES WHITTINGHAM HORSLEY (1850–1914), British general, was born on July 17, 1850, at the Cape of Good Hope. Entering the army when 19, he saw service with the 92nd Highlanders in the Afghan War of 1879–80, in the Boer War of 1881, in the Sudan campaign of 1884 and in the South African War of 1899–1901. In 1895 he had been made deputy assistant adjutant-general at Aldershot; in 1898 he became a colonel; in 1904 adjutant-general at the War Office and member of the new Army Council; in 1909 general officer commanding-in-chief, southern command; in 1910 full general; 1912 inspector-general, home forces, and in 1914 chief of the Imperial General Staff. Up to the time of his death on Oct. 25, 1914, he assisted Kitchener at the War Office.

DOUGLAS, DAVID (1798–1834), Scottish botanist, was born at Scone, Perthshire. After being a gardener at the botanical gardens of Glasgow, he went to Oregon in 1823 as a collector to the Royal Horticultural Society, in 1825 pushing on to British Columbia where he discovered many new plants, trees and birds, and in 1827 reaching Hudson Bay. Two years later he was sent

to California and the Fraser river. He died in the Sandwich islands on July 12, 1834. Douglas introduced into Britain many trees, shrubs and plants and gave his name to the Douglas spruce.

DOUGLAS, GAVIN (1474?–1522), Scottish poet and bishop, third son of Archibald, 5th earl of Angus (called the "great earl of Angus" and "Bell-the-Cat"), was born c. 1474, probably at one of his father's seats. He was a student at St. Andrews, 1489–94, and thereafter it is supposed at Paris. In 1496 he obtained the living of Monymusk, Aberdeenshire, and later he became parson of Lynton (mod. Linton) and rector of Hauch (*mod* Prestonkirk), in East Lothian; and about 1501 was preferred to the deanery or provostship of the collegiate church of St. Giles, Edinburgh, which he held with his parochial charges. From this date till the battle of Flodden, in Sept. 1513, he appears to have been occupied with his ecclesiastical duties and literary work. Indeed all the extant writings by which he has earned his place as a poet and translator belong to this period. After the disaster at Flodden he was completely absorbed in public business. Three weeks after the battle he, still provost of St. Giles, was admitted a burgess of Edinburgh, his father, the "Great Earl," being then civil provost of the capital. The latter dying soon afterwards (Jan. 1514) in Wigtownshire, where he had gone as justiciar, and his son having been killed at Flodden, the succession fell to Gavin's nephew Archibald (6th earl). The marriage of this youth to James IV.'s widow on Aug. 6, 1514 did much to identify the Douglases with the English party in Scotland, as against the French party led by Albany, and incidentally to determine the political career of his uncle Gavin. During the first weeks of the queen's sorrow after the battle, Gavin, with one or two colleagues of the council, acted as personal adviser, and it may be taken for granted that he supported the pretensions of the young earl. The first outcome of the new connection was his appointment to the abbacy of Aberbrothock by the queen regent, before her marriage, probably in June 1514. Soon after the marriage she nominated him archbishop of St. Andrews, in succession to Elphinstone, archbishop-designate. But Hepburn, prior of St. Andrews, having obtained the vote of the chapter expelled him, and was himself in turn expelled by Forman, bishop of Moray, who had been nominated by the pope. In the interval, Douglas's rights in Aberbrothock had been transferred to James Beaton, archbishop of Glasgow. The breach between the queen's party and Albany's had widened, and the queen's advisers had begun an intrigue with England, for the removal of the royal widow and her young son to Henry's court. In those deliberations Gavin Douglas took an active part, and for this reason stimulated the opposition which successfully thwarted his preferment.

In Jan. 1515 on the death of George Brown, bishop of Dunkeld, the queen nominated him to the see, which he ultimately obtained, though not without trouble. For the earl of Athole had forced his brother, Andrew Stewart, prebendary of Craig, upon the chapter, and had put him in possession of the bishop's palace. The queen appealed to the pope and was seconded by Henry VIII., and the pope's sanction was obtained on Feb. 18, 1515. Some of the correspondence of Douglas and his friends incident to this transaction was intercepted. When Albany came from France and assumed the regency, these documents and the "purchase" of the bishopric from Rome contrary to statute were made the basis of an attack on Douglas, who was imprisoned in Edinburgh Castle, thereafter in the castle of St. Andrews (under the charge of his old opponent, Archbishop Hepburn), and later in the castle of Dunbar, and again in Edinburgh. The pope's intervention procured his release, after nearly a year's imprisonment. The queen meanwhile had retired to England. After July 1516 Douglas appears to have been in possession of his see, and to have patched up a diplomatic peace with Albany.

On May 17, 1517 the bishop of Dunkeld proceeded with Albany to France to conduct the negotiations which ended in the Treaty of Rouen. He was back in Scotland towards the end of June Albany's longer absence in France permitted the party-faction of the nobles to come to a head in a plot by the earl of Arran to seize the earl of Angus, the queen's husband. The issue of this plot was the well-known fight of "Clear-the-Causeway," in which Gavin Douglas's part stands out in picturesque relief. The triumph over the Hamiltons had an unsettling effect upon the earl of Angus. He made free of the queen's rents and abducted Lord Traquair's daughter. The queen set about to obtain a divorce, and used her influence for the return of Albany as a means of undoing her husband's power. Albany's arrival in Nov. 1521, with a large body of French men-at-arms, compelled Angus, with the bishop and others, to flee to the Borders. From this retreat Gavin Douglas was sent by the earl to the English court, to ask for aid against the French party and against the queen, who was reported to be the mistress of the regent. Meanwhile he was deprived of his bishopric, and forced, for safety, to remain in England, where he effected nothing in the interests of his nephew. The declaration of war by England against Scotland, in answer to the recent Franco-Scottish negotiations, prevented his return. His case was further complicated by the libellous animosity of Beaton, archbishop of St. Andrews (whose life he had saved in the "Clear-the-Causeway" incident), who was anxious to thwart his election to the archbishopric of St. Andrews, now vacant by the death of Forman. In 1522 Douglas was stricken by the plague which raged in London, and died at the house of his friend Lord Dacre. During the closing years of exile he was on intimate terms with the historian Polydore Vergil, and one of his last acts was to arrange to give Polydore a corrected version of Major's account of Scottish affairs. Douglas was buried in the church of the Savoy, where a monumental brass (removed from its proper site after the fire in 1864) still records his death and interment.

Douglas's literary work, now his chief claim to be remembered, belongs, as has been stated, to the period 1501–13, when he was provost of St. Giles. He left four poems.

1. The *Palice* of *Honour,* his earliest work, is a piece of the later type of dream-allegory, extending to over 2,000 lines in nine-lined stanzas. The poem carries on the literary traditions of the courts of love, as shown especially in the "Romaunt of the Rose" and "The House of Fame." It is dedicated to James IV. No ms. of the poem is extant. The earliest known edition (c. 1553) was printed at London by William Copland; an Edinburgh edition, from the press of Henry Charteris, followed in 1579.

2. King Hart described King Heart in his castle, surrounded by his five servitors (the senses), Queen Plesance, Foresight and other courtiers. The poem runs to over goo lines and is written in eight-lined stanzas. The text is preserved in the Maitland folio ms. in the Pepysian library, Cambridge. It is not known to have been printed before 1786, when it appeared in Pinkerton's Ancient Scottish Poems.

3. Conscience is in four seven-lined stanzas. Its subject is the "conceit" that men first clipped away the "con" from "conscience" and left "science" and "na mair." Then they lost "sci," and had nothing but "ens" ("that schrew, Riches and geir").

4. Douglas's longest, last, and in some respects most important work is his translation of the Aeneid, the first version of a great classic poet in any English dialect. The work includes the 13th book by Mapheus Vegius; and each of the 13 books is introduced by a prologue. The subjects and styles of these prologues show great variety; some have little or no connection with the books which they introduce, and were perhaps written earlier and for other purposes. In the first, or general, prologue, Douglas attacks Caxton for his inadequate rendering of a French translation of the Aeneid. That Douglas undertook this work and that he makes a plea for more accurate scholarship in the translation have been the basis of a prevalent notion that he is a Humanist in spirit and the first exponent of Renaissance doctrine in Scottish literature. Careful study of the text will not support this view. Douglas is in all important respects even more of a medievalist than his contemporaries; and, like Henryson and Dunbar, strictly a member of the allegorical school and a follower, in the most generous way, of Chaucer's art. There are several early mss. of the *Aeneid* extant: (a) in the library of Trinity College. Cambridge, *c.* 1525, (b) the Elphynstoun ms. in the library of the University of Edinburgh, c. 152j, (c) the Ruthven ms. in the same collection, c. 1535, (d) in the library of Lambeth Palace, 1545–46. The first printed edition appeared in London in 1j53. An Edinburgh edition was

issued from the press of Thomas Ruddiman in 1710.

For Douglas's career *see*, in addition to the public records and general histories, Bishop Sage's *Life* in Ruddiman's edition, and that by John Small in the first volume of his edition of the *Works of Gavin Douglas* (4 vols., 1874, the only collected edition of Douglas's works). A new edition of the texts is much to be desired. On Douglas's place in Scottish literature see SCOTLAND: SCOTTISH LITERATURE, also G. Gregory Smith's *Transition Period* (1900) and chapters in the *Cambridge History of English Literature*, vol. ii. (1908). P. Lange's dissertation *Chaucer's Einfluss auf die Originaldichtungen des Schotten Gavin Douglas* (Halle, 1882) draws attention to Douglas's indebtedness to Chaucer. Further discussion of the question of Douglas's alleged Humanism will be found in Courthope's *History of English Poetry*, i. (1895), T. F. Henderson's *Scottish Vernacular Literature* (1898), and J. H. Millar's *Literary History of Scotland* (1903). For the language of the poems *see* G. Gregory Smith's *Specimens of Middle Scots* (1902). (G. G. S.)

DOUGLAS, SIR HOWARD, BART. (1776–1861), British general, younger son of Admiral Sir Charles Douglas, was born at Gosport in 1776. He was commissioned second lieutenant in the Royal Artillery in 1794. In 1795 he was shipwrecked while in charge of a draft for Canada, and lived with his men for a whole winter on the Labrador coast. In 1804 he was placed in charge of the senior department of the R.M.C. at High Wycombe, the forerunner of the Staff College. Douglas served in 1808–09 and again in 1812 in the Peninsula, but was recalled to the Royal Military College. In 1816 appeared his *Essay on the Principles and Construction of Military Bridges* (subsequent editions 1832, 1853); in 1819, *Observations on the Motives, Errors and Tendency of M. Carnot's System of Defence*, and in 1820 his *Treatise on Naval Gunnery*, which became a standard text-book, and indeed first drew attention to the subject of which it treated. From 1823 to 1831 Sir Howard Douglas was governor of New Brunswick, and had to deal with the Maine boundary dispute of 1828. He also founded Fredericton college. On his return to Europe he published *Naval Evolutions*, a controversial work dealing with the question of "breaking the line" (1832). Douglas was lord high commissioner of the Ionian islands (1835–40), and sat in Parliament from 1842 to 1847. His later works included *Observations on the Modern System of Fortification, etc.* (1859) and *Naval Warfare Under Steam* (1858 and 1860). He died on Nov. 9, 1861, at Tunbridge Wells. Douglas was a F.R.S., one of the founders of the R.G.S., and held many honours. He was created full general in 1851.

See S. W. Fullom, *Life of Sir Howard Douglas* (1862), and *Gentleman's Magazine*, 3rd series, xii. 90–92.

DOUGLAS, SIR JAMES (1803–1877), Canadian administrator, was born on June 5, 1803, in Lanarkshire, Scotland, where he was educated. In 1820 he went to Canada, and four years later became the organizer of the property of the Hudson's Bay company west of the Rockies. In 1830 he was transferred to Ft. Vancouver in the Oregon Territory, where he extended the company's forts. In 1843 he made Camosun, the place where Victoria now stands, the chief northern centre of the fur trade. After the north-west Boundary Treaty of 1846, which moved the British frontier back to the 49th parallel, Douglas was appointed senior officer of the western department, and in 1851 became governor of Vancouver. In 1859 his statesmanship made possible the joint occupation of the island of San Juan by an equal number of British and American troops. When British Columbia was made a Crown colony in 1858, Sir James Douglas held its governorship with that of Vancouver until 1863. He died at Victoria on Aug 1, 1877.

See Coats and Gosnell, *Sir James Douglas* (Makers of Canada Series, vol. ix., 1926).

DOUGLAS, SIR ROBERT KENNAWAY (1838–1913), English orientalist, was born in Devon. In 1858 he became attached to the Chinese Consular Service. Seven years later he returned to England and was made assistant in charge of the Chinese library in the British Museum and, in 1893, keeper of the Oriental books and manuscripts. He was also professor of Chinese in London. He died at Chippenham on May 20, 1913. His chief publications are *Life of Jenghiz Khan* (trans. from Chinese, 1877); *Confucianism and Taoism* (1879); *China* (1882); *Society in China* (1894); *Li Hung-Chang* (1895); and *Europe and the Far East* (1904).

DOUGLAS, STEPHEN ARNOLD (1813–1861), American political leader, was born in Brandon, Vt., on April 23, 1813. Left in infancy to the care of a widowed mother and a bachelor uncle, he became a cabinet-maker's apprentice in Middlebury and Brandon. He attended schools at Brandon and Canandaigua, N.Y., and began the study of law. In 1833 he went west and finally settled in Jacksonville, Ill., where he was admitted to the bar in March 1834. From the first he took an active interest in politics, and his rise was remarkably rapid. In Feb. 1835 he was elected public prosecutor of the first judicial circuit; in Dec. 1836 he became a member of the State legislature. In 1837 he was appointed by President Van Buren registrar of the land office at Springfield, which had just become the State capital. In 1840 he did much to carry the State for Van Buren; and for a few months he was secretary of State of Illinois. He was a judge of the supreme court of Illinois from 1841 to 1543. In 1843 he was elected to the national House of Representatives.

In Congress, though one of the youngest members, he at once sprang into prominence by his clever defence of Jackson for alleged contempt of court in New Orleans. He was soon recognized as one of the ablest and most energetic of the Democratic leaders. An enthusiastic believer in the destiny of his country and more especially of the West, and a thorough-going expansionist, he heartily favoured the measures which resulted in the annexation of Texas and in the Mexican War—in the discussion of the former foreshadowing his doctrine of "popular sovereignty." Taking an active share in the Oregon controversy, he opposed yielding "one inch" of the territory to Great Britain and advocated extending United States settlements under military protection. He was an advocate of the construction, by the aid of Government land grants, of a trans-continental railway, and the chief promoter (1850) of the Illinois Central. As chairman of the committee on territories, at first in the House, and then in the Senate, of which he became a member in Dec. 1847, he introduced the bills for admitting Texas, Florida, Iowa, Wisconsin, Minnesota, California and Oregon into the Union, and for organizing the Territories of Minnesota, Oregon, New Mexico, Utah, Washington, Kansas and Nebraska.

In the bitter debates concerning the keenly disputed question of slavery in the Territories, Douglas was particularly prominent. Against slavery itself he seems never to have had any moral antipathy; and his first wife and children were by inheritance the owners of slaves, though he himself never was. He did more, probably, than any other one man, except Henry Clay, to secure the adoption of the Compromise Measures of 1850. Nevertheless the bill for organizing the Territories of Kansas and Nebraska, which Douglas reported in Jan., 1854, and which in amended form was signed by the president on May 30, reopened the whole slavery dispute—wantonly, his enemies charged, for the purpose of securing Southern support—and caused great popular excitement. It repealed the Missouri Compromise, and declared the people of "any State or Territory" "free to form and regulate their domestic institutions in their own way, subject only to the Constitution of the United States"; that is, "popular sovereignty" or "squatter sovereignty" would determine the admission of slavery. The passage of this Kansas-Nebraska bill, one of the most momentous in its consequences ever passed by the Federai Congress, was largely a personal triumph for Douglas, who showed marvelous energy, adroitness and resourcefulness, and a genius for leadership, but was universally condemned in the free States. His hostility to "knownothingism" and his plea for religious toleration also caused him trouble, but in 1852 and again in 1856 he was a strong candidate for the presidential nomination in the National Democratic Convention.

In 1857 he broke with President Buchanan and the "administration" Democrats and lost much of his prestige in the South, but partially restored himself to favour in the North, and especially in Illinois, by his vigorous opposition to the method of voting on the Lecompton constitution, which he maintained to be fraudulent, and (in 1858) to the admission of Kansas into the Union under this constitution. In 1858, when the Supreme Court, after

the vote of Kansas against the Lecompton constitution, had decided that Kansas was a "slave" territory, thus quashing Douglas's theory of "popular sovereignty," he engaged in Illinois in a close contest for the senatorship with Abraham Lincoln, the Republican candidate, whom he met in a series of debates. Although in Illinois his followers did not poll so large a vote as Lincoln's, Douglas won the senatorship by a vote in the legislature of 54 to 46. In the senate he was not reappointed chairman of the committee on territories.

In 1860, in the Democratic national convention in Charleston, the adoption of Douglas's platform brought about the withdrawal from the convention of Alabama, Mississippi, Louisiana, South Carolina, Florida, Texas and Arkansas. The convention adjourned to Ealtimore, where the Virginia, North Carolina, Tennessee, Kentucky and Maryland delegations left it, and where Douglas was nominated for the presidency by the northern Democrats. He campaigned vigorously but hopelessly, boldly attacking disunion, and in the election, though his popular vote was 1,376,957, he received an electoral vote of only 12, against Lincoln's 180. Douglas urged the south to acquiesce in Lincoln's election, and he and his second wife, Adèle Cutts, were among the foremost to welcome the Lincolns to Washington. On the outbreak of the Civil War he denounced secession as criminal! and was one of the strongest advocates of maintaining the integrity of the union at all hazards. At Lincoln's request he undertook a mission to the border states and the northwest to rouse the spirit of unionism; he spoke in West Virginia, Ohio and Illinois. He died on June 3,1861, at Chicago, where he was buried on the shore of Lake Michigan.

In person Douglas was conspicuously small, being hardly five feet in height, but his large head and massive chest and shoulders gave him the popular sobriquet "The Little Giant." As a resourceful political leader, and an adroit, ready, skilful tactician in debate, he has had few equals in American history. His generosity in defeat, his courage and his capacity for inspiring warm personal friendships are among his most attractive qualities. It was regretted that his death came just when a new and great era of usefulness seemed opening before him.

One of the most sympathetic biographies is that by Allen Johnson (1908). Other biographies are by H. M. Flint (1860); J. W. Sheahan (1860); W. G. Broun (1902); Wm. Gardner (1905); C. E. Carr (1909); H. P. Willis (1910); and Louis Howland (1920). See also P. O. Ray, Repeal of *the* Missouri *Compromise* (1900), and an autobiographical sketch in the 111. State Hist. Soc. Journal (vol. v, Oct., 1912).

DOUGLAS, capital of the Isle of Man, municipal borough and favourite watering place. Pop. (1939) 20,014. Area, 1.9 sq.mi. It stands on a fine semicircular bay on the east coast of the island, at the common mouth of two streams, the Dhoo and Glass, 54 mi. W.N.W. of Fleetwood, and 70 mi. N.W. of Liverpool. The older streets are irregular and narrow, but the town has greatly extended in modern times, with numerous terraces of good dwelling houses. A fine parade sweeps round the bay, which, from Derby castle (north) to Douglas Head (south), has a circuit exceeding 2 mi. Low hills, penetrated by the valleys of the Dhoo and Glass, encircle the town on the north, west and south, the southern spur forming Douglas Head. The harbour, in the river mouth, lies immediately north of this; vessels drawing g ft. may enter it during neap tides, and those drawing 13 ft. during spring tides. A castellated building (Tower of Refuge, 1832), marks the dangerous Conister rocks, north of the harbour entrance. The harbour is protected by three piers, the Battery pier, the Red pier and the Victoria pier (at which passengers can load and embark at all tides). There is regular daily communication with Liverpool, and during the season there are connections with Fleetwood, Heysham, Barrow, Dublin, Belfast and Glasgow. Douglas is connected by electric tramway northward with Laxey, the summit of the mountain of Snaefell and Ramsey, and southward with Port Soderick; while the Isle of Man railway runs to Peel in the west, and Castletown and Port Erin in the southwest. The various popular attractions include theatres, dancing halls, a racecourse and two golf links. The shore of the bay is of firm sand, and the sea bathing is good. Among buildings and institutions are the legislative buildings (1893), the town hall (1899), the free library, the courthouse and the Isle of Man hospital. St. George's church, oldest in Douglas, dates from 1780. Douglas was incorporated in 1895.

DOUGLAS, village and parish, Lanarkshire, Scotland. Pop. (1931) 2,948. It is on Douglas water, 4 mi. from Douglas station and 1¼ mi. from Douglas West station, on the branch line of the L.M.S.R. from Carstairs to Ayr, S.S.W. of Lanark. It is the original home of the Douglas family. Of the old castle, Scott's Castle Dangerous, only a tower exists; it repeatedly changed hands during the wars of Edward I. The modern castle is the seat of the earl of Home. Only choir and spire remain of the 12th-century church of St. Bride, patron saint of the Douglases. The vault beneath the choir was, until 1761, the burial place of the family, and it contains a silver case said to hold the ashes of the heart of the "good Sir James" (1286–1330). In 1879 the choir was restored and the tombs (including that of Sir James Douglas) repaired. On the hill of Auchensaugh, 2½ mi. S.E., the Cameronians assembled in 1712 to renew the Solemn League and Covenant.

DOUGLAS, a city of Cochise county, Arizona, U.S.A., 25 mi. S.E. of Bisbee, on the Mexican border line. It is on federal highway 80 and the Southern Pacific railway. The population was 9,916 in 1920 (29% foreign-born white), and it was 8,623 in 1940 by the federal census. Cattle raising and copper-smelting are the main occupations of this part of Arizona, and the Sonora mining region of Mexico lies directly south. The city has immense copper smelters, to which carloads of ore are brought daily from the mines at Bisbee and other points in Arizona and in Mexico. There is a U.S. army post (Camp Harry J. Jones) at Douglas. The Coronado national forest, within which is the Chiricahua national monument, is 55 mi. north. Douglas was settled about 1904 and incorporated as a city in 1905.

DOUGLAS-FIR (Pseudotsuga *taxifolia*), an important North American timber tree of the pine family (Pinaceae), called also red-fir, yellow-fir and Douglas-spruce. Botanically it exhibits some of the characteristics of the firs and the hemlock, although it most closely resembles the spruces. It is found from South Dakota to British Columbia and southward to Texas and Mexico, but attains its maximum development in Washington and Oregon, where it forms immense forests, furnishing the valuable structural timber known also in the lumber trade as yellow-fir, Oregon-fir or Oregon-pine. In the forests of Washington it commonly reaches a height of 180 ft. or 190 ft. with a trunk diameter of 3½ ft. to 6 ft. and sometimes attains a height of 250 ft. and a trunk diameter of 10 ft. or 12 ft. Among North American trees it is exceeded in height and massiveness only by the giant sequoias of California. According to the U.S. department of agriculture, the lumber cut of Douglas-fir in 1940 amounted to 7,121.-000,000 bd.ft., with a value at the mill exceeding $140,000,000, in footage more than one-fourth of the total lumber cut of the United States during that year. Of this production of Douglas-fir lumber the states of Washington and Oregon contributed more than 90%. The closely related bigcone-spruce (P. *macrocarpa*), a much smaller tree, native to southern California, with large cones sometimes 3 in. thick and 7 in. long, hanging from the widely spreading branches, is of value chiefly as cover on arid mountain slopes. (E. S. HR.)

DOUGLASS, FREDERICK (1817–1895), American orator and journalist, was born in Tuckahoe, Md., probably in Feb. 1817. His mother was a Negro slave of exceptional intelligence, and his father was a white man. Until nearly eight years of age, he was under the care of his grandmother; then he lived for a year on the plantation of Col. Edward Lloyd, of whose vast estate his master, Capt. Aaron Anthony, was manager. After a year he was sent to Baltimore, where he lived in the family of Hugh Auld, whose brother, Thomas, had married the daughter of Capt. Anthony; Mrs. Auld treated him with marked kindness and without her husband's knowledge began teaching him to read. With money secretly earned by blacking boots he purchased his first book, *The Columbian Orator;* he soon learned to write "free passes" for runaway slaves Upon the death of Capt. Anthony in 1833, he was sent back to the plantation to serve Thomas Auld, who hired him out for a year to one Edward Covey, who had a

wide reputation for disciplining slaves, but who did not break Frederick's spirit. Although a new master, William Freeland, who owned a large plantation near St. Michael's, Md., treated him with much kindness, he attempted to escape in 1836, but his plans were suspected, and he was put in gaol. From lack of evidence he was soon released, and was then sent to Hugh Auld in Baltimore, where he was apprenticed as a ship caulker. He learned his trade in one year, and in Sept. 1838, masquerading as a sailor, he escaped by railway train from Baltimore to New York city. For the sake of greater safety he soon removed to New Bedford, Mass., where he changed his name from Frederick Augustus Washington Bailey to Frederick Douglass, "Douglass" being adopted at the suggestion of a friend who greatly admired Scott's *Lady of the Lake*. For three years he worked as a day labourer in New Bedford. An extempore speech made by him before an anti-slavery meeting at Nantucket, Mass., in Aug. 1841 led to his being appointed one of the agents of the Massachusetts Anti-Slavery Society, and in this capacity he delivered during the next four years numerous addresses against slavery, chiefly in the New England and middle states. To quiet the suspicion that he was an impostor, in 1845 he published the *Narrative of the Life of Frederick Douglass, an American Slave*. Fearing his recapture, his friends persuaded him to go to England, and in 1845–47 he lectured in Ireland, Scotland and England, and did much to enlist the sympathy of the British public with the Abolitionists in America. Before his return a sum of £150 was raised by subscription to secure his legal manumission, thus relieving him from the fear of being returned to slavery in pursuance of the Fugitive Slave law. From 1847 to 1860 he conducted an anti-slavery weekly journal, known as *The North Star*, and later as *Frederick Douglass's Paper*, at Rochester, N.Y., and, during this time, also was a frequent speaker at anti-slavery meetings. At first a follower of Garrison and a disunionist, he allied himself after 1851 with the more conservative political abolitionists, who, under the leadership of James G. Birney, adhered to the national Constitution and endeavoured to make slavery a dominant political issue. He disapproved of John Brown's attack upon Harper's Ferry in 1859, and declined to take any part in it. During the Civil War he was among the first to suggest the employment of negro troops by the United States Government, and two of his sons served in the Union army. After the war he was for several years a popular public lecturer. In 1871 he was assistant secretary of the Santo Domingo commission, appointed by President Grant. He was marshal of the District of Columbia in 1877–81, was recorder of deeds for the district in 1881–86, and from 1889 to 1891 was the American minister resident and consul-general in the Republic of Haiti. Douglass was widely known for his eloquence, and was one of the most eifective orators whom the negro race has produced in America. He died in Anacostia Heights, D.C., on Feb. 20, 1895.

His autobiography appeared, after two revisions, as *The Life and Times of Frederick Douglass* (1882). *See* F. M. Holland, *Frederick Douglass, the Colored Orator* (1891); *C. W.* Chesnutt, *Frederick Douglass* (Boston, 1899); and Booker T. Washington, *Frederick Douglass* (Philadelphia, 1907), in the series of American Crisis Biographies.

DOUKHOBORS, a name given by the Russian Orthodox clergy to a community of nonconformist peasants. The word signifies "spirit-fighters," and was intended by the priesthood to convey that they fight against the Spirit of God; but the Doukhobors themselves accepted it as signifying that they fight, not against, but for and with the Spirit, though later they decided to give up this name and call themselves "Christians of the Universal Brotherhood." The community was first heard of in the middle of the 18th century; by the beginning of the 19th their doctrine had become so clearly defined, and the number of their members had so greatly increased, that the Russian government and Church, considering the sect to be peculiarly obnoxious, started an energetic campaign against it. The foundation of the Doukhobors' teaching consists in the belief that the Spirit of God is present in the soul of man, and directs him by its word within him. They understand the coming of Christ in the flesh, His works, teaching and sufferings, in a spiritual sense. The object of the sufferings of Christ, in their view, was to give an example of suffering for truth. Christ continues to suffer in us even now when we do not live in accordance with the behests and spirit of His teaching. The whole teaching of the Doukhobors is penetrated with the Gospel spirit of love; worshipping God in the spirit, they affirm that the outward Church and all that is performed in it and concerns it has no importance for them; the Church is where two or three are gathered together, *i.e.*, united in the name of Christ. They pray inwardly at all times; an fixed days they assemble for prayer-meetings, at which they greet each other fraternally with low bows, thereby acknowledging every man as a bearer of the Divine Spirit. Their teaching is founded on tradition, which is called among them the "Book of Life," because it lives in their memory and hearts. It consists of sacred songs or chants, partly composed independently, partly formed out of the contents of the Bible, which, however, has evidently been gathered by them orally, as until lately they were almost entirely illiterate and did not possess any written book. They found alike their mutual relations and their relations to other people and to all living creatures exclusively on love, and therefore they hold all people equal and brethren. They extend this idea of equality also to the government authorities, obedience to whom they do not consider binding upon them in those cases when the demands of these authorities are in conflict with their conscience; while in all that does not infringe what they regard as the will of God they willingly fulfil the desire of the authorities. They consider killing, violence, and in general all relations to living beings not based on love as opposed to their conscience and to the will of God. They are industrious and abstemious in their lives, and when living up to the standard of their faith present one of the nearest approaches to the realization of the Christian ideal which has ever been attained. In many ways they have a close resemblance to the Quakers.

For these beliefs and practices the Doukhobors long endured cruel persecution. Under Nicholas I., in 1840 and 1850, when, on religious grounds, they refused to participate in military service, they were banished from the government of Tauris — whither they had been previously deported from various parts of Russia by Alexander I. — to Transcaucasia, near the Turkish frontier. But neither the severe climate nor the neighbourhood of wild and warlike hillmen shook their faith, and in the course of half a century, in one of the most unhealthy and unfertile localities in the Caucasus, they transformed a wilderness into flourishing colonies, and continued to live a Christian and laborious life, making friends with, instead of fighting, the hillmen. But the wealth to which they attained in the Caucasus weakened for a time their moral fervour, and little by little they began to depart somewhat from the requirements of their belief. As soon, however, as events happened among them which disturbed their outward tranquillity, the religious spirit which had guided their fathers immediately revived within them. In 1887, in the reign of Alexander III., universal military service was introduced in the Caucasus; and even those for whom, as in the case of the Doukhobors, it had formerly been replaced with banishment, were called upon to serve. This measure took the Doukhobors unawares, and at first they outwardly submitted to it. About the same time, by the decision of certain government officials, the right to the possession of the public property of the Doukhobors (valued at about £50,000) passed from the community to one of their members, who had formed out of the more demoralized Doukhobors a group of his own personal adherents, which was henceforth called the "Small Party." Soon afterwards several of the most respected representatives of the community were banished to the government of Archangel. This series of calamities was accepted by the Doukhobors as a punishment from God, and a spiritual awakening of a most energetic character ensued. The majority (about 12,000) resolved to revive in practice the traditions left them by their fathers, which they had departed from during the period of opulence. They again renounced tobacco, wine, meat and every kind of excess, many of them dividing up all their property in order to supply the needs of those who were in want, and they collected a new public fund. They also renounced all participation in acts of violence, and therefore refused military service. In confirmation of their sincerity, in the summer of 1895 the Doukhobors of the

"Great Party," as they were called in distinction from the "Small Party," burnt all the arms which they, like other inhabitants of the Caucasus, had taken up for their protection from wild animals, and those who were in the army refused to continue service. At the commencement of the reign of Nicholas II., in 1895, the Doukhobors became the victims of a series of persecutions, Cossack soldiers plundering, insulting, beating and maltreating both men and women in every way. More than 400 families living in the province of Tiflis were ruined and banished to Georgian villages; of 4,000 thus exiled, over 1,000 died in the course of the first t o years from exhaustion and disease; and more would have perished had not information reached Tolstoy, and through him the Society of Friends in England, and funds were immediately raised for alleviating their sufferings. At the same time an appeal, written by Tolstoy and some of his friends, requesting the help of public opinion in favour of the oppressed Doukhobors, was circulated in St. Petersburg and sent to the emperor and higher government officials. The Doukhobors themselves asked for permission to emigrate, and the Society of Friends petitioned the emperor to the same effect. In March 1898 the desired permission was granted, and the first party (1,126) in the summer were able to sail for Cyprus, which was originally chosen for their settlement because at that time funds were not sufficient for transferring them to any other British territory. Later it was found possible to send two parties of over 4,000 to Canada, whither they arrived in Jan. 1899. They were joined in the spring of the same year by the Cyprus party, and some 2,000 from the Caucasus, and in all about 7,500 Doukhobor immigrants arrived in Canada, the government allotting them land in the provinces of Assiniboia near Yorktown and of Saskatchewan near Thunder Hill and Prince Albert. They were very cordially received by the population of the Canadian port towns. In April 1901, in the Canadian House of Commons. the minister of justice made a statement about them in which he said that "not a single offence had been committed by the Doukhobors; they were law-abiding, and if good conduct was a recommendation, they were good immigrants. . . . The large tracts of land demanded population, and if they were not given to crime, the conclusion was that they would make good citizens" Nevertheless the Canadian government has had difficulties with the sect owing to their objection to acknowledge any allegiance except to their leader Verigin, who, however, proved himself an eminently practical man.

See V. Tchertkoff, *Christian Martyrdom in Russia (1897)*; Aylmer Maude, *A Peculiar People (N.Y.,* 1904); and reff. in article "Doukhobors," by **A. A.** Stambouli, in Hastings, *Encyclopaedia of Religion and Ethics.*

DOULLENS, a town of northern France, capital of an arrondissement in the department of Somme, on the Authie, 27 mi. N. of Amiens by rail. Pop. (1936) 4,429. Doullens, the ancient *Dulincum,* was an important stronghold in the middle ages. In 1475 it was burnt by Louis XI. for openly siding with the house of Burgundy. In 1595 it was besieged and occupied by the Spaniards, but was restored to France by the treaty of Vervins (1598). It was an important British centre in the war of 1914–18. It has a citadel of the 15th and 16th centuries, now a girls' school. The old hôtel de ville has a fine belfry and dates from the 15th to the 17th century. The town is the seat of a subprefect and has a tribunal of first instance; it has trade in phosphates, of which there are workings in the vicinity, and carries on cotton-spinning and the manufacture of leather and paper.

DOULTON, SIR HENRY (1820–1897), English inventor and manufacturer of pottery, was born in Vauxhall on July 25, 1820, and died in London on Nov. 18, 1897. From the age of 15 he was employed in the pottery works of his father, John Doulton, at Lambeth. One of the first results of his experiments was the production of good enamel glazes. In 1846 he initiated in Lambeth the pipe works for the manufacture of the drainage and sanitary appliances which have helped to make the firm of Doulton famous. In 1870 the manufacture of "Art pottery" was begun at Lambeth, and in 1877 works were opened at Burslem, and later at Rowley Regis, Smethwick, St. Helens, Paisley and Paris. After the Paris exhibition of 1878 Henry Doulton was made a chevalier of the Legion of Honour. In 1872 the "Art department" was instituted in the Doulton works, giving employment to both male and female artists, amongst whom George Tinworth and the Misses Barlow obtained a reputation outside their immediate sphere. In 1885 Doulton was awarded the Albert medal by the Society of Arts, and was knighted in 1887.

DOUMER, PAUL (1857–1932), French statesman, was born at Aurillac on March 22, 1857, and entered the Chamber of Deputies in 1888. As minister of finance in the Bourgeois cabinet (Nov. 3, 1895, to April 21, 1896), he tried without success to introduce an income-tax. In Jan. 1897 he became governor of Indo-China, where he carried out important public works. In 1902 he returned to France and to the Chamber of Deputies. He refused to support the Combes ministry, and formed a Radical dissident group, which eventually caused the fall of the ministry. Doumer was elected president of the chamber in Jan. 1905, being re-elected in Jan. 1906. Senator in 1921, he was minister without portfolio in the Painlevé Government, and in 1921–22 and 1925–26 was minister of finance. In 1932, shortly after his election as president of the Republic, he was assassinated by a Russian. Doumer wrote *L'Indo-Chine française* (1903).

DOUMERGUE, GASTON (1863–1937), 12th president of the Third French Republic, was born at Aigues-Vives on Aug. 1, 1863, and was educated at the Lycée at Nimes. He studied law, became a barrister, and, after holding magisterial appointments in Cochin China and Algiers, was elected deputy for Nimes in 1893. In the Chamber he spoke with authority on colonial questions and was minister for the colonies in the Combes Government, 1902–05, being elected vice-president of the Chamber when this administration fell. In 1936 he was minister of commerce in the Sarrien cabinet, retaining his portfolio in the succeeding Clemenceau Government. When M. Clemenceau reconstituted his cabinet, M. Doumergue became minister of education and held the same post in the Briand ministry (July 1909 to Nov. 1910). In the latter year he became senator for the Gard Department and strongly advocated the Three Years' Military Service Bill.

On the fall of M. Barthou's administration in Dec. 1913, M. Doumergue formed a cabinet in which he himself took charge of foreign affairs. He was forced to resign, however, after the general elections of May 1914, which resulted in a majority in the Chamber opposed to the Three Years' Military Service law. On the outbreak of the World War he again became minister for the colonies in the Viviani Government of national defence. In 1917 he left the Government, and was sent on a mission of inquiry into conditions in Russia. On his return he re-entered the senate. After the resignation of M. Léon Bourgeois on Feb. 22, 1923, M. Doumergue was elected to succeed him as president of the senate. He supported the policy of M. Poincaré with regard to Germany and the Ruhr. On June 13, 1924, he was elected president, and remained in office until 1931 He was prime minister of a National Government from February to November, 1934.

DOUMIC, RENÉ (1860–1937), French critic and Academician. was born in Paris, and after a distinguished career at the École Normale began to teach rhetoric at the Collège Stanislas. He was a contributor to the *Moniteur,* the *Journal des Débats* and the *Revue bleue,* but was best known as the independent and uncompromising literary critic of the *Revue des Deux Mondes.* Many of his critical essays are reprinted in *Etudes sur la littérature française* (5 vols. 1896–1905); *Les Hommes et les idées du XIX^e siècle* (1903), etc. He died in Paris, Dec. 2, 1937.

DOUNE, police burgh, Perthshire, Scotland, $8\frac{3}{4}$ m. N.W. of Stirling by the L.M.S.R. Pop. (1931) 822. It is on the left bank of the Teith, here crossed by the bridge built in 1535 by Robert Spittal, tailor to James IV. The town was once famous for pistols and sporrans. Doune castle, in a commanding position on the Teith, is believed to have been built by Murdoch, 2nd duke of Albany (d. 1425). A nephew of Rob Roy held it for Prince Charlie, and it figures in Scott's *Waverley.* It belongs to the earl of Moray (Murray). The braes of Doune lie to the north-west of the town and extend towards Uam Var. Deanston, 1 m. S.W. of Doune, on the right bank of the Teith, has cotton mills, and was the scene of James Smith's (1789–1850) agricultural experi-

ments in deep ploughing and machine-design.

DOURO (Span. *Duero*, Port. *Douro*, anc. *Durius*), a river of the Iberian peninsula. The Douro rises south of the Sierra de la Demanda in the Pico de Urbion, an isolated mass 7,389 ft. high. It curves past Soria and then flows westward across Old Castile. It passes south of Valladolid and proceeds westward to the Portuguese frontier. The numerous tributaries have been most important influences in the growth of Castile's power in the middle ages. The northern tributaries, especially the Pisuerga, Valderaduey and Esla, come from the region of heavy rainfall. The tributaries from the south, of which the Adaja, Tormes and Yeltes are the most important, come from the drier Meseta.

From the great highland basin the Douro turns south-west, forming from a point east of Paradella to Barca d'Alva a section of the boundary between Spain and Portugal. This marked north-east to south-west line of the middle Douro has some relation to the general direction of the old mountain ribs of the Meseta. The river leaves the ancient plateau in a series of deep gorges in the difficult country of northern Portugal. In this country it receives the Aqueda, Côa and Paiva from the left, and the Sabor, Tua and Tamega from the right. The river enters the Atlantic 3 m. below Oporto at São Jõao da Foz. The probable length of the river is about 485 m., and the area of its basin upwards of 37,500 sq. miles. The rapids *(pontos)* and gorges of the Portuguese section of the river seriously impede navigation. The lower reaches of the river are also liable to heavy floods. The difficulty of navigation is compensated for by the railway that follows the valley through most of the Portuguese section. The mouth of the river is partly blocked by a sand-bar, which only allows small ships to enter. The large vessels have to be accommodated at Leixões, an artificial harbour to the north of the estuary. The Douro is the outlet for the important wine-producing region of the Paiz do Vinho. The Douro yields an abundance of fish.

DOURBUCOULI, the native name of a small group of American monkeys ranging from Nicaragua to Amazonia and eastern Peru, and forming the genus *Nyctipithecus*. In addition to the absence of prehensile power in their tails, douroucoulis are distinguished by their large eyes. The ears are short, and the hair round the eyes forms a disc. Douroucoulis live in parties, and are nocturnal. They feed on insects and fruit and, when excited, utter piercing screams.

DOUSA, JANUS (JAN VAN DER DOES), lord of Noordwyck (1545–1604), Dutch statesman and scholar, was born at Noordwyck on Dec. 6, 1545, and studied at Delft, Louvain, Douai and Paris. His name stood first on the list of nobles who in 1565 formed a league against Philip II. of Spain. He was living at Leyden at the time of the famous siege, and took a gallant and leading part in the defence against the Spaniards. William the Silent made him first curator of the new university in Leyden, a post which he held for nearly 30 years. After the assassination of William, Dousa went to England to persuade Queen Elizabeth to support the cause of the States. The rest of his life was devoted to literary work. His position of keeper of the State archives put within his reach the materials for his valuable *Annals of Holland*. He also wrote commentaries on Horace, Plautus and Catullus. He died at Noordwyck on Oct. 8, 1604.

DOUVILLE, JEAN BAPTISTE (1794?–1837), French traveller, was born at Hambye (Manche), and is said to have been murdered in 1837 on the banks of the São Francisco in Brazil. He received the gold medal of the Paris Société de Géographie for his *Voyage au Congo* (1832), but his account of his travels was proved to be fictitious and there is no evidence that he went beyond the coast. His narrative was based on unpublished Portuguese sources.

DOUW (or Dow), **GERRIT** (GERARD) (1613–1675), Dutch painter, was born at Leyden on April 7, 1613. His first instructor was Bartholomew Dolendo, an engraver; and he afterwards learned the art of glass-painting under Peter Couwenhorn. In 1628 he became a pupil of Rembrandt, from whom he acquired his skill in colouring, and in the more subtle effects of lighting; and the style of Rembrandt is reflected in several of his earlier pictures, notably in a portrait of himself at the age of 22, in the Bridgewater House gallery, London, and in the "Blind Tobit going to meet his Son," at Wardour castle, Wiltshire, England. His more mature manner was in some respects antagonistic to that of his master. He cultivated a minute treatment of his subjects, but notwithstanding his meticulous style, the general effect was harmonious and free from stiffness, and his colour was always admirably fresh and transparent. He was fond of representing subjects in lantern or candle light, the effects of which he reproduced with a fidelity and skill which no other master has equalled. He frequently painted by the aid of a concave mirror, and to obtain exactness looked at his subject through a frame crossed with squares of silk thread. His practice as a portrait painter, which was at first considerable, gradually declined, sitters being unwilling to give him the time that he thought necessary. His pictures were always small in size, and represented chiefly subjects in still life. Upwards of aoo are attributed to him, and specimens are to be found in most of the great public collections of Europe. Among his more famous works are: the "Woman sick of the Dropsy," in the Louvre, the "Evening School," in the Amsterdam gallery; the "Poulterer's Shop," and a portrait of himself in the National Gallery, London. Douw's pictures brought high prices, and it is said that President Van Spiring of The Hague paid him 1,000 florins a year simply for the right of pre-emption. Douw died in Leyden in Feb. 1675. His most celebrated pupil was Francis Mieris.

See W. Martin, ***Het leven en de werken van Gerrit Douw*** (1901).

DOVE, ALFRED (1844–1916), German historian, was born on April 4, 1844, in Berlin, and studied medicine and science at Heidelberg and Berlin. From 1870 he edited *Grenzboten* and then *Im Neuen Reich*. In 1874 he became professor of history at Breslau and in 1884 at Bonn. In 1890 he edited the *Sämtliche Werke* of von Ranke, whose posthumous manuscript completing the *Weltgeschichte* he had already published and in 1891 the final volumes of Bismarck's speeches. Dove also wrote *Deutsche Gesch. im Zeitalter Friedrichs des Grossen u. Joseph 11.* (1883); *Kaiser Wilhelms geschichtl. Gestalt* (1888); *Grossherzog Friedrich von Baden als Landesherr und deutscher Fürst* (1902). He died at Freiburg on Jan. 19, 1916.

DOVE, HEINRICH WILHELM (1803–1879), German meteorologist, was born at Leignitz, Silesia, on Oct. 6, 1803. He studied mathematics and physics at Berlin and Breslau. He was professor of physics at Konigsberg (1826–29), supplementary professor (1829–45), and finally, professor of physics at Berlin. He made an exhaustive and exact study of the distribution of temperature over the surface of the earth, giving many of his results in carefully drawn maps. This work has been of great importance to geographers and geologists. He also carried out a series of investigations on winds and phenomena allied with winds; he was considerably hampered in this work by the fact that the barometers in use at the time did not give reliable readings. Dove was a foreign member of the Royal Society. He died at Berlin on April 6, 1879. Among his publications were *Über Mass* und *Messen* (1835); *Meteorologisclze Untersuchungen* (1837); and *Klimatologische Beitriige* (1857–69).

See H. Newmann, ***H.*** W. *Dove* (1925).

DOVE, a river of England, tributary to the Trent, rising in Axe Edge, Derbyshire, and through almost its entire course forming the boundary of that county with Staffordshire. In its upper course it traverses a fine narrow valley, where the limestone hills exhibit many picturesque cliffs, gullies and caves. Dovedale, that part between Dove Holes and Thorpe Cloud, is especially famous. Below Thorpe Cloud the Dove receives on the west the Manifold, which, like its tributary, the Hamps, and other streams in the limestone district, has part of its course below ground. Near the village of Rocester the Churnet joins the Dove on the west, and then its course, hitherto southerly, bends nearly easterly on passing Uttoxeter, and, winding through a widening valley, joins the Trent below Burton-on-Trent at Newton Solney. The length of the valley is about 40 m. and the total fall of the river about 1,450 feet. The Dove is well known for trout-fishing, and Beresford Dale, below Hartington, has a special interest for fishermen through its associations with Izaak Walton and Charles Cotton, whose fishing-house stands near the Pike Pool.

DOVE, a name applied to the smaller members of the order Columbae, but no sharp distinction can be drawn between pigeons (*q.v.*) and doves.

The English ring-dove or wood-pigeon (*Columba palumbus*) is a common bird in most parts of Europe, where it is the largest species. It may be recognized by the large white patches on the wings and the white spot (sometimes absent, however) on either side of the neck, whence it gets its name. Its familiar cooing song is remarkable for its abrupt close. It makes a slight platform of slicks on the horizontal bough of a tree and thereon lays two white eggs. In the wild state, it is very wary and the flight is strong and rapid.

The stock-dove (C. aenus) is smaller and breeds in hollow trees or rabbit-holes. It is darker than the ring-dove, lacking the white on the wings and neck, and is locally distributed.

The rock-dove (C. *livia*) is the parent stock of our domestic pigeons. In the wild state it haunts the rocky coasts of Europe. Domestic pigeons have been classified by Darwin (Variation of *Animals* and Plants under *Domestication*) in four groups:

I. The "Pouters," having the gullet of great size, barely separated from the crop and capable of inflation.

II. Three races: (1) "Carriers," with a long bill and eyes surrounded by bare skin. (2) "Runts," with a long massive bill and large body. (3) "Barbs," with a short bill and bare skin round the eyes. There are numerous sub-races.

III. An artificial group, comprising five races: (1) "Fan-tails," whose tail may consist of 42 rectrices, instead of the normal 12. (2) "Turbits" and "Owls," with the feathers of the throat diverging and a short thick bill. **(3)** "Tumblers," which tumble backwards during flight. (4) "Frill-backs," in which the feathers are reversed. (5) "Jacobins," with the neck-feathers forming a hood.

IV. Resembling the normal form and including two races: (1) "Trumpeters," with a tuft of feathers at the base of the neck, curling forward, and a peculiar voice. (2) Pigeons scarcely differing from the wild stock.

The differences extend to every part of the body. Doves have from time immemorial been employed as messengers (*e.g.,* Gen. viii. 8–12).

The headquarters of the Columbidae are the Papuan sub-region (see PIGEON).

The turtle-dove of Europe (Turtur *auritus*) is a summer visitor to the northern parts of the Continent. The collared or Barbary dove (T. risorius) is distinguished by its cream-coloured plumage and black necklace.

In North America the name is given to the very widely distributed mourning dove (*Zenaidura* macroura); the white-fronted dove (Leptotila *fulviventris* brachyptera), from southern Texas to Guatemala; the Mexican ground dove (*Columbigallina passerina* pallescens), and the Inca dove (*Scardapella inca*) of Texas and Mexico.

DOVEKIE, the common name in North America for the little auk (*Alle alle*). (See AUK.) The name is applied by sailors to the black guillemot. (See GUILLEMOT.)

DOVER, GEORGE JAMES WELBORE AGARELLIS, BARON (1797–1833), English man of letters, was the only son of the 2nd Viscount Clifden. He secured the grant of £57,000 to purchase John Julius Angerstein's collection of pictures, which formed the foundation of the National Gallery. He was president (1832) of the Royal Society of Literature, a trustee of the British Museum and of the National Gallery, and a commissioner of public records.

Lord Dover edited the *Ellis* Correspondence (1829) and *Walpole's* Letters to Sir Horace Mnnn (1833), and he was the author of some historical works.

DOVER, ROBERT (1575–1641), English captain and attorney, is known as the founder and director for many years of the "Cotswold Games," which he originated as a protest against the growing Puritanism of the day. These sports, which were referred to by contemporary writers as "Mr. Robert Dover's Olimpick Games upon the Cotswold Hills," consisted of cudgel-playing, wrestling, running at the quintain, jumping. casting the bar and hammer, hand-ball, gymnastics, rural dances and games and horse-racing, the winners in which received valuable prizes. They continued from about the year 1604 until three years after the death of Dover, which took place in 1641. They were revived for a brief period in the reign of Charles II.

DOVER, a seaport and municipal borough in the Dover Parliamentary division of Kent, England, one of the Cinque Ports, 76 mi. E.S.E. of London by the Southern railway. Pop. (est. 1938) 39,950. Area, 5.7 sq.mi. It is situated at the mouth of a small stream, the Dour, whose valley here breaches the high chalk cliffs which fringe the coast on either hand. The dominant object is the castle, on the east height, 375 ft. above sea level. Within its precincts are a Roman pharos or lighthouse, still exhibiting the Roman masonry; the ancient fortress church (St. Mary in Castro); some remains of the Saxon fort; and the massive keep and subsidiary defenses (such as the Constable's, Avranche's, and other towers) of the Norman building. The church, substantially unaltered, forms an almost unique Christian relic. It has been called Roman, but is later. It is cruciform in shape, and the walls are built mainly of flint, but jambs and arches are formed of Roman bricks. At the end of the 12th century it was remodelled and given an Early English character. In the beginning of the 18th century it was dismantled and turned into a storehouse; and so continued until 1863, when, having been restored by Sir G. G. Scott, it was again opened for divine service, and is now the chapel of the castle garrison.

The castle is probably of extremely early origin. The earthworks on the line of the outer curtain may be British, or even Roman, or may possibly represent the Saxon "burg" which Harold is said to have constructed. To these early banks and ditches. with perhaps stockades and wooden towers the conqueror added according to William of Poitiers, such additional "firmamenta" as were needful. This probably means a Norman "motte and bailey"; and a moat, and in part a bailey, still remain inside the earlier *castrum.* The moat is unusually big, and the bailey, south of it, had an unusual loop to the southeast apparently to include the already extant church and pharos. Henry II is responsible for the first stone fortification. He encircled the Norman moat with a wall and crowned it with a keep. Finally the outer rampart was translated into stone, with a line of at least 17 towers at intervals in the time of Henry III, perhaps by Hubert de Burgh. The small inner ward, on the moat, has an area of about two acres; the Norman bailey about four; the whole *castrum* enclosing about 34 acres. Though the castle has suffered many alterations for modern military requirements, especially during the scare of a Napoleonic invasion, which have much obliterated the walls of the middle ward, the remainder of the castle stands substantially as it stood in the time of Henry III. With the exception of the Tower of London, it is probably at once the largest, most complete and most complex example of mediaeval fortification. Nine wards named in a list of Dover wards and their fees, dated 1211–12, in the Red Book of the exchequer, are all reproduced in names still attached to towers. These names had become fixed probably not later than the reign of Henry II. The constableship was attached to the honour of Haughley, known in consequence as the honour of the constable. It reverted to the crown on the forfeiture of Henry of Essex in 1163. At the time of Domesday it was held by Hugh de Montfort. The constableship later was held jointly with the lord wardenship of the Cinque Ports.

Reniains were discovered in 1854 of a round church of the Templars (Holy Sepulchre), 32 ft. in diameter, which has been restored; the church, doubtless, in which King John made his submission to the papal nuncio in 1213. Archcliffe fort lies to the southwest of old Dover. There is a remnant of the Saxon collegiate church of the canons of St. Martin. The remains of the splendid foundation of St. Martin's priory, of the 12th century, include the great gate, the house refectory, with campanile, and the spacious strangers' refectory, now incorporated in Dover college. The college of St. Martin for 22 secular canons, which had been established in the castle before 640, was removed to the church of St. Martin in the town in 696 and in 1136 became a Bene-

dictine priory under the jurisdiction of that at Canterbury, to which see the lands are still attached. The interior of the refectory is very fine and on its east wall are remains of a 12th century mural painting of the Last Supper; some of the nimbi surrounding the heads may still be made out. King Stephen is said to have died in the priory guesthouse, which is the chapel of the modern college The gatehouse, now the library of the college is a good piece of Decorated work, and has a fine open fireplace In High street may be seen the noble hall and truncated fabric of the Maison Dieu founded by Hubert de Burgh in the 13th century for the reception of pilgrims of all nations. From the time of Henry VIII to 1830 it was used as a crown victualling office, but was subsequently purchased by the corporation and adapted as a town hall The new town hall adjoining the old hall of the Maison Dieu was opened in 1883 The museum (1849) contains an interesting collection of local antiquities and a natural history collection. A bell taken from Antwerp by the Germans during World War I and used as an air-raid warning at Zeebrugge was presented to Dover by the king of the Belgians and hung in a turret outside the town hall.

During World War II Dover suffered from constant "hit-and-run" air raiding, as well as shelling from Cape Gris Nez. To the end of 1941 about 9,000 houses had been damaged, also the parish church of St. Mary the Virgin (rebuilt and enlarged in 1843–44, but preserving the three bays of the Saxon church with its western narthex, on which was superimposed the Norman tower, whose rich front faced the street; the rest of the building mas Norman and Early English), and the churches of St. James-the-Less (originally Norman, but vigorously restored) and St Barnabas.

Among various charitable institutions are the National Sailors' home and the Gordon Boys' and Victoria Seaside orphanages. Among educational establishments is Dover college, occupying the site and remaining buildings of St. Martin's priory, with additional modern buildings. It was instituted in 1871, and educates about 220 boys. There is a separate junior school.

Dover is the only one of the Cinque Ports which is still a great port. It is one of the principal ports for passenger communications across the channel, steamers connecting it with Calais and Ostend The Admiralty pier was completed to a length of about 2,000 ft in 1871- The construction of a new commercial harbour was begun in 1893. The works included the east pier ("Prince of Wales's pier" completed, 1902), running parallel to the general direction of the Admiralty pier, and in conjunction with it enclosing an area of sheltered water of 75 ac. The Admiralty harbour, begun in 1896, has an area of 610 ac., of which 322 ac. have a depth of not less than 30 ft. at low water. It comprises three enclosing breakwaters—on the west an extension of the Admiralty pier in a southeasterly direction for 2,000 ft.; on the south an isolated breakwater, 4,200 ft. long, curving round shoreward at its eastern end to accord with the direction of the third breakwater, on the east, which runs out from the shore in a southerly direction for 3,320 ac. These three breakwaters, with a united length of more than $1\frac{3}{4}$ mi., are each built of massive concrete blocks in the form of a practically vertical wall rising to a quay level of 10 ft. above high water. There are two entrances, one 800 ft. and the other 600 ft in width, with a depth of about seven fathoms at low water. In 1919 the naval base was given up and in 1923 the Admiralty harbour was transferred to the Dover harbour board for commercial purposes. Near the Admiralty pier is the train ferry dock, completed in 1936, the English terminal of a train ferry service between Dover and Dunkirk, which enabled a through service to be operated between London and Paris. Besides the mail service and harbour trade, Dover has a trade in ship supplying, and there are paper and flour mills and an iron foundry. Dover is a bishopric suffragan in the diocese of Canterbury. The town returned two members to parliament until 1885, when the number was reduced to one, and it was disfranchised in 1918.

Dover (*Dubris*) was one of the ports for continental traffic in Roman times. In the 4th century it was guarded by a fort lying down near the harbour. and forming part of the defenses of the Saxon shore (*Litus Saxonicum*). As a Cinque Port, Dover *(Dofra, Dovorra)* contributed 20 of the quota of ships furnished by those ports. A charter of liberties was granted to the ports as a body by Edward I in 1278, confirming charters of Henry II and John. which in the case of Dover had confirmed privileges enjoyed by the town in the time of Edward the Confessor and later kings Edward I's charter was confirmed by subsequent kings, with additions, down to James II. During the middle ages Dover castle was an object of contention both in civil wars and foreign invasions, and was considered the key to England. It was successfully defended in 1216 against the French under the dauphin Louis by Hubert de Burgh. In 1685 Charles II confirmed to the inhabitants of Dover a fair beginning on Nov. 11, which had been held of old in the town, and granted two others on April 23 and 24 and on Sept. 25 and 26. After the decay of Richborough harbour the passage from Dover to Whitsand, and later to Calais, became the accustomed route to France, and by a statute of 1465 no one might ship for Calais except at Dover. The guardians of the harbour were incorporated by James I in 1607.

See S. P. *H.* Statham, *History of the Castle, Town and Port of Dover* (1899); and *Dover Charters and Other Documents* (1902).

Battle of Dover.—This famous and important naval victory was won off the town of Dover by the ships of the Cinque Ports on Aug. 21, 1217, during the minority of King Henry III The barons, who were in arms against his father King John, had called Louis, son of Philip Augustus, king of the French, to their aid. Having been recently defeated in Lincoln, they were hard pressed, and reinforcements were sent to them from Calais in a fleet commanded by a pirate and mercenary soldier called Eustace the Monk. He passed the Straits of Dover with a numerous flotilla laden with military machines and stores, and also carrying many knights and soldiers. The Monk's fleet was seen from Dover, where the regent, Hubert de Burgh, lay with the naval force of the Cinque Ports, said to have been very small. Sixteen vessels, large for that time, and a number of smaller craft, is said to have been their total strength It put to sea, and by hugging the wind gained the weather gage of the French adventurer.

Eustace is said to have been under the impression that they meant to attack Calais in his absence, and to have derided them because he had left the town well guarded. When they were to windward of his fleet the Cinque Port ships bore down on the enemy. As they approached they threw unslaked lime in the air and the wind blew it in the faces of the French. This form of attack, and the flights of arrows discharged by the English (which flew with the wind), produced confusion in the crowded benches of the French vessels, which in most cases must have been little more than open boats. The Monk was defeated, and his fleet was entirely scattered, sunk or taken. His own vessel was captured. Eustace, who had concealed himself in the bilge, was dragged out. In answer to his appeals for quarter and promises to pay ransom, he was told by Richard, the bastard son of King John, that he was a traitor who would not be allowed to deceive more men. His head was struck off by Richard, and was sent round the ports on a pike. The Cinque Port seamen returned in triumph, towing their prizes, after throwing the common soldiers overboard, and taking the knights to ransom according to the custom of the age. The political importance of the battle was great, for it gave the deathblow to the cause of the barons who supported Louis, and it secured Henry III on his throne. But the defeat and death of the Monk was widely regarded as in a peculiar sense a victory over the powers of evil. The man became within a few years after his death the hero of many legends of piracy and necromancy.

Ascertainable fact is less picturesque, but enough is known to show that he was an adventurous and unscrupulous scoundrel In his youth he was a monk, and left the cloister to claim an inheritance from the count of Boulogne. Not having received satisfaction he became a freebooter on land and sea, and mercenary soldier. He is frequently mentioned in the Pipe, Patent and Close Rolls. For a time he served King John, but when the king made friends with the count of Boulogne, he fled abroad, and entered the service of the French prince Louis and his father

Philip Augustus. Chroniclers lavish on him the titles of *"archipirata,"* *"vir flagitiosissimus et nequissimus,"* and poets made him an associate of the devil.

The evidence concerning Eustace is collected by Herren Wendelin Förster and Johann Trost, in their edition of the French poem "Wistasse le moine" (Halle, 1891). *See* for the battle Sir N. Harris Nicolas, *History of the Royal Navy* (London, 1847).

The Dover Patrol.—Dover harbour provided the headquarters of the Dover Patrol during World War I. The area of the Patrol extended roughly from the North Foreland to Beachy Head, including both sides of the Channel. The functions of the Patrol were, primarily, to keep the narrows of the Channel open to traffic. London could not be fed by rail alone. Had sea traffic to London been stopped it would have been necessary at once to transport one third of the population to the west coast. The traffic had to be protected from mines, submarine boats and destroyer attacks. On an average 66 trawlers were used for minesweeping and traffic duties; approximately 100,000 merchant vessels passed during 1915–17 inclusive, and of these only 48 were mined and 7 torpedoed; the percentage loss for the three years was .035, .08 and .066 respectively; 5,614,500 troops were transported between Folkestone and Boulogne without a single casualty or accident. Nine and a half million mail bags were sent without the loss of a single letter or parcel.

The next important duty of the Patrol was hunting submarines. At first these vessels passed down the straits on the surface, diving only when they were sighted. It was then simple to attack them. After 1915 they dived when well to the eastward and passed the narrows entirely submerged. Many schemes were tried to defeat them, and as soon as mines became available a barrage of lines of mines moored at various depths was laid between Folkestone and Gris Nez. This was nearly completed by January 1918 and the first submarine was destroyed in it in December 1917. This in the end completely stopped the passage of submarines and destroyed a considerable number of them.

At the commencement of the war the Dover Patrol force operated with the army in checking the German advance through Belgium by their gun fire and made the shore road difficult for the Germans to use. Subsequently the Patrol was called on to defend the sea flank of the army and by feints of landings to draw troops from the main offensive to the coast. To assist in the advance which was contemplated in 1917 three 12 in. guns, seven 9.2 and eight 7.5 in. guns were landed and mounted, at the same time arrangements were made for landing 20,000 men on the coast between Ostend and Westend. Pontoons 55 feet long loaded with men and accessories were constructed to be pushed ahead of the monitors on to the beach. This landing was never carried out, as the commander-in-chief did not consider it advantageous to land troops until the army had reached Roulers. It never pushed on beyond the Passchendaele Ridge. The only attacks by the enemy prior to 1918 on the Dover defenses were those made by destroyers at night. Darkness and surprise coupled with the meagre allowance of destroyers for Dover made these raids very difficult to cope with, but the damage done was insignificant, the total lcsses being two merchant vessels (one empty), two destroyers and six drifters. During the fourth raid the *Broke* and *Swift* sank two German destroyers, and for a time the raids ceased. During 1918 a last raid was made on the vessels protecting the mine barrage and several were sunk.

An examination service for the detection of contraband was established in the Downs. All North and South going traffic had to anchor and be examined. This work was largely undertaken by Naval Reserve officers under a post captain. In 1917, when raids by German destroyers threatened the safety of the vessels in the Downs, the Northern examination service was moved inside the Thames shoals.

Vessels at Dover were also called on to undertake bombardments of the dockyard at Ostend and the submarine base at Zeebrugge. The result of these operations was that the dockyard was made untenable and the destroyers and submarines forced up the canal to Bruges. In 1916 the aircraft were used for spotting with successful results, several of the bombardments being carried out without the Belgian coast being sighted by the ships. The force of destroyers available at Dover before 1917 was very small having regard to the duties they were called on to perform, only six mounted 4-in. guns. During the latter year they were augmented. Of the 12 Tribal class half were mined or torpedoed. A constant patrol was kept up eight miles off the Belgian coast during the summer months of 1916–17. This was made possible by first laying down the barrage of mines and mined nets seven miles from the coast to protect the ships from attack on the shore side. The only ship damaged while on patrol was the monitor Terror which was struck by a boat controlled electrically from the shore.

Blocking operations were carried out during 1918 when Zeebrugge was attacked and blocking ships skilfully sunk in the Channel which however owing to its physical formation was not, and could not be, effectively blocked. A similar attempt on Ostend failed, though attempted with great gallantry. The drifters like the trawlers were invaluable in the English Channel, first drifting nets to entangle submarines, then watching the barrages. On the Belgian coast they laid 12 miles of armoured mine nets for two years in succession. The motor launches also were of considerable value for sundry services, specially burning smoke screens to hide the ships bombarding. These screens were necessary since the effective range of the monitors' guns was only about 75% that of the shore batteries. The French naval armaments on the north coast of France were under the orders of the Admiral of the Dover Patrol and did excellent service throughout the war. The air service at Dunkirk was also one of the arms of the Patrol and was invaluable both on the coast and also in assisting the army, notably at the battle of the Somme when the army was very deficient in aircraft. Without the breakwater and harbour facilities at Dover the protection of the straits would have been impossible, and the evacuation of the wounded most difficult. Practically the whole of the wounded at the front were safely landed at the Admiralty Pier and from there despatched to the various hospitals.

DOVER, the capital city of Delaware, U.S.A., and the count)? seat of Kent county, on the St. Jones river, in the central part of the State. It is on federal highway 13, and is served by the Pennsylvania railroad. The population was 4.042 in 1920 (26% Negroes) and was 5,517 in 1940 by the federal census. The state house, built about 1722 for a courthouse and remodelled in 1791 for its present purpose, is a beautiful building of dignified colonial architecture, set in a spacious green. Near Dover still stands the home of Caesar Rodney (1728–1784), who rode to Philadelphia through the night of July 3, 1776, in order to be present at the roll call on the Declaration of Independence, and thus made possible a unanimous vote of the 13 Colonies in favour of its adoption. Dover is a shipping point for the strawberries, apples, peaches, grapes, poultry, vegetables and other products of the fertile surrounding country, and has many canneries and packing plants, including one of the oldest and largest in the country (established 1855). The State college for Negro students (1892) is near the city. Dover was laid out in 1717, by order of William Penn. In 1777 it replaced New Castle as the capital of the State. It was incorporated as a town in 1829, and re-incorporated as a city in 1925 with an area almost double its former size.

DOVER, a city of southeastern New Hampshire, on the Cocheco river, 10 mi. N.W. of Portsmouth; the county seat of Strafford county. It is served by the Boston and Maine Railroad and motorbus lines. The population was 13,029 in 1920 (80% native white), and was 13,573 in 1930 and 14,990 in 1940 by the federal census. It has abundant water power and large manufacturing industries, with an output in 1937 valued at $12,-162,901.

Leading products are cotton sheeting, woollen goods, leather belting, machinery and shoes. A settlement was established in 1623 by Edward Hilton on Dover Point, 5 mi. S.E. of the Cocheco falls, and in 1633 several families under Captain Thomas Wiggin settled on Dover Neck (on the Piscataqua river, 1 mi. above Dover Point) which for the first century, while shipbuilding was the important occupation, was the business centre of the town. With the

development of manufacturing, business and population shifted to the Cocheco river, which is now the centre. For nearly half a century after 1641 the plantation (by will of the majority) was under the jurisdiction of Massachusetts. Between 1675 and 1725 the town suffered greatly from attacks by the Indians, notably on June 28, 1689.

Dover was chartered as a city in 1855. At Durham, 5 mi. southwest, is the University of New Hampshire, established as an agricultural college in 1866, at Hanover; moved to Durham in 1893, following the death of Benjamin Thompson, a farmer of that town, who left to the college almost his entire estate; and incorporated as a university in 1923.

DOVER, a town of Morris county, New Jersey, on the Rockaway river, 40 mi. W.N.W. of Jersey City, at an altitude of 570 ft. It is served by the Central of New Jersey and the Lackawanna railways. The population was 9,803 in 1920; in 1930 it was 10,031 and in 1940, 10,491. Iron is mined in the vicinity, and the town has large railroad shops and important manufactures, including hosiery, silk, bar iron, furnaces and ranges, boilers, bridges, drills and air compressors. Dover was settled as early as 1748 and was separately incorporated in 1869.

DOVER, a city of Tuscarawas county, Ohio, U.S.A., on the Tuscarawas river, 82 mi. S. by E. of Cleveland. It is on federal highway 21, and is served by the Baltimore and Ohio and the Pennsylvania railways and excellent highways. The population was 8,101 in 1920 (87% native white); it was 9,716 in 1930 and 9,691 in 1940 by the federal census. The city lies on a plateau 884 ft. above sea level, commanding diversified views. Iron ore, coal, fireclay and limestone abound in the vicinity. The manufactures include electric irons, sweepers, stearic acid, bronze tubes, steel, flour and wall tile. A town was laid out in 1807. It was on the Ohio canal (opened 1832) and was formerly called Canal Dover, but "Canal" was dropped in 1915. It was incorporated as a village in 1842, reincorporated in 1867 and became a city in 1903.

DOVER, TREATY OF. A secret treaty concluded on May 22, 1670 between Charles II. of England and Louis XIV. of France, whereby Charles II. agreed to embrace the Roman Catholic faith and the king of France to assist him in this with a large sum of money and the use of 6,000 troops. It was agreed that the two countries should declare war jointly on the United Provinces, and also that England should support the claim of Louis, should he "acquire new titles and rights to the Spanish Monarchy." The treaty was negotiated through Henrietta, Duchess of Orleans and sister of Charles II. *(See* CHARLES II.)

The treaty did not however become operative as such owing to the religious controversy involved; in a later version (Dec. 1670) the proposed conversion of the English king was omitted. and a date fixed for the declaration of war against the United Provinces

DOVERCOURT, a watering place and parish in the borough of Haruich, Essex, England, with a station on the L N.E.R., 70 mi. E.N.E. from London. The esplanade and sea-wall front the North sea, and there is a fine expanse of sand. Much attention has been given to laying out public walks and gardens and providing recreation facilities. There is also a chalybeate spa. The scenery of the neighbouring Orwell and Stour estuaries is pleasant. The church, which stands inland in the old village distinguished as Upper Dovercourt, is Early English; it formerly possessed a miraculous rood which became an object of pilgrimage. It is said to have been stolen and burned in 1532, three of the four thieves being subsequently taken and hanged.

DOW, NEAL (1804–1897), American temperance reformer, was born at Portland, Me., March 20, 1804. He drafted the Maine prohibitory law of 1851. He was mayor of Portland, 1851, 1855, a member of the Maine legislature, 1858–59, and in the Civil War colonel of the 13th Maine Volunteer Infantry.

He served in General B. F. Butler's New Orleans expedition, was commissioned brigadier-general of volunteers in April 1862, and commanded for a time the department of Florida. After the war he devoted a great part of his time to the extension of prohibition in America and England. Through his exertions the prohibitory amendment was added to the Maine Constitution in 1884. He died at Portland, Oct. 2, 1897.

His *Reminiscences* were published *at* Portland in 1898.

DOWAGER, strictly, a widow in the enjoyment of dower. "Dowager" is also applied to widows of high rank to distinguish them from the wives of their sons, as queen-dowager, dowager-duchess, etc. The title was first used in England of Catherine of Aragon, widow of Arthur, prince of Wales, who was styled princess dowager till her marriage with Henry VIII. By transference the word is used of an elderly lady.

DOWAGIAC (dō-waw′-jăk), a city of Cass county, Michigan, in the south-western part of the State, on the Michigan Central railroad. Population 5,440 in 1920 (86% native white) and was 5,007 in 1940 bv federal census. It is in a fertile region of many lakes. The city manufactures furnaces and fish-bait; ships wheat, corn, fruit, celery, peppermint and other agricultural products; and is a summer resort and touring centre. It was founded about 1838 and incorporated in 1852.

DOWDEN, EDWARD (1843–1913), Irish critic and poet, was born at Cork and educated at Queen's college, Cork, and Trinity college, Dublin. He became professor of English literature at Trinity college in 186;. His first book, *Shakespeare, his Mind and Art* (1875), a revision of a course of lectures, was translated into German and Russian, and his *Poems* (1876) went into a second edition. His *Shakespeare Primer* (1877) was also translated into Italian and German. Later works by him in Shakespearean criticism were his *Shakespeare's Sonnets* (1881), *Passionate Pilgrim* (1883), *Introduction to Shakespeare* (1893), and editions of *Hamlet* (1899), *Romeo and Juliet* (1900) and *Cymbeline* (1903). His *Studies in Literature* (1878), *Transcripts and Studies* (1888), *New Studies in Literature* (1895), and other works, many of them biographical, showed a profound knowledge of the currents and tendencies of thought in various ages and countries; but it was his *Life* of *Shelley* (1886) that made him best known to the public at large. In 1900 he edited an edition of Shelley's works. In 1889 he became the first Taylorian lecturer at Oxford, and from 1892 to 1896 was Clark lecturer at Trinity college, Cambridge.

DOWER, in law, the life interest of the widow in a third part of her husband's lands. There were originally five kinds of dower: (1) at common law; (2) by custom; (3) *ad ostium ecclesiae,* or at the church porch; (4) *ex assensu patris;* (5) *de la plus belle.* The last was a conveyance of tenure by knight service, and was abolished in 1660, by the act which did away with old tenures. Dower *ad ostium ecclesiae,* by which the bride was dowered at the church porch (where all marriages used formerly to take place), and dower *ex assensu patris,* by the father of the bridegroom, though long obsolete, were formally abolished by the Dower act 1834. Dower was governed in Great Britain, so far as women married after Jan. 1, 1834 were concerned, by the Dower act 1834, and under it only attached on the husband's death to the lands which he actually possessed for an estate of inheritance at the time of his death. It did not attach to any land actually disposed of by him in his lifetime or by his will, or to any land from which he declared by deed or will his wife should not be entitled to dower. Dower was finally abolished by the Administration of Estates act 1925. The right to dower still obtains in some colonies, while in others it has been superseded by Homestead acts, or the acts dealing with devolution of property *(see* Burge's *For. and Col. Laws,* vol. iv. pt. ii. Wyndham A. Bewes ed.)

In the United States, in such States as have not enacted statutes to the contrary, dower continues as at common law. Some statutes are in effect which declare the principles of the common law. In most States, however, the common law doctrines of dower have been very greatly modified by statute. In some States dower either has been abolished or a different right or interest has been substituted therefor. Even where it has been abolished, the term often popularly is used. Where dower is abolished the interest substituted may be in one of several forms, perhaps a certain portion of the husband's property or of the community property of both or of a life estate in a portion of his realty.

DOWIE, JOHN ALEXANDER (1847–1907), founder of the "Christian Catholic Apostolic Church in Zion," born in Edin-

burgh, and went as a boy to Australia with his parents. He returned in 1868 to study for the Congregationalist ministry at Edinburgh University, and subsequently became pastor of a church near Sydney, Australia. Imbued with belief in his powers as a healer of disease by prayer, he moved to Melbourne, where he founded "The Divine Healing Association of Australia and New Zealand." In 1888 he went to America, preaching and "healing," and in spite of opposition and ridicule attracted a number of adherents. In 1896 he established "The Christian Catholic Apostolic Church in Zion," with himself as "First Apostle"; and in 1901, with money liberally contributed by his followers, he founded Zion City, on a site covering about 10 sq.m. on the west shore of Lake Michigan, with a central Zion Temple. In 1903 and 1904, in the course of a visit to the branches of the Christian Catholic Church throughout the world, he appeared in London, but was mobbed. In April 1906 a revolt against his domination took place in Zion City. He was charged with peculation and with practising polygamy, and was deposed, with the assent of his own wife and son. Dowie was now broken in health and unmistakably insane; he was struck with paralysis and died in Zion City in March 1907 Dowie was succeeded by Wilbur Glenn Voliva.

DOWLAS, plain cloth, similar to sheeting, but usually coarser. It is made in several qualities, from line warp and weft to two warp and weft, and is used chiefly for aprons, pocketing, soldiers' gaiters, linings and overalls. The finer makes are sometimes made into shirts for workmen, and occasionally used for heavy pillow-cases. The word is spelt in many different ways, but the above is the common way of spelling adopted in factories, and it appears in the same form in the first part of Shakespeare's *Henry IV.*, Act III. scene 3. The modern dowlas is a good strong and closely woven linen fabric.

DOWN, a maritime county of Ireland, occupying the most easterly part of the island, bounded north by Co. Antrim and Belfast Lough, east and south by the Irish sea, and west by Co. Armagh. The land area is 952 sq.mi. Pop. (1937) 210,687.

The foundation of this county is Silurian rock throughout, the slates and sandstones striking as a whole north-east, but giving rise to a country of abundant small hills. The granite that appears along the same axis in Armagh continues from Newry to Slieve Croob, furnishing an excellent building stone. South of it, the Eocene granite of the Mournes forms a group of rocky summits, set with scarps and tors, and divided by valleys, which are not yet choked by the detritus of these comparatively youthful mountains (Slieve Donard 2,796 ft.). Lower lands occupy the east, north and large portions of the west of the county. Basalt dykes abound. being well seen along the coast south of Newcastle. At the head of Strangford Lough, the basalt, possibly as intrusive sheets, has protected Triassic sandstone, which is quarried at Scrabo hill. A strip of marine Permian occurs on the shore at Holywood. The north-west of the county includes, at Moira, a part of the great basaltic plateaux, with Chalk and Trias protected by them. The chief drainage is to the river Lagan in the north, and to the Bann and the Newry on the west. The period at which Down was constituted a county is not certain. A district, however, appears to have borne this name before the beginning of the 14th century, but little is known of it even later than this. However, when in 1535 Sir John Perrot undertook the shiring of Ulster, Down and Antrim were excepted as already settled counties. That some such settlement would have been attempted at an early period is likely, as this coast was a place of Anglo-Norman colonization, and to this movement was due the settlement of the baronies of Lecale, the Ards and others.

At Slidderyford, near Dundrum, there is a group of ten or twelve pillar stones in a circle, about 10 ft. in height. A cairn on the summit of Slieve Croob is 80 yds. in circumference at the base and 50 at the top, where is a platform on which cairns of various heights are found standing. Cromlechs, or altars, are numerous, the most remarkable being the Giant's Ring, which stands on the summit of a hill near the borders of Antrim. This altar is in the centre of an enclosure about a third of a mile in circumference, formed of a rampart about 20 ft. high, and broad enough on the top to permit two persons to ride abreast. Near Downpatrick is a rath, or encampment, three-quarters of a mile in circumference. In its vicinity are the ruins of Saul Abbey, said to have been founded by St. Patrick, and Inch Abbey, founded by Sir John de Courcy in 1180. The number of monastic ruins is also considerable. The most ancient and celebrated is the abbey or cathedral of Downpatrick. Dundrum Castle, attributed to the de Courcy family, stands above that town, and affords an unusual example (for Ireland) of a donjon keep. The castle of Hillsborough, seat of the marquesses of Downshire, is of Carolean date. There are three round towers in the county, but all are fragmentary.

The predominating soil is a loam of little depth, in most places intermixed with considerable quantities of stones of various sizes, but differing materially in character according to the nature of the subsoil. Clay is mostly confined to the eastern coast, and to the northern parts of Castlereagh. Of sandy soil the quantity is small; it occurs chiefly near Dundrum. Moor grounds are mostly confined to the skirts of the mountains. Bogs, though frequent, are scarcely sufficient to furnish a supply of fuel to the population. Agriculture is in a fairly satisfactory condition. The bulk of the labouring population dwells in reasonably good circumstances. Tillage land declines somewhat in favour of pasture land. Oats, potatoes and turnips are the principal crops; flax, formerly important, is almost neglected. Some of the best racehorses in Ireland have been bred in this county. The native breed of sheep is confined to the mountains. The various other kinds of sheep have been much improved. Pigs are reared in great numbers, chiefly for the Belfast market. Poultry farming is a growing industry. The fisheries, of less value than formerly, are centred at Donaghadee, Newcastle, Strangford and Ardglass. The chief industries in the county generally are linen manufacture and bleaching, and brewing.

The haematite of Deehommed, near Banbridge, is well spoken of. Topaz and aquamarine occur in hollows in the granite of the Mournes. The Mourne granite is quarried above Annalong, and an ornamental dolerite is worked at Rosstrevor.

The Great Northern railway has an alternative branch to its main line by Portadown, from Lisburn through Banbridge to Scarva, with a branch from Banbridge to Ballyroney and Newcastle. Newry is on a branch from the Dublin-Belfast line to Warrenpoint on Carlingford Lough. The main line between Lisburn and Portadown touches the north-western extremity of the county. The eastern part of the county is served by the Belfast and County Down railway with its main line from Belfast to Newcastle, and branches from Belfast to Bangor, Comber to Newtownards and Donaghadee, Ballynahinch Junction to Ballynahinch, and Downpatrick to Ardglass and Killough. The Newry Canal skirts the west of the county, and the Lagan Canal intersects the rich lands in the Lagan valley to the north.

Newry (Pop. 1937, 12,738) is the largest town, Downpatrick is styled the county town. Other towns include Banbridge and Bangor, and there are popular watering-places on the coast and residential villages on Belfast Lough. Co. Down returns eight members to the parliament of Northern Ireland and two members to the parliament of Great Britain and Northern Ireland.

DOWN, an expanse of high rolling ground destitute of trees; occasionally used for a smooth rounded hill. The system of chalk hills in England is known as "The Downs" *(see* DOWNS). The usual English word "dune" is taken directly from the French. Low sandy tracts north and south of Yarmouth, Norfolk, are known as the "Dunes." The adverb "down," meaning, from above, had an earlier form "adown," *i.e.*, off the hill.

DOWNES (D[o]UNAEUS), **ANDREW** *(c.* 1549–1628), English classical scholar, was born in Shropshire. He did much to revive the study of Greek at St. John's college, Cambridge, and was elected fellow in 1571. In 1585 he was appointed regius professor of Greek. According to Simonds d'Ewes (*Autobiography,* ed. J. O. Halliwell, i. pp. 139, 141), who attended his lectures, Downes was accounted "the ablest Grecian of Christendom." He edited Lysias *Pro caede Eratosthenis* (1593); *Praelectiones in Philippicam de pace Demosthenis* (1621), dedicated to King James I.; some letters (in Greek) to Isaac Casaubon,

printed in the *Epistolae* of the latter; and notes to St. Chrysostom, in Sir Henry Savile's edition. Downes was also one of the seven translators of the *Apocrypha* for the "authorized" version of the Bible, and one of the six learned men appointed to revise the new version after its completion.

DOWNING, SIR GEORGE, BART. (*c.* 1624–1684), English soldier and diplomatist, son of Emmanuel Downing, barrister, and of Lucy, sister of Governor John Winthrop, was born in England. His family joined Winthrop in America in **1638,** settling in Salem, Mass., and Downing studied at Harvard. In **1645** he sailed for the West Indies as a preacher and instructor of the seamen, and arrived in England some time afterwards, becoming chaplain to Colonel John Okey's regiment. In **1650** he was scout-master-general of Cromwell's forces in Scotland; in Cromwell's parliament of 1654 he represented Edinburgh, and Carlisle in those of **1656** and 1659 In 165j he was sent to France to remonstrate on the massacre of the Protestant Vaudois. Later in 1657 he was appointed resident at The Hague, to effect a union of the Protestant European powers, to mediate between Portugal and Holland and between Sweden and Denmark, to defend the interests of the English traders against the Dutch, and to inform the government concerning exiled royalists.

He was maintained in his post during the interregnum after the fall of Richard Cromwell, and in April **1660** made his peace with Charles II., to whom he communicated Thurloe's despatches, and declared his abandonment of "principles sucked in" in New England, of which he now "saw the error." Downing was knighted in **1660.** He showed indecent zeal in arresting in Holland and handing over for execution the regicides Barkstead, Corbet and Okey. In **1663,** he was created a baronet. Downing had from the first been hostile to the Dutch as the commercial rivals of England. He had strongly supported the Navigation Act of **1660,** and he now deliberately drew on the fatal and disastrous war. During its continuance he took part in the management of the treasury, introduced the appropriation of supplies, and in May **1667** was made secretary to the commissioners, his appointment being welcomed by Pepys. He sat in parliament for Morpeth from **1660** till his death, and spoke with ability on financial and commercial questions. He was appointed a commissioner of the customs in **1671.** The same year he was sent to Holland to replace Sir William Temple, to break up the policy of the Triple Alliance and incite another war between Holland and England in furtherance of the French policy. After three months' residence Downing fled to England, in fear of the fury of the mob. For this unauthorized step he was sent to the Tower for some weeks. Downing Street, London, is named after him, while Downing College, Cambridge, derived its name from his grandson, the 3rd baronet. The title became extinct when the 4th baronet, Sir Jacob G. Downing, died in **1764.**

Downing's great talents were rarely employed for the advantage of his country and his character was marked by treachery, servility and ingratitude. "A George Downing" became a proverbial expression in New England to denote a false man who betrayed his trust. He published many declarations and discourses, mostly in Dutch, enumerated in Sibley's biography, and wrote also "A True Relation of the Progress of the Parliament's Forces in Scotland" (1651), *Thomason Tracts,* Brit. Mus., E **640 (5).**

See J. L. Sibley, *Biographical Sketches of Harvard* vol. i. (Cambridge, 1873); J. Beresford, *The Godfather of Downing Street, Sir G. Downing* **(1927).**

DOWNINGTOWN, a borough of Chester county, Pa., U.S.A., on Brandywine creek, **33** mi. W. of Philadelphia. It is on federal highways 30 and 322, and is served by the Pennsylvania and the Reading railways. The population was **4,548** in 1930, and was **4,645** in 1940 by the federal census. The principal manufacturing industries are paper and woollen mills, brick yards, boiler factories and machine works. Downingtown was settled about 1714 and incorporated in 1859. Valley Fcrge and the Brandywine battlefield are near by.

DOWNMAN, JOHN (1750–1824), English portrait painter. His pencil portrait drawings, slightly tinted in colour, usually from the reverse, are many of them of remarkable beauty. Several volumes of sketches for these drawings are still in existence. Downman is believed to have been "pressed" for the navy as a young man, and on his escape settled down for a while in Cambridge, eventually coming to London, and later (1804) going to reside in Kent in the village of West Malling. He afterwards spent some part of his life in the west of England, especially in Exeter, and then travelled all over the country painting his dainty portraits.

See G. C. Williamson, *John Downman, his Life and Works* (1907).

DOWNPATRICK, market town and county town of Co. Down, Ireland, **28** m. S.S.E. of Belfast by rail. Pop. (1926), 3,147. It stands near the south-west extremity of Strangford Lough. It is the seat of the Roman Catholic and Protestant dioceses of Down. St. Patrick founded the see about 440, but the present Protestant cathedral dates from 1790, the old structure having been in ruins for 250 years. A round tower adjoining it was destroyed in 1790. The rath or dun, from which the town is named, remains as one of the finest in Ireland. It was called Rath-Kaltair and covers 10 acres. In the vicinity are remnants of the monastery of Saul, a foundation ascribed to St. Patrick, and of Inch abbey (1180), founded by Sir John de Courcy. Three miles south is a stone circle and to the south-east are the wells of Struell. The town was called *doun-leth-plas,* the fort of the broken fetters, from the deliverance from bondage of two sons of Dichu, prince of Lecale, and the first convert of St. Patrick. It is the Dunum of Ptolemy and was the residence of the kings of Ulster. It was already incorporated early in the 1jth century.

A small trade is carried on at Strangford Lough, the quay being below the town. Linen manufacture, brewing, tanning and soap-making are the chief industries.

DOWNS, the name of a system of chalk hills in the south-east of England. It is most familiar in its application to the two ranges of the North and South Downs. Of these the North Downs are in the counties of Surrey and Kent, and the South in Sussex. Each forms a well-defined long range springing from the chalk area of Dorsetshire and Hampshire, to which latter the general name of the Western Downs is given. The Downs enclose the rich district of the Weald (*q.v.*).

The North Downs extend for **95** m. from Farnham to the English channel between Dover and Folkestone. The crest is not continuous, as the hills are breached by a series of deep gaps, through which northward flowing rivers, roads and railways pass. The entrances to these gaps are the locations of important town sites. The South Downs show similar characteristics, the rivers flowing southward. The river system of the Weald is an excellent example of a drainage system consequent upon an anticlinal structure. The western end of the North Downs is the Hog's Back, a narrow ridge, altitude **489** ft., a quarter of a mile broad on the top and sloping sharply north and south. At the west end is a depression, once occupied by the Blackwater, the head-waters of which have been captured by the Wey. In this depression lies Farnham. The Wey, flowing south of the Hog's Back, breaches the Downs at the Guildford gap. The next gap is that of the Mole, in which Dorking lies. Between Guildford and Dorking the main line of the Downs reaches **712** ft., but a lateral depression, followed by the railway, marks off on the south a loftier range of lower Greensand, in which Leith hill is 965 ft. in height. East of the hfole the northward slope of the Downs is deeply cut by narrow valleys and the depression between Redhill and Croydon was once traversed by a stream subsequently beheaded by the Mole. A height of **868** ft. is attained east of Caterham. The next river to break through is the Darent, but here another lateral depression marks off the Ragstone ridge, south of Sevenoaks, reaching 800 feet. The lateral depression is continued eastward, so that as far as Ashford the Downs consist of two parallel ranges; but the Medway itself breaches both, Maidstone lying in the gap. The elevation now begins to decrease, and **682** ft. is the extreme height east of the Medway. The final breach is made by the Great Stour, between Ashford and Canterbury. but the valley of the Little Stour offers a well-marked pass followed by the Folkestone-Canterbury railway. The North Downs end in the white cliffs between Dover and Folkestone.

The South Downs present similar characteristics on a minor

scale. Springing from the main mass of the chalk, south of Petersfield, they have their greatest elevation (889 ft. in Butser hill), and extend for 65 m. to the English channel at Beachy Head. Here also a succession of rivers breach the hills, and towns mark the gaps. These are, from east to west, the Arun, with the town of Arundel, the Adur, with Shoreham, the Ouse, with Lewes and Newhaven and the Cuckmere, with no considerable town. The steep slope of the South Downs is northward. The southern slopes reach the coast east of Brighton, but west of this town a flat coastal belt, the Hampshire basin, intervenes, widening westward. Apart from the complete breaches, the South Downs, scored on the south with many deep vales, are generally more easily penetrable than the North Downs, and the coast is less continuous.

Smooth convex curves are characteristic of the Downs; their graceful and striking outline gives them an importance in the landscape in excess of their actual height; their flanks are well wooded, their summits covered with close springy turf.

"THE DOWNS" is also the name of a roadstead in the English Channel off Deal between the North and the South Foreland. It forms a favourite anchorage during heavy weather, protected, except during severe southerly gales, by the Goodwin Sands. It has depths down to 12 fathoms.

DOWNSHIRE, WILLS HILL, 1ST MARQUESS OF (1718–1793), son of Trevor Hill, 1st Viscount Hillsborough, was born at Fairford in Gloucestershire on May 30, 1718. He became a member of parliament in 1741. In 1751 he was created earl of Hillsborough in the Irish peerage, and in 1756 a peer of Great Britain as Baron Harwich. For nearly two years he was president of the Board of Trade and Plantations under George Grenville, and after a brief period of retirement he filled the same position. and then that of joint postmaster-general, under the earl of Chatham. From 1768 to 1772 Hillsborough was secretary of State for the Colonies and also president of the Board of Trade, becoming an English earl on his retirement; in 1779 he was made secretary of State for the northern department, and he was created marquess of Downshire seven years after his final retirement in 1782. Both in and out of office he opposed all concessions to the American colonists, but he favoured the project for a union between England and Ireland. He died on Oct. 7, 1793.

DOWRY, the property which a woman brings with her or is given to her at her marriage, a wife's marriage portion *(see* SETTLEMENT).

DOWSER and **DOWSING,** one who uses, or the art of using, the dowsing-rod or "striking-rod" to find subterranean minerals or water (from the Cornish "dowse," M.E. *duschen,* to strike or fall. *See* DIVINING-ROD). More commonly with the spelling "douse" the verb is also used, especially in nautical parlance, with the meaning to lower or strike sail suddenly, as well as to quench or extinguish, as a light; or to close, as a port-hole.

DOWSON GAS PRODUCER: *see* GAS MANUFACTURE.

DOXOLOGY, an ascription of glory to God (Gr. δοξολογία, a praising). The name is applied specially to the *Gloria in excelsis Deo* (known as the Greater Doxology) and the *Gloria Patri* (the Lesser Doxology, usually called "the doxology" simple); but also, more generally, to the *Tersanctus* ("Holy, Holy, Holy," often called *Trisagion,* though that is strictly the name of the Greek invocation beginning Ἅγιος ὁ θεός), to the Alleluia of Rev. xix. and of many of the Psalms, to the last clause of the Lord's Prayer as found in Matt. vi. 13, and to such passages of glorification as Rom. xvi. 27, Eph. iii. 21, etc.

The Greater Doxology, in a slightly different form from that now used in the Greek Church, is given in the 4th century *Apostolical Constitutions* (vii. 47); and a very similar form is found in the Alexandrine Codex (jth century). The translation into Latin is traditionally attributed to St. Hilary of Poitiers (d. 367). The date of its introduction into the public services of the church cannot be determined precisely. In the Eastern Church it was used in the morning office apparently as early as the 4th century, but has never formed part of the Liturgy. In the West, where it is used in the Mass, Pope Symmachus (498–514) is said in the Liber Pontificalis to have ordered it to be sung on Sundays and festival days; it is mentioned in the Gregorian Sacramentary, but not in the Gelasian. Until the 11th century its use was confined to bishops, and to priests at Easter and on their installation. In the English prayer book it comes near the end of the communion office, but is not in either the morning or evening service. It is also used in the Protestant Episcopal and Methodist Episcopal churches of America, as indeed in most Protestant churches at the Eucharist.

The Lesser Doxology, or *Gloria Patri,* in its present form, is the result of the Arian controversies concerning the nature of Christ. There is no trace of its use in the first three centuries; and the second clause, "As it was in the beginning," etc., first appears in A.D. 529, when the and council of Vaison asserted its use as already established in the East *propter haereticorum astutiam,* and ordered its adoption throughout the West. In the Western Church the *Gloria Patri* is repeated at the close of every psalm, in the Eastern Church at the close of the last psalm. This last is the optional rule of the American Episcopal Church.

Metrical doxologies are often sung at the end of hymns, and the term has become especially associated with the stanza beginning "Praise God from whom all blessings flow," with which Thomas Ken, bishop of Bath and Wells, concluded his morning and evening hymns.

See J. Bingham, *Biog. eccles.* xiv. 2; Siegel, *Christl. Alterthümer,* i. 515, etc.; F. Procter, *Book of Common Prayer,* p. 212; *W.* Palmer, *Orig. Liturg.* iv. § 23; art. "Liturgische Formeln" (by Drews) in Hauck-Herzog, *Realencyk. für prot. Theol.* xi. *547; Cath. Encycl.*

DOYEN, GABRIEL FRANÇOIS (1726–1806), French painter, was born at Paris in 1726. He became in his 12th year a pupil of Vanloo, obtained at 20 the Grand Prix, and in 1748 set out for Rome. Among his greatest works are counted the "Miracle des Ardents," painted for the church of Ste Geneviève at St. Roch (1773); the "Triumph of Thetis," for the chapel of the Invalides; and the "Death of St. Louis," for the chapel of the Military School. In 1776 he was appointed professor at the Academy of Painting. Soon after the beginning of the Revolution he accepted the invitation of Catherine II. and settled at St. Petersburg, where he died on June 5 1806.

DOYLE, SIR ARTHUR CONAN (1859–1930), English novelist, knighted in 1902, eldest son of the artist Charles Doyle, was born on May 22, 1859. He was educated at Stonyhurst College, in Germany, and at Edinburgh University where he graduated M.B. in 1881 and M.D. in 1885. He was practising as a doctor in Southsea when he published *A Study in Scarlet* in 1887. *Micah Clarke* (1888), a tale of Monmouth's rebellion, *The Sign of Four* (1889), and *The White Company* (1891), a romance of Du Guesclin's time, followed. In *Rodney Stone* (1896) he drew an admirable sketch of the prince regent; and he collected a popular series of stories of the Napoleonic wars in *The Exploits of Brigadier Gerard* (1896). In 1891 he attained immense popularity by *The Adventures of Sherlock Holmes,* which first appeared in *The Strand Magazine.* These ingenious stories of the success of the imperturbable Sherlock Holmes, who had made his first appearance in *A Study in Scarlet* (1887), in detecting crime and disentangling mystery, found a host of imitators. The novelist himself returned to his hero in *The Memoirs of Sherlock Holntes* (1893) *The Hound of the Baskervilles* (1902), and *The Return of Sherlock Holmes* (1905). Other books by him include numerous novels; plays, *The Story of Waterloo* (1894), in which Sir Henry Irving played the leading part, *The Fires of Fate* (1909), *The House of Temperley* (1909), *The Poison Belt* (1913); two books in defence of the British army in South Africa—The *Great Boer War* (1900) and *The War in South Africa; its Causes and Conduct* (1902). During the World War Doyle wrote propaganda for the Allies. His *Cause and Conduct of the World War* appeared in 12 languages besides English. In his later years Doyle was a convinced spiritualist and a lecturer and writer on spiritualism. He died on July 7, 1930.

Among his later works were; *History of the British Campaign in France and Flanders* (vols. i. to vi., 1915–20); *A New Revelation* (1918); *History of Spiritualism* (2 vols., 1926); and *My Memories and Adventures* (1924).

DOYLE, SIR FRANCIS HASTINGS CHARLES, 2ND BARONET (1810–1888), man of letters, the son of Sir F. H.

Doyle, chairman of the board of excise, was born at Nunappleton, Yorkshire. Doyle published several volumes of verse, and was a fellow of All Souls and professor of poetry at Oxford from 1867 to 1877. He also held various positions in the customs department. Doyle is remembered for a few spirited pieces, among them "The Loss of the Birkenhead" and "The Private of the Buffs."

See his *Reminiscences and Opinions* (1886).

DOYLE, JOHN ANDREW (1844–1907), English historian, the son of Andrew Doyle, editor of the *Morning Chronicle*, was born on May 14, 1844, and died on Aug. 4, 1907. He was educated at Eton and at Balliol college, Oxford, and was a fellow of All Souls from 1870 until his death. His principal work is *The English Colonies in America* (5 vols. 1882–1907), dealing with the history of the colonies from 1607 to 1759.

DOYLE, RICHARD (1824–1883), English artist, son of John Doyle, the caricaturist known as "H.B." (1797–1868), was born in London in Sept. 1824, and died there on Dec. 11, 1883. His father's political sketches took the town by storm in the days of Lord Grey and Lord Melbourne. The son, who was extremely precocious, had no art training outside his father's studio, where he was not allowed to draw from the model, the result being that he never attained a higher position that than of an extremely skilful amateur. He was possessed, however, of an extraordinary power of fanciful draughtmanship and a keen sense of the grotesque. He was on the staff of *Punch* from 1843 to 1850 and the design of the cover is by him. After his resignation from that paper his work was mainly that of book illustration and water colour painting. He illustrated three of the *Christmas Books* of Charles Dickens and The *Newcomes* by Thackeray. His *Comic English Histories*, published after his death, and his *Manuscript Journal*, now in the British Museum and published in facsimile in 1886, were both executed when he was only 1 j.

See G. Everitt, *English Caricaturists* (1886); *M.* H. Spielmann, *The History of "Punclz"* (1895); *F.* G. Kitton, *Dickens and his Illustrators* (1899).

DOZSA, GYORGY (d. 1514), Hungarian revolutionary, was a Szekler squire and soldier of fortune, who won such a reputation for valour in the Turkish wars that the Hungarian chancellor, Tamás Bákocz, on his return from Rome in 1514 with a papal bull preaching a holy war against the Muslims, appointed him to organize and direct the movement in Hungary. In a few weeks he collected thousands of so-called *Kuruczok* (a corruption of *Cruciati*), consisting largely of the most oppressed portion of the community, to whom alone a crusade against the Turk could have the slightest attraction. They assembled in their counties and by the time Dozsa had drilled them into some sort of discipline and self-confidence, they began to air the grievances of their class. No measures had been taken to supply the volunteers with food or clothing; at harvest time the landlords ordered them to return to reap the fields, and when they refused to do so, maltreated their wives and families and set their armed retainers upon the half-starved multitudes. Instantly the movement was changed into a war of extermination against the landlords. Dozsa had lost control of the rabble, who were led by a socialist parson of Szegled, Lorincz Mészáros. Hundreds of manor-houses and castles were burnt and thousands of the gentry done to death by impalement, crucifixion and other unspeakable methods. The rising soon attained the dimensions of a revolution; the feudal levies of the kingdom were called out against it, and mercenaries were hastily hired from Venice, Bohemia and the emperor. At first it seemed as if the Government were incapable of coping with Dozsa and his bands. In the summer he took the fortresses of Arad, Lippá and Világos, and one of his bands got within five leagues of the capital. But at last his peasants were overmatched by the mail-clad nobles. Dozsa, too, had become demoralized with success. He was finally routed at Temesvár by the combined forces of János Zápolya and István Báthory, taken prisoner and afterwards put to death with the most unspeakable barbarities.

See Sandor Marki, *Dozsa Gyorgy* (Budapest, 1884); and a novel by Eotvos trans. into German as *Der Bauernkrieg in Uugarn* (1850).

DOZY, REINHART PIETER ANNE (1820–1883), Dutch Arabic scholar of French (Huguenot) origin, was born at Leyden. His monumental *Histoire des Mussulmans d'Espagne, jusqu'à la conquête de l' Andalousie par les Almoravides, 711–1110* (Leiden, 1861; 2nd ed., *ibid.*, 1881; Eng. trans. 1913), a graphically written account of Moorish dominion in Spain, which shed new light on many obscure points, has remained the standard work on the subject. Dozy's *Rechcrches sur l'histoire et la littérature de l'Espagne pendant le moyen âge* (Leiden, 2 vols., 1849; recast edns. in 1860 and 1881) forms a trenchant addition to his *Histoire*. His *Supplément aux dictionnaires arabes* (Leiden, 1877–1881, 2 vols.), a work full of research and learning, a storehouse of Arabic lore, followed, and to the same class belongs his *Glossaire des mots espagnols et portugais, dérivés de l'Arabe*, edited with Dr. W. H. Engelmann of Leipzig (Leiden, 1866; 2nd ed., 1868). Dozy also edited many Arabic texts. *Het Islamisme (Islamism;* Haarlem, 1863, 2nd ed., 1880; French translation) is a popular exposition of Mohammedanism, of a more controversial character; and *De Israelieten te Mekka* ("The Israelites at Mecca," Haarlem, 1864) became tbe subject of discussion in Jewish circles. Dozy died at Leiden, where he was a professor of history for thirty years, in May 1883.

See J. de Goeje, *Biographie de Reinhart Dozy* (1883); and biographical introduction to F. G. Stokes's English translation of Dozy's *Histoire des Mussulmans d'Espagne, Spanish Islam* (1913).

DRACAENA, a genus of the family Liliaceae, containing about 50 species in the warmer parts of the old world. They are trees or shrubs with long, generally narrow leaves, panicles of small whitish flowers and berried fruit. The most remarkable species is *Dracaena draco*, the dragon tree of the Canary Isles, which reaches a great size and age. The famous specimen in Teneriffe, which was blown down by a hurricane in 1868, when measured by Alexander von Humboldt, was 70 ft. high, with a circumference of 45 ft. several feet above the ground, and was supposed to be 6,000 years old. A resin exuding from the trunk is known as dragon's blood (*q.v.*). D. *fragrans* and *D. goldieana* are common greenhouse plants.

Some of the cultivated Dracaenas belong to the closely-allied genus *Cordyline*. They are grown for the beauty of form, colour and variegation of their foliage and are extremely useful as decorative house or greenhouse plants and for table decoration. A large number of the garden species of Dracaena are varieties of *Cordyline terminalis* of eastern Asia.

DRACHENFELS, a mountain of the Siebengebirge range, situated above the Rhine near Königswinter. It occupies a magnificent position overlooking Bonn at an altitude of 1.066 feet. The ruins of a mediaeval castle are at the summit.

DRACHM: *see* DRAM.

DRACHMA. The monetary unit of Greece, divided into 100 lepta. Until 1936 it was nominally equivalent to the franc, the par of exchange with London being Dr. 25.22 to the pound, while at par in New York it exchanged for 19·295 cents.

Greece entered the Latin Union in 1875, following on the law of 1867, but the currency in circulation has always been paper, and even before the World War was quoted at a discount to gold. During the War, Greece occupied what was in one respect a favourable position, as the presence of the Allied forces at Salonika was the cause of a steady demand for drachmae by the Allied Governments. Foreign exchanges, consequently, were well maintained, and this favourable position continued for a year or so after the Armistice.

The outbreak of war with Turkey dealt the first blow to the drachma, and by the end of 1920, it had fallen in New York to 7.56 cents, while the note issue had risen to Dr. 1,508,000,000 from Dr. 245,000,000 in 1913. Defeat in the field and its consequences led to further depreciation, and from 1921 to 1927 the drachma remained between one and two cents. In 1924 the Greek Refugee Loan was issued under League of Nations' auspices, and ineffective steps towards stabilization were taken at the end of 1927. In Sept. 1936 stabilization was finally achieved by the linking of the drachma to sterling, the buying price being fixed within the limits of 540 to 550 to the £ and the price of other currencies

on the basis of their parity to sterling.

See also CURRENCY and GREECE: *Economy and Finance.*

DRACHMANN, HOLGER HENRIK HERBOLDT (1846–1908), Danish poet and dramatist, son of Dr. A. G. Drachmann, a physician of Copenhagen, whose family was of German extraction, was born in Copenhagen on Oct. 9, 1846. At various periods he travelled very extensively in England, Scotland, France, Spain and Italy, and his literary career began by his sending letters about his journeys to the Danish newspapers. After returning home, he settled for some time in the island of Bornholm, painting seascapes. He now issued his earliest volume of poems, *Digte* (1872), and joined the group of young Radical writers who gathered under the banner of Brandes. By this time he had enjoyed a surprising experience of life, especially among sailors, fishermen, students and artists, and the issues of the Franco-German War and the French Commune had persuaded him that a new and glorious era was at hand. His volume of lyrics, *Daempede Melodier* ("Muffled Melodies," 1875), proved that Drachmann was a poet with a real vocation, and he began to produce books in prose and verse with great rapidity. *Ungt Blod* ("Young Blood," 1876) contained three realistic stories of contemporary life. But he returned to his true field in his magnificent *Sange ved Havet; Venezia* ("Songs of the Sea; Venice," 1877), and won the passionate admiration of his countrymen by his prose work, with interludes in verse. called *Derovre fra Graensen* ("Over the Frontier there," 1877), a series of impressions made on Drachmann by a visit to the scenes of the war with Germany. During the succeeding years he visited most of the principal countries of the world, and familiarized himself by protracted voyages with the sea and with the life of man in maritime places. In 1879 he published *Ranker og Roser* ("Tendrils and Roses"), love lyrics in which he showed a great advance in technical art. To the same period belongs *Paa Somands Tro og Love* ("On the Faith and Honour of a Sailor," 1878), a volume of short stories in prose. About this time Drachmann broke with Brandes and the Radicals, and led a "nationalist" or popular-Conservative party in Denmark. He continued to celebrate the life of the fishermen and sailors in books, whether in prose or verse, which were the most popular of their day. *Paul og Virginie* and *Lars Kruse* (both 1879); *Östen for Sol og vesten for Maone* ("East of the Sun and West of the Moon," 1880); *Puppe og Sommerfugl* ("Chrysalis and Butterfly," 1882); and *Strandby Folk* (1883) were among these. In 1882 Drachmann published his fine translation, or paraphrase, of Byron's *Don Juan.* In 1885 his romantic play called *Der var en Gang* ("Once upon a Time") had a great success on the boards of the Royal theatre, Copenhagen; and his tragedies of *Volund Smed* ("Wayland the Smith") and *Brav-Karl* (1897) made him the most popular playwright of Denmark. He published in 1894 a volume of exquisitely fantastic *Melodramas* in rhymed verse, a collection which contains some of Drachmann's most perfect work. His novel *Med den brede Pensel* ("With a Broad Brush," 1887) was followed in 1890 by *Forskrevet,* the history of a young painter, Henrik Gerhard, and his revolt against his bourgeois surroundings. With this novel is closely connected *Den hellige Ild* ("The Sacred Fire," 1899), in which Drachmann speaks in his own person. There is practically no story in this autobiographical volume, which abounds in lyrical passages. In 1899 he produced his romantic play called *Gurre;* in 1900 a brilliant lyrical drama, *Hallfred Vandraadeskjald;* and in 1903, *Det grönne Haab.* He died in Copenhagen on Jan. 14, 1908.

See an article by K. Gjellerup in *Dansk Biografisk Lexikon* vol. iv. (1890). (E. G.)

DRACO (DRACON) (7th century B.C.), Athenian statesman, was Archon Eponymus (but *see* Sandys, *Const. of Athens,* p. 12, note) in 621 B.C. He codified the laws, which had previously been unwritten and administered arbitrarily by the Eupatrids. The fixing of the law was a great boon to the people, although later ages regarded Draco's code, in which "for nearly all crimes there was the same penalty of death" (Plut. *Solon),* as barbarously severe. For the institution of the 51 Ephetae and their relation to the Areopagus in criminal jurisdiction, *see* GREEK LAW.

But in 1891 appeared Aristotle's treatise on the constitution of Athens, the 4th chapter of which credits to Draco the construction of an entirely new constitution for Athens, the main features of which were: (1) extension of franchise to all who could provide themselves with a suit of armour; (2) the institution of a property qualification for office (archon 10 minae, strategus 100 minae); (3) a council of 401 members *(see* BOULĒ); (4) magistrates and councillors to be chosen by lot; further, the four Solonian classes are said to be already in existence.

But the passage is now generally considered spurious on the following grounds: (1) It is ignored by every other ancient authority, except an admittedly spurious passage in Plato;[1] whereas Aristotle says of his laws "they are laws, but he *added the laws to an existing constitution"* (Pol. ii. 9. 9). (2) It is inconsistent with other passages in the *Constitution of Athens.* It embodies some of the most advanced features of Solon's constitution, yet, according to ch. vii., Solon repealed all laws of Draco except those relating to murder. (3) Its ideas are alien to the 7th century. That the qualification of the strategus should be ten times that of the archon is reasonable in the 5th but preposterous in the 7th century. Again it is unlikely that, had a wealth qualification for citizenship been established, Solon, a democratic reformer, would have reverted to an aristocratic birth qualification. (4) The terminology of Draco's constitution is that of the 5th century, whereas the chief difficulty of Solon's laws is the obsolete 6th century phraseology. (5) Lastly, the "Draconian Constitution" (hoplite census, nobody to hold office a second time until all duly qualified persons had been exhausted, fine for non-attendance in Boulē), embodies the ideals of Theramenes and the moderate oligarchs, which they expressed by the phrase ἡ πάτριος πολιτεία.

Criticism of the text supports the hypothesis that ch. iv. is an interpolation. Chapter iv. breaks the connection of thought between iii. and v. Moreover, an interpolator has inserted phrases to remove obvious contradictions: thus *(a)* in ch. vii., where we are told that Solon divided the citizens into four classes the interpolator adds "according to the division formerly existing," which was necessary in view of the statement that Draco gave the franchise to the Zeugites; *(b)* in ch. xli., the words "the Draconian" (ἡ ἐπὶ Δράκοντος) are inserted in the list of constitutions, though the subsequent figures are not accommodated to the change. Solon is also here spoken of as the founder of democracy, whereas the Draconian constitution of ch. iv. contains several democratic innovations. Two further points may be added, namely, that whereas Aristotle's account mentions a money fine, Pollux quotes a law of Draco in which fines are assessed at so many oxen; secondly, that though the treatise was widely read in antiquity there is no reference to Draco's constitution except the two quoted above. In any case, whatever were Draco's laws, Solon abolished all of them (Plut. *Solon)* except those dealing with homicide.

See J. E. Sandys, *Aristotle's Constitution of Athens* (2nd ed. 1912); G. Gilbert, *Constitutional Antiquities* (Eng. trans. 1895) and works, quoted in article CONSTITUTION OF ATHENS; Grote, *Hist. of Greece* (ed. 1907), pp. 9–11, with references; and histories of Greece published after 1894.

DRACO ("the Dragon"), in astronomy, a constellation of the northern hemisphere. The Greeks had many fables concerning this constellation; one is that when Heracles killed the dragon guarding the Hesperian fruit, Hera transferred the creature to heaven as reward for its services. The star γ Draconis has acquired historic interest because from his observations of it Bradley discovered the phenomenon of aberration of light *(see* ABERRATION). It enjoyed this distinction because it chances to be the brightest star that passes close to the zenith of Greenwich. so that errors of observation arising from refraction are minimized.

DRACONTIUS, BLOSSIUS AEMILIUS, of Carthage (according to the early tradition, of Spanish origin), Christian poet, flourished in the latter part of the 5th century A.D. He belonged to a family of landed proprietors and practised as an advocate in his native place. After the conquest of the country by the Vandals, Dracontius was at first allowed to retain his

[1] A passage (long overlooked) in Cicero, De *republica,* shows that, by the 1st century B.C. the interpolation had already been made; the quotation is evidently taken from the list in ch. xli. of the *Constitution,* which it reproduces.

estates but was later thrown into prison by the Vandal king. He addressed an elegiac poem to the king, asking pardon and pleading for release. The result is not known, but it is supposed that Dracontius obtained his liberty and migrated to northern Italy. This is consistent with the discovery at Bobbio of a 15th century ms., now in the Museo Borbonico at Naples, containing a number of poems by Dracontius (the *Carmina minora).* The most important of his works is the *De laudibus Dei* or *De Deo* in three books, wrongly attributed by ms. tradition to St. Augustine. The account of the Creation, which occupies the greater part of the first book, was at an early date edited separately under the title of *Hexaemëron,* and it was not till 1791 that the three books were edited by Cardinal Arevalo. The apology *(Satisfactio)* consists of 158 elegiac couplets; it is generally supposed that the king addressed is Gunthamund (484–496). The *Carmina minora,* nearly all in hexameter verse, are school exercises and rhetorical declamations. It is also probable that Dracontius was the author of the *Orestis tragoedia,* a poem of some 1,000 hexameters, which in language, metre and general treatment resembles the other works of Dracontius. His works show considerable vigour of expression and a remarkable knowledge of the Bible and of Roman classical literature.

DRAFT. A written order drawn on a banker or other holder of funds for the payment of money to a third person; thus a cheque (*q.v.*) is a draft. **A** special form of draft is a banker's draft, an instruction by one bank to another bank, or to a branch of the bank making the instruction, to pay a sum of money to the order of a certain specified person.

The term is also used to describe an outline, plan or sketch, or a preliminary drawing-up of an instrument, measure, document, etc., which, after alteration and amendment, will be embodied in a final or formal shape; an allowance made by merchants or importers to those who sell by retail, to make up a loss incurred in weighing or measuring; and a detachment or body of troops "drawn off" for a specific purpose, usually a reinforcement from the depôt or reserve units to those abroad or in the field. For draft in compulsory military service, *see* CONSCRIPTION.

DRAFTED MASONRY, in architecture, masonry formed of large stones, dressed or cut round the edge to a single plane, with the face between left as it came from the quarry. Many notable Roman examples exist, such as that of the Porta Maggiore, at Rome (period of the emperor Claudius, c. A.D. 50). It was also particularly common in the Near East, being found from the time of Cyrus, in the platform at Pasargadae *(c.* 530 B.C.), up to the time of the castles built by the crusaders. In the Renaissance drafted masonry was used occasionally for decorative purposes, as in the Riccardi palace at Florence by Michelozzi (c. 1430). When so used it is sometimes loosely termed "rustication."

DRAG. The term is applied to a harrow for breaking up clods of earth, or to an apparatus, such as a grapnel, net or dredge, used for searching water for drowned bodies or other objects. As a name of a vehicle, "drag" is sometimes used as equivalent to "break," a heavy carriage without a body used for training horses, and also a large kind of wagonette, but is more usually applied to a privately-owned four-horse coach for four-in-hand driving. The word is also given to the "shoe" of wood or iron placed under the wheel to act as a brake, and also to the "drift" or "sea-anchor," usually made of spars and sails, employed for checking the lee-way of a ship when drifting. In fox-hunting, the "drag" is the line of scent left by the fox, but more particularly the term is given to a substitute for the hunting of a fox by hounds, an artificial line of scent being laid by the dragging of a bag of aniseed or other strong smelling substance which a pack will follow.

DRAGASHANI (Rumanian *Dragaşani*), a town of Rumania, near the right bank of the river Olt, and on the railway between Caracal and Râmnicu Vâlcea.

The vineyards on the neighbouring hills produce some of the best Walachian wines. Dragashani stands on the site of the Roman Rusidava. In 1821 the Turks routed the troops of Ypsilanti near the town.

DRAGO DOCTRINE. The government of every state, declared Lord Palmerston in 1848, is entitled by diplomatic methods to take up the complaint of any of its subjects against the government of another state, and if well founded, to demand redress. It has been the policy of the British Government not to encourage its subjects to hazard their capital by investing in foreign loans, and consequently it has usually refused to interfere when foreign governments have failed to meet their obligations. Lord Palmerston, however, added that in certain circumstances the Government might be prepared to go to the length of using force. To this statement Lord Salisbury subsequently gave his assent in 1880. In 1902 Venezuela having failed to comply with the demands made by Great Britain, Germany and Italy to make good its default in respect of its external loans, was called upon by these Powers to honour its obligations. Failing to obtain satisfaction, a blockade of certain Venezuelan ports was instituted. This led to the despatch of a note from Dr. Drago, foreign minister of the Argentine Republic, to the Argentine minister at Washington declaring that the principle should be accepted that for the common safety of the South American Republics, just as the Monroe doctrine is a principle enforced by the United States for the preservation of the territorial *status quo* throughout the American Continent against European aggression, the collection of pecuniary claims of citizens of any country against the Government of any South American Republic should not be effected by armed force. This proposal, however, did not find general acceptance, but by the Hague Convention (1907), the contracting Powers agreed not to have recourse to armed force for the recovery of contract debts claimed from the Government of one state by the Government of another state as due to its nationals. This agreement, however, does not apply if the debtor state refuses or neglects to accept an offer of arbitration, or after accepting the offer, prevents any *compromis* being reached, or after an award, fails to carry it out. *See* Sir T. Barclay, *Problems of International Law and Diplomacy* (1907); Phillimore, *International Law,* vol. II. (1854–61).

DRAGOMAN OF CAIRO, EGYPT, WHO ACTS AS INTERPRETER AND GUIDE

DRAGOMAN, a comprehensive designation applied to anyone who acts as an intermediary between Europeans and Orientals, whether as hotel tout or travellers' guide, or as the chief dragoman of a foreign embassy whose functions may include the carrying on of important political negotiations. (Ar. *terjuman,* an interpreter, cf. Heb. *targum.*)

The original employment of dragomans by the Turkish government arose from its religious scruples to use the language of any peoples which had not adopted Islam, while its political relations compelled the sultan's ministers to make use of interpreters, who rapidly acquired considerable influence. The first chief dragoman of the Porte was Panayot Nikousia, who held his office from 1665 to 1673. His successor, Alexander Mavrocordato (*q.v.*), Exaporritos, was charged by the Turkish government with the delicate and arduous negotiation of the treaty of Carlowitz, and succeeded in becoming the factotum of Ottoman policy. From that time until 1821 the Greeks monopolized the management of Turkey's foreign relations, and soon established the regular system whereby the chief dragoman passed on as a matter of course to the dignity of hospodar (*q.v.*) of one of the Danubian principalities.

In the same way, the foreign representatives accredited to the

former sultan of Turkey, found it necessary, in the absence of duly qualified countrymen of their own, to engage the services of natives, Greek, Armenian or Levantine, more or less thoroughly acquainted with the language, laws and administration of the country, who became the confidential go-betweens of the foreign missions and the Porte. But the disadvantages of the system soon became apparent, and as early as 1669 the French government decided on the foundation of a school for French dragomans at Constantinople, for which in later years was substituted the *École des langues orientales* in Paris; most of the great powers eventually took some similar step, England also adopting in 1877 a system, since modified, for the selection and tuition of a corps of British-born dragomans.

The functions of the first dragoman are mainly political and connected with diplomatic negotiations, while the subordinate dragomans transact the less important business comprising in general all the various matters in which the interests of foreign subjects may be concerned. The high estimation in which the dragomans are held by most foreign powers is shown by the fact that they are promoted to the most important diplomatic posts. In the Russian, Austrian and German services more than one ambassador began his career as a junior dragoman, and the French chief dragoman usually attains the rank of minister plenipotentiary. The more important consulates in the provinces of Turkey are also provided with one or more dragomans, whose duties, *mutatis mutandis,* are of a similar though less important nature. In the same way banks, railway companies and financial institutions employ dragomans for facilitating their business relations with Turkish officials.

DRAGOMIROV, MICHAEL IVANOVICH (1830–1905), Russian general and military writer, was born on Nov. 8, 1830. He entered the Guards in 1849 and from 1854 to 1859 studied military science first at the Russian staff college (Nicholas Academy) and then abroad. On his return to Russia he became professor of tactics at the staff college. He played a leading part in the reorganization of the educational system of the army, and acted as instructor to several princes of the imperial family. He took part in the suppression of the Polish insurrection of 1863–64. During the Austro-Prussian War of 1866, Dragomirov was attached to the headquarters of the II. Prussian army. He was present at the battles on the upper Elbe and at Koniggratz, and his comments on the operations which he witnessed are of the greatest value to the student of tactics and of the war of 1866.

In the Russo-Turkish war of 1877–78 he commanded the 14th division, which led the way at the crossing of the Danube at Zimnitza. Later, after the reverses before Plevna, he, with the tsarevich and Generals Todleben and Milutine, strenuously opposed the suggestion of the Grand Duke Nicholas that the Russian army should retreat into Rumania, and the demoralization of the greater part of the army was not permitted to spread to Dragomirov's division. He was wounded at the Shipka pass, and further disabled for active service. For 11 years thereafter General Dragomirov was chief of the Nicholas Academy. He collated and introduced into the Russian army all the best military literature of Europe, and improved the morale and technical efficiency of the Russian officer-corps, especially of the staff officer. In 1889 Dragomirov became commander-in-chief of the Kiev military district, and governor-general of Kiev, Podolsk and Volhynia, retaining this post until 1903. He was promoted to the rank of general of infantry in 1891. During the Russo-Japanese War of 1904–05 he was consulted by the general headquarters at St. Petersburg (Leningrad), and while he disagreed with General Kuropatkin in many important questions of strategy and military policy, they both recommended a repetition of the strategy of 1812, even though the total abandonment of Port Arthur was involved. General Dragomirov died at Konotop on Oct. 28, 1905.

His larger military works were mostly translated into French and German, and his occasional papers, extending over a period of nearly 50 years, appeared chiefly in the *Voienni Svornik* and the *Razoiedschik;* his later articles in the last-named paper were, like the general orders he issued to his own troops, attentively studied throughout the Russian army. His critique of Tolstoi's *War and Peace* attracted even wider attention. Dragomirov was, in formal tactics, the head of the "orthodox" school. He inculcated the "offensive at all costs," and the combination of crushing short-range fire and the bayonet charge. He carried out the ideas of Suvarov to the fullest extent, and many thought that he pressed them to a theoretical extreme unattainable in practice.

DRAGON, a fabulous monster, usually conceived as a huge-winged, fire-breathing lizard or snake. The word is derived through the French and Latin from the Greek δράκων, connected with δέρκομαι "see," and interpreted as "sharp-sighted." The equivalent English word "drake" or "fire-drake" is derived from Anglo-Saxon *draca.* In Greece the word δράκων, was used originally of any large serpent, and the dragon of mythology, whatever shape it may have assumed, remains essentially a snake. For the part it has played in the myths and cults of various peoples and ages *see* the article SERPENT-CULTS. Here it may be said, in general, that in the East, where snakes are large and deadly (Chaldaea, Assyria, Phoenicia, to a less degree in Egypt), the serpent or dragon was symbolic of the principle of evil. Thus Apophis, in the Egyptian religion, was the great serpent of the world of darkness vanquished by Ra, while in Chaldaea the goddess Tiāmat, the female principle of primeval Chaos, took the form of a dragon. Thus, too, in the Hebrew sacred books the serpent or dragon is the source of death and sin, a conception which was adopted in the New Testament and so passed into Christian mythology. In Greece and Rome, on the other hand, while the oriental idea of the serpent as an evil power found an entrance and gave birth to a plentiful brood of terrors (the serpents of the Gorgons, Hydra, Chimaera and the like), the *dracontes* were also at times conceived as beneficent powers—sharp-eyed dwellers in the inner parts of the earth, wise to discover its secrets and utter them in oracles, or powerful to invoke as guardian genii. Such were the sacred snakes in the temples of Aesculapius and the *sacri dracontes* in that of the Bona Dea at Rome; or, as guardians, the Python at Delphi and the dragon of the Hesperides.

In general, however, the evil reputation of dragons was the stronger, and in Europe it outlived the other. Christianity, of course, confused the benevolent and malevolent serpent deities of the ancient cults in a common condemnation. The very "wisdom of the serpent" made him suspect; "the devil," said St. Augustine, "is a lion and a dragon; a lion because of his rage and a dragon because of his wiles." The dragon myths of the pagan East took new shapes in the legends of the victories of St. Michael and St. George; and the kindly snakes of the "good goddess" lived on in the *immanissimus draco* whose baneful activity in a cave of the Capitol was cut short by the intervention of the saintly pope Silvester I. In this respect indeed Christian mythology agreed with that of the pagan north. The similarity of the northern and oriental snake myths seems to point to a common origin in remote antiquity. Whatever be the origin of the northern dragon, the myths, when they first appear, show him to be in all essentials the same as that of the south and east. He is a power of evil, guardian of hoards, the greedy withholder of good things from men; and the slaying of a dragon is the crowning achievement of heroes—of Siegmund, of Beowulf, of Sigurd, of Arthur, of Tristram—even of Lancelot, the *beau idéal* of mediaeval chivalry. Nor were these dragons anything but very real terrors. In the works of the older naturalists, even in the great *Historia animalium* of so critical a spirit as Conrad Gesner (d. 1564), they still figure as part of the fauna known to science.

As to their form, this varied from the beginning. The Chaldaean dragon Tiāmat had four legs, a scaly body, and wings. The Egyptian Apophis was a monstrous snake, as were also, originally at least, the Greek *dracontes.* The dragon of the Apocalypse (Rev. xii. 3), "the old serpent," is many-headed, like the Greek Hydra. The dragon slain by Beowulf is a snake (worm), for it "buckles like a bow"; but that done to death by Sigurd, though its motions are heavy and snake-like, has legs, for he wounds it "behind the shoulder." On the other hand, the dragon seen by King Arthur in his dreams is, according to Malory, winged and active, for it "swoughs" down from the sky. The belief in dragons

and the conceptions of their shape were undoubtedly often determined by the discovery of the remains of the gigantic extinct saurians.

The qualities of dragons being protective and terror-inspiring, and their effigies decorative, they were early used as warlike emblems. Thus, in Homer *(Iliad,* xi. 36 *seq.),* Agamemnon has on his shield, besides the Gorgon's head, a blue three-headed snake, just as ages afterwards the Norse warriors painted dragons on their shields and carved dragons' heads on the prows of their ships. From the conquered Dacians, too, the Romans in Trajan's time borrowed the dragon ensign which became the standard of the cohort as the eagle was that of the legion; whence, by a long descent, the modern dragoon. Under the later East Roman emperors the purple dragon ensign became the ceremonial standard of the emperors, under the name of the δρακόντειον. In England before the Conquest the dragon was chief among the royal ensigns in war. Its origin, according to the legend preserved in the *Flores historiarum,* was as follows: Uther Pendragon, father of King Arthur, had a vision of a flaming dragon in the sky, which his seers interpreted as meaning that he should come to the kingdom. When this happened, after the death of his brother Aurelius, "he ordered two golden dragons to be fashioned, like to those he had seen in the circle of the star, one of which he dedicated in the cathedral of Winchester, the other he kept by him to be carried into battle." From Uther Dragonhead, as the English called him, the Anglo-Saxon kings borrowed the ensign, their custom being, according to the *Flores,* to stand in battle "between the dragon and the standard." The dragon ensign which was borne before Richard I. in 1191, when on crusade, "to the terror of the heathen beyond the sea," was that of the dukes of Normandy; but even after the loss of Normandy the dragon was the battle standard of English kings, and was displayed, *e.g.,* by Henry III. in 1245 when he went to war against the Welsh. Not till the 20th century was the dragon officially restored as proper only to the British race of Uther Pendragon, by its incorporation in the armorial bearings of the prince of Wales. Thus the dragon and wyvern (*i.e.,* a two-legged snake, M.E. *wivere,* viper) took their place as heraldic symbols *(see* HERALDRY).

In the East the dragon is the national symbol of China and the badge of the imperial family, and as such plays a large part in Chinese art. Chinese and Japanese dragons, though regarded as powers of the air, are wingless. They are among the deified forces of nature of the Taoist religion, and the shrines of the dragon-kings, who dwell partly in water and partly on land, are set along the banks of rivers. *(See* also DRACO.)

See J. B. Panthot, *Histoire des dragons et des escarboucles* (Lyons, 1691); C. V. Daremberg and E. Saglio, *Dictionnaire des antiquitds grecques et romaines (1886,* etc.), *s.v.* "Draco"; Pauly-Wissowa, *Realencyklopadie, s.v.* "Drakon"; Du Cange, *Glossarium, s.v.* "Draco"; *La Grande Encyclopddie, s.v.* "Dragon." *See* also the articles EGYPT: *Religion;* and BABYLONIAN AND ASSYRIAN RELIGION. (W. A. P.)

The term "dragon" has no zoological meaning, but by the lay public it has been applied to two groups of existing lizards. The genus *Draco* includes a number of species of small lizards, found in the Indo-Malayan region, which are characterized by the possession of wing-like folds of skin projecting from the sides of the body and supported by the greatly elongated ribs. These structures do not involve the legs and cannot be used as actual wings for flight; they serve merely as gliding planes which extend the distance over which the animal can leap from one to another of the trees in which it lives. The largest form is only about 10 in. in length.

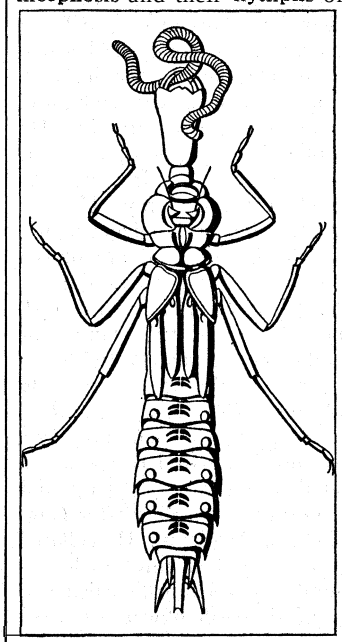
The other lizard to which the name is popularly applied is the giant monitor, *Varanus komodensis,* recently discovered in Komodo, one of the Dutch East Indies. It is a heavily built lizard of dull colour and reaches a length of at least 10 ft, thus vastly exceeding all other living lizards, although the extinct *Varanus priscus* of Australia attained perhaps twice the length.

In military use the name was applied to the musket—ornamented with the head of a dragon—from which the dragoons derive their name; and to-day it is given to a mechanical tractor for drawing guns, propelled by an internal combustion engine and running on caterpillar tracks. This machine, a variant of the steam tractor for heavy guns in use in most European armies before and during the World War, and of the war-time tank, has recently replaced teams of horses for the traction of guns and limbers in certain British field artillery brigades. *(See* further ARTILLERY.)

DRAGONET (*Callionymus lyra),* a small marine fish of the coasts of Europe, with slender naked body and large eyes close together on top of the flattish triangular head. The male is larger and more ornamental than the female, the body and the large dorsal fins having blue spots and bands on an orange ground. There is courtship and pairing, the male and female swimming upwards in an embrace.

DRAGONETTI, DOMENICO (1763–1846), Italian double-bass player, was born in Venice on April 7, 1763, and died in London on April 16, 1846. Dragonetti was a virtuoso of the first rank, and one of the best-known figures in the musical life of his day. His first appearance in London was in 1794. In London he met Lindley, with whom he played regularly from that time. In 1798 he visited Haydn at Vienna, and in 1808–09, on another visit to Vienna, he met Beethoven, whom he worshipped. In 1845, at the age of 82, he led the double-basses in the Beethoven Festival at Bonn.

DRAGON-FLY, the popular English name applied to members of a remarkable group of insects forming the order Odonata (or Paraneuroptera). They are sometimes known among country folk as "devils' darning needles" or "horse stingers," though they are incapable of stinging. Dragon-flies are easily recognized by their large eyes, minute antennae, two pairs of very similar narrow, glassy wings, the forward position of the legs, and their very elongated abdomen. They pass through an incomplete metamorphosis and their nymphs or naiads are aauatic. They attract notice by their rapid, skilful flight and the beauty of their form and coloration: none of the species is very small, and they are often large insects, the female of *Megaloprepus coerulatus,* for example, has a wing-expanse of 7½in., while the Carboniferous fossil *Meganeura* measures 2ft. across the wings.



BY COURTESY OF W. J. LUCAS

DRAGON-FLY NYMPH. WITH MASK EXTENDED, SEIZING ITS PREY

The female lays its eggs near or below the water, and, after they are hatched, the nymphs spend their lives in the water until full development

General Structure.—The head is large and very mobile, being capable of turning almost as on a pivot. Correlated with the great size of the eyes the antennae are correspondingly reduced and represented by very short 3- to 8-jointed bristle-like organs. The mouth-parts are adapted for biting, the mandibles being armed with powerful teeth while the labium is broad and plate-like. The wings are elongate, sub-equal and membranous with a complex network of veinlets between the principal veins, the wing-membrane being thus divided up into numerous cells which may exceed 3,000 in a single wing. The legs, being placed near together and far forward are little used for walking and are mainly employed for alighting and grasping. The abdomen is elongate and often extremely slender, and the male intromittent organ is placed beneath the second segment instead of at the apex as in other insects.

Classification.—Dragon-flies are divided into two principal sub-orders—the *Anisoptera* and the *Zygoptera.*

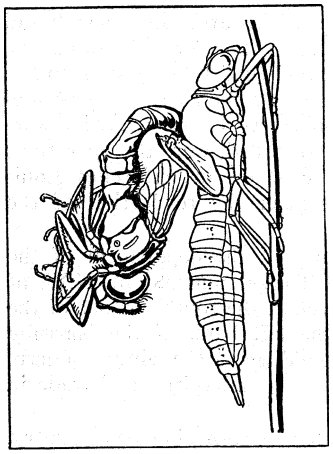
The *Anisoptera* hold their wings open when at rest and the hind wings are broader at their bases than are the fore wings. Included here are all the larger and stouter species to which the

name dragon-fly is commonly applied. There are five families, and well known genera are Libellula, Aeschna and Sympetrum.

The Zygopteru hold their wings closed in the vertical plane above the body when at rest, both pairs being closely alike with very narrow bases. The weaker, slow-flying species, often called damsel-flies, belong here: the sub-order includes nine families, and among common genera are Agrion, Ischnura and Calopteryx.

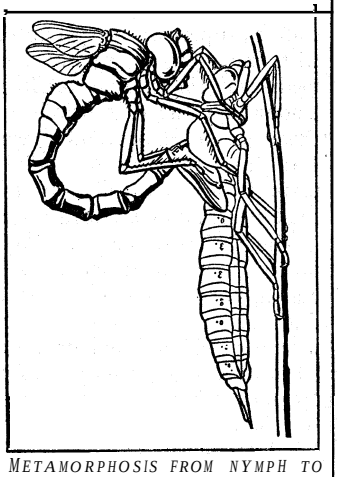
A third sub-order—the Anisozygoptera—includes a number of fossil dragon-flies and the single living genus *Epiophlebia* from Japan and India.

Reproduction and Development.—The pairing habits of dragon-flies are of a remarkable nature. Since the opening of the ducts from the testes lie on the ninth abdominal segment, and the male intromittent organ is situated on the second segment, this organ has to become charged with spermatozoa before mating occurs. The male when flying seizes the female across the prothorax using its claspers at the extremity of the body for the purpose: the abdomen of the female is then curved forwards so as to bring the genital orifice on the under side of her eighth abdominal segment in contact with the organ on the second segment of the male, so that insemination can take place. Most of the Anisoptera lay rounded eggs, which are either dropped freely in the water, or attached to aquatic plants: the Zygoptera and some Anisoptera have elongated eggs which they insert by means of slits cut by the ovipositor of the female in aquatic plants etc., near or beneath the water. In some cases the female (alone, or accompanied by the male) descends beneath the water for this purpose. The nymphs upon hatching spend their whole lives in water and are predacious, devouring various forms of aquatic life: those of the larger species will attack tadpoles and even small fish. Their mouth-parts are specially adapted for predatory habits, the labium (or mask) being modified into an organ for seizing the prey. When at rest it is folded away between the bases of the fore-legs, and, upon the appearance of a victim, it is rapidly extended and shot forward, impaling the prey upon the raptorial palpi which retain it while it is being devoured. In conformity with their aquatic life dragon-fly nymphs are supplied with special respiratory modifications in the form of gills. In most Zygoptera these take the form of three leaf-like lamellae at the caudal end of the body, but in the Anisoptera there is a very elaborate system of gills within the rectum or terminal chamber of the gut. In both sub-orders the gills are penetrated by tracheae and are covered by a thin membrane which allows of the inward passage by osmosis of oxygen dissolved in the water: in the Anisoptera water is alternately taken in and expelled from the rectum, and, in this way, the gills are kept aerated.



METAMORPHOSIS FROM **NYMPH** TO DRAGON-FLY

On leaving the water, the final change takes place, the anterior portion of the dragon-fly being liberated through the nymph-cuticle as shown in the drawing



METAMORPHOSIS FROM NYMPH TO **DRAGON-FLY**

The second stage shows the tail being extricated from the nymph-cuticle

Dragon-fly nymphs undergo frequent moults which probably range between about 11 and 15 in number. The length of life in nymphs of different species is subject to wide variation: in the smaller forms it does not exceed one year, but in some species it is probable that two, three or more years are spent in the water. Certain structural changes occur during growth, and in the later stages the developing wings becoming evident on the dorsal side of the body. When a nymph has attained its full growth it ceases to feed, leaves the water and often wanders some distance before it comes to rest for the final change: the latter is effected by the longitudinal splitting of the thoracic cuticle through which fissure the perfect insect gradually emerges. The figures illustrate the process in the common British Aeschna cyanea.

METAMORPHOSIS FROM NYMPH TO DRAGON-FLY

The third stage shows the whole body extricated from the nymph-cuticle

Geographical **Distribution.**—Over 2,500 species of dragon-flies are known and the whole group is very widely distributed. The largest number of species occur in Central and South America: Europe and northern Asia together have much fewer representatives than North America and rather more than 40 species occur in the British Isles. New Zealand is very poor in these insects, only 13 kinds being known, while just over 200 species are found in Australia. The species *Pantala flavescens* is one of the widest distributed of all insects, being found throughout the tropics, the Pacific islands, Australia, in Asia as far north as Kamchatka, and in South America as far south as Chile, but not in Europe

Geological **Distribution.**—Dragon-flies occupy an important place as fossils and occur in all the main geological periods from the Carboniferous onwards. In strata of Carboniferous age at Commentary, France, C. Brongniart has brought to light several gigantic fossil forms which differ sufficiently from those of today to require a separate order (the Protodonata) for their reception. These great insects extend into the Permian age where they seem to die out. The earliest true dragon-flies occur in the lower Permian rocks of Kansas and, although very rare in the Trias, they become more frequent in Liassic times when the Anisozygoptera flourished—a sub-order which is almost extinct today. In the Jurassic rocks of Siberia dragon-fly nymphs have been found: the Purbeck and Stonesfield-slate beds of England and the Solenhofen slates of Bavaria have all yielded dragon-fly remains. Coming to Tertiary times, the Miocene beds of Colorado and of Oeningen (Switzerland) have yielded abundant remains, including *Libellulid* nymphs from the latter locality. Scarcely any dragon-flies have been found in amber; probably such insects could release themselves if entrapped in the resin.

Natural History.—Although dragon-flies are aquatic in their early stages, the perfect insects are by no means confined to the vicinity of water, and many species seldom frequent such situations except for pairing and egg-laying. They are essentially sun-loving insects although some oriental species are known only to fly at night: many are exceedingly swift on the wing, and a speed of nearly 60m. an hour is recorded in the case of one species. Dragon-flies are predatory insects, capturing their prey upon the wing and holding it by their prehensile legs while devouring it. Most orders of winged insects are preyed upon including smaller species of their own kind. Although most, species seldom wander far and have often been noted returning again and again to a particular twig or other chosen spot, there are some with strong migratory instincts. Great swarms of the common European *Libellula quadrimaculata* have often been recorded, sometimes travelling far out to sea, and an Australian species has occasionally been noted to behave in a like manner.

Probably no order of insects rivals Odonata in the beauty of their coloration. In some species a whitish or bluish pruinescence

is often present over the usual body colours, appearing as a kind of bloom as on some fruits. It is abraded by age or wear and is most frequent in the male. The coloration of the two sexes is commonly very different—the males in some species may be unicolorous and their females bicolorous: in other species the females exist in two colour forms, one of which closely resembles that of the male. Most dragon-flies have hyaline wings, but in

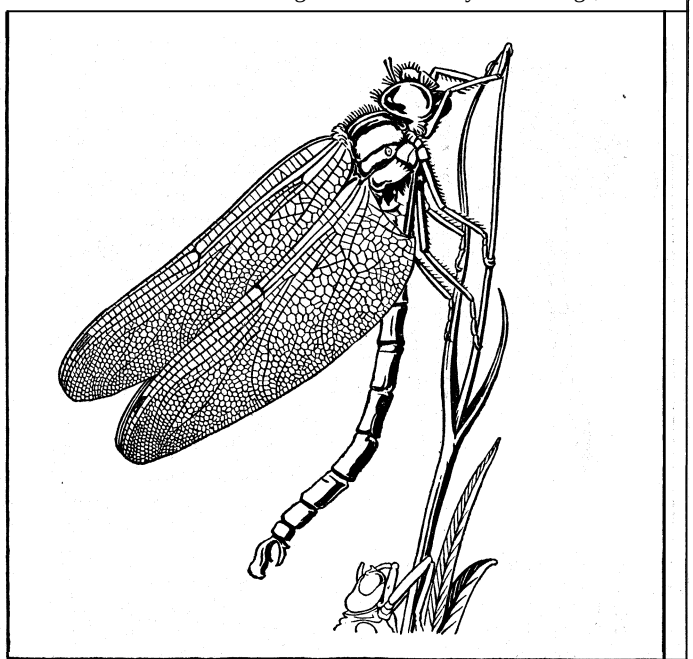


FIG. 5.—THE PERFECT DRAGON-FLY. ITS METAMORPHOSIS COMPLETE
The wings have acquired their full dimensions. The dragon-fly is seen resting to dry itself, before the wings are horizontally extended

species of *Calopteryx,* and other genera. the males have deep metallic green or blue wings: in certain tropical forms the wings exhibit a combination of glistening metallic green, purples, bronzes etc., that almost baffles description.

Economic Importance.—Dragon-flies are to be regarded as beneficial since they devour many noxious insects such as flies and mosquitoes. Their nymphs are active consumers of mosquito larvae and are themselves an important food for fishes.

BIBLIOGRAPHY.—The best general work on Odonata is R. J. Tillyard, *The Biology of Dragon-flies* (1917 bibl.). The British species are dealt with by W. J. Lucas, *British Dragon-flies* (1900); and an account of the European species is given by F. Ris, in *Süsswasserfauna Deutschlands* (1909), and by R. Tumpel, *Die geradflügler Mitteleuropas (1922).* For habits and transformations *see* L. C. Miall, *Natural History of Aquatic Insects* (1912). Keys to the North American genera and their nymphs are given in H. B. Ward and G. C. Whipple, *American Freshwater Biology* (1918). (A. D. I.)

DRAGON'S BLOOD, a red-coloured resin obtained from several species of plants. *Daemonorops draco,* one of the rotang or rattan palms, which produces much of the dragon's blood of commerce, is a native of Further India and the Eastern Archipelago. The fruit is round, pointed, scaly, and the size of a large cherry, and when ripe is coated with the resinous exudation known as dragon's blood. The substance in commerce is dark red-brown, nearly opaque and brittle, contains small shell-like flakes, and gives when ground a fine red powder: it is soluble in alcohol, ether and fixed and volatile oils. If heated it gives off benzoic acid. In Europe it was once valued as a medicine on account of its astringent properties, and is now used for colouring varnishes and lacquers; in China, where it is mostly consumed, it is employed to give a red facing to writing paper. The drop dragon's blood of commerce is still one of the products of Socotra, and is obtained from *Dracaena cinnabari.* The dragon's blood of the Canary Islands is a resin procured from the surface of the leaves and from cracks in the trunk of *Dracaena draco.* The hardened juice of a euphorbiaceous tree, *Croton draco,* a resin resembling kino, is the dragon's blood of the Mexicans, used by them as a vulnerary and astringent.

DRAGOON, originally a mounted soldier trained to fight on foot only. *(See* CAVALRY and MOUNTED INFANTRY.) This mounted infantryman of the late 16th and early 17th centuries, like his comrades of the infantry who were styled "pike" and "shot," took his name from his weapon, a species of carbine or short musket called the "dragon." Dragoons were organized not in squadrons but in companies, like the foot, and their officers and non-commissioned officers bore infantry titles. The invariable tendency of the old-fashioned dragoon, who was always at a disadvantage when engaged against true cavalry, was to improve his horsemanship and armament to the cavalry standard. Thus "dragoon" came to mean medium cavalry, and this significance the word has normally retained since the early wars of Frederick the Great. The light cavalry of the British army in the 18th and early 19th centuries was for the most part called light dragoons. The phrases "to dragoon" and "dragonnade" bear witness to the mounted infantry period, this arm being the most efficient and economical form of cavalry for police work and guerrilla warfare. The "Dragonnades," properly so called, were the operations of the troops (chiefly mounted) engaged in enforcing Louis XIV.'s decrees against Protestants after the revocation of the edict of Nantes.

DRAGUIGNAN, the chief town of the department of the Var in S E. France; 51 m. N E. of Toulon, and 28½ in. N.W. of Fréjus by rail; 679 ft. above sea-level, at the southern foot of the wooded heights of Malmont, on the left bank of the Nartuby river; pop. (1936) 10,257. The buildings are mainly modern. There are manutactures of leather, soap and spirits and trade in olive oil and grapes.

DRAINAGE, ARTERIAL. Rivers form, in every country, the natural system of arterial drainage, but it is often necessary to supplement them by artificial means to prevent land in the low-lying districts from becoming water-logged. In some countries, notably Holland, large areas lie near to, and in some cases below, the sea-level so that a complete system of arterial drainage, depending for its efficiency on continuous pumping operations, is essential to enable the land to be cultivated or, indeed, to be inhabited.

In England a large part of the country was originally marshland which was gradually reclaimed and brought into agricultural use. It could only be prevented from reverting to its primitive state by a permanent system of drainage, combined, on the coast, with embankments against the inroads of the sea. Where, as in mediaeval times, vast territories were controlled by individual landowners, the responsibility for executing such work fell upon them, as the improvement would accrue solely to their benefit. But where interests were divided, disputes as to liability would naturally arise. In this way, it may be surmised, the need for the establishment of authorities armed with legal powers arose.

The earliest drainage authority of which there is record was set up in the reign of Henry III., with jurisdiction over Romney marsh, but the first public statute dealing generally with arterial drainage was the Bill of Sewers passed in 1531, "sewer" then meaning only a canal or water-course. That statute, on which all later legislalion on the subject was founded, provided for the appointment of commissioners of sewers with extensive powers for the prevention of floods and the improvement of rivers. The Land Drainage Act, 1861, defined more clearly the powers and duties of commissions of sewers (*i.e.,* drainage), and also provided, for the first time, for elective drainage boards having all the powers of the old commissioners (who were appointed by the Crown) but were elected by the ratepayers of the area over which they had jurisdiction. Such a board could be established for any "bog, moor or other area of land that requires a combined system of drainage, warping or irrigation," on the petition of the proprietors of not less than one-tenth of the area concerned, provided that the owners of two-thirds of the area were in favour of it. The provisions of this act were extended and amended by legislation in 1918 and 1926, which gave certain powers to the ministry of agriculture and to county councils and county boroughs.

In 1927 there were 361 drainage authorities of various types in England and Wales, viz., 49 commissions of sewers, 198 drainage authorities under special acts and 114 elective drainage boards. In addition, county and county borough councils have certain powers under the Land Drainage Act, 1926, and the county councils of Middlesex, Lancashire, Yorkshire (West Riding) and Surrey have powers under private acts.

The multiplication by the spasmodic legislation of 500 years of authorities having varied powers and functions and exercising jurisdiction over areas of all sorts and sizes has resulted in an imperfect system of arterial drainage, while it is estimated that the productive value of 4,362,000 acres of agricultural land in England and Wales depends on its efficiency. Of this area one-third is not included in the district of any drainage authority, and it is stated that over $1\frac{1}{4}$ million acres are in immediate need of considered and more or less extensive systems of arterial drainage.

The lack of a comprehensive and effective system for Great Britain is largely attributable to the fact that principles of legislation and administration which were applicable to the conditions existing when they were first laid down are not applicable to modern conditions. In the first instance the liability to take action to prevent the flooding and waterlogging of land was regarded as falling on the owners of the land, and it was granted that any depreciation in value was the natural result of its situation, and a normal incident of its tenure for which no other person was responsible or by which they were affected. But as time went on new conditions arose; improvements in agriculture led to the extensive adoption of land drainage on farms (see DRAINAGE, LAND) which had the effect of sending water from the uplands into the valleys much more rapidly and effectively and so contributing to the flooding of the lower levels, and, in addition, the growth of towns along the rivers, and particularly at their outfall to the sea, tended to obstruct the escape of flood-water. By their systems of water-supply—in some cases drawn from far-distant sources—and of sewerage. the towns also increase the difficulty and complicate the problem confronting authorities responsible for arterial drainage; whence it appears evident that the old principle of charging the whole cost of arterial drainage on the land directly affected—in practice on that lying at approximately the level of the highest recorded flood—has become inequitable.

In 1927 a royal commission was appointed to consider and report whether "any amendment of the law is needed to secure an efficient system of arterial drainage without any undue burdens being placed on any particular section of the community." They recommended the repeal of all existing public acts relating to arterial drainage and the enactment of a single comprehensive statute. They suggested that where drainage problems exist the country should be divided into "catchment areas."

Catchment Areas.—This term denotes "the whole of the land which directs the drainage towards one river" discharging into the sea, though a tributary stream, especially when it joins the main river near the estuary, may be of sufficient magnitude and importance as to constitute a separate one. It was proposed to constitute 101 catchment areas with a responsible authority for each, such authority to consist of representatives of the county councils, and county boroughs lying wholly or partly within the area and of other persons elected by any drainage authorities within the area, or, if none exist, of persons directly interested in the drainage of the lowlands. The complexity of the problem is fairly indicated by the fact that the suggested catchment areas varied in size from 4,133 to 24 square miles, the largest being that of the Yorkshire Ouse, and the next in order the catchment areas of the Trent, Thames, Severn and Great Ouse.

On the long-disputed question of chargeability the royal commission recommended that rating for drainage purposes should be based, like rates for all other purposes, on annual value. By a wide interpretation of the established principle of "benefit" they proposed that rates should be levied on the whole of a catchment area, but that the rate on the uplands should be proportionately less than that on the lowlands, the precise amount in each case being determined by the authority subject to confirmation by the ministry of agriculture and fisheries.

One of the difficulties of adjusting the chargeability for works of arterial drainage on a comprehensive and uniform basis is the existence over large areas of a liability ratione tenurae. This in some cases was imposed under old inclosure acts and awards and in other cases dates from time immemorial. These obligations are often very difficult to trace, and the land on which they were originally charged cannot now be identified. It is proposed that catchment area authorities should be empowered and directed to commute all such liabilities within their districts either by way of a capital sum or an annual payment. There already exists a precedent for this course of action in the Somersetshire Drainage Act, 1877.

The subject of arterial drainage overlaps that of the reclamation of land. Great operations, such as that of the conversion of the Fens in the 17th century, from an immense swamp into a tract of fertile agricultural land, involved the establishment of an elaborate system of arterial drainage. This, like that of Holland, depended for its efficiency on continuous pumping and on effective embankments against the inroads of the sea. Many other areas have been similarly reclaimed and added to the agricultural area, and in all these cases, after the initial operations, reversion to their original condition is only prevented by the maintenance of a system of drainage, combined very frequently with the upkeep of sea defence works as the new nodes of the Netherlands in the Zuider Zee. (See also RECLAMATION OF LAND; CATCHMENT AREAS.) (*R. H. R.*)

DRAINAGE, HOUSE: *see* SANITATION OF BUILDINGS.

DRAINAGE *OF* LAND. Agricultural or field drainage consists in freeing the soil from stagnant and superfluous water by means of surface or underground channels. Surface drainage is usually effected by ploughing the land into convex ridges off which the water runs into intervening furrows and is conveyed into ditches.

The presence of stagnant water in the soil is the source of many evils. Wet pasture land produces only the coarser grasses, and many subaquatic plants and mosses, which are of little or no value for feeding; its herbage is late in spring, and fails early in autumn; the animals grazed upon it are unduly liable to disease, and sheep, especially, to foot-rot and liver-rot. In the case of arable land the crops are poor and moisture-loving weeds flourish. Tillage operations on such land are easily interrupted by rain, and the period is limited in which they can be prosecuted at all; the compactness and toughness of the soil render each operation more arduous, and its repetition more necessary than in the case of dry land. The best seed time is often missed, and this usually proves the prelude to a scanty crop, or to a late and disastrous harvest. The cultivation of root crops, which require the soil to be wrought to a deep and free tilth, either becomes altogether impracticable and must be abandoned for the safe but costly bare fallow, or is carried out with great labour and hazard; and the crop, when grown, can neither be removed from the ground, nor consumed upon it by sheep without damage to the soil by "poaching."

The Water-table.—The roots of plants require both air and warmth. A deep stratum through which water can percolate, but in which it can never stagnate, is therefore necessary. A waterlogged soil is impenetrable by air, and owing to the continuous process of evaporation and radiation, its temperature is much below that of drained soil. The surface of the water in the supersaturated soil is known as the "water-table" and is exemplified in water standing in a well. Above the "water-table" the water is held by capillarity, and the percentage of water held decreases as we approach the surface, where there may be perfect dryness. Water will rise in clay by capillarity to a height of 50in.; in sand to 22in. Draining reduces the "surface tension" of the capillary water by removal of the excess, but the "water-table" may be many feet below.

In setting about the draining of a field, or farm, or estate, the first point is to secure a proper outfall. The lines of the receiving

drains must next be determined, and then the direction of the parallel drains. The former must occupy the lowest part of the natural hollows, and the latter must run in the line of the greatest slope of the ground. In the case of flat land, where a fall is obtained chiefly by increasing the depth of the drains at their lower ends, these lines may be disposed in any direction that is found convenient; but in undulating ground a single field may require several distinct sets of drains lying at different angles, so as to suit its several slopes.

The depth and distance apart of the parallel drains have been the subject of much controversy. At one time a minimum depth of 4 feet was considered necessary in all cases. This was frequently proved unsatisfactory because the distance apart was too great. It has been laid down as a general rule in Britain that in clay soils the drains should be 16 to 24ft., in medium soils 26 to 32ft. and in light soils 40 to 60 feet apart, assuming that the depth in all cases is 4 feet.

The desirability of drawing stagnant water from the land was apparent to the earliest cultivators of the land, but the methods of so doing were primitive. Surface drainage by the ridge and furrow and open ditches were practically the only means adopted. Walter Blith in the middle of the 17th century advocated the removal of the excess of stagnant water on or near the surface by mears of channels filled with faggots or stones, but his teaching was little regarded. In the latter half of the 18th century Joseph Elkington, a Warwickshire farmer, invented a plan of draining sloping ground that is drowned by the outbursting of springs When the higher-lying portion of such land is porous, rain falling upon it sinks down until it is arrested by clay or other impervious matter, which causes it again to issue at the surface and wet the lower-lying ground. Elkington showed that by cutting a deep drain through the clay, aided when necessary by wells or auger holes, the subjacent bed of sand or gravel in which a body of water is pent up by the clay, as in a vessel, might be tapped and the water conveyed in the covered drain to the nearest ditch or stream. In the circumstances to which it is applicable, and in the hands of skilful drainers, Elkington's plan, known as "sink-hole drainage," by bringing into play the natural drainage furnished by porous strata, was often successful.

Essential Principles. — During the subsequent 30 or 40 years most of the draining that took place was on this system. About 1823 James Smith of Deanston, Perthshire re-discovered those principles of draining so long before indicated by Blith and proceeded to exemplify them in his own practice, and to expound them to the public in a way that speedily effected a revolution in the art of draining, and marked an era in agricultural progress. He insisted on the necessity of providing every field that needed draining with a complete system of parallel underground channels, running in the line of the greatest slope of the ground, and so near to each other that the whole rain falling at any time upon the surface should sink down and be carried off by the drains. A main receiving drain was to be carried along the lowest part of the ground, with sub-drains in every subordinate hollow that the ground presented. The distances between drains he showed must be regulated by the greater or less retentiveness of the ground operated upon, and gave 10 to 40ft. as the limits of their distance apart. The depth which he prescribed for his parallel drains was 30in., and these were to be filled with 12in. of stones small enough to pass through a gin. ring. Josiah Parkes, engineer to the Royal Agricultural Society, advocated a greater distance apart for the drains, and a depth of at least 4ft.

The sound principles promulgated by Smith were speedily adopted and extensively carried into practice. The great labour and cost incurred in procuring stones in adequate quantities, and the difficulty of carting them in wet seasons, soon led to the substitution of "tiles," and soles of burnt earthenware. The limited supply and high price of these tiles for a time impeded the progress of the new system of draining; but the invention of tile-making machines removed this impediment, and gave a stimulus to this fundamental agricultural improvement. The substitution of cylindrical pipes for the original horse-shoe tiles has still further lowered the cost and increased the efficiency and permanency of drainage works.

The drainage of land is an obligation falling on the owners, being part of the permanent equipment of a farm. If the farm is let the tenant is entitled under the Agricultural Holdings Acts to carry out any necessary drainage operations himself and to claim compensation on quitting the holding provided he has before executing the work notified the landlord and given him the opportunity of doing it himself. A very large amount of capital has been expended by landowners on the drainage of land and special legislation was passed in the last century to enable them to obtain loans for the purpose and charge the cost on their property on a sinking fund basis. In recent years, especially since the World War, little has been done and although no trustworthy statistics are available there is little doubt that much agricultural land is deteriorating and its productivity being reduced by lack of effective-field drainage. This takes no account of the necessity in many districts for arterial drainage, which is the subject of another article (see DRAINAGE, ARTERIAL). (X.)

MARSH FLOODED WITH STAGNANT WATER BEFORE BEING DRAINED

THE UNITED STATES

Drainage of land by means of small open ditches was probably practised by individual owners in the seaboard States at an early date, but there are no records of such work prior to the 19th century. The first recorded use of tiles for underdraining farm lands was in 1835. Co-operative reclamation began in 1850, when Congress passed the swamp act. Under this law such of the public lands as were too wet to cultivate were granted to the States in which they lay with the understanding that the States were to drain and sell them. The real era of land drainage began about 1885 with the invention of the dipper dredge, which made it possible to construct large ditches at small cost. The invention of machines for making both clay and concrete tiles in large quantities at a reasonable cost made underdrainage practicable and profitable.

The census of 1930 showed that of the 1,903,21j 360 ac. of land in the United States, 986,771,016 ac were in farms. Of the latter area, 44,523,685 ac. were reported as having been provided with underdrainage by the individual farm onners, and 18,173-703 ac. as in need of underdrainage. The census also showed that 84 408.093 ac. of land had been included in operating drainage enterprises. More than 88% of this drainage work was done after 1890 Drainage enterprises in most instances merely provide outlet facilities for the tile drains of the individual land owners. Undoubtedly most of the 44,523,685 ac. mentioned are included in drainage enterprises.

To facilitate land reclamation on a large scale, practically all the States have passed drainage laws under which a majority of land owners or the owners of a major portion of the land proposed to be reclaimed can organize a drainage district and compel the minority owners to join them in paying for the improvement. These districts have corporate powers and are managed by commissioners. Funds are raised by special assessments, proportional to the benefits received. The assessments are paid in from ten to 15 annual instalments, and are a lien against the land until paid. Serial bonds are sold to meet the construction costs and are retired annually as the assessments are paid.

Along the flood plains of large streams, each of tht districts may construct (1) levees to keep out the flood waters, (2) ditches to convey the run-off to the pumping station, (3) a pumping station to pump the interior drainage water over the levee, and sometimes (4) a diversion ditch at the foot of the high ground to intercept the drainage from the high ground and to carry it around the lower end of the district. The tile underdrains are laid by the individual land owners.

Along smaller streams, drainage involves channel cleaning and

straightening and the construction of small ditch or large tile laterals to serve as outlets for the small tile underdrains. The drainage of large upland areas is accomplished by one or more main ditches and as many lateral ditches as are necessary. The laterals are generally spaced at either half mile or mile intervals, so that no land in the district will be more than half a mile from an outlet. Drainage districts range in size from small tile districts of a few hundred acres to large outlet districts of 500,000 acres.

Underdrainage is effected by systems of parallel tile drains laid at a customary depth of $2\frac{1}{2}$ to 4 ft. and spaced 60 to 150 ft. apart. The present practice is to use 4- or 5-in. tiles for these laterals.

THE SAME MARSH AFTER BEING DRAINED BY CHANNELS

In 1922, the bureau of public roads, U.S. Department of Agriculture, made a compilation of the unreclaimed swamp, overflowed, and tidal marsh lands in the United States, and found 95 million ac. of such lands divided as follows: Swamp and periodically swamp lands, $56\frac{2}{3}$ million ac.; periodically overflowed lands, $30\frac{2}{3}$ million ac.; and tidal marsh lands, 75 million acres.

See G. W Pickels, *Draznage and Flood-Control Engineering* (1925); C. G. Elliott, *Engineering for Land Drainage* (1919); W. L Powers and T. A H. Teeter, *Land Drainage* (1932); B A. Etcheverry, *Land Drainage and Flood Control* (1936). (G. W. P.)

DRAKE, SIR FRANCIS (*c.* 1545–1596), English admiral, was born near Tavistock, Devonshire, about 1545 according to most early authorities, but possibly as early as 1539 (*see* Corbett, vol. i., Appendix A). His father, a yeoman and a zealous Protestant, took refuge in Kent during the reign of Queen Mary. Young Drake was educated at the expense and under the care of Sir John Hawkins, who was his kinsman; he was apprenticed on a coasting vessel, and at 18 was purser of a ship trading to Biscay. At twenty he made a voyage to Guinea; and at twenty-two he was made captain of the "Judith." He fought his ship gallantly in the Gulf of Mexico under Sir John" Hawkins, and returned with him to England, having acquired great reputation, though with the loss of all the money which he had embarked in the expedition. In 1570 he obtained a regular privateering commission from Queen Elizabeth, and embarked on a cruise in the Spanish Main. He planned an attack against the Spaniards in the West Indies to indemnify himself for his former losses, and set sail in 1572, with two small ships named the "Pasha" and the "Swan." He was afterwards joined by another vessel; and with this small squadron he took and plundered the Spanish town of Nombre de Dios. He penetrated across the isthmus of Panama, and committed great havoc among the Spanish shipping. From the top of a tree on the isthmus he obtained his first view of the Pacific, and resolved "to sail an English ship in these seas." In these expeditions he was assisted by the Maroons, descendants of escaped negro slaves. Having filled his ships with plunder, he bore away for England, and arrived at Plymouth on Aug. g, 1573.

Having fitted out three frigates at his own expense, he sailed to Ireland, and served as a volunteer, under Walter, earl of Essex. After his patron's death he returned to England, where he was well received by Queen Elizabeth. The first proposal he made to her was a voyage into the South Seas through the straits of Magellan, which no Englishman had hitherto ever attempted. The queen furnished him with means; and his own fame quickly attracted the men. The fleet with which he sailed consisted of only five small vessels, manned in all by 166 men. Starting on Dec. 13, 1577, he laid his course by the west coast of Morocco and the Cape Verde Islands. He reached the coast of Brazil on April 6, and entered the Rio de la Plata, where he parted company with two of his ships; but having met them again, and taken out their provisions, he turned them adrift. On June 19 he entered the port of St. Julian's, where he remained two months, partly to lay in provisions, and partly delayed by the trial and execution of Thomas Doughty, who had plotted against him. On Aug. 21 he entered the Straits of Magellan. The passage of the straits took sixteen days, but then a storm carried the ships to the west; on Oct. 7, having made back for the mouth of the strait, Drake's ship and the two vessels under his vice-admiral Captain Wynter were separated, and the latter, missing the rendezvous, returned to England. Drake went on, and came to Mocha Island, off the coast of Chile, on Nov. 2j. He thence continued his voyage along the coast of Chile and Peru, taking all opportunities of seizing Spanish ships, and attacking them on shore, till his men were satiated with plunder; and then coasted along the shores of America, as far as 48° N. lat, in an unsuccessful endeavour to discover a passage into the Atlantic. He named the country New Albion, and took possession of it in the name of Queen Elizabeth. He sailed on July 26, 1579, for the Moluccas. On Nov. 4 he got sight of those islands, and, arriving at Ternate, was extremely well received by the sultan. On Dec. 10 he made the Celebes, where his ship unfortunately struck upon a rock, but was taken off without much damage. On March 11 he arrived at Java, whence he intended to have directed his course to Malacca; but he found himself obliged to alter his purpose, and to think of returning home. On March 26, 1580, he again set sail; and on June 15 doubled the Cape of Good Hope, having then on board only 57 men and three casks of water. He passed the line on July 12 and on the 16th reached the coast of Guinea, where he watered. On Sept. 11 he made the Island of Terceira, and on Sept. 26 (?) he entered Plymouth harbour. This voyage round the world, the first accomplished by an Englishman, was thus performed in two years and about ten months.

The queen hesitated for some time whether to recognize his achievements or not, on the ground that such recognition might lead to complications with Spain, but she finally decided in his favour. She went on board his ship at Deptford and there conferred upon him the honour of knighthood. She likewise gave directions for the preservation of his ship, the "Golden Hind," that it might remain a monument of his own and his country's glory. After the lapse of a century it decayed and had to be broken up. Of the sound timber a chair was made, which was presented by Charles II. to the university of Oxford.

In 1581 Drake became mayor of Plymouth; and in 1585 he married a second time, his first wife having died in 1583. In 1585 hostilities having commenced with Spain, he again went to sea, sailing with a fleet to the West Indies, and taking the cities of Santiago (in the Cape Verde Islands), San Domingo, Cartagena and St. Augustine. In 1587 he went to Lisbon with a fleet of thirty sail; and having received intelligence of a great fleet being assembled in the bay of Cadiz, and destined to form part of the Armada, he entered the port on April 19, and there burnt upwards of 10,000 tons of shipping—a feat which he afterwards called "singeing the king of Spain's beard." In 1588, when the Spanish Armada was approaching England, Sir Francis Drake was appointed vice-admiral under Lord Howard, and made prize of a very large galleon, commanded by Don Pedro de Valdez, who struck at once on learning his adversary's name.

In 1589 Drake commanded the fleet sent to restore Dom Antonio, king of Portugal, the land forces being under the orders of Sir John Norreys; but they had hardly put to sea when the commanders differed, and thus the attempt proved abortive. But as the war with Spain continued, an expedition was fitted out, under Sir John Hawkins and Sir Francis Drake, against their settlements in the West Indies. Here, however, the commanders again disagreed about the plan; and the result disappointed public expectation. These disasters were the principal cause of his death, which took place on board his own ship, near the town of Nombre de Dios, in the West Indies, on Jan. 28, 1596.

The older Lives by Samuel Clarke (1671) and John Barrow, junr. (1843), have been superseded by Julian Corbett's two admirable volumes on *Drake and the Tudor Navy* (1898), the best source of information on the subject, which were preceded by the same author's *Sir Francis Drake* in the "English Men of Action" series (1890). *See* also E. J. Payne's edition of *Voyages of the Elizabethan Seamen to America: Thirteen original narratives from the collection*

of Hakluyt (new ed., 1893); *A.* Brereton, *Sir Francis Drake* (1917); Sir Walter Hunciman, *Drake, Nelson and Napoleon,* etc. (1919); E. F. Benson, *Sir Francis Drake* (1927); and *Sir Francis Drake's Voyage round the World, 1577–1580: Two contemporary maps* (Brit. Mus. printed books, 1927).

DRAKE, NATHAN (1766–1836), English essayist and physician, son of Nathan Drake, an artist, was born at York. He was apprenticed to a doctor in York in 1779, and in 1786 proceeded to Edinburgh University, where he took his degree as N.D. in 1789. In 1790 he set up as a general practitioner at Sudbury, Suffolk, where he found an intimate friend in Dr. Mason Good. In 1792 he removed to Hadleigh, Suffolk, where he died in 1836. His most important production was *Shakespeare and his Times, including the Biography of the Ppet; Criticisms on his Genius and Writings; a new Chronology of his Plays; a Disquisition on the Object of his Sonnets; and a History of the Manners, Customs and Amusements, Superstitions, Poetry and Elegant Literature of his Age* (1817).

DRAKENBERG or **KAHLAMBA,** the highest portion of the great eastern scarp of the South African plateau.. It forms the eastern boundary of Basutoland and Orange Free State.

DRAM or **DRACHM,** a weight approximately equal to that of the ancient Greek coin; in apothecaries' weight one-eighth of an ounce, or 60 grains *(3.888* grams); in avoirdupois weight one-sixteenth of an ounce, or *27·34375* grains (1·772 gram). For short the term is used for a fluid dram (drachm), a measure of capacity equal to one-eighth of a fluid ounce.

DRAMA is a transliteration of the Greek δρᾶμα, which means a thing done; theatre is a transliteration of the Greek θέατρον, which means a seeing-place. The word audience, meaning those who listen, is derived from the Latin and therefore represents a later idea of play-going. From this use of two Greek words and one Latin a useful hint is given us as to the first dramatic values. Drama begins with action and spectacle; the deed comes before the word, the dance before the dialogue, the play of body before the play of mind. The audience is subsequent to the spectators. The history of drama is largely a history of changing dramatic values. Gradually the presentation of thought becomes as important as the representation of emotion, which was the main element of theatrical origins. Nowadays a person who talks about the drama may actually be thinking of a literary form and of something that will be read and discussed but will rarely or never live up to the original meaning of its name and be "done." Modern drama includes work in which the discussion of ideas is the whole purpose of the play. Of the play it is sometimes permissible to observe that it is just as effective in book-form as when "done." Indeed, in the first decade of the 20th century the drama of the intellectuals definitely revolted so far from the idea of "four boards and a passion" that Granville-Barker could describe it in this way: "Plays grew so austerely intellectual that their performance seemed a profanation, and we saw the actors moving apologetically through their parts as if they had been told that they were rather vulgar people with no real right there at all." This was a paradoxical fate to befall the men of action in "the seeing-place," but those who read or listen to the political and philosophical discussions in Bernard Shaw's "metabiological pentateuch" *Back to Methuselah* will appreciate the point of this and realize how great is the change from the simple conception of a drama as a thing done to the later use of "the seeing-place" as a school-room for the continued instruction and entertainment of the adult who is hungry for ideas. If we are to find a definition of drama which will cover all theatrical manifestations from the wordless ritual and mummery of primitive man to the actionless dialectic of a modern philosopher that definition will be so loose as to be almost useless. It is more profitable to ask and answer two simple questions about the thing which is done. They are: Why is it done, and how is it done?

The Laws of Aristotle.—To the query "Why?" the answers fall into two main groups. It is possible to reply from a psychological or a historical point of view. It is also possible to combine the two kinds of reply. Such a combination is made in the *Poetics* of Aristotle, Owing to the classical domination over Western thought which has prevailed since the Renaissance, Aristotle's *Poetics* has had an enormous influence on academic views of drama, He laid down laws of drama in general and of various types of drama in particular. Horace presented the Aristotelian lore to Rome (whose theatre was almost entirely derivative from Greek models), and the French classicists carried on the tradition of a dramatic discipline expounded in Greek lecture-rooms as a small part of Aristotle's encyclopaedic survey of all human problems. So diligent mas the pursuit of the classic ideal that Aristotle's hints about observing the three Unities of Time, Place and Action are incorporated and strengthened in the great French curriculum, being expanded and expounded by Chapelain, Richelieu, Corneille and Boileau. A last echo of the Aristotelian authority was to be heard in the dramatic criticism of A. B. Walkley who used to complain of Bernard Shaw that he did not keep to the familiar classical rules. The critic was twitted in turn by Shaw for his obeisance to "the immortal Stagirite" (see *Fanny's First Play,* Introduction). During the first decades of the 20th century the revolt against classical authority in the art of the theatre was finally driven home.

Imitation in Drama.—Aristotle gave both a brief historical explanation of the rise of Greek drama from ritual choruses and a psychological interpretation of the dramatic impulse. Of the latter he said *(Poetics,* 4). "Imitation is natural to man from childhood, one of his advantages over the lower animals being this, that he is the most imitative creature in the world, and learns at first by imitation. And it is also natural for all to delight in works of imitation." That is true. Man is a natural mimic as birds and beasts have been before him, and anthropologists who examine the origin of drama and seek all manner of esoteric causes for acting are seriously mistaken if they omit to allow also for the simple impulse to dress up and play at "let's pretend." But, however much the world's first player may have enjoyed his primitive masquerade or mischievous apeing of a neighbour, as soon as the fun becomes regularized in a ritual a great change occurs. We soon discover that acting has become immensely serious and is directed by prudential considerations. Possibly the first "thing done" was done for a joke, as Aristotle suggested when he cited the universal delight in works of imitation. But, undeniably, when the things done became seasonal rites, they were carried on for serious and sacred purposes. The idea of going to the play as a form of relaxation or holiday treat belongs to the civilized and not to the primitive state. It is true that as early as Roman times Terence, an adroit adapter of the Greek New Comedy, complained of the rivalry of jugglers and rope walkers in the Roman entertainment market, which shows how far the secular notion of playgoing had prevailed over the primeval concept of dramatic ritual. Comedy had naturally lost its religious significance before tragedy. But the essential fact about early drama, both comic and tragic, is that, all over the world, the primitive peoples have regarded it as a utility and an obligation. It is only after civilization has firmly established itself that the atmosphere of a religious service no longer surrounds the thing mimed and is replaced by the less strenuous air of an entertainment for an idle occasion. Thus the development of drama presents us with a double change. On the one hand physical action directed towards an emotional climax is no longer the supreme quality of drama, since the mind insists that the mental march may be movement of the dramatic kind; on the other hand secularization sets in and what had been in its infancy a propitiation of gods and heroes becomes in its mellower years a popular show and source of mundane merriments and excitements. Drama did quite literally begin with song and dance and the most popular form of drama to-day is still mainly compact of song and dance. But the difference in purpose and temper of the old dithyramb as offered to the gods and the new musical comedy "number" as projected at the stalls and gallery is, by its very immensity, indicative of a change that is fundamental. But by no means is the change final, since it is continually the object of theatrical reformers to recapture the drama for the exalted social purposes towards which, in other circumstances, its childhood was directed.

The Origin of Dramatic Rites.—It is not necessary to discuss at this point the rival theories as to the origin of dramatic rites. These theories fall into two main groups. It is claimed by one party that the song and dance from which drama sprang were a celebration of the life-force in the natural world and that the traditional dramatic conflict is a repetition or a restatement of the old battle between the New Year and the Old which is fought out with ubiquitous regularity in the folk-lore of races. The other party, of which Prof. Ridgeway was an active and important protagonist, surveyed the primitive folk dances and mummings of the world and found the significant common factor to be a tomb-ritual. The "thing done" was inspired by a wish to honour the great departed and to help him to immortality in order that he might, from his place of influence in the next world, continue to guide and protect his kinsmen and his tribesmen in this world. There is much evidence which both parties can fruitfully exploit. For the believers in a vegetation-cult there are the old mummers' plays which have survived in many countries and in which a slaying of Age or Winter and a resurrection of Youth or Spring are constant features. For the other side there appears in the witness-box the constant presence of the mask which is traditionally associated with the impersonation of departed spirits. The world-wide researches of anthropology have, as Ridgeway demonstrated in his collection of far-flung testimony, proved a continual connection of early mimings, dances and choruses with the sites of tombs and occasions of remembrances. One cause of drama is certainly to be found in that pursuit of immortality which has been the devouring passion of man from his first rough struggles for existence down to the ceaseless quest of civilized thought into human origins and human destiny. Acting in the first form was a species of prayer. You imitate a thing in order that the gods may take the hint and do likewise. You leap round the growing corn that the corn may also leap in a large fertility; you pour out water as a sign to the god who controls the rain; you act the hero rising from the tomb or portray his sufferings and services that he may be strengthened in his immortality and pass on some of his grace and greatness and succour to mortals here below. From such ritual an art of drama was developed, from that art an entertainment.

A Birth in Holy Places.—Thus, what we must conceive, if we wish to understand the vigour and variety of drama in the light of its history, is a birth in holy places. The performer was no playboy, but a priest or servant of the priests. He was also a social worker engaged, as much as any prelate or politician, in saving the tribe. By sympathetic magic he might prevail for the common good; by his persuasive arts the sun might shine and the rain might fall in their proper seasons. Dionysos, to give the fertility-god his Greek name, might leap amid the leapers and pour out his power in appropriate response to the dithyramb or vigorous incantation of his cult. Or else the rite at the tomb might save from a black oblivion the vanished leader and keep him in ghostly power to help the tribe amid its difficulties and dangers. So we pass from Dionysos, the god, to the Greek Dionysia, the festival for which the tragedian wrote, and so out on to that winding highway of secular art and amusement whose final tributaries and turnings are Broadway and Drury lane.

Along such lines as these the many replies must be made to the question "Why is there drama, why is there a thing done?" Naturally the answers will vary according to the particular circumstances of time and place. Civilizations make drama according to their needs and develop it according to their capacities. To the second question "How?" the answers will be equally numerous and various. Drama may be purely communal or purely individual, poetical or prosaic, acted by individuals and by teams or presented through the medium of the puppet or the marionette. Here it borders on ballet, there it borrows from the library. Its literary form will be found to be conditioned by the particular stage or platform for which it was written and the particular social object at which it was originally aimed. There are no inclusive theatrical formulae Nor can a simple definition be found by use of the word "imitation." Many of the earliest forms of drama and some of the later are not representative in the sense that the players are trying to mimic the life they know. Instead of copying they are creating and their performance is a statement and not a simulation. It is true that some kind of imitation remains, but it is imitation tempered by traditional symbolism. The Greek actor, to take the most obvious instance, did not try to imitate a man; he attempted to present something larger than life. Accordingly he wore a mask, propped himself up on buskins, and was padded out to superhuman size. This made realistic acting, as we understand it, impossible, but created a suitable mouthpiece for the superb rhetoric of Greek tragedy and also assisted the atmosphere of religious ceremonial in which the play was produced. Similarly in the mystery plays of the middle ages the actor often wore the conventional symbol of his part as though that sufficed. The symbol announced what could not be imitated. A gilt beard, for example, was the traditional decoration of St. Peter, just as in the circus we may know the clown by his colour long before he has begun his antics. The clown is an actor, but he is not, in any close sense of the word, an imitator. He works in his own world of fancy free. The history of the theatre has contained every kind of presentation and representation from the purely fantastic and symbolic to the actualities of our modern stage on which producers will lavish infinities of care in order to get a trifling detail "correct," *i.e.*, as closely imitative of life as possible.

Varieties of Drama.—Accordingly, as our eyes range up and down the whole cycle of "things done," from the vast ritual of the resurrection-play of Osiris, the god-hero of Egypt, to the 20th century comedy with its cynical chatter and realistic cocktails and cigarettes, we find it difficult indeed to lay down boundaries and to make exclusive or inclusive definitions. After the broadcasting of plays had become a popular practice one could not even insist that drama must be a thing seen, and from its very beginning the silent mummery, the thing seen but not heard, has been an essential form of the theatre. But, if we rule out broadcasting, we can say that drama consists of emotions and opinions and occurrences presented in three dimensions with more or less approach to imitation by human agency. (It is true that one medium may be the marionette but that is controlled by the human hand and mind.) There may be as much or as little music, as much or as little scene, and as much or as little mechanical aid as the circumstance offers. The acting company may be a civic community, as in a pageant, or a single individual, like a modern reciter or the first Greek ὑποκρίτης who answered the chorus and so originated dialogue. A great amount of human ingenuity has been wasted on laying down rules for drama as though it were a small and single thing. But such law-giving either ends in academic and abstract formulae which are belied by the history and practice of the stage or else makes classifications which are so vague as to be valueless. The much discussed "dramatic conflict" is itself a widely inclusive term since the conflict may be of the mind as well as of the body; argument is simply mental action. In short, as we come to survey the various dramas of the various nations and cultures, we can only conclude that the techniques of drama are as widely divergent as the racial tendencies and individual qualities of mankind and that to lay down lists of rules and to impose conditions is only a vanity of the academic brain, against which all the diversity of performance stands in a complete and crushing defiance. (I. BR.)

BIBLIOGRAPHY.—The following works treat the general theory of the drama and the dramatic art, together with the principles of dramaturgy and of the art of acting. INDIAN DRAMA

The Indian drama was almost certainly a native growth, and, in spite of some points of resemblance, there is no real evidence for assuming any influence of Greek examples at any stage of its progress. On the other hand, it had passed into its decline before the dramatic literature of modern Europe arose.

The Hindu writers ascribe the invention of dramatic entertainments to an inspired sage Bharata, or to the communications made to him by the god Brahma himself concerning an art gathered from the Vedas. Three kinds of entertainments, of which the *nātya* (defined as a dance combined with gesticulation and speech) comes nearest to the drama, were said to have been exhibited before the gods by the spirits and nymphs of Indra's heaven, and to these the god Śiva added two new styles of dancing.

The ultimate source of the Indian drama, thus traditionally believed to have been religious, has indeed been traced by some scholars to certain hymns in the *Rigveda,* which took the form of dialogue. There is, however, no direct evidence of such a source, and the existence in Vedic times of popular mimes has been inferred from certain references in Vedic texts. Some features of modern plays and the so-called *yātrās* of Bengal, representing mythical scenes (especially the Kṛishṇa legend), may possibly point to the drama's originating from an ancient pantomimic art. The 12th century *Gīta-govinda,* in which three characters engage in lyrical monologues, is the earliest literary specimen of this primitive type of play. On the other hand there is no doubt that the influence of epic recitations was of continuous importance. Keith rejects the evidence for a secular origin and concludes *(Sanskrit Drama,* p. 45) that the Sanskrit drama was probably evolved by "the combination of epic recitations with the dramatic movement of the Kyishqa legend, in which a young god strives against and overcomes enemies."

Nothing certain is known of the history of the actual drama before about A.D. zoo, when it had already reached its zenith. We know it only in its glory, in its decline and in its decay.

To **the 11th** Century **A.D.**—This is the classical period of the Hindu drama, and includes the works of its two greatest masters.

The earliest dramatist of whose work we possess specimens is Aśva-ghosha, the Buddhist teacher (2nd century A.D.). Fragments of his drama, the *Sāriputra-prakarana,* which correspond closely with the classical type, have been found at Turfan in Central Asia, with parts of two other Buddhist dramas.

Kālidāsa, the brightest of the "nine gems" of genius in whom the Indian drama gloried, lived at the court of Ujjain. He is the author of *Śakuntalā*—the work which, in the translation by Sir William Jones (1789), first revealed to the Western world of letters the existence of an Indian drama, since reproduced in innumerable versions in many tongues. This heroic comedy, in seven acts, takes its plot from the first book of the *Mahābhārata.* It is a dramatic love-idyll of surpassing beauty, and one of the masterpieces of the poetic literature of the world. Another drama by Kālidāsa, *Vikrama and Urvaśī (The Hero and the Nymph),* though unequal as a whole to *Śakuntalā,* contains one act of incomparable loveliness; and its enduring effect upon Indian dramatic literature is shown by the imitations of it in later plays. (It was translated into English in 1827 by H. H. Wilson.) His third, and probably earlier play, *Mālavika and Agnimitra,* is inferior to the other two.

Kālidāsa had a famous predecessor, Bhāsa. Thirteen plays, supposed to have been his long lost works, were published in 191 2, but their genuineness, about which there has been much controversy, is most doubtful.

Probably not far removed in date from Kālidāsa is the pathetic *Mṛichchhakatikā (The Toy Cart),* attributed to King Śūdraka, but perhaps written by a court poet. It is a comedy of middle-class life, treating of the courtship and marriage of a ruined Brahman and a rich courtesan.

To Harshadeva, king of northern India, are ascribed three extant plays of considerable merit, including the famous *Ratnāvalī (The Pearl Necklace),* a court-comedy with a half-Terentian plot.

The palm of pre-eminence is disputed with Kālidāsa by Bhavabhiiti, who flourished in the earlier part of the 8th century. While he is considered more artificial in language than his rival, and in general more bound by rules, he can hardly be deemed his inferior in dramatic genius. Of his three extant plays, *Mahāvīra-Charita* and *Uttara-Rāma-Charita* are heroic dramas concerned with the adventures of Rāma (the seventh incarnation of Vishnu); the third, the powerful melodrama of *Mālatī and Mādhava,* has love for its theme, and has been called the *Romeo and Juliet* of the Hindus. It is considered by their critical authorities the best example of the *prakaraṇa,* or drama of domestic life. Bhavabhūti's plays are devoid of the element of humour.

The popular Veṇī-samhāra, by Bhaṭṭa-Nārāyana, must be dated before the year A.D. 800. Its main incident is derived from the Māhābhārata. The play is marred by too much detail and adherence to rule. More interesting is Viśākhadatta's *Mudrārākshasa (Rakshasa and the Seal),* a lively drama of political intrigue, in which Chandragupta appears as the founder of a dynasty. The plot turns on the gaining-over of the prime minister of the *ancien régime.*

The plays of Rājaśekhara, who lived about the end of the 9th century, deal, like those of Harshadeva, with harem and court life. One of them, *Karpūra Manjarī (Camphor Cluster),* is stated to be the only example of the *saṭṭaka* or minor heroic comedy, written entirely in Prakrit. Among the remaining chief works of the period are the favourite, but hyperbolical, *Anargharāghava* by Murāri, and the long and rambling *Hanumannaṭaka,* or *Mahānāṭaka,* both of which deal with the adventures of Rāma.

The Period of Decline.—This may be reckoned from about the 11th to the 14th century, the beginning roughly coinciding with that of a continuous series of Mohammedan invasions of India. Kṛishṇamiśra's remarkable allegorical play, *Prabodha-Chandrodaya (c.* 1100) is a glorification of the cult of Vishnu. This style of drama had many followers, mostly very inferior. Of the remaining plays of this period, as compared with the first, the general characteristics seem to be an undue preponderance of narrative and description, and an affected and over-elaborated style.

Isolated plays remain from centuries later than the 14th. These, which chiefly turn on the legends of Kṛishṇa (the last incarnation of Vishnu), exhibit the Indian drama in its decay. The latest of them, *Chitra-Yajna,* which was composed about A.D. 1820, is imperfect in its dialogue, which (after the fashion of Italian improvised comedy) it is left to the actors to supplement. Besides these there are farces or farcical entertainments, often indelicate, of uncertain dates.

The number of plays which have descended to us from so vast an expanse of time is still comparatively small. Nevertheless, Schuyler's bibliography (1906) enumerates over 500 Sanskrit plays. To these have to be added the plays in Tamil, about roo in number, and some in other vernaculars.

There is among the Hindus no dearth of dramatic theory. The sage Bharata, the reputed inventor of dramatic entertainments, was likewise revered as the father of dramatic criticism. The

commentators constantly cite his supposed *sūtras,* or aphorisms. (From *sūtra,* thread, was named the *sūtra-dhāra,* thread-holder, carpenter, a term applied to the architect and general manager of sacrificial solemnities, or of theatrical performances.) By the 10th century dramatic criticism had reached an advanced point; and the *Daśa-Rūpa* distinctly defines the ten main forms of drama. Other critical works followed, exhibiting a rage for subdivision unsurpassed by the efforts of Western theorists, ancient or modern.

Species of Drama. — The Indian drama is a Brahmanical production, aiming not at delineation but at the awakening of sentiment, and making its appeal to the cultured minority. This elevated disregard of popularity accounts for much that is characteristic of the higher class of Indian plays. It explains both their relative paucity and their great length, renders intelligible the chief peculiarity in their diction, and furnishes the key to their most striking ethical and literary qualities. Connected in their origin with religious worship, they were only performed on solemn occasions, more especially at seasons sacred to some divinity. They were always originally written for one particular representation. Again, the greater part of every one of the plays of northern India is written in Sanskrit, which ceased to be a popular language by 300 B.C., but continued the classical and learned form of speech. Sanskrit is spoken by the principal personages of the plays, while the female and inferior characters use varieties of the Prakrits. Hence, part at least of each play cannot have been fully understood by the general audience. It is, then, easy to see why the Hindu critics should make demands upon the art, into which only highly-trained and refined intellects were capable of entering. The general public could not be expected to appreciate the sentiments *(rasas)* expressed.

The Hindu critics know of no precise distinction between tragedy and comedy, still less of any determined by the nature of the close of a play. They dislike an unhappy ending, arid a positive rule prohibits a fatal conclusion in their dramas. The general term for all dramatic compositions is *rūpaka* (from *rūpa,* visible form), those of an inferior class being distinguished as *uparūpakas.* Of the various subdivisions of the *rūpaka,* in a more limited sense, the *nāṭaka,* or play proper, represents the most perfect kind. Its subject should always be celebrated and important — heroism or love — and the hero should be a demigod or divinity or a king. The *prakaraṇas* agree in essentials with the *nāṭakas* but are less elevated, their stories being taken from life in a respectable class of society (e g., *Mrichchhakatikā; Mālatī* and *Mādhava*). Among the species of the *uparūpaka* may be mentioned the *troṭaka,* in which the personages are partly human, partly divine, and of which a famous example remains — Vikranza *and Urvaśi.* The *bhāṇa* was a monologue of low life, and the *prahasana* a farce. These trifles represent the lower extreme of the dramatic scale, to which the principles that follow only partially apply.

Construction. — Unity of action is enjoined by theory, though not invariably observed. Episodical or prolix interruptions are forbidden; but the story of the play is sometimes carried on by narratives spoken by actors or "interpreters," something after the fashion of the Chorus in *Henry* V., or of Gower in *Pericles.* "Unity of time" is liberally understood by the later authorities as limiting the duration of the action to a single year; and even this is exceeded. The single acts are to confine the events occurring in them to "one course of the sun." "Unity of place" is unknown, by reason of the absence of scenery; for the plays were performed in the palace courts or in the open air. Hence change of scene is usually indicated in the texts.

Not only must a play end happily, but death and all deeply tragical incidents are excluded, while such operations as biting, scratching, kissing, eating and sleeping should never take place on the stage. Yet such rules are occasionally broken. The charming love-scene in the *Śakuntalā* (at least in the earlier recension) breaks off just as the hero is about to act the part of the bee to the honey of the heroine's lips (act iii.; cf. Nāgānanda, act iii.). But later writers are less squeamish, or less refined.

Indian plays usually open after a benediction with a prologue, in which the manager, with one or more actors, discusses the play which is to follow. This is divided into acts *(ankas)* and scenes; of the former seven is a common number; "the great *nātāka*" reaches 14. Thus the length of the higher class of Indian plays is considerable — about that of an Aeschylean trilogy. Comic plays are restricted to two acts. It is a characteristic merit that the business is rarely concluded before the last act. The piece closes with a prayer. Within this framework room is found for situations as ingeniously devised and highly wrought as those in any modern Western play. Recognition — especially between parents and children — frequently gives rise to scenes of a pathos which Euripides has not surpassed (*Śakuntalā; Uttara-Rdma-Charito).* The device of a "play within the play" is employed with great success by Bhavabhūti. On the other hand, miraculous metamorphosis *(Vikmma and Urvaśī,* act iv.) and, in a later play (*Ratnāvali),* vulgar magic are introduced. With scenes of strong effectiveness contrast others of the most delicate poetic grace — such as the charming episode of the two damsels of the god of love helping one another to pluck the red and green bud from the mango tree; or of gentle domestic pathos. For the *dénouement* the expedient of the *deus ex machina* is often employed.

Characters. — Every species of drama having its appropriate kind of hero or heroine, theory here again amuses itself with an infinitude of subdivisions. Among the heroines, of whom not less than 384 types have been distinguished, are to be noticed the courtesans, whose social position somewhat resembles that of the Greek *hetaerae.* In general, the Indian drama indicates relations between the sexes freer than those which Mohammedan example introduced into India. Male characters are frequently drawn with skill. Prince Samsthanaka (*Mrichchhakatīkā*) is a type of royal selfishness worthy to rank beside figures of the modern drama; elsewhere (*Mudrā-Rakshasha*) the characters and principles of action of intriguing ministers are judiciously discriminated. Among the lesser personages two are especially worth noticing: the *vita,* or parasite, and the *vidlshaka,* the buffoon and humble associate of the prince. He is always a Brahman, or the pupil of a Brahman — perhaps a survival from a purely popular phase of the drama. His jokes are generally harmless and pointless.

With its mingling of prose and lyrical verse, and its highly ornate and figurative diction, the Indian drama essentially depended upon its literary qualities, and upon the familiar sanctity of its themes for its effects. Its scenic apparatus was scanty. Propriety of costume, on the other hand, seems always to have been observed.

Companies of actors seem to have been common in India at an early date. The player's social status shows a gradual rise, and in later times individual actors enjoyed a widespread reputation. The managers or directors were usually highly-cultured Brahmans. Female parts were in general, though not invariably, represented by females.

Summary. — The Indian drama would, if only for purposes of comparison, be invaluable to the student of this branch of literature. But from the point of view of purely literary excellence it holds its own against all except the very foremost dramas of the world. It cannot be described as national in the broadest and highest sense of the word; but, as the drama of a literary class, it exhibits many of the noblest as well as of the most characteristic features of Hinduism. Its ethics are lofty, but they are those of a scholastic system of religious philosophy, self-conscious of its completeness. To the power of Fate is occasionally ascribed a supremacy, to which gods as well as mortals must bow *(Vikrama and Urvaśī);* but, if man's present life is merely a phase in the cycle of his destinies, the highest of moral efforts at the same time points to the summit of possibilities, and self-sacrifice is the supreme condition both of individual perfection and of the progress of the world. Such conceptions as these seem at once to enfold and to overshadow the moral life of the Indian drama. The affections and passions forming part of self it delineates with fidelity; on the other hand, the freedom of the picture is restricted by conditions which to us may seem intolerable, but which it was impossible for the Indian poet to ignore. The sheer self-absorption of ambition or love appears inconceivable for these poets; and their social philosophy is based on the system of caste. On the other hand, they are

masters of many of the truest forms of pathos, above all of that which blends with resignation. In humour of a delicate kind they are by no means deficient; to its lower forms they are generally strangers. Of wit—as distinct from the play on words—Indian dramatic literature furnishes few examples intelligible to Western minds.

The distinctive excellence of the Indian drama is to be sought in the poetic robe which envelops it. In its nobler productions, at least, it is never untrue to its half religious, half rural origin; it weaves the wreaths of idyllic fancies in an unbroken chain of ever fresh beauties from an inexhaustible garden. Nor is it unequal to depicting the grander aspects of nature. A close familiarity with its native literature can here alone follow its figurative diction, listen with understanding to the hum of the bee as it hangs over the lotus, and contemplate with Śakuntalā's pious sympathy the creeper as it winds round the mango tree. But the poetic beauty of the Indian drama reveals itself in the mysterious charm of its outline, even to the untrained; nor should the study of it be omitted by any lover of literature.

CHINESE DRAMA

Like the Indian drama, the Chinese arose from the union of the arts of dance and song. To the ballets and pantomimes out of which it slowly developed, and which have continued to flourish by the side of its more advanced forms, the Chinese ascribe a primitive antiquity of origin; many of them originally had a symbolical reference to such subjects as the harvest, and war and peace. A very ancient pantomime is said to have symbolized the conquest of China by Wu-Wang.

There are traditions which carry back the characters of the Chinese drama to the 18th century before the Christian era. Others declare the emperor Wan-Te (*fl.* about A.D. 580) to have invented the drama; but this honour is more usually given to the emperor Yuen-Tsung (A.D. 720).

The Classical Age.—Four periods may be discovered. The first is that of the dramas coinposed under the T'ang dynasty, from A.D. 720 to 907. These pieces, called *Tchhouen-Khi,* were a species of heroic drama.

The second period is that of the Sung dynasty, from 960 to 1119 The plays of this period are called *Hi-Khio,* and presented a principal personage *who sings.*

The Middle Age.—The third and best-known age of the Chinese drama was under the Kin and Yuen dynasties, from 1125 to 1367. The plays of this period are called *Yuen-Pen* and *Tsa-Ki;* the latter seem to have resembled the *Hi-Khio.* .The *Yuen-Pen* are the plays from which our literary knowledge of the Chinese drama is mainly derived; the short pieces called *Yen Kia* were in the same style, but briefer. In 1735 the Jesuit missionary Prémare first revealed to Europe the existence of the tragedy *Tchao-Chi-Cu-Eul (The Little Orphan of the House of Tchao),* which was founded upon an earlier piece treating of the fortunes of an heir to the imperial throne, who was preserved in a mysterious box like another Cypselus or Moses. Voltaire seized the theme of the earlier play for a rhetorical tragedy, *L'Orphelin* de *la Chine.*

The justly famous *Pi-Pa-Ki (The Story of the Lute)* was composed towards the close of the 14th century by Kao-Tong-Kia, and reproduced in 1404, under the Ming dynasty, with the alterations of Mao-Tseu, a commentator of learning and taste. *Pi-Pa-Ki,* as *a* domestic drama of sentiment, possesses very high merit, and is regarded as the masterpiece of the Chinese theatre. The fourth period, under the Ming dynasty (1368–1644), developed little that was new.

Varieties of Drama.—In theory, no drama could be more consistently elevated in purpose and in tone than the Chinese, but. in practice, it falls short of this ideal. The Chinese classify their plays according to subjects in twelve categories The historical drama is not unknown to the Chinese; and although a law pro. hibited the bringing on the stage of "emperors, empresses, and the famous princes, ministers and generals of former ages," no such restriction was observed in practice. In *Han-Kong-Tseu (The Sorrows of Han),* which treats of a national historic legend strangely recalling in parts the story of Esther and the myth of the daughter of Erechtheus, the emperor Yuen-Ti (the representative, to be sure, of a fallen dynasty) plays a part, and a sufficiently sorry one. The favourite virtue is filial piety, of a formal or a practical kind; their favourite interest lies in the discovery of hidden guilt, and the vindication of persecuted innocence.

Free in its choice of themes, the Chinese draina is likewise remarkably unrestricted in its range of characters. Chinese society, it is well known, is not based, like Indian, upon the principle of caste; rank in China is determined by office, and this again depends on the results of examination. The *Tchoang-Yuen,* or senior classman on the list of licentiates, is the flower of Chinese society, and the hero of many a drama. But of mere class the Chinese drama is no respecter, painting with noteworthy freedom the virtues and the vices of nearly every phase of society.

The conduct of the plays exhibits much ingenuity, and an aversion from restrictions of time and place. The plays are divided into acts and scenes—the former being usually four in number, at times with an induction or narrative prologue spoken by some of the characters *(Sie-Tsen).* Favourite plays were, however, allowed to extend to great length; the *Pi-Pa-Ki* is divided into 24 sections, and in another recension apparently comprised 42.

One peculiarity of the Chinese drama remains to be noticed. The chief character of a play represents the author as well as the personage; he or she is hero or heroine and chorus in one. He or she *sings* the poetical passages, or those containing maxims of wisdom and morality. If this personage dies in the course of the play, another sings in his place. In these lyrical or didactic passages are to be sought those flowers of diction which, as Julien has shown, consist partly in the use of a metaphorical phraseology of infinite nicety in its variations. These features constitute the literary element *par excellence* of Chinese dramatic composition. A careful study of the Chinese drama will show that it possesses merits of constructional ingenuity and variety of character well presenting pathos, grace and delicacy of treatment, humour and burlesque. Scenic decorations of any importance were always out of question in the Chinese theatre. The costumes, on the other hand, are magnificent; they are traditionally those worn before the 17th century, in accordance with the historical colouring of most of the plays. The actor's profession was not a respectable one in China, but under the Republic conditions are changing rapidly.

JAPANESE DRAMA

The Japanese drama seems to remain what in substance it has always been—an amusement passionately loved by the lower orders, but hardly dignified by literature deserving the name. Apart from its native elements of legendary or historical narrative and pantomime, it is clearly to be regarded as a Chinese importation; nor has it in its more advanced forms apparently even attempted to emancipate itself from the reproduction of the conventional Chinese types. As early as the close of the 6th century Hada Kawatsu, a man of Chinese extraction, is said to have been ordered to arrange entertainments for the benefit of the country, and to have written as many as thirty-three plays. The Japanese, however, ascribe the origin of their drama to the introduction of the dance called *Sambāso* as a charm against a volcanic depression of the earth which occurred in 805. In 1108 lived a woman called Iso no Zenji, who is looked upon as "the mother of the Japanese drama." But her performances seem to have been confined to dancing or posturing in male attire (*otokomai*); and the introduction of the drama proper is universally attributed to Saruwaka Kanzaburō, who in 1624 opened the first theatre at Yedo.

The subjects of the serious popular plays are mainly mythological. The famous narrative of the feudal fidelity of the forty-seven *ronins,* who about the year 1699 revenged their chiefs judicial suicide upon the arrogant official to whom it was due,

is stirring rather than touching in its incidents, and contains much bloodshed, together with a tea-house scene which suffices as a specimen of the Japanese comedy of manners. Besides tragic (Nō) plays *(see* JAPANESE LITERATURE), the Japanese have middle-class domestic dramas of a very realistic kind. The language of these, unlike that of Chinese comedy, is often gross and scurrilous Fairy and demon operas and ballets, and farces and *intermezzos,* form an easy transition to the interludes of tumblers and jugglers. *(See* JAPAN.)

PERSIAN AND OTHER ASIATIC DRAMA

Such dramatic examples of the drama as may be discoverable in Siam will probably have to be regarded as belonging to a branch of the Indian drama. The drama of the Malay populations of Java and the neighbouring island of Sumatra also resembles the Indian, to which it may have owed its development. The Javanese distinguish among the lyrics sung on occasions of popular significance the *pantun,* a short simile or fable, and the *tcharita,* a more advanced species, taking the form of dialogue sung or recited by actors proper. From the *tcharita* the Javanese drama, which in its higher forms treats the stories of gods and kings, appears to have been derived.

The originally Aryan Persians exhibit no trace of the drama in their ample earlier literature, but later two species, widely different from one another, of the religious drama or mystery and of the popular comedy or farce, made their appearance.

Of the Persian *téaziés* (lamentations or complaints) the subjects are invariably derived from religious history, and more or less directly connected with the "martyrdoms" of the house of Ali. The plays are frequently provided by the court or by other wealthy persons, by way of pleasing the people or securing divine favour, and are performed, usually by natives of Isfahan, in courtyards of mosques, palaces and inns.

It would seem that, no farther back than the beginning of the 19th century, the *téaziés* were still only songs or elegies in honour of the martyrs, occasionally chanted by persons actually representing them. The *Miracle Play of Hasan and Hosain,* as we may call it, has now come to be a continuous succession of dramatic scenes The performance is usually opened by a prologue delivered by the *rouzékhán,* a personage of semi-priestly character claiming descent from the Prophet, who edifies and excites the audience by a pathetic recitation of legends and vehement admonitions in prose or verse concerning the subject of the action. It is thus a kind of Oberammergau play and complaint of the Nibelungs in one.

The other kind of Persian drama is the *témacha* (=spectacle), a kind of comedy or farce, sometimes called *teglid* (disguising), performed by wandering minstrels. A favourite and ancient variety of the species is the *karaguez* or puppet-play, of which the protagonist is called *kétchel péhlévan* (the bald hero).

The modern Persian drama seems to have admitted Western influences, as in such comedies as *The Pleaders of the Court.*

Dramatic elements are apparent in two of the books of the Hebrew scripture—the *Book of Ruth* and the *Book of Job,* of which latter the author of *Everyman,* and Goethe in his *Faust,* made so impressive a use.

POLYNESIAN AND PERUVIAN DRAMA

From Polynesia and the more civilized races of aboriginal America we also have isolated traces of drama. Among these are the performances, accompanied by dancing and intermixed with recitation and singing, of the South Sea Islanders, first described by Captain Cook, and reintroduced to the notice of students of comparative mythology by W. Wyatt Gill. Of the so-called Inca drama of the Peruvians, the unique relic, *Apu Ollantay,* said to have been written down in the Quichua tongue from native dictation by Spanish priests shortly after the conquest of Peru, has been translated by Spilsbury. With it may be contrasted the ferocious Aztec dramatic ballet, *Rabinal-Achi* (translated by Brasseur de Bourbourg), of which the text seems rather a succession of warlike harangues than an attempt at dramatic treatment of character. But these are mere isolated curiosities.

DRAMATIC ELEMENTS IN EGYPTIAN CULTURE

The civilization and religious ideas of the Egyptians so vitally influenced the people of whose drama we are about to speak that a reference to them cannot be altogether omitted. The doctrine of the immortality of the soul found in Egypt its most solemn expression in mysterious recitations connected with the rites of sepulture, and treating of the migration of the soul from its earthly to its eternal abode. These solemnities, whose transition into the Hellenic mysteries has usually been attributed to the agency of the Thracian worship of Dionysus, undoubtedly contained a dramatic element. The ideas to which they sought to give utterance centred in that of Osiris, the vivifying power or universal soul of nature, whom Herodotus identifies with Dionysus. The same deity was likewise honoured by processions among the rural Egyptian population, which, according to the same authority, in nearly all respects except the absence of choruses resembled the Greek phallic processions in honour of the wine-god.

(X.)

GREEK DRAMA: (A) ORIGIN

Modern drama, from Shakespeare onwards, is confessedly an entertainment. Its true intent is for our delight, and if it does not entertain it has difficulty in justifying its existence. Also each play as a general rule is, or affects to be, a piece of free fiction, with imaginary characters and invented plot. Greek drama in its origin was a ritual performed for a religious purpose. Its object was not to entertain the spectators, though it might do that incidentally, but to obtain certain blessings for the community. Tragedy was never a piece of free fiction: it was an acted representation of the *πάθος* or death of some hero; and comedy, though it used fictitious characters, followed certain fixed ritual forms. When dramas, or *ludi scenici,* were introduced *(361* B.C.) from Etruria into Rome, their object was to check a plague.

A series of researches by different scholars (*see* at end) during the past 30 years enables us now to understand much more clearly the real nature of the Dionysiac ritual which took form in tragedy and comedy.

1. Religious Origin.—The drama in both its forms is a performance connected with Dionysus. It is produced at his festival, in his theatre, under the presidency of his priest, by performers who are technically known as *Διονύσου τεχνῖται.* In Aristophanes' *Frogs* Dionysus, the god presiding over drama, is the hero of the play.

Drama (*δρᾶμα*) means "a thing done" or "performed"; and the drama is a performance in honour of Dionysus. One may compare the *δρώμενα* or "things done" and the *δείκηλα,* "tableaux" or "things shown" in the mysteries at Eleusis and elsewhere (*cf.* Lobeck, *Aglaophamus,* pp. 50, 688 *seq.*); and even more helpfully the ecclesiastical plays of the middle ages. These were sometimes tableaux, sometimes extracts from the liturgy made dramatic and divided between performers, sometimes they were developed into plays in the full sense, representing such subjects as the Passion or the Massacre of the Innocents. Such plays sometimes included characters outside the Gospel, *e.g.,* the *unguentarius* from whom Mary Magdalene buys cosmetics. Sometimes they left both the Bible and the Liturgy aside and dealt with the adventures of saints. In the original plays of the nun, Hroswitha. again, we find a performance completely detached from the Church ritual, and standing on its own feet.

Thus we see that the mediaeval religious plays were gradually extended both in subject and treatment far beyond the original limits. And the same process seems to have taken place in Athens. The extant plays are mostly concerned with non-Dionysiac legends; and the Greek proverb *οὐδὲν πρὸς τὸν Διόνυσον* ("nothing to do with Dionysus") is supposed to refer to this extension of the field of drama. Yet it would be rash to suppose that all Attic drama dealt originally with Dionysus and thence spread to other cults. It is more likely that *dranzata* existed in many rituals of the Mediterranean religion from the earliest times.

Aristotle in his account of drama remarks that man is "by nature imitative"; extremely ancient χοροί, or dancing grounds, like those from which the drama developed, have been found in Thera, Crete, etc.; they are assumed as an ordinary institution in the Homeric poems; while in the dialogue *Minos* (attributed to Plato) it is remarked that tragedy was "ancient in Athens." There is also sufficient, though not abundant, evidence of the use of tableaux and acting in other cults besides the Dionysiac to justify this hypothesis. However, it remains certain that in classical Greek times the drama was the *sacer ludus* of Dionysus.

2. Tragedy and Comedy.—Drama took two forms, distinct and never combined, κωμῳδία and τραγῳδία, *kômos*-song and *tragos-song* respectively. The first name is transparent, a *kômos* being a revel, and almost every extant comedy ending with a revel scene. The second is obscure, and must be considered more carefully below.

To begin with comedy, we find in it almost always a kômos and associated therewith, as habitually on Greek drinking vases, a γάμος (*gamos*) or union of the sexes. Of the 11 plays of Aristophanes eight end in a *gamos: Ach.* 1,198 *seq.; Equ.* 1,389 *seq.; Vesp.* 1,342 *seq.; Pax* 1,316; *Av.* 1,728; *Lys.* 1,275 *seq.; Eccl.* 876 *seq.; Plut.* 1,042 *seq.* And we may note that in the first three of these it is dragged in and not naturally deduced from the plot. That is to say, it probably comes from the underlying ritual.

Also, all through the classical period, the chorus and the performers in comedy wear artificial *phalli, i.e.,* visible representations of the male organ of generation. This was of course contrary to normal manners, and was to some extent disguised in the 5th century, except in the bird or beast choruses. This feature also is usually (except *e.g.,* in the *Lysistrata*) quite irrelevant to the plot. It comes from the ritual, and the ritual is a well-known fertility ritual connected with the vegetation-spirit or year-daemon.

In its historical development we may notice how comedy moves further and further away from a mere phallic fertility rite, becoming more intellectual, literary and, incidentally, decent. Aristophanes boasts more than once how he has raised the tone of comedy, but amid all refinements the ritual *phalli* were still retained, in inconspicuous form, even in plays like the *Frogs* and the *Birds.* By the time of Menander they had disappeared (cf. *Nub.* 537 *seq.; Vesp.* 1,015 *seq.; Pax* 736 *seq*).

Thus Comedy is a perfectly intelligible performance of *kômos* and *gamos* in the ritual of the vegetation or fertility spirit, Dionysus. It represents, we may say, the triumph and marriage of the year-daemon.

3. Essentials of Tragedy.—If we seek for some similar constant feature in tragedy, we find generally *(a)* an Αἴτιον (*aition*) *i.e.,* the explanation or cause of some rite or custom. Thus the *Prometheus* trilogy explained the festival Prometheia, the *Ajax* explains the ritual of the Aianteia, the *Eumenides* explains the origin of the worship of the Eumenides at the Areopagus, the *Hippolytus* the worship of that hero by maidens, the *Iphigenia in Tauris* the curious ritual of Artemis at Brauron, the *Medea* the lamentation for Medea's children, etc. We find *(b)* that the *aition* is almost always a death, and the ritual to be explained a tomb worship: *e.g.,* that of Alcestis, Hippolytus, Eurystheus *(Hclid)* Neoptolemus, Peleus and Thetis *(Androm.),* Rhesus, etc. Some tragedies indeed seem to be taken more from the epic tradition than from any ritual. The *Septem* is a treatment of the old siege-motive, found in very early Minoan paintings as well as in the *Iliad* and the *Thebais;* but the trilogy to which it belongs is based on the regular year-king sequence, in which the Old King is killed by the Young King helped by the Queen. Some of the plays about Orestes *(e g.,* Soph. *Electra)* become epic rather than religious, but they also are rooted in the year-king ritual. And even the most definitely epic or heroic stories seem always to have in them a dirge or a sacred tomb, *e.g., Troades, Antigone, Persae.*

Thus it seems essential to tragedy to contain a dirge or a tomb ritual, and to act the *aition* of it: *i.e.,* the story from which the observance is supposed to be derived. It is also noticeable that the death of the hero or heroine is normally not enacted, but, as in the year-ritual of Osiris, Adonis, Pan, etc., regularly related by a messenger.

4. **Death** and Resurrection.—Thus, as comedy gives the *kômos-gamos,* so tragedy gives the πάθος-θρῆνος ("violent death and lamentation") of its hero or heroine.

Now a marriage-revel plus a slaying and lamentation is the content of the traditional pre-Christian religious drama once prevalent all over the Mediterranean world, and still not quite extinct under the name of "the Mummers' Play." It celebrates the birth and growth, the victorious battle and marriage; the lost battle and death, and sometimes the resurrection, of a hero representing the year, or the annual revivification of the world, first new and then old. And Dionysus was just such a being, akin, as Sir James Frazer has shown, to Attis, Adonis and Osiris. Comedy gives the triumph and marriage of the hero, tragedy his defeat and death, narrated always by a messenger. As for his birth and growth, we have that described in the *Hymn to Hermes,* the *Zchneutae* and the *parodos* of the *Bacchae;* and it is possible that this was properly the content of the dithyramb. At least Plato says that the dithyramb was Διονύσου γένεσις, οἶμαι ("the birth of Dionysus, I imagine") *(Laws* 700B).

There is one further element commonly, though not always, present in the mummers' play, viz., the resurrection of the slain hero. This resurrection or renewal motive occurs in many myths (Cook, *Zeus,* ii. 210 *seq.)* and is common in comedy *(Knights, Gêras, Amphiaraus,* cf. *Clouds, Wasps: see* Cornford, *Attic Contedy,* pp. 87–93; cf. also *Bacchae* 184 *seq.; Hclid.* 786 *seq.; Andr.* 548–765). It seems possible that this was represented in the satyr play, which normally followed the third tragedy, and represented the arrival of Dionysus with his attendant daimones (*Themis* p. 344 *seq.*; Cook, *Zeus,* i. pp. 680, 696 *seq.).* .At any rate a trace of it seems to exist in the constantly recurring deification or heroization of the chief characters: Alcestis, Hip. polytus, Heracles, etc.

Thus it seems that in dithyramb, comedy, tragedy and satyr play we have traces of the birth and growth, the marriage, the death and the resurrection of the year-daemon, which formed the subject of a complete ancient mummers' play. We may notice that the tragic hero is never Dionysus himself but regularly some hero who in some way takes his place.

5. The Goat **Song.**—We have seen above that the *tragôdia* or goat-song, with its enigmatic name, describes the πάθος or violent death of the hero, generally by some form of ritual slaying and particularly by *sparagmos* or dismemberment. When we observe that a goat was the animal commonly sacrificed to Dionysus, and particularly was so at Icaria, where tragedy is said to have been invented by Thespis, it seems reasonable to suppose that the goat-song was the song sung over the sacrificed and often dismembered goat. It is certain that in Graeco-Roman tradition generally the goat was specially associated with Dionysus, and practically certain that the dismembered kid or goat, of which we hear so often, was the representative or the embodiment of the god. (Farnell, *Cults,* v. pp. 165 *seq.* 302e, 303.) In particular the *sparagmos* or διασπασμός of the kid, whose blood the worshippers sacramentally drank, tells its own tale. The goat-song is the song of the dismembered goat, which is really the god. *(Cf.* Eratosthenes' "The Icarians then first danced around a goat.") In the lists of typical sacrifices we find: "a pig to Ceres, a goat to Liber (Dionysus) (Serv. Aen. 3, 18; *id. zb.* 8, 343; other passages in Farnell, *Cults,* p. 393). Also when the Gods disguised themselves, *proles Semeleia capro . . . latuit* (Ov. *Met.* v. 329); so *Baccho caper omnibus aris caeditur; caper Bacchi mactatur ad aras,* etc. For the sacramental *sparagmos* of small animals *cf.* the horrible word νεβρίζειν and lines such as Aesch *Eum.* 26 (λαγὼ δίκην Πενθεῖ καταρράψας μόρον) and the many examples of animals, children, etc. alleged or supposed to be torn in Dionysiac rites (Farnell, *Cults,* v. p. 301). These victims, it is generally agreed, are torn as surrogates or substitutes for the god himself.

When, therefore, Herodotus tells us (v. 67) that at Sicyon they used to honour Adrastus instead of Dionysus, celebrating

his "sufferings" (πάθεα) with tragic choruses, we may naturally suppose that other people in their tragic choruses celebrated the "sufferings" of Dionysus. What were these "sufferings"?

6. The Dismemberment. — It is commonly argued that the accounts we possess of the *sparagmos* or dismemberment of Dionysus are "late," occurring mainly in Plutarch and the Christian fathers. As a matter of fact they occur in Eratosthenes *(cf.* 240 B.C.). But further we have the express testimony of Herodotus, a contemporary of the bloom of tragedy, that the characteristic worship of Dionysus was "in almost all respects the same" as that of Osiris (see *Themis,* p. 342; Hdt. ii. 48: τὴν δὲ ἄλλην ἀνάγουσι ὁρτὴν τῷ Διονύσῳι οἱ Αἰγύπτιοι, πλὴν χορῶν, κατὰ τἀυτὰ σχέδον *ahvra* Ἕλλησι). Ordinarily Herodotus simply uses the name Dionysus for Osiris (as here, *cf.* ii. 144 "Osiris is Dionysus in Greek"; *cf.* ii. 42, etc). That is to say, Dionysus *is* Osiris, and the ritual is, apart from the dramatic choruses, almost exactly the same. We know the ritual of Osiris; and must therefore conclude that the ritual of Dionysus also contained a *sparagmos,* mourning, search, discovery and resurrection. It seems at first sight extraordinary that, if this was so, there is no mention of this ritual in classical times. The explanation is given by Herodotus. When there is mention of Osiris's death and lamentation he has a religious scruple against mentioning Dionysus' name in such a connection (ii., 61, "They lament but whom they lament I must not say"; *cf.* ii. 132, "When the Egyptians lament the god whom I may not name in this connection," so ii. 170, 86). It was forbidden to speak of the death of the god who was the life of the world. It was ἄρρητον (ineffable), and, in the manner of ancient religion, a surrogate took the god's place. We find a frequent *sparagmos* of beings who have committed some sin against Dionysus or other gods: of Pentheus by Maenads, Orpheus by Maenads, Lycurgus by horses, Hippolytus by horses, Dirce by a bull, Actaeon by hounds, etc. This use of a surrogate was made easier by the fact that both at Eleusis (Lobeck, *Aglaophamus,* pp. 50, 688 *seq.)* and in the Osiris rite (Hdt. ii. 171) the myth was conveyed by tableaux, not words. Thus the death of Pentheus, wearing Dionysiac dress, would be shown by exactly the same tableau as that of Dionysus. The truth could be shown to the wise and at the same time veiled from the unknowing. Such facts help to explain the charge of "profaning the mysteries" which was brought against Aeschylus.

Aristotle's two statements, that tragedy arose "from the leaders of the dithyramb" and comedy "from those of the phallic [songs]" are thus intelligible. The dithyramb *(see* above) is perhaps used for the whole birth and death story of Dionysus; the *exarchontes* are the actors as opposed to the chorus. Τὰ φαλλικά form that part of the year ritual which is concerned with the *gamos,* and perhaps also, as in the Osiris rite, with re-birth or resurrection.

In the remains of tragedy that we possess a few plays, like the *Bacchne,* and Aeschylus' *Edoni,* show the full Dionysus ritual almost unaltered; its influence is visible in others, such as the *Hippolytus* and *Andromache,* which have a sequence of scenes showing *agon, pathos* or *sparagmos,* messenger, *threnos,* theophany. Rut elsewhere we find that other rituals have left almost equally clear traces: the regular earth-and-year sequence —Old King, Young King who with the help of the Queen slays him, Third King who avenges or saves—in the *Oresteia,* the *Prometheus* and the Laius-Jocasta-Oedipus story. The rite of supplication at an altar occurs in a great number of plays, from Aeschylus' *Supplices* onwards. One can see also great influence exerted by the idea of the theophany or resurrection. Not only do most of Euripides' plays end with the appearance of a divine being, and a large number of comedies with the rejuvenescence of an old man, but most tragedies end with the quasi-deification of some hero or heroine, or at least the foundation of some worship. Most influential of all these ritual types is the figure of the *pharmakos,* the old polluted year, the sin-bearer, who has to be stoned or cast out, to suffer for his people. Oedipus and Orestes are typical; but almost every tragic hero has the traces of the *pharmakos* about him, he bears some pollution and he dies for the sake of others.

Thus, while we must allow for the influence of epic legends and heroic sagas upon tragedy, and of mere stories upon comedy, in the main Greek drama grows from a dramatization of ritual, and almost always of some ritual connected with the cult of the year spirit or vegetation spirit. When drama was put specially under the charge of Dionysus the specific Dionysus ritual, resembling that of Osiris, with its *sparagmos* and search and discovery, became prominent; but it was not exclusive, and through the earlier part of the 5th century other themes were fully as common. It is the year-religion in general which provides tragedy with its main scheme and exhibits life in the tragic pattern as a thing which, like the corn and flowers, like the young animals, like the sun and earth themselves, begins gentle and gracious, grows gradually great and commits the sin of *hubris* (pride), and at last in payment of that sin must fall and die.

Development of the Present View.—The researches referred to above have, after much controversy, arrived at something like a firm and generally accepted result, which is really a restatement of the traditional doctrine better understood. That doctrine, as stated in old books like Müller and Donaldson's *History of Greek Literature* (1858) regarded tragedy as a performance developing from the cult of Dionysus, the god of wine, ecstasy, and the forces of nature, especially the joy of the spring. It was obviously a little difficult to get from this god to tragedy, though to comedy the way was easy enough. In Haigh's *Tragic Drama of the Greeks* (1896) this difficulty is felt but not solved. The first bold stroke at a solution was made by the late Prof. Ridgeway, who simply denied the Dionysiac origin of drama, and explained tragedy as a funeral performance at the grave of a warrior. ("Origin of Tragedy," in *Quarterly Review,* 1908; also a book, same title, 1910.) These were followed in 191j by *Dravzas and Dramatic Dances of Non-European Races.* Part of Ridgeway's theory was obviously true. Tragedy is a *Trauerspiel,* a ritual lamentation over a death, and almost every tragedy contains a sacred or "heroic" tomb. On the other hand all the ancient testimony describes tragedy as a Dionysiac celebration, and no one had properly emphasized the words of Dionysius, Hal. *Roman Antiquities,* ii. 19, about "black-robed festivals, with beatings of the breast and lamentation over the disappearance (or death) of gods, as for the rape of Persephone and the sufferings of Dionysus."

Meantime the real nature of Dionysus was made much clearer by Frazer's *Attis, Adonis, Osiris,* which emphasized the element of death and mourning in this type of cult; and Farnell's account of Dionysus in *Cults,* vol. v. Farnell rightly (chap. v.) derived tragedy from the contest between the Fair and the Dark, *ie.,* day and night or summer and winter, using a hint of Usener's in the *Archiv für Religionswissenschaft,* 1904 (vii. pp. 303–313), while Dieterich in a remarkable article in the same *Archiv* (1908, vii.) developed the conception of tragedy as a *sacer ludzis,* for the purpose of averting the disasters which it portrayed. The connection between the Dionysus cult, dithyramb, tragedy, etc.. and the wide-spread year-celebration known as the mummers' play, with its sequence of birth, growth, victory, marriage, defeat, death and (sometimes) resurrection, was first brought out by Dawkins, *A Modern Carnival in Thrace and the Cult of Dionysus,* in the *Journ. Hell. Stud.* xxvi. (1906). Gilbert Murray in a chapter contributed to the late Dr. Jane Harrison's book *Themis* (1912, revised 1927), pointed out the knowledge by Herodotus of a Dionysus cult practically identical with the mourning-cult of Osiris; and the regular presence in tragedy of a ritual death, together with the traces in many tragedies of the regular sequence of scenes which is known to be characteristic of the Osiris cult—Agon, Pathos, Messenger, Thrênos, Theophany. Finally, F. M. Cornford in *The Origin of Attic Comedy* (1914) combined with this conception of Tragedy as the death and lamentation of the year daemon the observation that Comedy represented his victory, revel and marriage. An attempt to deny all these results is made by Pickard-Cambridge, *Dithyramb, Tragedy and Comedy* (1927)

GREEK DRAMA: (B) HISTORY

Tragedy.—Archilochus said that he could lead the dithyramb

as well drunk as sober, which is not true of tragedy; and neither with him (c. 650 B.C.) nor with the (*c.* 600) chorus of 50 of Arion of Lesbos at Corinth can tragedy legitimately be considered to have begun. Ancient tradition, which there is no valid reason to challenge, states that in Attica, at the Dionysia of 534 B.C. one Thespis, of the Icarian deme, produced a chorus of which he was himself leader (κορυφαῖος). But instead of merely exchanging dialogue with the chorus he had included a person called the Answerer (ὑποκρίτης, afterwards the word for actor—but the word is also interpreted as "the poet's spokesman," see Bywater's ed. of Arist. Poet., p. 136) with whom also he spoke. He now had the materials from which he constructed rude tragedies; narrative, and some very limited action were possible, but the entertainment was still chiefly lyrical. From his day the history of Greek tragedy is purely Attic. His chief successors, Choerilus, Pratinas and Phrynichus, produced plays of a similar character; Phrynichus is credited with the introduction of female characters, and with especially charming lyrics. His two most famous pieces, the Capture of *Miletus* and the Phoenician *Women,* dealt with contemporary events.

Greek tragedy enters upon its classical and greatest period with the appearance of Aeschylus (525–456) about 500 B.C. Under GREEK LITERATURE, and more briefly under CLASSICS will be found a study of the content and style of his plays and of those of his successors: further reference should be made to their respective biographies. Under THEATRE are discussed the various technical devices of the Greek stage—the "buskins," the masks, the scenery, etc. Here we shall merely indicate briefly the changes introduced by each of the more important authors. The greatest innovator of all was without doubt Aeschylus. He introduced a second answerer, or actor. Each actor might "double" parts as much as he could, so that, with the chorus and its leader taking an active part, a developed drama was now possible. The limitations of a small cast were less felt than they would be to-day owing to the conditions of performance. The plays were presented out of doors at the Great Dionysia before unmanageably huge audiences, consisting of the whole population, citizens, slaves, women, children, visitors; the writer had necessarily to rely very largely upon the music and upon the "mass effects" provided by the chorus. To the conditions of performance was due also the typical Aeschylean arrangement of the trilogy or tetralogy (though the words are of later, probably Alexandrian, date). The trilogy is the day's sequence of three plays, forming one vast play, though each section is a comprehensible and if necessary detachable unit. Of a trilogy we have one example, the Oresteia (*Agamemnon, Choephori, Eumenides*) dealing with the story of Orestes. A tetralogy is the trilogy with the addition of a fourth play, the "satyric drama," which, as might be expected after so long a performance, was of a light character, contained much comic relief and had a happy ending. The one surviving example, Euripides' Cyclops (large parts of Sophocles' Ichneutae have also recently been discovered) does not suggest that by the disappearance of these dramas much has been lost. Aeschylus left a further profound trace on Greek drama by his lavish use of "Homer" for his subject matter, and his modelling of the language of tragedy upon the solemnity of the Homeric verse. He called his plays "dry scraps from Homer's banquet." By "Homer" he meant not the Iliad and Odyssey so much as the vast mass of myth contained in the cyclic poems generally (see HOMERIC POEMS).

With Sophocles (495–405) the associate of Pericles, Greek tragedy reaches, if not its highest, at least its most characteristic development; appreciation of his plays is a cultivated taste. He released Greek drama from certain of the limits accepted by Aeschylus. He provided a third actor, thus enlarging the author's field, he began to abandon the trilogical connection of plays, he increased the numbers of the chorus, and brought the language nearer to that of everyday life. He further introduced the use of scenery, states Aristotle (*Poet.* 1449a 18, σκηνογραφίαν; the exact meaning of this has been somewhat fruitlessly disputed). Euripides (480–406) increased still more the flexibility of the drama. He separated the chorus from the action—the first step to its complete destruction—he used the prologue openly as an introduction and explanation to the play, and his language, subjects and sentiments seemed to his contemporaries excessively realistic. He was, however, charged with an intemperate use of the *deus* ex *machina* device, by which a god is brought in abruptly at the end of a play to set right a confusion which is beyond human powers.

These three great writers in their life-time and even more since have towered above all others. But there were many other playwrights, of whom Ion and Agathon appear to have been of outstanding merit. The latter used a very florid style, invented his subjects if necessary, and allotted to his chorus *embolima,* "inserted numbers," which had no connection with the play. After them came numerous poets, all of whose works are also lost; we may mention Euphorion. Aeschylus's son. Iophon the son of Sophocles, and Euripides, his namesake's nephew. The conquests of Alexander spread theatres all over the East, and shortly afterwards the rise of Alexandria attracted from Athens to that city the remaining dramatic talent. The productions of this age are lost. There is little reason to believe that the loss is a very serious one, though the Alexandrian theatre survived till the days of the Roman empire.

Comedy.—The Thespis of comedy was Susarion of Megara (*fl.* 580–562 B.C.) who added broad jokes (possibly practical jokes) and rustic satire to the phallic song. Epicharmus (c. 500 B.C.) and Sophron (c. 430 B.C.) of Syracuse must also be counted among the earliest exponents of comedy, which thus appears to have a Dorian origin. The character of Epicharmus' comedies is uncertain: Sophron's mimes were dramatic recitations of everyday Sicilian life, classed as for "male" or "female" characters (μῖμοι ἀνδρεῖοι καὶ γυναικεῖοι). But Athens soon asserted her dominion with the trinity of *Eupolis* atque *Cratinus Aristophanesque poetae,* of whom the last alone has had the fortune to survive. To these poets of the Old Comedy should be added the names of Magnes, Pherecrates, Crates, Phrynichus and Plato comicus. Comedies, though some were presented at the Great Dionysia, were chiefly played at the Lenaea, in Gamelion (the month January–February) at a time when the Athenians were isolated by winter and were free to indulge in the most intimate comedy and self-criticism. The poets presented but one comedy, and were not subject to the artistic restrictions of tragedy, or indeed, as for Old Comedy, to restrictions of matter at all The phallic element survived; the comedies were grossly indecent, either incidentally or as in the case of one of the best (Lysistrata), organically. Political attacks of the freest kind were permitted nearly till the end of the Peloponnesian War. Their chief vehicle was the parabasis, a break in the middle of the play when the chorus moved towards the audience (παραβαίνω), faced it and delivered a long speech in the name of the poet dealing with current events.

From 414, when a law was passed checking this free comment, Old Comedy was doomed and from the end of the century till about 338 (Macedonian conquest) we have what is conventionally called Middle Comedy. The *Plutus* of Aristophanes is an example of it. The vitality of comedy has been impaired, the *parabasis* has vanished, the chorus is dying and conventional types begin to appear. In reality, the division between Middle and New Comedy is an unhelpful one and one not countenanced by the Alexandrians. The characteristics of New Comedy (from 338 onwards) are merely exaggerations of the characteristics of Middle Comedy. The chorus has vanished, and the play is merely an 'imaginary story of the events occurring to certain typical figures—the Rich Miser and so forth. They may best be studied in the plays of Plautus and Terence, their imitators (see below). The reputation of Menander, the most famous of New Comedy writers, has been injured rather than enhanced by the recent discovery of considerable fragments. A successor of Sophron the mime writer may be found in the Alexandrian Herodas, whose *Mimes* are a purely literary production.

ROMAN DRAMA

Early Dramatists. — The art of the drama was at Rome a res *peregrina,* and, according to Livy (vii. 2), took its rise from the performances of the Etruscan ludii who were summoned to Rome in 364 B.C. to avert by their dancing and playing the wrath of the gods who had sent a plague. Livy is, no doubt, following the accepted antiquarian view of contemporary scholars, such as Varro, and too much reliance must not be placed upon his details; but that Roman drama came under Etruscan influence at an early stage is proved by the Etruscan origin of the words hister (player), and (probably) persona (a player's mask). Rome had been in contact with the Italian Greeks much earlier than the middle of the 4th century and must have been aware through them of the existence of dramatic exhibitions; and the "Fescennine verses" were germs out of which the art of dramatic representation might have been developed. Further, the Oscan town of Atella from an early time had possessed (possibly under Greek influence) a rude native drama, afterwards developed at Rome into a distinctive form under the name of the *fabula* Atellana. Under the combined influence of the Etruscan *ludii* and the rude jesting of the Fescennine verses there developed (according to Livy) a form of drama called the *satura,* with full musical accompaniment by a flute and an appropriate style of acting: but the details of the development are obscure and the very existence of the dramatic *satura* is doubtful.

It was not till the Punic Wars that Rome possessed a regular drama. Livius Andronicus, a Greek captured at Tarentum and afterwards a schoolmaster at Rome, translated a Greek tragedy and comedy for production at the Roman games of 240 B.C. The titles of nine tragedies and three comedies of his survive; the skill with which Greek metres are handled in his extant fragments. and the success with which the Latin language is adapted to their use, are so remarkable as to cause hesitation in accepting the current view that he was absolutely the pioneer of verse translation from the Greek. His contemporary Cn. Naevius inclined more towards comedy than tragedy; we have the titles of 34 comedies of his as against seven tragedies: he was the first to choose as subjects for tragedies traditional Roman legends (*e.g.,* Romulus) or contemporary events such as the battle of Clastidium (222 B.c.) : this type of tragedy was known as *fabula* praetextata. The fragments of his comedies contain references to contemporary life and manners worked into the framework of his Greek original: one of his most famous comedies was the *Tarentilla,* which turned upon the adventures of two young men detected by their fathers living with two girls in Tarentum and haled back to respectability. Naevius thus pointed the way for the later type of comedy which found its subject matter in Roman (or Italian) life, the *fabula* togata. The work of the two pioneers was continued by Q. Ennius who was born in Calabria in 239 and lived till 169 B.C. We know by name only two comedies of his, but there are fragments of 22 tragedies, and two *fabulae* praetextatae. He seems to have been especially attracted by Euripides: his translation of the Medea was famous and his *Andromache* in Captivity was well known and appreciated as late as the time of Cicero.

Plautus and Terence. — After Ennius no one attempted both branches of the drama; indeed the practice had already been abandoned by his elder contemporary T. Maccius Plautus, a native of Sarsina in Umbria, whose dramatic career began during the later years of the Second Punic War. Plautus confined himself to comedy, and is the great representative of the *fabula palliata,* the comedy translated or adapted from the Greek masters of the Middle or New Comedy, Menander, Philemon, Diphilus and their fellows. Of the poet himself we know next to nothing: the only certain dates in his career are those of his death (184 B.C.) and of the production of the *Stichus* (200 B.C.) and the *Pseudolus* (191 B.C.). The name Plautus may be a nickname ("flat-foot"), and Maccius may be derived from the name of one of the stock characters in the fabula *Atellana* (v. *infra*) in which he may have appeared during his youth. The detsils of his life given by later writers are either inventions or inferences, or modelled upon stories in Greek biographies. The twenty complete comedies which we possess along with the *Vidularia,* extant only in fragments, were all that Varro recognized as genuine out of the 130 attributed to Plautus in his day (hence known as the *fabulae Varronianae*). Besides these we have insignificant fragments of 32 of the plays rejected by Varro. Of the prologues to the extant plays some are certainly (and all may be) post-Plautine.

Though Plautus invariably adapted a Greek original he preserved his independence, fitting in upon occasion scenes from other plays where they served his purpose (a method known to subsequent critics as *contaminatio*): he introduced quite freely allusions to Roman legal procedure, manners and customs; he abandoned the previous convention with regard to the metres of dialogue; his boisterous humour breaks through the artistic restraint imposed by tradition upon his Greek masters. One of the greatest masters of the Latin language, Plautus riots and gambols in dialogues in which everything is sacrificed to the desire to raise a laugh: but the nimbleness and suppleness of his diction are extraordinary. His high spirits and his mastery of dialogue remained unique in Roman comedy.

Plautus's younger contemporary, Statius Caecilius, who died in 168 was by some later critics regarded as the chief of Roman comedians. Mastery of plot and *grauitas* were regarded as his principal merits; following the advice of his friend Ennius he avoided *contaminatio.* His chief model was Menander, to whom he owed the plots of 16 out of his 42 known comedies, and his fragments show that (in spite of Cicero's *malus* latinitatis *auctor* est) he had caught something of Menander's happy brevity A new movement which roused the hostility of the dominant school of comedy was represented by P. Terentius Afer, who, coming to Rome from Carthage as a slave, became a literary friend of Scipio and his circle and died at an early age in 159 B.C. Of Terence's six plays the first (the *Andria*) was produced in 166 B.C., and the last (the *Adelphi*) in 160 B C. Terence avoided the boisterous mirth of his predecessors, and lacks the rich vocabulary of Plautus: he excelled in the portrayal of character: his style is choice and correct without formality: he avoids the anachronisms and carelessness of Plautus, and simplifies his medium by confining himself practically to two metres and by omitting the lyrical passages in irregular verse known as *cantica.* His prologues wage war upon the popular taste and the views of his critics. Without the strength and vigour of Plautus, Terence is superior to him in dramatic construction and deftness of phrase, and became the acknowledged model of cultivated Latin speech. After Terence the comedy modelled upon Greek originals declined; amid a number of writers Sextus Turpilius who died in 103 B.C , alone deserves mention. He represents the extreme reaction from the fine correctness of Terence to the vocabulary of the crowd. But the public taste was turning to other forms of comedy, though *palliatae* continued to be produced and earlier plays were revived and imitated. It is to this period that many of the plays afterwdrds attributed to Plautus can be assigned, including (perhaps) the *Asinaria.*

Later Developments. — Roman tragedy after Ennius was continued by his nephew and pupil M. Pacuvius, born at Brundisium about the beginning of the Second Punic War. He was regarded down to the time of Quintilian as the chief Roman tragedian, though Cicero finds fault with his style. We possess fragments of one *praetextata* and 13 tragedies modelled on the Greek. His plays continued to be performed till the first century AD., the most famous being the Teucer, the *Antiopa* and the *Niptra,* parts of which Cicero preferred to Sophocles's play on the same subject. Pacuvius's metre conformed closely to Greek models, and he was noted for his copious, flowing style and his love for compounds, and unusual grammatical forms His technical competence was contrasted by later critics with the spirited and lofty genius of L. Accius (born 170 B.c.), whom Ovid seems to have rated higher than Pacuvius. Fragments survive of 43 of his tragedies and of two pmetextatae. His plays cover the whole of Greek mythology and his favourite master is Sophocles. His first tragedy, the *Atreus,* was produced in 139 and. though Pacuvius, to whom it was read, found it somewhat harsh and immature

in spite of its stately and sonorous style, it remained a favourite acting piece. His style shows the influence of rhetoric, and he provided models for more than one of Seneca's plays. Quintilian considered him a master of dialectic.

By the last century B.C. the comedy borrowed from Greece was supplanted by the *fabula* togata, the subject of which was the life of country towns and obscure people. Its chief writers were the plebeian Titinius, a younger contemporary of Terence. T. Quinctius Atta (d. 77 B.C.) and L. Afranius (b. about 150 B.C.). The last brought the togatae to the highest finish and his plays were popular till the Augustan Age. Sulla's predilection for the *fabula Atellana* gave it a vogue during the same century. These farces originally dealt with stock characters (Maccus, the simpleton, Pappus, the old fellow, Dossennus, hunchback, etc.), but later were assimilated to the *fabula* fogata. The same century witnessed the rise of the *mimus,* which by the time of Cicero had ousted the *Atellana* as an *exodium.* The principal writers of these, generally licentious, plays were Dec. Laberius (105–143) and his contemporary Publilius Syrus, a liberated slave from Antioch; the fame of the latter rests mainly on the collections, dating from the second century A.D., of *sententiae* or pithy sayings from his works.

During this century the tragedies of the earlier masters were frequently reproduced, but there was no tragedian of repute until the reign of Nero, when Seneca composed his tragedies, whether for the theatre or not is uncertain. He borrowed freely from his predecessors, Greek and Latin, and produced nine tragedies, in which plot and character were subordinated to declamation and expositions of Stoic morality: but as models of tragic composition they long exercised great influence. The *praetextata* entitled *Octavia* which is included in the list of his plays is of later date.

Production of Plays.—The early Roman drama laboured under great restrictions: plays were produced only at the great festivals, such as the *ludi* Komani, the *Megalesia,* etc., or at funerals, triumphs and dedications of temples. The theatre was a temporary structure of wood and for long no seats were permitted. An attempt in 154 B.C. to build a stone theatre was prevented by the consul Scipio Nasica: Pompey's stone theatre was not built till 55 B.C.: though wooden seats for the spectators had been provided a century before. There were three stock changes of scene, and the only music was provided by a flute player (*tibicen*). At first authors acted in their own plays but later a manager (such as Ambivius Turpio who produced for Terence) with a troupe of actors (*grex*) brought out the play, engaging their services to the magistrate who had charge of the festival. These actors were generally slaves, though the Atellan farces were for long produced by freeborn citizens: in course of time (however) great actors like Roscius and Aesopus had a certain social position, though the actor in a mime (*planipes*) was despised until Imperial times

(R. M. HE)

DOWNFALL OF THE CLASSICAL DRAMA

The end of the ancient classical drama has been already foreshadowed The elements of dance and song, never integrally united with the dialogue in Roman tragedy, were now altogether separated from it. While it became customary simply to recite trsgedies to the small audiences who continued (or, as a matter of courtesy. affected) to appreciate them. the *pantomimus* commended itself to the heterogeneous multitudes of the Roman theatre and to an effete upper class by confining the performance of the actor to gesticulation and dancing, a chorus singing the accompanying text. The species was developed with extraordinary success already under Augustus by Pylades and Bathyllus; and so popular were these entertainments that even eminent poets, such as Lucan (d. A.D. 65), wrote the librettos for these *fabulae salticae* (ballets), of which the subjects were generally mythological, only now and then historical, and chiefly of an amorous kind. Comedy more easily lost itself in the cognate form of the *mimus,* which survived all other kinds of comic entertainments because of its more audacious immorality and open obscenity. Women took part in these performances, by means of which, as late as the 6th century, a *mima* acquired a celebrity which ultimately raised her to the imperial throne, and perhaps occasioned the removal of a disability which would have rendered her marriage with Justinian impossible.

Meanwhile, the regular drama had lingered on, enjoying in all its forms imperial patronage in the days of the literary revival under Hadrian (117–138); but the perennial taste for the spectacles of the amphitheatre, which was as strong at Byzantium as it was at Rome, and which reached its climax in the days of Constantine the Great (306–337), under whom the reaction set in, determined the downfall of the dramatic art. It was not absolutely extinguished even by the irruptions of the northern barbarians; but a bitter adversary had by this time risen into power. The whole authority of the Christian Church had, without usually caring to distinguish between the nobler and the looser elements in the drama, involved all its manifestations in a consistent condemnation (as in Tertullian's De *spectaculis,* 200 c.), comprehended them all in an uncompromising anathema. When the faith of that Church was acknowledged as the religion of the Roman empire, the doom of the theatre was sealed. At Rome the last mention of *spectacula* as still in existence seems to date from the sway of the Ostrogoths, in the earlier half of the 6th century. In the capital and provinces of the Eastern empire the decline and fall of the stage cannot be similarly traced; but its end is authoritatively assigned to the period of Saracen invasions which began with the Omayyad dynasty in the 7th century. Gradually, however, as they lost all footing in the centres of civic life, the mimes and their fellows became a wandering fraternity, who doubtless appeared at festivals when their services were required, and vanished again into the depths of the obscurity which has ever covered the strollers' life. It was thus that these strange intermediaries of civilization carried down such traditions as survived of the acting drama of pagan antiquity into the succeeding ages.

MEDIAEVAL

In the midst of the condemnation with which the Christian Church visited the stage, we find such works as the Χριστὸς πάσχων (*Passion of* Christ), formerly attributed to St. Gregory Nazianzen, and the *Querolus,* long fathered upon Plautus himself, which were doubtless mostly written for educational purposes. The same was probably the design of the famous "comedies" of Hroswitha, the 10th century Benedictine nun of Gandersheim, in Eastphalian Saxony. While avowedly imitated in form from the comedies of Terence, these religious exercises derive their themes—martyrdoms (*Gallicanus,* part ii.; *Sapientia*), and miraculous or otherwise startling conversions (*Gallicanus,* part i.; *Callimachus;* Abraham; *Paphnutius*)—from the legends of Christian saints. Thus, from perhaps the 9th to the 12th centuries, Germany and France, and through the latter, England, became acquainted with the literary monastic drama. Thus the *Play of St. Katharine* was acted at Dunstable about the year 1110 in 'copes" by the scholars of Geoffrey, the Norman, afterwards abbot of St. Albans, and was certainly not regarded as a novelty.

From about the 6th to the 11th century the Latin and the Teutonic elements of mediaeval "minstrelsy," more or less imperceptibly, coalesced. The traditions of the disestablished *mimus* combined with the "occupation" of the Teutonic *scôp,* who is found under this name or that of the "gleeman," in Anglo-Saxon literature, before it fell under the control of the Christian Church. How far these *joculatores* kept alive the usage of entertainments more essentially dramatic than the minor varieties of their performances, we cannot say. In different countries these entertainers suited themselves to different tastes, and to different literary tendencies The literature of the *troubadours* or Prov-

ence, which communicated itself to Spain and Italy, came only into isolated contact with the beginnings of the religious drama; in northern France the *jongleurs*, as the *joculatores* were now called, were confounded with the *trouvères* (*q.v.*). As appointed servants of particular households they were here, and afterwards in England, called nzenestrels (from *ministeriales*) or minstrels. In England such accomplished minstrels enjoyed the favour of the Norman, Angevin and Plantagenet kings. But here, as elsewhere, the humbler members of the craft spent their lives in strolling from castle to convent, from village-green to city-street, exhibiting their skill as dancers, tumblers, jugglers proper, and as masquers and conductors of bears and other dumb contributors to popular wonder and merriment.

Pagan Elements. — From the days of Gregory the Great, the Western Church tolerated and even attracted to her own festivals popular customs, which were in truth relics of heathen ritual. Such were the Mithraic feast of Dec. 25, or the egg of Eostre-tide, and a multitude of Celtic or Teutonic agricultural ceremonies of a semi-dramatic nature — such as processions of beasts or men in beast-masks, dressing trees with flowers, and the like, but above all ceremonial dances, often in disguise. The sword-dance, recorded by Tacitus, of which an important feature was the symbolic threat of death to a victim, endured (though it is rarely mentioned) till the later middle ages, by which time it had attracted to itself a variety of additional features, and of characters familiar as pace-eggers, mummers, morris-dancers (probably of distinct origin). The dramatic "expulsion of death," or winter, by the destruction of a lay-figure — common through western Europe about the 8th century — seems connected with a more elaborate rite, in which a disguised performer (who perhaps originally represented summer) mas slain and afterwards revived (the *Pfingstl*, Jack in the Green, or Green Knight). This representation, after acquiring a comic complexion, was annexed by the character dancers, who about the 15th century took to adding still livelier incidents from songs treating of popular heroes, such as St. George and Robin Hood; which latter found a place in the festivities of May Day with their central figure, the May Queen. The feast of fools (or asses), which enjoyed the greatest popularity in France (though protests against it are on record from the 11th century till the 17th), was well known from London to Constantinople. It was probably derived from the ancient Kalend feasts. In the 16th century the feast of fools was combined with the elaborate festivities of the 12 Christmas-feast-days — the season when throughout the previous two centuries the "mummers" especially flourished, who in their disguising and "*viseres*" began as dancers gesticulating in dumb-show, but ultimately developed into actors proper.

Christian Elements. — Thus the literary and the professional element, as well as that of popular festive usages, had survived to swell the main stream of the early Christian drama, which had its direct source in the liturgy of the church itself. The service of the Mass contains in itself dramatic elements, and at a very early period — certainly already in the 5th century — it was usual on special occasions to illustrate the Gospel narrative by living pictures accompanied by songs. The insertion, before or after sung portions of the service, of tropes, originally one or more verses of texts, usually serving as introits and in connection with the gospel of the day, and recited by the two halves of the choir, led to dialogue chanting; and this was frequently accompanied by illustrative action, such as drawing down the veil from before the altar.

This practice of interpolations in the offices of the church, which is attested by texts from the 9th century onwards (the so-called "Winchester tropes" belong to the 10th and 11th), progressed till the *liturgical* mystery — the earliest form of the Christian drama — was gradually called into existence. As early as the 10th century on great ecclesiastical festivals the priests performed in the churches these offices (as they were called). The whole Easter story, from the burial to Emmaus, was thus presented, the Maries and the angel adding their lyrical *planctus;* while the surroundings of the Nativity — the Shepherds, the Innocents, etc. — were linked with the Shepherds of Epiphany by a recitation of "Prophets," including Virgil and the Sibyl. Before long, from the 11th century onwards, *mysteries*, as they were called, were produced in France on scriptural subjects such as the Wise and Foolish Virgins, Adam (mith the fall of Lucifer), Daniel, Lazarus, etc. These mysteries and miracles being as yet represented by the clergy only, the language in which they were usually written is Latin, the earliest example in the vernacular being the 11th century mystery of the Resurrection.

Mysteries, Miracles and Moralities. — The productions of the mediaeval religious drama, it is usual technically to divide into three classes. The *mysteries* proper deal with scriptural events only, and set forth, with the aid of the prophetic history of the Old Testament and the fulfilling events of the New, the central mystery of the Redemption of the world, as accomplished by the Nativity, the Passion and the Resurrection. But in fact these were not kept distinctly apart from the miracle-plays, or miracles, which are strictly speaking concerned mith the legends of the saints. Thirdly, the moralities, or nzoral-plays, teach and illuslrate the same truths allegorically, their characters being personified virtues or qualities.

As the plays grew more elaborate, and their spectators more numerous, they began to be represented outside as well as inside the churches, at first in the churchyards, and in the vulgar tongue. A Beverley Resurrection play (c. 1220) and some others are bilingual. Miracles were less dependent on this connection with the church services than mysteries proper; and lay associations, guilds in particular, soon began to act plays in honour of their patron saints in or near their own halls. Lastly, as some of these characters came to be depended on by the audiences for conventional extravagance or fun, every new Herod seeking to out-Herod his predecessor, and the devils asserting themselves as indispensable favourites, the comic element in the religious drama increased, and that drama itself grew more profane. The endeavour to sanctify the popular tastes to religious uses, which connects itself with the institution of the great festival of Corpus Christi (1264, confirmed 1311), when the symbol of the mystery of the Incarnation was borne in solemn procession, led to the closer union of the dramatic exhibitions (hence often called *processus*) with this and other religious feasts; but it neither limited their range nor controlled their development.

France. — In France, where dramatic performances had never fallen entirely into the hands of the clergy, the progress was speediest and most decided towards forms approaching those of the modern drama. The earliest play in the French tongue, however, the 12th-century Adam, supposed to have been written by a Norman in England (as is a fragmentary *Résurrection* of much the same date), still reveals its connection with the liturgical drama. Jean Bodel of Arras' niiracle-play of St. *Nicolas* (before 1205) is already the production of a secular author, and has some realistic features. On the other hand, the *Theophilus* of Rutebeuf (d. c. 1280) treats its Faust-like thenie in a rather lifeless form but in a highly religious spirit, and belongs to the cycle of niiracles of the Virgin, of which examples abound throughout this period. Easter or Passion plays were fully established in the towns of France by the end of the 14th century; and in 1402 the *Confrérie* de la Passion obtained a royal privilege for their performance. Of these series of religious plays perhaps the most notable (c. 1450) is that by Arnoul Greban, a canon of Le Mans. Its revision, by Jean Michel (first performed at Angers in 1486), was very popular. Still more elaborate is the Rouen Christmas mystery of 1474, and the celebrated *Mystère du* vieil testament, produced at Abbeville in 1458, and performed at Paris in 1500. Most of the Provençal Christmas and Passion plays date from the 14th century, as well as a miracle of St. Agnes. The miracles of saints were popular in all parts of France, and the diversity of local colouring contributed materially to the growth of the early French drama.

The earliest known secular plays presented by university students in France were moralities, performed in 1426 and 1431. These plays, depicting the struggle between good and evil in the human soul, become more frequent from about this time. Now it is (at Rennes in 1439) the contention between *Bien-avisé* and

Mal-avisé; now, one between *l'homme juste* and *l'homme mondain.* Political and social problems are likewise similarly treated; the *Mystère du Concile* de Rile—an historical morality—dates back to 1432, and in 1507 we even meet with a hygienic or abstinence morality (by N. de la Chesnaye) in which "Banquet" enters into a conspiracy with "Apoplexy," "Epilepsy" and the whole regiment of diseases.

From the beginning of the 14th century onwards the famous fraternity of the Basoche (clerks of the Parlement and the Châtelet) had been entrusted with the conduct of popular festivals at Paris, and had performed plays. But after the *Confrérie* de la Passion had monopolized the religious drama, the basochiens confined themselves to moralities and farces, in which political satire found a place. A third association, the *Enfants* sans *souci,* had, apparently also early in the 15th century, acquired celebrity by their performances of short comic plays called soties, not very distinct from the farces of the Basoche. Other confraternities and associations readily took a leaf out of the book of these devil-may-care good-fellows, and interwove their religious and moral plays with comic scenes and characters from actual life, thus unconsciously preparing the transition to the regular drama.

The earliest known example of a serious secular play written in the French tongue is the Estoire de Griseldis (1393), which is largely indebted to Petrarch. The *Mystère du siège d'Orléans,* on the other hand, written about half a century later, in the epic tediousness of its manner comes near to a chronicle history, and interests us chiefly as the earliest of many efforts to bring Joan of Arc on the stage. Jacques Milet's celebrated mystery of the *Destruction* de Troye la grant (1452) seems to have been addressed to readers and not to hearers only. The beginnings of the French regular comic drama are more difficult to ascertain. But there is ample evidence that the most famous of all mediaeval farces, the immortal *Maistre* Pierre *Pathelin* (otherwise *L'Avocat Pathelin*), was written before 1470 and acted by the *basochiens;* and we may conclude that this delightful story of the biter bit and the profession outwitted typifies a multitude of similar comic episodes of real life, dramatized for the delectation of clerks, lawyers and students, and of all lovers of laughter.

Other Countries.—In the neighbouring Netherlands many Easter and Christmas mysteries are noted from the middle of the 15th century, and with them the celebrated series of the Seven Joys of Mary. To about the same date belongs the small group of abele *spelen* (as who should say plays easily managed), chiefly on chivalrous themes. The moralities were specially cultivated during this century by the *Rederijkers* (rhetoricians)—civic associations which cultivated learned poetry and took an active share in the festivals that formed one of the most characteristic features of the life of the Low Countries. Among these moralities was that of Elckerlijk (printed 1495) which is regarded as the original of the finest of English moralities, *Everyman.*

In Italy traces of the liturgical drama are few, and confined to the north-east. The collective mystery, so common in other Western countries, is represented by a single example only—a *Passione* di *Gesù* Cristo, performed at Revello in Saluzzo in the 15th century; though there are some traces of other cyclic dramas of the kind. The Italian religious plays, called figure when on Old, vangeli when on New, Testament subjects, differ from those of northern Europe chiefly by the less degree of coarseness in their comic characters, and seem largely to have developed from the processional element in the festivals of the church. Besides such processions as that of the Three Kings at Epiphany in Milan, there were the penitential processions and songs (laude), which at Assisi, Perugia and elsewhere already contained a dramatic element; and at Siena, Florence and other centres these again developed into the so-called (*sacre*) *rappresentazioni.* Such a piece was the *San Giovanni* e *San* Paolo (1489), by Lorenzo the Magnificent; another was the *Santa* Teodora, by Luigi Pulci (d. c. 1484); San *Giovanni Gualberto* (of Florence) treats the religious experience of a latter-day saint; Rosana e Ulimento is a love-story with a Christian moral. Passion plays were performed at Rome in the Coliseum by the *Compagnia* del *Gonfalone;* but there is no evidence on this head before the end of the 15th century. In general, the spectacular magnificence of Italian theatrical displays accorded with the growing pomp of the processions both ecclesiastical and lay—called *trionfi* already in the days of Dante; while the religious drama gradually acquired an artificial character and elaboration of form assimilating it to the classical attempts, to be noted below, which gave rise to the regular Italian drama.

Remnants of the ancient popular drama survived in the improvised farces performed at the courts, in the churches (farse *spirituali*), and among the people; the Roman carnival had preserved its wagon-plays, and various links remained to connect the modern comic drama of the Italians with the Atellanes and *mimes* of their ancestors. But the later comic developments will be noticed below.

In Spain hardly a monument of the mediaeval religious drama has been preserved. There is manuscript evidence of the 11th century attesting the early addition of dramatic elements to the Easter office; and a Spanish fragment of the Three Kings Epiphany play, dating from the 12th century, is one of the very earliest examples of the mediaeval drama in the vernacular. But that religious plays were performed in Spain is clear from the permission granted by Alphonso X. of Castile (d. 1284) to the clergy to represent them, while prohibiting juegos de escarnio (mocking plays). The earliest Spanish plays which we possess belong to the end of the 15th or beginning of the 16th century, and already show humanistic influence. In 1472 the couplets of Mingo *Revulgo* (*i.e.,* Domingo Vulgus, the common people), and about the same time another dialogue by the same author, offer examples of a sort resembling the Italian *contrasti* (see below).

The German religious plays in the vernacular, the earliest of which date from the 14th and 15th centuries and were produced at Trier, Wolfenbuttel. Innsbruck, Vienna, Berlin, etc., were of a simple kind; but in some of them, though they were written by clerks, there are traces of the minstrels' hands. The play of *The Wise and* the Foolish Virgins, in a Thuringian ms. thought to be as early as 1328, a piece of remarkable dignity, was evidently based on a Latin play. In the same century miracle-plays began to be performed, in honour of St. Catherine, St. Dorothea and other saints. The Corpus Christi plays, or *Frohnleichnamsspiele,* are notable, since that of Innsbruck (1391) is probably the earliest extant example of its class. The number of non-scriptural religious plays in Germany was much smaller than that in France; but the theme of the last judgment was common in Germany in the later middle ages. Of this theme Antichrist may be regarded as an episode, though in 1469 an Antichrist appears to have occupied at Frankfort four days in its performance. The earlier (12th century) Antichrist is unique of its kind; this political protest breathes the Ghibelline spirit of the reign (Frederick Barbarossa's) in which it was composed. While the Shrove-Tuesday plays (*Fastnachtsspiele*) of the professional strollers (jahrende Leute) reproduced the practical fun of common life, they occasionally, as in the Liibeck *Fastnachtsspiel* of the Five Virtues, contained an element of the morality, but the main productivity of the writers of moralities and cognate productions falls into the periods of Renaissance and Reformation; and the religious drama proper survived far beyond either in Catholic Germany, and, in fact, was not suppressed in Bavaria and Tirol till the end of the 18th century.

The performance of miracle-plays is traceable in Sweden in the late 14th century; and the Germans who immigrated into the Carpathian lands, and into Galicia in particular, in the later middle ages, brought with them their religious plays. This fact is the more striking, as, though Czech Easter plays were performed about the end of the 14th century, we hear of none among the Magyars, or among their neighbours of the Eastern empire.

Religious Drama in England.—Coming now to the English religious drama, we find that from its extant literature a fair general idea may be derived of the character of these mediaeval productions. The nziracle-plays, miracles or plays (these being the terms used in England) of which we hear in London in the 12th century were probably written in Latin and acted by

ecclesiastics; but in the following century mention is made—in the way of prohibition—of plays acted by professional players. In England as elsewhere, the clergy either sought to control the religious plays, which were occasionally acted in churches even after the Reformation, or else reprobated them, with or without qualifications. In Cornwall miracles in the native Cymric dialect were performed at an early date in extensive amphitheatres constructed for the purpose—one of which, at St. Just near Penzance, has been restored; but those which have been preserved are apparently copies of English or French originals.

The flourishing period of English miracle-plays begins with the practice of their performance by trading-companies in the towns. Of this practice Chester is said to have set the example (1268–76), which was followed by many other towns. These towns with their neighbourhoods include, starting from East Anglia, where the religious drama was particularly at home, Wymondham, Norwich, Sleaford, Lincoln, Leeds, Wakefield, Beverley, York, Newcastle-on-Tyne, with a deviation across the border to Edinburgh and Aberdeen. In the north-west they are found at Kendal, Lancaster, Preston, Chester; whence they may be supposed to have migrated to Dublin. In the west they are noticeable at Shrewsbury, Worcester and Tewkesbury; in the Midlands at Coventry and Leicester; in the east at Cambridge and Bassingbourne, Heybridge and Manningtree; to which places have to be added Reading, Winchester, Canterbury and London, in which last the performers were the parish-clerks. Four collections, in addition to some single examples of such plays, have come down to us: the *York* plays, the so-called *Towneley* plays, which were probably acted at the fairs of Widkirk, near Wakefield, and those bearing the names of *Chester* and of *Coventry*. Their dates are more or less uncertain; that of the *York* seems to be earlier than that of the *Towneley*, which were probably put together about the middle of the 14th century; the *Chester* may be ascribed to the 14th or early 15th; the body of the *Coventry* to the 15th or 16th. Many of the individual plays in these collections were doubtless founded on French originals; others are taken direct from Scripture, from the apocryphal gospels, or from the legends of the saints. Their characteristic feature is the combination of a whole series of plays into one *collective* whole, exhibiting the entire course of Bible history from the creation to the day of judgment. The oldest of the series—the *York* plays—exhibits a fairly close parallel to the scheme of the *Cursor mundi* (*q.v.*). Among the isolated plays may be mentioned *The Harrowing of Hell* and several belonging to a series known as the *Digby Mysteries*, including *Parfre's Candlemas Day* (the massacre of the Innocents), and the miracle of *Mary Magdalene*. Of the so-called "Paternoster" and "Creed" plays (which exhibit the miraculous powers of portions of the church service) no example remains, though of some we have an account; the Croxton *Play of the Sacrament*, the late 15th century ms. of which is preserved at Dublin, exhibits the triumph of the holy wafer over wicked Jewish wiles.

Each play was performed by the representatives of a particular trade or company, after whom it was called the fishers', glovers', etc., *pageant;* while a general prologue was spoken by a herald. As a rule the movable stage sufficed for the action. though we find horsemen riding up to the scaffold, and Herod instructed to "rage in the pagond and in the strete also." There is no evidence that the stage was, as in France, divided into three platforms with a dark cavern at the side of the lowest, appropriated respectively to the Heavenly Father and his angels, to saints, to mere men, and to souls in hell. But hell was frequently displayed in the English miracles, with or without fire in its mouth. The costumes were in part conventional—divine and saintly personages being distinguished by gilt hair and beards, Herod being clad as a Saracen, the demons wearing hideous heads, the souls black and white coats according to their kind, and the angels gold skins and wings. The plays contained an element of humour, often broadly farcical; but much that seems ludicrous or coarse to modern standards of taste would not have so struck contemporaries. The *York* Corpus Christi plays (48) are comparatively free from the tendency to jocularity and vulgarity observable in the *Towneley;* several of the plays concerned with the New Testament and early Christian story are, however, in substance common to both series. The *Towneley Plays* or *Wakefield Mysteries* (32), composed by the friars of Widkirk or Nostel, are of a popular character; and are superior in vivacity and humour to both the later collections. The *Chester Plays* (25) were indebted to the *Mystère du vieil testament* and to earlier French mysteries; they are less popular in character than the two earlier cycles, and on the whole undistinguished by pathos or humour. While these plays were performed at Whitsuntide, the *Coventry Plays* (42) were Corpus Christi performances. They are far more effectively written than the *Chester Plays*, and occasionally rise to real dramatic force. In the *Coventry* series there is already to be observed an element of abstract figures, which connects them with the moralities.

English Moralities.—The *moralities* corresponded to the love for allegory which, while dominating the whole field of mediaeval literature, was nowhere more evident than in England. Moreover, a specially popular element was supplied to these plays in a character borrowed from the miracles and usually provided with a companion whose task it was to lighten the weight of such abstractions as Sapience and Justice. These were the *Devil* and his attendant, the *Vice;* of whom the latter seems to have been of native origin, and, as he was usually dressed in a fool's habit, was probably suggested by the custom of keeping an attendant fool at court or in great houses. The Vice had many *aliases (Shift, Ambidexter, Sin, Fraud, Iniquity*, etc.), but his usual duty is to tease the Devil his master for the edification and diversion of the audience. He was gradually blended with the domestic fool, who survived in the regular drama.

The earlier English moralities—from the reign of Henry VI. to that of Henry VII.—usually allegorize the conflict between good and evil in the mind and life of man, without any side-intention of theological controversy. Such also is still essentially the purpose of the extant morality, *Maguyfycence*, by Henry VIII.'s poet, the witty Skelton. *Everyman* (pr. *c.* 1529), perhaps the most perfect example of its class, contains passages certainly designed to enforce the specific teaching of Rome. But its Dutch original was written at least a generation earlier, and could have no controversial intention. On the other hand, R. Wever's *Lusty Juventus* breathes the spirit of the dogmatic reformation of the reign of Edward VI. Theological controversy largely occupies the moralities of the earlier part of Elizabeth's reign, and connects itself with political feeling in Sir David Lyndsay's *Satire of the Three Estaitis*, written and acted (at Cupar, in 1539) on the other side of the border, where the religious drama proper had been extinguished by the Reformation. Only a single English political morality proper remains to us, which belongs to the beginning of the reign of Elizabeth (*Albyon Knight*). Another series connects itself with the ideas of the Renaissance rather than the Reformation, treating of intellectual progress rather than of moral conduct; this extends from the reign of Henry VIII. to that of Elizabeth. Besides these, there remain some Elizabethan moralities which have no special theological or scientific purpose, and are none the less lively in consequence.

The transition from the morality to the regular drama in England was effected, on the one hand, by the intermixture of historical personages with abstractions—as in Bishop Bale's *Kyng Johan* (c. 1548)—which easily led over to the *chronicle history;* on the other, by the introduction of types of real life by the side of abstract figures. This latter tendency is observable in several of the 16th-century moralities; but before most of these were written, a further step had been taken by a man of genius, John Heywood (b. *c.* 1500, d. between 1577 and 1587), whose "interludes" were short farces in the French manner. Heywood's interludes dealt entirely with real—very real—men and women. Other writers, such as T. Ingeland, took the same direction; and the allegory of abstractions was thus undermined on the stage. Thus the interludes facilitated the advent of comedy, without having superseded the earlier form. Both moralities and miracle-plays survived into the Elizabethan age after the regular drama had already begun its course.

BIBLIOGRAPHY.—The following works treat of the mediaeval drama, religious or secular. H. Anz, *Die lateinischen Magierspiele* (Leipzig, 1905); E. K. Chambers, *The Medieval Stage* (2 vols., 1903, bibl.); E. de Coussemaker, *Drames liturgiques du moyen Bge* (1861); du Méril, *Theatri liturgici quae Latina supersunt monumenta* (Caen and Paris, 1849); W. For mediaeval English in particular:—Ahn, *English Mysteries and Miracle Plays* (Trèves, 1867); S. W. Clarke, *Tlze Miracle Play in England* (1897); F. W. Fairholt, *Lord Mayor's Pageants,* 2 vols. (Percy Soc., 1843–44); A. W. Pollard, *English Miracle Plays, Moralities and Interludes* (8th ed., 1927); *Clzester Plays* ed. T. Wright, 2 vols. (Shakespeare Soc., 1843), re-ed. by H. Deimling (part only) (E.E.T.S., 1893); *Ludus Coventriae;* ed. K. S. Block (E.E.T.S., 1922); T. Sharp, *Coventry Plays; Dissertation on the pageants or mysteries at Coventry* (Coventry, 1825); *Digby Plays,* ed. F. J. Furnivall (E.E.T.S., 1896); *Towneley Mysteries,* ed. G. England and A. W. Pollard (E.E.T.S., 1897); *York Plays,* ed. L. T. Smith (1885); *The New-Cycle Mystery Plays,* ed. O. Watcrhouse (E.E.T.S., 1909); W. W. Greg, *Bibliographical and Textual Problems of the English Miracle Cycles* (1914); S. B. Hemingway, *English Nativity Plays* (1909).

For mediaeval German in particular:—F. J. Mone, *Altteutsche Schauspiele* (Quedlinburg, 1841); H. Reidt, *Das geistliche Schauspiel des Mittelalters in Deutschland* (Frankfort, 1868); E. Wilken, *Gesch. der geistlichen Spicle in Deutschland* (Göttingen, 1872).

The revival of the classical drama in the Renaissance age is treated in P. Bahlmann, *Die Erneuerer des antiken Dramas und ihre ersten dramatischen Versuche, 1314–1478* (Münster, 1896); A. Chassang, *Des essais dramatiques imités de Pantiquite' au XIVe et XVe siècle* (1852); and in V. de Amitis, *L'Imitazione latina nella commedia del XVI. secolo* (Pisa, 1871).

Both the mediaeval and portions of the later drama are treated in W. Cloetta, *Beiträge zur Litteraturgeschichte des Mittelalters und der Renaissance* (2 vols.. Halle, 1890–92); W. Creizenach, *Geschichte des neueren Dramas,* vols. i.–iii (Halle, 1893–1903); R. Prölss, *Geschichte des neueren Dramas* (3 vols., Leipzig, 1881–83). *See* also L.-V. Gofflot, *Le Théâtre au collège, du moyen Bge à nos jours,* Préface par Jules Claretie (1907). (X.)

THE MODERN NATIONAL DRAMA

The literary influence, which finally transformed the growths noticed above into the national dramas of Europe, was that of the Renaissance. Among the remains of classical antiquity which were studied, translated and imitated, those of the drama necessarily held a prominent place. They now became subjects of devoted research and models for more or less exact imitation, first in Greek or Latin, then in modern tongues. This process it will be most convenient to pursue *seriatim,* in connection with the rise and progress of the several dramatic literatures of the West. For no sooner had the stream of the modern drama, whose source and contributories have been described, been brought back into the ancient bed, than its flow diverged into a number of national currents.

ITALY

The priority in this as in most of the other aspects of the Renaissance belongs to Italy. In ultimate achievement the Italian drama fell short of the fulness of the results obtained elsewhere. The cause is doubtless to be sought in the social and political conditions of the period. Literature and the arts were by many considered a refuge from the harassing necessities of daily life, not an incentive to virtue and virtuous action. Violent strife between neighbouring States was followed by a brief period of peace (after 1452) and then by foreign domination. Disgust was as deep as despair. Classical imitation was no help to original creation and to the representations of a society that had no real connection with the society of Rome, and the realistic Italian genius seemed averse to the idealism of tragic characterization.

It is, of course, necessary to take Latin models into account in dealing with the Italian literature of the middle ages and the Renaissance; but learned imitations need not be overrated or mistaken as the only source of the Italian drama. No less than in other countries the religious ritual, particularly of the Holy Week, gave rise, locally to dramatic representations performed inside and outside the churches, and on these liturgical plays, which were originally in Latin, depended the earliest mystery plays in the vernacular. They are sometimes difficult to distinguish from the dramatic dialogues which sprang out of religious song in the vernacular *(laudi)* in the 13th and 14th centuries. The 14th century mystery plays of Cividale, Florence and Rome are traces of such early and rudimentary dramatic shows, and it is interesting to note that they made their appearance independently in different parts of the country. Favourable conditions for the development of a national drama were, however, lacking. On the one hand the establishment of tyrannies in the place of feudal States and free cities, on the other the intentional imitation of the classics hindered spontaneous development and overshadowed such timid attempts as had been made. Intellectual life became centred in the courts, and courtiers and princes were fond of gorgeous shows and rare spectacles. There are records of complex allegorical shows during the 15th century which mere partly based on the forms of the mystery plays. The daring innovation of the 17-year-old Politian who composed a pastoral mystery play on a mythological instead of a Christian subject *(Orfeo,* 1471) should be connected with these allegorical shows. In the *Orfeo,* no less than in the allegorical shows, a considerable part is made over to musical interludes, thus pointing the way to the later transformation of pastoral drama into the modern opera. At the same time the refined and not a little sophisticated audiences at the courts showed some interest at first in the production of Latin plays of Terence and Plautus, in translations, mostly bad and verbose, of the same plays, and later in imitations. The revival of learning had before then stimulated university students and learned scholars to write, and occasionally to perform, shapeless plays in which the technique of the classical comedy and of mystery plays was combined. Petrarch is said to have written a comedy *(Philologia),* Leonardo Bruni wrote the *Poliscena,* Piccolomini the *Chrisis* before he became Pope Pius II; and many others could be cited, but none that achieved real success and was capable of influencing later works; and all were comedies. Tragedy had been in Italy a purely literary exercise from the beginning.

To the later middle ages classical tragedy meant Seneca and the first mediaeval follower of Seneca, Albertino Mussato (1261–1330), may in a sense be called the father of modern dramatic literature. Born at Padua, to which city all his services were given, he in 1315 brought out his *Ecerinis,* a Latin tragedy very near to the confines of epic poetry, intended to warn the Paduans against the designs of Cangrande della Scala. Other tragedies of much the same type followed during the ensuing century; such as L. da Fabiano's *De casu Caesenae* (1377) a sort of chronicle history in Latin prose on Cardinal Albornoz' capture of Caesena. Of G. Manzini della Motta's Latin tragedy on the fall of Antonio della Scala only a chorus remains. He died after 1389. Later plays in Latin of the historic type are the extant Laudivio de' Nobili's *De captivitate Ducis Jacobi* (the *condottiere* Jacopo Piccinino, d. 1464); C. Verardi's *Historia Baetica* (1492), and the same author's *Ferdinandus* (of Aragon) *Servatus.* Purely classical themes were treated in the *Achilleis* of A de' Loschi of Vicenza (d. 1441), in the sketchy *Progne* of the Venetian Gregorio Coraro (c. 1430), and in later Latin productions.

This dramatic revival was confined to the learned class, and it hindered rather than helped the spontaneous growth of Italian drama from mystery plays.

Italian Tragedy. — Early in the 16th century, tragedy began to be written in the native tongue; but it retained from the first, and never wholly lost, the impress of its origin. The chorus, stationary on the stage as in old Roman tragedy, was not reduced to a merely occasional appearance between the acts till the beginning of the 17th century, or ousted altogether from the tragic drama till the earlier half of the 18th. The honour of having been the earliest tragedy in Italian belongs to A. da Pistoia's Pamfila (1499); Carretto's Sofonisba followed in 1502 and M Guazzo's *Discordia d'amore* (c. 1540). But the play usually associated with the beginning of Italian tragedy was another Sofonisba, acted before Leo X. in 1515, and written in blank hendecasyllables instead of the ottava and *terza rima* of the earlier tragedians (retaining, however, the lyric measures of the chorus), by G. G. Trissino. Other tragedies of the former half of the 16th century, largely inspired by Trissino's example, were the Rosmunda and the *Oreste* of Rucellai, a nephew of Lorenzo the Magnificent (1j16); Martelli's *Tullia;* A. de' Pazzi's Dido (1524); Alamanni's *Antigone* (1531); the *Canace* of Sperone Speroni, closely based on Speroni's interpretation of Aristotle's Poetics; Orazia, the earliest dramatic treatment of this famous subject by the notorious Aretino (1549); and the nine tragedies of G. B. Giraldi (Cinthio) of Ferrara, among which *L'Orbecche* (1541) is accounted the best and bloodiest. In the latter half of the 16th century may be mentioned the *Didone* and the *Marianna* of L. Dolce, the translator of Euripides and Seneca (1565); A. Leonico's *Il* Soldato (1550); the *Adriana* (acted before 1561 or 1586) of L. Groto, which treats the story of Romeo and Juliet; Tasso's *Torrismondo* (1587); the *Tancredi* of Asinari (1588); and the *Merope* of Torelli (1593), the last to employ the stationary chorus (*coro* fisso) on the Italian stage.

It was realized at the end of the 16th century that Italian tragedians could claim no outstanding success, and this feeling, becoming ever stronger during the following century, was partly responsible for an activity as feverish as it was unsuccessful. Lacking genius and inspiration, tragedians tried to win fame by technical innovations and changes in the subject matter. Next to tragedies composed in the strictest adherence to classical models, there were plays of romantic adventure and love. Besides ancient subjects religious subjects were favoured, particularly by the Jesuits, among whom Ferrante Pallavicino and Scammacca may be mentioned; also historical subjects were treated, if with little respect for historical truth, and with them could be classed many tragedies dealing with contemporary events. The scene was seldom placed in Italy; it was mostly in Asia as being conveniently remote and unknown, occasionally it was in Spain and in England (*e.g.,* Graziani's *Cromuele,* Savaro's Anna Bolena, Maria *Stuarda*). In romantic and sacred tragedies the influence of the Spanish drama is clearly traceable, but in the course of time French influence triumphed. As if all hopes of an Italian masterpiece were abandoned, at the end of the 17th century only poor imitations and bad translations of French neo-classical plays were produced.

At the beginning of the 18th century a strong reaction set in against such an influence; it took the form of searching criticism and advocated a return to the spirit of the classics combined with a more liberal interpretation of classical rules. Before long the marquis S. Maffei with his *Merope* (first printed in 1713) achieved one of the most brilliant successes recorded in the history of dramatic literature. This play, which is devoid of any love-story, long continued to be considered the masterpiece of Italian tragedy. A. Conti (1677–1749) comes next to Maffei in importance; he much admired the French and was familiar with the Shakespearian drama. Among the lesser tragedians P. J. Martelli (1665–1727), V. Gravina (1664–1718) and V. Bettinelli (1718–1808) may be mentioned. The influence of Voltaire had now come to predominate over the Italian drama; and, in accordance with the spirit of the times, greater freedom prevailed in the choice of tragic themes. Thus the greatest of Italian tragic poets, Count V. Alfieri (1749–1803), found his path prepared for him. Alfieri, an adventurous and romantic man, accepted the most rigid interpretation of the "rules" as expounded by Voltaire, but he aimed at freeing the Italian drama from French influence, at creating a rugged style suited to the expression of patriotic sentiments, and above all at inspiring love of freedom and hatred of political tyranny. Despite formal defects he certainly achieved his end, for his influence was lasting on modern Italian literature in general and particularly strong on Foscolo and Carducci. Among his numerous plays (21), *Merope* and *Saul,* and perhaps Mirra, are accounted his masterpieces.

The political colouring given by Alfieri to Italian tragedy reappears in the plays of U. Foscolo and A. Manzoni, both of whom are under the influence of the romantic school of modern literature; and to these names must be added those of S. Pellico and G. B. Niccolini (1785–1861), Paolo Giacometti (b. 1816) and others, whose dramas treat largely national themes familiar to all students of modern history and literature.

Italian Comedy. — In comedy, the efforts of the scholars of the Italian Renaissance for a time went side by side with the progress of the popular entertainments noticed above. The farsa was still under mediaeval influences, and in this popular form Alione of Asti and P. A. Caracciolo of Naples (soon after 1500) were specially productive. Such diversions became popular and were at first performed by guildsmen (such as the Rozzi of Siena) who soon were succeeded by professional actors; the improvised comedy (*commedia* a soggetto) required special histrionic gifts and training, and was thence called the cornmedia dell' arte. Its scenes, still unwritten except in skeleton (scenario), were connected together by the ligatures or links (*lazzi*) of the arlecclzino. Parallel to this growth was that of the masked comedy, the action of which was chiefly carried on by certain typical figures in masks, speaking in local dialects. Its earliest exponents were A. Beolco of Padua (1502–42), who called himself Ruzzante (joker), and is memorable under that name as the first actor-playwright and A. Calmo (1510–TI), the inventor of the mask of Pantalone.

Meanwhile, the Latin imitations of ancient comedies early led to the production of Italian translations, several of which were performed at Ferrara in the last quarter of the 15th century, whence they spread to Milan, Pavia and other towns of the north. Contemporaneously, imitations of Latin comedy made their appearance. The earliest plays still gave a large part to the mythological and pastoral elements (*e.g.,* Boiardo's Timone and G. del Carretto's *Tempio d'Amore*), but soon a regular comedy was produced by P. F. Mantovano (*Formicone,* 1506) who was almost immediately followed by Ariosto (Cassaria, 1508). Ariosto mostly kept close to his Latin models. His plots are cleverly arranged, but he seldom shows real gifts of dramatic characterization and *vis comica;* among his six completed comedies the *Negromante* (1520) and the *Lena* (1528) are considered the best. Comedies on plots from the classics or the novelists were written by J. Nardi, B. Dovizi (Calandria, 1j13) and others. Machiavelli's *Mandragola* (1513) stands out as by far the best of all and gives a wonderful picture of the corruption of his day. While many discussed the nature of drama, it was P. Aretino who excelled as a playwright, two among his comedies (*Cortigiana,* 1525, and *Marescalco,* 1527) being good fun and true to life. Among the countless comedians of the age may be mentioned L. Alamanni (1495–1556), L. Groto (1541–85), Lorenzino de' Medici (1514–48), G. F. Grazzini, called I1 Lasca (1503–84), whose Strega and *Spiritata* were known in England and whose *Assiuolo* is rightly celebrated, the prolific G. B. della Porta (1535–1615), imitated by Tomkins and Ruggle, and finally G. Bruno, the philosopher, whose pessimistic views of life found a masterly expression in Candelaio (1582).

Pastoral Drama. — During the same century the "pastoral drama," a purely literary development of the bucolic idyll, flourished in Italy; its earliest example is Polilian's Orfeo (1472), which begins like an idyll and ends like a tragedy. N. da Correggio's (1450–1508) Ccfalo and others followed, before in 1554

A. Beccari produced his Arcadian pastoral drama *Il Sagrifizio,* in which the comic element predominates. But an epoch in the history of the species is marked by the Aminta of Tasso (1573); its charm lies not in the interest of its action, but in the passion and sweetness of its sentiment. This work was the model of many others, and the pastoral drama reached its height of popularity in the famous Pastor *fido* (written before 1590) of G. B. Guarini. The artificiality of the pastoral drama impressed itself in an intensified form upon the opera. The foremost Italian masters of the last-named species, so far as it can claim to be included in the poetic drama, were A. Zeno (1668–1750) and P. Metastasio (1698–1782), the master of melodious verse, who succeeded in writing librettos of so rare a literary merit as to call forth Voltaire's unstinted praise.

The comic dramatists of the 17th century are grouped as followers of the classical and of the romantic school, G. B. della Porta (q v.) and G. **A.** Cicognini being regarded as the leading representatives of the former. But neither of these largely intermixed groups of writers could prevail against the competition of the musical drama, of the popular farcical entertainments and of those introduced in imitation of Spanish examples. Italian comedy had fallen into decay, when its reform was undertaken by the wonderful theatrical genius of C. Goldoni. One of the most fertile and rapid of playwrights (of his 150 comedies 16 were written and acted in a single year), he at the same time pursued definite aims as a dramatist. Disgusted with the conventional buffoonery, and ashamed of the rampant immorality of the Italian comic stage. he drew his characters from real life and succeeded best when he employed the Venetian dialect instead of the literary language. Goldoni met with a severe critic and a temporarily successful rival in Count C. Gozzi (1722–1806), who sought to rescue the comic drama from its association with the actual life of the middle classes, and to infuse a new spirit into the figures of the old masked comedy by the invention of a new species which has found favour with recent writers.

Italian Drama of the 19th Century. — During the latter part of the 18th century French influence was strong in all departments of literature and acted as a dissolvent of traditional distinctions. There were tragedians who imitated Alfieri's models with considerable freedom, as Monti and Foscolo; comedians who kept more or less close to Goldoni; but lesser playwrights sought easier success by falling in with the predominant taste for sentimental and lachrymose drama. Romanticism was at the gates. Manzoni's *Carmagnola* (1820) and *Adelchi* (1822) were historical tragedies wholly free from the observance of the unities; they were praised by Goethe but met with scant success Pellico's tragedies lacked fire and characterization; G. B. Niccolini (1782–1861) attempted the classical as well as the romantic drama and owed his fame to the patriotic sentiments that his characters embodied (G. da Procida, 1830; Arnaldo da *Brescia,* 1843). Also P. Cossa at first imitated Alfieri, but he later won fame with historical tragedies (*Nerone,* 1870).

For a time comedians continued in Goldoni's tracks, as G. G. de' Rossi (1754–1827), G. Giraud (1776–1834) and A. Nota (1775–1847); later from France there was imported a new form of drama which partook of tragedy and comedy, and aimed at a realistic representation of life. In a land in which dialects were regularly spoken even by the educated classes. realism necessarily led to the purely dialectal drama such as Goldoni had long since written; thus P. Ferrari (1822–89) began by writing comedies in Modenese dialect, later he won success with historical comedies (Goldoni, *Parini*), and later still, prompted by the example of contemporary French writers. he brought social problems on to the stage (*Il duello*). With him contemporary drama may be said to begin. Stress was laid on social conditions and psychological problems by G. Verga (1840–1928), G. Giacosa (1847–1906), E. A. Butti (1865–1911) and with less force by G. Rovetta. The same subjects on a more realistically described background were treated in dialectal plays by the Venetian G. Gallina (1852–97), by Milanese, Piedmontese, Florentine, Neapolitan and Sicilian playwrights. During the last years of the 19th century the dialectal drama appeared to be losing ground, but it was later revived, particularly in some regions, as in Naples nherc it was helped by so gifted a writer as S. di Giacomo (1862–1934). The fortunes of dialectal drama depend as much on the actors as on playwrights, a circumstance of some relevance for Italian drama in general; at different periods during the 19th century great actors such as G. Modena. C. Rossi, T. Salvini, A. Ristori, E. Duse, E. Novelli and E. Zacconi exercised a notable influence on the taste of the public and of the playwrights themselves. Among dialectal actors E. Ferravilla, F. Benini, G. Grasso should be remernbered. D'Annunzio (1863–1938) tried without success to force the fashion of lyrical tragedy (*e.g., Città morta,* 1898, *Francesca* da *Rimini,* 1901) by sheer beauty of staging and literary skill; and he found followers in Butti (Castello del sogno, 1910), S. Benelli (Cena delle *beffe,* 1909), E. A. Morselli (*Orione,* 1910). Much interest was aroused by R. Bracco's plays, in which psychological problems are studied from an intellectual angle not unlike Ibsen's (*Piccola* fonte, 1905, Piccolo santo, 1912), and by the work of the prolific L. Pirandello (1867–1936) who succeeded by great technical skill in making his challenge to reality a source of interest to his audiences. This "cerebral" drama has had imitators in L. Chiarelli (La maschera e *il volto,* 1917), L. Antonelli, F. M. Martini and others.

GREECE

Dramas began to be composed from the beginning of the 19th century, but those early works were literary rather than dramatic, and their obvious imitation of the ancient tragedies makes them rather lifeless. The only tragic poet of this early period worthy of the name is **I.** Zamkelios. About the middle of the century there were signs of theatrical life in Athens. Alexandros Rhizos Rhankavēs cultivated all its branches, writing comedies and historical dramas not devoid of interest. But the best and only surviving work of the Othonian age is the Babylonia of Byzantios, a graceful representation of the dialects and customs of the different Greek provinces. The dramatic movement was somewhat systematized during the last decades of the 19th century; two species were specially cultivated — the metrical Byzantine drama (inspired by the German and French romanticists with mediaeval plots), and the comedy of manners. The leading representative of the former was Demetrios Bernardakes; of the latter, Demetrios Koromelâs. About the beginning of the 20th century there was a great movement, suggesting the "busy '90s" of the English theatre. Ring George founded the Royal (now National) theatre, and K. Chrestomanos the "New Stage"— both short-lived foundations, but nevertheless training-schools for actors and authors. During the 1st decade of the 20th century were played remarkable metrical works of Bernardakes, Kleon Rhangabês and I. Polemes, historical comedies describing the political history of 1830–80 (of which the best was the Occupation, *i.e.*, the Anglo-French occupation during the Crimean War, by Bokos), and many social comedies. This last class has alone survived World War I, its three chief representatives being Spyros Melâs, Gregorios Xenopoulos and Penteles Horn.

There are several good dramatists and many good actors; Greece possesses in Kotopoule and Kybele two great actresses. But the general belief is that the Greek theatre requires the foundation of a State playhouse or, at least, of one unconnected with the earning of profits.

SPAIN

Spain is the only country of modern Europe which shares with England the honour of having achieved, at a relatively early date, the creation of a genuinely national form of the regular drama. The tragi-comedy of *Calisto and Melibea* by *F.* de Rojas, which was completed (in 21 acts) by 1499, became famous under the name of *Celestina*. But the father of the Spanish drama was J. de la Enzina, whose *representaciones* under the name of "eclogues" were dramatic dialogues of a religious or pastoral character. His attempts were imitated by the Portuguese Gil Vicente. who wrote for the stage in the period 1502–36, and used both Spanish and his native tongue. A further impulse came, as was natural, from Spaniards, resident in Italy, and especially from B. de Torres Naharro, who in 1517 published, as the chief among the "firstlings of his genius" *(Propaladia)*, a series of eight *comedias*—*a* term generally applied in Spanish literature to any kind of drama. He claimed some knowledge of the theory of the ancient drama, divided his plays into *jornadas* (to correspond to acts), and opened them with an *introyto* (prologue). Bible plays continued to be acted in church and square, sometimes with elaborate stage scenery. Though the universities produced both translations from the classical drama and modern Latin plays, these exercised very little general effect; but in 1528 H. Perez de Oliva published *La Vengança de Agamenon*, a Spanish adaptation of the *Electra* of Sophocles. Juan Perez's (Petreius') posthumous Latin comedies were mainly versions of Ariosto.

Thus the foundation of the Spanish national theatre was reserved for a man of the people. Cervantes has vividly sketched the humble resources which were at the command of Lope de Rueda, a gold-beater of Seville, who with his friend the bookseller Timoneda, and two brother authors and actors in his strolling company, succeeded in bringing dramatic entertainments out of the churches and palaces into the public places of the towns, where they were produced on temporary scaffolds. The manager carried about his properties in a corn-sack; and the "comedies" were still only "dialogues, and a species of eclogue between two or three shepherds and a shepherdess," enlivened at times by intermezzos of favourite comic figures, such as the negress or the Biscayan. Rueda is now remembered for the lively brief scenes of his *pasos*.

Lope **de Vega.**—The Sevillian J. de la Cueva gave the Spanish drama an ampler and more national expression and thus paved the way for Lope de Vega, one of the most astonishing geniuses the world has known. His fertility, which was such that he wrote about 1,800 plays, besides 400 dramatic works classed as *autos sacramentales* and *entremeses*, and a vast series of other literary compositions, has indisputably prejudiced his reputation with those to whom he is but a name and a number. Yet as a dramatist Lope more fully exemplifies the capabilities of the Spanish theatre than any of his successors, though as a poet Calderon may deserve the palm. With all its inventiveness and vigour, the genius of Lope primarily set itself the task of pleasing his public, —the very spirit of whose inner as well as outer life is accordingly mirrored in his dramatic works.

The plays of Lope, and those of the national Spanish drama in general, are divided into classes which it is naturally not always easy, and which there is no reason to suppose him always to have intended, to keep distinct from one another. After composing, in his early youth, eclogues, pastoral plays, and allegorical moralities in the old style, he began his theatrical activity at Madrid about 1590, and the plays which he thenceforth produced have been distributed under the following heads. The *comedias*, all of which are in verse, include (1) the so-called c. *de capa y espada*—not comedies proper, but dramas in which the principal personages are taken from the class of society that wears cloak and sword. Gallantry is their main theme, an interesting and complicated, but well-constructed and perspicuous intrigue their chief feature; and this is usually accompanied by an underplot in which the *gracioso* (the comic servant domesticated in the Spanish drama by Lope) plays his part. Their titles are frequently taken from the old proverbs or proverbial phrases of the people, upon the theme suggested by which the plays often constitute a kind of gloss *(glosa)* in action. This is the favourite species of the national Spanish theatre; and to the plots of the plays belonging to it the drama of other nations owes a debt almost incalculable in extent. (2) The *c. heróicas* are distinguished by some of their personages being of royal or very high rank, and by their themes being often historical and largely (though not invariably) taken from the national annals, or founded on contemporary or recent events. Hence they exhibit a greater gravity of tone; but in other respects there is no difference between them and the cloak-and-sword comedies with which they share the element of comic underplots. Occasionally Lope condescended in the opposite direction, to (3) plays of which the scene is laid in common life, but for which no special name appears to have existed. After a few dramas on scriptural subjects he turned to the legends of the saints; and the *comedias de santos*, of which he wrote a great number, became an accepted later Spanish variety of the miracle-play. True, however, to the popular instincts of his genius, he threw himself with special zeal and success into the composition of another kind of religious plays—a development of the Corpus Christi pageants, in honour of which all the theatres had to close their doors for a month. These were the famous *autos sacramentales* (*i.e.*, solemn "acts" or proceedings in honour of the Sacrament), which were performed in the open air by actors who had filled the cars of the sacred procession. Of these Lope wrote about 400.

He wrote for a popular audience at Madrid, where the first permanent theatre, the Teatro de la Cruz, was established in 1579. In his *Arte Nuevo de hacer comedias* (1609) he showed that theoretically he favoured the unities but deliberately locked up these rules in obedience to popular demand. Against this overwhelming popularity the protests of Cervantes and L. L. de Argensola, who advocated a more serious, less fantastic drama, were unavailing.

The genius of Cervantes was not technically more dramatic than that of Argensola, although his *Numancia* still holds the reader by its vigorous national spirit, and his short *entremeses* display his wonderfully graphic delineation of types. The real rivals and peers of Lope were J. Ruiz de Alarcón and the Mercenarian friar Gabriel Tellez, who adopted the pseudonym Tirso de Molina. The latter, author of the famous *El Burlador de Sevilla y Convidndo de Piedra*, composed over 400 plays in 20 years; in terse versification, natural presentment of scenes and characters, comic force and in studies of women he can equal and excel Lope himself. The Mexican Ruiz de Alarcón disdained to woo the crowd; he wrote few but masterly plays, marked by careful finish and a serious moral purpose. By the side of these giants, other playwrights who would otherwise have taken first rank almost fade into insignificance. Lope's most devoted disciple, J. P. de Montalban died mad at the age of 36 in 1638, seven years after Guillén de Castro, whose *Las Mocedades del Cid* was the basis of Corneille's play. A. Mira de Amescua's plays were constantly laid under contribution by contemporary dramatists; and a greater playwright, F. de Rojas Zorrilla, was largely plundered by the French dramatists of the latter half of the century. His play *Del rey abajo ninguno* is as celebrated as the historical play *La Estrella de Sevilla*, which is now definitively known not to be by Lope and is tentatively ascribed to P. de Cardenas.

Calderon.—The glories of Spanish dramatic literature reached their height in P. Calderon de la Barca, though in the history of the Spanish theatre he holds only the second place. He elaborated some of the forms of the national drama, but brought about no changes of moment in any of them. Even the brilliancy of his style, glittering with a constant reproduction of the same family of tropes, and the variety of his melodious versification, are mere intensifications of the poetic qualities of Lope. In fertility Calderon was inferior to Lope (for he wrote not many more than 100 plays); but he surpasses the elder poet in richness of style, and more especially in fire of imagination. In his *autos* (of which he is said to have left not less than 73), Calderon probably attained to his most distinctive excellence; some of these appear to take a wide range of allegorical invention, while they uniformly possess great beauty of poetical detail. Other of his most famous or interesting pieces are *comedias de santos*. In his secular plays

he treats as wide a variety of subjects as Lope, but it is not a dissimilar variety; nor would it be easy to decide whether a poet so uniformly admirable within his limits has achieved greater success in romantic historical tragedy *(El Principe constante)*, in the comedy of amorous intrigue *(La Dama duende)*, or in a dramatic work combining fancy and artificiality in such a degree that it has been diversely described as a romantic caprice and as a philosophical poem *(La Vida es sueño)*.

The *autos* continued to flourish till in 1765 (shortly before the expulsion of the Jesuits from Spain) their public representation was prohibited by royal decree. In the world of fashion, the opera had reached Spain already during Calderon's lifetime, together with other French influences, and the great dramatist had himself written one or two of his plays for performance with music. But the regular national drama continued to command popular favour, and A. Moreto (1618–69), although imitative, achieved notable success with his *comedias de figurón* and with his masterpiece, *El desddn con el desdén*.

Later **Dramatists.**—After the end of the 17th century the Spanish drama suffered half a century of eclipse. The earliest Spanish comedy in the French form (a translation only, though written in the national metre) Luzán's *La Razón contra la moda* (1751), and the first original Spanish comedy on the same model, Nicolás Moratin's *Petimetra*, printed in 1726 with a critical dissertation, failed to effect any change in the popular theatre, which was raised from its deepest degradation by R. de la Cruz, a fertile author of light pieces of genuine humour, especially *sainetes*, depicting the manners of the middle and lower classes. The comedies of the younger Moratin, e.g., *El Si de las niñas* (in prose), raised him to the foremost position among the dramatists of his age.

In the hands of the Romantics the Spanish drama produced a series of brilliantly effective first nights rather than a permanent literature. The *Don Alvaro* (1835) of the duke of Rivas, the *El Trovador* (1836) of A. Garcia Gutierrez, the *Los Amantes de Teruel* (1837) of J. E. Hartzenbusch, can scarcely be said to have worn well, although they are still famous; but the *Don Juan Tenorio* (1844) by the later Romantic poet J. Zorrilla retains its popularity. The tradition of Moratin the younger was continued in the genuine comic vein and brilliant versification of M. Bretón de los Herreros and in the vigorous irony of Ventura de la Vega; while M. Tamayo y Baus lives chiefly in his remarkable *Un Drama Nuevo* (1867) in which Shakespeare is represented on the stage. He was the author of many other plays which held the stage until the advent in 1874 of J. Echegaray (1832–1916), mathematician, political economist and playwright, the powerful effects of whose *El Gran Galeoto* (1882) and *El Loco Dios* (1900) are now almost forgotten but who dominated the Spanish stage during the last quarter of the 19th century.

The vogue of the *gdnero chico* began at the Teatro del Recreo in 1868 and continued for 40 years, during which several thousands of these light, one-hour pieces, brief as the *entremés* or satirical *sainete*, were composed by scores of popular authors, including T. Luceño, R. de la Vega, J. de Burgos and C. Arniches. The best of them contained sharply etched popular types recalling those of R. de la Cruz. A revolution was effected by the introduction of the philosophical theatre of ideas by J. Benavente, whose first play was *El Nido Ajeno* (1894) and who, with the more lyrical G. Martinez Sierra, during the first quarter of the 20th century replaced the melodramatic art of Echegaray by a subtle "drama of double planes." They had a rival in the witty M. Linares Rivas, but both his society plays and other contemporary work, the poetical plays of E. Marquina, the political drama of Pérez Galdós, were eclipsed in popularity by the charming dramatic sketches, nearly 200 in number, of the brothers S. and J. Alvarez Quintero. A noticeable feature of all this 20th century dramatic work is that, despite the excellence of the actress Maria Guerrero (d. 1928), who rivalled the popularity of the great actor Maiquez of a century earlier, it loses comparatively little by being read instead of seen on the stage.

PORTUGAL

The Portuguese drama in its earlier phases, especially before the nation completely achieved its independence in the latter part of the 14th century, seems to have followed much the same course as the Spanish; and the religious drama in all its prevailing forms and direct outgrowths retained its popularity even by the side of the products of the Renaissance. In the later period of that movement translations of classical dramas into the vernacular were stimulated by the cosmopolitan example of George Buchanan, who for a time held a post in the University of Coimbra. The rather vague title of "the Plautus of Portugal" is accorded to an earlier comic writer, the celebrated Gil Vicente, who died about 1536, after producing 42 plays of great variety and charm. In order to counteract the popularity of Vicente's farces F. de Sáde Miranda wrote comedies on the classic model (*Os Estrangeiros, Os Vilhalpandos*) and a classical tragedy, *Cleopatra* (*c.* 1550) of which only a few lines survive. A few years later A. Ferreira produced the most celebrated tragedy in Portuguese literature, *Inés de Castro* (*c.* 1557). Among Vicente's most gifted successors are A. Ribeiro, called *Chiado*, who died in 1590; his brother Jeronymo, B. Dias, A. Prestes and J. Pinto. The dramatic efforts of the illustrious poet Luis de Camões (Comoens) are relatively of slight importance; they consist of one of the many modern versions of the *Amphitruo*, and of two other comedies, of which the earlier *(Filodemo)* was acted at Goa in 1553, the subjects having a romantic colour. The prose plays of Jorge Ferreira de Vasconcellos, which bear some resemblance to the Spanish *Celestina*, are valuable as pictures of contemporary manners in city and court.

In the 18th century Alcino Mycenio (1728–70), known as Domingos dos Reis Quita in everyday life, was remarkably successful with a series of plays, including an *Inés de Castro*, which in a subsequent adaptation by J. B. Gomes long held the national stage. Another dramatist, of both merit and higher aspirations, was Lycidas Cynthio *(alias* Manoel de Figueiredo, 1725–1801). But the romantic movement was very late in coming to Portugal. Its chief representative, the viscount da Almeida Garrett, after writing the plays *Merope* and *Catão* (1821) in his student days, turned to national themes in *Um Auto de Gil Vicente* (1835) and *O Alfageme de Santarem* (1842), and in 1844 produced a romantic tragedy of real power, *Frei Luiz de Sousa*. His plays are remarkable for the excellence of their prose. The best known of the dramatists of the latter half of the century were D. João da Camara, who wrote with insight and charm, M. Mesquita, and H. Lopes de Mendonça, who achieved success in both historical and contemporary themes. E. Biester and G. Lobato wrote sparkling comedies of contemporary manners, their successors in the 20th century being Augusto de Castro and E. Schwalbach. But the most prominent dramatist of the 20th century was J. Dantas, who excelled in literary charm, technical skill and variety of subject. Numerous younger dramatists cropped up, but despite these constant efforts Portuguese literature retained its essentially undramatic character.

FRANCE

France was the only country, besides Italy, in which classical tragedy was naturalized. In 1531 the Benedictine Barthélemy of Loches printed a *Christus Xylonicus;* and a very notable impulse was given both to the translation and to the imitation of ancient models by a series of efforts made in the University of Paris and other French places of learning. The most successful of these attempts was the *Johannes Baptistes* of George Buchanan, who taught in Paris for five years and at a rather later date resided at Bordeaux, where in 1540 he composed his celebrated tragedy (afterwards translated into four or five modern languages), in which it is now ascertained that he had in view the trial and condemnation of Sir Thomas More. He also wrote *Jephthah,* and

translated into Latin the Medea and *Alcestis* of Euripides. At a rather later date the great scholar M. A. Muret (Muretus) produced his *Julius* Caesar, a work perhaps superior in correctness to Buchanan's tragic masterpiece, but inferior to it in likeness to life. About the same time the enthusiasm of the Paris classicists showed itself in several translations of Sophoilean and Euripidean tragedies into French verse, and in 1540 Ronsard translated the *Plutus* of Aristophanes. Thus the beginnings of the regular drama in France came to connect themselves directly with the great literary movement of the Renaissance.

Jodelle.—Among the disciples who gathered round Ronsard, and with him formed the "Pleiad" of French literature, Etienne Jodelle, the reformer of the French theatre, soon held a distinguished place. The stage of this period left ample room for the enterprise of this youthful writer. The popularity of the old entertainments had reached its height when Louis XII., in his conflict with Pope Julius II., had not scrupled to call in the aid of Pierre Gringoire (Gringon), and when the *Mère* sotte had mockingly masqueraded in the petticoats of Holy Church. In the reign of Francis I. the Inquisition, and on occasion the king himself, had to some extent succeeded in repressing the audacity of the actors, whose follies were at the same time an utter abomination in the eyes of the Huguenots. For a time the very mysteries of the Brethren of the Passion had been prohibited; while the moralities and farces had sunk to an almost contemptible level. Isolated translations of Italian as well as classical dramas had in literature begun the movement which Jodelle now transferred to the stage itself. His tragedy *Cléopâtre* captive was produced on the same day as his comedy *L'Eugène,* in 1552, his *Didon se sacrifiant* following in 1558.

The history of French tragedy begins with *Cléopâtre* captive, in the representation of which the author, together with other members of the "Pleiad," took part. It is a tragedy in the manner of Seneca, devoid of action and provided with a ghost and a chorus. Though mainly written in the five-foot iambic couplet, it already contains passages in the Alexandrine metre, which soon afterwards J. de La Péruse by his *Médée* (pr. 1556) established in French tragedy, and which Jodelle employed in his *Didon.* Numerous tragedies followed in the same style by various authors, among whom Gabriel Bounyn produced the first French regular tragedy on a subject neither Greek nor Roman (La *Soltane,* 1561) and the brothers de la Taille, and J. Grévin, distinguished themselves by their style. Montchrétien exhibited unusual vigour of rhetoric and in R. Garnier French tragedy reached the greatest height in nobility and dignity of style, as well as in the exhibition of dramatic passion, to which it attained before Corneille. In his tragedies choruses are still interspersed among the long Alexandrine tirades of the dialogue.

Comedy Under Italian Influence.—During this period comedy had likewise been influenced by classical models; but the distance was less between the national farces and Terence, than between the mysteries and moralities and Seneca and the Greeks. *L'Eugène* differs little in style from the more elaborate of the old farces; and while it satirizes the foibles of the clergy without any appreciable abatement of the old licence, its theme is the favourite burden of the French comic theatre in all times—le *cocuage.* The foremost French comic poet of the century, P. de Larivey, likewise an Italian born (of the name of Pietro Giunto), openly professed to imitate the poets of his native country. His plays are more or less literal translations of L. Dolce, Secchi and other Italian dramatists; and this lively and witty author, to whom Molibre owes much, thus connects two of the most important and successful growths of the modern comic drama.

Much of the French drama of the next age is of the same kind as its romance-literature, like which it fell under the polite castigation of Boileau's satire. Heroic love (quite a technical passion), "fertile in tender sentiments," seized hold of the theatre as well as of the romances; and La Calprenbde, G. de Scudéry (*L'Amour tyrannique*) and his sister and others were equally fashionable in both species. J. Mairet was noted for superior vigour. P. Du Ryer's style is described as, while otherwise superior to that of his contemporaries, Italian in its defects. A mixture of the forms of classical comedy with elements of Spanish and of the Italian pastoral was attempted with great temporary success by A. Hardy, a playwright who thanked Heaven that he knew the precepts of his art while preferring to follow the demands of his trade. The mixture of styles begun by him was carried on by the marquis de Racan, J. de Rotrou and others; and among these comedies of intrigue in the Spanish manner the earlier efforts of Corneille hiniself are to be classed. Rotrou's noteworthier productions are later in date than the event which marks an epoch in the history of the French drama, the appearance of Corneille's Cid (1636).

Corneille.—P. Corneille is justly revered as the first, and in some respects the unequalled, great master of French tragedy. The attempts of his predecessors had been without life, because they lacked really tragic characters and the play of really tragic passions; while their style had been either pedantically imitative or a medley of plagiarisms. He conquered tragedy at once for the national literature by a few masterpieces, which may be held to be comprehended within the ten years 1636 to 1646; for in his many later tragedies he never again proved fully equal to himself. The French tragedy, of which the great age begins with the Cid, Horace, Cinna, Polyeucte and *Rodogune,* was not, whatever it professed to be, a copy of the classical tragedy of Greeks or Romans, or an imitation of the Italian imitations of these; nor, though in his later tragedies Corneille depended less and less upon characters and more and mare, after the fashion of the Spaniards, upon situations, and even more upon spectacles, were the forms of the Spanish drama able to assert their dominion over the French tragic stage. The mould of French tragedy was cast by Corneille; but the creative power of his genius was unable to fill it with more than a few examples. His range of passions and characters was limited; he preferred, he said, the reproach of having made his women too heroic to that of having made his men effeminate.

In comedy also Corneille begins the first great original epoch of French dramatic literature; but Le Menteur (the parent, with its sequel, of a numerous dramatic progeny) was itself derived from a Spanish original, which it did not (as was the case with the Cid) transform into something new. French tragi-comedy Corneille can hardly be said to have invented; and of the mongrel growths of sentimental comedy and of domestic drama or drame, he rather suggested than exemplified the conditions.

Racine.—The tragic art of Racine supplements rather than surpasses that of his older contemporary. His works reflect the serene and settled formality of the age. That Racine should permanently hold the position which belongs to him in French dramatic literature is due to the fact that to him it was given to present the forms approved by his age in what may reasonably be called perfection; and, from the point of view of workmanship, Sophocles could not have achieved more. T. Corneille, Campistron, Joseph Duché (1668–1704), Antoine de Lafosse (c. 1653–1708) and Quinault were mere followers of one or both of the great masters of tragedy, though the last-named achieved a reputation of his own in the bastard species of the opera.

The type of French tragedy thus established, like everything else which formed part of the "age of Louis XIV.," proclaimed itself as the definitively settled model of its kind, and was accepted as such by a submissive world. Proud of its self-imposed fetters, French tragedy dictatorially denied the liberty of which it had deprived itself to the art of which it claimed to furnish the highest examples. The unities of time and place, with the Greeks mere rules of convenience, French tragedy imposes upon itself as a permanent yoke. The Euripidean prologue is judiciously exchanged for the exposition of the first act, and the lyrical element essential to Creek tragedy is easily suppressed in its would-be copy; lyrical passages still occur in some of Corneille's early masterpieces, but the chorus is consistently banished, to reappear only in Racine's latest works as a scholastic experiment appropriate to a conventual atmosphere. Its uses for explanation and comment are served by the expedient, which in its turn becomes conventional, of the conversations with confidants and confidantes, which more than sufficiently supply the foil of general sentiments. The epical element is allowed full play in narrative passages, more especially in those

which relate parts of the catastrophe, and, while preserving the stage intact from realisms, suit themselves to the generally rhetorical character of this species of the tragic drama.

18th Century Tragedy.—The universal genius of Voltaire found it necessary to shine in ali branches of literature, and in tragedy to surpass predecessors whom his own authority declared to have surpassed the efiorts of the Attic muse. He succeeded in impressing the world with the belief that his innovations had imparted a fresh vitality to French tragedy; in truth, however, they represent no essential advance in art, but augmented the rhetorical tendency which paralysed true dramatic life. Such life as his plays possess lies in their political and social sentiments, their invective against tyranny, and their exposure of fanaticism. In other respects his versatility was barren of enduring results. Voltaire's would-be rival, the "terrible" Crébillon the elder, professed to vindicate to French tragedy, already mistress of the heavens through Corneille, and of the earth through Racine, Pluto's supplementary realm, but, though thus essaying to carry tragedy lower, failed to carry it farther. Shakespeare, as manipulated by Ducis—an author whose tastes were better than his times—failed to bring about a change. "It is a Moor, not a Frenchman, who has written this play," cried a spectator of Ducis' *Othello* (1791); but Talma's conviction was almost as strong as his capacity was great for convincing his public; and he certainly did much to prepare the influence which Shakespeare was gradually to assert over the French drama, and which was aided by translations, more especially that of Pierre Letourneur (1736–88), which had attracted the sympathy of Diderot and the execrations of the aged Voltaire. No great artist has ever more generously estimated the labours of a predecessor than Talma judged those of Le Kain; but it was Talma himself whose genius was pre-eminently fitted to reproduce the great figures of antiquity in the mimic world, which, like the world outside, both required and possessed its Caesar. He, like Rachel after him, reconciled French classical tragedy with nature; and it is upon the art of great original actors such as these that the theatrical success of this form of the drama in France depends.

Molière.—The rival influences, under which classical tragedy has after a long struggle virtually become a thing of the past in French literature, are also to be traced in the history of French comedy, which under the co-operation of other influences produced a wide variety of growths. The germs of most of these—though not of all—are to be found in the works of the most versatile, the most sure-footed, and, in some respects, the most consummate master of the comic drama whom the world has known—Molikre. What Molikre found in existence was a comedy of intrigue, derived from Spanish or Italian examples, and the elements of a comedy of character, in French and more especially in Italian farce and ballet-pantomime. Corneille's Menteur had pointed the way to a fuller combination of character with intrigue, and in this direction Molière's genius exercised the height of its creative powers. After beginning with farces, he produced in the earliest of his plays (from 1652), of which more than fragments remain, comedies of intrigue which are at the same time marvellously lively pictures of manners, and then proceeded, with the Ecole des *maris* (1661), to begin a long series of masterpieces of comedy of character. Yet even these, the chief of which are altogether unrivalled in dramatic literature, do not exhaust the variety of his productions.

Molière is both a satirist and a humorist; he displays at times the sentiments of a loyal courtier, at others that gay spirit of opposition which is all but indispensable to a popular French wit. His comedies offer elaborate and subtle—even tender—pictures of human character in its eternal types, lively sketches of social follies and literary extravagances, and broad appeals to the ordinary sources of vulgar merriment. Light and perspicuous in construction, he is master of the delicate play of irony, the penetrating force of wit, and the expansive gaiety of frolicsome fun. Faithful to the canons of artistic taste and under the sure guidance of true natural humour, his style suits itself to every species attempted by him. His morality is the reverse of rigid, but its aberrations are not those of prurience, nor its laws those of pretence; and, wholly free as he was from the didactic aim which is foreign to all true dramatic representation, the services rendered by him to his art are not the less services rendered to society, concerning which the laughter of genuine comedy tells the truth. He raised the comedy of character out of the lower sphere of caricature, and in his greatest creations subordinated to the highest ends of all dramatic composition the plots he so skilfully built, and the pictures of the manners he so faithfully reproduced.

Molière's Successors.—But if the mantle of Molikre can be said to have fallen upon any of his contemporaries or successors, this honour must be ascribed to J. F. Regnard, who imitated the great master in both themes and characters, while the skilfulness of his plots, and the gaiety of his treatment even of subjects tempting into the bypath of sentimental comedy, entitle him to be regarded as a comic poet of original genius.

In the next generation (that of Voltaire) comedy gradually—but only gradually—surrendered for a time the very essence of its vitality to the seductions of a hybrid species, which disguised its identity under more than a single name. A. R. Lesage, who as a comic dramatist at first followed successfully in the footsteps of Molikre, proved himself on the stage as well as in picturesque fiction a keen observer and inimitable satirist of human life. The light texture of the playful and elegant art of J. B. L. Gresset was shown on the stage in a character comedy of merit (Le *Méchant*); and in a comedy which reveals something of his pointed wit (La *Métromanie*) A. Piron produced something like a new type of enduring ridiculousness.

P. C. de Marivaux is usually supposed to have formed the connecting link between the "old" French comedy and the "new" and bastard variety. Yet, though his minute analysis of the tender passion excited the scorn of Voltaire, it should not be overlooked that in *marivaudage* proper the wit holds the balance to the sentiment, and that in some of this writer's earlier and most delightful plays the elegance and gaiety of diction are as irresistible as the pathetic sentiment, which is in fact rather an ingredient in his comedy than the pervading characteristic of it. Some of the comedies of P. H. Destouches no doubt have a serious basis, and in his later plays he comes near to a kind of drama in which the comic purpose has been virtually submerged. The writer who is actually to be credited with the transition to sentimental comedy, and who was fully conscious of the change which he was helping to effect, was Nivelle de La Chaussée, in whose hands French comedy became a champion of the sanctity of marriage, and reproduced the sentiments—in one instance even the characters—of Richardson To his play La *Fausse Antipathie* the author supplied a critique, amounting to an apology for the new species of which it was designed as an example.

The new species known as *comédie larmoyante* was now fairly in the ascendant; and it would be easy to show how even Voltaire, who had deprecated the innovation, had to yield to a power greater than his own, and introduced the sentimental element into some of his comedies. The further step, by which *comédie larmoyante* was transformed into tragkdie bourgeoise, from which the comic element was to all intents and purposes extruded, was taken by a great French writer, D. Diderot, to whose influence it was largely due that the species which had attained to this consummation for more than a generation ruled supreme in the dramatic literature of Europe. Diderot announced his plays as examples of a third dramatic form—the genre skrieux—which he declared to be the consummation of the dramatic art. Making war upon the frigid artificiality of classical tragedy, he banished verse from the new species. The effect of these plays was intended to spring from their truth to nature—a truth such as no spectator could mistake, and which should bring home its moral teachings to the business as well as the bosoms of all. The theatre was to become a real and realistic school of the principles of society and of the conduct of life.

Comedy of the Revolution and First Empire.—Among the successful dramatists following on Diderot may be mentioned the critical and versatile J. F. Marmontel, and more especially M. J. Sedaine, who though chiefly working for the opera produced two comedies of acknowledged merit (Le Philosophe *sans le savoir*

and La Gageure *imprévue*). P. A. C. de Beaumarchais (1732–99), who for his early sentimental plays, in which he imitated Diderot, invented the appellation drame—so convenient in its vagueness that it became the accepted name of the hybrid species to which they belonged—in two works of a very different kind, the famous *Barbier* de *Séville* and the still more famous *Mariage* de Figaro, boldly carried comedy back into its old Spanish atmosphere of intrigue; but, while surpassing all his predecessors in the skill with which he constructed his frivolous plots, he drew his characters with a lightness and sureness of touch peculiar to himself, animated his dialogue with an unparalleled brilliancy of wit, and seasoned action as well as dialogue with a political and social meaning which caused his epigrams to become proverbs, and which marks his Figaro as a herald of the Revolution.

The comedy of the empire is, in the hands of Collin d'Harleville, Louis Picard (1769–1828), A. Duval, Etienne and others, mainly a harmless comedy of manners. Sedaine was the father of the *opéra-comique* proper; Marmontel, as well as Rousseau, likewise composed *opérettes*—a smaller sort of opera, at first of the pastoral variety; and these flexible species easily entered into combination. The melodrama proper, of which the invention is also attributed to Rousseau, in its latter development became merely a drama accentuated by music, though usually in little need of any accentuation.

The chief home of the regular drama, however, demanded efforts of another kind. At the Théâtre Français, or Comédie Française, whose history as that of a single company of actors had begun in 1680, the party-strife of the times made itself audible; and the most prominent tragic poet of the Revolution, M. J. de Chénier, a disciple of Voltaire in dramatic poetry as well as in political philosophy, wrote for the national stage the historical drama—with a political moral—in which in the memorable year 1789 the actor Talma achieved his first complete triumph But the victorious Revolution proclaimed among other liberties that of the theatres in Paris, of which soon not less than 50 were open. In 1807 the Empire restricted the number to 9, and reinstated the Théâtre Français in sole possession (or nearly such) of the right of performing the classic drama. The tragedies of C. Delavigne represent the transition from the expiring efforts of the classical to the ambitious beginnings of the romantic school of the French drama.

The Romantic School.—Of modern romantic drama in France it must suffice to say that it derives some of its characteristics from the general movement of romanticism which in various ways and at various points of time transformed nearly every modern European literature, others from the rhetorical tendency which is a French national feature. Victor Hugo was the founder whom it followed in a spirit of high emprise to success upon success, his own being the most conspicuous of all; A. Dumas the elder its unshrinking middleman. Together with them, may, with more or less precision, be classed in the romantic school of dramatists A. de Vigny and George Sand, neither of whom, however, attained to the highest rank in the drama; Jules Sandeau; and A. de Musset, whose originality pervades all his plays, and whose later works, more especially his prose "proverbs" and pieces of a similar kind, have a flavour of delicacy altogether indescribable.

The romantic school was not destined to exercise a permanent control over French public tastr; but it can hardly be said to have been overthrown by the brief classical revival begun by F. Ponsard, and continued, though in closer contact with modern ideas, both by him and by E. Augier, a dramatist who gradually attained to an extraordinary effectiveness in the self-restained treatment of social as well as of historical themes. The theatrical fecundity and the remarkable constructive ability of E. Scribe supplied a long series of productions attesting the rapid growth of the playwright's mastery over the secrets of his craft. After a fashion which would have startled even Diderot, while recalling his efforts in the earnestness of its endeavour to arouse moral interests to which the theatre had long been a stranger, A. Dumas the younger set himself to reform society by means of the stage.

The extraordinary versatility of V. Sardou and his unfailing constructive skill was applied by him to almost every kind of serious or serio-comic, drama—even the most solid of all. In the same period, while E. Pailleron revived some of the most characteristic tendencies of the best French satirical comedy in ridiculing the pompous pretentiousness of learning for its own sake, the lighthearted gaiety of E. Labiche changed into something not altogether similar in the production of the comic muse of L. Halévy and H. Meilhac, ranging from the licence of the musical burlesque which was the congenial delight of the later days of the Second empire to a species of comedy in which the ingredients of bitterness and even of sadness found a place.

Modern Schools.—The long disputed success of the Naturalistic school carried everything before it during the years 1875-85, and its triumphant leaders were tempted to make the best of their advantage by annexing a new province and establishing a footing on the stage. In this they failed signally, both when they were assisted by professional dramatists and when left to their own resources. It became evident that Naturalism, to be acceptable on the stage, would have to undergo a special process of transformation and be handled in a peculiar way. Henry Becque succeeded in embodying the new theories in two plays, which at first met with very indifferent success, but were revived at a later period, and finally obtained permanent recognition in the French theatre even with the acquiescence of the most learned critics, when they discovered, or fancied they discovered, that Becque's comedies agreed, in the main, with Molière's conception of dramatic art. In Les Corbeaux (1882) and La *Parisienne* (1885) the plot is very simple; the episodes are incidents taken from ordinary life. No extraneous character is introduced to discuss moral and social theories, or to acquaint us with the psychology of the real *dramatis* personae, or to suggest humorous observations about the progress of the dramatic action. The characters are left to tell their own tale in their own words, which are sometimes very comical, sometimes very repulsive, but purport to be always true to nature.

Jean Richepin is half *naturaliste* and half *romantique* and he also represents the Villon and Rabelais tradition mixed with the Hugo influence; he wrote Le *Flibustier* (1888), Par *le* glaive (1897), *Miarka* (1905). Wholly romantic is Edmond Rostand. who created a great sensation with Cyrano de Bergerac (1897) and *L'Aiglon* (1900); but the favourable impression did not last. *Chantecler* (1910) was only half a success, and the reputation of Rostand has steadily declined. The naturalistic tendency took a social direction with Paul Hervieu: Les *Tenailles* (189j), La *Loi* de *l'homme* (1897), La *Course du Flambeau* (1901); his view of humanity is harsh and pessimistic. E. Brieux tackled even bigger social problems, which he perhaps over-simplified in La Robe rouge (1900), Les *Avariés* (1901), Les *Remplaçantes* (1901), *Maternité* (1904). F. de Curel, in Les *Fossiles* (1892), studies the decadence and death of the old aristocracy. Lavedan wrote also a satire of the nobility in Le *Prince d'Aurec* (1894). His best known play is Le *Duel* (1905). Georges de Porto Riche, whose best work is Le *vieil* homme (1911), has been somewhat sarcastically called le *Racine juif;* he tried to bring the stage back to a more genuine kind of psychological drama, mixing the realistic and the classical tradition. Maurice Donnay, Robert de Flers and Armand de Caillavet, Tristan Bernard, Courteline, Alfred Jarry have all achieved success in the lighter and sometimes the lightest or the grossest kind of comedy.

Paul Claudel (b. 1868) brought his own conception of symbolism to the stage with *L'Annonce faite à Marie* (1912) but his historical play *L'Otage* (1911) is generally considered a masterpiece of much greater value than anything given on the French stage since perhaps *Ruy Blas.*

After the War, an attempt to re-install verse drama was made by François Porché (1877–) (*Les Butors* et la *Finette,* 1916). There seemed to be symptoms of a revival of the French stage, the naturalistic play having sunk to a very low level. A vigorous, almost violent effort was made by Romain Rolland, in Le Jeu *de l'Amour* et de la *Mort* (1924), coming after many attempts at dramas on the French Revolution A merrier and better comedy than had been seen for many years was produced by Jules

Romains with *Le Docteur Knock* (1924) and his *Le Dictateur* (1926) is a fine psychological study of a benevolent modern tyrant's soul. A somewhat similar subject is dealt with in a different manner by Jean Richard Bloch, whose *Le dernier Empereur* (1926) was a great success. His best dramatic work so far is *Sous le genou des Amazones* (1928), a forecast of the future of the race which is a satire on the present. Pierre Hamp (1876–), celebrated as a novelist, has turned to the stage with vigour in *La Compagnie* (1927) which deals with the conflict between railwaymen and the big railway companies. A remarkable symptom in these last mentioned authors is the practical suppression of the love interest, which is a welcome change on the French stage. At present French drama is not on a level with the great contemporary achievements in the essay or the novel, but the plays just mentioned give us hope of a brighter future at hand.

Early Tudor Drama. — Recent investigation has shown that English secular drama takes its beginning from the earliest Tudor period, and in all probability from the end of the 15th century. *Fulgens and Lucres (a* copy of which came to light in 1919), an interlude by Henry Medwall, chaplain to Cardinal Morton, may be dated about 1496. Its theme, the contest between a pleasure-loving patrician and a high-principled commoner for the hand of Lucres is based upon a humanist tale; but it anticipates Shakespearian technique by adding a comic underplot which is a variation of the main subject. Medwall's other extant play *Nature*, though in form a Morality, shows much of the technical skill and realistic observation of *Fulgens and Lucres.* John Rastell, brother-in-law of Sir Thomas More, who printed *Fulgens and Lucres,* was himself the author of *The Interlude of the Four Elements* and of *Gentleness and Nobility,* two didactic plays, without action, but reflecting his interest in scientific and social problems. He also probably adapted from its Spanish source the fragmentary romantic *drama — Calisto and Melibea.* John Rastell's daughter, Joan, married John Heywood, with whose name six interludes are traditionally associated. His authorship of four of these, the ms. *Witty and Witless,* the *Play of Love* and the *Play of the Wether* (both printed by his brother-in-law, William Rastell) and *The Fowe PP.* (printed by *W.* Middleton) is beyond reasonable doubt. *Wether* and *The Foure PP.* have a raciness of dialogue and characterization that are almost Chaucerian. Two other, more acidly farcical plays, *Johan Johan* and *The Pardoner* and *The Frere,* have points of affinity with *The Foure PP.,* but there is no external evidence for Heywood's authorship of these. It has been suggested that they may have been among the *Comoediae juveniles* attributed by Bale to Sir T. More. In any case all the plays mentioned above form an early Tudor group, predominatingly English in spirit and treatment, unaffected in their construction by classical influences.

It was chiefly through the schools and universities that these influences gradually spread and, blending with native and traditional elements, produced the distinctively Elizabethan "Romantic" types of comedy and tragedy. The boys of St. Paul's school acted plays of Plautus and Terence before Wolsey in 1527 and 1528, and among the performances, which were part of the regular curriculum at Eton, Westminster, Merchant Taylors' and other schools, the two masters of Roman comedy had an important place. Scarcely less influential were a group of Continental neo-Latin playwrights such as Ravisius Textor, Macropedius, and Gnaphaeus, whose dramas on the theme of the prodigal son gained great popularity. The most famous of these, the *Acolastus* of Gnaphaeus, was issued in England with a translation by John Palsgrave in 1540.

Classical. neo-classical and native elements are blended in the work of Nicholas Udall, successively headmaster of Eton and Westminster. His *Ralph Roister Doister* (probably 1553), a clever adaptation to English conditions of types from the *Miles Gloriosus* of Plautus, was probably written for his Westminster boys and is the first English play divided into acts on the classical model. Udall was also (as has been recently shown) probably the author about 1537 of the clever adaptation of Textor's dialogue, *Thersites,* and there is reason to suppose that his biblical play, *Ezechias* (revived at Cambridge before Elizabeth in 1564), was another early work. Another attractive biblical play *Jacob and Esau* has features in common with *Roister Doister,* and may well be from Udall's pen. *Jacob and Esau* belongs to the prodigal son class, and other variations on this type are T. Ingelend's *The Disobedient Child,* adapted from a Textor dialogue; the powerful anonymous *Misogonus;* and George Gascoigne's *The Glasse of Government* (1575), heavily didactic, but notable as the first prodigal son play written in prose.

It was however not from the neo-classical but from the Italian drama that the English amateur stage had taken the crucial step of borrowing prose as the instrument of comedy. In 1j66 Gascoigne had translated for performance before the lawyers of Gray's inn Ariosto's *Gli Suppositi,* of which there were both prose and verse forms, but which he turned entirely into English prose. For a time his innovation found no imitators. *The Bugbears,* another (anonymous) adaptation of an Italian comedy, J. Phillip's recently recovered *Pacient Grissell,* and the numerous lost plays on Italian themes mentioned in the Revels' accounts were (so far as we know) in the traditional rhyming metres. So also were the few plays still surviving from the early years of Elizabeth's reign on purely English themes, such as *Tom Tyler and his Wife,* and the admirably constructed Cambridge farcical comedy, whose authorship is still a problem, *Gammer Gurton's Needle.* In another group, represented by *Common Conditions, The Rare Triumphs of Love and Fortune* and *Sir Clyomon and Sir Clamydes,* romantic subjects, sometimes combined with allegorical features, were boldly but unskilfully handled.

Influence of Seneca. — If English comedy intermingled traditional native elements with those borrowed from ancient and Renaissance Italy, English tragedy in its beginnings was predominantly indebted to one classical source, the rhetorical drama of imperial Rome. In the year of Elizabeth's accession a group of English university scholars began to put forth a series of translations of the ten tragedies of Seneca, which one of them, T. Newton, in 1581 collected into a single volume. To the direct influence of Seneca is to be ascribed the composition of the first English tragedy which we possess. *Gorboduc* or *Ferrex and Porrex,* by T. Norton and T. Sackville was first acted on Jan. 18, 1562, by the members of the Inner Temple before Queen Elizabeth. Though its subject is a British legend, and though the action is neither copied nor adapted from any treated by Seneca, yet the resemblance between this tragedy and the *Thebais* is too strong to be fortuitous. In all formal matters — chorus, messengers, etc. — *Gorboduc* adheres to the usage of classical tragedy; but the authors show no respect for the unities of time or place and they introduce before each act the non-classical device of a dumb-show. What gives the play its chief importance is the use for the first time in English drama of blank verse. The model of *Gorboduc* was followed at Gray's inn in 1566 when Gascoigne produced with the aid of two associates (F. Kinwelmersh and Sir C. Yelverton) *Jocasta,* a virtual translation of L. Dolce's *Giocasta,* which was an adaptation of a Latin translation of the *Pkoenissae* of Euripides. *R.* Edwards' *Damon and Pithias (c.* 1564–65) shades off from tragedy into what soon came to be called tragi-comedy. Other more rudely constructed plays of the same class, also on classical themes are J. Pickering's *Horestes* (pr. 1567), R. B.'s *Apius and Virginia* (pr. 1575) and T. Preston's *Cambises (c.* 1569). Two more notable examples have Italian sources. *Gismonde of Salerne,* a play drawn from Boccaccio, was acted before Queen Elizabeth at the Inner Temple in 1568, nearly a generation before it was published, rewritten in blank verse by R. Wilmot, one of the performers. G. Whetstone's *Promos and Cassandra,* founded on a tale by G. Cinthio (from which came the plot of *Measure for Measure*) followed in 1578.

In addition the universities provided a field for neo-Senecan tragedy and tragi-comedy, both in Latin and English. N. Grimald's *Christus Redivivus* and *Archipropheta* (on John the Baptist) were followed from 1581 onwards by W. Gager's series of Latin plays at Christ Church. Oxford, of which *Ulysses Redux* is the most notable. At Cambridge T. Watson's *Absolom,* J. Christopherson's *Jephtha* (both in Greek and Latin) and T. Legge's *Richardus III.* (1579) cast biblical or national history into classical moulds.

Chronicle Histories.—From the double danger which threatened English tragedy in the days of its infancy—that it would congeal on the wintry heights of classical themes, or dissolve its vigour in the glowing heat of a passion fiercer than that of the Italians—it was in part preserved by its association with the traditions of the national history. An exceptional position might seem to be in this respect occupied by T. Hughes's tragedy *The Misfortunes of Arthur* (1587). But the author of this play—in certain portions of whose framework there were associated with him seven other members of Gray's inn, including Francis Bacon, and which was presented before Queen Elizabeth like *Gorboduc*—followed the example of the authors of that work both in choice of theme, in details of form, and in a general though far from servile imitation of the manner of Seneca.

Fortunately at this time a new sphere of activity suggested itself, in which English dramatists speedily came to feel at home. In their dramatization of portions of English history classical models would be of scant service, while Italian examples of the treatment of national historical subjects, having to deal with material so wholly different, could not be followed with advantage. Nor did Bishop Bale's experiment in *King Johan* (*c.* 1547) of combining historical matter with personifications like Sedition, find imitators. The typical English *chronicle history*, which designedly assumed this name in order to make clear its origin and purpose, essayed nothing more or less than a dramatic version of an existing chronicle. Obviously, while the transition from half historical, half epical narrative often implied carrying over into the new form some of the features of the old, it was only when the subject matter had been remoulded and recast that a true dramatic action could result. But the *histories* to be found among the plays of Shakespeare and one or two other Elizabethans are true dramas, and it would be inconvenient to include these in the transitional species, of those known as *chronicle histories.* Among these is *The Famous Victories of Henry the Fifth,* known to have been acted before 1588; in which both the verse and the prose are frequently of a very rude sort, but which has considerable vigour and freshness. Another is *The Troublesome Raigne of King John,* in two parts (pr. 1591), neither a didactic effort like Bale's, nor a living drama like Shakespeare's, but in its own way an effective treatment of its historical theme. The *True Chronicle History of King Leir* (acted in 1593) seems, with all its defects, only to await the touch of the master's hand to become a tragedy of supreme effectiveness.

Elizabethan Theatres and Companies.—Out of such promises as these the glories of English drama were ripened by the warmth and light of the great Elizabethan age—of which the beginnings may fairly be reckoned from the third decennium of the reign to which it owes its name. Against the attacks which a nascent Puritanism was already directing against the stage by the hands of J. Northbrooke, the repentant playwright S. Gosson, P. Stubbes and others, were to be set the steady though frugal favour of royalty and the more liberal patronage of great nobles. This patronage was made a necessity by the Act of 1572 by which all common players were declared rogues and vagabonds unless they were in the service of some lord. Hence the rapid development of companies bearing the name of a prominent nobleman, of which the two chief in the later years of Elizabeth were known as the lord chamberlain's (including R. Burbage, Kemp and Shakespeare) and the lord admiral's (of which Edward Alleyn was the leading figure). These organized companies needed permanent playhouses, of which the first, "the Theater," was built by J. Burbage in Shoreditch in 1576, and was soon followed by the Curtain in Finsbury. These were the predecessors of the Rose and the Swan, the Globe and the Fortune, the first and the second Blackfriars theatres. How intimately the construction of Elizabethan plays is bound up with the "platform stage" of these theatres, and with the absence of a drop-curtain has been made increasingly clear by recent research. And the employment of boys in women's parts accounts for the numerous plots in which the heroine dons doublet and hose. Nor did the "little eyases" perform only in the professional companies. The children of the chapel and the children of Paul's (the choristers of the chapel royal and the cathedral) stood midway between the young professionals and the purely amateur schoolboys.

Shakespeare's Predecessors.—It was for the children of the chapel and thechildren of Paul's that John Lyly wrote his plays. The euphuism, to which his famous romance gave its name, likewise distinguishes his mythological, quasi-historical, allegorical and satirical comedies. But his real service to the progress of English drama is to be sought neither in his choice of subjects nor in his imagery—though to his fondness for fairy lore and for the whole phantasmagoria of legend, classical as well as romantic, his contemporaries, and Shakespeare in particular, were indebted. It does not even lie in the songs interspersed in his plays, which did not appear till the publication of the edition of 1632 and are of doubtful authorship. It consists in his adoption of Gascoigne's innovation of writing plays in prose; and in his having, though under the fetters of an affected style, given the first example of brisk and vivacious dialogue—an example to which even such successors as Shakespeare and Jonson were indebted. Thomas Ryd, the author of the *Spanish Tragedy,* had the born playwright's instinct for effective situations, often but not always of a lurid kind, and may have preceded Christopher Marlowe in the use of blank verse on the popular stage. He almost certainly wrote a lost play on *Hamlet,* while *Soliman and Perseda* and *Arden of Feversham* belong to his school if not to his pen. Marlowe's earliest play, *Tamburlaine the Great,* captured the theatrical public by its "high astounding terms" in which the hero's passion for infinite power found superb though at times too grandiloquent utterance. In *Doctor Faustus* the passion for infinite knowledge, and in *The Jew of Malta* the passion for infinite wealth (both as sources of power) are the leading motives. In *Edward II.* the colours are quieter but there is an advance in dramatic technique, and the closing scenes are marked by truly tragic pity and terror. Compared with *Edward II.* Peele's *Chronicle of Edward I.* still stands on the level of the species to which its title and character alike assign it. His finest play is *David and Bethsabe,* which resembles *Edward I.* in construction, but surpasses it in beauty of language and versification, besides treating its subject with superior dignity. We seem to come into something like a Shakespearian atmosphere in more than one passage of the plays of Robert Greene. His art, most conspicuous in plays treating English life and scenes, could at times free itself from the pedantry apt to beset the flight of Peele's and at times even of Marlowe's muse; and his most delightful work, *Friar Bacon and Friar Bungay,* seems to breathe something of the air which blows over an English countryside. Thomas Lodge, Thomas Nashe, Henry Chettle and Anthony Munday, who wrote the original text of the composite play *Sir Thomas More* (of which Shakespeare has been credited with three leaves in the ms.) and other works, are among the other more important writers of the early Elizabethan drama.

Although the chief of these poets are marked off from one another by the individual genius which impressed itself upon both the form and the matter of their works, yet the stamp of the age is upon them all. Writing for the stage only, of which some of them possessed a personal experience, they acquired an instinctive insight into the laws of dramatic cause and effect, and infused a warm vitality into the dramatic literature which they produced, so to speak, for immediate consumption. On the other hand, the same cause made rapidity of workmanship indispensable to a successful playwright. *How* a play was produced, how many hands had been at work upon it, what loans and what spoliations had been made in the process, were considerations of less moment than the question *whether* it was produced, and whether it succeeded.

This period of the English drama could not therefore yet be one of full consummation. In tragedy the advance which had been made in the choice of great themes, in knitting closer the connection between the theatre and the national history, in vindicating to passion its right to adequate expression, was already enormous. In comedy the advance had been less decisive and less independent; much had been gained in reaching greater freedom of form and something in enlarging the range of subjects; but artificiality had proved a snare in one direction, and the licence of the comic stage in another.

Shakespeare.—These were the circumstances under which the greatest of dramatists began to devote his genius to the theatre. Shakespeare's (*q.v.*) career as a writer of plays can have differed little in its beginnings from those of his contemporaries and rivals. Before or while he was proceeding from the re-touching and re-writing of the plays of others to original dramatic composition, the most gifted of his predecessors had passed away. Shakespeare was no doubt happy in his times, which intensified the strength of the national character, expanded the activities of the national mind, and were able to add their stimulus even to such a creative power as his. He was happy in the antecedents of the form of literature which commended itself to his choice, and in the opportunities which it offered in so many directions for an advance to heights yet undiscovered and unknown.

The great and irresistible demand on the part of Shakespeare's public was for *incident—a* demand which of itself necessitated a method of construction different from that of the Greek drama, or of those modelled more or less closely upon it. Hence in part arises the circumstance that Shakespeare so constantly combined two actions in the course of a single play, not merely supplementing the one by means of the other as a bye- or under-plot. And where he thus led many have followed. Should it, however, be sought to express in one word the greatest debt of the drama to Shakespeare, this word must be the same as that which expresses his supreme gift as a dramatist. It is in *characterization—in* the drawing of characters ranging through almost every type of humanity which furnishes a fit subject for the tragic or the comic art—that he remains absolutely unapproached; and it was in this direction that he pointed the way which the English drama could not henceforth desert without becoming untrue to itself.

Pastoral and Mask.—By the numerous body of poets who, contemporary with Shakespeare or in the next generation, cultivated the wide field of the national drama, every form commending itself to the tastes and sympathies of the national genius was essayed. None was neglected except those from which the spirit of English literature had been estranged by the Reformation, and those which had from the first been artificial importations of the Renaissance. The mystery could not in England, as in Spain, produce such an aftergrowth as the *auto,* and the confines of the religious drama were only now and then tentatively touched. The direct imitations of classical examples were few and feeble. S. Daniel (1562–1619) may be regarded as a belated disciple of Seneca, while experiments like Sir W. Alexander's *Monarchicke Tragedies* (1603–05) are the isolated efforts of a student. At the opposite end of the scale, the light gaiety of the Italian and French farce could not establish itself on the English popular stage without more substantial adjuncts; the Englishman's festive digestion long continued robust, and he liked his amusements solid. In the pastoral drama and the mask, however, many English dramatists found opportunities for the exercise of their lyrical gifts and of their inventive powers. The former could never become other than an exotic, so long as it retained the artificial character of its origin. Shakespeare had accordingly only blended elements derived from it into the action of his romantic comedies. In more or less isolated works Jonson, Fletcher, Daniel, Randolph, and others sought to rival Tasso and Guarini—Jonson in *The Sad Shepherd* coming nearest to nationalizing an essentially foreign growth by the fresh simplicity of his treatment, Fletcher in *The Faithful Shepherdess* by beauty of poetic execution; Daniel in *The Queen's Arcadia* by simpler beauties of style in both verse and prose.

The mask was a more elastic kind of composition, mixing in varying proportions its elements of declamation and dialogue, music and dancing, decoration and scenery. It was introduced, after the manner of Italy, at the court of Henry VIII. in 1512. A frequent ornament of Queen Elizabeth's court festivities and progresses, it was cultivated with increased assiduity in the reign of James I., and in that of his successor outshone, by the favour it enjoyed, the attractions of the regular drama itself. Most of the later Elizabethan dramatists contributed to this species; but by far the most successful writer of masks was Ben Jonson, of whose numerous compositions of this kind many hold a permanent place in English literature, and "next" to whom, in his own judgment, "only Fletcher and Chapman could write a mask." From a poetic point of view, however, they were at least rivalled by Dekker and Ford; in productivity and favour T. Campion seems for a time to have excelled. It was for the performance of a mask in a great nobleman's castle that Milton in 1634 wrote one of the loftiest and loveliest of English poems (*Comus*). In later times the mask merged into the opera, or continued a humble life of its own apart from contact with higher literary effort.

Later Elizabethan Drama.—The annals of English drama proper in the period reaching from the closing years of Elizabeth to the outbreak of the great Revolution include, together with names relatively insignificant, many illustrious in the history of our poetic literature. Among Shakespeare's contemporaries and successors Ben Jonson alone by the energy of his genius, not less than by the circumstances of his literary career, reached undisputed primacy among his fellows. Yet his pre-eminence did not extend to both branches of the regular drama. In tragedy he fell short of the highest success; the weight of his learning lay too heavily upon his efforts to draw from deeper sources than those which had sufficed for Shakespeare. Such as they are, his tragic works stand almost, though not quite, alone in this period as examples of sustained effort in historic tragedy proper. G. Chapman treated stirring themes, especially from modern French history, with genuine effectiveness; but, though rich in beauties of detail, he failed in this branch of the drama to follow Shakespeare in the art of fully developing a character by means of the action. With the great body of the English dramatists of this and of the next period, tragedy had passed into a phase where its interest depended mainly upon plot and incident. The romantic tragedies and tragi-comedies which crowd English literature at this time constitute together a growth of astonishing exuberance, and in mere externals of theme—ranging as these plays do from Byzantium to ancient Britain, and from the Caesars of ancient Rome to the tyrants of the Renaissance—of equally astonishing variety. The sources from which these subjects were derived had been perennially augmenting. Besides Italian, Spanish and French fiction, original or translated, besides British legend in its Romance dress, and English fiction in its humbler or in its more ambitious and artificial forms, the contemporary foreign drama, especially the Spanish, offered opportunities for resort. To the English, as to the French and Italian drama, of both this and the following century, the prolific dramatists clustering round Lope de Vega and Calderon, and the native or naturalized fictions from which they drew their materials supplied a whole arsenal of plots—among others to Middleton, to Webster, and most signally to Beaumont and Fletcher. And, in addition to these resources, a new field of supply was at hand since English dramatists had begun to regard events and episodes of domestic life as fit subjects for tragic treatment. Domestic tragedy of this description was indeed no novelty on a stage which had produced *Arden of Faversham* and *A Yorkshire Tragedy,* but T. Heywood was the first playwright who can be identified as having achieved any work of considerable value in this class (*A Woman Killed with Kindness; The English Traveller*), to which some of the plays of T. Dekker, T. Middleton, and others likewise more or less belong. Yet the number of *motives* employed—at least as a rule—in the tragic drama of this period was comparatively small and limited. Scheming ambition, conjugal jealousy, absolute female devotion, unbridled masculine passion—such are the motives which continually recur. But though the common features of the romantic tragedy are sufficiently marked they leave unobscured the distinctive features in its indi-

vidual writers. In J. Nebster, master as he is of *nzacabre* effects. and in J. Ford, seductive in his sweetness, the monotony of exaggerated passion is broken by those marvellously sudden and subtle touches through which their tragic genius creates its most thrilling effects. Nor will the tendency to excess of passion which F. Beaumont and J. Fletcher exhibit be coniounded with their distinctive power of sustaining tenderly pathetic characters and irresistibly moving situations in a degree unequalled by any of their contemporaries—a power seconded by a beauty of diction and softness of versification which for a time raised them to the highest pinnacle of popular esteem. and which entitles them in their conjunction, and Fletcher as an independent worker, to an enduring pre-eminence among their fellows. Distinctive, too, are the manliness of sentiment and occasionally greater width of outlook which ennoble the rhetorical genius of P. Massinger, and the gift of poetic illustration which entitles J. Shirley to be remembered not merely as the latest and the most fertile of this group of dramatists.

In comedy, on the other hand, the genius and the insight of Jonson pointed the way to a steady and legitimate advance. His theory of "humours" (which found the most palpable expression in two of his earliest plays), if translated into the ordinary language of dramatic art, signifies the paramount importance in the comic drama of the presentation of distinctive human types. In the actual reproduction of humanity in its infinite but never, in his hands, alien variety, it was impossible that Shakespeare should be excelled by Jonson; but in the consciousness with which he recognized and indicated the highest sphere of a comic dramatist's labours, he rendered to the drama a direct service which the greater master had left unperformed. By the rest of his contemporaries and his successors, some of whom, such as R. Brome, were content avowedly to follow in his footsteps, Jonson mas only occasionally rivalled in individual instances of comic creations; in the entirety of its achievements his genius as a comic dramatist remained unapproached in its own sphere. The favourite types of Jonsonian comedy, to which Dekker, J. Marston and Chapman had added others of their own, were elaborated with incessant zeal by their contemporaries and successors. The inexhaustible *verve* of T. Middleton, the buoyant productivity of Fletcher, the observant humour of N. Field, and the artistic versatility of Shirley mirrored in innumerable pictures of contemporary life the follies and foibles of mankind.

Later Academic Drama.—The academic drama of the later Elizabethan period and of the first two Stuart reigns did not fall off either in activity or in variety from that of the preceding generations. At Oxford a long succession of English and Latin plays were performed, from the early years of the 17th century onwards. The production of these plays as distributed among several colleges, among which the most conspicuously active were Christ Church and St. John's, where a series of performances took place in 1607–08 under the collective title of *The Christmas Prince.* Other notable Oxford plays are S. Daniel's pastoral drama, *The Queen's Arcadia* (1605), Barten Holiday's *Technogamia* (1618), W. Strode's *Floating Island* and W. Cartwright's *The Royal Slave* (1636), all of which formed part of royal entertainments. At Cambridge the list of plays performed in the latter half of Elizabeth's reign at Trinity, St. John's, Queens' and a few other colleges, contains several of special interest. Among Latin comedies E. Forsett's *Pedantius,* probably acted at Trinity in 1581, ridicules Gabriel Harvey; *Laelia,* acted at Queens' in 1590 and again in 1598, resembles *Twelfth Night* in part of its plot; while in *Silvanus,* performed in 1597 at St. John's, there are similarities to *As You Like It.* The most interesting of the English plays of the later Cambridge series are the *Parnassus Plays,* successively produced at St. John's in 1598–1602, which illustrated the unfortunate relations between university life and the outside world, including the world of letters and of the stage as represented by Shakespeare's fellows Burbage and Kemp. Upon a different aspect of English university life—the relations between town and gown—a partisan light is thrown by *Club-Law,* acted at Clare in 1599—and by G. Ruggle's Latin comedy of *Ignoramus,* twice acted by members of Clare at Trinity in 1615 before King James I. Other Cambridge English plays of note are T. Tomkis's allegorical *Lingua* (1607) and Phineas Fletcher's *Sicelides* (1615), a "piscatory" (*i.e.,* a pastoral drama in which the place of the shepherds is taken by fishermen). Latin and English plays continued to be brought out in Cambridge till the year of the outbreak of the Civil War, T. Randolph and A. Cowley being among the authors of some of the latest so produced.

The Drama and Puritanism.—Up to the outbreak of the Civil War the drama in all its forms continued to enjoy the favour of the court, although a close supervision was exercised over attempts to make the stage the vehicle of political references. The official agent of this supervision was the Master of the Revels; but under James I. a special ordinance, in harmony with the king's ideas concerning the dignity of the throne, was passed "against representing any modern Christian king in plays on the stage." But the sympathies of the dramatists were so entirely on the side of the court that the real difficulties against which the theatre had to contend came from an opposite quarter. With the growth of Puritanism the feeling of hostility to the stage increased in a large part of the population, well represented by the civic authorities of the capital. Puritans of the more pronounced type openly aimed at the permanent closing of the theatres. The war between them and the dramatists was accordingly of a life-and-death kind. On the one hand, the drama heaped its bitterest and often coarsest attacks upon whatever savoured of the Puritan spirit; gibes, taunts, caricatures in ridicule of Puritans make up a great part of the comic literature of the later Elizabethan and Stuart drama. On the other hand, the looseness of tone, the mockery of ties sanctioned by law and consecrated by religion, the tendency to treat middle-class life as the hunting-ground for the diversions of the upper classes, which infected so much of the dramatic literature of the age, intensified the Puritan opposition to all and any stage plays. This was most loudly voiced in Prynne's *Histrio-Mastix* (1632), which involved its author in persecution, but did not remain wholly without effect upon the tone of the dramatic literature of the subsequent period. The quarrel between Puritanism and the theatre was, however, too old and too deep to end in any but one way, so soon as the latter was deprived of its protectors. The Civil War began in Aug. 1642, and early in the following month was published the ordinance of the Lords and Commons, which, after a brief and solemn preamble, commanded "that while these sad causes and set-times of humiliation do continue, public stage plays shall cease and be forborne." Though there is evidence that dramatic entertainments of one kind or another continued to be occasionally presented, stringent ordinances gave summary powers to magistrates against any players found engaged in such proceedings (1647), and bade them treat all stage-players as rogues, and pull down all stage galleries, seats and boxes (1648). **A** few dramatic works were published in this period; while at fairs about the country were acted farces called "drolls," consisting of the most vulgar scenes to be found in popular plays. Thus the life of the drama was not absolutely extinguished.

Revival **of the** Drama.—Already "in Oliver's time" private performances took place from time to time at noblemen's houses and (though not undisturbed) in the old haunt of the drama, the Red Bull. In 1656 the ingenuity of Sir William Davenant, whose name is memorable as connecting two distinct periods, ventured on a bolder step in the production of a quasi-dramatic entertainment "of declamation and music"; and in the following year he brought out with scenery and music a piece which was afterwards acted in an enlarged form and printed as the first part of his opera The *Siege* of *Rhodes.* This entertainment he afterwards removed from the private house where it had been produced to the Cockpit, where he soon ventured upon the performance of regular plays written by himself. Thus, under the cover of two sister arts, whose aid was in the sequel to prove by no means altogether beneficial to its progress, the English drama had boldly anticipated the Restoration, and was no longer hiding its head when that event took place. Soon after Charles II.'s entry into London, two theatrical companies are known to have been acting in the capital. For these companies patents were soon granted, under the names of "the Duke (of York)'s" and "the King's

Servants," to Davenant and Thomas Killigrew respectively—the former from 1662 acting at Lincoln's Inn Fields, then at Dorset Garden in Salisbury court, the latter from 1663 at the Theatre Royal near Drury lane. These companies were united from 1682, a royal licence being granted in 1695 to a rival company which performed in Lincoln's Inn Fields, and which migrated to Covent Garden in 1733. Meanwhile, Vanbrugh had in 1705 built the theatre in the Haymarket; and a theatre in Goodman's Fields—afterwards rendered famous by the first appearance of Garrick—led a fitful existence from 1729 to 1733. The Act of 1737 deprived the Crown of the power of licensing any more theatres; so that the history of the English stage for a long period was confined to a restricted area. The rule which prevailed after the Restoration, that neither of the rival companies should ever attempt a play produced by the other, operated beneficially both upon the activity of dramatic authorship and upon the progress of the art of acting. This art has rarely flourished more in England than in the days of T. Betterton and his contemporaries, including Hart, Mohun, Kynaston, Nokes, Mrs. Barry, Mrs. Betterton, Mrs. Bracegirdle and Mrs. Eleanor Gwyn. It is to be noted also that during the greater part of the 18th century the Dublin stage rivalled the English in the brilliancy of its stars. Betterton's rival, R. Wilks, Garrick's predecessor in the homage he paid to Shakespeare, Macklin, and his competitor for favour, the "silver-tongued" Barry, were alike products of the Irish stage, as were Peg Woffington and other well-known actresses.

Restoration Drama: Heroic Tragedy.--Owing in part to the influence of the French theatre, which by this time had taken the place of the Spanish as the ruling drama of Europe, the separation between tragedy and comedy is clearly marked in post-Restoration plays. Lord Orrery, in deference, as he declares, to the expressed tastes of his sovereign King Charles II. himself, was the first to set up the standard of *heroic plays.* This new species of tragedy (for such it professed to be) commended itself by its novel choice of themes, to a large extent supplied by recent French romance—the *ronzans de longue haleine* of the Scudérys and their contemporaries—and by French plays treating similar themes. It likewise borrowed from France that garb of rhyme which the English drama had so long abandoned, and which now reappeared in the heroic couplet. In conjunction with his brother-in-law, Sir R. Howard, and afterwards more confidently by himself, Dryden threw the vigour and brilliancy of his genius into the scale. At first, in his *Essay* of *Dramatic Poesy,* he claimed for English tragedy the right to combine her native inheritance of freedom with these valuable foreign acquisitions. Nor was he dismayed by the ridicule which the burlesque (by the duke of Buckingham and others) of *The Rehearsal* (1671) cast upon heroic plays, but returned, in his *Essay of Heroic Plays,* to the defence of a species which he himself was to abandon in the end. Among the other tragic poets of this period, N. Lee, in the outward form of his dramas, accommodated his practice to that of Dryden, like whom he allowed political partisanship to intrude upon the stage. His rhetorical genius was not devoid of genuine energy, nor is he to be regarded as a mere imitator. T. Otway, the most gifted tragic poet of the younger generation contemporary with Dryden, inherited something of the spirit of the Elizabethan drama; he had at his command tragic pathos and melting tenderness. Among dramatists who contributed to the vogue of the "heroic" play may be mentioned J. Bankes, J. Weston, C. Hopkins, E. Cooke, R. Gould, S. Pordage, T. Rymer and Elkanah Settle. The productivity of J. Crowne (d. *c.* 1703) covers part of the earlier period as well as of the later, to which belong T. Southerne, a writer gifted with much pathetic power, but probably chiefly indebted for his long-lived popularity to his skill in the discovery of "sensational" plots; and Lord Lansdowne ("Granville the polite") (*c.* 1667–1735). Congreve, by virtue of a single tragedy *(The Mourning Bride),* and *N.* Rowe, may be further singled out from the list of the tragic dramatists of this period, many of whom were, like their comic contemporaries, mere translators or adapters from the French. The tragedies of Rowe indicate the transition from the fuller declamatory style of Dryden to the calmer and thinner manner of Addison. The excesses of the past period had produced an inevitable reaction; decorum was asserting its claims on the stage as in society; and French tragedy had set the example of sacrificing what passion—and what vigour—it retained in favour of qualities more acceptable to the "reformed" court of Louis XIV. Addison, in allowing his *Cato* to take its chance upon the stage, when a moment of political excitement (April 1713) ensured to it an extraordinary success, unconsciously sealed the doom of English national tragedy. The "first reasonable English tragedy," as Voltaire called it, had been produced, and the oscillations of the tragic drama of the Restoration were at an end.

Restoration Comedy.—English comedy in this period displayed no similar desire to cut itself off from the native soil and it exhibits the influence of Jonson and Fletcher though it freely borrowed the materials for its plots and many of its figures from Spanish, and afterwards more generally from French, originals. The higher efforts of French comedy of character, as well as the refinement of expression in the list of their models, notably in Molière, were alike seasoned to suit the grosser palates of English patrons. This is especially true of the comedies of Dryden from *The Wild Gallant* (1663) to *The Spanish Friar* (1680). In no field did Dryden's versatile genius appear, on the whole, to less advantage, but in his presentation of pairs of witty lovers he anticipates one of the main features of the comedy of manners, which is the most typical product of the Restoration stage. As the latest historian of that stage (A. Nicoll) observes, "the invariable elements of the comedy of manners are the presence of at least one pair of witty lovers, the woman as emancipated as the man, their dialogue free and graceful, an air of refined cynicism over the whole production, the plot of less consequence than the wit, an absence of crude realism, a total lack of any emotion whatever." There is a further approach to the type in Sir C. Sedley's *The Mulberry Garden* (1668) and it is definitely established in plays of Sir George Etherege. Other comic types are exemplified in T. Shadwell's Jonsonian plays, from the *Sullen Lovers* (1668) to *The Squire of Alsatia* (1688); in Sir S. Tuke's and Mrs. Aphra Behn's comedies of intrigue (1672–79); and in T. D'Urfey's partly farcical, partly sentimental plays (1676–96). But it was in the comedy of manners that the most powerful, and the most polished, dramatist of the age found each his medium. W. Wycherley drew his characters with vigour and distinctness, and constructed his plots and chose his language with natural ease. He lacks gaiety of spirit, and his wit is of a cynical turn. But, while he ruthlessly uncloaks the vices of his age, his own moral tone is affected by their influence in as marked a degree as that of the most light-hearted of his contemporaries. W. Congreve is not only one of the wittiest of English writers, but excels in the graceful ease of his dialogue, and draws his characters with the same masterly skill. His *Way of the World* has been truly called "the master-creation of the school of manners." Mirabell and Millamant look back to Benedick and Beatrice and forward to Tanner and Ann Whitfield in Shaw's *Man and Superman.* Sir J. Vanbrugh lacked Congreve's brilliance, but his lively wit and theatrical sense give salt to his two best plays, *The Relapse* and *The Provok'd Wife.* G. Farquhar, whose morality is on a par with that of the other members of this group, is inferior to them in brilliancy; but the pictures of manners, in a wider sphere of life than that which contemporary comedy usually chose to illustrate, give distinction to two of his plays (*The Recruiting Officer* and *The Beaux' Stratagem),* in which we seem to be entering the atmosphere of the 18th century novel.

Sentimental Comedy.—The improvement which now begins to manifest itself in the moral tone and spirit of English comedy is partly due to the reaction against the reaction of the Restoration, partly to the punishment which the excesses of the comic stage had brought upon it in the invective of Jeremy Collier (1698), best-founded of all the assaults on the theatre in England and most productive of perceptible results. Writers like Mrs. Centlivre became anxious to reclaim their offenders with much emphasis in the fifth act; and Colley Cibber may be

credited with having first deliberately made the pathetic treatment of a moral sentiment the basis of the action of a comic drama. But he cannot be said to have consistently pursued the vein which in his Careless Husband (1704) he had essayed. His *Non-Juror* is a political adaptation of *Tartuffe;* and his Provoked *Husband* only supplied a happy ending to Vanbrugh's unfinished play. Sir R. Steele, in accordance with his general tendencies as a writer, pursued a still more definite moral purpose in his comedies; but his genius lacked the sustained vigour necessary for a dramatist, and his humour naturally sought the aid of pathos. From partial he passed to more complete experiment; and thus these two writers, who transplanted to the comic stage a tendency towards the treatment of domestic themes noticeable in such writers of Restoration tragedy as Southerne and Rowe, set the fashion of sentimental *comedy,* a species which exercised a debilitating influence upon the progress of English drama. With Cato English tragedy committed suicide, though its pale ghost survived; with The Conscious Lovers English comedy sank for long into the tearful embraces of artificiality and weakness.

There is every reason to conclude that the art of acting progressed in the same direction of artificiality, and became stereotyped in forms corresponding to the "chant" which represented tragic declamation in a series of actors ending with Quin and Macklin. It was reserved to the genius of Garrick, whose theatrical career extended from 1741 to 1776, to open a new era in his art. His unparalleled success was due in the first instance to his natural gifts; yet these were enhanced by a careful literary training, and confirmed by a purpose which prompted him to essay the noblest, as he was capable of performing the most various, range of English theatrical characters. By devoting himself as actor and manager with special zeal to the production of Shakespeare, Garrick permanently popularized on the national stage the greatest creations of English drama.

Eighteenth Century Tragedy.—The contrast between the tragedy of the 18th century and those plays of Shakespeare and other Elizabethans which in the period before Garrick were known to the English stage, was weakened by the mutilated form in which the old masterpieces generally, if not always, made their appearance there. Even so, however, there are perhaps few instances in theatrical history of so unequal a competition being so long sustained. In the hands of the tragic poets of the age of Pope, as well as that of Johnson. tragedy had hopelessly stiffened into the forms of its accepted French models. Direct reproductions of these continued, as in Ambrose Philips's and Charles Johnson's (1679–1748) translations from Racine, and Aaron Hill's from Voltaire. Among other tragic dramatists of the earlier part of the century may be mentioned J. Hughes, who, after assisting Addison in his Cato, produced at least one praiseworthy tragedy of his own (The Siege of Damascus); E. Fenton, a joint translator of "Pope's Homer" and the author of one extremely successful drama on a theme of enduring interest (*Mariamne*), and L. Theobald the first hero of the Dunciad. A more distinguished name is that of J. Thomson, whose unlucky *Sophonisba* and subsequent tragedies are, however, barely remembered by the side of his poems. The literary genius of E. Young, on the other hand, possessed vigour and variety enough to distinguish his tragedies from the ordinary level of Augustan plays; in one of them (*The* Revenge) he seems to challenge comparison in the treatment of his theme with *Othello,* but by his main characteristics as a dramatist he belongs to the school of his contemporaries. The endeavours of G. Lillo, in his *London Merchant,* or George *Barnwell* (1731), to bring the tragic lessons of terror and pity directly home to his fellow-citizens exercised an astonishingly widespread as well as enduring effect on the history of the 18th century drama. At home, they gave birth to the new. or, more properly speaking, the revived, species of domestic tragedy. Abroad, this play supplied the text to the teachings of Diderot, as well as an example to his own dramatic attempts; and through Diderot the impulse communicated itself to Lessing, and long exercised a great effect upon the literature of the German stage. "Ciassical" tragedy in the generation of Dr Johnson pursued the even tenor of its way, the dictator himself treading with solemn footfall in the accustomed path, and W. Mason making the futile attempt to produce a close imitation of Greek models. The best-remembered tragedy of the century, Home's *Douglas* (1757), was the production of an author whose famous kinsman, David Hume (though no friend of the contemporary English stage), had advised him "to read Shakespeare, but to get Racine and Voltaire by heart."

English Opera.—While thus no high creative talent arose to revive the poetic genius of English tragedy, comedy, which had to contend against the same rivals, naturally met the demands of the conflict with greater buoyancy. In one form the English opera was preserved as a pleasing species of the popular drama. The pastoral drama had (in 1725) produced an isolated aftergrowth in Allan Ramsay's Gentle Shepherd, which, with genuine freshness and humour, but without a trace of burlesque, transferred to the scenery of the Pentland hills the tale of Florizel and Perdita. The dramatic form of this poem is only an accident, but it doubtless suggested an experiment of a different kind to the most playful of London wits. Gay's "Newgate pastoral" of The Beggar's Opera (1728), in which the text of a burlesque farce was interspersed with songs set to popular airs, caught the fancy of the town and became the ancestor of a series of productions, none of which, however, not even its own continuation, Polly, have ever rivalled it in success or celebrity. Among these may be mentioned the pieces of I. Bickerstaffe (Love *in a* Village, etc.) and C. Dibdin (The *Waterman,* etc.). The opera in England thus absorbed what vitality remained to the pastoral drama, while to the ballet and the pantomime (whose glories in England began at Covent Garden in 1733, and to whose popularity even Garrick was obliged to defer) was left the inheritance of the external attractions of the mask and the pageant.

Later **18th** Century Comedy.—In the face of such various rivalries it is not strange that comedy, instead of adhering to the narrow path which Steele and others had marked out for her, should have permitted herself some vagaries of her own. Gay's example pointed the way to a fatally facile form of the comic art; and burlesque began to contribute its influence to the decline of comedy. In an age when party-government was severely straining the capabilities of its system, dramatic satire had not far to look for a source of effective seasonings. The audacity of H. Fielding, whose regular comedies have secured no enduring place on the stage, accordingly ventured in two extravaganzas (*Pasquin* and *The* Historical Register *for 1736)* upon a larger admixture of political with literary and other satire. A third attempt (The Golden Rump), which never reached the stage, furnished the offended minister, Sir Robert Walpole, with the desired occasion for placing a curb upon the licence of the theatre, such as had already been advocated by a representative of its old civic adversaries. The Act of 1737 asserted no new principle, but converted into legal power the customary authority hitherto exercised by the lord chamberlain (to whom it had descended from the Master of the Revels).

Farce had now become a genuine English species, and has as such retained its vitality through all the subsequent fortunes of the stage; it was actively cultivated by Garrick as both actor and author; and he undoubtedly had more than a hand in the best farce of this age, which is ascribed to clerical authorship (High Life Below Stairs, 1759). S. Foote, whose comedies and farces are distinguished both by wit and by variety of characters, introduced into comic acting the abuse of personal mimicry. Meanwhile, the domestic drama of the sentimental kind achieved, though not immediately, a success only inferior to that of Tlze London Merchant, in Tlze Gamester of E. Moore, to which Garrick seems to have contributed; and sentimental comedy gained sympathetic applause in the works of R. Cumberland, F. Reynolds and H. Kelly. It cannot be said that this species was extinguished, as it is sometimes assumed to have been, by Goldsmith; but he certainly published a direct protest against it between the production of his admirable character-comedy of The *Good-Natured* Man, and his delightfully brisk and fresh *She Stoops* to *Conquer.* The most successful efforts of the elder G. Colman had in them something of the spirit of genuine comedy,

besides a finish which is one of the qualities which ensure a long life to a play. And in the masterpieces of R. B. Sheridan some of the happiest features of the comedy of Congreve were revived, together with its too uniform brilliancy of dialogue, but without its indecency of tone. The varnish of the age is indeed upon the style, and the hollowness of its morality in much of the sentiment (even where that sentiment is meant for the audience) of *The Rivals* and *The School for Scandal;* but in tact of construction, in finish of character drawing, and in pungency of social satire, they are to be ranked among the glories of English comedy. Their continued popularity has in fact unduly overshadowed the merits of other later 18th century plays. T. Morton's *Speed the Plough* (where we first hear of "Mrs. Grundy"); A. Murphy's *The Way to Keep Him* and *The School for Guardians;* and the humanitarian drama of T. Holcroft *(The Road to Ruin* and *The Deserted Daughter)* and Mrs. Inchbald *(Every One Has His Faults* and *Wives As They Were And Maids As They Are)* all have distinctive qualities. Notable too are Mrs. Cowley ("Anna Matilda") and G. Colman the younger, both writers of popular comedies, as well as the prolific J. O'Keefe (1746–1833), who contributed to nearly every species of the comic drama.

19th Century Drama.—With the beginning of the 19th century came a decline of dramatic composition of the higher class. Joanna Baillie's well-meant but anaemic attempts to rejuvenate in her plays on the passions poetic tragedy and comedy were based on a misleading theory. In any case the times were out of joint for such an endeavour. The poems, with which Scott and Byron, and the novels, with which Scott both satisfied and stimulated the imaginative demands of the public, diverted the attention of the cultivated classes from dramatic literature, which was unable to escape, with the light foot of verse or prose fiction, into "the new, the romantic land." Scott, who in his earlier days had translated Goethe's *Götz von Berlichingen,* gained no reputation by his own dramatic compositions. W. S. Landor, apart from those *Imaginary Conversations* upon which he best loved to expend his powers of observation and characterization, cast in a formally dramatic mould studies of character of which the value is far from being confined to their wealth in beauties of detail. Of these the magnificent, but in construction altogether undramatic, *Count Julian,* is the most noteworthy. Shelley's *The Cenci,* on the other hand, is not only a poem of great beauty, but a drama of true power, abnormal in theme, but singularly pure and delicate in treatment. A humbler niche in the temple of dramatic literature belongs to some of the plays of C. R. Maturin, Sir T. N. Talfourd and Dean Milman.

Never was the divorce between the theatre and literature so complete and prolonged as during the major part of the 19th century. Fertilizing ideas, distinction of style, whether in poetry or prose, and originality in technique were all wanting. Among the professional playwrights only a few have a claim to remembrance. Sheridan Knowles composed his conventional semblance of genuine tragedy and comedy (*Virginius* and *The Hunchback*) with a thorough knowledge of stage effect. The first Lord Lytton, though his plays were for the most part of a lighter texture, showed even more artificiality of sentiment in their conception and execution; but the romantic touch which he imparted to the *Lady of Lyons* accounts for its long-lived popularity. T. W. Robertson in *School* and *Caste* brought back a refreshing breath of naturalness into the acted comic drama; Tom Taylor made little pretence to original invention, but adapted with an instinct that rarely failed him.

But in the last decades of the Victorian age, the revival of public interest in the theatre co-operated with a gradual change in poetic taste to awaken the hope of a future living reunion. Among English poets who lived in this period, Sir Henry Taylor and R. H. Horne caught something of the Elizabethan accent and spirit. Of the chief poets of the age, Tennyson in his later years attempted, with only partial success, a form of composition not well suited to his genius (though his *Becket,* as interpreted by Irving, was a memorable stage ecclesiastic). Memorable also are the plays of Robert Browning, some of whose distinctive gifts are displayed in his dramatic work; and the sustained endeavours of A. C. Swinburne, after adding a flower of exquisite beauty to the wreath which the lovers of the Attic muse have laid at her feet, to enrich the national historic drama by a trilogy instinct with the ardent eloquence of passion.

The Theatre of Charles Kean and **Phelps.**—During the greater part of the 19th century the English drama was more fitly to be considered as a part of the general industry of entertainment than as a serious contribution to the world's art of the theatre. When Matthew Arnold protested in 1879 that there was

no English theatre he did not, of course, mean that there were no stages, no actors, and no audiences, but that England was not taking a considerable or a worthy part in the development of a dramatic form of expression which had other ambitions than mere showmanship and the establishment of box-office standards of success. The English drama did, in fact, conform to its position in the industry of catering for the popular leisure by expanding with expanding commerce. It even followed the economic trend so closely that it acquired Free Trade at the time when Free Trade was becoming a dominant social issue. The lingering and rather futile efforts to protect the economic interests of the two historic patent theatres of London, Drury Lane and Covent Garden, by giving them a monopoly of the legitimate drama were abandoned in 1843, when an Act of parliament granted a comprehensive freedom to the stage. Drama was thus liberated like any article of commerce and, as the population was growing rapidly in numbers and in wealth, there was a swift expansion of dramatic output. But what was offered to the new public must, unfortunately, be considered in terms of quantity rather than of quality. Commercial standards became more frankly accepted and the ideal of the "long run" supplanted the old conceptions of a classical repertory in which it was the function of the leading players to appear continually and to display their various powers and graces in a great variety of traditional and testing parts. The old policy, however, of a classical routine was maintained by Charles Kean who became lessee of the Princess's in 18jo and by Samuel Phelps at Sadler's Wells. Kean, on the one hand, was endeavouring to sustain the best kind of dramatic appeal by throwing in costly embellishments which a later taste would have considered unnecessary or even absurd. Phelps, on the other, did splendid work, not only for the public that still wanted Shakespeare. but for the Shakespearian text itself by going back to the Folio for his matter instead of using the adaptations and "versions" which had been started during the Restoration with the authority of Dryden and had continued to grow in numbers and stupidity throughout the 18th century. Even John Philip Kemble, who had been considered something of a purist in these matters, played a musical version of *The Tempest* which contains lyrics in the style of an 18th century ballad opera. Against such barbarism, long taken for granted even by cultured people, Phelps made a strong and splendid stand at Sadler's Wells and during his management there, which lasted from 1844 till 1862, he maintained a dignified level of dramatic art while the national theatre as a whole was only concerned with rhetoric and sensation and with reaping the financial benefits of its new freedom. The drama was still governed by a State censor, for whose office the lord chamberlain was responsible, and by local licensing authorities who could restrict productions either on account of unsuitable premises or unsuitable matter such as might give moral offence or be a likely cause of riots and unrest. But in mid-Victorian times there was little interference with the industry and the players lived and worked in that conipanionable anarchy which is so picturesquely described in the Crummles episodes of *Nicholas Nickleby*.

After the Act of 1843 there was a rapid growth of theatres proper or lord chamberlain's houses; they could multiply according to popular demand, while the old saloon theatres, which had been outside the patent and had dealt mainly in imported romantic dramas and light operas, found that the new rivalry necessitated new measures The saloon theatres accordingly relied more and more upon song and dance and became the parents of the music-hall, while the orthodox houses were occupied by all that early Victorian England could offer in the shape of drama. It was not very much. Right on up to the '80s the Victorian theatre was dominated by the French tradition in farce and melodrama with the result that many English writers who might have been the "abstracts and brief chronicles" of their time, or who might at least have given to the actors opportunities for fulfilling the high function ascribed by Hamlet to the players, remained mere hacks engaged in adapting imported material.

T. W. Robertson's Comedies.—A distinct change was made by T. W. Robertson (1829–71), whose comedies seem to a generation used to Ibsen and Shaw to be painfully stilted and artificial. Robertson, none the less, was the supposed rebel and realist of his times; he believed that he was bringing the drama back to life from the pretty Alsatias and the riotous nonsense-worlds to which it had been driven. He became dramatist to the Bancroft management at the Prince of Wales's theatre where a new school of realistic staging and acting was begun in self-conscious revolt against the tawdry romanticism, the pomposities of rhetoric and spectacle, and the wild fustian of the general drama of the time. Robertson's most important contribution to the theatre of that period was his refusal to accept the battered types which passed for figures of fun. To playgoers 50 years later *Society* (1865) and *Caste* (1867) seemed almost laughably artificial, but they were considered by conteniporary critics to be daring essays in naturalism and actuality. Before Robertson's time the writing and the acting of character parts were limited by certain acknowledged formulae. There was a routine of the ridiculous in the theatre, as there was afterwards in the music-halls where noses had to be red by regulation and umbrellas broken as it were by schedule. The Bancrofts, working on Robertson's pieces, abolished these traditional restrictions upon truth and tried to substitute fresh individual characters for the stale humours of the type, The whole policy was to let in the breeze of actuality into the hot, stale atmosphere of the playhouse, and in this invigorating change they had important allies in two actors of consequence, Sothern and Hare. The latter wrote of Robertson that "As nature was the basis of his work, so he sought to make actors understand that it should be of theirs. He thus founded a school of natural acting which completely revolutionized the then existing method and, by so doing, did incalculable good to the stage." Unfortunately Robertson lacked successors. James Albery was credited with imagination and wit but he found the way of the adapter easier than that of the creator and H. J. Byron altogether fell away from the standards which Robertson had endeavoured to institute. Adaptations went briskly on and it was significant that when Beerbohni Tree went into management at the Haymarket in 1887 he relied niainly upon plays of foreign origin. Until the '80s were well advanced the practice of adaptation from the French (and sometimes, as in the case'of the ever-popular farce *The Private Secretary*, from the German) was held to be the legitimate as well as the customary occupation of a British playwright. To create episode or character was a rarity. Among those who occasionally created and more often adapted were Albery, Gilbert, Godfrey and Tom Taylor.

The **New** Theatre.—But, while the mid-Victorian years were largely sterile in authorship, important changes were being made in the organization and social status of the English theatre. In early Victorian times the actor was usually expected to be a Bohemian and might even be an outcast. The playhouse itself might be rough and ready and the society to be met there little better. The Bancrofts were responsible, not only for freshening the quality of stage writing and production, but for reintroducing the theatre to the attention of the prosperous middle-class and of those who might previously have hesitated before being seen in such a place. Whether it was that they raised the tone by raising prices or were able to raise the prices because they had raised the tone, the fact remains that they gave to their theatre a *cachet* and a *clientèle* which confirmed the place of drama among the arts of a civilized London community. Their theatre was as attractively upholstered as their stage was attractively set. Playgoing was made safe for the well-to-do levels of the democracy and respectability replaced the old notions of a rakish entertainment for rackety people. The half-guinea stall, which became a familiar London institution, was introduced and, what was more. it was sold and filled. It is interesting to notice that complaints made 60 years later about the high prices of seats in London theatres were not based on any historical sense of comparative values. The half guinea of 1868 was at least equivalent in general purchasing power to the pound of 1928. The return of the wealthy people to the play-going class did not work altogether for good; their taste might be more limited than their purse, and they certainly did not demand a form of theatrical art which should be intellectually ambitious. But it was, on the whole, an excellent

tiling that the English theatre should be rescued from its association with the histrionic booth at the fair and the blood-tub of the street-corner melodramas. The Bancrofts may not have found that polite and cultivated society of playgoers which Meredith postulated as essential to the production of comedy, but they rendered admirable service to the drama by restoring it to its place among the exercises and adornments of a civilized community.

The Provincial Tour.—Another of their achievements was the reorganization of theatrical life throughout the country. Provincial production had hitherto been left to stock companies or to travelling troupes working on local circuits. Lovers of Mr. Vincent Crummles will know that the strolling players added more to the strange pleasures of life than to the attractions of the theatre as a recreation for educated and adult people. The great mid-i'ictorian alteration was to bring to the provinces touring companies in recent successful plays with casts efficiently chosen in London and trained under expert supervision. The national development of communications made travel far easier than it had been and it was possible to carry proper scenery from place to place instead of relying upon the accident of local provision. In 1867 Bancroft organized for tour an exact reproduction of the London presentation of *Caste* and the quality of the performance appears to have been greatly appreciated in the towns which were visited. Buckstone's company from the Haymarket followed suit and it soon became common for actor-managers to go on tour and so bring to the various towns a smoothness and a virtuosity of performance to which the local audiences were quite unused. By the end of the 19th century all the great London actors and important foreign visitors, like Sarah Bernhardt, habitually took their companies on tour and the centralization of theatrical activity in the capital was considerably diminished. There were obvious advantages in this, but the old stock companies, which were displaced by the new touring combinations, had been extremely valuable as training-schools. A player brought up in them had to learn to play all kinds of parts at very short notice; he had therefore to be elastic in his technique and to be versatile in his range. He might be king one day and beggar the next. But with the touring companies from London the player went on repeating one part and then was expected to continue in another *rôle* of the same kind. He became a specialist and was cast only for parts in which he was known to specialize. The result was the elaboration of smoothness in certain types of work, but not the creation of actors with plastic masks and personalities who were ready to go anywhere and to do anything. Even those who least approve the type of drama produced by the old conditions of the pre-Bancroft stage would admit that those conditions were likely to evoke a rich and resourceful type of acting in which full command of movement and of diction were absolutely essential.

The Stage Divorced from National Culture.—It is plain from what has been said of the early and mid-Victorian stage-that the play was not the thing. The playgoer's motive was rarely literary nor did he regard it as the function of the dramatic art to hold the mirror up either to human nature, to current manners, or to problems of the hour or of eternity. The period was one of intensely dramatic changes in the national life. The whole economic structure of society was altering; science was coming forward to challenge dogma; the strife of classes and of generations was taking shape in conflicts whose natural artistic expression should surely have been dramatic. But to the student who wishes to map out the social landscape of the time the stage offers extremely little evidence. In no sense were the actors the abstracts of their time. Both the pride in the new progress and the protests against it were made vocal in the novel and in poetry. Unfortunately the English stage was so far divorced from the national culture that it totally failed to interpret in terms of drama the immensely important and immensely exciting developments in the knowledge, wealth and power of mankind. If ever history was throwing material to the playwright it was then; but the playwright was too busy with importing French trivialities or concocting the farces of the routine to pay any attention to his superb opportunities of doing for the theatre what Dickens and Thackeray were doing for the novel. It was only after Ibsen had revolutionized the European theatre by making his drama into a vivid criticism of actual social values that English writers who had a similar artistic purpose came to use the dramatic medium.

An Actor's Theatre.—But in the absence of a great school of playwrights there was both demand and supply of great acting. There are always three parties to the art of the theatre. There is the man who writes, the man who acts, and the man who makes the spectacle. That is a simple analysis which is capable of much refinement in one way or expansion in another. The history of the theatre shows that those three parties are continually engaged in rivalry as well as in co-operation. A struggle for the balance of power is ever in progress. Accordingly, whereas one epoch or generation is particularly distinguished for the quality of its plays and of the authors whom it attracts to theatrical service, another is the golden age of the great actor who is admired for himself alone and not in relation to the splendour or the subtlctjj of that in which he acts, while at another time the emphasis centres on display of scene or on the mass-effects controlled by the producer and the pageant-master. The theatre of England in the 19th century (or at least until the renaissance of English dramatic composition in the '80s) was predominantly an actor's theatre. Pageantry there might be; personality there had to be. The playgoer thought in terms of the actor and his individual magnetism and, whereas the man of culture in 1920 would have said to his friend "Shall we go and see the new Galsworthy or the new Shaw?" his predecessors in polite playgoing would have said in the various earlier periods "Shall we go and see Kemble or Kean or Macready, or Phelps, or Irving?" The primary interest was not in the thing written, but in the thing done. The great actors did not wish to be brief chronicles appearing in the works of the moment but liked to take part in the histrionic tournament provided by rival appearances in the great historic *rôles*. They appealed to connoisseurs who would match their Hamlet or Macbeth against another's. What mattered was neither the mind of the original Shakespeare, nor the absence of a new one, but the arrival of a new virtuoso who would berattle the town with his rhetoric or conquer it with his grace in some grand Shakespearian *rôle*.

The Reign of Henry Irving.—The sovereignty of Henry Irving in the theatre of the time can best be understood if we remember to what extent that theatre was under the actor's domination. Irving carried on the social service of the Bancrofts in bringing honour to his art and rescuing his profession from squalor and from disrepute. Yet of this most eminent Victorian, whose name is almost synonymous with the national theatre of his time, an otherwise sympathetic critic could remark "His managerial career had scarcely any significance for the living English drama. He seldom experimented with a new play, and, of the few which he did produce, only *The* Cup and *Becket* by Lord Tennyson have the remotest chance of being remembered." And even these were soon forgotten. But the man was not. To see *The Bells*, an adaptation from the French of Erckmann-Chatrian, without Irving was to see an ordinary melodrama which might in later years have formed part of a Grand Guignol programme. But Irving's emotional powers enabled him to turn "tushery" into tragedy; he could strike terror, though he sometimes failed to raise compassion, with the result that his melodramatic villains were more successful than his tragic heroes. His reign at the Lyceum (1878–99), in which for so long he had Ellen Terry as his colleague in command, was a sustained and, on the whole, successful demonstration of the benefits that may lie in an actor's dominion over the dramatic art. His Richard III., Iago, and Shylock were commonly accepted as brilliant and he could raise a melodrama like *The* Lyons *Mail* from its natural level of efficient artifice to the higher category of the tragedian's art. There will always be different delights of the theatre and it is a fair distinction which separates the drab talents from the flamboyant. By drab one seeks, without slight, to denote the quiet pleasures of logic, the whisper of realism, and the puissance of that art which is, on the surface, no more than a hint. The

Victorian theatre was the home of the rhetoricians and the flamboyants, and Irving, who went into battle nightly with all his drums beating, was at once the sovereign and the symbol of his time.

Melodrama.— This cult of flamboyance had naturally its various levels. One aspect was the popularity of translations of Sardou, a French playwright who exploited situation with exceptional cunning. His play *Dora*, first produced in English as *Diplomacy* at the Prince of Wales's in 1878 and since frequently revived in London and elsewhere, is a perfect example of the well-made play built to frame highly coloured acting. Lower down the scale there was a steady flow of melodrama, and Henry Arthur Jones, afterwards to be a considerable master of the comedy of manners, won an early success with *The Silver King*, which was produced at the Princess's in 1882 and showed a technical adroitness later to be expended on less crude material. In this *genre* Wilson Barrett was a great performer, George R. Sims a competent and fluent librettist, and the Adelphi theatre a constant home of flamboyant spectacle and unabashed sensationalism. At Drury Lane the famous Christmas pantomimes with their vast display and costly transformation scenes were followed by equally resplendent dramas and the management of Sir Augustus Harris (1879–96) provided many popular triumphs in this type of work. Arthur Collins, who later carried on and developed the tradition of Drury Lane, was no less successful. Melodrama in its crudest form had great difficulty in surviving the competition of the films, but it stayed on obstinately at the Elephant and Castle theatre in south London and during 1927 and 1928 there was a large middle-class audience which made pilgrimages to see and to titter at such flamboyant folk-plays as *Maria Marten* and *Sweeney Todd*.

The mid-Victorian musical stage was in subjection to the Offenbach tradition. That might have meant delightful entertainments, but the adaptations were badly made and now seem pitifully inane. Another form of entertainment was the burlesque which was initiated by J. R. Planché and well developed by the founder's hand; but it was grossly abused by less competent people and the fact that the lamp might shine brightly at the Gaiety did not guarantee a parallel radiance elsewhere. The great mid-Victorian contribution to light opera and the musical theatre in general was the partnership of W. S. Gilbert with Arthur Sullivan. The brief extravaganza *Trial by Jury* (1875) was followed by a long series of operettas, gently satirical and exquisitely melodious, of which *Patience*, a brilliant lampoon of the aesthetic movement, was perhaps the cleverest, while *The Mikado* and *The Yeomen of the Guard* have remained the most popular. Though the two great co-operators were frequently at odds with one another they did their best work in association and the D'Oyly-Carte management at the Savoy theatre from 1881 onwards enjoyed a constant, a wide, and a discriminating support. Meanwhile burlesques fell out of favour and were displaced by a type known as "musical comedy," of which the first example was *In Town*, produced in 1892. The musical comedy adds light airs and "lyrics" to a plot of no consequence; it is less ambitious musically than light opera and it can absorb, on the other hand, the more obvious humours associated with the music-hall stage. It, in turn. found a new rival in "revue," a form of song-and-dance show interspersed with skits and sketches. It may be intimate and satirical or imposing and spectacular. Revues were popular at the Empire music-hall before the World War when ballet was an important element in their composition. Afterwards their elastic form made them a useful medium for any form of light entertainment. In the hands of Ronald Jeans and Noel Coward they were often the containing vessels of really brilliant satire on the fashions of the day and the follies of the town.

H. A. Jones and A. W. Pinero.—The orientation of theatrical effort towards great feats of acting and displays of personal magnetism continued until the end of the century. The visits to England of Duse and Bernhardt and the emergence of an English actress of great power and individuality in Mrs. Patrick Campbell created an intense and stimulating rivalry and a triangular tournament of talent. In June 1895, Bernard Shaw, then critic of The *Saturday Review* wrote "We critics can at last outdo Hazlitt and Leigh Hunt if we have a mind to; for we have just had two Mrs. Ebbsmiths to compare, beside a fourth Fédora, and Duse and Bernhardt playing *La Dame aux Camellias* and Sudermann's *Heimat* against one another at Daly's theatre and at Drury Lane." At the same time, however, the author was recovering his position in the English theatre and a distinct renaissance of the playwright's art began to be noticeable in the '80s. Henry Arthur Jones graduated from emotional drama to write urbane comedy like *The Liars* (1897), or deft plays of situation like *Mrs. Dane's Defence* (1900), while A. W. Pinero, beginning (1885–87) as a *farceur* with three very promising pieces *The Magistrate*, *The Schoolmistress* and *Dandy Dick*, passed on by way of sentimental comedy *(Sweet Lavender)* to become a master of drawing-room drama and England's most important manipulator of the fashionable problem-piece. After composing some pieces of improving quality he wrote *The Second Mrs. Tanqueray* which was produced at the St. James's theatre in 1893 and caused an immediate sensation. Undoubtedly the power and the expertness of this drama presented Pinero with a reputation which was European as well as English. Mrs. Tanqueray's story was followed up by a rapid succession of pieces which kept the dramatist in perpetual discussion and made attendance at his work an essential pleasure for the educated members of London society. *Trelawny of the Wells* was one of his most popular comedies, while *The Gay Lord Quex*, *Iris*, *Letty* and *His House in Order* revealed the many facets of his industry and his technical competence. Meanwhile the successes of Pinero and Jones were calling the notice of managers and actor-managers to the possibilities of using the fresh work of English authors instead of relying, as of old, upon a flow of adaptations. Hence it was that Sydney Grundy, R. C. Carton, Haddon Chambers and others found their opportunities and took them. The partnership of Jones's writing with Wyndham's acting was a notable feature of the '90s. Carton turned out a very capable sequence of light comedies in which his wife, who acted as Miss Compton. was a constant and all-conquering performer. *Lady Huntworth's Experiment* and *Mr. Hopkinson* were typical of his light invention. A new generation of playwrights began to appear. The theatre had recovered its esteem and men of letters need no longer hesitate to contribute to it lest their work should be botched by vulgarity of performance or despised owing to the house in which it was lodged. Oscar Wilde, for instance, turned to the theatre in 1892 and brought to the art of comedy his extraordinary brilliance in artificial dialogue. His mastery of epigram and paradox may seem a brittle talent, but it carried distinction of style into a region from which style had long been absent. Between 1892 and 1895 Wilde wrote *Lady Windermere's Fan*, *A Woman of No Importance*, *An Ideal Husband*, and, most durable of all, *The Importance of Being Earnest*. Between 1902 and 1908 J. M. Barrie, a journalist turned novelist and then dramatist, gave to the stage *Quality Street*, *The Admirable Crichton*, *Little Mary*, *Peter Pan*, *Alice Sit by the Fire* and *What Every Woman Knows*. Among other names that must be mentioned as valuable servants of the stage at that period are those of H. V. Esmond, Albert Sutro and Hubert Henry Davies.

Ibsen's Influence.— At this point it is necessary to turn back and to trace as briefly as possible the external forces which were helping to re-create the English drama after the long inertia of the 19th century. Ibsen's influence had begun to penetrate Europe in 1875 and for the next 20 years his steady output of plays, in which the driving actuality of a realistic method was applied to a social criticism and a radical philosophy of personal independence, made him a pre-eminent figure in any centre where the stage was considered as something more than a pastime and a plaything. When the rebellious wife, Nora, banged the door of *A Doll's House* (1880), the echo of that violence was heard across the continent, and the bitter criticisms of respectability which followed in *Ghosts* started a battle of the critics and a storm of discussion wherever that play was produced. As Ibsenism gathered force there were sporadic but simultaneous movements in the great capitals with the common goal of a new theatrical art freed from the old bondage of routine entertainment, from the rhetoric and the rant of the old acting, and from the fripperies of

the old method of presentation. The new drama was to be expressive of the social needs and purposes of the time. Antoine, a gasworks clerk who began his theatrical experiments in a garret to which he pushed his properties in a hand-cart, founded the Théâtre Libre in Paris in *1887* and transferred to the stage the naturalism which had replaced rdmanticism in the French fiction of his time. He strove to develop a drama which should mirror the pains, pleasures and problems of the day and a style of acting which should be quietly harmonized with the new method of writing. The revolt spread rapidly and "free theatres" were founded in the various capitals and, in turn, gave rise to other small, independent play-houses with such titles as the Modern theatre or the Art theatre. The famous Moscow Art theatre was founded in *1895* as a practical protest against the fustian of alien origin and the eternal traffic in stale French trifles which obstructed all progress on the Russian stage. The idea of the founders, Danchenko and Stanislavsky, was to elicit in terms of what they called "spiritual realism" a native Russian drama which should be representative of the younger generation, of its criticism of life, and of its aspirations and its resolves. "In our destructive and revolutionary aims," wrote Stanislavsky, '(in order to rejuvenate the art we declared war on all the conventionalities of the theatre wherever they might occur—in the acting, the properties, the scenery, or the interpretation of the play." As a result the author Chekhov, who had been on the verge of a suicidal despair, was able to do his work in sympathetic company and comparative cheerfulness and so to achieve his loveliest self-expression before he died. The new theatres, in short, were fostering new dramatists who, in turn, were fostering a new modesty and veracity in the players for whom they provided truthful and subtle dialogue and situations sincerely contrived instead of the familiar *clichés* of theatrical word and melodramatic deed.

The Arrival of Bernard Shaw.—The English parallel of the various free theatres was called the Independent by its founder J. T. Grein and was opened in *1891* with a performance of *Ghosts.* To begin with its directors were naturally attracted by translations of the new and important foreign work. The Independent gave Ibsen and Zola. But in the winter of *1892* it found its man. *Widowers' Houses* by Eernard Shaw was produced and met with no particular enthusiasm. But a new master had broken into the theatrical world and one who was claimed by many to be the greatest English dramatist since Shakespeare began to compose regularly for the stage. The theatre, viewed as a section of the industry of entertainment, may have begun by resenting his invasion as it had resented the arrival of Ibsen and the Ibsenites. But the art of the drama was not to be kept for ever in complete subjection to the commercial machine. The new drama had to live from hand to mouth, by subscription performances on Sunday nights, by special matinées, and by the efforts of amateurs. But it lived audaciously and obstinately and so established its independence. The Stage Society was founded in 1900 to produce on Sunday evenings the plays of merit and of experiment which could not find a home inside the ordinary playhouse, and there have been many subsequent organizations of a similar type and a similar object. The Stage Society discovered Granville Barker as author and producer and it was the Vedrenne-Barker partnership at the Court theatre (1904–07) which won for the first time a considerable English public and a wide recognition for Bernard Shaw. The Court became a practical academy for young actors in search of experience and an outlet for the new authors who were using the method of Ibsen to record their affirmations about every aspect of life. The chief Shaw successes at the Court were *You Never Can Tell, Man and Superman,* in which Granville Barker gave a particularly brilliant performance of the chief part, *John Bull's Other Island, Major Barbara* and *The Doctor's Dilemma.* Another outstanding production was that of *The Silver Box,* which introduced John Galsworthy to the playgoing public, and Prof. Gilbert Murray's translations of Euripides were also among the novel features of the Court programme. St. John Hankin (1869–1909) was a new dramatist to whom the commercial theatre was not usually hospitable. The Court season gave him new opportunities, while Granville Barker's own play *The Voysey Inheritance* was staged under the inspiring direction of the author.

The "Literary" Drama.—From this it may be seen that a remarkable and valuable change had come to the English theatre. The sovereignty of the actor and the actor-manager did not pass away because a few challenging trumpets had been blown outside the walls of the commercial theatre. Sir Herbert Beerbohm Tree continued at His Majesty's theatre to blend poetry with pageantry and both with personality. Stephen Phillips, a poet whose reputation stood astonishingly high in his time but was doomed to an almost complete eclipse after his death, composed *Ulysses* (1902) and *Nero* (1906) for Tree, who also employed Comyns Carr and Louis N. Parker as dramatists or perhaps it would be fair to say as librettists for his grand essays in stage-craft and mass-production. Tree's Shakespearian ventures were launched upon a full spread of scenic canvas and he himself was an actor of resource with a rich technique for the elaboration of character parts. But outside and beyond the splendours of His Majesty's with its tonnage and poundage of panoramic effects, its occasional droves of livestock, and its constant largesse of the incidentals and accessories of drama, the new English voice was making itself heard. It was often quiet and argumentative in distinction to the rhetoric and the colour of conventional work, but it became attractive to the young men and women who found in the theatre a mode of expression which would never have been contemplated by their fathers. There had, of course, been a Victorian "literary" drama. All Tennyson's verse-plays have been acted *(Harold,* long neglected, was given in London in, *1928)* while Swinburne's large output of tragedy has been strangely underrated: despite his lack of concentration he had some sense of the theatre as well as a superb fluency, and his trilogy on Mary Queen of Scots might yet survive if carefully prepared for the stage. Most poets of the period composed occasionally in dramatic form. Robert Bridges wrote *Prometheus (1883)* and *Nero* (1885) while John Davidson poured his wild fancy, anger and despair into a series of published plays. Thomas Hardy also presented his gigantic study of the Napoleonic wars in three volumes of acts and scenes. *The Dynasts,* with its cosmic sweep and philosophic chants as well as its routs and triumphs of embattled hosts, might seem to be beyond the compass of any stage, but Granville Earker produced an epitome which was in fact its essence at the little Kingsway theatre in 1914 and a similar version was played at Oxford in *1921.* But the drama of the poets never exercised a strong hold upon the playgoer: the English had lost their tradition of poetic drama and the manager who sought to revive it was taking serious risks. What did come into the English theatre at the turn of the century was a drama that was only "literary" in the sense that it might be composed by authors who were demonstrating their taste and talent in other fields.

Repertory Theatres.—The Vedrenne-Barker season at the Court was the prelude to the revival of the English stock-company system with a heightened ambition. The new movement abandoned the name of "stock" for that of "repertory" and it was to the new repertory theatres that the men of letters and the young dramatists eagerly turned for their opportunities. Shaw had already revealed an example of how inclusive the kingdom of drama might become. The new dramatists were not only to abandon the old theatricalism with its tedious repetition of plots in which farcical misunderstandings or sexual intrigues were almost the only constituents; they were to shrink from nothing in politics or economics, in ethics or metaphysics. They were to resume the Ibsenite tradition and make the English theatre an informed critic and mouthpiece of its age with the actor no longer domineering in all the richness of a star-part and exhibiting a star-personality but co-operating with the dramatist as an abstract and brief chronicle of the time.

At the Court theatre in London the example had been set; it was in the provinces, however, that the distinctive "repertory" movement was established. The absence of any national or municipal endowments for the theatre meant that the necessary funds for the creation of theatres which could hardly be (and

were not intended to be) serious competitors in the industry of entertainment had to be found among private patrons of the arts and enthusiasts for dramatic enterprise. Alfred Wareing, a young touring-manager fired by a great enthusiasm for the new drama, was enabled by some men of civic spirit in Glasgow to take over the Royalty theatre as a citizens' playhouse and there he maintained an ambitious repertory for several years. Meanwhile Miss A. E. F. Horniman, who had been private secretary to W. B. Yeats and had backed the production of Shaw's *Arms and the Man* at the Avenue theatre in 1894, opened the Abbey theatre in Dublin ten years later. In 1907 she used the Midland theatre, Manchester, to produce Charles MacEvoy's play *David Ballard,* and next purchased the Gaiety theatre in the same town and ran it until 1921, when it was sold to a cinema syndicate. The great period of the Gaiety was in the years between 1908 and 1914, during which time it attracted the widespread attention of critics and authors, enlisted the services of young players and producers who were afterwards to become leaders of the English theatre and gave the name of "Manchester school" to a particular kind of play and type of presentation in which quietness and sincerity were familiar characteristics. Among the authors who found fine opportunities at the Gaiety were Charles MacEvoy, Allan Monkhouse, John Masefield, Stanley Houghton, Elizabeth Baker, and St. John Ervine, while the works of now established playwrights of the new school like Shaw and Galsworthy were constantly in the programme. Iden Payne was for a long time Miss Horniman's chief-of-staff, while among those who were graduating in mastering their art in the "Manchester school" were Miss Sybil Thorndike, Lewis Casson and Basil Dean. Dean conducted an experimental repertory season at Kelly's theatre, Liverpool, in 1911 and became director of the Liverpool Playhouse repertory later in the same year. In 1913 Barry Jackson founded and directed the Birmingham repertory company and built for it a special theatre. The Liverpool and Birmingham repertories survived the war and the peace, and the latter was able to send companies to London where important conquests were made. The Birmingham company, for instance, was the first to act Shaw's vast "metabiological pentateuch" *Back to Methuselah,* which was given in 1923 at Birmingham and subsequently at the Court theatre in London. It may reasonably be asked what London was doing for itself. The answer is that the repertory system had been tried in London by Charles Frohman and had failed. This experiment lasted at the Duke of York's theatre for 17 weeks in 1910. The artistic successes of this season were the productions of *Justice* by John Galsworthy and *The Madras House* by Granville Barker. The most popular piece, however, given by the brilliant company which Frohman had enlisted was Pinero's *Trelawny of the Wells.* The Frohman repertory differed from that of the provinces because he kept bringing pieces in and out of the bill on the Continental model, while the provincial repertories used the method of the "short run," changing their Programme usually once in every week. The latter plan involved a serious strain upon the actor who lived laborious days at constant rehearsals while playing in another piece at night. However, if the obligations were oppressive, the experience was invaluable. The repertory movement may have often been responsible for hasty and unripe presentations, but there is no doubt that it evoked new talents in writing and acting and had a freshening and vitalizing effect upon the whole British drama of the period. The theatre was honoured. No man of letters henceforward could be too proud to write for it and it is significant that the most distinguished novelists of the time were anxious to be dramatists. John Galsworthy frequently succeeded, Arnold Bennett had several successes, particularly in association with Edward Knoblock, John Masefield continually directed his poetry and sometimes his taut and vigorous prose towards the theatre, even Joseph Conrad made dramatic efforts, and only H. G. Wells left it to others to adapt his stories. One effect, and that an important one, of the repertory movement was to restore the theatre to its proper place in the national culture. The drama became once more representative and expressive of the living mind and the social purpose. The future historian of the first decades of the 20th century will be rash if he neglects the theatre which had become a valuable source of evidence about the opinions and aspirations of the age.

The **War and** the Theatre. — But it must riot be supposed that the repertory movement was as widely prosperous as it was intellectually significant. From a financial point of view it mas often a failure and the London theatre was still dominated by the actor-manager who chose his plays to suit his particular talent. Yet the sovereignty of such men as Sir Herbert Beerbohm Tree. Sir George Alexander, and Sir Charles Wyndham, all of whom died during the war, was a beneficent form of government compared with that of the financial syndicates which followed them and turned the playhouses into counters in a great game of hazards rather than of skill. The effect of the war on the English drama was inevitably disastrous. When so many towns, particularly the capital, were lodging houses between life and death in which men on leave snatched what relief they could, the industry of entertainment naturally flourished at the expense of the art of the theatre. The new syndicates which trafficked in playhouses and plays found a ready market for anything trivial or specracular which would bring some anodyne to the mind oppressed with care. London was packed with soldiers from all over the world to all of whom a rousing display or a rackety farce was at least intelligible. Hence it was that the typical war-play was *Chu Chin Chow*—an elaborately oriental panorama with music, which ran at His Majesty's theatre for 2,238 performances, or *The Maid of the Mountains,* a highly competent musical comedy, which was played st Daly's 1,352 times, or *A Little Bit of Fluff,* a hilarious and *risqud* farce, whose life extended to 1,241 nights. The war brought enormous runs because money was plentiful and taste was not exacting. It was a period of quantity not quality. Sir Gerald du Maurier, one of the surviving actor-managers, did, however, maintain a standard of dignity and restraint and had a long run with *Dear Brutzu,* One disastrous casualty out of the many suffered by the theatre during the war was the death of Harold Chapin, a clever actor and writer of promising comedies of which *Art and Opportunity* is the best.

After the war there were distinct signs of a theatrical renaissance. Conditions were difficult because the competition to acquire London theatres in order to produce revues and farces had driven up the rents to appalling levels. A short lease of a London theatre was now on the average four times as expensive as it was before the war, while the prices of seats had risen very little. None the less small theatres like the Ambassadors' and the St. Martin's were available for the intelligent manager and playgoer The Reandean management, directed by Alec Rea and Basil Dean, continued for season after season to stage the best available work at the latter, while H. M. Harwood, a dramatist manager, was responsible for some clever productions at the former. His best play was *The Grain of Mustard Seed,* while the chief Reandean successes were Galsworthy's *The Skin Game* and *Loyalties, A Bill of Divorcement* by Clemence Dane, *R. U. R.* by Karel Capek, and *The Likes of 'Er* by Charles MacEvoy.

Theatres in the Suburbs. — The result of the economic pressure in central London was to drive experimental work into the suburbs where old buildings could be purchased and reconstructed without risk of such ruinous losses as might overtake the producer who failed with a piece in the West End. At Hampstead Norman Macdermott opened the Everyman theatre, where work of merit was continually on view on the short run principle a3d where many players obtained precious experience in pieces which could not have faced the financial difficulties of a West End production At Hammersmith Nigel Playfair, who was knighted in 1928, working in association with Arnold Bennett, reopened the old Lyric theatre and made it into a home for the revival of period pieces, particularly of the ballad operas of the 18th century. Playfair had admirable musicians and designers to help him and the name of Claud Lovat Fraser will be always associated with the painted stage of the Hammersmith convention. The most popular of the Hammersmith revivals was *The Beggar's Opera,* which was produced in June 1920, became the rage of the town, and ran for nearly four years. Previously Hammersmith had

yielded a long run to John Drinkwater's chronicle play *Abraham Lincoln*. Another of Playfair's excellent productions was Congreve's *Way of the World* to which Miss Edith Evans, an actress who rose to the front rank by her brilliance in artificial comedy, contributed a fascinating study of Millamant.

Meanwhile at Barnes Philip Ridgeway made a theatre out of a disused cinema and had the sagacity to employ the Russian producer, Komisarjevsky, to direct his revivals of Chekhov's plays. There, on an inadequate stage, were given some of the finest performances of the time. Komisarjevsky had been trained under Stanislavsky of the Moscow Art Theatre and he brought to these revivals both a long experience of the naturalistic Russian method of stage-craft and a sympathy which enabled him to elicit from English actors a temperamental quality not usually to be found. Another of Ridgeway's productions at Barnes was *Tess of the D'Urbervilles* which Thomas Hardy had dramatized himself. Among the "outer circle" theatres to win prestige and popularity was the "Old Vic." The history of this house is an epitome of recent theatrical history. During the great days of acting the Coburg, as it was then called, was visited by such masters of craft as Edmund Kean. In the bad Victorian times it declined in esteem and became a very rough house with a very rough set of patrons who wanted only the crudest kind of fare. It was rescued by Miss Emma Cons, whose niece, Miss Lilian Baylis, carried on the reforming policy. A Shakespearian repertory was maintained during the war and afterwards a first-rate company was built up. With Robert Atkins as producer the "Old Vic" became a London, as well as a south London, institution, and the version of *Peer Gynt*, given in the summer of 1922, was widely approved and supported. The "Old Vic" has since the war performed the whole canon of plays printed in the First Folio in addition to undertaking some modern and classical adventures outside the Shakespearian routine. Moreover, the management alternated opera with Shakespeare and built up a fine social loyalty and corporate spirit among the patrons. Among the players who either made or increased their reputations at the "Old Vic" were Miss Sybil Thorndike and Miss Edith Evans.

Miss Sybil Thorndike. — The progress of Miss Sybil Thorndike and her husband, Lewis Casson, after the war was one of the remarkable features of the time. Passing from the "Old Vic" to melodrama at Drury Lane and thence to experiments in English "Grand Guignol," Miss Thorndike became a representative of the best type of actor-manager, and in this she was greatly helped by her husband's skill as producer. Among her best impersonations were her Hecuba and Medea in Prof. Murray's version of Euripides, and her Jane Clegg in St. John Ervine's play of that name; but her greatest popular success came with Bernard Shaw's *Saint Joan* which was produced at the New theatre in 1924 and had an unexpectedly long run. By means of this play with its religious interest and fierce human tragedy to leaven the author's familiar argumentative zeal Shaw found a new and larger public. *Saint Joan* was immediately translated and produced in every country with a sense of theatrical values. Among other names that emerged during this period was that of Noel Coward, who began to pour out light and cynical comedies that immediately captured the taste of the time. He did not apply himself to the technique of construction and his plays were frankly dashed off in a way that is in complete contrast to the careful and considered work of men like Pinero. But he was master of terse dialogue which perfectly hit off the accent and the affectations of contemporary Society; in *The Vortex*, his first big success, he attempted something more serious and made signs of a promise which he hardly sustained. Other dramatists to win new distinction were Allan Monkhouse with *The Conquering Hero* (1924), generally accepted as the most sensitive English war-play of the time, Ashley Dukes with *The Man with a Load of Mischief (1925)* and Somerset Maugham with *Our Betters* which had 500 performances. On the lighter stage Frederick Lonsdale had some triumphant receptions for his comedies, which seem as inconsequent as charades, and Eden Phillpotts had a tremendous run at the Court theatre with his rustic farce *The Farmer's Wife*, which was given as a holiday piece by the Birmingham repertory company after their gallant appearance in *Back to Methuselah*. This light affair kept them at their pastoral comedy labours for more than three years.

Outside London as well as in it, times were difficult for the theatre. The competition of the cinema, of broadcasting, and of outdoor sports, booms in dancing during the winter and in lawn-tennis during the summer all helped to weaken the appeal of the touring company. Moreover the important London actors seemed more reluctant than ever to leave town and the quality of the travelling teams was lower than it used to be. But the starved playgoer of the provinces determined to provide for himself. Thus, while from external signs such as the closing of historic theatres or their transmutation into cinemas, it might seem that the drama was hard hit, there was also a distinct dramatic revival which found expression in the institution of many small repertory theatres, worked on a professional or semi-professional basis, and a large extension of the amateur movement whose ambitions were now very much higher than of old. No longer did the amateur content himself with repetitions of faded West End farces; the community drama ranged from experiments in mediaeval mystery to the latest philosophy of the intellectual theatre. By 1928 there was no large town which had not some form of stock company engaged upon the kind of play which the touring system habitually missed. The well-established repertories of Liverpool and Birmingham continued to do their work consistently well and occasionally to win encouraging remuneration in money as well as in repute, while at Newcastle, Hull, Sheffield, Leeds, Manchester, Bristol, Oxford and Cambridge and other towns there were little theatres at work. The relations between the touring managers and their new rivals became strained; but there was no real cause for suspicion or jealousy. The amateur player and the new repertory theatres were creating a public interested in drama and eager to attend the professional playhouse whenever it improved the quality of its wares.

The Scottish National Players. — In Scotland one phase of the dramatic revival was the foundation of the Scottish National Players; this organization found its dramatist in John Brandane, whose best known pieces are *The Glen is Mine* and *The Lifting*. In 1928 an appeal was made to consolidate the position won by the Players and to lay the foundations of a Scottish national theatre. The supporters of this scheme included Sir Johnstone Forbes-Robertson, Sir J. M. Barrie and Neil Munro. In Wales there was a big development of community drama and the movement had its dramatist in J. O. Francis; Richard Hughes was another who at one time seemed likely to write well for the theatre and who was especially interested in the Welsh village drama In Ireland the native drama had had far deeper roots and had already matured before the war. The foundation of the Abbey theatre was a natural part of the Irish literary renaissance which came in with the 20th century. Its origins are complicated because it owes its intellectual origins to the earlier experiments and encouragements of George Moore and Edward Martyn (author of *The Heather Field)*, and their efforts to give dramatic expression to peculiarly Irish views and problems, while Miss A. E. F. Horniman had much to do with the financial organization of the new venture.

Synge and the Irish Drama. — The impulse to found an Irish theatre was in itself both natural and national; it was due to the reaction upon Irish intellectuals and poets of the general wave of independent theatres, stage societies, Vedrenne-Barker seasons and the like. The governing influence fell in the end to W. B. Yeats and Lady Gregory, both dramatists, and it was under their direction that the genius of J. M. Synge found its opportunity and its guidance. Synge was an invalid and died in 1909 before he was 40, but he had completed his *Riders to the Sea, The Well of the Saints* and *The Playboy of the Western World;* and left an unfinished and beautiful version of the Deirdre saga. It was courageous of the management to produce *The Playboy* because the Abbey theatre, on the whole, was devoted to Gaelic idealism and Synge's harshly brilliant comedy was a scathing satire on the credulity and cruelty underlying Gaelic romanticism. This production was the cause of some riots and violent recriminations,

but Synge's matchless translation of rural phrase into a rhythmic prose illumined by metaphors and similes of an exquisite fancy was bound to live down a merely local and sectional discontent caused by his notions of satirical comedy. The smallness of the Abbey stage and of the possible rewards to be won did not prevent an eager crowd of dramatists from offering their services: of these Lady Gregory, W. B. Yeats and Lennox Robinson, who were still directing the theatre in 1928, were distinguished by a variety of gifts, Lennox; Robinson, as producer, having a useful sense of the stage and its practical uses. Others who wrote and wrote finely for the Abbey included William Boyle, T. C. Murray, Padraic Colum, Seumas O'Kelly and St. John Ervine.

Sean **O'Casey.**—That the Abbey was not dependent on one or a few names was shown by its ability to find a dramatist who could express the growing pains of the new Ireland which was being born during the struggle with England. Sean O'Casey, a plasterer from the waterside tenements of Dublin, first made his reputation with a short piece, *The Shadow of a Gunman,* and then confirmed it with *Juno and the Paycock,* produced at the Royalty theatre, London, in 1925. His third piece *The Plough and the Stars* was acted in Dublin and London in 1926. The Dublin production caused some troubles because the Republicans held the play to be an insult to their cause and their martyrs. Whether or not it was an insult, it was certainly a criticism of pretentious nationalism and as such a far more bitter medicine to swallow than ever Synge had offered to his fellow-countrymen. O'Casey's acid humour and his merciless unmasking of the slum patriots were accompanied by a sharp sense of theatrical emphasis and his plays 'are likely to endure. English literary opinion was demonstrated by the award to O'Casey of the Hawthornden prize in 1926. The durability of the Abbey theatre itself was made more probable by the grant of £850 a year from the Free State Exchequer. At the same time £600 was given to the Gaelic players. No other English-speaking Government (if one may so term the Irish Free State Ministry) has ever done even this much for dramatic art. One cannot leave the question of the Irish theatre without a tribute to the extraordinary brilliance of the Irish players, a team built up at the Abbey in its early days and persisting in partnership over more than 20 years of touring and chequered history. In their rhythm of speech they found the perfect articulation for Synge's idiom; in their racy and vigorous realism they were the perfect interpreters of O'Casey. The broad humours of Arthur Sinclair, the early beauty and maturing powers of Sara Allgood and Maire O'Neill, may be selected for particular praise, but the team, as a whole, had a common quality that made their visits to England an exceptional pleasure to connoisseurs of acting. In 1920 Lennox Robinson with his play *The Whiteheaded Boy* had a really popular English success to which he was assisted by these admirable comedians.

Gordon Craig and Stage Design.—During the period under review we have seen distinct phases of theatrical history. From 1840–90 it is roughly true to say that the balance of power in the playhouse lay with the actor; from 1890–1920 the author was reinstating himself and making the drama a vehicle for his own opinions and his criticisms of life. The Ibsenite theatre temporarily defeated the Irvingite theatre. The change from a rhetorical and resonant theatre of grandiose passions to a quiet and argumentative theatre of observation and actuality was the mark of the time. On the Continent, however, there was another change in the years following the war and the producer asserted himself. Reinhardt's reputation had been made before the war, but it was not till the third decade of the century that his lieutenants established themselves and constituted a theatrical school of mass-effect and plastic design in which architectural settings and the abolition of the old proscenium-arch were important features. The influence of Edward Gordon Craig as a theorist on stage-design and as an occasional producer under conditions carefully chosen was greater in Europe and America than in England. Craig's active mind at one time saw that the logical result of a producer-controlled drama would be the reduction of the individual actor to the status of a puppet and in a relentless fit of rationalism he proclaimed the necessity of supplanting men by marionettes. That opinion, though not sustained by its originator, was really a severe criticism of the producer's theatre and of the extreme forms of sovereignty assumed by the *régisseur* in Central and Eastern Europe. Where Craig helped the English stage was by his demand for simplicity and dignity in design: he led a meritorious campaign for the use of imagination in the control of lighting and background in the theatre. His lessons were learned and English methods of production during 1918–28 showed a capacity to derive what was sensible from Continental models without accepting the rackety methods of Expressionism (the dramatic equivalent of Post-Impressionism in painting) or the relapse into mere pageantry which was typical of the annual dramatic festivals at Salzburg. The best producers of the time, Basil Dean, Nigel Playfair, A. E. Filmer, H. K. Ayliff and others, showed their power to experiment without treating the author's text as a mere libretto or the actor as a unit in a regiment of automata. In short, they accepted the three-fold partnership between actor, author, and producer and worked loyally to sustain it. **(I.** BR.)

AMERICA

The first specimens of dramatic writing in the United States of America, reflecting the tastes and tendencies of colonial and revolutionary life, showed definite English, with now and then suggestions of Teutonic influences. They were all imitative and have no interest to-day except as curios. Only two plays written by Americans were actually presented on the stage before the Revolution: *The Prince of Parthia, a* blank-verse tragedy by Thomas Godfrey the younger, arid *The Conquest of Canada, or the Siege of Quebec,* an attempt at historical drama by George Cocking. Neither contained a symptom of promise so far as native drama was concerned, nor was any discernible in the plays written by Americans in the period immediately after. Among these we have as outstanding examples the recreant Maj. Robert Rogers's blank-verse tragedy, *Ponteach, or The Savages of America;* a blank-verse lampoon of certain Boston celebrities of the day, under the title *The Group,* written by Mrs. Mercy Warren (wife of Gen. James Warren), who had gained a measure of partisan notoriety previously with a play called *The Blockheads,* an answer to Gen. Burgoyne's satiric farce, *Tlte Blockade of Boston;* a patriotic play in blank-verse. *The Rattle of Bunkers Hill,* by Hugh Henry Brackenridge; another patriotic affair, *The Fall of British Tyranny,* by John Leacock, incidentally the first example of an American chronicle play and the first in which George Washington appeared as a character; and a comedy reflecting the political spirit of the time (*c.* 1798) called *The Politician Out-Witted,* by Samuel Low, in which we have the earliest known instance of the local theatrical use of negro dialect.

The beginning of what, though still somewhat euphemistically, may be termed the real American drama was synchronous with the active appearance on the American scene of William Dunlap, in many respects the father of the American stage, and Royall Tyler. The latter's comedy *The Contrast* (the second play written by an American to be produced in America by a professional company of actors, *The Prince of Parfhia* being the first) was acted in 1787 and was the first dramatic work to introduce the character that has since become known as the stage Yankee. Written under the inspiration of *The School for Scandal,* it was also the first American play to achieve a box-office success. Dunlap wrote or adapted some 60 plays, of which the best known is his blank-verse tragedy, *André,* produced in 1798. These two men seemed to give an impetus to dramatic writing and to theatrical interest in the new Republic. Among the more significant of their successors, at least in an historical sense, were James Nelson Barker, author of *The Indian Princess, or La Belle Sauvage,* the earliest play on the Pocahontas theme, converted into a libretto for a so-called "operatic melo-drame," and produced in 1808; Mordecai M. Noah, whose *She Would Be a Soldier, or The Plains of Chippewa,* an historical drama, was shown in 1819; Joseph Hutton, actor and playwright, author of *Fashionable Follies;* John Howard Payne, fabricator of such compounds as *Brutus, or the Fall of Tarquin* and *Charles the Second;* and Richard Penn Smith, author of the historical play dealing with the war of 1812 and called *The Triumph of Plattsburg.*

In the '30s of last century there was much dramatic activity. Such things as George Washington Parke Custis's *Pocalzontas, or The Settlers of Virginia;* Robert Montgomery Bird's *The Gladiator* and *The Broker of Bogota;* and John Augustus Stone's *Metamora—all* ranting *opera* written under the inspiration of the actor, Edwin Forrest; Nathaniel P. Willis's *Torfesa the Usurer,* written under the eye of James Wallack for his own use; Joseph Stevens Jones's *The People's Lawyer* (with the unforgotten character, "Solon Shingle"); and Robert T. Conrad's *Jack Cade,* another machine-made Edwin Forrest vehicle, cleared the way for what may fairly be called the first American play of social manners—*The Contrast,* though a social satire, may be dismissed as negligible—and the first native comedy of even mild merit, namely, Mrs. Mowatt's *Fashion,* written under the strong influence of Sheridan, and produced in 1845. This *Fashion,* which enjoyed success in England as well, marks what is practically the birth of a native drama, however modest, worth critical consideration. In the years following its presentation there came into being *Uncle Tom's Cabin,* dramatized from Mrs. Harriet Beecher Stowe's novel by George L. Aiken, Mrs. Sidney F. Bateman's *Self,* Clifton W. Tayleure's *Horseshoe Robinson,* the transplanted Dion Boucicault's *The Octoroon,* dealing with the slavery question in 1859, Frank Mayo's *Davy Crockett,* the dramatization of Irving's *Rip Van Winkle,* made a theatrical classic by Joseph Jefferson, and, finally, Steele MacKaye's *Hazel Kirke* and *Paul Kauvar.*

Gradually, now, the American drama began to move on feet of its own, instead of relying almost entirely upon foreign crutches. MacKaye revolutionized the mechanics of the American stage as he had found it and, with them, certain phases of dramaturgy, at least as it had been practised. A new order of playwrights grew up. Among these, the first was Bronson Howard, the dominant dramatist in the American theatre of his day. Howard is best known for his military melodrama, *Shenandoah,* based upon a work written 20 years before, subjected to several revisions and produced in the late '80s. Among his other plays were *Saratoga* (produced as early as 1870), *Tlze Young Mrs. Winthrop, The Henrietta* and *Aristocracy.* Foreign influences were clearly discernible in some of these, as well as in others that he wrote, but above them sounded a distinctly native note that was not lost upon American audiences. The last decade of the century witnessed the abandonment of the European crutches to an even greater degree. William Gillette with his melodramas, *Held by the Enemy* and *Secret Service,* established American drama as a thing of itself. James A. Herne with his pioneer realism in *Shore Acres, Griffith Davenport* and *Sag Harbor—to* say nothing of *Margaret* Fleming—brought the American drama even more positively into its own. Charles H. Hoyt with his farces and comedies brought American types and phases of American life bodily into the theatre. The movement was furthered by Clyde Fitch, with his commentaries on the lighter side of American society, and by Augustus Thomas, with his series of so-called "State plays," beginning with *In Mizzoura.* Langdon Mitchell appeared with *The New York Idea.* George M. Cohan, whose influence was to colour much of American dramatic writing for many years afterwards, began to write musical pieces, and later on farces and comedies that were genuinely American, as also were George Ade's *The College Widow* and *The County Chairman.* William Vaughn Moody with *The Great Divide* and *The Faith Healer* took the drama into higher literary reaches. A half dozen artistically inferior but theatrically skilful playwrights like Charles Klein, Eugene Walter and Edward Sheldon busied themselves with American types and American themes and completed the divorce from European drama. These men, then, were the stems from which the present-day American drama took flower, a drama that has begun in certain of its phases to repay to Europe its long-standing debt. and to repay that debt with a measure of brilliance.

One of the foremost figures in this present-day American drama is Eugene O'Neill, whose more notable works, such as *Strange Interlude, Mourning Becomes Electra, The Emperor Jones, The Great God Brown, Desire under the Elms, Beyond the Horizon* and *The Hairy Ape,* show genuine dramatic force and'literary merit. Among hii contemporaries are men and women nho are raising American dramatic writing to a distinguished level. Maxwell Anderson and Laurence Stallings in *What Price Glory?* contributed to the stage a war drama of sweeping eloquence and devastating irony. George Kelly's *Craig's Wife* and to a lesser degree *The Show-off,* Paul Green's *In Abrahant's Bosom,* Rita Wellman's *The Gentile Wife,* the comedies of Vincent Lawrence, Zoe Akins's *A Texas Nightingale,* S. N. Behrman's *The Second Man,* and *Rain From Heaven,* Maurine Watkins's *Chicago,* Maxwell Anderson's *Saturday's Children,* Ernest Howard Culbertson's *Goat Alley,* Frank Craven's *The First Year,* George Kaufman's and Edna Ferber's *The Royal Family,* Arthur Richman's *Ambush,* Elmer Rice's *Street Scene,* Hecht and MacArthur's *The Front Page,* John Wexley's *The Last Mile,* Patrick Kearney's *A Man's Man* are other examples of modern American playwriting that call for the scrutiny of serious criticism. On a lower level it may be, but rich in illumination of the American scene, we have a procession of comedies, farces and melodramas of striking originality and suggestive humour. Competition from talking pictures and general economic depression combined to reduce patronage of the legitimate theatre for several years after 1929 and consequently. perhaps, the incentive to writers of good plays. There continued, nevertheless, to be produced each year at least a few noteworthy additions to the national dramatic record. Among those certainly deserving of mention were *The Green Pastures,* adapted by Marc Connolly from Roark Bradford's book of sketches, *Tobacco Road,* adapted from Erskine Caldwell's novel by Jack Kirkland, *The Children's Hour* by Lillian Hellman, and finally Maxwell Anderson's drama in verse *Winterset.* A reflection of political and social disillusionment appeared in a new type of satirical musical show, *Of Thee I Sing* by George Kaufman and George Gershwin. Among the other more recent valuable additions were John Steinbeck's *Of Mice and Men,* William Saroyan's *My Heart's-in the -Highlands,* Robert Turney's *Daughters of Atreus,* Robert Sherwood's *Abe Lincoln In Illinois,* Lillian Hellman's *The Little Foxes,* Paul Green's *Johnny Johnson,* Clifford Odet's *Awake and Sing,* Sidney Kingsley's *Dead End,* Arthur Arent's . . . *one-third of a Nation.*

(G. J. N.)

BIBLIOGRAPHY.—The most complete survey is A. H. Quinn, *A History of the Anzerican Drama from the Beginning to the Civil War* (1923) and *A History of the Anterican Drama from the Civil War to the Present Day* (2 vols., 1927), both works containing bibliography and an annotated list of American plays Excellent collections of plays giving a historic survey of the American drama with biographical and bibliographical notes are M. J. Moses, *Representative Plays by Anzerican Drainatzsts* (3 vols., 1918–27) and A. H. Quinn, *Representative American Plays* (rev. ed., 1925). Margaret G Mayorga, *Representative One Act Plays by Anzerican Authors* (1919) and G. P. Baker, *Modern American Plays* (1920) are also helpful collections. Among the books on recent American drama are B. H. Clark, *The Brztish and American Dranza of To-day* (1915), T. H. Dickinson, *Playwrights of the New Anzerican Theatre* (1925) and G. J. Nathan's *The Theatre of the Moment* (1937) and *The Morning After the First Night* (1938).

GERMANY

The dramatic literature of Germany, though in its beginnings, intimately connected with the great national movement of the Reformation, soon fell under the domination of foreign models. It was not until the end of the 18th century that Germany possessed a national drama of comprehensive character.

The first German (and indeed the earliest transalpine) writer to follow in the footsteps of the Italians was the famous Strasbourg humanist Jacob Wimpheling (1450–1528), whose comedy of *Stylpho* (1480) marks *a* kind of epoch in the history of German dramatic effort. It was succeeded by many other Latin plays of various kinds: Johann Reuchlin (1455–1522) wrote two plays, of which one, *Henno,* was exceedingly popular; and Konrad Celtes (1459–1508) a *Ludus Dianae,* in honour of the emperor Maximilian I The *Acolastus* (1525) of W. Gnaphaeus should also be mentioned, as, though a Dutchman by birth, he spent most of his literary life in Germany. Macropedius (Langhveldt) belongs wholly to the Low Countries; but two of the greatest Latin dramatists of the 16th century, Thomas Kirchmayer (Naogeorgus) (1511–1563) and P. N. Frischlin (1547–1590) were Germans. The flourishing period of the Jesuit drama begins with the spread of the order in the west and south-nest of the empire in

the last decade of the 16th century, and continues until well into the 18th. These productions ranged in their subjects from biblical and classical story to themes of contemporary history.

Side by side with this Latin drama there grew up an interesting literature in the vernacular which was almost exclusive of Protestant inspiration. In Switzerland, P. Gengenbach (d. 1524) and Niklas Manuel (*c.* 1484–1530) defended the new faith in plays of a kind; and in the north B. Waldis (c. 1490–1556), Sixt Birck (1501–54) and Paul Rebhun (*c.* 1500–46) wrote dramas not wanting in poetic skill. Towards the close of the middle ages dramatic performances had in Germany, as in England, largely fallen into the hands of the civic gilds, and play-writing was more especially cultivated by the master-singers of Nuremberg and other towns. Hans Sachs (1494–1576), the immortal shoemaker of Nuremberg, seemed destined to become the father of the popular German drama. In his plays, "spiritual," "secular" and *Fastnachtsspiele* alike, the interest indeed lies in the dialogue rather than in the action, nor do they display any attempt at development of character. But his healthy vigour and fresh humour, and his sympathy with the sentiments of the burgher class to which he belonged, were elements of genuine promise.

Among the foreign actors of various nations who flitted through the innumerable courts of the empire, special prominence was acquired, towards the close of the 16th and in the early years of the 17th century, by "English comedians." Through these players a number of early English dramas found their way into Germany, where they called forth imitations by native authors. Duke Heinrich Julius of Brunswick-Liineburg (1564–1613) and Jacob Ayrer (a citizen of Nuremberg, where he died, 1605) represent the endeavours of the early German drama to suit its still uncouth forms to themes suggested by English examples. The popularity of these strollers was owing to the blood and other horrors with which their plays were deluged, partly to the comic scenes with which they seasoned their performances. The English clown was a model for the various types of German buffoon, known as Hans Wurst, Pickelharing, Ian Bouset, etc., who for generations were the real masters of the German stage. The grossness and ribaldry into which the popular theatre degenerated estranged it from the tastes and sympathies of the educated classes; then came the Thirty Years' War which put its development and improvement in the 17th century out of the question.

When German poets once more began to essay the dramatic form, the national drama was left outside their range of vision. M. Opitz (1597–1639) contented himself with translations of classical dramas and of Italian pastorals. A. Gryphius (1616–64), though as a comic dramatist lacking neither vigour nor variety, chiefly devoted himself to the imitation of Dutch tragedy, the rhetorical dialogue of which he effectively reproduced in the Alexandrine metre. Neither the turgid dramas of D. C. von Lohenstein (1635–83), nor the more natural comedies of Chr. Weise (1642–1708) were brought upon the public stage. The frigid allegories commemorative of contemporary events, and the pastoral dramas of the Nuremberg "shepherds of the Pegnitz" had little value, except in so far as they kept alive the love of dramatic composition and representation.

The history of the German stage remains to about the second decennium of the 18th century one of the most melancholy chapters of theatrical history. Improvisation reigned supreme, not only in farce, where *Hans Wurst* never ceased to charm his public, but in the serious drama likewise (in which, however, he also played his part) the so-called *Haupt- und Staatsactionen* (high-matter-of-State dramas). The hero of this period is "Magister" J. Velthen (or Veltheim) (1640–92), who at the head of a company of players for a time entered the service of the Saxon court, and, by reproducing comedies of Molière and other writers, sought to restrain the general licence. After his death (c. 1693) chaos ensued. But the strolling companies continued to foster the popular love of the stage, more especially at Vienna, where from about 1712 the first permanent German theatre was maintained. But for the actors in general there was little permanence, and amidst miseries of all sorts, and under the growing ban of clerical intolerance, the popular stage seemed destined to hopeless decay.

The first endeavours for reform were neither wholly nor generally successful; but this does not diminish the honour due to two names which deserve all respect. Karoliiie Neuber's (1697–1760) biography is the story of a long-continued effort which may almost be described as heroic. As directress of a company of actors which from 1727 had its headquarters at Leipzig, she resolved to put an end to the formlessness of the existing stage, to separate tragedy and comedy, and to abolish the Harlequin. In this endeavour she was supported by the Leipzig professor, J. Chr. Gottsched (1700–66), who induced her to establish French tragedy and comedy as models of the regular drama, and himself supplied a tragedy, *Der sterbende Cato* (1731), based on English and French models. Literature and the stage thus for the first time joined hands. Men of letters now began to subject their dramatic compositions to the test of performance; the tragedies and comedies of J. E. Schlegel (1719–49), the sentimental comedies of Chr. F. Gellert (1715–69) and others, together with the vigorous popular comedies of the Danish dramatist Holberg, were brought into competition with translations from the French. On the other hand, the Leipzig school exercised a continuous effect upon the progress of the art of acting, and before long produced in K. Ekhof (1720–78) an actor of distinction.

Lessing.—Among the authors contributing to Mme. Neuber's Leipzig enterprise was G. E. Lessing (1729–81), whose services both to the German drama and to dramatic criticism cannot be overestimated. His *Hamburgiscke Dramaturgie,* a series of criticisms of plays and (in its earlier numbers) of actors, was undertaken in furtherance of the attempt, unfortunately unsuccessful, to establish at Hamburg the first national German theatre (1767–69). But the most important effect of the *Dramaturgie* was to overthrow the dominion of the arbitrary French rules and the French models established by Gottsched. Lessing vindicated its real laws to the drama, and established the claims of Shakespeare as the modern master of tragedy. His own *Miss Sara Sampson* (1755) introduced the realism of the English domestic drama to Germany. Then, in his *Minna von Barnhelm* (1767), which owed something to Farquhar, he essayed a national comedy drawn from real life, and appealing to patriotic sentiments as well as to broad human sympathies. It was written in prose, like *Miss Sara Sampson,* but in form held a judicious mean between French and English examples.

The note sounded by the criticisms of Lessing met with a ready response. On the stage, Harlequin and his surroundings proved by no means easy to suppress, more especially at Vienna; but even here a reform was gradually effected, and, under the intelligent rule of the emperor Joseph II., a national stage grew into being. The mantle of Ekhof fell upon the shoulders of his eager younger rival, F. L. Schroder (1744–1816), who was the first to domesticate Shakespeare upon the German stage. In dramatic literature few of Lessing's earlier contemporaries produced any works of value; his friend Chr. F. Weisse (1726–1804) wrote many popular plays; S. Gessner, J. W. L. Gleim and G. K. Pfeffel (1736–1809) composed pastorals; while F. G. Klopstock's (1724–1803) patriotic and religious dramas hardly concern the actual stage. But a far more potent stimulus prompted the efforts of the younger generation. The translation of Shakespeare, begun in 1762 by C. M. Wieland (1733–1813), and completed in 1775 by J. J. Eschenburg, helps to mark an epoch in German literature. Under the influence of Shakespeare arose a youthful group of writers who worshipped their idol as the representative of nature in the theatre. Lessing in his third important drama, the prose tragedy *Emilia Galotti* (1772), set the example of a work of incomparable nicety in its adaptation of means to end. But successful as it proved, it could not stay the excesses of the *Sturm und Drang* period which now set in. Lessing's last drama, *Nathan der Weise* (1779), was not measured to the standard of the contemporary stage; but it caused a reaction in tragedy from prose to blank verse (first essayed in J. W. von Brawe's *Brutus,* 1770), ennobling by its moral dignity the branch of literature to which in form it belongs.

Goethe.—Meanwhile the young geniuses of the *Sturm und Drang* had gone forth, as worshippers rather than followers of Shakespeare, to conquer new worlds. The name of this group of

writers was derived from a drama by one of the most prolific of their number, M. F. von Klinger (1752–1831); other members of the fraternity were J. A. Leisewitz (1752–1806), J. M. R. Lenz (1751–92), H. L. Wagner (1747–79), and F. Mdller the "painter" (1749–1825). The youthful genius of the greatest of German poets contributed to the movement the first of its masterpieces. Goethe's (1749–1832) *Götz von Berlichingen* (1773), both by the choice and treatment of its national theme, and by its freshness and originality, holds a position of its own in German dramatic literature. Though its irregularity of form prevented its complete success upon the stage, yet its influence is far from being represented by the series of mostly feeble imitations, the so-called *Ritterdramen* (plays of chivalry), to which it gave rise; it destroyed the last remnants of theatrical conventionality, and extinguished with them the lingering respect for rules and traditions of dramatic composition which even Lessing had treated with consideration.

Thus, in the classical period of that literature, of which Goethe and Schiller were the ruling stars, the drama had a full share. The dramatic works of Goethe vary widely in form and character, and his way of composition was so peculiar to himself that the history of his dramas cannot be severed from his biography. His *Clavigo* and *Stella,* which succeeded *Götz,* are domestic dramas in prose; but they could not influence the progress of the national drama. In the first conception of his *Faust,* he had indeed sought the suggestion of his theme partly in popular legend, partly in a domestic motive, the story of Gretchen; but the later additions to the First Part (1808), and the Second Part (1832) generally, are the results of meditations belonging to wholly different spheres of thought and experience. The dramatic unity of the whole is thus external only; and the standard of judgment to be applied to this wondrous poem is not one of dramatic criticism. *Egmont* (1788), originally designed as a companion to *Gotz,* was not completed till many years later; in *Iphigenia* (1787) and *Tasso* (1790), Goethe exhibited the perfection of form of which his classical period had enabled him to acquire the mastery.

Schiller.—Schiller's (1759–1805) genius, unlike Goethe's, was naturally and consistently suited to the claims of the theatre. His juvenile works, *Die Rauber, Fiesco, Kabale und Liebe* (1781–84), vibrating under the influence of an age of social revolution, combined in their prose form the truthful expression of passion with considerable extravagance. But Schiller gradually emancipated himself from his earlier style; and with his earliest tragedy in verse, *Don Carlos,* the first period of his dramatic authorship ends. The works of his maturity (1798–1805)—from the *Wallenstein* trilogy to *Wilhelm* Tell—are the acknowledged masterpieces of the German poetic drama, treating historic themes reconstructed by conscious dramatic workmanship, and clothing their dialogue in a noble vestment of rhetorical verse.

Schiller gradually conquered the stage, on which his *Don Carlos* had met with a cold welcome. For a long time, however, its favourites were authors of a very different order, who suited themselves to the demands of a public indifferent to the literary progress of the drama. Popular tastes oscillated between the imitators of *Gotz* and those of *Emilia Galotti,* and as the establishment of standing theatres at the courts and in the large towns increased, demanded above, all good "acting" plays. Famous actors, such as Schroder and A. W. Iffland (1759–1814), sought by translations or compositions of their own—sentimental domestic dramas—to meet the popular likings. But the most successful purveyor of such wares was an author who understood the theatre with a professional instinct—August von Kotzebue (1761–1819). His productivity ranged from the domestic drama and comedy to attempts to rival Schiller and Shakespeare in verse; and though his popularity brought upon him bitter attacks, his self-conceit is not astonishing, and the time has come for saying that there is some exaggeration in the contempt which has been lavished upon him by posterity. Nor should it be forgotten that German literature had so far failed to furnish the comic stage with any successors to *Minna von Barnhelm.* The joint efforts of Goethe and Schiller for the Weimar stage, important in many respects for the history of the German drama, at the same time revealed the want of a national dramatic literature sufficient to supply the needs of a theatre endeavouring to satisfy the demands of art.

The Romantic School.—Meanwhile the so-called Romantic School of German literature was likewise beginning to extend its labours to the drama. To its leaders Germany owed its classical translation of Shakespeare, and other great foreign dramatists. But the original drama of the romanticists was strangely ineffectual. Outside the school, the youthful talent of Th. Körner (1791–1813) was full of promise, cut off prematurely by his patriotic death. But of the leaders of the romantic school, A. W. and F. von Schlegel (1767–1845; 1772–1829) contented themselves with frigid classicalities; and L. Tieck's (1773–1853) plays are written with small consideration for the stage. F. de La Motte Fouqué (1777–1843) tried to infuse poetry into the chivalry drama. Klemens Brentano (1778–1842) was a fantastic dramatist unsuited to the stage. Here a feeble outgrowth of the romanticists, the "destiny dramatists" Z. Werner (1768–1823)—the most original of the group—A. Müllner (1774–1829) and C. E. v. Houwald (1778–1845) achieved a temporary success; and it was with a play of this kind, *Die Ahnfrau* (1817), that the Austrian dramatist F. Grillparzer (1791–1872) began his career. He is assuredly the foremost of the later dramatic poets of Germany, unless that tribute be thought due to the genius of H. von Kleist (1777–1811), who in his short life produced, besides other works, a romantic drama and a rustic comedy of genuine merit, and an historical tragedy of singular originality and power. Grillparzer's long series of plays includes poetic dramas on classical themes and historical subjects from Austrian history. The romantic school, which through Tieck had satirized the drama of the *bourgeoisie,* was in its turn satirized by Count A. von Platen-Hallermunde's (1796–1835) admirable imitations of Aristophanic comedy. Among the objects of his banter were the popular playwright E. Raupach (1784–1852) and K. Immermann (1796–1840), a true poet, who is, however, less generally remembered as a dramatist. F. Hebbel (1813–63) is justly ranked high among the foremost later dramatic poets of his country, few of whom equal him in psychological insight. Other names of literary mark are those of C. D. Grabbe (1801–36), J. Mosen (1803–67), O. Ludwig (1813–65) and in Austria, "F. Halm" (E. F. J. von Münch-Bellinghausen) (1806–71), E. von Bauernfeld (1802–90) and in the domain of fairy-play and farce, F. Raimund (1790–1836) and J. Nestroy (1801–62). The popular dramatists about the middle of the century were K. Gutzkow (1811–78), G. Freytag (1816–95) and H. Laube (1806–84); while, a little later, L. Anzengruber (1839–89), a writer of real genius though restricted range, imparted a new significance to the Austrian popular drama.

During the long period of transition which may be said to have ended with the establishment of the new German empire, the German stage made rapid progress. This was due, partly to a succession, from Ludwig Devrient onwards, of brilliant actors, and partly to theatre managers inspired by the best ideals. The ablest of these was perhaps H. Laube, director of the Vienna Burgtheatre and afterwards of the theatre in Leipzig. F. Dingelstedt, again, in Munich, and subsequently at Weimar and Vienna, raised the theatre to a high level of artistic achievement. At a rather later period, of which the height extended from 1874 to 1890, the company of actors in the service, and under the personal direction, of Duke George of Saxe-Meiningen, created a great effect by their performances both in and outside Germany, both by their artistic settings and the extraordinary perfection of their *ensemble.* But no dramaturgic achievement in the century could compare in grandeur either of conception or of execution with Richard Wagner's Bayreuth performances, where, for the first time in the history of the modern stage, the artistic instinct ruled supreme in all the conditions of the work and its presentment. Though the *Ring of the Nibelung* and its successors belong to opera rather than drama proper, the importance of their production (from 1876 on) should be overlooked by no student of dramatic art.

The Coming of the Realists.—The most significant development of the German theatre during the last century took place at

its close, under the influence of French and Scandinavian realism. The younger generation of German dramatists freed themselves from the persistent Schillerian tradition of the iambic drama on the one hand, and, with the assistance of Ibsen's example, from the tyranny of the machine-like intrigue drama, which had dominated the French stage from Scribe to Sardou, on the other. The revolt was inaugurated by Gerhart Hauptmann (b. 1862) with his *Vor Sonnenaufgang,* and by Hermann Sudermann (1857–1928) with his *Die Ehre,* both produced in the autumn of 1889. With them were associated a number of young playwrights, of whom Max Halbe (b. 1865), O. E. Hartleben (1864–1905) and G. Hirschfeld (b. 1873) produced plays that left a mark on their time. Against this new realism the efforts of the ablest of the more conservative dramatists, E. von Wildenbruch (1845–1909), to keep the historical drama alive, had a difficult stand. But realism on the German stage was short-lived. After the production of his *Die Weber* (1892) and the excellent comedy *Der Biberpelz* (1893), Hauptmann turned to more poetic themes *(Die versunkene Glocke,* 1897); the dramatic fairy-tale came into honour again. Hauptmann has shown himself exceedingly sensitive to the changes in literary taste and skilfully adapted himself to them. He has returned repeatedly to realism, but has employed it rather in the presentation of subtle psychological conflicts than in the depiction of *milieu,* while in verse he has written a number of dramas of imaginative beauty — notably *Und Pippa tanzt* (1906) and the two Mexican plays of his last period (1920) — without, however, repeating the popular success of *Die versunkene Glocke.* The democratic sentiments of his *Festspiel für die Jahrhundertfeier,* written in 1913 to celebrate the centenary of the downfall of Napoleon, were unpalatable to the ruling classes, which led to its withdrawal. Sudermann, who attained a world-wide fame with his *Heimat* in 1893, was less successful in keeping himself abreast of the literary movement; the essentially theatrical nature of his talent brought him into undue discredit in an age which was endeavouring to get away from the traditions of the "well-made play." But he cannot be accused of lack of significant ideas, and his powers of dramatic characterization were superior to those of most of his more ambitious contemporaries.

In Austria, where the great Burgtheater still maintained, in spite of the growing rivalry of Berlin, the premier place among German theatres, the realistic drama bears a definitely Austrian stamp. Here the leading dramatists were Arthur Schnitzler (1862–1931) and Hermann Bahr (1863–1934); while in the domain of the poetic drama Hugo von Hofmannsthal (1874–1929) proved a significant force in subsequent developments of the higher drama. Here, too, Karl Schonherr (1869–)has attained wide popularity with his dramas of peasant life, notably *Glaube und Heimat* (1910).

Expressionism. — Frank Wedekind (1864–1918), whose somewhat violent and grotesque plays may not have great abiding value, had nevertheless a decisive influence on the development of German realism, and prepared the way for the last phase of the drama, that of the so-called "expressionism." The expressionistic drama emerged on the very eve of the World War; and its best known exponents were Georg Kaiser (1878–) and Ernst roller (1894–1939). The former an exceedingly prolific writer, gave the new movement such characteristic plays as *Die Burger von Calais* (1914), *Von Morgens bis Mitternachts* (1916) and the trilogy *Gas* (1918–20), while Toller's most characteristic contribution was *Massemensch* (1921). Other expressionist dramatists of distinction were Karl Sternheim (1878–), Walter Hasenclever (1890–), Reinhard Sorge (1891–1916) and Reinhard Goering (1887–1936). Of finer calibre is F. von Unruh (1885–), who, during the World War, became a convert from militarism to pacifism. But expressionism promises to be an even less stable force in German drama than realism had been; and the demand for a return to actuality is already making itself felt. Meanwhile there have been since the beginning of the century a large number of dramatists who have cultivated the poetic drama of mediaeval history and story. Conspicuous among these are H. Eulenberg (b. 1876), Ernst Hardt (b. 1876), K. G. Vollmoller (b. 1878) and Paul Ernst (1866–1933); one of the most successful and poetically significant dramas of this class has been *Spiegelmensch* (1920) by Franz Werfel (1890–).

Particularly interesting has been the technical development of the German theatre in recent years. A new art of stage production was initiated by Max Reinhardt (b. 1873), who, setting out from the careful *ensemble* productions of the Meiningen, substituted for their often excessive historical accuracy in scene and costume a more imaginative interpretation of the background of the dramatic work. In turn Reinhardt has applied his art to the great classical writers of the past, and to the symbolic and expressionist work of the present, finally to experiment with the new "illusionless" theatre in which the barrier of the footlights between actor and spectator is dispensed with.

The war has brought about significant changes in German theatre organization. The old conservative traditions of the German court theatres have necessarily disappeared with their transference to the direct control of the State; while economic difficulties have rendered it necessary to have recourse to large co-operative undertakings. These have, in particular, led to the establishment of "Volksbiihnen," the financial resources of which are supplied by comparatively small annual subscriptions which entitle the subscribers to an extraordinarily varied theatrical fare. But the general level of German acting and stage-production remains as high as ever, a result principally due to systematic organization and training, to the constantly changing repertory of practically all theatres, the enormous range of that repertory, and, not least, to the stability of the actor's profession, which makes his career less dependent than in other lands, on the speculative commercial manager and the success or lack of success of individual plays.

BIBLIOGRAPHY.—The most comprehensive history of the German drama (with an excellent bibliography) is *Das deutsche Drama, by* various writers ed. by R. F. Arnold (Munich, 1925); of German comedy, K. Holl, *Geschichtr des deutschen Lustspiels* (Leipzig, 1923). Of the German stage, E. Devrirnt, *Geschichte der deutschen Schauspielkunst* (Berlin, 1848–61; new ed., 1905), and R. Proelss, *Geschichte der deutschen Schauspielkunst bis 1850* (Leipzig, 1900).

For the older drama, R. Froning, *Das Drama des Mittelalters, Das Drama der Reformationszeit,* and *W.* Creizenach, *Schauspiels der englischen Komddianten,* all in Kurschner's *Deutsche Nationalliteratur,* vols. xiv., xxii., xxiii. (1889, 1892, 1895). The drama of the 16th century has also been edited by J. Tittmann in the series *Deutsche Dichter des 16ten Jahrhunderts* (4 vols., Leipzig, 1868, 1880). K. Heine, *Das Schauspiel der deutschen Wanderbühne vor Gottsclzed* (Halle, 1889); *A.* Eloesser, *Das bürgerliche Drama* (Berlin, 1898); H. Bulthaupt, *Dramaturgie der Klassiker,* vols., i., iii. and iv. (Oldenburg, 1882 *sqq.,* and later editions). For the 19th century S. Friedmann, *Das deutsche Drama des 19 Jahrhunderts* (2 vols., Leipzig, 1900); G. Witkowski, *Das deutsche Drama des 19 Jahrhunderts* (Leipzig, 1904; 5th ed., 1923). (X)

HOLLAND

The oldest specimens of Dutch mediaeval drama in existence date from the end of the 14th and the beginning of the 15th centuries. Of the religious plays several have been preserved. *Die Eerste Bliscap van Maria* (The First Joy of Mary), typical of the old mystery plays, was produced by the Brussels Chamber of Rhetoric about 1444. There are also a few so-called *abele spelen,* plays of chivalry with a religious tendency. Those *abele spelen* or "serious plays" were usually followed by a farce or a comically realistic picture from daily existence. One of the most amusing of those farces which has been preserved is *Buskenblaser* which tells the story of an old man who went through a pretended rejuvenation-cure.

The 16th century is the century of the morality or *Spel van Sinnen,* which is the typical rhetoricians' play, and where all or practically all the characters are allegorical. One of the earliest and most beautiful of these moralities, *Elckerlyc,* is still performed in the Netherlands at the present time. Its title means "Everyman" and its contents are almost the same as those of the English play of that name. It has not yet been finally settled which of the two plays is the original. Meanwhile, the farce maintained its position throughout the 16th century, but it was usually known under the name of *Esbattement.* At the same period there is a remarkable middle-class drama, the *Spieghel der Minnen* (Mirror of Love), by Colijn van Rijssele. During the 16th century there was also an interesting school-literature consisting of dramas written in Latin.

The so-called "Golden Century" was the summit of the Renaissance and a most important period in the history of Dutch drama. Gerbrand Adriaensz Bredero (1585–1618) began his career with romantic adaptations of Spanish romances of chivalry. Soon he displayed his original talent in comical interludes which he expanded into farces. He also wrote comedies. Pieter Cornelisz Hooft wrote, mainly under the influence of Seneca, such plays as *Achilles* en Polyxena. The greatest Dutch dramatist, however, is Vondel, the author of 32 dramas, of which 24 are original. (See the article on Dutch literature.) Vondel's preference was for the treatment of stories from the Bible. The sublimest of his plays was *Lucifer* (1654), which shows a considerable resemblance to Milton's Paradise Lost.

At the end of the 17th century there were a few poets who wrote *comédies* de moeurs. Thomas Asselijn is the author of a play called Jan Klaasz, of de Gewaende *Dienstmaagt* (Jan *Klaasz,* or *the Supposed* Maidservant), which deserves attention because of its witty irony at the expense of the ultra-pious. Meanwhile the time of the Dichtgenootschappen (Poetic Societies) had arrived. Their entire theory of art consisted in advising the imitation of the French classical drama. One of the most influential of these societies was called Nil volentibus *arduum.* Foremost among the members was Andries Pels, who made propaganda for his ideas in his rhymed Ars *poetica* called Q. Horatius *Flaccus'* Dichtkunst, *op onze tijden en zeden* gepast (The Ars *Poetica* of Horace Applied to Our Times and Customs). Meanwhile the comedies of Pieter Langendijk, a disciple of Molière, represented something of higher value.

After 1760 the French middle-class drama was extensively translated and copied in Holland. In the 19th century romanticism triumwhed on the Dutch stage in the works of Hendrik Jan Schimmel (1823–1906), who wrote among other plays *Twee* Tudors, and some patriotic dramas. His best work for the stage was a drama in verse, *Struensee.* His contemporary, Lodewijk Mulder, produced an amusing burlesque of the Dutch mania for public meetings in De *Kiesvereeniging* van *Stellendijk* (The Electoral Society of Stellendijk). A play by Eduard Douwes Dekker (better known under his pseudonym "Multatuli"), called Vorstenschool (*The* School for Princes), made a sensation when it appeared in 1872.

Representatives of the modern drama in Holland are Nouhuys, J. de Koo (whose pseudonym is "Doctor Juris"), and especially Marcellus Emants and Herman Heyermans. Emants' first play was a historical drama in verse, Adolf *van* Gelder. His later plays belong to the naturalist genre. Herman Heyermans obtained recognition as a dramatist not only in Holland but far beyond its frontiers, and his vogue surpasses that of any of his colleagues. His first plays are not often performed at the present day, but in 1898 he began that series of socialistic plays which show an unusual theatrical sense and to which he owes his world reputation. In a few of his later plays, such as *Allerzielen* (All Souls) and Dageraad (Dawn), the subject is treated in a symbolic manner. Frederik van Eeden wrote a few amusing comedies while he was still at the university. Among his later works we may mention Lioba, a drama in verse, and *Minnestrel.* Among later authors we shall limit ourselves to the mention of Mrs. J. A. Simons-Mees who brought upon the stage the psychological conflicts of modern existence. Alphonse Laudy made a happy attempt at the reintroduction of the monumental play in verse in his De Paradijs Vloek (Paradise-Ban) which is a sequel to the Adam *in Ballingschap* of Vondel.

DENMARK

Before the Reformation the Danish drama had an international character. It consisted of rather unimportant mysteries, moralities and farces. The 16th century was the time of the school-comedies, among which the best is H. J. Ranch's Karrig *Nidding* (*c.* 1600) a work that can compare with the best of Hans Sachs. In the 18th century Denmark's first and foremost dramatist, Ludvig Holberg, was influenced by Molière, but both his vivacious and witty dialogue and his brilliant characterization were highly original. His comedies were performed at the time of the opening of the first Danish theatre (1722). Holberg made use of a set of typical figures, which corresponded to those of the *commedia* dell' arte (servants: Henrik, Pernile; masters from the middle-class: Jeronimus, Magdelone; lovers: Leander, Leonore), but at the same time he created, especially in the title-parts, a great many original satirical portraits. The Danish peasantry and the middle-class of his own time provide the social setting for his plays. He describes them in a jocular way. Altogether the feature of middle-class comedy continued to predominate in the Danish drama. About the turn of the century it was represented by P. A. Heiberg and Olufsen. At the beginning of the 19th century it dissolved into the romantic movement, which was heralded by Ewald. Its most representative figure was Oehlenschlager. At first his tragedies and dramas were related to the German romantic movement, and afterwards to the German classics. They are of great lyric beauty and declamatory power, richly imaged in language. At the same time the middle-class comedy was continued, partly by the romantic poets themselves, *e.g.,* Hertz and J. L. Heiberg, who was the author of a kind of vaudeville, charming musical middle-class plays, which were very characteristic of the Danish mind. The comedies of Hostrup, in the middle of the 19th century, are not so elegant, but they have a pleasantly direct appeal. They have a joviality, a kind of popular romanticism in the best sense of the word, which is also found, in an even larger degree, in the work of Holger Drachmann. At the same time Drachmann was also influenced by the realistic movement, which at the end of the century strongly affected the Danish drama. Among these realistic authors may be mentioned Sven Lange, one of the most important pupils of Ibsen.

NORWAY

The Norwegian drama, which reached its zenith in the plays of Ibsen, is the most vigorous revelation of the mind of a nation that has occurred in recent times. It is no sudden growth, but rather a natural development of the Norwegian genius which first manifested itself in the national folklore. The chief characteristics of both are a spirit of individual independence tempered with good humour and considerable self-reliance. For the latter, the natural difficulties of the country, with its secluded community life, must be held responsible. From an artistic point of view, Norwegian drama owes much to the saga literature, which was both rich in characterization and dramatic in vein.

The drama, as a special branch of art, was unknown in Norway practically up to the 19th century, and there existed none of the elements that are required for the growth and prosperity of a national drama. The country possessed no reigning court and no wealthy nobility; nor was there, with the single exception of Bergen, any town in Norway that possessed sufficient vision to lay the foundations of dramatic art of the future. In Bergen was born Ludvig Holberg (*q.v.,* 1684–1754), one of the greatest dramatists of all time, and the founder of modern Norwegian and Danish literature. Owing to Norway being too impoverished to support a considerable intellectual and cultural life, Holberg took up his abode in Denmark, and though his plays, which were all comedies, deal with Danish manners and customs, and are concerned with life in the district of Copenhagen, they are nevertheless unmistakably Norwegian. His most typical characters are, in fact, not only his compatriots but also natives of Bergen, like himself. Holberg's drama contains all the essentials of the national saga literature and folklore, and his plays, among which may be mentioned *The* Tinker *Politician, Jappe* on the Hill and Erasmus Montanus, became the connecting link between ancient and modern literary Norway, and also formed the foundations of the modern stage. After Holberg, Johan Herman Wessel (1742–85) should be mentioned. He also was a Norwegian, and his well-known burlesque *Love Without* Stockings is still popular, despite the fact that the school of tragedy against which it was originally directed has long since ceased to exist.

Notwithstanding the basis of drama laid by Holberg and Wessel it need hardly be said that a national drama in the true sense of the word could exist only after the dissolution of the union with Denmark in 1814. By this event Norway became once more possessed of the sovereign liberty necessary for the evolution of an independent culture, yet more than a generation had to elapse before the first national theatre was founded in Bergen in 1850. This theatre, which was due to the initiative of Ole Bull (1810–1880), an art enthusiast and one of the foremost violinists of Europe, marks the first step in the direction of an exclusively Norwegian stage. At this time the Christiania theatre, which had opened in 1837, had an entirely Danish personnel. Though the Bergen theatre numbered Ibsen and Bjornson among its managers, it was eventually forced to close, overburdened with financial difficulties Despite its defeat. the National Stage of Bergen, still the official name of the Bergen theatre, had proved the possibility of a Norwegian theatre and after a struggle lasting for a number of years a national theatre was established at both Bergen and Christiania. From 1899 the theatre in the capital naturally became known as the national theatre, and was the centre of the dramatic activities of the country.

Ibsen and **Björnson.**—Meanwhile Henrik Ibsen (1828–1906) and Bjornstjerne Björnson (1832–1910) had come to the front in Norwegian literature in the late '50s, and within less than ten years they both produced a number of dramatic works of rare value, of which Ibsen's *The Warriors at Helgeland* and *The Pretenders* and Bjornson's *Between the Battles* and *Sigurd Slembe,* all dealing with characters and episodes of the saga period, are among the most famous. To the generation which first witnessed them they came as a perfect revelation of the spirit of the sagas, and the intensely human passions and the typically Norwegian outlook of the leading characters bridged the gulf that the archaic form and historical subject matter tended to create.

From the beginning of the '70s, a change came over Norwegian literature that was to exercise a considerable influence over Ibsen and Björnson The chief characteristic of this period was its pronounced realistic spirit which produced the modern social drama. As early as 1865 Bjornson in his little two-act drama *The Newly-Married Couple* and Ibsen in *The League of Youth* had taken the first step into the field of social drama, but it was not until the '70s that they succeeded in leaving all their contemporaries far behind. Bjornson's *A Failure* (1874) made a sensation over the whole of Europe five years before Ibsen impressed the world with *A Doll's House* (1879), followed by *Ghosts* (1881), *The Wild Duck* (1884) and *Rosmersholm* (1886), to mention only the most famous of his plays. The dramas of Ibsen and Bjornson were not only stamped with the keen intellect and the intense sensitiveness of their creators, but they represented the supreme attainment of European culture at the moment. They are also revelations of typically Norwegian characters unfolding themselves under conditions which have been justly described as tending more to develop the spirit of individual independence in man than the corporate spirit of organized society. This latter feature should be remembered since it mas also the breath of life in the sagas and folklore. It may be said of Holberg and Wessel in the 18th century, and of Ibsen and Bjornson in the 19th, that they are the true exponents of the various manifestations of the Norwegian mind and temper.

Later **Dramatists.**—Next to Ibsen and Björnson, Gunnar Heiberg (1857–1929) must be mentioned as the greatest Norwegian dramatist of our time. The chief characteristic of his drama is the sharp and trenchant dialogue, but with the exception of *The Balcony* (1894) and *Love's Tragedy* (1904) his plays can scarcely be considered lasting works of art These two plays in which he has shown love as a destructive force of nature, overwhelrning in its consequences, will always bear witness to his talent. Unfortunately Heiberg did riot develop as a dramatic author, and as a whole the Norwegian drama since Ibsen and Björnson has followed more fortuitous lines This applies, by way of example, to *The Happy Election* (1914) by Niels Kjaer (1870–1924), in which this author, who is considered one of the most accomplished writers of modern Norwegian prose, deals with certain contemporary phenomena of Norwegian politics. among them the language question, in a very clever and realistic way. Another example is Oskar Braaten (b. 1881) who has scored great success on the stage with his comedies *The Kid* (1911) and *The Wholesale Christening* (1925), written in the characteristic language of the industrial population in the vicinity of Oslo and dealing with its life and manners. A dramatist of an entirely different type is Hans E. Kinck (1865–1926), whose remarkable drama *The Cattle Dearer* (1908) is, in the opinion of many critics, unrivalled in Norwegian literature since Ibsen's *Peer Gynt*. This drama, which is too unwieldy for the stage notwithstanding its intrinsic merits as a work of fiction, has never been performed, unlike his Italian drama *Agilulf the Wise,* which was acted at the national theatre in the spring of 1910, when it gave rise to a lively discussion engendered primarily by the sovereign way in which the author disregarded the conventional rules of rhythm and stanzas

Finally it should be mentioned that Knut Hamsun (*q.v.*), the famous novelist, has also appeared as a dramatist But his four plays, of which three were produced in the '90s and one in 1910, have not added anything to the already considerable reputation of their author.

See G. Brandes, *Ibsen-Björnson Studies* (Eng trans, *1899*); E Tissot, *Le Drame norvégien* (1893). (S. C. H)

SWEDEN

The Swedish drama begins with the Reformation, the first work being a *Tobiae Komedia* (1550), ascribed to the reformer Olaus Petri (1493–1552). From the following century we have a considerable number of school-dramas, the earliest a *Thisbe* by M. O. Asteropheros (d. 1647). Johannes Messenius (1579–1636) wrote six dramas based on Swedish saga and history; but they are little more than stories in dialogue form; and the *Rosimunda* (1663) of Urban Hiarne (1641–1724), a Renaissance drama with choruses, is little more. Georg Stiernhielm (1598–1672), the greatest literary figure of the 17th century. was the author of masques in the Italian style Meanwhile the first Swedish troupe of actors was established between 1686 and 1691 in the so-called Lejonkula (lion's den) in Stockholm, and stimulated an interest in the theatre. The classical drama persisted all through the 18th century. 0. von Dalin (1708–63) wrote an Alexandrine tragedy, *Brynhilda* (1743) and a comedy, *Den avundsjuke* (*The Envious Man*) (1738), which shows the influence of Steele. King Gustav III. gave great encouragement to both drama and opera, and was himself a dramatist, or at least planned dramas which the poets of his court executed. Amongst these the most eminent were J. H. Kellgren (1751–95), G J Adlerbeth (1751–1818) and K. G. Leopold (1756–1829). The comedies of this age are much more readable to-day than its turgid Voltairian tragedies. In 1737 Karl Gyllenborg (1679–1746) produced his *Svenska Sprätthöken* (*The Swedish Fop),* the first genuine comedy in the literature. Other successful writers mere R G. Modée (1698–1752), K. I. Hallman (1732–1800), O Kexél (1748–96), and especially K. Envallsson (1756–1806).

The Romantic era in Swedish literature differs from that not only in Denmark, but also in every other land, in being almost wholly lacking in dramatic literature. P. D A. Atterbom (1790–1835), it is true, wrote his greatest work, *Lycksalighetens* O *(The Isle of Bliss)* (1824–27) in dramatic form, but it is in no real sense a drama. Nor did the plays of E. J. Stagnelius (1793–1823), the historical dramas, in Schiller's style, of B. von Beskow (1796–1868) or the experiments of K. J. L. Almqvist (1793–66) leave any mark on the stage. About the middle of the century the most successful playwright in Sweden was August Blanche (1811–68), who acclimatized the art of Scribe; while the plays of J Borjesson (1790–1866) show the influence of Shakespeare, admirably translated about this time by K. A. Hagberg (1810–64). F. A. Dahlgren (1816–95) produced in 1846 *Vermländingarna* (*The Vermlanders*), a peasant play with song and dance, probably the most popular of all Swedish plays. Johan Jolin (1818–84) was also successful in the same *genre* Blanche's successor in comedy was Frans Hedberg (1828–1908), whose son, Tor (1862–1931), inherited his father's talent.

The drama of the last period has been cultivated by writers of talent, notably Alfhild Agrell (1849–1923), H. Molan-

der (1858-goo), Ernst Didring (b. 1868); but it is entirely overshadowed by Sweden's one dramatist of European rank, August Strindberg (*q.v.*). To the realistic drama of the end of last century Strindberg contributed powerful works like *Fadren (Tlze Father)*; while in the smaller plays for the *intime* theatre he has created what is virtually a new *genre*. In later life, after his own spiritual crisis, mysticism assumes very large proportions, notably in *Till Damascus;* and unfortunately morbid and unpleasant themes preponderate in his work. Other forms of his drama are fairy-plays, often of great beauty, and the long series of historical dramas which opens with a masterpiece of the first order, *Master Olof*. No dramatist of our time, except Ibsen, has exerted a deeper and more widespread influence than Strindberg; and he is largely responsible for the trend to mysticism and expressionism in the contemporary Continental drama. (X.)

POLAND

Polish drama is of late growth. Through the first centuries of Polish literature it appeared merely in sporadic or exotic forms, Kochanowski's *Dismissal of the Greek Envoys* (1578) being its sole masterpiece until the end of the 18th century. At that date the Polish theatre rose under King Stanislas Augustus' patronage. Founded on French models it rapidly developed on national lines. After the partition of Poland it reached high artistic beauty during the years of the nation's bondage, frequently serving as a patriotic stimulus. Fredro (1783–1876) remains the master of Polish comedy. His *Maidens' Vows, Revenge,* etc., sparkle with wit and national colour. Slowacki (1809–49) gave Poland her finest tragedies in his dramas on Polish history and legend (*Mazeppa, Balladyna, Lilla Weneda*). Two of the greatest masterpieces of Polish literature were written at the same period in dramatic form:—Mickiewicz's national lamentation, *The Ancestors* (1832), and Krasinski's forecast of social revolution, *The Undivine Comedy* (1835). The brilliant symbolical plays, notably *The Wedding*, of the painter poet S. Wyspiánski (1869–1907) created an epoch in Polish drama. Although no subsequent work has equalled those already mentioned the Polish dramatic output has steadily continued. Among contemporary dramatists Rostworowski *(Caligula; Charitas)* merits special mention. (M. GA.)

RUSSIA

Old Russia had no theatre and no drama. Plays taken from the repertory of the German strolling actors and mysteries and moralities after the Jesuit school-model were first introduced in the second half of the 17th century. The continuous output of original drama begins with the production, in 1747, of the first tragedy, in the French classical style, by Alexander Sumarokov. This style dominated tragedy as well as comedy till about 1825. The classical comedy writers, especially Fonvizin (1744–1792) were more original than the tragic poets, and present many features anticipatory of 19th century realism. This classical realism culminated in the great comedy of Alexander Griboyedov (1791–1829) (*q.v.*), *Woe from Wit,* and in the still greater plays of Gogol (*q.v.*), *The Inspector-General* (1836). Character-drawing is the strongest side of all these writers, but Gogol was also a great master of dramatic construction. His tradition was continued by Sukhovo-Kohylin (1817–1902) and Pisemsky (1820–1881), whose masterpiece is a realistic tragedy of great power. The main current of the Russian drama however neglected action and plot. Its principal representative was Alexander Ostrovsky who from 1850 to 1886 gave the Russian stage about a play a year, and created a new type of dramatic realism, based on character drawing and local colour. Owing to Ostrovsky the Russian drama was alone in Europe to be free from the dictatorship of Scribe. The historical drama in verse, after the "Shakespearean" model introduced already by Pushkin (1831) flourished in the sixties and seventies but produced little of outstanding merit, its principal claim to be remembered being its close connection with the Russian opera. In the end of the 19th century Chekhov (*q.v.*) carried the Russian tradition of inactive and plotless drama still further, producing masterpieces of realistic atmosphere (1896–1904). He was imitated without much success by Gorki and Andreyev. After 1906 realism began to be abandoned and various forms of symbolism and modernism invaded the theatre. With the exception of Blok (*q.v.*) and, perhaps, of Evreinov they produced no work of significance, and the Russian theatre has been within recent years emancipated from the playwright and become the unrestricted playground of the producer. Post-revolutionary dramatic literature has produced little of any value, except the brilliant propaganda plays of the Futurists, Mayakovsky and Tretiakov, and the tensely-constructed though immature plays of action of Leo Lunts (1901–1924).

See Leo Wiener, *The Contemporary Drama of Russia* (Boston, 1924). (D. S. M.)

CZECHOSLOVAKIA

The theatre contributed very appreciably towards the progress of the Czech literary revival which began to gain impetus at the beginning of the 19th century. The earliest plays, which were the work of such pioneers as Václav Klicpera (1792–1859) and J. K. Tyl (1808–56), were largely imitations or adaptations of foreign models. After a short period of romanticism, associated with the first Czech translations of Shakespeare by J. J. Kolar (1812–go), the Czech stage was dominated by realism. The French comedy of Scribe found a skilful follower in Emanuel Bozděch (1841–89), while Ladislav Stroupežnický (1850–92) specialized in the realistic presentation of Czech rustic life.

An important landmark in the history of Czech drama was the opening of the Prague national theatre in 1883. Its first manager was F. S. Šubert (1849–1915) and his wide knowledge of the theatre ensured a repertoire of great variety. The influence of Ibsen now made itself felt, especially in the plays of Jaroslav Kvapil (b. 1868) and Jaroslav Hilbert (b. 1871), but it was followed by a reaction, leading to the vogue of historical drama. One of the best works of this category was *Falkenstein* (1910) written by Hilbert himself, and other examples of this tendency were provided by J. Karásek ze Lvovic (b. 1871) with his *Caesar Borgia* (1905) and by Arnošt Dvořák (1881–1932) whose *Václav IV.* (1910) is perhaps the most noteworthy Czech historical play. Among prominent modern Czech dramatists should also be mentioned Otakar Fischer (1883–1938), who translated Shakespeare and wrote several plays, both historical and contemporary, and Fráňa Šrámek (b. 1877), whose plays are distinguished and sometimes, from a dramatic point of view, marred by the subtle lyrical spirit pervading thern.

The post-war Czech drama is remarkable chiefly for the work of Karel Čapek (1890–1938) who was the first Czech author to win world-wide celebrity. His *R U* R. (1921) was played in the greater part of Europe and America. In *The Life of the Insects* (1921) he collaborated with his brother Josef (b. 1887), whose independent dramatic experiment *The Land of Many Names* (1923) is also a stimulating piece of work. Finally, there is František Langer (b. 1882) whose tragedy *Slums* (1925) is a skilful blend of realism and psychological subtlety.

No reference has here been made to the drama of the Slovaks, which is still in the process of formation. The repertory of the recently established Slovak theatre at Bratislava consists mainly of Czech plays and translations of foreign works, but a few native Slovak dramas by such writers as Urbánek, Rbzus, Tajovský and Hurban have already been produced. On the whole, however, the Slovak drama, like Slovak literature generally, is marked more by promise than achievement. (P. SE.)

DRAMA AND THE STAGE, ARTICLES ON. Drama as a whole is divided into 24 sections, as under: (1) General, (2) Indian, (3) Chinese, (4) Japanese, (5) Persian and other Asiatic drama, (6) Dramatic elements in Egyptian culture, (7) Greek, (8) Roman, (9) Downfall of the Classical Drama, (10) Mediaeval and Early English, (11) Italy, (12) Modern Greece, (13) Spain and Portugal, (14) France, (15) England, (16) Germany, (17) Holland, (18) Denmark, (19) Norway, (20) Sweden, (21) Poland, (22) Russia, (23) Czechoslovakia, (24) America. In addition there are articles on subdivisions of the dramatic arts which will be found under their own headings. An article on STAGE DESIGN embodies the latest ideas on the subject, and other special articles worthy of mention are THEATRES. LAW RELATING TO; NŌ DRAMA; THEATRE, THEATRICAL PRODUCTION and COSTUME DESIGN, THLATRICAL.

DRAMATIC CRITICISM extends from dramatic theory on the one hand to theatrical criticism on the other. Its founder was Aristotle, whose *Poetics* (*c.* 325 B.C.) laid down, miraculously for its time, the basis of all dramatic theory. His definition of tragedy as "an imitation of an action that is serious, complete, and of a certain magnitude . . . in the form of action, not of narrative; through pity and fear affecting the proper purgation of these emotions" lies behind all subsequent discussion. For comedy the *Tractatus Coislinianus*, conjecturally related to Aristotle, gives an analysis that can be supported from Aristophanes, Shakespeare and Molière. Roman theory is represented by Horace's *Ars Poetica* (*c.* 10 B.C.), a clever and superficial work suggesting "good sense," entertainment combined with instruction and a five act division, as the road to success. Horace first, and Aristotle when he was accessible, formed the basis of Renaissance criticism, and ultimately of modern theory. Ancient dramatic criticism in action may be seen at its most amusing in Aristophanes' *Frogs*. Mediaeval theory was in the main concerned with the still popular formal distinction between tragedy, with its unhappy, and comedy with its cheerful, ending. Dante calls his epic a Divine *Comedy* because "in its beginning it is horrible and foul, because it is Hell; in its ending, fortunate, desirable, and joyful, because it is Paradise."

With the Renaissance the rediscovery of Aristotle's *Poetics* gave a new and fierce life to dramatic discussion. A Latin translation by Valla appeared in 1498, the *editio princeps* of the Greek text in 1508, Robertelli's critical edition in 1548, and an Italian translation, the first in any modern tongue, in 1549. Aristotle's cryptic lecture notes needed clarifying, and most commentators loyally interpreted, altered and expanded in accordance with contemporary theatrical conditions. Plays were composed on Aristotelian principles. Theorists were intimidated, but practical men revolted. Dryden later put the matter at its clearest. "It is not enough that Aristotle has said so, for Aristotle drew his models of tragedy from Sophocles and Euripides; and if he had seen ours, might have changed his mind." Ludovico Castelvetro was the powerful and individual founder of the Renaissance neo-classical doctrine, which survived until the Romantic movements of the mid-18th century. In his Aristotelian commentary of 1570 he insisted that plays must be acted and not read, that tragedy is concerned with kings and public characters, and comedy with low and private people, that tragedy might have either a happy or miserable end, as well as comedy, and in so doing looked back, unwittingly, to Plato's concluding comment in his *Symposium* "that the genius of comedy was the same with that of tragedy," and forward to the practice of Chekhov, Benavente and Pirandello. His farthest reaching contribution was the formulation of the doctrine of the three unities. Aristotle has only the unity of *action*, and a part of that of *time*. Castelvetro gave definite shape to the unities of *action*, *time* and *place*.

The Age of Shakespeare. — On the threshold of the great national dramas of England and Spain, Renaissance theory was epitomized in Sidney's *Defence of Poesie* (1595) and in Cervantes' *Don Quixote* (1605). But the world of practice became insistent, and Shakespeare's point of view in England was matched by Lope de Vega's New *Art of* ***Writing*** *Plays* (1609) in which, on the experience gained from writing 483 plays, he put forward the first classic of box-office criticism. "Since the crowd pays for the comedies, it is fitting to talk foolishly to it to satisfy its taste," give plenty of variety, let women wear men's costumes, keep up the suspense and mystery to the last scene, and don't bore your audience with pregnant silences. There is surprisingly little criticism in the Elizabethans. Ben Jonson's is largely second-hand, and Shakespeare's advice on acting, bold and vivid as it is, has Italian forerunners.

With the 17th century, the age of criticism, important changes occur. There was a vast body of drama to discuss. Theatre-going became fashionable, and coffee-house and bookshop comment was a matter of course. Pepys's *Diary* illustrates the tone of lay criticism. In France, Chapelain, the Abbé D'Aubignac, Racine, and above all Corneille, contributed to serious theory. Corneille, in his *Discours* and *Examens* of 1660, for which he claimed "50 years of practical experience of the theatre," took up the problems of decorum, verisimilitude, and the three unities, which had already occupied Castelvetro, and gave them new and live interpretation. It was Corneille's alertness of mind and not his dull position, to please according to the rules, that stimulated Dryden to his *Essay of Dramatick Poesie* (1668) and his prefaces modelled after Corneille's *Examens*. Dryden, as befits an individual Englishman, was torn between the formalist or "good sense" view continued by Boileau and Rapin in France, and Milton and Rymer in England, and the saner view based on practice, of which he was perhaps the only representative. His views on tragi-comedy and on character-drawing, by giving chapter and verse, laid the foundation of modern criticism in England, and his definition of action foreshadowed something of Ibsen's attitude. For comedy, Molière in his scanty utterances, and Congreve, in his *Concerning Humour in Comedy* (1696), express urbanely what can be more robustly gathered from their works.

The 18th Century. — With the decline of drama, adjacent criticism, largely of morals and of theatrical art, becomes more insistent. Jeremy Collier's *Immorality and Profaneness of the English Stage* (1698) is an important landmark, and Colley Cibber's *Apology* (1740) contains some of our earliest and finest descriptions of acting. The 17th century was the age of the fashionable, Baroque theatre, the 18th the age of great or much applauded actors. Diderot's *Paradoxe sur le comédien* (not published till 1830), and Lichtenberg's descriptions of Garrick, not only exemplify the interest in acting, but, together with Lessing's *Hamburgische Dramaturgie* (1767–68) give proof of the growing international interest already shown by St. Evremond and Voltaire. The chief contributions of the 18th century are the flood of Shakespearian criticism and the spread of the theatrical periodical. In Germany alone 133 periodicals have been traced between the *Hamburgische Dramaturgie* and the end of the 18th century. Lessing, leaning heavily on English example, did much to overthrow French post-Cartesian standards in favour of Shakespearian grandeur and liberty, and in his *Laokoon* (1766) gave so powerful a thrust and so rigid an integrity to critical procedure as to earn him a position second to none but Aristotle.

The Romantic rejection of neo-classical dogma in favour of a misty and grandiose Nature, and a grotesque mediaevalism, gave a new dignity to the emotions and their representation. Lessing. Diderot and Schlegel on the Continent, Dr. Johnson (in one outburst against the unities), Lamb, Hazlitt, and above all Coleridge, in England, expressed, more or less ripely, the doctrines of the individual, and from their utterances emerged principles which unfortunately were not exemplified in the new drama. The chief materialization of this activity was the new conception of Hamlet as an amalgam of Byron, Prometheus and Werther. In France alone, with the theory and practice of Victor Hugo (Prefaces to *Cromwell*, 1827, and *Hernani*, 1830), was there a satisfactory Romantic drama. Joanna Baillie, with her dramas of the passions, and Kotzebue with his pre-Pirandellian metaphysics, left little impression after their popularity had died down.

The 19th century was dominated by the "well made play" of Scribe and Sardou, and Sarcey was its critical prophet. His *Essai d'une esthétique de théâtre* (1876) discusses the principles by which, for the average audience, reality is replaced by illusion. The newer schools of Naturalism and Realism endeavoured to restore reality to the theatre, and criticism followed in their wake. Zola wrote much on the theatre and wished his characters to *live* rather than *perform*. Brunetihre's La *Loi du théâtre* (1894) introduced a new topic of discussion. "In drama or farce what we ask of the theatre is the spectacle of a *will* striving towards a goal and conscious of the means which it employs." In Germany Hebbel and Freytag contributed to non-European movements. Ibsen's practice rendered theory unnecessary. The best comments for English readers can be found in C. E. Montague's *Dramatic Values* (1911) and the prefaces and writings of Bernard Shaw.

Theories of the 20th century follow dramatic fashions. Most harm, perhaps, has been done by the writings in which Maeterlinck invites us "to draw nearer to the spheres" in which echoes and whispers and silences reign. Theory has, for the most part,

been side-tracked into discussion of scenery, or into the philosophical abstractions of Pirandello and Benavente. Expressionism has not yet found its critic. Its theory must be sought in Nietzsche's *Birth of* Tragedy (1877) and in the writings of Strindberg and Wedekind.

DRAMBURG, town, province of Pomerania, Prussia, Germany, on the Drage, a tributary of the Oder, 50 m. E. of Stettin, on the railway Ruhnow-Neustettin. Population 7,300. Its industries include brewing and distilling, spinning and brush and cloth manufactures. It trades in live stock.

DRAMMEN, a town in the county of Buskerud, Norway, at the junction of the Drammen river with the Drammen fjord, the western branch of the Oslofjord. Pop. (1936) 25,000. The town is divided into two sections, Bragernes north of the river and Stromso and Tangen to the south. A fishing village existed here in the 13th century. In 1615 Bragernes and Stromso were incorporated and in 1811 they were united into a municipal town under the name of Drammen. The town is an important railway junction and the export centre for one of the richest forest districts of Norway. Along the Drammen watercourse is centred much of the Norwegian wood-pulp, cellulose and paper industry. The town has several engineering works and saw mills. Wood-pulp, cellulose, paper, timber, frames and mouldings are ordinarily exported while coal is the most important import.

DRAPER, JOHN WILLIAM (1811–1882), American scientist, was born in St. Helen's, near Liverpool on May 5, 1811. He studied at Woodhouse Grove, at the University of London, and again, after removing to America in 1832, at the medical school of the University of Pennsylvania (1835–36). In 1837 he was elected to a medical professorship in the New York university, but, as its medical school was not organized at once, he began his work in its college as professor of chemistry (1839), and was a professor in its school of medicine (1840–so), president of that school (1850–73), and professor of chemistry until 1881. He died in Hastings, N.Y., on Jan. 4, 1882. He made important researches in photo-chemistry, and was the first to take the human portrait by light, having made portrait photography possible by his improvements on Daguerre's process. He was also responsible in great measure for the prominence of New York city as a centre of medical education.

He wrote: *Treatise on the Forces which Produce Organization in Plants* (1844); *Treatise on Chemistry* (1846); *Treatise on Human Physiology or The Condition and Course of Life of Man* (1856); *History of the Intellectual Development of Europe* (1863); *Thoughts on the Future Civil Policy of America* (1864); *History of American Civil Wur* (1867–70); *Distribution of Calorific and Chemical Activities in the Solar Spectrum* (1872); *Contributions to Chemistry* (1874); *History of the Conflict between Religion and Science* (1875); and a collection of published works under the title of *Scientific Memoirs* (1878).

See *Transactions of the New York Academy of Sciences,* vol. i., pp. 106–108 and the *American Journal of Science,* vol. xxiii., pp. 163–166.

His son, HENRY DRAPER (1837–1882), graduated from the medical school of the New Pork university in 1858. He was appointed to the medical staff of Bellevue Hospital in 1858, and served there 18 months. He was professor of natural science in New York university in 1860, professor of physiology (in the medical school), and dean of the faculty in 1866–73. He succeeded his father as professor of chemistry, but only for part of a year, as he died in New York on Nov. 20, 1882. Henry Draper's most important contributions to science were made in spectroscopy; he ruled metal gratings in 1869–70, made valuable spectrum photographs after 1871 and proved the presence of oxygen in the sun in a monograph of 1877. Edward C. Pickering carried on his study of stellar spectra with the funds of the Henry Draper Memorial at Harvard, endowed by his widow (*née* Mary Anna Palmer).

He wrote: *Changes of the Blood Cells in the Spleen* (1858); *Petroleum: Its Importance* (1865); *American Contributions to Spectrum Analysis* (1865); *A Text Book on Chemistry* (1866); and *Discovery of Oxygen in the Sun by Photography* (1877).

See *Bzographical Memoirs of the National Acadenzy of Science,* vols. ii. and iii.

DRAPER. One who deals in cloth or textiles generally. The Fr. *drap,* cloth, from which *drapier* and Eng. "draper" are derived, is of obscure origin. It is possible that the Low Lat. *drappus* or *trappus* (the last form giving the Eng. "trappings") may be connected with words such as "drub," Ger. *treffen,* beat; the original sense would be fulled cloth. "Drab," duil, pale, brown, is also connected, its first meaning being a cloth of a natural undyed colour. The Drapers' Company is one of the great livery companies of the City of London. The fraternity is of very early origin. Henry Fitz-Alwyn (d. 1212?), the first mayor of London, is said to have been a draper. The first charter was granted in 1364. The Drapers' Gild was one of the numerous subdivisions of the clothing trade, and appeared to have been confined to the retailing of woollen cloths, the linen-drapers forming in the 15th century a separate fraternity, which disappeared or was merged in the greater company. It is usual for drapers to combine the sale of "drapery," *i.e.,* of textiles generally, with that of millinery, hosiery, etc. In *Wills* v. *Adams* (reported in *The Times,* London, Nov. 20, 1908), the term "drapery" in a restrictive covenant was held not to include all goods that a draper might sell, such as fur-lined goods.

DRAUGHT, the act or action of drawing, extending, pulling, etc. (from the common Teutonic word "to draw"; *cf.* Ger. *Tracht,* load; the pronunciation led to the variant form "draft," *q.v.,* now confined to certain specific meanings). It is thus applied to animals used for drawing vehicles or loads, "draught oxen," etc., to the quantity of fish taken by one "drag" of a net, to a quantity of liquid taken or "drawn in" to the mouth, and to a current of air in a chimney, a room or other confined space. In furnaces the "draught" is "natural" when not increased artificially, or "forced" when increased by mechanical methods (see BOILERS). The water a ship "draws," or her "draught," is the depth to which she sinks in the water as measured from her keel. The word was also formerly used of a "move" in chess or similar games, and is thus, in the plural, the general English name of the game known also as "checkers" (see DRAUGHTS). For the use of the term "draft" or "draught" in masonry and architecture see DRAFTED MASONRY.

DRAUGHTS. Draughts is a game of skill usually played by two persons on a chequered board of 64 squares. Each player to commence has 12 men of a distinctive colour. In the United States the game is known as checkers.

Fig. 1 shows the board and men set out ready to commence a game. The Black squares are not used throughout the game, and in order to record moves and give a coherent description of play the actual field of operations (*i.e.,* the White system of squares) is numbered as shown in fig. 2. At the outset it should be noted that the board is placed with a "double corner" on the right hand of each player, Black's double corner being the squares 1 and 5 and White's corresponding double corner 32 and 28. Each player has a "single corner" on his left, Black at 4 and White at 29.

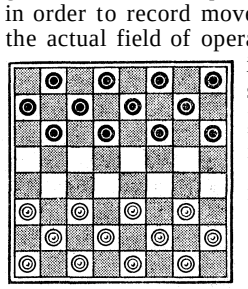

FIG. 1.— DRAUGHT BOARD, OR CHECKER BOARD SET FOR PLAY

The convention is adopted of assuming that at the commencement of a game the Black men always occupy the first 12 squares (1–12), and White the last 12 (21–32). This is merely to get uniformity in recording.

A man moves forward diagonally one step at a time into the next playing square to the right or left provided such square be unoccupied. Thus at the beginning of a game Black has choice of seven different moves—he may play the man on 9 to 13, or the same man to 14, or he may choose 10–14, 10–15, 11–15, 11–16 or 12–16. Suppose he plays 11–15, then White has choice of seven replies, viz., 21–17, 22–17, 22–18, 23–18, 23–19, 24–19 and 24–20 A capturing move (shortly "capture" or "take") occurs when a hostile piece is situated in a square contiguous to one belonging to the player whose turn it is to play, with an empty square imme-

diately behind it. The capture is effected by passing the playing man into the empty square mentioned, removing the man passed over from the board. A cardinal rule is that *it is compulsory to take whenever it is possible to do so.* When two ways of taking present themselves, the player is free to choose between them. Capturing play is continuous as far as there are opposing pieces *en prise*, and it is often possible to take two or more in one move, the only condition being that they shall be strung out, each with a vacant square behind it.

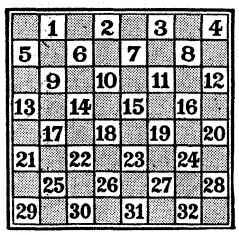

FIG. 2.— DRAUGHTBOARD NOTATION: BLACK OCCUPIES SQUARES 1 TO 12, AND WHITE 21 TO 32

When a man reaches the extreme end of the board he is promoted to a "King." Black men crown on reaching any of the squares 29 to 32, and White men similarly on 1 to 4. A King has the privilege of moving and taking backwards as well as forwards, and thus doubles the functions of a man. It is only in rare or exceptional positions that a King equals two men in value.

The object of each player is to leave his adversary without a move, and in more than 99% of cases this has to be effected by capturing all his pieces. Briefly, you play to clear him off. The only other way of winning is by so confining what pieces he may have left that he cannot move any of them; this sometimes happens, and is technically known as a "block," of which more a little later.

If you cannot win you must if possible avoid loss and try to draw. A draw is when neither player can force a win, such as when the opposing forces are reduced to two or three pieces each with no positional advantage to either side. A draw is usually a matter of easy agreement, drawn positions being readily recognized.

As an elementary exercise, to gather up some of the points already explained, play over the following game, No. 1:—Black moves first, 11–15, White replies 22–18, offering an exchange which forms the "Single Corner" opening; 15–22 (must take), 25–18 (he has the option of 26–17, but that is a bad move as it would seriously divide the White forces); 8–11, 29–25 (bringing up the single corner man in this way as a support is usually good play); 4–8 (the same remark here applies), 25–22 (note that 24–19? instead would allow Black a simple three-for-one by 1—15, 19–10, 6–29); 12–16, 24–20; 10–15 (by this move Black sets a trap) 27–24? (now this move on the surface looks good, because it threatens 24–19 winning a "two-for-one," but the first thing a Draughts player should learn is to distrust the obvious); 15–19! (Black could dispose of the two-for-one threat by playing 8–12, but that course is unnecessary, as he can make a three-for-three exchange which gains a King and leads to a won game), 24–15; 16–19! 23–16; 9–14, 18–9; 11–25 (the man on 9 is safely pocketed to be taken next move), 32–27 (to the uninitiated White's game does not look entirely hopeless, but trial will show that he is in a very bad way however he may play); 5–14 (stronger than taking 6–13), 27–23; 6–10, 16–12; 8–11, 28–24; 25–29 (crowns; Black has not been in a great hurry to do this, but has first massed the body of his men into a solid position), 24–19 (the exchange by 30–25; 29–22, 26–17 affords a little more fight, but with the White forces fatally squandered); 14–18 (the first move of a useful four-for-four stroke, the mechanism of which should be remembered), 23–14; 10–17, 21–14; 29–25! 30–21; 11–16, 20–11; 7–30 Black wins with great ease, as White can only run his men down the board with an almost unbroken "crown-head" facing them and a free King behind them.

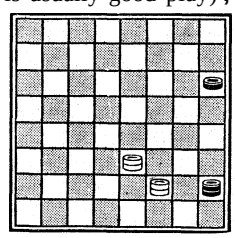

FIG. 3.— "FIRST POSITION," WHITE TO PLAY AND WIN

The trap which White falls into in the above game when playing 27–24 at the 12th move is of very common occurrence, and is known by the quaint designation of the "Goose Walk." It is easily avoided by moving 21–17, and so drawing the game.

There are a few points in connection with Draughts which are subject to much misapprehension among those who have little acquaintance with the game or rules. One knotty point is in connection with the "huff," *i.e.*, a penalty which *may* be enforced against a player who neglects to capture a piece when he should do so. The "huff" simply consists of the removal by the adversary (before he moves) of the piece which should have effected the capture. Now the offending party has *no say whatever* as to whether the penalty shall be exacted or not in any particular case. His adversary may require him to put back the illegal move he has just played, and make the proper capture. In such case there is no huff. It would obviously be absurd if a player could evade a well-planned coup by blandly standing the huff.

It is neither good form nor bad form to "man off." The player who objects to exchanges being forced upon him when he himself is in a minority (on the ground that it is "not sport") is simply displaying ignorance. A player is entitled to make, and should make, the *best move he can see* in any position. Frequently, the only way to press home numerical advantage is to exchange, and so increase the ratio of such advantage.

If a player touch a piece when it is his turn to move, he must play that piece, and if the piece be pushed so as to show over the angle of the square, the move must be completed in that direction.

A man, on reaching the square on the opposing back rank, rests there to be crowned. If he lands there in the course of a capture, he cannot continue capturing as a King.

The ending of two Kings to one is simple. It is a win in all cases for the two Kings, with just one exception which can occur in either single corner.

The ending of three Kings to two, when the weaker party holds one or both the double corners, is apt to be a little puzzling at first. The win is obtained by forcing an exchange, reducing the ending to 2 x 1.

In general esteem, Draughts is placed at a disadvantage by the simplicity of its initial presentation. One can play a game with so very little instruction. Critics sometimes point to the large preponderance of drawn games (between experts) over those that are won, and infer from this that as a subject Draughts is approaching exhaustion. It is not appreciated (but such is the fact) that every well-balanced and easy-looking draw between two good players is the product of long and concentrated preparatory study and analysis on strict lines of scientific method. It is necessary for a player to keep himself informed of all contemporary analytical discoveries, or he will find his play out of date. Notwithstanding all preparation, every player becomes involved in strange positions in actual games; he then must find the best move, knowing well that nothing less will suffice. It is an intellectual feat to draw a game at Draughts against a really fine player.

Combination.— Some of the beauties of the games are exhibited in the following examples, each of which has been selected on account of some striking combination, brilliant idea or other artistic merit displayed.

Game No. 1 AYRSHIRE LASSIE OPENING

*a*11–15	25–18	10–15	22–17	*b*15–18	24–6
*a*24–20	3–8	23–19	13–22	24–20	2–9
8–11	26–22	6–10	26–17	18–27	17–10
28–24	5–9	*c*} *d*} 27–23		11–16	31–24	8–11
9–13	30–26	9–14		20–11	16–23	Drawn
22–18	1–5	18–9		7–16	20–16	**R.** Jordan
15–22	32–28	5–14		29–25	12–19	

a. 11–15, 24–20 forms the "Ayrshire Lassie" opening, so named by Wyllie. It is generally held to admit of unusual scope for the display of critical and brilliant combinations.

b. 16–20, 25–22, 20–27, 31–24, 8–11, 17–13, 2–6, 21–17, 14–21, 22–17 21–25, 17–14, 10–17, 19–1. Drawn.

Game No. 2 PAISLEY OPENING

Played between E. R. Jacques and D. Campbell

11–16	17–14	16–23	25–22	20–27	23–18
24–19	10–17	26–19	7–11	14–9	14–23
8–11	21–14	4–8	19–15	7–14	21–7
28–24	1 6	29–25	12–16	9–6	3–10
16–20	25–21	13–17	15–10	1–10	26–3
22–17	6–9	31–26	2–7-a	18–9	27–31
9–13	23–18	9–13	27–23	5–14	3–7

White wins.

(a) Black's "side game" has not paid him very well, and his forces are now badly divided.

No. 3 LAIRD AND LADY

A classic, by J. Steel, Kilbirnie, Scotland

11–15	17–14	4–8	26–23	12–16	12–3
23–19	1 1	24–19	16–20	19–12	2–7
8–11	21–14	13–17	31–26-a	7–10	3–10
22–17	15–18	28–24	18–22-b	14–7	6–31
9–13	19–15	11–16	25–18	3–28	

Black wins.

(a) Plausible but loses. (b) "The Steel Shot."

No. 4 BRISTOL CROSS

Played at Halifax, Yorlrshire, between C. Horsfall (Black) and S. Greenslade (White)

11–16	12–16	16–23-a	11–16	7–11	6–31
23–18	17–14	17–13	31–26	26–19	13–6
16–19	8–12	4–8	16–20	3–8	1–26
24–15	22–17	28–24	25–22	12–3	30–23
10–19	19–23	8–11	12–16-b	2–7	11–16
21–17	26–19	24–19	19–12	3–10	

Black wins.

(a) Enterprising play. A man so thrust forward is a menace if it can be maintained. (b) Notice how the man on 23 is completely surrounded. Now begins a lovely combination.

No. 5 OLD FOURTEENTH

Played at Buffalo, U.S.A., between Mugridge (Black) and Hodges (White)

11–15	18–9	11–15	26–23	28–32	7–14-d
23–19	1	19–16	24–28	19–15	6–10-e
8–11	26–23	12–19	20–16	32–28	14–7
22–17	1–6	23–16	15–24	15–11	32–28
4–8	30-26-a	15–19	23–19	28–32	21–14
25–22	6–9	27–23	14–18	11–7-b	22–25
9–13	32–27	8–11	22–15	3–10	29–22
27–23	2–6	16–12	13–22	2–7	24–27
6–9	24–20	19–24	15–11	9–13	31–24
23–18	15–24	23–19	10–14	12–8	28–26
9–14	28–19	11–15	11–2	14–17-c	

Black wins.

(a) Evidently this is inferior, but the subsequent play is masterly. (b) A bid for freedom. (c) Very fine. (d) Taking the other way, he would be a man down permanently. (e) This stroke removes all the White pieces from the board.

No. 6 CROSS

The following is an example of a "Block":

11–15	30–26	15–19	27–24	6–10	29–25
23–18	9–13	18–14	8–12	27–23	
7–11	24–20	10–15	25–21	2-6	
26–23	12–16	23–18	1–6	31–27	
3–7	21–17	6–9	32–27	4–8	

and White wins, having the last move. It is now Black's turn to play, and having no move available, he has lost. A counterpart "block" with no piece taken on either side is sure to end in a White win. The game, however, is only a freak.

General Principles.— The foregoing games are entertaining enough, but such spectacular play is rare between accomplished players, although great skill, as well as vigilance, is required to avoid falling occasionally into some subtly prepared stroke. Novices often lose games by stroke play—sometimes indeed they are allowed to make an inviting stroke on their own account, only to find that the resulting position runs badly against them. Strokes and combinations are used by experts as *threats*, and are useful adjuncts to position play, their avoidance by the opponent probably entailing some precautionary move on his part which if not entirely inferior will not improve the strength of his game. Setting traps, however, which if avoided will allow the adversary an improved position, is strictly eschewed by good players.

Of general theory which can be expressed in anything like precise terms there is none. The game is not amenable to treatment by any of the methods of pure mathematics, which seems strange at first, because above everything it demands, constantly, the most exact calculation. The circumstance is fortunate. Investigation of the possibilities and potentialities of the game depends entirely on practical analysis—actual trial and selection of moves in given positions. Such research is being carried on without ceasing by hundreds of busy brains throughout the world, merely multiplying the available data, without getting an inch nearer any conclusion, except the probability that one does not exist.

The authors of textbooks, therefore, are chary of giving general advice, and such as they offer is obscure and sometimes contradictory. Beyond recommending the student to play towards the centre of the board in preference to the sides they say little, preferring instead to recommend a plunge into the columns of figures (representing moves) which bulk so largely in every book on Draughts.

There are several coherent general schemes for bearing the men well understood by experienced players. (Note, however, that such schemes do *not* constitute anything like a complete theory of play.) The more important are: 1. Play a centre-of-the-board game, *i.e.*, move to the middle, bringing up the side men as supports, and try to divide the adversary's men by driving a wedge into his formation. 2. Play to the sides. encouraging the opponent to take up a central position, but with the view of surrounding his front and undermining his supports. 3. Play to occupy the squares 14 and 19 with supported men, as such formation will attack the opposing double corner and secure one's own. 4. Play to attack the single corner by establishing a supported piece (if Black) on 18, or (if White) on 15. 5. Play to keep the game open, especially in the centre, by making judicious exchanges, and refrain from any pronounced attack or defence (especially attack).

There are other general plans, some of which cannot be quite so simply described as the above, but as the experienced player very well knows they are all subject to the qualification of if *permitted* or *as far* as *may be possible and prudent.* Nos. 1 and 2, for instance, are reciprocal to some extent, and the one may be met by the other in many cases without advantage to either. They are opposed very prettily for instance, in certain lines of the "Old Fourteenth" (11–15, 23–19; 8–11, 22–17; **4–8** forms the opening, usually continued 17–13, 15–18, 24–20; 11–15, 28–24; 8–11, 26–23, etc.). No. 3 was the subject of a serious attempt by the American champion, N. W. Banks, to develop a system of play as described, and he shows many applications of it in his book ***Scientific*** *Checkers* (1923). The idea was not original with Banks, but he carried it further than any previous writer, without much practical success, however, as his advocacy tended to make him overrate the scheme, which he recommended in some games where stronger play was demonstrable. The number 3 plan is well exemplified from Black's point of view in the "Dyke" opening (11–15, 22–17; 15–19, 23–16; 12–19, 24–15; 10–19, etc.). No. 4 is not as feasible as some of the others, but is developed by Black fairly strongly in the "Maid of the Mill" opening (11–15, 22–17; 8–11, 17–13; 15–18, 23–14; 9–18—seldom permitted by White, who can easily evade it). No. 5 is often the style of thing which occurs' as a result of compromise or desire to keep the draw in sight: it leads to the adoption of such openings as the "Defiance" (11–15, 23–19; 9–14, 27–23 avoiding many complications consequent on 22–17 and usually continued 8–11, 22–18, the exchange of two-for-two leading to an open game).

Before leaving this discussion of system the following example of the success of the second scheme when opposed to the first may be cited as worthy of more than casual examination. It is selected to show that such advice as "play to the centre" and "do not play to the sides" is not capable of universal application, but is also a splendid exposition of Draughts.

No. 7 ALBEMARLE

It is uncertain who was the first to show the win in the main play of this game.

11–15	9–14-b	7–11	12–16	8–12	9–18
22–17	25–21	30–26-d	32–28	27–23	21–17
8–11	15–18-c	2–7	16–19-e	3–8	23–26
17–13	29–25	24–20	23–16	23–18-f	17–14
4–8	11–15	5–9	18–23	14–23	
21–17-a	26–22	28–24	26–19	17–14	

White wins.

(a) An uncommon opening, but the position after the next two moves can arise in several ways.

(b) The best move is 15–18—an application of scheme No. 4.

(c) Although this move is suggested by scheme No. 1 it loses outright. A draw is obtainable by 15–19, 24–15; 10–19 (11–18 loses), 17–10; 6–15, 23–16; 12–19, which is according to scheme No. 3.

(d) The win is forced by a logical application of scheme No. 2. This man is the pivot of both wings.

(e) An attempt to break the cordon—the only chance.

(f) This counter sacrifice ensures the win.

To resume our consideration of general principles it is safe to say that the main thing which the experienced player keeps in view (assuming that he is opposed by an adversary of equal skill) is the probable state of his end-game, which indeed he begins tentatively to forecast as soon as a few of the opening moves have been made. Normally Draughts is a shortish game, and one or two crises quickly bring about the ending, which if not presenting some feature of difficulty may as well be declared drawn at once To be sure of a draw, however, a player must not be in any numerical inferiority, and must be able to see his way to crown his remaining men, as any man unable to obtain a clear course is a possible source of weakness. Strength in the end-game consists of being able to occupy the centre of the board with Kings, pinning backward men of the opponent's forces to the side squares, and preventing any Kings he may have from actively ca-operating with each other. With a strong ending of such scope a player will be able to dictate replies, force advantageous exchanges, prevent the release of the tied-up men, and eventually exhaust the moves of the last one or two badly placed pieces belonging to his opponent. The "play to the centre and avoid the sides" advice thus becomes intelligible in the ending, however doubtful of application it may be in many cases earlier in the game. In the mid-game therefore the chief object is to shape an end-game with favourable possibilities. Skill to do this may only be acquired by hard practice and judicious book-work.

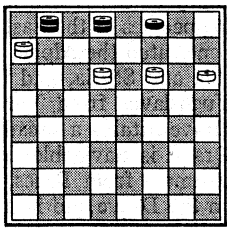

FIG. 4 —"FOURTH POSITION"
(a) White to move and win
(b) Black to move and draw

The End Game. — Perhaps higher qualities are required in playing for the end-game than in actually manipulating the end-game when it has arrived. End-play requires great exactitude and much patience, but its principles are well known, as a number of root endings constantly recur and their handling is purely a matter of technique. Several of these root end-games have special names such as First, Second, Third and Fourth Positions, Payne's Draw, Barker's Triangle, Bowen's Twins, Strickland's Position, the Mackintosh Position, etc., etc End-play largely depends upon calculating the influence of "the move" ("opposition" or "vantage" as it is sometimes called) which consists in ascertaining, after pairing off the forces, piece against piece, which party will have the last move. The virtue of "having the move" is that the opponent's pieces, being obliged to give way, ultimately become confined and held unless "the move" can be altered or a defensive stronghold established

Two root endings, in which the play is not of an elementary nature, are diagramed as examples.

In "First Position" the stronger party has two Kings against King and man. The defending player has his King in the opposing double corner, and his man held up somewhere on his left wing, perhaps farther back than shown. The attacking player (who must have "the move") can drive the King out of the double corner or compel the man to advance, and this course on trial will be found to lead to the win. With the backward man on the other wing the game is drawn.

In Fourth Position the defending player is a man short, but can draw with "the move" in his favour by simple repetition When the attack has "the move" he can construct the following situation: Black man on 21, Kings, 20, 22, 28; White man on 30, Kings 27, 32. Black to play wins by the sacrifice 22–26, 30–23, 28–24, etc. The single White man may be a King without altering the essentials.

History. — The records of the game do not go back farther than the invention of the art of printing. All conjecture as to its origin is purely speculative, and its ancient history (if any) is lost. It is not doubted that board games were played in ancient Egypt, Greece and Rome, but there is no evidence that such games resembled Draughts, even in rudimentary form.

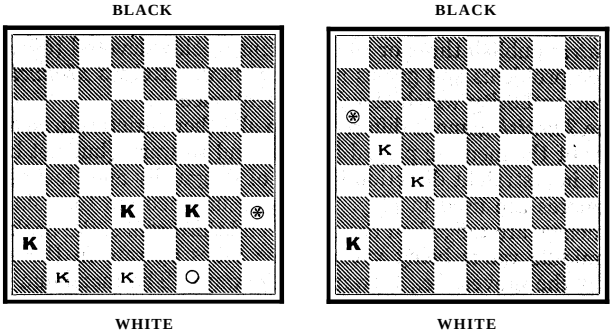
The Spanish authors are the oldest, dating back to the 16th century. The Spanish game to-day is the same as they then described. The early French authors treated of the form which is now generally styled the English game, but the so-called Polish game was evolved and introduced in Paris about the year 1721, superseding the older form. The Polish game spread from France to Holland, Flanders and Switzerland, and its influence is traceable in the German and Russian games. In the meantime the Italians also evolved their own special rules.

The records of English Draughts begin with William Payne (1756) and its form was permanently fixed by Joshua Sturges (1800). Comparatively neglected in the south of England in the beginning, it was developed successfully in Scotland and the north of England. The rise of modem master-play dates from Andrew Anderson, who retired about 1850, after playing five matches (four of which he won) with the celebrated James Wyllie, another Scotsman. Wyllie assumed the title of champion, but the honour was wrested from him by Robert Martins (a Cornishman), only to be regained. A young American named Robert D. Yates defeated both Wyllie and Martins in set matches in 1876–77, but retired, and the title reverted to Wyllie. James Ferrie (of Glasgow) finally defeated Wyllie for the world's championship in 1894. Ferrie lost by the odd game in 40 to Richard Jordan (of Edinburgh) in 1896. The latter died unbeaten in 1909 but it should be mentioned that an American champion, Charles F. Barker, played a drawn match with him in 1900. The present holder and successor to Jordan is Robert Stewart of Blairadam, Fifeshire.

Organization — The game is fairlv well organized in all English-speaking countries: including the' United States, but there is no supreme parliament recognized. There are many bodies such as State and county associations, and city and town clubs, Institutes and recreation clubs generally have draughts circles, and the game has a big following. All the national associations promote periodical tournaments and international team matches have been played. There is an annual British Counties' Championship for teams of 12 players.

Varieties of the Game. — What we have been describing is the English form of the game.

The *Spanish* game is played in a similar manner, but with the following exceptions: (a) The board is placed with the double corner to the left (an English board in the looking-glass, as it were); (b) the King can move over any number of unoccupied squares on the same diagonal; (c) It is compulsory to capture the greatest number of pieces which may be *en prise* at any play, which of course limits or eliminates choice when there are pieces *en prise* in more than one direction. The long moves of the King vastly increase his power in comparison with the ordinary man. The Spanish game, although still practised, is



in a backward state and has never been properly developed. The most recent authority is Dr. M. Carceles Sabater (Madrid, 1904).

The *Italian* game differs from the Spanish game (from which it was probably derived) in the powers of the King. The Italian King moves precisely the same as an English King (subject however to the maximum take being compulsory) but is immune from capture by a man. The Italian game is a very "live" proposition. and analytical discoveries in the English game are readily adapted by the Italian players. The modern authorities are G. Bassani (*La Dama Scientifica*, Milan, 1919) and L. Avigliano (*Il Giuoco della Dama*, 1918, and *La Dama nel Giuoco Moderno*, Milan, 1927).

The *Polish* game is the form most popular on the Continent.

We have already referred to its origin; it appeared in France, but one of its earliest exponents in Paris was a Pole. It is played upon a board of 100 squares, 50 being used; 20 men a side; double corner to the right. The King (*i.e.*, Dame or Queen) has the same powers as the Spanish King, extended to the larger board. The men, whilst moving forward as in the English game, take both backward and forward. The maximum take is compulsory, and in capturing play a man may touch the back rank without crowning if further pieces remain to be taken. The "huff" has been abolished. The characteristic feature of the Polish game is the backward take of the man, which players used to the English, Spanish or Italian rules find both novel and puzzling Polish Draughts is a magnificent game, well suited to the genius and scientific bent of the French and Dutch peoples. One of the declared objects of the French Draughts Association is to convert the draughts players of other countries to the use of the 100 squared board and the Polish rules. The literature of the Polish game is voluminous, although it certainly falls short of the output of books devoted to the English game. Amongst the older French authors Manoury (about 1780) is still in good repute, and his book has been many times reprinted. Le Damier by G. Balédent (Amiens, 1881–87) is a monumental work in four volumes, and later French treatises of value which are readily procurable are those of Barteling, Chiland, Weiss, Felix Jean, etc. The best Dutch writers have produced much progressive work, and after Van Embden (the ancient authority) should be mentioned the modern treatises of Broekkamp, De Haas and Battefeld, Springer and De Jongh. The Polish game is served by no less than four monthly magazines.

The German game is the Polish game on the smaller (8x8) board, and does not call for much special comment. The treatises of J. Dufresne and H. Credner may be referred to, but neither is very modern. This game, by the way, has some minor vogue in the United States.

The Russian game is also minor Polish, with two important differences. The choice which may be exercised in capturing is free, *i.e.*, is identical with the English rule. A man on reaching the back rank in capturing is promoted on touching the crowning square and immediately functions as a King, continuing that play as a King. "Shashki," as it is called, is immensely popular in Russia, and has a fairly good body of literature and a monthly magazine published in Moscow.

In Canada the Montreal or Quebec game is the favourite of the French-speaking people, who refer to it as "Le Jeu Canadien." It is a major form of the Polish game, with identical rules, played on a 12x12 board with 72 playing squares and 30 men aside. This game is also practised in the New England States of the U.S.A. by the French community. Two Montreal newspapers, *La* Presse and *La* Patrie publish three or four columns weekly devoted to it, and include problems and games as well as news. Roby's Manuel is a current authority which should be mentioned.

The Turkish game is different from all other varieties in that the moves of the men are played laterally and forward (but not backward) in a straight direction instead of diagonally and thus all the 64 squares are used in play. The opposing men, 16 to a side, to commence, are ranged on the second and third ranks, the back and two middle ranks being vacant. The takes operate in the same way as the moves, *i.e.*, forward or sideways. The maximum take is compulsory and the pieces are removed one by one as captured. The King has a sweep of any number of squares. This game is practised in the North of Africa, Stamboul and the Levant, but its literature is practically negligible, although some highly interesting mss. are in existence.

The ***Losing*** game (in English or foreign forms) is a reversal of the ordinary rules, as the name implies.

DRAUPADI, in Hindu legend daughter of Drupada, king of Panchāla, and wife of the five Pāndava heroes in the *Mahābhārata*.

DRAVE or DRAVA (Ger. Drau), one of the principal right-bank affluents of the Danube. It rises below the Innichner Eck, in Tirol, at an altitude of over 4,000 ft., runs eastward, and forms the longest longitudinal valley of the Alps, the Drau Thal. The Drave is 450 m. long; near Zakkany it is joined by the Mur. The valley of the Drave was the chief road through which the invading peoples of the East, such as the Huns, the Slavs and the Turks, penetrated the Alpine countries. The Drave flows through Carinthia and Styria, and forms the boundary between Hungary and Yugoslavia from Varaždin to near Osijek. At its mouth the Drave attains a breadth of 1,055 ft. and a depth of 20 ft. The Drave is navigable for rafts only from Villach, and for river steamers from Bárcs, a distance of 95 m. The principal towns on the Drave and its affluents are Klagenfurt, Graz, Maribor and Osijek. (See DANUBE.)

DRAVIDIAN, a name only applied in Indian usage to the "Southern" group of the Brahmans *q.v.* But "Dravidian" is applied, unfortunately, to the indigenous peoples of India south of the Vindhyas and the northern half of Ceylon; it should be confined to the languages of this area. At least four different stocks have contributed elements in their population. The earliest is dark, short, with wavy hair, broad noses and long heads, so that some have detected affinities with Negroids. This stock, represented by Kadirs and Kurumbas, is akin to the Veddas and to Australian peoples and to the Semang and Sakai (see FURTHER ASIA). Other elements are physically distinct and we have in the Nambutiri Brahmans the purest Aryan stock. The range of culture is equally wide. The Dravidians occupy the oldest geological formation in India, the medley of forest-clad ranges, terraced plateaux, and undulating plains, from the Vindhyas to Cape Comorin, and among them we find the construction of dolmens, the use of the boomerang, kinship in the female line, totemism and many primitive usages. But in the same are found a high degree of civilization, with a remarkable literature and evidence of artistic skill.

DRAVIDIAN LANGUAGES, the name given to a collection of Indian languages comprising all the principal forms of speech of Southern India (Sanskrit Dravida). Their territory, which includes the northern half of Ceylon, extends northwards up to an irregular line drawn from a point on the Arabian sea about 100m. below Goa along the Western Ghats as far as Kolhapur, thence north-east through Hyderabad, and farther eastwards to the Bay of Bengal. Farther to the north, Dravidian dialects are spoken by small tribes in the Central Provinces and Chota Nagpur, and up to the banks of the Ganges in the Rajmahal hills. A Dravidian dialect is, finally, spoken by the Brāhūīs of Baluchistan in the far north-west.

Classification.—Tamil and Malayālam can be considered as two dialects of one and the same language, which is, in its turn, closely related to Kanarese. Tulu, Kodagu, Toda, and Kōta lie between Tamil-Malayslam and Kanarese, though more nearly related to the latter than to the former. The same is the case with Kurukh and Malto, while Kui and Gondi gradually approach Telugu, which latter language seems to have branched off from the common stock at an early date. Finally, the Brāhūī dialect of Baluchistan has been so much influenced by other languages that it is no longer a pure Dravidian form of speech.

The Dravidian languages are gradually losing ground in the north, where they meet with Aryan forms of speech. This process has been going on from time immemorial, but it is still possible to trace a Dravidian element in the Aryan languages of North India.

The Dravidian languages form an isolated group, and it has not been possible to prove a connection with any other family of languages. Such attempts have been made with reference to the Munda family, the Tibeto-Burman languages, the Ural-Altaic languages, and the dialects spoken by the aborigines of the Australian

continent. The arguments adduced have not, however, proved to be sufficient. The Dravidian family has several characteristic features of its own. The phonetic systems of the smaller dialects deserve close study and analysis. In general the pronunciation is soft and mellifluous.

Main Features. — In Dravidian words a line above a vowel shows that it is long. The dotted consonants *ṭ, ḍ,* and *ṇ* are pronounced by striking the tip of the tongue against the centre of the hard palate. The dotted *ḷ* is distinguished from *l* in a similar way. Its sound, however, differs in the different districts. A Greek *χ* marks the sound of ch in "loch"; *ṣ* is the English *sh;* c the *ch* in "church"; and *ṛi* is an *r* which is used as a vowel. Abruptness and hard combinations of sounds are avoided. There is a distinct tendency to avoid pronouncing a short consonant at the end of a word, a very short vowel being often added after it. Thus the pronoun of the third person singular, which is *avan,* "he," in Tamil, is pronounced *avanu* in Kanarese; the Sanskrit word *vāk,* "speech," is borrowed in the form *viku* in Tamil; the word *gurram,* "horse," is commonly pronounced *gurramu* in Telugu, and so on. Combinations of consonants are further avoided in many cases. This tendency is illustrated by the changes undergone by some borrowed words. Thus the Sanskrit word *brāhmaṇa,* "a Brahman," becomes *barāmaṇa* in Kanarese and *pirāmaṇa* in Tamil; the Sanskrit *Dramida,* "Dravidian," is borrowed by Tamil under the form *Tirāmiḍa. Dramida* which also occurs as *Dravida* is in its turn developed from an older *Damiḷa* which is identical with the word *Tamiṛ,* Tamil.

The forms *pirāmaṇa* and *Tirāmiḍa* in Tamil illustrate another feature of Dravidian enunciation. There is a tendency in all of them, and in Tamil and Malayālam it has become a law, against any word being permitted to begin with a stopped voice consonant (*g,j,ḍ,d,b*), the corresponding voiceless sounds (*k,c,ṭ,t,p,* respectively) being substituted. In the middle of a word or compound on the other hand, every consonant must be voiced. Thus the Sanskrit word *danta,* "tooth," has been borrowed by Tamil in the form *tandam,* and the Telugu *anna,* "elder brother," *tammulu,* "younger brother," become when compounded *annadammulu,* "elder and younger brothers."

There is no strongly marked accent on any one syllable, though there is a slight stress upon the first one. In some dialects this equilibrium between the different parts of a word is accompanied by a tendency to approach to each other the sound of vowels in consecutive syllables. This tendency, which has been called the "law of harmonic sequence," is most apparent in Telugu, where the short *u* of certain suffixes is replaced by *i* when the preceding syllable contains one of the vowels *i* (short and long) and *ei.* Compare the dative suffix *ku, ki,* in *gurramu-ku,* "to a horse"; but *tammuni-ki* "to a younger brother." This tendency does not, however, play a prominent rôle in the Dravidian languages.

Words are formed from roots and bases by means of suffixed formative additions. The root itself generally remains unchanged throughout. Thus from the Tamil base *per,* "great," we can form adjectives such as *per-iya* and *per-urn,* '(great"; verbs such as *per-u-gu,* "to become increased"; *per-u-kku* "to cause to increase," and so on.

Many bases can be used at will as nouns, as adjectives, and as verbs. Thus the Tamil *kadu* can mean "sharpness," "sharp," and "to be sharp." Other bases are, of course, more restricted in their respective spheres.

The inflexion of words is effected by agglutination; *i.e.,* various additions are suffixed to the base in order to form what we would call cases and tenses. Such additions probably once were separate words. Most of them are, however, now only used as suffixes. Thus from the Tamil base *kōn,* "king." we can form an accusative *kōn-ei,* a verb *kōn-en,* "I am king,"–and so on.

Dravidian nouns are divided into two classes, which Tamil grammarians called high-caste and casteless respectively. The former includes those nouns which denote beings endowed with reason, the latter all others. Gender is only distinguished in the former class, while all casteless nouns are neuter. The gender of animals (which are irrational) must accordingly be distinguished by using different words for the male and the female, or else by adding words meaning male, female, respectively, to the name of the animal — processes which do not, strictly speaking, fall under the head of grammar.

There are two numbers, the singular and the plural. The latter is formed by adding suffixes. It, however, often remains unmarked in the case of casteless nouns.

Cases are formed by adding postpositions and suffixes, usually to a modified form of the noun which is commonly called the oblique base. Thus we have the Tamil *maram,* "tree," *maratt-āl,* "from a tree"; *maratt-u-kkzc,* "to a tree," *vīḍu,* "a house"; *vīṭṭ-āl,* "from a house." The case terminations are the same in the singular and in the plural. The genitive, which precedes the governing noun, is often identical with the oblique base, or else it is formed by adding suffixes.

The numeral system is decimal and higher numbers are counted in tens; thus Tamil *pattu,* "ten"; *iru-badu,* "two-tens," "twenty."

The personal pronoun of the first person in most dialects has a double form in the plural, one including and the other excluding the person addressed. Thus, Tamil *nām,* "we," *i.e.,* I and you; *nhngal,* "we," *i.e.,* I and they.

There is no relative pronoun. Relative clauses are effected by using relative participles. Thus in Telugu the sentence "the book which you gave to me" must be translated *miru nāku iccina pustakamu, i.e.,* "you me-to given book." There are several such participles in use. Thus from the Telugu verb *koṭṭa* "to strike," are formed *koṭṭ ut-unna,* "that strikes," *koṭṭi-i-na,* "that struck," *koṭṭe,* "that would strike," "that usually strikes." By adding pronouns, or the terminations of pronouns, to such forms, nouns are derived which denote the person who performs the action. Thus from Telugu *koṭṭe* and *vāḍu,* "he," is formed *koṭṭe vhdu,* "one who usually strikes." Such forms are used as ordinary verbs, and the usual verbal forms of Dravidian languages can broadly be described as such nouns of agency. Thus, the Telugu *koṭṭinăḍu,* "he struck," can be translated literally "a striker in the past."

Verbal tenses distinguish the person and number of the subject by adding abbreviated forms of the personal pronouns. Thus in Kanarese we have *māḍid-enu,* "I did," *māḍid-i,* "thou didst," *māḍid-evu,* "we did"; *māḍid-aru,* "they did."

One of the most characteristic features of the Dravidian verb is the separate negative conjugation. It usually has only one tense and is formed by adding the personal terminations to a negative base. Thus, Kanarese *mid-enu,* "I did not," *mid-evu,* "we did not"; *mhd-aru,* "they did not."

The vocabulary has adopted numerous Aryan loan-words. This was a necessary consequence of the early connection with the superior Aryan civilization.

The oldest Dravidian literature is largely indebted to the Aryans, though it goes back to a very early date. Tamil, Malayslam, Kanarese, and Telugu are the principal literary languages. The language of literature in all of them differs considerably from the colloquial. The oldest known specimen of a Dravidian language occurs in a Greek play which is preserved in a papyrus of the 2nd century A.D. The exact period to which the indigenous literature can be traced back, on the other hand, has not been fixed with certainty.

DRAWBACK, the repayment of a duty, previously exacted, when excisable goods are exported or foreign goods re-exported. The object of a drawback is to enable commodities which are subject to taxation to be exported and sold in a foreign country on the same terms as goods from countries where they are untaxed. It differs from a bounty in that the latter enables commodities to be sold abroad at less than their cost price; under certain conditions, however, the giving of a drawback has an

effect equivalent to that of a bounty. The tariffs of many countries contained tables of the drawbacks allowed on the exportation or re-exportation of commodities, but so far as the United Kingdom is concerned the system of "bonded warehouses" practically abolished drawbacks, as commodities can be warehoused (placed "in bond") until required for subsequent exportation. (*See* BONDED WAREHOUSE.)

DRAWING, the art of delineation or of portrayal by means of lines, is so primitive that its history is practically that of man. That it was practised 50,000 years ago we know but for how long before that, it is difficult to establish. Its beginnings, however, must have been early, for one of the first things a child will busy its hands with is the making of marks in the dirt, and the walls of many a schoolhouse or home stand as mute witnesses to the inherent tendency of man to draw. It is a deep-rooted instinct whose satisfaction gives great pleasure.

Early Art.—In the beginning the primitive mind with its usual groping for essentials was satisfied with simple structural lines and, at times, outlines of those objects wherein the structure was less evident. The cave-man drew his pictures of men just as the child does—with the inverted Y for the body and legs, a cross-piece for the arms and a circle for the head, part of his drawing showing structure and part outline. The first of these drawings of the child are always without consideration of motion but it does not take long before, with the addition of feet, the figure is walking and soon the arms are brought to the front. Thus we see the early beginnings of the three elements which are essential to all drawing, if it is to please man who has for thousands of generations and from childhood up been trained to expect them: structure, outline and motion. (See fig. 1.)

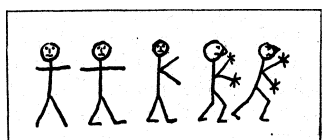

FIG. 1.—CHILD'S DRAWING SHOWING NATURAL DEVELOPMENT OF MOTION

In order to draw the human figure successfully the artist must first learn about its bony structure. He must master the knowledge of the lengths of the various units and of their possibilities for movement (see DRAWING: *Anatomy).* But his work does not cease in this study of structure. Trees spread their branches in certain characteristic ways each of which is slightly different, and in fact each type of leaf has its own anatomy as has every animal, bird and flower. Rocks must be closely examined and their origin understood or they cannot be given the proper structure. The artist cannot slight this work or his drawing will be unconvincing. We must spend much time in finding out how things were put together or how they grew and why.

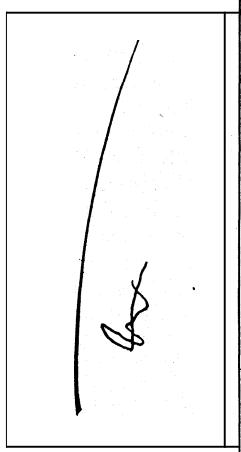

FIG. 2.—LINES WHICH ARE ESSENTIALLY BEAUTIFUL AND UNBEAUTIFUL

In speaking of outline we should think first of line itself. It has been contended that "It cannot be reasonably held that one purely abstract line or curve is more beautiful than another, for the simple reason that people have no common ground upon which to establish the nature of abstract beauty." This is, of course, false, for if there were no common ground in beauty there would be very little incentive to draw other than as a simple record. But to put into words just what this beauty consists of, is a difficult task. Fig. 2 illustrates two lines. It will be agreed that one is more beautiful than the other. One has a sureness and sensitive taper while the other wanders in a hesitant and aimless manner without object, without character. Perhaps that is it. Perhaps a line can have character and therefore can show those beauties and weaknesses which we see in the characters of our fellows. This is undoubtedly possihle, for no two men can draw a line exactly alike and certainly into the lines of each must creep something of the man himself (*see* TECHNIQUE IN ART). Therefore, beauty of line does exist but is difficult to analyze, as it is dependent upon the personality of the artist. It may be as difficult to tell why you like one line better than another as why you like one friend better than another; nevertheless, there is no doubt of your preference in the matter.

Besides this beauty of abstract line we find the age-old necessity for outlining objects, and when asked to describe a thing our minds at once turn to its shape. Its consistency, its structure, its movement are all often secondary unless they assert themselves strongly. The artist has only his eyes to help him in this work but a knowledge of what lies within is also an aid to him. The author on drawing in the eleventh edition makes use of an illustration given herewith, to show how hard it often is to guess the shape of an object by its silhouette alone. (See fig. 3.) As soon as the three lines are added which indicate its structure it is obvious in shape.

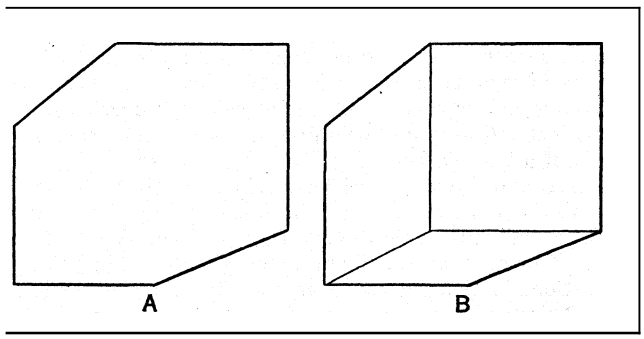

FIG. 3.—DIAGRAM SHOWING (A) DEFICIENCY OF OUTLINE ALONE (B) NECESSITY FOR STRUCTURE IN ORDER TO MAKE FORM UNDERSTANDABLE

It is sometimes possible to erect an imaginary structure which is of assistance and artists frequently resort to this method. For instance, in the drawing of a vase (see fig. 5) the straight lines might be sketched in lightly and would be of some assistance in judging both curves and proportions. In other words a sort of scaffolding is first erected and then the outline drawn upon it. After a little practice the scaffolding need not be drawn for the artist can visualize it without the aid of actual lines. Another help in drawing the silhouette of an object is to reverse the idea and look at the silhouette of the background instead. This process is often employed by sculptors in their work and is undoubtedly of some assistance to them. But all of these are simply suggested aids to seeing, and it takes practice to be able to draw what one sees. (See fig. 4.)

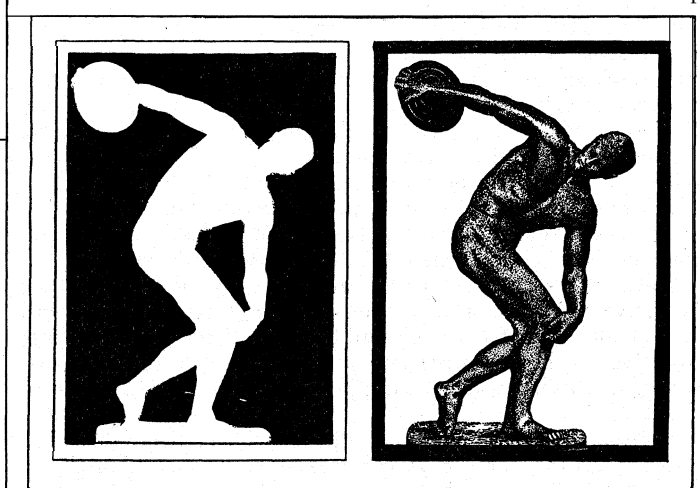

FIG. 4.—TWO REPRESENTATIONS OF THE SAME STATUE ILLUSTRATING THE VALUE OF A SILHOUETTED FIGURE (LEFT) OVER A STRAIGHT RENDERING (RIGHT) IN OBSERVING FORM

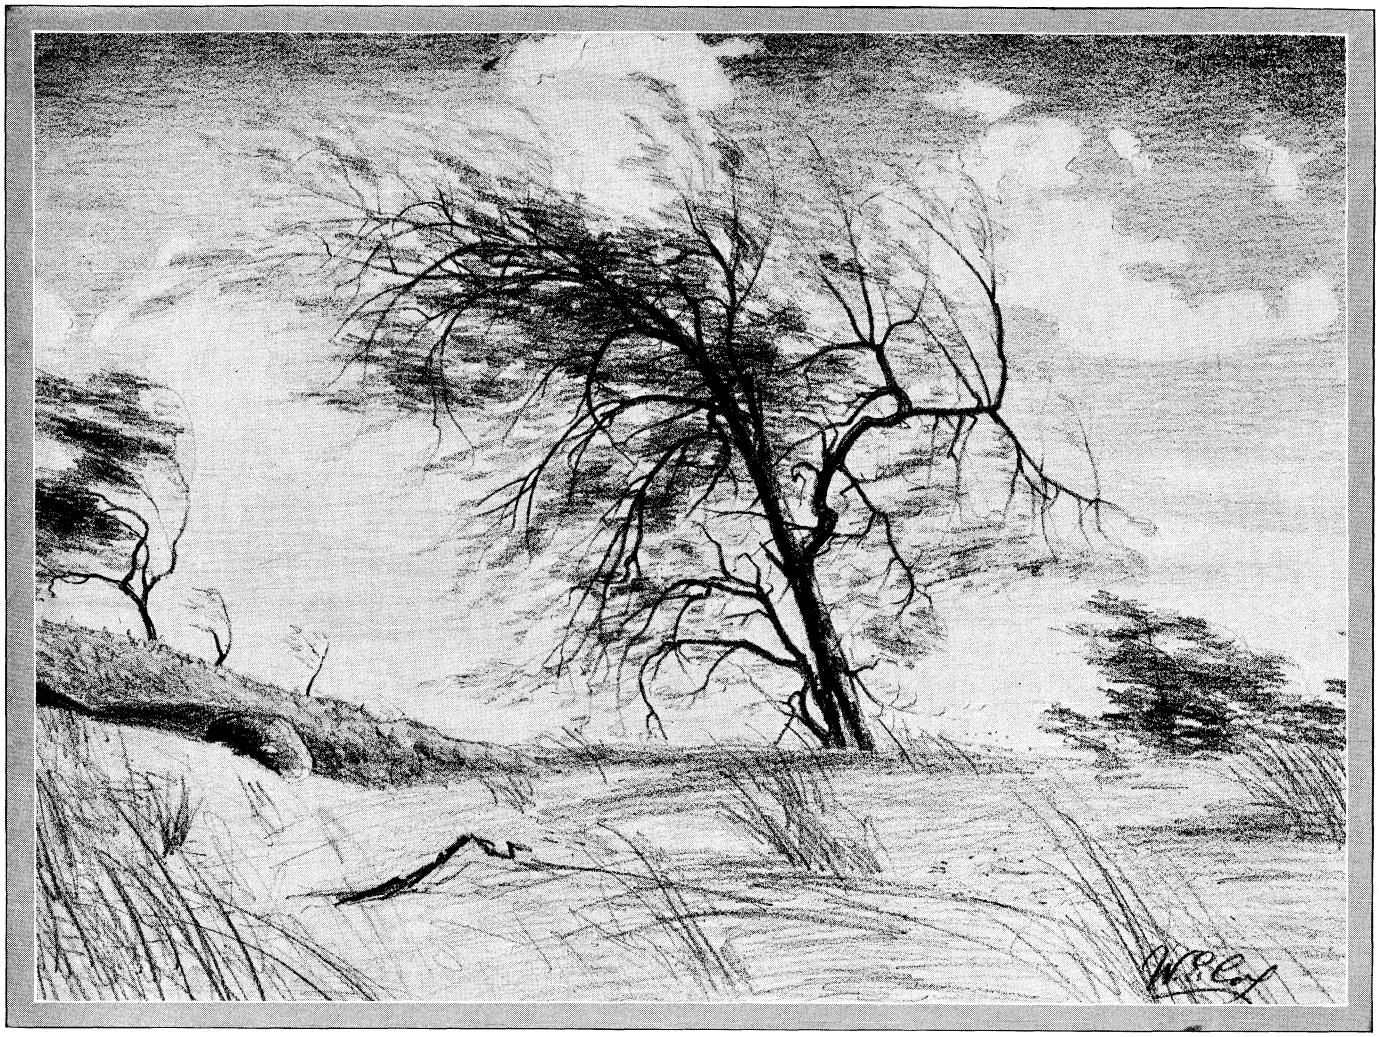
THE REQUIREMENTS OF A DRAWING

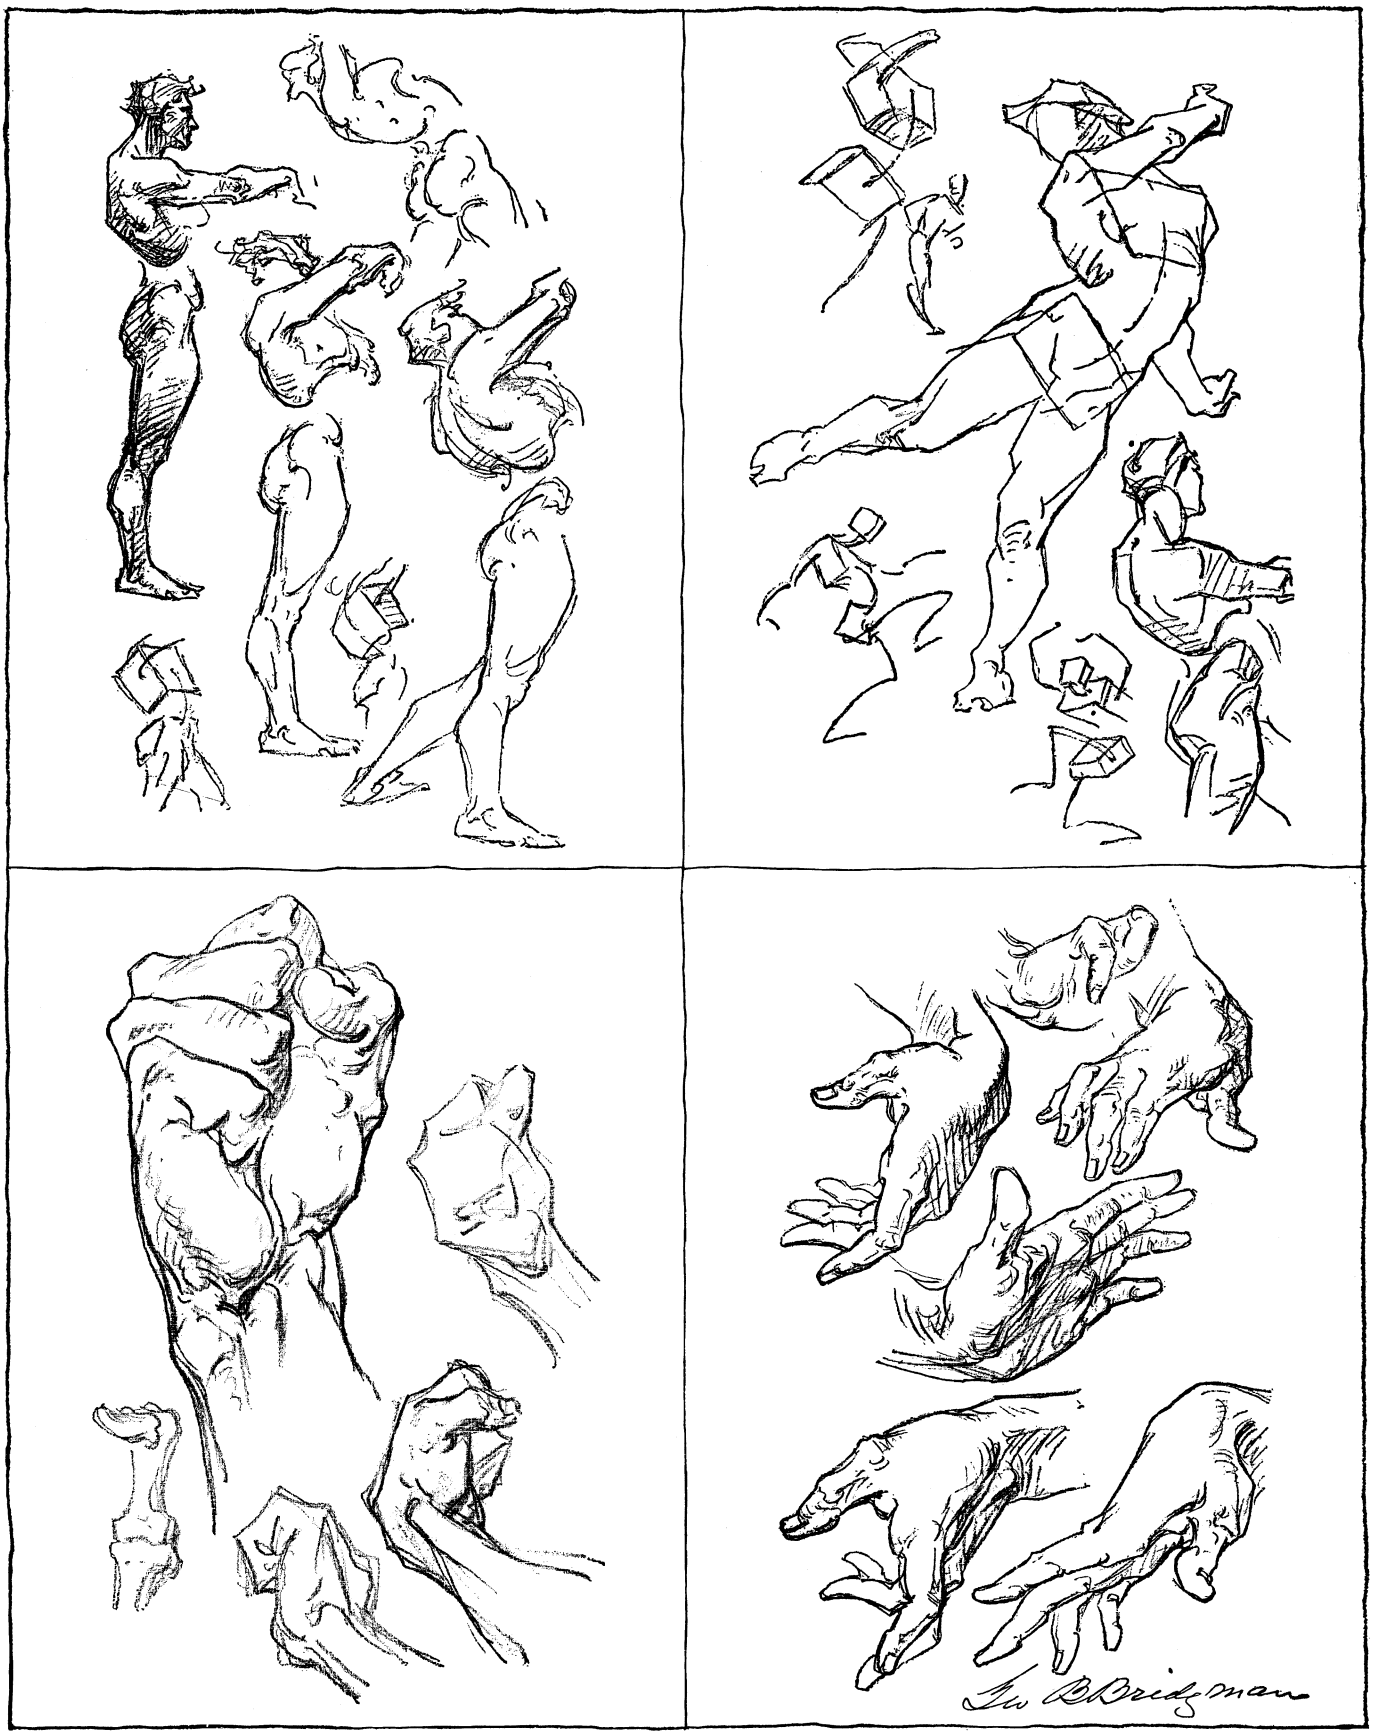
Even more practice and observation are necessary to catch the movement which is also one of the fundamental appeals of good draughtsinanship. First it must be understood that there



LITHOGRAPHIC CRAYON DRAWING BY WARREN E. COX

This drawing was especially prepared by the author of this article to show the appeal which is obtainable through the proper observance of the fundamental laws of structure, movement and composition. The structure of the old tree clearly suggests its struggle against the prevailing winds. The movement of the foliage and grasses is immediate and vital. This movement is aided by the slower movement of the clouds and the even slower movement of the sand dunes and is opposed by that of the tree branch to the right, the dead stick in the sand and the boulder to the left, all of which only help to indicate the strength of the wind. The composition is well balanced but made dynamic by the small tree placed at the extreme lett just disappearing off the picture as does the crow described on the Japanese screen in the text. By the use of these elements the artist has attempted to give the feeling that the sea is just out of sight over the dunes

DRAWING



FROM BRIDGMAN, "CONSTRUCTIVE ANATOMY"

DRAWINGS OF THE FIGURE IN MOVEMENT AND STUDIES OF THE HAND

Upper left. Unchanging masses of the head, torso and pelvis, to be conceived as blocks, and the turning or twisting of these blocks or masses

Upper right. Blocked movements of the figure, showing tilting of the masses

Lower left. Studies of the hand on the wrist indicating power or force

Lower right. Studies of the hand showing rhythm

is movement in everything. Trees, when well drawn, seem to show how through years they have twisted and grown up out of the ground. Rocks show the bending of their hot masses by volcanic eruptions and the splitting and eroding of their surfaces. Just as each thing has characteristic structure and outline so too has it characteristic movement, and this movement must be caught in the drawing and should be emulated to a degree in the very movement of the lines. One does not draw the placid sea of a summer night with the same quality of line and movement as one would use to portray its raging strength in a storm. Without typical movement a drawing lacks life and therefore interest. The savage all over the world typifies a snake by a simple wavy line showing its motion, and he feels that an animal is "not himself" in a drawing, if not shown in typical movement.

Composition. — Closely related to these three fundamental requirements in good drawing is a fourth which came into the consciousness of man undoubtedly at a later date, but thousands of years ago, that is, composition. No doubt the first artists drew without any consideration of a boundary or limitation to their work, but at some time in the dim past, in the decoration of a clay vase or some other object, a discovery was made that the design was related to the space in which it was executed. Slowly through thousands of years drawings were developed which seemed to be a part of the structure of the limitations or borders themselves; outlines were so related that the eye of the observer was held within the limited area and led from one important detail to another, and it was found that movement was somewhat assisted by the proper placing of figures in the surrounding border.

Much has been written about composition. The Far Eastern artist is perhaps its greatest master. After observing carefully the object to be drawn, he sits and looks at the piece of silk or paper upon which he is to work and plans where he is to place the main features. He does not start at once to sketch as do many of our western artists, for he has found that once the pencil or brush is touched to paper one's ideas crystallize and it is difficult to get away from the slightest commitment. It is, therefore, much better to keep the mind at first in a fluid state so that the final arrangement can be unhampered and things can take their proper relationship.

Simple proportions in composition are easy to grasp and have more meaning than have those proportions which the eye does not understand. Rhythmical or parallel movements are interesting methods of accenting what seem to be the most typical lines and are often used. Perfect symmetry is tiring. It is as though one were to sit upright in a chair for a long time. The balance should then be thrown to a greater or lesser degree away from the centre to indicate the movement of the picture and give it ease. The story is told of a famous artist in Japan who was asked to paint a screen for the emperor, showing crows in flight. He at length painted one crow just disappearing off of the fourth panel, leaving the other three untouched. Thus composition helped the movement of the drawing, and the finished work is famous.

If these four simple laws of drawing are observed, it is possible that the finished work will be excellent, but, if any one be omitted, this is impossible. Man has for so long learned to observe structure, outline, movement and composition that the most casual observer feels a lack, if the work does not show them all. Good modelling, perspective and all other considerations can be neglected, and yet a drawing may be a masterpiece aesthetically, though there is no doubt that these do add to its appeal. But these four elements do not in themselves make a great work of art but rather their proper balancing and expression, which may be called taste.

Good Taste. — In considering taste it is first necessary to understand what enters into a good drawing, or any outstanding work of art. The personality of the artist or his style is a great part of it and this may be dashing and strong or delicate and sensitive; it may be keen and light, or ponderous and powerful There are as many styles as there are artists and much of the love that people have for some works of famous artists is due to the fact that these works give some idea of the man himself. There is also the medium used, be it drypoint, graphite, etching, lithographic crayon or brush, and each medium has advantages and disadvantages. The drypoint line is strong and delicate without much flexibility but with a burr which is distinctive. The etched line has a sure clean-cut quality, but neither admit the soft shading possible with the pencil and the crayon or the flexibility of the brush. The appropriateness of the medium and its adaptation to the subject expressed are considerations often neglected, for artists sometimes become used to one medium alone and never find out the possibilities of the others. Finally there are the mood and character of the subject to be expressed. The woodlands which Corot chose to paint seemed to be a part of an enchanted world. The jagged rocks crashing into heaven which Li Lung Mien so deftly rendered with his brush are like flames crackling against the sky. These artists added much of their own imagination to what already existed; but it is nevertheless necessary to have something to start with, and without having seen the elms of France Corot would have found it difficult to paint, as would Li Lung Mien without the rough mountains of China.

Good taste is the perfect fusion of the personality of the artist through long years of practice into a skilful wielding of the tool, which in turn expresses the vital and inner meaning of the object portrayed with all due attention to its structure, its typical silhouette and motion, with appropriate and reasonable composition. When a thing is drawn in good taste one can see what the artist felt while drawing and what his reactions were to the subject shown. Each mark on the paper not only tells how he felt and what his mood was, but what he saw in the mood of the subject. If his subject be a gladiator he may have felt the glory of battle, the vigorous strength, the cruel beauty of the contest; or on the other hand he may have felt the pity and pathos of the inevitable destruction of so beautiful a body. In the one case his strokes would be sharp and vigorous; in the other heavy and dull. Moreover the composition, structure and movement would also reflect both the artist's feelings and those of the subject; both the artist's soul and that of the subject for it is only in this dual expression finely balanced that we ever find the really great works of art.

Some artists fail in good taste because they are so self-centred that they portray everything with too much of themselves and too little of the subject in the work. Others fail because they are so weak that they attempt a totally different treatment for each subject and have nothing to say about any. A drawing may also be in good taste in its expression of line, in its balance of the subjective and objective, but fail because the composition has not been studied to express this condition and is therefore not appropriate. Drawing is like music: it has tempo, key, pitch and many other elements, all of which, when perfectly handled by a master, make for beauty; but which, in the hahds of one untrained or unfeeling, may prove terrible pitfalls.

Three Dimensions. — In this discussion nothing has been said of the attempt to portray three dimensions on a two dimensional surface (see PERSPECTIVE). It is the consensus of opinion that a work of fine drawing can be just as great in two as in three dimensions. Nay, it has often been pointed out that drawing is fundamentally two dimensional art and that the introduction of the third dimension savours of trickeries, and either builds lumps on the two dimensional surface or pushes holes into it. However, since the discovery of perspective, such superb trickery is it that a great vogue for its use has sprung up, and in the development of realistic painting which found its apex in the early 19th century much was done to make man expect the third dimension in drawing. Others, led perhaps by Cézanne, have attempted to give an even greater feeling of solidity to objects by the use of exaggeration and distortion. This is all interesting and may, in thousands of years to come, grow so into the consciousness of man that children drawing in the sand with a stick will spontaneously depict the third dimension, but at present it is a comparatively new development and has not yet penetrated deeply enough to make it one of the fundamental requisites. A

work of art can be a masterpiece if drawn in only two dimensions and does not gain an appreciable aesthetic advantage, if drawn in three.

The Teaching of Drawing.— Owing to a faulty understanding of terms and a general misunderstanding of the underlying principles of art there has been a great etiort in the last generation to teach "originality" and individual expression in all the arts. One might as well try to teach character or soul. These are things which grow through the years and which cannot be taught. The result is a chaotic condition hampered by the belief that artists are born, and that they express their "gift" suddenly and without the work which a careful study of the lives of all great masters proves to be necessary. Some schools do not feel it is necessary to teach the pupils the fundamentals of art, so cautious are they in the foolish etiort to protect their pupils' freedom. Therefore it seems necessary to consider the sane and proper method which should be followed in the instruction of others or of self.

First of all, become friendly with a ruler. A large part of the artist's work consists in measuring with the eye, and it is imperative that the eye be trained to accuracy. Only by judging distances and proportions and then checking one's judgment by measurement can this accuracy be obtained. A good plan for the beginner is to purchase a drawing board, T square, triangles, compasses and pair of medium size calipers. With these instruments an attempt should be made to draw vases of simple form so that the eye may be trained to see curves and proportions. For example (see fig. 5) after the piece of paper is fixed to the board with thumb-tacks (drawing pins) so that its lower edge is in line with the T square when pressed in place at the left side of the board, a line is drawn near the bottom to act as base line and upon this line a portion is measured off with a ruler, equal to the diameter of the base. This line is then divided in half and a perpendicular is erected at its centre, upon which the height of the vase is laid off; at this point another horizontal line is drawn, upon which is laid off the diameter of the lip centred immediately above the base. The ruler is then stood perpendicular to the table upon which the vase stands and moved until it touches the side of the vase at a point where it is widest, and another horizontal line is drawn with the T square, the same distance from the base line as this point is from the table. With the calipers this widest diameter is found and it is laid off on this line. Similar measurements are taken of the narrowest diameters and of their height from the table, and finally the curves are drawn in, touching those points which have been established.

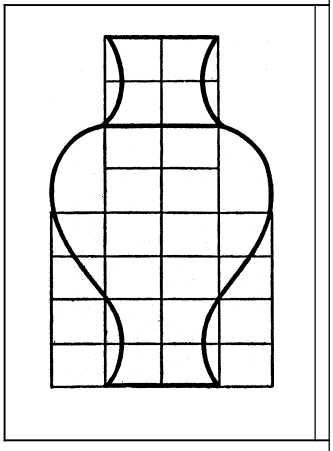


FIG. 5.— DRAWING OF VASE SHOWING METHOD OF TAKING MEASUREMENTS

It will be surprising to the beginner to find how accurate his first drawing is, if done in this manner. It will also be surprising to find how quickly he can grasp the amount of concavity or convexity of a curve no matter in what position it may occur; and to grasp its changes into another curve after he has drawn a number of vases. He will begin to see where one curve becomes more abrupt and another more gentle in its course. Looking back upon his first drawing, he will see all the slight delicacies of line which he missed, and will begin to appreciate the fine innuendoes the potter had put into the vase, which had at first completely escaped his eye.

The modernist may criticize this method and say that it will make the student a slave to the ruler. This is not true, for as time goes on the student needs fewer and fewer actual measurements, until at length he can draw a vase on any scale accurately. It is then time to attempt more complicated forms and these too should be measured at first. The greatest sculptors do not entirely trust their eyes for this work, and it is only by long training and much hard though interesting work that real efficiency can be accomplished, but new beauties will reward the student at every turn as he begins to train his eye to see. There is time enough later to try certain distortions or caricatures of the objects, to gain points which it is wished to stress. These distortions must be based upon correct drawing, or they will not be convincing. During this training the student should constantly observe masterpieces of various kinds, and remember that masterpieces are not only paintings which hang in museums but vases, sculpture, furniture and all of the thousand and one other things which show the touch of real art. The East should be studied as well as the West and every thing which especially appeals should be copied; for it will be found that one sees into a thing much more, if it is actually copied, than one can by any amount of mere looking at it. Through all of this study, the principles which were first pointed out should be kept in mind and an attempt should be made at all times to incorporate them in the actual work as it goes along. (W. E. **Cx.)**

DRAWING, ANATOMICAL. The study of the anatomy of the human body is approached by the artist and the anatomist from different points of view. The former, by a process of artistic selection, seeks the ideal and adopts the proportions which give the most pleasing effect, while the latter desires to know only the mean, or average, of a large series of measurements. *(See* COMPARATIVE ANATOMY.)

ARTISTIC ANATOMY

The representation of the anatomical form of man as applied to the Graphic Arts may be called *Artistic Anatomy*. This form of illustration may be divided into three groups: (1) The schematic, (2) That which represents the subject exactly, (3) The ideal conception or the ideal figure, constructed from the mean proportion of several types.

The schematic drawing is one which represents in outline the main characteristics of the object. It may be drawn with little or no regard as to the exact knowledge of the form. It has been of use in setting forth certain physiologic principles by the general form and location of the organs of the body, and especially used in post-mortem and zootomic comparisons.

The true drawings occur particularly in pathologic anatomy, where various and unknown forms are sought and where certain organs have to be shown in the individual, as in the case of human embryology and comparative anatomy.

The representation of the ideal is the only form suitable for teaching — and the very development of this figuration corresponds with the growth of the science of anatomy in all its periods. This type of drawing presupposes a vast amount of previous study of the human figure. It cannot come out of a period in which the artistic development overshadows that of the science of anatomy. This vague feeling for beauty, with a corresponding neglect of the real, was evidenced in an early period of anatomical illustration, when conditions favoured an artistic point of view, as was the case in the first half of the 16th century. This, however, changed as the cold scientific and extensive dissection was practised during the 17th and 18th centuries. It is only the combination of these two tendencies which can satisfactorily serve the advanced science of anatomy and the modern art of drawing, bringing to perfection through exactness of detail and ceaseless observation a comprehension of beauty in the entire figure.

In artistic anatomy, nothing else is of value to the artist but the idealized drawing. The more he eliminates unessential, the better; the keener his eye for the unnecessary, the bigger his vision of the true needs of the artist. The unnecessary is harmful, and the artist's presentation of too much anatomy makes of him a professional anatomist. Of immediate necessity is the study of the antique, or the older plaster models of Greek figures, for in drawing the nude the young artist visualizes the actual healthy form in all its fulness of life and movement, thus adding an element which can never be supplied by purely anatomic delineation.

HISTORY

The development of artistic anatomy was not of outstanding consequence before the 16th century. Only a few anatomical en-

ANATOMICAL STUDIES FOR ELEMENTARY DRAWING

1–6. Illustrate the method of applying the egg-shape to a profile by means of *a* square

7–13. Are variations controlled by the principle of the egg-shape and square

14–15. Show the construction of nose and eye

16. Shows the proportional measurements of male and female forms

17. Shows six stages in a single step illustrating balance in walking

18–22. Illustrate distribution of weight in figure at rest and in action

gravings and woodcuts are found to that date. Even the drawings that Aristotle used in supplementing his works on anatomy have been lost. Figurations of skeletons and representations of bodies on cameos, seals and bronzes were common, but these delineations never served the purpose of anatomic instruction; they were rather of an emblematic nature: symbols of death, magic amulets, references to the fable of Prometheus, etc. In view of this, artistic anatomy may be divided into the following periods:

To the 16th Century. — Anatomical drawings of the Classic Period and the Middle Ages were known, and even mentioned by Aristotle, but so few have come to us for study that the subject cannot be adequately covered. Before the time of Berengario, commonly called Berenger of Carpi, about 1521, most of the attempts were schematic drawings for medical observation, artistic anatomy remaining in the background as a private study and depending largely upon professional anatomists for its development.

The 16th Century. — Although the name Berengario belongs only to the annals of medicine and will be remembered as the most zealous and eminent in cultivating the anatomy of the human body, it was his day, and that of Vesalius (1514–64), that marked the beginning of the attempt to free the anatomical drawing from schematic and arbitrary features and recognized its place in art. This artistic anatomy, was promoted by both artist and anatomist for the sole purpose of instruction. It was during this period that the Italian School of Anatomy reached its height of interest in the woodcut; it was during this period that sculpture and painting adopted proportions of the human body never before developed; it was during this period that Michelangelo lived. Other 16th century artists who contributed to the study of anatomical figures were Leonardo da Vinci, Raphael, Titian and Diirer.

The **17th** Century. — A comparative study of the antique, a clinging to Vesalian patterns, and the advent of independent publications on artistic anatomy mark the development of the study in the 17th century. A closer training in details and an effort toward the artistically perfect reproduction may also be included.

18th–19th **Century.**—Albinus (1697–1770) was one of the most famous teachers of anatomy in Europe, his classroom at the Leyden School of Anatomy being frequented not only by students but by many practising physicians. The Leyden school exerted untold influence in creating a greater exactness in all details. The styles of both Vesalius and Albinus were used as patterns in anatomical drawinq, many independent attempts proving unsuccessful.

About 1778 combinations of utmost anatomic truths with artistically beautiful reproductions were brought out. The adoption of the steel engraving, lithography, the daguerreotype, as well as the revival of the woodcut in an improved form, meant an advance in the art; the exclusive use of the Albinian patterns gave rise to a greater independence. In fact, 1778 may be given as the beginning of the period in which the most valuable material on artistic anatomy was produced. Modern scientific medicine had gained its stride and was already moving swiftly toward the goal of a well-organized body of real knowledge capable of continuous growth. And this development may be shown in the bibliographic list as given below, the chain running from the first half of the 18th century to the present day. This bibliographic account gives the distinctive examples of anatomic illustration, including the modern work in both the technical and the artistic.

TECHNIQUE

For the young student of anatomy as applied to art the simple drawing is the most effective in learning to construct the human figure. The eye must follow a line or a plane or a mass, which in construction becomes a moving line, a moving plane, a moving mass. But the mental construction must precede the physical, and in this the concept of mass must come first, that of the plane second, that of line last.

Certain laws enter into the functioning of the various organs of the body, just as pronounced as they are in controlling any other machinery. To the bones, for example, which make up the pressure system, belong the laws of architecture. as in the dome of the head, the arches of the foot, the pillars of the legs, etc.; also the laws of mechanics, such as the hinges of the elbows, the levers of the limbs, etc. Ligaments constitute the retaining or tension system, and express other laws of mechanics. Muscles produce action by their contraction or shortening and are expressed in the laws of dynamics and power, as well as the laws of leverage.

In giving herewith only an outline of the construction of the main parts of the body, the author presupposes a rudimentary knowledge of drawing, on the part of the student, and offers the following, in connection with the illustrations only as a further guide in studying the elements of anatomy and becoming more adept in the art of drawing.

The Hand. — In drawing the hand the artist must realize that, as in the human figure, there is an action and inaction side. When the thumb side is the action side the little finger is the inaction side. The inaction construction line runs straight down the arm to the base of the little finger. The action construction line runs down the arm to the base of the thumb at the wrist, from there out to the middle of the joint, at the widest part of the hand; thence to the knuckle of the first finger, then to that of the second finger, and then joins the inaction line at the little finger. However, with the hand still prone, when it is drawn *from* the body the thumb side becomes the inaction side and is straight with the arm, while the little finger, corresponding previously to the thumb, is at almost right angles with it. The inaction construction line now runs straight to the middle joint of the thumb, while the action line runs to the wrist on the little finger side, thence to the first joint.

The Fingers. — Each of the four fingers has three bones. The middle finger is the longest and largest, because in the clasped hand it is opposite the thumb and with it bears the chief burden. The little finger is the smallest and shortest and most freely movable for the opposite reason. The middle joint of each finger is the largest, and, like all the bones of the body, the bones of the finger are narrower in the shaft than at the ends. In the clenched fist it is the end of the bone of the hand that is exposed to make the knuckle. Each of the three joints moves about one right angle except the last, which moves slightly less. The movements of the joints are also limited to one plane, except the lower one, which has also a slight lateral movement, as shown when the fingers are spread.

The Thumb. — The centre of all the activities of the fingers. the hand, and the forearm, is the thumb. The fingers, gathered together, form a corona around its tip. Spread out, they radiate from a common centre at its base; and a line connecting their tips forms a curve whose centre is the same point. This is true of the rows of joints also. The thumb has three joints, and its bones are heavier and its joints more rugged than those of the fingers. It is pyramidal at the base, narrow in the middle, pear-shaped at the end. The ball faces to the front more than sideways. The thumb reaches to the middle joint of the first finger. The last segment bends sharply back, its joint having about one right angle of movement, and only in one plane. The middle segment is square with rounded edges, smaller than the other two, with a small pad. Its joint is also limited to one plane. The basal segment is rounded and bulged on all sides. The joint of its base is a saddle joint, with the free and easy movement of one in a saddle.

The Arm. — The forearm has two bones, lying side by side. One, the radius, is large at the wrist and the other, the ulna, is large at the elbow. Diagonally opposite the thumb, on the ulna, is a bump of bone which is the pivot for both the radius and also the thumb. Muscles must lie above the joint they move, so the muscles that bulge the forearm are mainly the flexors and extensors of the wrist and hand. The flexors and pronators form the inner mass at the elbow, the extensors and supinators form the outer mass.

Both the above masses arise from the condyles of the humerus, which is the bone of the upper arm. The part of the humerus near the shoulder is rounded and enlarged, where it joins the shoulder blade. The lower end is flattened out sideways to give

attachment to the ulna and radius, forming the condyles. The shaft itself is straight and nearly round, and is entirely covered with muscles except at the condyles.

The Shoulder.—The deltoid muscle, triangular in shape, gives form to the shoulder. Just below the base is a ripple which marks the head of the arm bone. The masses of the shoulder, arm, forearm and hand do not join directly end to end with each other, but overlap and lie at various angles. They are joined by wedges and wedging movements. Constructing these masses first as blocks, we will have the mass of the shoulder, or deltoid muscle, with its long diameter sloping down and out, leveled off at the end; its broad side facing up and out; its narrow edge straight forward. The mass of the forearm overlaps the end of the arm on the outside by a wedge that rises a third of the way up the arm, reaches a broad apex at the broadest part of the forearm and tapers to the wrist, pointing always to the thumb; and on the inside by a wedge that rises back of the arm and points to the little finger. In the lower half of the forearm, the thin edge of the mass, toward the thumb, is made by a continuation of this wedge from the outside. In the back view of the arm, the mass of the shoulder sits across its top as in the front view.

The Neck.—Curving slightly forward, the neck rises from the sloping platform of the shoulders. The strength of the neck is at the back of the head, this portion being somewhat flat and overhung by the base of the skull. The sternomastoid muscles descend from the bony prominences back of the ears to meet almost at the root of the neck, forming a triangle whose base is the canopy of the chin. In this triangle below is the thyroid gland, larger in women, and above it the angular cartilage of the larynx, or Adam's apple, larger in men.

The Head.—Both the oval and the cube have been used by artists as a basis for drawing the head, but the cube seems preferable in that the oval is too indefinite and offers no points for comparison, no basis for measurement, and the eye does not fix on any point in a curved line. The block not only carries the sense of mass, but provides a ground plan on which any form may be built, as well as its perspective and foreshortening. The element of bilateral symmetry enters the drawing of the head. A vertical line in the centre divides the head or the trunk into parts equal, opposite and complemental. The right eye is the counterpart of the left; the two halves of the nose are symmetrical; the limbs, except for changes of position, are nearly exact though reversed duplicates of each other.

The cranium, the skeleton of the face, and the jaw constitute the masses of the head. Into the rounded mass of the cranium sets the narrower mass of the forehead bounded by the temples at the sides and by the brows below. From the lower outer corners of the forehead the wedge of the cheek bones begins, moves outward and downward until it just passes the curve of the cranium, then down and in, in a long sweep, to the corner of the chin. The two cheek bones together form the central mass of the face, in the middle of which rises the nose.

The planes of the head are those of the forehead, sloping upward and backward to become the cranium. The sides turn sharply to the plane of the temples. The plane of the face, divided by the nose, is broken on each side by a line from the outer corner of the cheek bone to the centre of the upper lip, making two smaller planes. The outer of these tends to become the plane of the jaw, which is again divided, etc. The relations of these masses and planes is to the moulding of a head what architecture is to a house. They vary in proportion with each individual and now must be carefully compared with a mental standard.

The Eye.—Below the eyebrow, on the lid, are three planes, wedging into each other at different angles. The first is from the bridge of the nose to the eye. The second is from the brow to the cheek bone, which is again divided into two smaller planes, one sloping toward the root of the nose, the other directed toward and joining with the cheek bone. The lower lid is stable; it is the upper lid that moves. It may be wrinkled and slightly lifted inward, bulging below the inner end of the lid. The cornea is always curtained by the upper lid, in part. The immovable masses of the forehead. nose and cheek hones form a strong setting for the most variant and expressive of the features.

The Nose.—The bony part of the nose is a very clear wedge, its ridge only half the length of the nose. The cartilaginous portion is quite flexible, the wings being raised in laughter, dilated in heavy breathing, narrowed in distaste, and wings and tips are raised in scorn, wrinkling the skin over the nose.

The ears, the mouth, the lips, and the chin, all offer variations in construction, and it is through comparison with others that the art of drawing them can best be acquired.

The Trunk.—The upper part of the body is built around a bony cage called the thorax, conical in shape, and flattened in front. The walls of this cage are the ribs, twelve on each side, fastening to the spine behind and to the sternum or breast bone in front. The first seven are called true ribs, the next three false, and the last two floating ribs. The masses of the torso are the chest, the abdomen or pelvis, and between them the epigastrum, the first two comparatively stable, the middle one quite movable. The shoulders are also movable, changing the lines of the first mass and bulging the pectoral muscles, but the mass itself changes little except the slight change in respiration. The mass of the abdomen is even more unchanging.

The Torso.—In profile the torso presents three masses: the chest, the waist and the abdomen. The mass of the chest is bounded above by the line of the collar bones; below, by a line following the cartilages of the ribs. This mass is widened by the expansion of the chest in breathing, and the shoulder moves freely over it, carrying the shoulder blade, collar bone and muscles. The back view of the torso presents numerous depressions and prominences, due to its bony structure and the crossing and recrossing of a number of thin layers of muscles. The outside layers mardfest themselves only when in action, and for this reason the spine, the shoulder-blade, and the hip-bone are the landmarks of this region.

The Lower Limbs.—The thigh, the leg, and the foot constitute the lower limb. The thigh bone is the longest and strongest bone of the body, and the mass of the thigh is inclined inward from hip to knee, and is slightly beveled toward the knee from front, back and outside. Below the knee is the shin bone, the ridge of which descends straight down the front of the leg, a sharp edge toward the outside, a flat surface toward the inside, which at the ankle bends in to become the inner ankle bone. The outer bone of the foreleg soon overlaid by a gracefully bulging muscular mass, emerges again to become the outer ankle bone. Two large muscles form the mass on the back of the leg.

The Foot.—In action, the foot comes almost into straight line with the leg, but when settling upon the ground it bends to keep flat with the ground. A series of arches form the symmetry of the foot, the function of these arches being that of weight-bearing. The five arches of the foot converge on the heel, the toes being flying buttresses to them. The balls of the foot form a transverse arch. The inner arches of the foot are successively higher, forming half of a transverse arch whose completion is in the opposite foot. (See COMPARATIVE ANATOMY; ILLUSTRATION; SCULPTURE.)

Elementary. — The young artist is primarily interested in making drawings of people, faces and particularly, profiles. A series of charts giving the simple and fundamental rules of proportion is shown as a practical means of starting him in this art.

For the profile, a square is drawn and divided into four equal squares, and the eyes, nose, mouth, chin and ear are placed upon this chart as shown in the progressive illustrations. When the head is complete, the student will discern the egg-shape, which is his first and constant principle, and which should be practised constantly until an egg can be drawn perfectly with one sweep of the hand. Proportions can soon be found on an egg-shape without the aid of a square. Next, the full face is attempted, following the same principles of proportion. It will be observed that the eyes divide the width of the egg-shape into approximately five equal spaces. The two-thirds view and all other variations of the human Bead should be drawn by means of the egg. With the profile the beginner will discover that all types of heads, fat, thin and old, may be drawn over the square chart with only minor variations in line. The baby and the gorilla are opposite extremes and present exceptions to the rule for placing the eye on the half-way point.

The "Greek Ideal" divided the human figure into eight divisions, each equal to one head in height; but actually it is seven and one half heads high. The woman's head is smaller, but the divisions of the body are in similar proportion. Note that in the figure of the man the shoulders are wider than the hips, and the woman's hips are wider than her shoulders.

Taking up these two figures in action, the young artist must learn to look at the figure as a whole; he must consider the one line which expresses the motion he desires, and forget that the figure is made of arms and legs and torso. He must also consider balance. The distribution of weight is directly over the feet, no matter how heavy the load. Without carrying a weight, the chin of the figure is directly over the foot which sustains the weight.

(P. H. St.)

DRAWING, ENGINEERING, the general term for the drawing used in the industrial world by engineers and designers, mechanical, architectural, structural, etc., as the formula in which is expressed and recorded the ideas and information necessary for the building of machines and structures. It is distinguished from drawing as a fine art in that it is not pictorial representation but a complete graphical language in which exact and positive information is given regarding every detail of the structure or machine to be built. Since it describes the object as it actually is to be and does not show it in pictorial form as it would appear to the eye it can be read and understood only by one trained in its use. When this language is written exactly and accurately it is done with the aid of mathematical instruments and is called *mechanical drawing*. When done freehand it is known as *technical sketching*. As it cannot be read aloud like a written language it must be interpreted by forming a mental image of the subject represented, and the engineer in reading a drawing that would appear to be only a complicated mass of lines has as clear a picture of the structure standing in space as if it were actually before him. Apart from its practical utility, the value of teaching drawing in the schools is in the training of this constructive imagination, the perceptive ability to think in three dimensions, to visualize quickly and accurately, to build up a clear mental image, a training useful not only to professional designers but to all who may be interested in technical industries.

The basis of engineering drawing is orthographic projection, which may be defined as the method of representing the exact shape of an object by two or more views on planes at right angles to each other, by dropping perpendiculars from the object to the planes. There are two systems in use; the first and older is *first angle projection*, in which the object is assumed to be placed in the first quadrant of the four dihedral angles formed by the intersection of two reference planes called the co-ordinate planes or planes of projection, fig. 1 (*cf.* Descriptive Geometry). and its points projected to these planes, the horizontal plane (*H*) then revolved to coincide with the vertical plane (V), the two being represented by the plane of the drawing paper. A third or profile plane (P) perpendicular to the H and V planes is used for a third view if necessary. Fig. 2 shows an object in the first angle and fig. 3 the resulting arrangement of views when the planes are opened. This is the system in present use in Great Britain and other European countries except the Netherlands. It was used in the United States until about 1890 when the industrial works began to change to the newer system of *third angle projection* which in a few years entirely replaced the former method. It is significant that this movement originated in the shops instead

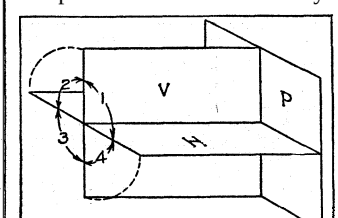

FIG. 1— THETHEORETICAL PLANES OF PROJECTION. SHOWING THE FOUR ANGLES

of in the colleges, after experiments with workmen demonstrated that they could read third angle drawings much more easily than those made in the first angle.

Third angle, or, as it is called in Europe, American projection, assumes the object to be placed in the third quadrant of the co-ordinate planes, and the observer to be looking *through* the planes at the object, as shown in fig. 4. These planes when opened into one plane give an arrangement of views as in fig. 5. Thus the object may be thought of as surrounded by a glass box with its sides hinged to each other (fig. 6), the object projected to these sides and the box opened up into one plane. In both systems the projection on the front plane is known as the *front view, elevation* or *vertical projection,* that on the top plane the *top view, plan* or *horizontal projection,* that on the side plane as the *side'view* or *end view, side* or *end elevation* or *profile projection.* For a simple object two views are often sufficient, others may require three or more. Sometimes the left side view can be used to better advantage than the right side. In some cases the bottom view, and more rarely the back view will be required. Fig. 7 shows the box as it opens and indicates the positions of these different views.

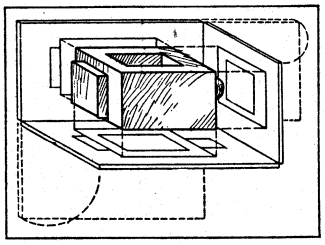

FIG. 2.—AN OBJECT IN THE FIRST ANGLE, PROJECTED TO THE PLANES

It is a growing practice in the United States to teach elementary projection drawing without reference to the planes of projection, by explaining that the problem is to represent a solid, with three dimensions, on a flat sheet of paper having only two dimensions in such a way as to tell its exact shape, and that this is done by drawing a system of "views" of the object as seen from different positions and arranging these views in a definite manner, each view showing two of the three dimensions. Taking, for example, the block shown in pictorial form in fig. 8, if the observer imagine himself as in a position directly in front (theoretically at an infinite distance, practically at a reasonable seeing distance but imagining the rays of light from each point to his eye as parallel) its front view would appear as in fig. ga. This view tells the length and height but not the width of the block nor the depth of the notch. Then let the observer change his position so as to look down from directly above the-block. He will see the top view (fig. gb), giving the length and width, and the shape of the notch. It is necessary to have another view from the side in this case to show the shape of the triangular part. Fig. 9c is the right side view. These three views arranged in their natural position with the top view directly above the front view and the right side view to the right of the front view, completely describe the shape of the block. Note that in the top and side views the front of the block always faces toward the front view.

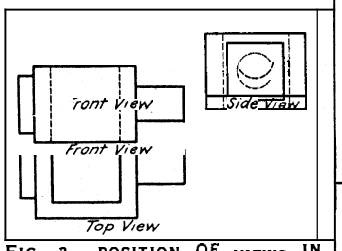

FIG. 3.—POSITION OF VIEWS IN

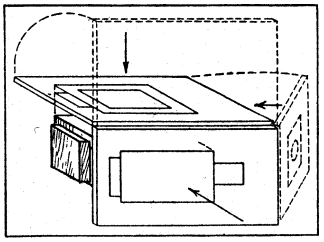

FIG. 4.— AN OBJECT IN THE THIRD ANGLE. PROJECTED TO THE PLANES

The argument for this teaching method is that the student visualizes the object itself without being confused in trying to visualize the projections. Its success is indicated in that some engineering schools are now teaching the whole subject of descriptive geometry without using the reference planes.

Reading a Drawing.—A line on a drawing always indicates either an intersection of two surfaces, as in the projection of a prism, or a contour, as in the projection of a cylinder (fig. 10), a visible edge being represented by a full line and an invisible one by a "dotted" line, *i.e.,* a line made up of short dashes. One cannot read a drawing by looking at one view. Each line on the view (except a contour line) denotes an abrupt change in direction, but the corresponding part of another view must be consulted to tell what the change is. For example, a circle on a front view might mean either a hole or a projecting boss. A glance at the side view or top view will tell immediately which it is. In reading a drawing one should first gain a general idea of the shape of the object by a rapid survey of all the views given, then should select for more careful study the view that best shows the characteristic shape, and by referring back and forth to the adjacent views see what each line represents. In looking at any view one should always imagine that it is the object itself, not a flat projection of it, that is seen, and in glancing from one view to another the reader should imagine himself as moving around the object and looking at it from the direction the view was taken.

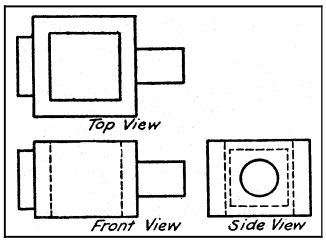

FIG. 5.—POSITION OF VIEWS IN THIRD-ANGLE PROJECTION

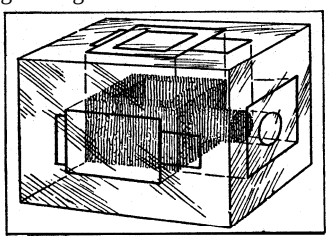

FIG. 6.— TRANSPARENT BOX. ILLUSTRATING THE THEORY OF THIRD-ANGLE PROJECTION

Auxiliary Views.—A surface is shown in its true shape when projected on a plane parallel to it. In the majority of cases an object may be placed with its principal facesparallel to the three reference planes and be fully described by the regular views. Sometimes however the object may have one or more inclined faces whose true shape it is desirable or necessary to show, especially if irregular in outline. This is done by making an auxiliary view looking straight against the surface, that is, imagining a projection on an extra or auxiliary plane parallel to the inclined surface, therefore perpendicular to the same reference plane to which the inclined surface is perpendicular, and revolving it into the plane of the paper There are three kinds of auxiliary views, first *auxiliary elevations* (fig 11), made on planes which are perpendicular to the horizontal plane but at an angle with the vertical plane, or in other words the kind of views that would be seen if one walked around the object starting from the position at which the front view is seen Thus an auxiliary elevation would have the same height as the front view. The second kind, called sometimes *left and right auxiliary views,* are used much more frequently. They are made on planes perpendicular to V but inclined to *H* Fig 12 is an example, showing that the width of the auxiliary view is the same as the width of the top view. Third, *front and rear auxiliary views,* on planes perpendicu-

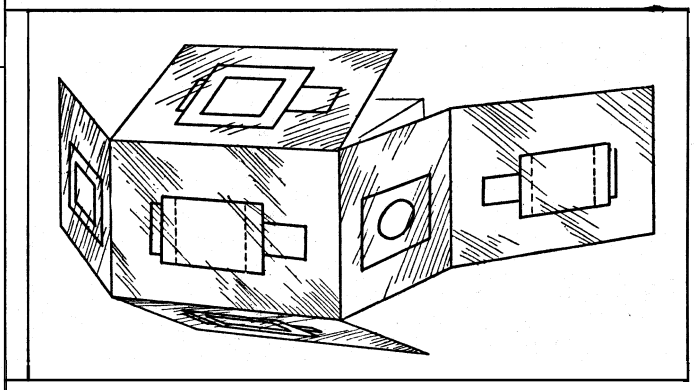

FIG. 7.— THE BOX PARTLY OPENED INTO THE PLANE OF THE PAPER. SHOWING THE RELATIVE POSITIONS OF TOP, FRONT, LEFT, RIGHT. REAR AND BOTTOM VIEWS

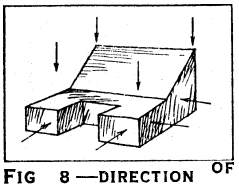

FIG 8 —DIRECTION OF VIEWS

lar to the profile plane but inclined to H and V, in which the width of the auxiliary view is the same as the width of the front view (fig. 13). Often an auxiliary view will save making one or more of the regular views and at the same time show the shape or construction of the object to better advantage. They are used extensively in the drawing of machine parts and usually are only partial views showing the inclined surface alone. In fig. 14 a front view, partial top view and two partial auxiliary views, describe the shape of the piece in the simplest way.

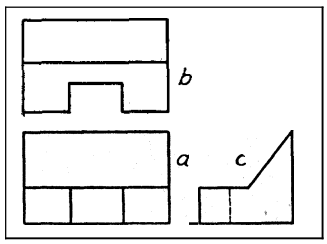

FIG. 9.— FRONT. TOP AND RIGHT SIDE VIEWS OF BLOCK

Sectional Views.—When an object is solid or the interior simple the invisible parts can be represented satisfactorily by dotted lines, but if there is much interior detail, especially if the object is made in more than one piece, the dotted lines become confusing and hard to read. In such cases a view is made "in section," as if for that particular view a part of the object were supposed to be cut away and removed, exposing the interior. This view is known as a sectional view or simply a *section.* If the object is symmetrical the cutting plane is usually passed through one of the main axes and the front half imagined as removed. The exposed cut surface of the material is indicated by "section-lining" or "cross-hatching" with uniformly spaced fine lines. It must be understood clearly that in thus removing the front portion in order to show the sectional view this portion is not removed from the other views. Fig. 15 shows in pictorial form a casting intersected by a cutting plane and its appearance when the front half is removed; fig. 16 shows the two views of the casting, the front view in section. The edge of the cutting plane is indicated by the line symbol of a dash and two dots, with reference letters and arrows showing the direction in which the view is taken. The cutting plane need not be in a single continuous plane but may be offset in any part of its length to go through some detail. Shafts, bolts, nuts, keys, rods, rivets and the like whose axes occur in the plane of the section are left in full and not sectioned. Adjacent pieces are section-lined in opposite directions, and are often brought out more clearly by varying the pitch, using closer spacing for smaller pieces. The same piece in different views or in different parts of the same view should always be section-lined identically in direction and spacing. A common and economical way of showing an object which is symmetrical about a centre line is by making what is called a *half section,* drawing one side in section and the other in full. In such a view dotted lines are unnecessary. *Revolved sections,* made by passing a cutting plane through some detail such as a rib or the arm of a wheel and turning it in place are often used (fig. 17). *Detail sections* are for the same purpose but instead of being drawn on the view they are set off to some adjacent place on the paper. The cutting plane, with reference letters, should always be indicated. *Phantom sections* are exterior views with the interior construction brought out by dotted cross-hatching.

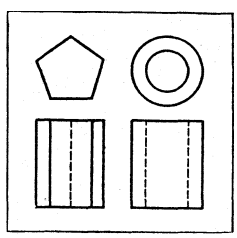

FIG. 10.— INTERSECTION LINES AND CONTOUR LINES

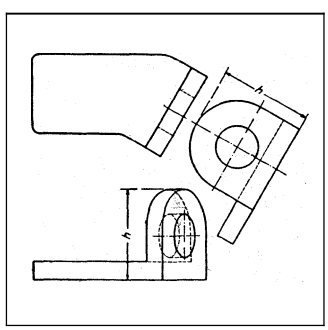

FIG. 11.— AUXILIARY ELEVATION, PROJECTED FROM TOP VIEW

A *working drawing* is a drawing that gives all the information necessary for the complete construction of the object represented. It includes (1) The full representation of the *shape* of every part of the object (orthographic projection). (2) The *size* of every part, in figures (dimensioning). (3) Explanatory notes giving specifications as to materials, finish, etc. (4) A descriptive title. Often as in architectural and structural drawing the notes of materials and workmanship are too extensive to be lettered on the drawings so are made up separately in typewritten or printed form and are called the *specifications,* hence the term "drawings and specifications." Working drawings are divided into two general classes, *assembly* drawings and *detail* drawings. An assembly drawing is, as its name implies, a drawing of the machine or structure put together, showing the relative positions of the different parts (fig 18). Its particular use is in the erection of the structure. It may give the all-over dimensions and distances from centre to centre or part to part of the different pieces, showing their relation to each other, usually indicating the different parts by "piece numbers," often enclosed in circles. It frequently includes a "bill of materials," a tabulated statement of all the used, including stock parts such as bolts, screws, cotters, etc. Classified under the general term of assembly drawings would be other forms, as the *design drawing,* the preliminary layout, full size if possible, on which the scheming, inventing and designing are worked out accurately after freehand sketches and calculations have determined the general idea. From it the detail drawings of each piece are made. Sometimes the finished assembly drawing is traced from the design drawing, more often it is redrawn, perhaps to smaller scale to fit a standard sheet, using the detail drawings to work from, thereby checking their correctness. An *outline assembly* is used to show the appearance of the machine, sometimes for catalogue or other illustrative purposes. Piping, wiring and oiling diagrams are also forms of assembly drawings. An *assembly working drawing* showing fully the dimensions and construction of each piece as well as their relative positions, so that no separate detail drawings are needed, may be made for a simple machine. A *unit assembly drawing* is a drawing of a related group of parts, in a complicated machine or structure.

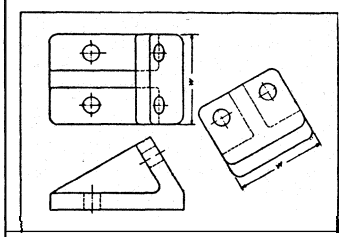

FIG. 12.— RIGHT AUXILIARY VIEW. PROJECTED FROM THE FRONT VIEW

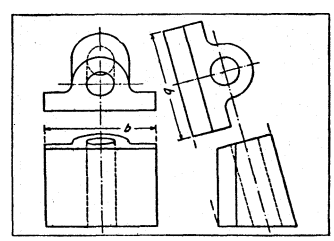

FIG. 13.—FRONT AUXILIARY VIEW, PROJECTED FROM SIDE VIEW

A *detail drawing* is a complete description of each separate piece, giving its shape, size, material and finish, what shop operations are necessary, what limits of accuracy are demanded and how many of each are wanted (fig. 19). Sometimes smaller parts of the same material or character are grouped together, as forgings on one sheet, special bolts and screws on another, etc., but in large production the accepted practice in a set of drawings is to have each piece, no matter how small, on a separate sheet.

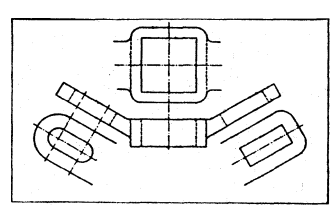

FIG. 14.—FRONT VIEW, WITH PARTIAL TOP VIEW AND PARTIAL AUXILIARY VIEWS

In commercial drafting, accuracy and speed are the two requirements. The drafting room is an expensive department. There are therefore many conventional methods or idioms and abbreviations of the language, with which the draftsman must be familiar. There are also allowable violations of the strict principles of projection when added clearness may be gained. One of the time-saving conventions is in the representation of screw threads. The helical curves are never drawn except on screws of very large diameter, but are conventionalized into straight lines, and on screws less than perhaps an inch in diameter the thread contours are omitted, the threaded portion of a shaft being represented by one of a number of conventional symbols, of which three are shown in fig. 20, A being the commonest. As another example: in making working drawings of gears and toothed wheels the

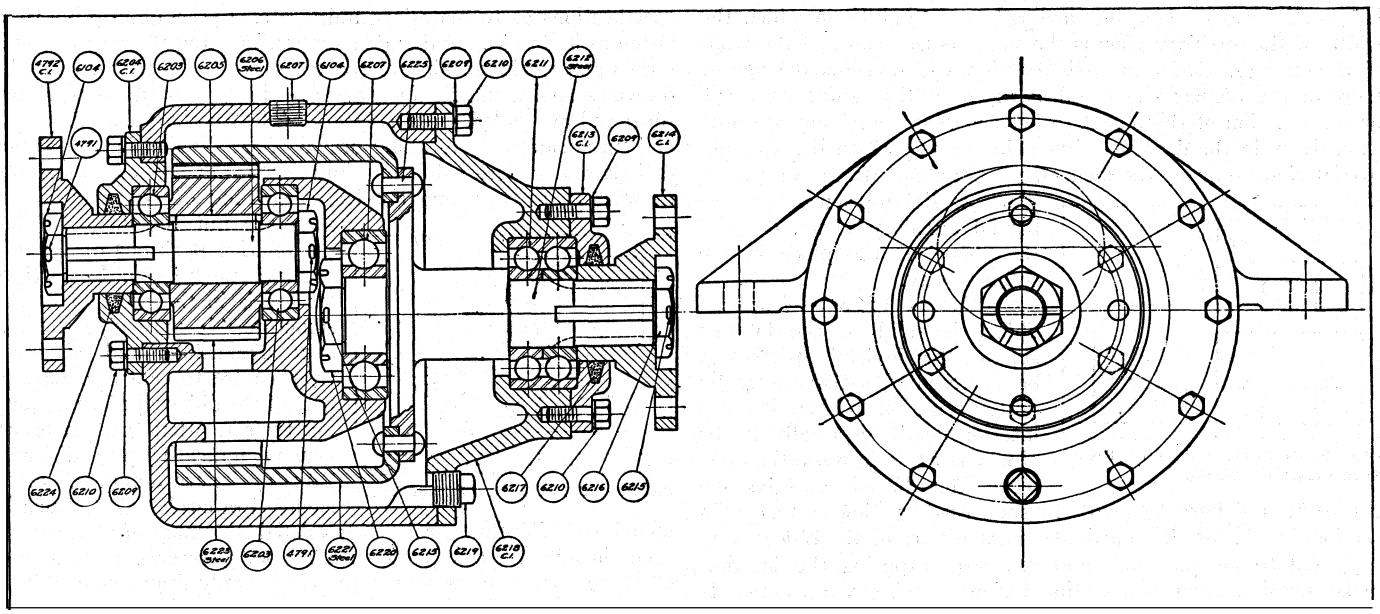

FIG. 18.— ASSEMBLY DRAWING WITH PIECE NUMBERS

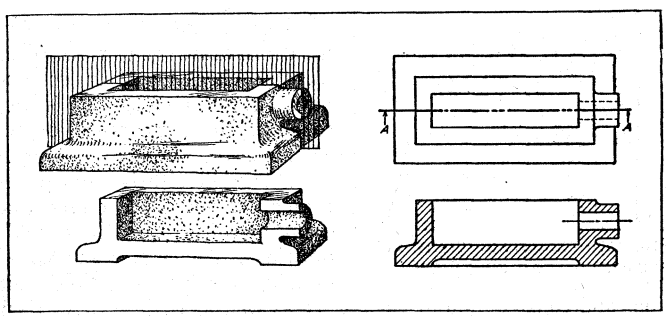
teeth are not drawn but are represented by drawing the pitch circle, addendum and root circles. On detail drawings for cast gears the full-size outline of one tooth is added and for cut gears the blank is drawn with notes and dimensions giving full information.



FIGS. 15 & 16 — SHOWING THE CUTTING PLANE AND SECTION ON A-A

On patent drawings, however, all the teeth on a gear must be shown.

Fig. 21 is an illustration of the violation of theory, in which the true projection of the sectional view is not as good an explanation of the piece as the preferred form in the second view. When a cutting plane passes through a rib (fig 22), a true section, *A* is heavy and misleading. The usual method is to omit the section lines from the rib, *B*, as if the cutting plane were just in front of it. Another method sometimes used is to section the rib as at C. There have been a number of different codes of symbols proposed and published for the indication of different metals and materials in section, but there is no established universal standard. At the present time, however, all the countries where drawings are made have either officially adopted each its own standard set of rules and symbols for all the conventions used in drawing, as threads, finish, dimensioning, materials, etc., or are working on such standards through the Government or the engineering societies.

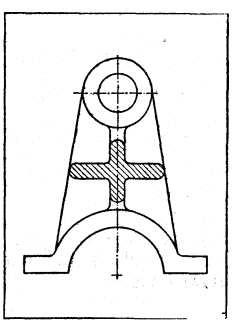


FIG 17.—A REVOLVED SECTION

Scales.—In representing objects which are larger than can be drawn to their natural or "full size" on the paper, it is necessary to reduce the dimensions on the drawing proportionally, and for this purpose the so-called architect's scale of proportional feet and inches is used The first reduction is to what is commonly called "half-size," or correctly speaking "to the scale of $6''=1'$. This scale reduction is used on working drawings even if the object be only slightly larger than could be drawn in full size, and is generally worked with the full size scale by halving the dimensions. If this is too large for the paper the drawing is made to the scale of $3''=1'$, commonly called quarter-size. This is the first scale of the usual commercial set. Others are $1\frac{1}{2}''$; $1''$; $\frac{3}{4}''$; $\frac{1}{2}''$; $\frac{3}{8}''$; $\frac{1}{4}''$; $\frac{3}{16}''$; $\frac{1}{8}''$; and $\frac{3}{32}''$ to the foot. Drawings to odd proportions as

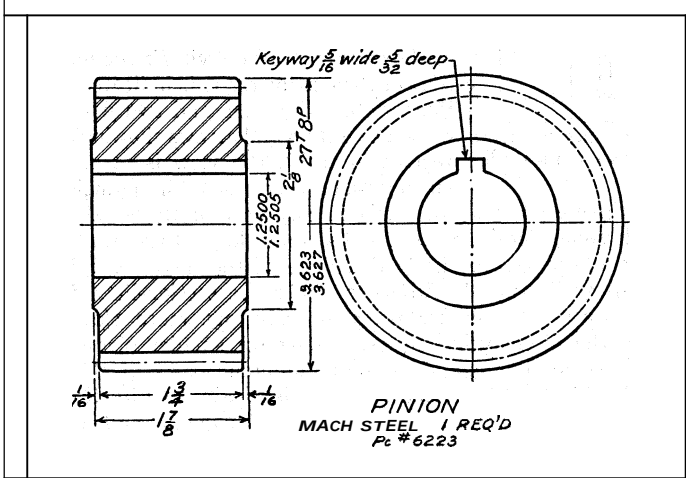

FIG. 19.— DETAILDRAWING

$9''=1'$, $4''=1'$, etc., are not used except in rare cases when it is desired to make it difficult or impossible for a workman to measure them with an ordinary rule. The scale $\frac{1}{4}''=1'$ is a usual one for ordinary house plans and is often called by architects "quarter-inch-scale," meaning not quarter size but that one-quarter inch on the drawing represents one foot on the building. For plotting and map drawing the civil engineer's scale of decimal parts, 10, 20, 30, 40, 50, 60, 80, 100 to the inch, is used but this scale should never be used for machine or structural work. Drawings in the metric system are not made to half-size or quarter-size. The first regular scale smaller than full size is one-fifth size, then one-tenth size, although sometimes the scale of 1 to $2\frac{1}{2}$ is used. The unit of measurement is the millimetre and figures are all understood to be millimetres, without any indicating mark.

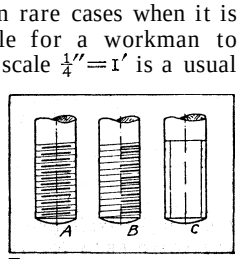

FIG. 20.—THREAD SYMBOLS

Dimensioning.— After the correct representation of the object by its projections, that is, telling the *shape,* the entire value of

the drawing as a working drawing lies in the dimensions, *i.e.*, telling the size. Successful dimensioning requires not only a knowledge of the principles and conventions but an acquaintance with the shop processes which enter into the construction. A dimension line is usually made as a fine full line terminated by carefully made arrow-heads which indicate exactly the points to which the dimension is taken. Some use a dash line and some a red line for dimension lines. On machine drawings a space for the

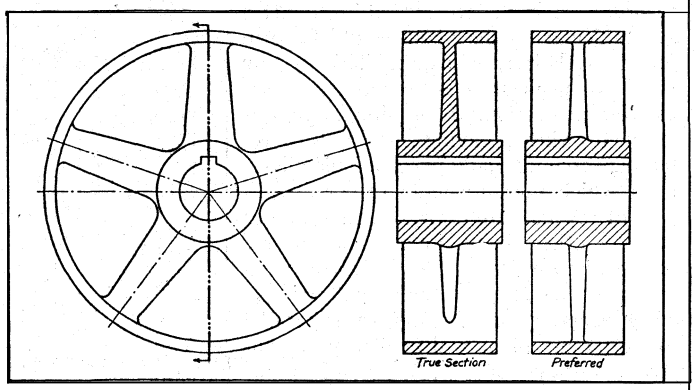

FIG. 21.— TRUE SECTION AND ITS PRACTICAL MODIFICATION

figures is left in the dimension line; in structural and much architectural practice the figure is placed above a continuous dimension line. Extension or witness lines not touching the outline, indicate the distance measured when the dimension is placed outside the figure.

In dimensioning there are some conventional practices which have come to represent good form to such an extent as to have the force of rules:

1. Dimensions on horizontal and inclined dimension lines should read from left to right; those on vertical lines from bottom to top; *i.e.*, so as to be read from the right hand side of the sheet.
2. Preferably keep dimensions outside the view unless added clearness, simplicity and ease of reading will result from placing them inside. They should for appearance's sake be kept off the cut surfaces of sections. When necessary to be placed there the section-lining is omitted around the numbers.
3. Feet and inches are designated thus, 5'-3". When a dimension is in even feet it is indicated thus 5'-0".
4. Fractions are always made with horizontal division lines.
5. Dimensions should generally be placed between views.
6. Do not repeat dimensions unless there is a special reason for it.
7. Do not crowd dimensions.
8. In general give dimensions from or about centre lines. Never locate holes or other machine operations from the edge of unfinished castings.
9. Never give dimensions to the edge of a circular part but always from centre to centre.
10. If it is practicable to locate a point by dimensioning from two centre lines do not give an angular dimension.
11. Never use a centre line as a dimension line.
12. Never use a line of the drawing as a dimension line.
13. Do not allow a dimension line to cross an extension line unless unavoidable.
14. The diameter of the "bolt circle" of holes in circular flanges is given, with the number and size of holes.
15. Give the diameter of a circle, not the radius.
16. Give the radius of an arc. marking it ***R*** or Rad.
17. Never place a dimension so that it is crossed by a line.

Fits and Tolerances — With the demand for interchangeability and quantity production the exact size in decimals is specified for "essential dimensions" with the amount of "tolerance" over and under which will be allowed by the inspector, since it is not possible to work to an absolutely accurate dimension. These limits are set by the engineering department and placed on the drawing, and the shop follows orders explicitly. In fitting one piece with another, as a shaft and hub, the diameters in decimals with allowed tolerances are given for each, superseding the older practice of leaving the amount of allowance for different kinds of fits to the machine shop. Much experience in manufacturing is needed as well as a study of the particular mechanism involved before the draughtsman is able to know just the accuracy necessary and to specify proper tolerance. When unnecessarily small tolerances are set the cost of manufacture is greatly increased. The general tolerance is often stated in a note near the title.

Checking. — Before being sent to the shop a working drawing is carefully checked for errors and omissions. A first check of the pencil drawing is made by the chief designer, who knows the price at which the machine is to be made and checks the design and its mechanism for soundness and economy, sees if existing patterns for any parts can be used, checks for correct representation, *e.g.*, adequate lubrication. He sees that every piece is correctly described, checks all dimensions by scaling and computation, checks for tolerances, checks for finishes, checks for specifications of material, looks for interferences and clearances, sees that small

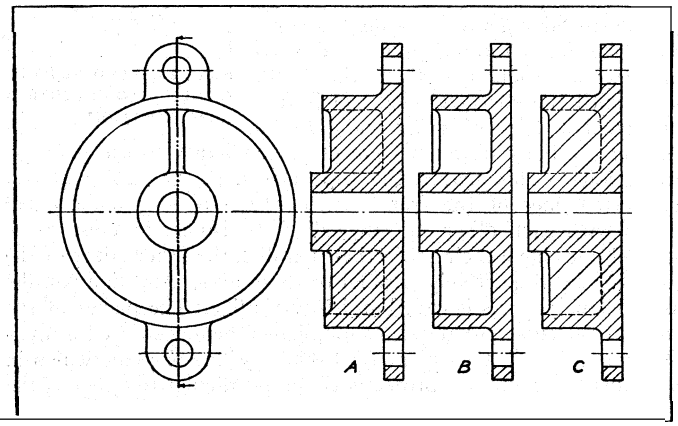

FIG. 22.— A, TRUE SECTION THROUGH A RIB; *B*, THE USUAL METHOD OF DRAWING SUCH SECTION; *C*, AN ALTERNATE METHOD

details are standard and stock sizes where possible, checks the title and bill of material.

Working drawings are always duplicated for shop use by some printing process, and the original is not allowed to be taken out of the office. The great majority are blueprinted. Photostat prints, and reproductions made by various forms of gelatine, stencil and lithographic processes are also used. Drawings are usually made in pencil on cream or buff detail paper and traced, either for economy on tracing paper, or on tracing cloth, a transparentized cotton fabric which gives a better print and is much more durable.

One-plane **Projection.**—Orthographic projection with its two or more views describes an object completely, but requires an effort of the geometrical imagination to visualize its appearance. On the other hand, a picture of the object showing it as it would appear to the eye can be made by perspective drawing, but is not useful as a working drawing as its lines cannot be measured directly. To obtain the pictorial effect of perspective drawing with the possibility of measuring the principal lines several kinds of one plane projection or conventional picture methods have been devised. With the combined advantages are some serious disadvantages which limit their usefulness. They are distorted until the appearance is often unpleasant, only certain lines can be measured, the execution requires more time, and it is difficult to add many figured dimensions, but with all this, a knowledge of these methods and facility in their use is of great value to the draughtsman. Mechanical or structural details not clear in orthographic projection may be drawn pictorially or illustrated by supplementary pictorial views. Technical illustrations, patent office drawings, layouts, piping and wiring diagrams, preliminary free-hand sketches, etc., can all be done advantageously in one-plane projection. Aside from perspective drawing there are two general divisions of pictorial projection, *axonometric* projection with its divisions into isometric, dimetric and trimetric, and *oblique* projection with several variations.

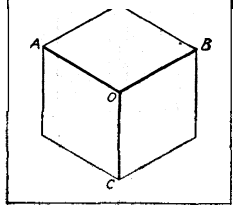

FIG. 23.—ISOMETRIC PROJECTION OF A CUBE

Axonometric projection, theoretically, is simply a form of orthographic projection in which only one plane is used, so placed with relation to the object that a rectangular solid projected on it would show three faces. Usually the object is considered as turned from

its natural position and the vertical plane taken as the plane of projection. Imagine a vertical plane with a cube behind (or in front) of it, having one face parallel to the plane. Its projection will be a square. Rotate the cube about its vertical axis through any angle less than 90°, the projection will now show two faces, foreshortened. From this position tilt the cube forward any amount and three faces will show on the projection. There are thus an infinite number of axonometric positions, only a few of which are ever used as a basis for drawing. The simplest of these is the "isometric" (equal measure) position, where the three faces are foreshortened equally, as would occur if the cube were rotated about the vertical axis through 45° then tilted forward until the edge *OC* (fig. 23) is foreshortened equally with *OA* and *OB* thus making the body diagonal from *O* perpendicular to the plane of projection. (This makes the top face slope 35°–16′ approx.) The three lines of the front corner, *OA, OB, OC,* make equal angles with each other and are called the isometric axes. Since parallel lines have their projections parallel, the other edges of the cube will be respectively parallel to these axes. Any line parallel to an isometric axis is called an isometric line. The planes of the faces of the cube and all planes parallel to them are called isometric planes. It will thus be noticed that any line or plane which in its regular orthographic projection is perpendicular to either of the reference planes, will be an isometric line or plane. In this isometric projection the lines have been foreshortened to approximately $\frac{81}{100}$ of their length and to measure them would require a special scale. In all practical use of the isometric system this foreshortened scale is not used but the full scale lengths are laid off on the axes. This gives a figure slightly larger but of exactly the same shape and is called *isometric drawing.* As the effect of increased size is usually of no consequence and the advantage of measuring the lines with standard scales is of such great convenience, isometric drawing is used almost exclusively instead of isometric projection. In making an isometric drawing the axes are first drawn, 120° apart, drawing one vertical and the other two with the 30° triangle. On these three lines are measured the length, breadth and thickness of the object. Lines not parallel to one of the isometric axes are called non-isometric lines. The one important rule is, measurements can be made only on isometric lines. Since a non-isometric line does not appear in its true length its extremities must be located by isometric co-ordinates. A circle on any isometric plane will appear as an ellipse, and is usually drawn as a four-centred approximation with the construction of fig. 24. It is sometimes desirable to show the lower face of an object, by tilting it back instead of forward, and drawing it on reversed axes. Fig. 25 shows a sketch on reversed axes. Isometric drawings are from their pictorial nature usually outside views but sometimes an isometric section or half-section can be employed to good advantage. The cutting planes are taken as isometric planes. Fig. 26 is a half-section, made by outlining the figure, then cutting out the front quarter.

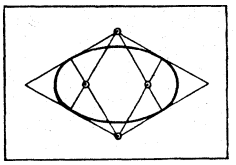

FIG. 24.— ISOMETRIC CIRCLE, FOUR-CENTRED APPROXIMATION

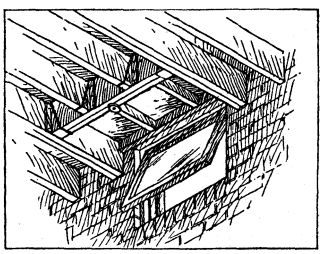

FIG. 25.—ISOMETRIC SKETCH ON REVERSED AXES

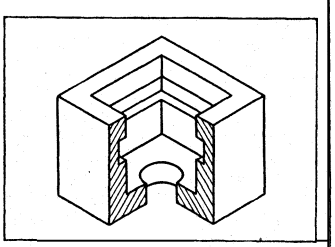

FIG. 26.—ISOMETRIC HALF-SECTION

The reference cube can be turned into any number of positions where two edges would be equally foreshortened and the third to a different length, and any one of these positions might be taken as a basis for a system of *dimetric drawing. A* simple dimetric position is one with the ratios 1:1:). In this position the tangents of the angles of the axes are $\frac{1}{8}$ and $\frac{7}{8}$ making the angles approximately 1 and 41 degrees. Fig. 27 is a drawing in this system. *Trimetric drawing,* with three unequal axes, has little if any practical value.

Oblique Proyection is a one-plane method in which the projecting lines are parallel but make an angle other than go° with the picture plane. Suppose the reference cube to be set with one face parallel to the picture plane and the projectors to make an angle of 45" with the plane, in any direction. The face parallel to the picture plane would be projected in its true size and the edges perpendicular to the plane would be projected in their true length. This system with 45° projectors is sometimes called cavalier projection. It is similar to isometric drawing in having three axes representing three mutually perpendicular lines, upon which measurements can be made. Two of the axes are always at right angles to each other, being in a plane parallel to the picture plane. The third or cross axis may be at any angle, 30° or 45" being generally used. Any face parallel to the picture plane will evidently be projected without distortion, an advantage over isometric of particular value in the representation of objects with circular or irregular outline, thus objects should always be placed with their characteristic contour parallel to the picture plane (fig. 28). Oblique drawing always gives the distorted effect of excessive thickness. *A* variation called *cabinet drawing* devised to overcome this effect is an oblique projection, with the projectors assumed at such an angle that all measurements in the direction of the cross axis are reduced one-half (fig. 29), which makes easy measurement but the effect is often too thin. Other ratios such as $\frac{2}{3}$ or $\frac{3}{4}$ may be used with more pleasing effect. The cross axes may be at any angle, but areusually made either 30° or· 45°. A special system of oblique projection called *clinographic projection,* used in drawing mineral crystals in crystallography, is based on the axes of a cube first revolved about a vertical axis through an angle whose tangent is $\frac{1}{3}$, then projected obliquely to the vertical plane with the eye (at an infinite distance) elevated through an angle whose tangent is $\frac{1}{6}$.

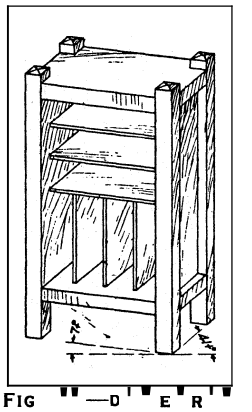

FIG DRAWING

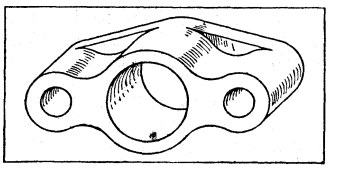

FIG. 28

Execution. — As drawing instruments are used for all accurate work, the first requirement in making a drawing is the ability to use them with facility and in good form. The drawing table, with softwood top or carrying a softwood drawing board, should be set so that the light comes from the left, the paper held in place with thumb tacks, and a hard pencil selected, sharpened to a long sharp point. A T-square, 45" and 30°–60° triangles, compasses, dividers, scale, pencil eraser and sandpaper pad should be at hand. Horizontal lines are drawn with the T-square guided by the left edge of the drawing board, and vertical lines are drawn with the triangle set against the T-square, always with the perpendicular edge nearest the head of the square and toward the light (fig. 30). These lines are always drawn up from the bottom to top, consequently their location points should be made at the bottom. With the triangles against the T-square, lines at 30°, 45° and 60" may be drawn, and the two triangles may be used in combination for angles of 15° and 75°, directly (fig. 31). Thus any multiple of 15° may be drawn and a circle may be divided with the 45° triangle into 4 or 8 parts, with the 60° triangle into 6 or 12 parts and with both into 24 parts. The *dividers,* used for transferring distances, etc , are manipulated with one hand, and opened by pinching at the chamfer with the thumb

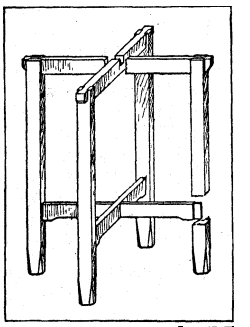

FIG 29—CABINET DRAWING

and second finger. This puts them in correct position with the thumb and forefinger on the outside of the legs and the second and third fingers on the inside (fig. 32). The compasses are manipulated in the same way, adjusting to the radius marked on the paper, then raising the hand to the handle and drawing the circle (clockwise) in one sweep by rolling the handle with the thumb and forefinger, inclining the compasses slightly in the direction of the line (fig. 33). In making a working diagram the order of pencilling should be somewhat as follows: first, make a preliminary freehand layout sketch, estimating the position and space required for each view; second, decide the scale to be used; third, draw the centre lines for each view and block in the views with the principal outlines; fourth, finish the projections, carrying them on together; fifth draw all dimension lines, then put in the dimensions; sixth, lay out the title; seventh, check the drawing as carefully as possible.

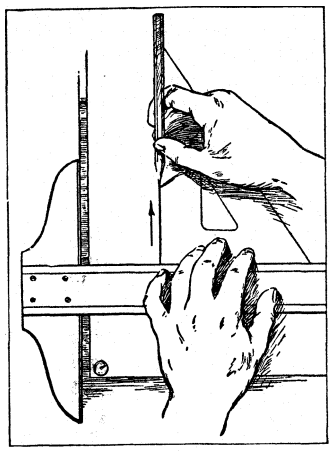

FIG. 30.—DRAWING A VERTICAL LINE

After being made in pencil, drawings, except when inked on the paper, as patent drawings or display drawings, are traced for blueprinting or other method of reproduction. When intended to be used perhaps only once, as tool-room drawings, architectural details, etc., they are very commonly traced in firm pencil lines on tracing paper. Production drawings and works of permanent value are traced in ink on tracing cloth. The ruling pen is always used with drawing ink and guiding edge, either T-square or triangle. To fill it touch the quill filler of the ink bottle between the nibs, being careful not to get any ink on the outside of the blades. The pen is held as in fig. 34 and the width of line adjusted by turning the screw. The pen is held against the straight-edge with the blades parallel to it and in a plane perpendicular to the paper. If the ink refuses to flow it is because it has dried and clogged in the point of the pen. If pinching the blades slightly or touching the pen on the finger does not start it, it should be wiped out and fresh ink supplied. Faulty lines may occur by pressing the pen too hard against the T-square, by sloping the pen away from the T-square, or by having it too close to the blade, when the ink will run under; by having ink on the outside of the blade; by not keeping the blades parallel to the line, or by letting the triangle slip into the wet line. Visible outlines should be strong full lines, invisible lines much lighter lines made with short dashes. Centre lines of long dash and dot, and dimension lines are made either of the same weight as invisible lines or still finer. Inking should be done in a systematic order, first, all visible circles, beginning with the smallest; second, full lines, horizontal, vertical, inclined; third, dotted circles and lines; fourth, centre lines; fifth, extension and dimension lines; sixth, arrow heads and dimensions; seventh, section lines; eighth, notes and title; ninth, border; tenth, check the tracing.

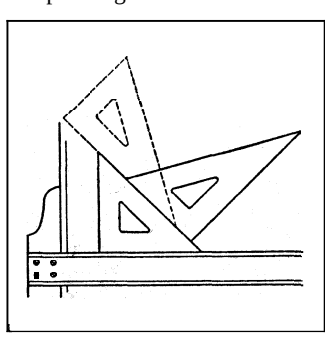

FIG. 31.—COMBINATION FOR 15° AND 75° ANGLES

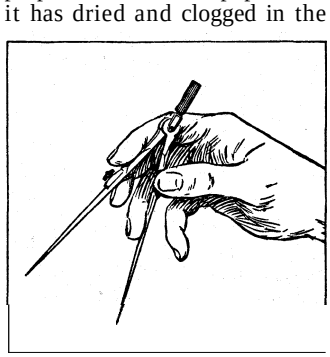

FIG. 32.—HANDLING THE DIVIDERS

In lettering a working drawing the two requirements are legibility and speed. Lettering is not mechanical drawing and the use of "geometrical" letters, "block" letters, etc., made of straight lines and ruled with T-square and triangles is not approved in good practice. The "commercial gothic" or "sans serif" letter made freehand in a single stroke, either vertical or inclined is the style almost universally used.

Technical Sketching.— From its use in connection with art the word sketch suggests a free or incomplete or careless rendering of some idea. This is not its meaning in engineering drawing. A sketch is a working drawing made freehand, a quick expression of graphic language, but complete in its information. In all mechanical thinking in invention, all preliminary designing, all explanation and instruction of the designer to the draftsman, sketching is the mode of expression. It represents the mastery of the language, gained only after proficiency in mechanical execution. Sketches of machine parts would be made in orthographic projection, explanatory of illustrative sketches either in orthographic or in one of the pictorial methods. Design sketches are often made on co-ordinate paper. The memory for form may be strengthened and the capacity for "stored observation" greatly increased by systematic practice in sketching from memory, studying a drawing or casting with close concentration until every detail is stored for future visualization, then making an accurate sketch without further reference to the original and comparing it when finished. FIG. 33.—DRAWING A CIRCLE WITH THE COMPASSES

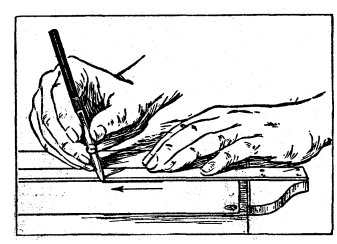

FIG. 34.— POSITIONOF THE RULING PEN

(T. E. F.)

DRAWING AND QUARTERING, part of the penalty anciently ordained in England for treason. Until 1870 the full punishment for the crime was that the culprit be dragged on a hurdle to the place of execution; that he be hanged by the neck but not till he was dead; that he should be disembowelled or drawn and his entrails burned before his eyes; that his head be cut off and his body divided into four parts or quartered. This brutal penalty was first inflicted in 1284 on the Welsh prince David, and a few years later on Sir William Wallace. Edward Marcus Despard and his six accomplices were in 1803 hanged, drawn and quartered for conspiring to assassinate George III. The sentence was last passed (though not carried out) upon the Fenians Burke and O'Brien in 1867.

DRAWING-ROOM, the English name generally employed for a room used in a dwelling-house for the reception of company. It is a shortened form of the 16th and 17th century "withdrawing room," and originated in the setting apart of a room for the ladies of the household, to which they withdrew from the dining-room.

DRAW-PLATE, a plate of hardened steel with a series of holes, with converging sides, graded in size and of similar shape, through which metal is drawn in manufacturing wire (*q.v.*).

DRAYTON, MICHAEL (1563–1631), English poet, was born at Hartshill, Warwickshire, and settled in London about 1590. His first volume of poems, The Harmony of *the* Church, appeared in 1591; the whole edition, with the exception of 40 copies seized by the archbishop of Canterbury, was destroyed by public order. In Idea; the *Shepherd's* Garland (1593), a collection of nine pastorals, and Idea's Mirror (1594), a cycle of 64 sonnets, he celebrated his love for a Warwickshire lady. *The Legend* of

Piers *Gaveston* (1593) is the first of Drayton's historical poems; it was followed by *Mortimeriados* (1596), written in ottava rima and afterwards enlarged as The Barons' Wars (1603); The Legend of Robert, Duke of *Normandy* (1596); and England's Heroical Epistles (1597) modelled on Ovid.

Drayton had been in high favour with Elizabeth, but his overtures to James I. were rejected, and his pique found expression in The Owl (1604), an unsuccessful satire. In 1606 he made a collection of poems entitled Poems Lyric and Pastoral, including among other hitherto unpublished works, his famous "Ballad of Agincourt."

As early as 1598 he had formed the plan of celebrating all the points of topographical or antiquarian interest in the island of Great Britain. In 1613, the first part of this vast work was published under the title of *Poly-Olbion,* 18 books being produced, to which Selden supplied notes. The success of this, his most famous work, was at first small, and the 12 more books of the second part only appeared in 1622. This completed the survey of England, and the poet, who had hoped "to crown Scotland with flowers," and arrive at last at the Orcades, never crossed the Tweed. In 1627 he published another of his miscellaneous volumes, and this contains some of his most characteristic and exquisite writing. It consists of the following pieces: *The* Battle of *Agincourt,* an historical poem in ottava *rima* (not to be cpnfused with his ballad on the same subject), and *The* Miseries of Queen Margaret, written in the same verse and manner; Nimphidia, the Court of *Faery,* a most graceful little epic of fairyland; The Quest of *Cinthia* and *The Shepherd's Sirena,* two lyrical pastorals; and finally *The* Moon Calf, a sort of satire. Of these Nimphidia is perhaps the best thing Drayton ever wrote, except his famous ballad on the battle of Agincourt; it is quite unique of its kind and full of rare fantastic fancy.

The last of Drayton's voluminous publications was The Muses' *Elizium* in 1630. He died in London and was buried in Westminster Abbey. Drayton corresponded familiarly with Drummond; Ben Jonson, William Browne, George Wither and others were among his friends. There is a tradition that he was a friend of Shakespeare, supported by a statement of John Ward, once vicar of Stratford-on-Avon, that "Shakespear, Drayton and Ben Jonson had a merry meeting, and it seems, drank too hard, for Shakespear died of a feavour there contracted." He had a share, with Munday, Chettle and Wilson, in writing Sir John Oldcastle, which was printed in 1600.

The poet with whom it is most natural to compare Drayton is Daniel; he is more rough and vigorous, more varied and more daring than the latter, but Daniel surpasses him in grace, delicacy and judgment. In their elegies and epistles, however, the two writers frequently resemble each other. Drayton, however, approaches the very first poets of the Elizabethan era in his charming Nimphidia, a poem which inspired Herrick with his sweet fairy fancies and stands alone of its kind in English literature; while some of his odes and lyrics are inspired by noble feeling and virile imagination.

In 1748 a folio edition of Drayton's complete works was published under the editorial supervision of William Oldys, and again in 1753 there appeared an issue in four volumes. But these were very unintelligently and inaccurately prepared. A complete edition of Drayton's works with variant readings was projected by Richard Hooper in 1876, but 3 vols. only were completed; a volume of selection, edited by A. H. Bullen, appeared in 1883. See especially Oliver Elton, *Michael* Drayton (1905). (E. G.)

DREADNOUGHT: see BATTLESHIP.

DREAM, the state of consciousness during sleep; it may also be defined as a hallucination or illusion peculiarly associated with the condition of sleep, but not necessarily confined to that state (from a root dreug, connected with Ger. *trügen,* to deceive). In sleep the withdrawal of the mind from the external world is more complete and the objectivity of the dream images is usually unquestioned, whereas in the waking state the hallucination is usually recognized as such; we may, however, be conscious that we are dreaming, and thus in a measure be aware of the hallucinatory character of our percepts. The physiological nature of sleep (*q.v.;* see also MUSCLE and NERVE) and of dreaming is obscure. As a rule the control over the voluntary muscles in dreams is slight; the sleep-walker is the exception and not the rule, and the motor activity represented in the dream is seldom realized in practice, largely, no doubt, because we are ignorant, under these circumstances, of the spatial relations of our bodies. Among the psychological problems raised by dreams are the condition of attention, which is variously regarded as altogether absent or as fixed, the extent of mental control, and the relation of ideas and motor impulses. There is present in all dreams a certain amount of dissociation of consciousness, or of obstructed association, which may manifest itself in the preliminary stage of drowsiness by such phenomena as the apparent transformation or inversion of the words of a book. We may distinguish two types of dreams, (*a*) representative or centrally initiated, (b) presentative or due to the stimulation of the end organs of sense. In both cases, the dream having once been initiated, we are concerned with a combination of ideas suggested by resemblances or other associative elements. The false reasoning of dreams is due in the first place to the absence, to a large extent, of the memory elements on which our ordinary reasoning depends, and, secondly, to the absence of the normal supply of sensory elements.

Apparent Objectivity **of** Dreams. — In waking life we distinguish ideas or mental images from real objects by the fact that we are able under normal circumstances to dismiss the former at will. In sleep, on the other hand, we have, in the first place, no real objects with which to compare the images, which therefore take on a character of reality comparable to the hallucination of waking life; moreover, powers of visualization and other faculties are enhanced in sleep, so that the strength of dream images considerably exceeds those of ordinary mental images; changes in powers of attention, volition and memory help to increase the hallucinatory force of the dream. In the second place, the ideas of our dreams are presented in the form of images, which we are unable to dismiss; we therefore mistake them for realities, exactly as the sufferer from delirium tremens in waking life is apt to regard his phantoms as real.

Representative Dreams. — Centrally initiated dreams may be due to a kind of automatic excitation of the cerebral regions, especially in the case of those clearly arising from the occupations or sensations of the day or the hours immediately preceding the dream. To the same cause we may attribute the recalling of images apparently long since forgotten. Some of these revivals of memory may be due to the fact that links of association which are insufficient to restore an idea to consciousness in the waking state may suffice to do so in sleep. Just as a good visualizer in his waking moments may call up an object never clearly seen and yet distinguish the parts, so in sleep, as L. F. A. Maury (1817–92) and others have shown, an image may be more distinct in a dream than it was originally presented (see also below, Memory).

Presentative Dreams. — The dreams due to seal sensations, more or less metamorphosed, may arise (a) from the states of the internal organs, (b) from muscular states, (c) from sensations due to the circulation, etc., or (d) from the ordinary cause of the action of external stimuli on the organs of sense.

(a) The state of the stomach, heart, etc., has long been recognized as important in the causation of dreams (see below, Classical Views). The common sensation of flying seems to be due in many cases to the disturbance of these organs setting up sensations resembling those felt in rapidly ascending or descending, as in a swing or a lift. Indigestion is a frequent cause of nightmare — the name given to oppressive and horrible dreams — and bodily discomfort is sometimes translated into the moral region, giving rise to the dream that a murder has been committed (b) Dreams of flying, etc., have also been attributed to the condition of the muscles during sleep; W. Wundt remarks that the movements of the body, such as breathing, extensions of the limbs and so on, must give rise to dream fancies; the awkward position of the limbs may also excite images. (c) Especially important, probably, for the dreams of the early part of the night are the retinal conditions to which are due the illusions *hypnagogiques* of the

preliminary drowsy stage; but probably Ladd goes too far in maintaining that entoptic stimuli, either intra- or extra-organic in origin, condition all dreams. Illusions *hypnagogiques*, termed popularly "faces in the dark," of which Maury has given a full account, are the not uncommon sensations experienced, usually visual and seen with both open and closed eyes, in the interval between retiring to rest and actually falling asleep; they are comparable to the crystal-gazing visions of waking moments; though mainly visual they may also affect other senses. Besides the eye the ear may supply material for dreams, when the circulation of the blood suggests rushing waters or similar ideas. (d) It is a matter of common observation that the temperature of the surface of the body determines in many cases the character of the dreams, the real circumstances, as might be expected from the general character of the dream state, being exaggerated. In the same way the pressure of bed-clothes, obstruction of the supply of air, etc, may serve as the starting-point of dreams The common dream of being unclothed may perhaps be due to this cause, the sensations associated with clothing being absent or so far modified as to be unrecognizable. In the same way the absence of foot-gear may account for some dreams of flying. It is possible to test the influence of external stimuli by direct experiment; Maury made a number of trials with the aid of an assistant.

Rapidity of Dreams.—It has often been asserted that we dream with extreme rapidity; but this statement is by no means borne out by experiment. In a trial recorded by J. Clavière the beginning of the dream was accurately fixed by the sounding of an alarm clock, which rang, then was silent for 22sec., and then began to ring continuously; the dream scene was in a theatre. and he found by actual trial that the time required in the dream for the performance of the scenes during the interval of silence was about the same as in ordinary life. Spontaneous dreams seem to show a different state of things; it must be remembered that (1) dreams are commonly a succession of images, the number of which cannot be legitimately compared with the number of extra-organic stimuli which would correspond to them in ordinary life; the real comparison is with mental images; and (2) the rapidity of association varies enormously in ordinary waking life. No proof, therefore, that some dreams are slow can show that this mentation in others is not extremely rapid. The most commonly quoted case is one of Maury's; a bed-pole fell on his neck, and (so it is stated) he dreamt of the French Revolution, the scenes culminating in the fall of the guillotine on his neck; this has been held to show that (1) dreams are extremely rapid; and (2) we construct a dream story leading up to the external stimulus which is assumed to have originated the dream. But Maury's dream was not recorded till many years after it had occurred; there is nothing to show that the dream, in this as in other similar cases, was not in progress when the bed-pole fell, which thus by mere coincidence would have intervened at the psychological moment; Maury's memory on waking may have been to some extent hallucinatory. But there are records of waking states, not necessarily abnormal, in which time-perception is disturbed and brief incidents seem interminably long; on the other hand, it appears from the experiences of persons recovered from drowning that there is great rapidity of ideation before the extinction of consciousness; the same rapidity of thought has been observed in a fall from a bicycle.

Reason in Dreams.—Studies of dreams of normal individuals based on large collections of instances are singularly few in number; such as there are indicate great variations in the source of dream thoughts and images, in the coherence of the dream, and in the powers of memory. In ordinary life attention dominates the images presented; in dreams heterogeneous and disconnected elements are often combined; a resemblance need not even have been consciously recognized for the mind to combine two impressions in a dream; for example, an aching tooth may (according to the dream) be extracted, and found to resemble rocks on the sea-shore, which had not struck the waking mind as in any way like teeth. Incongruence and incoherence are not, however, a necessary characteristic of dreams, and individuals are found whose dream ideas and scenes show a power of reasoning and orderliness equal to that of a scene imagined or experienced in ordinary life. In some cases the reasoning power may attain a higher level than that of the ordinary conscious life. In a well-authenticated case Prof. Hilprecht was able in a dream to solve a difficulty connected with two Babylonian inscriptions, which had not previously been recognized as complementary to each other; a point of peculiar interest is the dramatic form in which the information came to him—an old Babylonian priest appeared in his dream and gave him the clue to the problem (see also below, Personality).

Memory in Dreams.—Although prima facie the dream memory is fragmentary and far less complete than the waking memory, it is by no means uncommon to find a revival in sleep of early, apparently quite forgotten, experiences: more striking is the recollection in dreams of matters never supraliminally (see SUBLIMINAL SELF) apperceived at all.

The relation between the memory in dreams and in the hypnotic trance is curious: suggestions given in the trance may be accepted and then forgotten or never remembered in ordinary life; this does not prevent them from reappearing occasionally in dreams; conversely dreams forgotten in ordinary life may be remembered in the hypnotic trance. These dream memories of other states of consciousness suggest that dreams are sometimes the product of a deeper stratum of the personality than comes into play in ordinary waking life. It must be remembered in this connection that we judge of our dream consciousness by our waking recollections, not directly, and our recollection of our dreams is extraordinarily fragmentary; we do not know how far our dream memory really extends. Connected with memory of other states is the question of memory in dreams of previous dream states; occasionally a separate chain of memory, analogous to a secondary personality, seems to be formed. We may be also conscious that we have been dreaming, and subsequently, without intermediate waking, relate as a dream the dream previously experienced. In spite of the irrationality of dreams in general, it by no means follows that the earlier and later portions of a dream do not cohere; we may interpolate an episode and again take up the first motive, exactly as happens in real life. The strength of the dream memory is shown by the recurrence of images in dreams; a picture, the page of a book, or other image may be reproduced before our eyes several times in the course of a dream without the slightest alteration, although the waking consciousness would be quite incapable of such a feat of visualizing. In this connection may be mentioned the phenomenon of redreaming; the same dream may recur either on the same or on different nights; this seems to be in many cases pathological or due to drugs, but may also occur under normal conditions.

Personality.—As a rule the personality of the dreamer is unchanged; but it also happens that the confusion of identity observed with regard to other objects embraces the dreamer himself; he imagines himself to be some one else; he is alternately actor and observer; he may see himself playing a part or may divest himself of his body and wander incorporeally. Ordinary dreams, however, do not go beyond a splitting of personality; we hold conversations, and are intensely surprised at the utterances of a dream figure, which, however, is merely an alter ego. As in the case of Hilprecht (see above) the information given by another part of the personality may not only appear but actually be novel.

Supernormal Dreams.—In addition to dreams in which there is a revival of memory or a rise into consciousness of facts previously only subliminally cognized, a certain number of dreams are on record in which telepathy (*q.v.*) seems to play a part; much of the evidence is, however, discounted by the possibility of hallucinatory memory. Another class of dreams (prodromic) is that in which the abnormal bodily states of the dreamer are brought to his knowledge in sleep, sometimes in a symbolical form; thus a dream of battle or sanguinary conflict may presage a haemorrhage. The increased power of suggestion which is the normal accompaniment of the hypnotic trance may make its appearance in dreams, and exercise either a curative influence or

act capriciously in producing hysteria and the tropic changes known as "stigmata." We may meet with various forms of hyperaesthesia in dreams; quite apart from the recovery of sight by those who have lost it wholly or in part (see below, Dreams of the Blind), we find that the powers of the senses may undergo an intensification, and, *e.g.*, the power of appreciating music be enormously enhanced in persons usually indifferent to it. Mention must also be made of the experience of R. L. Stevenson, who tells in Across the Plains how by self-suggestion he was able to secure from his dreams the motives of some of his best romances.

Voluntary Action in Dreams.—Connected with dreams voluntarily influenced is the question of how far dreams once initiated are modifiable at the will of the dreamer. Some few observers, like F. W. H. Myers and Dr. F. van Eeden, record that they can at longer or shorter intervals control their actions in their dreams, though usually to a less extent than their imagined actions in waking life. Dr. van Eeden, for example, tells us that he has what he calls a "clear dream" once a month and is able to predetermine what he will do when he becomes aware that he is dreaming.

Dreams of Children.—Opinions differ widely as to the age at which children begin to dream; G. Compayré maintains that dreaming has been observed in the fourth month, but reflex action is always a possible explanation of the observed facts. S. de Sanctis found that in boys of eleven only one out of eight said that he dreamt seldom, as against four out of seven at the age of six; but we cannot exclude the possibility that dreams were frequent but forgotten.

Dreams of the Old.—In normal individuals above the age of 65 de Sanctis found dreams were rare; atmospheric influences seem to be important elements in causing them; memory of them is weak; they are emotionally poor, and deal with long past scenes.

Dreams of Adults.—Any attempt to record or influence our dreams may be complicated by (a) direct suggestion, leading to the production of the phenomena for which we are looking, and (b) indirect suggestion leading to the more lively recollection of dreams in general and of certain dreams in particular. Consequently it cannot be assumed that the facts thus ascertained represent the normal conditions. According to F. Heerwagen's statistics women sleep more lightly and dream more than men; the frequency of dreams is proportional to their vividness; women who dream sleep longer than those who do not; dreams tend to become less frequent with advancing age.

In the matter of complication of dream experiences the sexes are about equal; daily life supplies more material in the dreams of men; nearly twice as many women as men remember their dreams clearly, a fact which hangs together to some extent with the vividness of the dreams, though it by no means follows that a vivid dream is well remembered. There are great variations in the emotional character of dreams; some observers report twice as many unpleasant dreams as the reverse; in other cases the emotions seem to be absent; others again have none but pleasing dreams. Individual experience also varies very largely as to the time when most dreams are experienced; in some cases the great majority are subsequent to 6:30 A.M.; others find that quite half occur before 4 A.M.

Dreams of the **Neuropathic,** Insane, Idiots, **etc.**—Much attention has been given to the dreams of hysterical subjects. It appears that their dreams are specially liable to exercise an influence over their waking life, perhaps because they do not distinguish them, any more than their waking hallucinations, from reality. P. Janet maintains that the cause of hysteria may be sought in a dream. The dreams of the hysterical have a tendency to recur. Epileptic subjects dream less than the hysterical, and their dreams are seldom of a terrifying nature; certain dreams seem to take the place of an epileptic attack. Dreaming seems to be rare in idiots. De Sanctis divides paranoiacs into three classes: (a) those with systematized delusions, (b) those with frequent hallucinations, and (c) degenerates—the dreams of the first class resemble their delusions; the second class is distinguished by the complexity of its dreams; the third by their vividness, by their delusions of megalomania, and by their influence on daily life. Alcoholic subjects have vivid and terrifying dreams, characterized by the frequent appearance of animals in them, and delirium tremens may originate during sleep.

Dreams of the Blind, Deaf, *etc.*—As regards visual dreams the blind fall into three classes—(I) those who are blind from birth or become blind before the age of five; (2) those who become blind at the "critical age" from five to seven; (3) those who become blind after the age of seven. The dreams of the first class are non-visual; but in the dreams of Helen Keller there are traces of a visual content; the second class sometimes has visual dreams; the third class does not differ from normal persons, though visual dreams may fade away after many years of blindness. In the case of the partially blind the clearness of vision in a dream exceeds that of normal life when the partial loss of sight occurred in the sixth or later years. The education of Helen Keller is interesting from another point of view; after losing the senses of sight and hearing in infancy she began her education at seven years and was able to articulate at eleven; it is recorded that she "talked" in her dreams soon after. This accords with the experience of normal individuals who acquire a foreign language. Her extraordinary memory enables her to recall faintly some traces of the sunlit period of her life, but they hardly affect her dreams, so far as can be judged. The dreams of the blind, according to the records of F. Hitschmann, present some peculiarities; animals as well as man speak; toothache and bodily pains are perceived as such; impersonal dreaming, taking the form of a drama or reading aloud, is found; and he had a strong tendency to reproduce or create verse.

Dreams of *Animals.*—We are naturally reduced to inference in dealing with animals as with very young children; but various observations seem to show that dreams are common in older dogs, especially after hunting expeditions; in young dogs sleep seems to be quieter; dogs accustomed to the chase seem to dream more than other kinds.

Dreams Among the Non-European Peoples.—In the lower stages of culture the dream is regarded as no less real and its personages as no less objective than those of the ordinary waking life; this is due in the main to the habit of mind of such peoples (see ANIMISM), but possibly in some measure also to the occurrence of veridical dreams (see TELEPATHY). In either case the savage explanation is animistic, and animism is commonly assumed to have been developed very largely as a result of theorizing dreams. Two explanations of a dream are found among the lower races: (1) that the soul of the dreamer goes out, and visits his friends, living or dead, his old haunts or unfamiliar scenes and so on; (2) that the souls of the dead and others come to visit him, either of their own motion or at divine command. In either of the latter cases or at a higher stage of culture when the dream is regarded as god-sent, though no longer explained in terms of animism, it is often regarded as oracular (see ORACLE), the explanation being sometimes symbolical, sometimes simple.

There are two classes of dreams which have a special importance in the lower cultures: (1) the dream or vision of the initiation fast; and (2) the dream caused by the process known as incubation, which is often analogous to the initiation fast. In many parts of North America the individual Indian acquires a tutelary spirit, known as *manito* or nagual, by his initiation dream or vision; the idea being, perhaps, that the spirit by the act of appearing shows its subjection to the will of the man. Similarly, the magician acquires his familiar in North America, Australia and elsewhere by dreaming of an animal. Incubation consists in retiring to sleep in a temple, sometimes on the top of a mountain or other unusual spot, in order to obtain a revelation through a dream. Fasting, continence and other observances are frequently prescribed as preliminaries. Certain classes of dreams have, especially in the middle ages, been attributed to the influence of evil spirits (see DEMONOLOGY).

Classical and Mediaeval Views of Dreams.—Side by side with the prevalent animistic view of dreams we find in antiquity and among the semi-civilized attempts at philosophical or physiological explanations of dreams. Democritus, from whom the

Epicureans derived their theory, held the cause of them to be the simulacra or phantasms of corporeal objects which are constantly floating about the atmosphere and attack the soul in sleep—a view hardly distinguishable from animism. Aristotle, however, refers them to the impressions left by objects seen with the eyes of the body; he further remarks on the exaggeration of slight stimuli when they are incorporated into a dream; a small sound becomes a noise like thunder. Plato, too, connects dreaming with the normal waking operations of the mind; Pliny, on the other hand, admits this only for dreams which take place after meals, the remainder being supernatural. Cicero, however, takes the view that they are simply natural occurrences no more and no less than the mental operations and sensations of the waking state. The pathological side of dreams attracted the notice of physicians. Hippocrates was disposed to admit that some dreams might be divine, but held that others were premonitory of diseased states of the body. Galen took the same view in some of his speculations.

Symbolical interpretations are combined with pathological no less than animistic interpretations of dreams; they are also extremely common among the lower classes in Europe at the present day, but in this case no consistent explanation of their importance for the divination of future events is usually discoverable. Among the Greeks Plato in the *Timaeus* (ch. xlvi., xlvii.) explains dreams as prophetic visions received by the lower appetitive soul through the liver; their interpretation requires intelligence. The Stoics seem to have held that dreams may be a divine revelation and more than one volume on the interpretation of dreams has come down to us, the most important being perhaps the Ὀνειροκριτικά of Daldianus Artemidorus. We find parallels to this in a Muslim work by Gabdorrachaman, translated by Pierre Vattier under the name of *Onirocrite mussulman*, and in the numerous books on the interpretation of dreams which circulate at the present day. In Siam dream books are found (*Intern. Arckiv fur Anthr.* viii. 150); one of the functions of the Australian medicine man is to decide how a dream is to be interpreted.

Modern Views.—The doctrine of Descartes that existence depended upon thought naturally led his followers to maintain that the mind is always thinking and consequently that dreaming is continuous. Locke replied to this that men are not always conscious of dreaming, and it is hard to be conceived that the soul of the sleeping man should this moment be thinking, while the soul of the waking man cannot recollect in the next moment a jot of all those thoughts. That we always dream was maintained by Leibniz, Kant, Sir. W. Hamilton and others; the latter refutes the argument of Locke by the just observation that the somnambulist has certainly been conscious, but fails to recall the fact when he returns to the normal state.

It has been commonly held by metaphysicians that the nature of dreams is explained by the suspension of volition during sleep; Dugald Stewart asserts that it is not wholly dormant but loses its hold on the faculties, and he thus accounts for the incoherence of dreams and the apparent reality of dream images.

Cudworth, from the orderly sequence of dream combinations and their novelty, argues that the state arises, not from any "fortuitous dancings of the spirits," but from the "phantastical power of the soul." According to K. A. Scherner, dreaming is a decentralization of the movement of life; the ego becomes purely receptive and is merely the point around which the peripheral life plays in perfect freedom. Hobbes held that dreams all proceed from the agitation of the inward parts of a man's body, which, owing to their connection with the brain, serve to keep the latter in motion. For Schopenhauer the cause of dreams is the stimulation of the brain by the internal regions of the organism through the sympathetic nervous system. These impressions the mind afterwards works up into quasi-realities by means of its forms of space, time, causality, etc.

BIBLIOGRAPHY.—For full lists of books and articles *see* J. M. Baldwin's *Dictionary of Philosophy*, bibliography volume (1906), and S. de Sanctis, *I Sogni*, also translated in German with additions as *Die Traume*. Important works are: Binz, *Über den Traum;* Giessler, *Aus den Tiefen des Traumlebens;* Maury, *Le Sommeil et les rêves;* Radestock, *Schlaf und Traum;* Tessié, *Les Rêves;* Spitta, *Schlaf und Traumzustände*. For super-normal dreams *see* F. W. H. Myers, *Human Personality*, vol. i., and *Proc. S.P.R.* viii. 362. For voluntary dreams see *Proc. S.P.R.* iv. 241, xvii. 112. On prophetic dreams see *Monist*, xi. 161; *Bull. Soc. Anth.* (Paris, 1901), 196 (1902), 228; *Rev. de synthèse historique* (1901), 151, etc. On incubation *see* Deubner, *De incubatione;* Maury, *La Magie*. On the dreams of American Indians see *Handbook of American Indians* (Washington, 1907), *s.v.* "Dreams" and "Manito." On the interpretation of dreams *see* Freud, *Die Traumdeutung*. Other works are F. Greenwood, *Imagination in Dreams;* Hutchinson, *Dreams and their Meanings*. (N. W. T.)

DREDGERS AND DREDGING. Dredging is the name given to that branch of excavation which deals with the process of removing materials lying under water and disposing of them according to the requirements of the work in hand. The machines employed by engineers to that end are termed dredgers (dredges in America) and the term dredging plant covers not only the dredging machines themselves but much auxiliary apparatus employed in connection therewith. The ceaseless struggle of man's efforts against the mighty forces of nature involves an infinite variety of attack and a vast expenditure of wealth. Spurred by the demands for increased facilities for shipping, and assisted by the great advances of mechanical science, dredgers have developed rapidly from primitive tools to powerful and costly appliances.

Applications of Dredging.—Although dredging machinery is, from the nature of its duties, mounted on floating craft in the great majority of instances, the term does not exclude subaqueous excavation by plant mounted on land. Dredging may be divided broadly into two classes according to the object for which it is employed, viz., (a) as a means of removing material for the purpose of increasing existing depths of water or reclaiming low-lying ground, and (b) as a means of mining for making available earths useful in themselves or because they contain precious constituents; but its field covers a multitude of purposes within the bounds of these two main divisions, and the following uses to which the plant may be put will illustrate the wide scope of dredging operations.

Material Shifting Dredgers.—The creation and maintenance of satisfactory depths of water in harbours, docks, rivers and canals for the purposes of navigation; the removal of material for the foundations of marine and river works and for the preparation of sites for floating docks; the deepening, widening and straightening of rivers to increase or conserve their discharging capacity; the cutting of drainage and irrigation canals; the removal of material for the reclamation of low-lying land or the formation of dykes, levees or dams.

Mining Dredgers.—The recovery of gold from rivers or placer deposits, also platinum, tin and other heavy metals; the raising of gravel, sand and clay for building and industrial purposes.

Characteristics of Materials Dealt with.—Dredgers have been constructed to deal, in varying degrees of efficiency, with anything from mud to rock. The materials when removed from the bottom are termed "spoil" and naturally occur in endless variety of kinds and mixture of kinds. In general, however, the natural basins of alluvial deposits forming the rivers and bays in which harbours and other marine works are mostly sited, are the situations peculiar to dredging operations. Sand and mud are the most common materials met with in dredging, forming the bulk of obstruction to navigation and of accumulations in and about harbours and river channels. Materials other than sand and mud are more difficult to dredge. Clay and loam are classed as loose materials but can scarcely be regarded as "free-getting" as they may be somewhat difficult to dislodge from the apparatus when being discharged. Further along the scale of compactness comes a wide and rather indefinite class of mixtures of loam and boulders in various degrees of cementation. They are resistant to penetration and cause difficulty owing to size of the boulders. Gravel is often found in dense layers strongly compacted with sand, and this together with indurated sand, is difficult to disintegrate, but once penetrated removal is comparatively easy. Conglomerates, consisting of pebbles held together by natural forms of cement, and solid rock will require either the application of excessive power in the dredging tool or previous disintegration by percussion or blasting, with subsequent dredging of the débris.

Classification of Dredging Plant.—Dredgers fall into two main classifications according to the conditions under which they operate, viz., sea-going vessels and vessels for inland water service. The former are generally ship-shape vessels constructed as far as possible in the accepted manner for withstanding sea conditions and ocean voyages, and carrying their own propelling machinery. The latter class is of lighter construction partaking more of the box or pontoon form and generally lacking propelling machinery. There are, of course, intermediate types, and in general it may be said that dredging vessels of whatever type require to be more strongly constructed to withstand the working stresses to which they are subject than vessels for commercial purposes. Mining dredgers as a class are of the inland type. A further classification is possible according to the system on which they dispose of the dredged materials. "Stationary" dredgers discharge their spoil into barges brought alongside, or to river banks or shore either directly or through long shoots or pipes. "Hopper" dredgers receive the spoil into a specially formed hold or hopper in the hull of the dredger and, when full, proceed to sea or other convenient site to "dump" their load. The inland dredger class as a whole is of the stationary type, but sea-going dredgers are of either type according to the particular requirements of the work and situation; and not infrequently hopper dredgers include arrangements which make them capable of working on either system.

Basic Types of Plant.—The basic types of dredging machine are the bucket ladder dredger, the suction or hydraulic dredger, the dipper dredger and the grab dredger. In addition, dredging often necessitates the employment of a variety of auxiliary plants, and there are a number of appliances which, although not falling strictly within the definition of a dredger, in that they do no more than loosen without raising the spoil to the surface, yet serve to carry out in some measure with the help of moving water, the work of dredging.

The Ladder Dredger.—The main feature of the ladder dredger is a continuous chain of buckets running round a rigid frame called the ladder extending down from the ship to the bottom of the water, as shown in fig. 1. The buckets run empty down the underside of the ladder, dig into the material as they turn round the end, and return full along the top side of the ladder. On reaching the top each bucket, as it turns over, discharges its contents into a shoot which conveys the spoil to the vessel's own hopper, or to a barge, or in some cases to the shore. The revolving members at each end of the ladder are called tumblers and the top tumbler drives the bucket chain. The ladder of the typical ladder dredger is hinged at the top to a high structure on the vessel, the height of which is regulated by the requirements of the discharging operation, and extends downwards at an angle not exceeding 45° through an open recess or well in the hull, the lower end being supported by rope tackle which serves to adjust it to the dredging depth required or to raise it up entirely when it is desired to steam away.

The Suction Dredger.--On the other hand the suction dredger, shown in fig. 2, depends on quite different agencies for its operation. Whereas the ladder dredger removes and raises the material mechanically, the suction or hydraulic dredger, as its name implies, relies on suction to lift the material to the surface. The device consists essentially of an air-tight suction pipe, one end of which is lowered down to the bed of the sea or river, and the other connected with a centrifugal pump. The

GOLD AND CHANNEL DREDGES AT WORK

1. Digging ladder of a large gold dredge. The steel derrick supports the ladder arm, around which the bucket chain travels. Shell buckets raise the gold-bearing sand of river bed for panning within dredge house. The size of the machine is evident by comparison with the figures at left
2. Gold dredge in Bonanza Creek, Yukon, a forerunner of dredge in fig. 1. Right, bucket chain removing gold-bearing sand from creek bed; centre, power and separating house; left, discharge conveyor dumping gravel
3. Orange-peel dredge dipping up slag from side of pier. In this form of dredge the hoist controls a bucket divided into triangular sections pointed at base. When lowered the bucket is open until it strikes into bed of material, then closed upon the material. The filled bucket is shown being carried over wall of the pier
4. Large dipper dredge at work in the Panama canal. This type of dredge operates like a steam shovel, scooping up material from bed of waterway and depositing it in barge at side. A trap door in the bucket scoop is operated by a chain or rope under the movable arm in the swinging hoist
5. Hydraulic pipe-line dredge, showing arm raised above surface. The spiral dredging head revolves, digging silt which is drawn by suction into pipe located within dredging arm. At left edge of picture may be seen the discharge pipe, leading from dredge to barge or to land
6. Hydraulic dredge driven by Diesel engine used in shallow water. The dredge is shown removing grass-grown bank from river channel. A pipe line may be seen (right) in the rear of the dredge, supported by pontoons reaching the shore

latter comprises a casing within which an impeller or fan is revolved at high speed and by its action expels the contents, whether air or water, outwards from the centre through an outlet on the periphery or rim of the casing, thereby causing a partial vacuum at the centre, to which the suction pipe is attached. The atmospheric pressure on the water outside proceeds to repair this vacuum by forcing water in through the only available route, viz., the suction pipe, and the water in its mad rush into the pipe agitates and carries with it a proportion of solids. In some situations, means are provided at the suction pipe end, or nozzle, of disintegrating or actually cutting the compact materials to enable them to come under the influence of the so-called suction.

The Dipper Dredger.—The dipper and grab dredgers are also of the bucket type, but more intermittent in operation than the ladder dredger. The dipper dredger is illustrated diagrammatically in fig. 3. The principal features of the dipper dredger are the bucket and the arm to which it is attached, the boom which supports and guides the arm and which is mounted on a turntable so that dredging can be undertaken round a wide arc and the load deposited to either side, the hoisting rope which passes over a sheave at the boom head and gives the required excavating movement to the bucket, and the backing rope by means of which the vessel may be turned and moved forward using the bucket resting on the bottom as an anchor. The bucket has a hinged bottom, the catch of which is released by a hand rope to dump the load. To counteract the heavy digging reactions the vessel is made to rest on the bottom partly independent of water support on two anchor spuds, and a guide or poling spud is provided at the stern.

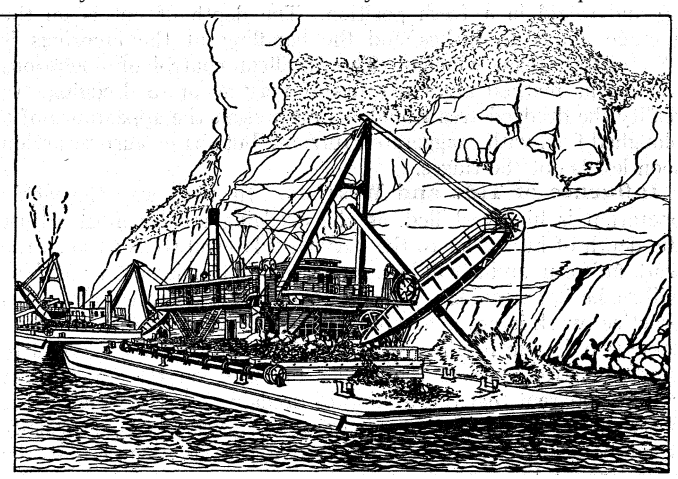
The Grab Dredger.—The grab dredger employs a slewing crane to operate its bucket which latter is in two parts hinged together, and controlled by levers and chains or ropes. The bucket is dropped to the bottom in an open condition by means of one rope, digs in partially by virtue of its own weight, and completes its bite by means of the strong leverage effected by the other rope on the two halves when the crane begins to hoist. By holding on the hoist or "holding" rope and releasing the "closing" rope the bucket opens and discharges its contents. Some grabs are specially arranged to operate with one rope only, discharge being effected by means of a tripping device suspended from the jib head.

Auxiliary Plant and Miscellaneous Appliances.—The auxiliary plant often to be found in connection with dredgers is of two types, one of which is employed before dredging and the other after. Examples of the former are rock-breakers and rock-drillers used to disintegrate rock by hammering or prepare it for blasting so that it may be dredged. The rock-breaker consists of a pointed heavy steel ram which is dropped through a guide repeatedly on the same spot, being raised by means of a rope operated by a special winch. Auxiliary plant used in the disposal of the dredged spoil comprises barges, either self-propelling or with tugs; reclamation vessels for delivering the spoil ashore; pipelines, floating and on shore; and shoots. The miscellaneous appliances comprise snag pullers, grapnels, rakes and harrows, mechanical stirrers, water jets and other devices for placing the material into suspension so that it may be carried away by river flow or by the ebb tide. Being for the most part makeshift devices and not capable of extended applications they do not exhibit any marked degree of development.

The Mining Dredger.—The mining dredger for the recovery of precious metals is generally an adaptation of the Ladder Dredger. It is often to be found at considerable distances from a river, having cut its way through the land and deposited the spoil behind it, in effect carrying with it the pool in which it Aoats. A typical tin dredger is shown in fig. 4. The earth brought up by the buckets is discharged into a perforated cylindrical revolving screen which disintegrates it and allows the heavier tin-laden soil to drop through the perforations into a distributing box, while the large rough materials pass out of the screen and are discharged over the stern by a belt conveyor. The soil from the distributing box, together with an ample supply of water, is led by shoots into pans in which it is agitated by mechanically operated jigs. This operation allows the heavy tin to sink to the bottom of the pans while the lighter soil remains in suspension in the water and passes overboard through a tail shoot. The metal is collected from the pans at intervals.

Prime Movers.—Steam is the universal motive power used on dredging plant, being particularly well adapted to the rough and fluctuating character of the work. Steam plant is comparatively simple and well understood, while its inherent flexibility is an invaluable characteristic for dredging operations, enabling it to accommodate itself conveniently to the constantly varying power requirements and, if need be, to sustain a heavy pressure on the tool when the latter has been brought to a dead stop by the severity of the work. The internal-combustion oil engine is finding some application in situations where economy of space and fuel are vital considerations, but, although suitable for driving centrifugal dredging pumps, is not yet the equal of steam plant for the majority of dredging applications. In general, its lower range of flexibility and inferior capabilities of sustained power at low speeds, together with the high pressures possible, necessitate the introduction of safeguards which operate to reduce the economy and convenience to be expected from its higher thermal efficiency and self-contained character. The diesel-electric drive in which the oil engine operates under favourable conditions as a prime mover for the electric secondary machinery, which drives the various motions, has also been applied and possesses characteristics more suited to many dredging machines than the direct oil engine drive, although with the added cost and complication of electrical equipment. The electric drive pure and simple is in use in the tin-mining areas where many dredgers are suppiied through cables from a central generating station.

Selection of Dredging Plant.—It will be evident that the selection of dredging plant to satisfy the requirements of diiferent localities and different circumstances needs the exercise of sound judgment. The ladder dredger is eminently adapted for dealing up to great depths with all classes of material from mud to the softer varieties of rock, including small boulders, and of preparing a level bottom. Its mechanism tends to make it very heavy and cumbrous, with correspondingly heavy capital cost and upkeep charges. It may, however, be regarded as the universal large dredging tool and is preferred in a great number of cases where accuracy of work in a wide variety of materials is required and



BY COURTESY OF THE WASHINGTON OFFICE OF THE PANAMA CANAL

DIPPER DREDGER AT WORK IN A "SLIDE" IN CULEBRA CUT DURING THE CONSTRUCTION OF THE PANAMA CANAL

it can be kept fully employed, provided its bulk and widespread moorings are not of grave consequence. Seventy feet is the maximum dredging depth in sea works and this the ladder dredger can tackle. Some of the mining dredgers, however, work down to 100 feet and more. In more restricted situations and for less extensive projects the grab dredger will generally prove more economical in first cost and upkeep, and is well suited to maintenance work and work of an intermittent nature or in awkward situations. The dipper dredger is as capable as the ladder dredger of dealing with all classes of materials and as a

tool for really difficult individual tasks at depths up to some 35ft. has no equal, owing to the great force which can be exerted with the cutting edge of its bucket and the large capacity, sometimes up to 15cu.yd., of the latter. The grab dredger is not so powerful but can dredge at great depths exceeding any other type, and is eminently suitable for pioneer inland work. The suction dredger succeeds when large quantities of soft materials have to be dealt with, provided there is no objection to the large admixture of water. Quantity not quality is its leading characteristic, for it effects its object in free-flowing materials by excavating large holes in the bottom. The irregularities are subsequently levelled down by sea or river action, thus effecting an increase in the depth of water. In the more compact sands a series of high-pressure water jets around the nozzle serve to break up the material sufficiently, but in clay and similar substances a rotary cutter is required and serves to increase the accuracy of dredging to as great a degree as any dredger can attain. By reason of the large quantity of water, often 90% of the total volume pumped, the suction dredger is relatively inefficient, but the operation is continuous and has the valuable property of enabling, when required, the spoil to be discharged direct through a pipe system to considerable distances without expensive re-handling. The majority of all types of dredgers have their excavating member so located in advance of the hull that the vessel can cut its own flotation.

Methods of Dredging.— In the case of the bucket dredger practically only one general method of dredging is pursued. The vessel is moored by means of six anchors and chain cables set out as shown diagrammatically in fig. 5. The head and stern moorings are much longer than the side moorings, and the vessel swings to or pivots about the head mooring **A** and is dragged slowly transversely by one pair of side moorings C and D. On reaching the limit of the cut to that side the vessel is advanced about six feet by pulling on the head mooring, the stern line being paid out to correspond, and the vessel is dragged across to the other side of the cut by side moorings E and F, the other side moorings C and D being paid out the while. This operation goes on until the head chain becomes too short and the angles of the side chains tend to become ineffective, when the vessel is pulled back by the stern mooring B to commence a fresh series of cuts at a lower depth or, if the required depth has been reached, dredging is stopped for the time being and the whole of the anchors taken up and relaid in a fresh position. The depth of cut is on the average about 18 inches and the handling of the moorings is effected by steam winches. The excellent control of operations which this method gives permits of very accurate dredging. In reality the dredged area would at first present the appearance of a ploughed field with exaggerated furrows, but sea or current action soon levels out the ridges.

Influence of Tide and Weather.— In a sea-way the whole operation is highly skilled, as the dredging master must adjust the depth of his ladder to the varying tide level so as to keep the work uniform, and it will be appreciated that inclement conditions will make it exceedingly difficult to maintain a level bottom. In practice, work is nat generally permissible when the swell attains some two feet in height, owing to the structure being exposed to immense stresses from the ladder bumping on the bottom. It will be apparent that this system of dredging constitutes a serious obstruction to shipping in a narrow waterway, more especially when barges are employed to remove the spoil, and that the operation of lifting and relaying moorings on a fresh field is a heavy undertaking. **A** hopper dredger will present less of an obstacle but loses, for dredging, the time occupied in transporting the dredgings to the dumping site and returning to its work. When the hopper is full, the three forward chains are coupled together and let go, and similarly with the three stern moorings, the ends being attached to mark buoys. The operation of picking up these moorings again and connecting them to the winches is also one of considerable moment.

Suction Dredging.— The suction dredger operates generally on the same principles as the bucket dredger, but in some cases the six anchor moorings are dispensed with in favour of two "walking" spuds, placed abreast some distance apart at the stern, together with two forward side or "breast" moorings, consisting of wire ropes and anchors. In operation under this system one spud is let down to the bottom to act as an anchor and the forward end with suction pipe is swung by one breast mooring to the limit of the cut. Their relative positioning now brings the other spud in advance of the pivot spud; the former is let down to act as pivot, the latter raised, and the dredger swung on a new advanced arc back to the opposite side of the cut by the other breast mooring. The two spuds thus act as legs and the dredger "walks" forward. Fig. 6 illustrates this method.

Bar Dredging.— A particular case in which a different method is employed is the dredging of a navigable channel through a sand bar blocking a river entrance. Here large quantities require to be removed under arduous open sea conditions, precluding in most cases the employment of such a rigid structure as a bucket ladder, or in some cases even the use of moorings. The suction dredger is eminently adapted to this work as its suction pipe can be made flexibly jointed, thus relieving the ship of any bumping stresses. The dredger simply steams to the dredging position, lowers the suction pipe, maintains position roughly with the propellers, and takes on board into her hopper a load of sand in a comparatively short space of time. The power is arranged so that this operation is generally performed in some 30 to 40 minutes even with the largest hoppers up to 4,000 tons or more capacity. Without further ado the dredger steams out to sea, deposits the load through the doors arranged in the bottom, and returns to carry out the same procedure. In those cases where the sand will not run freely to the suction pipe, the latter requires to be made somewhat more rigid and is fitted with a drag head or cutting edge. The dredger steams slowly ahead, and the drag head slices off the material to a depth of 18 inches or two feet to bring it under the influence of the suction pipe. This is of course a rough operation, as the result is simply the cutting of a series of longitudinal furrows. In such situations the bar is often of sufficient width to permit of a full load being obtained in one cut. The drag method is also employed successfully where the area is large and the depth to be removed small, and it is capable of more accurate work than ordinary suction dredging.

Stationary Dredging.— In the case of the dipper dredger which relies on spuds, no external moorings are necessary. The dredging machinery being arranged on a turntable, cuts are taken round an arc of some go° or more while the vessel remains stationary. The anchor spuds are then lifted and the vessel moved up to suit the next series of cuts by means of the backing rope and the stern spud acting after the manner of a punt pole. The anchor spuds are then re-set and dredging operations continued. **A** development of the suction dredger employs a suction pipe mounted on a turntable after the manner of a dipper dredger, and operates on a similar method, the hull being kept stationary during the progress of each arc of cut either by moorings or by spuds. The grab dredger is another example of this system of operation, but requires some three or four moorings only to retain and adjust its position at its work, the dredging reactions being purely vertical.

Determination of Work Done.—The work done by dredgers is measured either "in the solid" or "in the loose" as the two methods are termed. Measurement in the solid involves the determination by soundings taken before and after dredging of the levels of the excavation. Measurement in the loose is based on a determination of the amount of spoil actually issuing from the dredger, either from the known capacity of the barges or hopper used, or in the case of pipe-line work, by survey of the deposit. Rough and ready methods based on known data are sometimes employed, such as by counting the rate at which the buckets travel on a ladder dredger, the number of dips or grabs per hour, or estimation of the velocity of flow and percentage of solids in a pipeline. Spoil, originally lying closely compacted in its natural state on the bottom, has been dug into, stirred up, and mixed with water by the action of the dredging tool, hence a swelling, generally taken as 30% in the absence of definite data, is observable in "loose" or "barge" measurement, as compared with "solid" or "place" measurernent.

Disposal of Spoil.—The disposal of spoil demands close consideration as it has an important effect on the cost of dredging. Where it is desired simply to get rid of the spoil, as in the improvement and upkeep of navigable channels, it is usually requisite to transport it considerable distances out to sea and deposit it in deep water whence there is little likelihood that it will find its way back under the influence of currents or sea action. For this purpose a fleet of barges, either self-propelled or towed, may be employed or the dredger itself conveys to sea the spoil which it excavates. In each case the hopper bottom is formed of a number of doors which can be opened to allow the spoil to drop out. The conditions determining the method to be adopted vary almost with every project. Obviously it is advisable to keep such an expensive item of plant as a dredger fully employed if at all possible, and the use of hopper dredgers is only resorted to when attendant barge traffic is either impracticable on account of inclement conditions or likely to cause serious additional obstruction to navigation in a busy and restricted waterway. The hopper type is useful also in the smaller sizes for general maintenance work as a self-contained unit. In those cases where the distance to the dumping site does not exceed a mile or two or where the material is required for reclamation purposes, towed barges are used, while for long distances, large speedy self-propelling barges holding up to 1,200 tons are necessary. Large quantities have been dredged from the Suez Canal by high tower ladder dredgers and deposited directly on the banks through long shoots, but this direct method is more generally applicable to the suction dredger for wide waterways and to the dipper or grab dredgers for narrow channels. For the important work of reclaiming land the suction dredger and a long pipe-line are generally employed so long as free-getting materials are to be dealt with. The portion of the pipe-line from the dredger to the shore is made in sections 30 to 50ft. long, flexibly connected together by ball and socket joints so as to permit the dredger its necessary range of movement. Each section of the pipe is carried on a pontoon and the floating pipe-line connects to a shore delivery pipe-line laid directly on the ground or mounted on trestles. If harder materials must necessarily be used or the conditions of exposure or obstruction to navigation preclude the use of a pipe-line, it becomes necessary to employ a fleet consisting of a cutter-suction or ladder dredger and a special reclamation vessel with barges as the connecting links. The reclamation vessel is in most respects equipped like a suction dredger except that its suction pipe is arranged over one side so as to dip into a barge; it is moored to a wharf or staging on the other side and its discharge pipe is flexibly connected direct to the shore pipe-line. By this means low-lying areas situated up to 6,000 feet from the water-front can be reclaimed, and at still further distances by the employment of boosting pumps.

Those desirous of pursuing the subject further will find the following useful:—C. Prelini, *Dredges & Dredging* (1912); T. C. Earl, *Gold Dredging* (1913); Sergeant, *Centrifugal Pumps & Suction Dredgers* (1918); A. B. McDaniel, *Excavation Machinery, Methods & Costs* (1919); F. L. Simon, *Dredging Engineering* (1920); G. B. Massey, *The Engineering of Excavation* (1923); P. M. Dekker, *Dredging & Dredging Appliances* (1927).

The writer is indebted to the many firms in Europe and America who have furnished particulars of plant, of which special mention may be made of the following British constructors: Messrs. Wm. Simons & Co., Ltd., Renfrew; Lobnitz & Co., Ltd., Renfrew; Fleming & Ferguson, Ltd., Paisley; Ferguson Brothers (Port Glasgow), Ltd., Port Glasgow; and Priestman Brothers, Ltd., Hull. A number of the examples have been taken from the writer's own practice. (A. T. C.)

DREISER, THEODORE (1871–), American author, was born at Terre Haute, Ind., on Aug. 27, 1871. He attended the public schools at Warsaw, Ind., and for a brief period Indiana university. He then went into newspaper work in Chicago, St. Louis and Pittsburgh. He began writing for various periodicals, engaged in editorial work, and became in 1907 editor-in-chief of the Butterick publications in New York city. This post he held until 1910. His first novel, *Sister Carrie,* published in 1900, was suppressed, but not before it had aroused the admiration, for its unsparing and poignant realism, of Frank Norris, the noted American realist, and later in England of Arnold Bennett, H. G. Wells and Hugh Walpole. Dreiser's second novel, *Jennie Gerhardt,* did not, however, follow until 1911. It had been written as a relief from editorial work, and its publication found Dreiser now devoting himself entirely to literature. In 1912 he brought out *The Financier,* the first of two books based upon the career of the traction magnate, Charles T. Yerkes. The second, *The Titan,* followed in 1914. In the year between Dreiser published *A Traveller at Forty,* an autobiographical volume, the fruit of a first trip abroad. *The Genius,* in 1915, was a long and detailed study of the ruthless type of artistic temperament. This was followed by Dreiser's first venture into intimate drama, *Plays of the Natural and Supernatural,* and the same year, 1916, brought forth *A Hoosier Holiday,* based upon a revisiting of his native State. Subsequent volumes included *The Hand of the Potter,* a tragedy (1918); *Twelve Men* (1919); *Hey, Rub-a-Dub-Dub* (1920); *A Book about Myself* (1922); *The Color of a Great City* (1923) and *A Gallery of Women* (1929). The publication in 1925 of *An American Tragedy,* based upon an actual American crime, brought Dreiser his first widespread popular recognition. The novel was dramatized by Patrick Kearney, presented by the Theatre Guild, and proved the sensational play of the season.

Theodore Dreiser was in 1929 probably the most important realist writing fiction in the United States, and this, in spite of the fact that he has been called "the most suppressed and insuppressible writer in America," and the more important fact that he can hardly be said to have achieved a style, his writing being often heavy-handed and clumsy. His large attempts, his close attention to detail, the cumulative effect he gains by laborious presentation of the exact truth are qualities that would not in themselves account for the stature he has attained as a novelist. A greater quality than these is to be found in the deep human sympathy underlying his treatment even of the most sordid and sombre human affairs. It goes hand in hand with a sincerity that has never swerved. The manner of Dreiser's writing has been the subject of much criticism from an artistic point of view; but there is general agreement as to the value of his super-reportorial presentation of some of the most significant aspects of modern American civilization. He builds solidly the story, for the most part, of tragic lives, tracing their inevitable course every step of the way and refraining from any comment save that implicit in the lives themselves. He has achieved a remarkable detachment in his writing.

A brother of Theodore Dreiser was the late Paul Dresser, the popular song-writer. A collection of his best songs has recently appeared with an introduction written by Dreiser. Further biographical and bibliographical material upon this novelist may be found in Burton Rascoe's *Theodore Dreiser* (1925), in Bessie Graham's *The Bookman's Manual* (1924) and in H. L. Mencken's *A Book of Prefaces* (1917). (W. R. BE.)

DRELINCOURT, CHARLES (1595–1669), French Protestant divine, born at Sedan on July 10, 1595, became minister of the Reformed Church at Charenton. His *Catechism* (*Catéchisme ou instruction familière*, 1652) and *Christian's Defense against the Fears of Death (Consolations de l'âme fidèle contre les frayeurs de la mort,* 1651) became well known in England by means of translations, which were very frequently reprinted. It has been said that Defoe wrote his fiction of Mrs. Veal (*A True Relation of the Apparition of Mrs. Veal*), who came from the other world to recommend the perusal of *Drelincourt on Death,* for the express purpose of promoting the sale of the English translation of the *Consolations,* to the fourth edition of which (1706) his contribution is added. Drelincourt died on Nov. 3, 1669.

DRENTE (or DRENTHE), a province of Holland, bounded north and northeast by Groningen, southeast by Germany, south and southwest by Overysel, and northwest by Friesland; area, 1,028 sq.mi.; pop. (1938) 245,321. Drente is a sandy plateau forming the nucleus of the surrounding provinces. The sandy soil is covered with bleak moorland, patches of wood, and fen. This is only varied by the strip of fertile clay and grass-land which is found along the river banks, and by the areas of high fen in the southeastern corner and on the western borders near Assen. The surface slopes from southwest to northeast,

where it ends in the ridge the Hondsrug (Dog's Back) along the eastern border. The watershed runs from east to west, along the line of the Orange canal. The southern streams are all collected at two points on the southern borders, namely, at Meppel and Koevorden, whence they communicate with the Zwarte Water and the Vecht respectively by means of the Meppeler Diep and the Koevorden canal. The Steenwyker Aa, however, enters the Zuider Zee independently. The northern rivers all flow into Groningen.

History. — The megalithic sepulchral mounds, the *Hunnebedden,* particularly along the western edge of the Hondsrug suggest the early settlement of the region. In the 5th and 6th centuries the country was overrun by Saxon tribes, and later on was governed by counts under the Frankish and German kings. In 1046 the emperor Henry III. gave the countship to the bishop and chapter of Utrecht, who governed it through the burgrave, or châtelain, of Koevorden, a dignity which became hereditary after 1143 in the family of Ludolf or Roelof, brother of Heribert of Bierum, bishop of Utrecht (1138–1150). After 1232 the countship passed to Henry I. of Borculo (1232–1261). In 1395 Reinald IV. (d. 1410) of Borculo-Koevorden was deposed by Bishop Frederick of Utrecht, and the country was henceforth administered by an episcopal official (amtmann). With its popularly elected assembly of twenty-four Etten (*jurati*) Drente remained practically independent. In 1522 it was conquered by Duke Charles of Gelderland, from whom it was taken by the emperor Charles V. in 1536, and from that time it became part of the Habsburg dominions.

Drente took part in the revolt of the Netherlands, but owing to its poverty and sparse population, it had no separate representation in the assembly of the states general. It was subdued by the Spaniards in 1580, but reconquered by Maurice of Nassau in 1594. Drente retained its local independence and had its own stadtholder. At the general assembly of 1651 Drente unsuccessfully claimed admission as a province. After the deaths of William II. (1650) and of William III. (1702) Drente remained for a time without a stadtholder, but in 1722 William Charles Henry, who had become prince of Orange, was elected. His descendants held the office, which was declared hereditary, until the French conquest in 1795. In 1796 Drente at length obtained representation in the states general. Between 1806 and 1813 Drente, with the rest of the Netherlands, was incorporated in the French empire, and, with part of Groningen, formed the department of Ems Occidental. With the accession of William I. it was restored as a province of the new kingdom. The province was speedily conquered by Germans in invasion of May 1940.

Two industries have for centuries been associated with the barren heaths and sodden fens so usually found together on the sand-grounds, namely, the cultivation of buckwheat and peat-digging. The latter being directed also towards the draining of the land and its subsequent use for cultivation. The soil thus prepared is, however, soon exhausted. Potatoes, rye, oats, beans and peas are cultivated. In connection with the cultivation of potatoes, the by-products (spirits, potato meal, etc.), are important. Furthermore, agriculture is accompanied on the sand-grounds by the rearing of a poor type of sheep and cattle, which assist in fertilizing the soil. The breeding of pigs is also widely practised. Of the fen-colonies in Drente the best known are those of Frederiksoord and Veenhuizen.

Owing to the general condition of poverty which prevailed after the French evacuation early in the 19th century, attention was turned to the unreclaimed heath-lands in the eastern provinces, and the Society of Charity began by establishing the free agricultural colony of Frederiksoord, about 10 m. N. of Meppel. In addition, various industries, such as mat and rope making, and jute, and cotton weaving were introduced. In later times forest culture was added, and the Gerard Adriaan van Swieten schools of forestry, agriculture and horticulture were established. To this colony were added those of Willemsoord and Kolonie VII. in Overysel, and Wilhelminasoord partly in Friesland. The colony of Veenhuizen lies about 7 mi. N.W. of Assen, and was founded by the same society in 1823. In 1859, the Veenhuizen estates were sold to the government.

Owing to its geographical isolation, the development of Drente has remained behind that of the other provinces of the Netherlands, and the character and customs of the people likewise conservative. Assen is the chief town. In the south are Meppel and Koevorden. Hoogeveen, situated between these two, owes its origin to the fen reclamation which was begun here in 1625. Extensive fir woods have been laid out in the neighbourhood. Zuidlaren. at the northern end of the Hondsrug, has an important market. The railway from Amsterdam to Groningen traverses Drente; branch lines connect Meppel with Leeuwarden and Assen with Delfzÿl.

DRESDEN, a city of Germany, capital of the Land of Saxony, 71 mi. E.S.E. from Leipzig and 111 mi. S. from Berlin by railway. Pop. (1939) 625,174, mainly Lutheran. It lies 402 ft. above the Baltic, in a broad valley on both banks of the Elbe. The prospect. of cupolas, towers, spires and copper green roofs is of striking beauty. On the left bank of the river are the Altstadt (old town) with old and new suburbs, and the Friedrichstadt (separated from the Altstadt by a long railway viaduct); on the right, the Neustadt (new town), Antonstadt, and Alberstadt. Five fine bridges connect the Altstadt and Neustadt. The beautiful central bridge — the Alte or Augustusbriicke — with 16 arches, built in 1727–1731, and 1,420 ft. long, has been demolished (1906) and replaced by a wider structure. Up-stream are the two modern Albert and Konigin Carola bridges, and, down-stream, the Marien and the Eisenbahn (railway) bridges.

History. — Dresden (Old Slav Drezga, forest, *Drezgajan,* forest-dwellers), which is known to have existed in 1206, is of Slavonic origin, and was originally founded on the right bank of the Elbe, on the site of the present Neustadt, which is thus actually the old town. It became the capital of Henry the Illustrious, margrave of Meissen, in 1270, but belonged for some time after his death, first to Wenceslaus of Bohemia, and next to the margrave of Brandenburg. Early in the 14th century.it was restored to the margrave of Meissen. On the division of Saxony in 1485 it fell to the Albertine line, which has since held it. Having beeh burned almost to the ground in 1491, it was rebuilt; and in the 16th century the fortifications were begun and gradually extended. John George II., in the 17th century, formed the Grosser Garten, and otherwise greatly improved the town; in the first half of the 18th century, Augustus I. and Augustus II., kings of Poland as well as electors of Saxony, modernized Dresden. The Neustadt, which had been burned down in the 17th century, was founded anew by Augustus I.; he also founded Friedrichstadt. The town was bombarded in 1760 during the Seven Years' War. Napoleon made it a centre of operations in 1813, and one buttress and two arches of the old bridge were blown up. The dismantling of the fortifications, begun by the French in 1810, was completed after 1817, and gardens and promenades made. Many buildings were completed or founded by King Anthony, from whom Antonstadt derives its name. Dresden again suffered severely during the revolution of 1849, but all traces of the disturbances which then took place were soon effaced. In 1866 it was occupied by the Prussians, who did not finally evacuate it until the spring of the following year. There was a good deai of fighting in the streets during the year of 1919.

Situation and Buildings. — Dresden is often called "German Florence," because of its situation, its art treasures and the educational advantages it offers. Within two decades (1880–1900) the capital almost at a single bound advanced into the front rank of German commercial and industrial towns; but while gaining in prosperity it lost much of its mediaeval aspect, and old buildings in the heart of the Altstadt were swept away. The Theaterplatz in the Altstadt is especially fine.

The most imposing churches include the Roman Catholic Hofkirche, built (1739–1751) by C. Chiaveri, in rococo style, with a tower 300 ft. high. It contains a fine organ and pictures, the outside being adorned with 59 statues. On the Neumarkt is the Frauenkirche, with stone cupola rising 311 ft.; close to the Altmarkt, the Kreuzkirche, rebuilt after destruction by fire in 1897, also with a lofty tower surmounted by a cupoia; and near the

AIR VIEWS OF DRESDEN, SAXONY

1. The city of Dresden, Germany, showing the Albertplatz
2. The centre of Dresden, showing the Elbe River and three of its bridges. The Zwinger, one of the most famous art galleries and museums in the world, with its enclosed court, is in the right foreground. The opera house is to the left. Across the open Theater-Platz is the former court church, and across the narrow street from this the former royal palace

Postplatz the Sophienkirche, with twin spires. In the Neustadt is the Dreikonigskirche (dating from the 18th century) with a high pinnacled tower.

The former royal palace in the Altstadt built in 1530–1535 by Duke George (and thus called Georgenschloss), was thoroughly restored between 1890 and 1902, in German Renaissance style. The Georgentor has been widened, and through it, and beneath the royal apartments, vehicular traffic from the centre of the town is directed to the Augustusbriicke. The whole is surmounted by a lofty tower—387 ft.—the highest in Dresden. The interior is splendidly decorated. In the palace chapel are pictures by Rembrandt, Nicolas Poussin, Guido Reni and Annibale Caracci. The adjoining Prinzen-Palais on the Taschenberg, built in 1715, has a fine chapel, in which are various works of S. Torelli; it has also a library of 20,000 volumes. The Zwinger, begun in 1711 in the rococo style was intended to be the vestibule to a palace, but now contains a number of collections of great value. Until 1846 it was open at the north side; but this space has since been occupied by the museum, a building in Renaissance style, the exterior of which is adorned by statues of Michelangelo, Raphael, Giotto, Dante, Goethe and other artists and poets by Rietschel and Hahnel, and it contains the famous picture gallery. The Briihl palace, built in 1737 by Count Briihl, minister of Augustus II., has been in some measure demolished to make room for the new Standehaus (diet house), with its main façade facing the Hofkirche; before the main entrance there is an equestrian statue (1906) of King Albert. Close by is the Briihl Terrace, approached by a fine flight of steps, on which are groups, by Schilling, representing Morning, Evening, Day and Night. The terrace commands a view of the Elbe and the distant heights of Loschwitz and the Weisser Hirsch, but the prospect has become somewhat marred, owing to the extension of the town up the river and to the two new up-stream bridges. The Japanese palace in the Neustadt, built in 1715 as a summer residence for Augustus II., receives its name from certain oriental figures with which it is decorated; it is sometimes called the Augusteum and contains the library. Among other buildings of note is the Hoftheater, in the Renaissance style, built after the designs of Semper, to replace the theatre burnt in 1869, and completed in 1878. A new town hall of huge dimensions, also in German Renaissance, with an octagon tower 400 ft. in height, stands on the former southern ramparts of the inner town, close to the Kreuzkirche.

In the Altstadt the most striking of the newer edifices is the Kunstakademie. The Albertinum, which was formerly the arsenal, originally built in 1559–1563, was rebuilt 1884–1889, and fitted up as a museum of oriental and classical antiquities, and as the depository of the state archives. On the right bank of the Elbe in Neustadt stand many administrative buildings. In the suburbs which encircle the old town are to be noted the vast central Hauptbahnhof (1893–1898) occupying the site of the old Bohmischer railway station, the municipal hospital and the exhibition buildings.

The chief pleasure-ground of Dresden is the Grosser Garten, in which there are a summer theatre, the Reitschel museum and a château containing a museum of antiquities, chiefly objects removed from the churches in consequence of the Reformation. Near the château is the zoological garden, formed in 1860. A little south of Dresden, on the left bank of the Elbe, is the village Räcknitz, in which is Moreau's monument, erected on the spot where he was mortally wounded in 1813. The mountains of Saxon Switzerland are seen from this neighbourhood, and are much visited in summer.

Art.—Dresden owes part of its fame to its splendid picture gallery, founded by Augustus I, and increased by his successors at great cost. It is in the museum, and contains about 2,500 pictures, being especially rich in specimens of the Italian, Dutch and Flemish schools. The gem of the collection is Raphael's "Madonna di San Sisto," for which a room is set apart. There is also a special room for the "Madonna" of the younger Holbein. Other paintings with which the name of the gallery is generally associated are Correggio's "La Notte" and "Mary Magdalene"; Titian's "Tribute Money" and "Venus"; "The Adoration" by Paul Veronese; Andrea del Sarto's "Abraham's Sacrifice"; Rembrandt's "Portrait of Himself with his Wife sitting on his Knee"; "The Judgment of Paris" and "The Boar Hunt," by Rubens; Van Dyck's "Charles I., his Queen and their Children."

Of modern painters, this magnificent collection contains masterpieces by Tefregger. Vautier, Makart, Munkacsy, Fritz von Uhde, Bocklin, Hans Thoma; portraits by Leon Pohle, Delaroche and Sargent; landscapes by Andreas and Oswald Achenbach and allegorical works by Sascha Schneider. In separate compartments there are a number of crayon portraits, most of them by Rosalba Carriera, and views of Dresden by Canaletto and other artists. Besides the picture gallery the museum includes a magnificent collection of engravings and drawings, arranged so as to mark the great epochs in the history of art. A collection of casts, likewise in the museum, is designed to display the progress of plastic art from the time of the Egyptians and Assyrians to modern ages. This collection was begun by Raphael Mengs, who secured casts of the most valuable antiques in Italy, some of which no longer exist.

The Japanese palace contains a large public library with about 3,000 mss. and 20,000 maps. It is especially rich in the ancient classics, and in works bearing on literary history and the history of Germany, Poland and France. There are also a valuable cabinet of coins and a collection of ancient works of art. A collection of porcelain in the "Museum Johanneum" (which once contained the picture gallery) is made up of specimens of Chinese, Japanese, East Indian, Sbvres and Meissen manufacture, carefully arranged in chronological order. There is in the same building an excellent historical museum. In the Griines Gewolbe (Green Vault) of the Royal Palace, so called from the character of its original decorations, there is an unequalled collection of precious stones, pearls and works of art in gold, silver, amber and ivory. The objects, which are about 3,000 in number, are arranged in eight rooms. They include the regalia of Augustus II. as king of Poland; the electoral sword of Saxony; a group by Dinglinger, in gold and enamel, representing the court of the grand mogul Aurungzebe, and consisting of 132 figures upon a plate of silver 4 ft. 4 in. square; the largest onyx known, $6\frac{2}{3}$ in. by $2\frac{1}{4}$ in.; a pearl representing the dwarf of Charles II. of Spain; and a green brilliant weighing 40 carats. The royal palace also has a gallery of arms consisting of more than 2,000 weapons of artistic or historical value. In the Zwinger are the zoological and mineralogical museums and a collection of instruments used in mathematical and physical science. The Korner museum contains numerous reminiscences of the Goethe-Schiller epoch, and of the wars of liberation (1813–15).

Education.—Dresden is the seat of a number of well-known scientific associations. The educational institutions are numerous. including a technical high school (with about 1,100 students), which enjoys the privilege of conferring the degrees of doctor of engineering, doctor of technical sciences, etc., a veterinary college, a political-economic institution (Gehestiftung), with library, a school of architects, a royal and four municipal gymnasia, numerous lower grade and popular schools, the royal conservatorium for music and drama, and a celebrated academy of painting.

Music.—The orchestra attached to the *Hoftheater,* founded by Augustus II, became famous throughout the world, owing to its masters, Paer, Weber, Reissiger and Wagner. Symphony and popular concerts are held throughout the year in various public halls, and, during the winter, concerts of church music are frequently given in the churches.

Communications and Industries.—Dresden lies at the centre of an extensive railway system, which places it in communication with the chief cities of northern and central Germany as well as with the southeast. Here cross the grand trunk lines Berlin-Vienna. Chemnitz-Gorlitz-Breslau. It is connected by two lines of railway with Leipzig and by local lines with neighbouring smaller towns. The navigation on the Elbe has largely developed, and, in addition to trade by river with Bohemia and Magdeburg-Hamburg, there is a considerable pleasure-boat traffic during the summer months. Among the more notable industries of Dresden may be mentioned the manufacture of china, of gold and silver ornaments, cigarettes, chocolate, coloured postcards, per-

fumery, leather, lace, soap, straw-plaiting, artificial flowers, agricultural machinery, paper, musical, photographic and other instruments. There are several distilleries and breweries; corn trade is carried on, and an extensive business is done in books and objects of art.

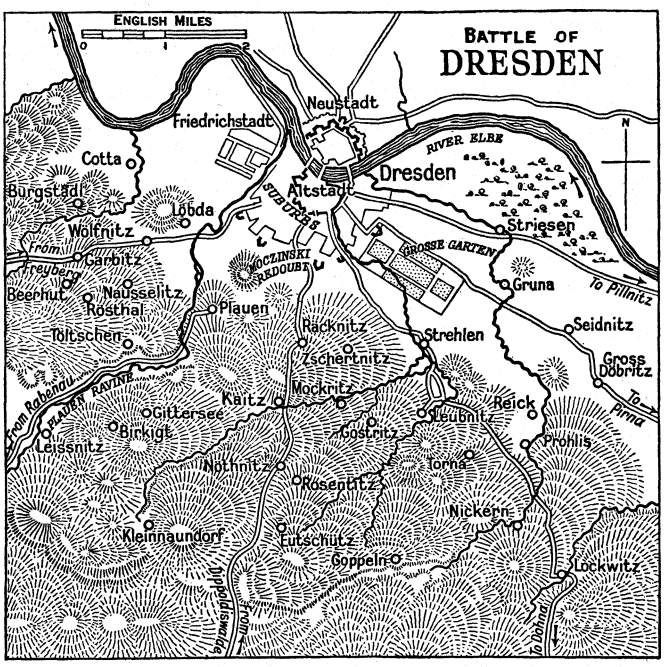
BATTLE OF DRESDEN

The battle of Dresden, the last of the great victories of Napoleon, was fought on Aug. 26 and 27, 1813. The intervention of Austria in the War of Liberation, and the consequent advance of the Allies under the Austrian field-marshal Prince Schwarzenberg from Prague upon Dresden, recalled Napoleon from Silesia, where he was engaged against the Prussians and Russians under Blucher. Only by a narrow margin of time, indeed, was he able to bring back sufficient troops for the first day's battle. He detached a column under Vandamme to the mountains to interpose between Schwarzenberg and Prague (see NAPOLEONIC CAMPAIGNS); the rest of the army pressed on by forced marches for Dresden, around which a position for the whole army had been chosen and fortified, though at the moment this was held by less than 20,000 men under Gouvion St. Cyr, who retired thither from the mountains, leaving a garrison in Königstein, and had repeatedly sent reports to the emperor as to the allied masses gathering to the southward. The battle of the first day began late in the afternoon, for Schwarzenberg waited as long as possible for the corps of Klenau, which formed his extreme left wing on the Freiberg road. At last, about 6 P.M. he decided to wait no longer, and six heavy columns of attack advanced against the suburbs defended by St. Cyr and now also by the leading troops of the main army. Three hundred guns covered the assault, and Dresden was set on fire in places by the cannonade, while the French columns marched unceasingly over the bridges and through the Altstadt. On the right the Russians under Wittgenstein advanced from Striesen, the Prussians under Kleist through the Grosse Garten, whilst Prussians under Prince Augustus and Austrians under Colloredo moved upon the Moczinski redoubt, which was the scene of the most desperate fighting, and was repeatedly taken and retaken. The attack to the westward was carried out by the other Austrian corps; Klenau, however, was still far distant. In the end, the French defences remained unshaken. Ney led a counter-attack against the Allies' left, the Moczinski redoubt was definitely recaptured from Colloredo, and the Prussians were driven out of the Grosse Garten. The *coup* of the Allies had failed, for every hour saw the arrival of fresh forces on the side of Napoleon, and at length the Austrian leader drew off his men to the heights again. He was prepared to fight another battle on the morrow—indeed he could scarcely have avoided it had he wished to do so, for behind him lay the mountain defiles, towards which Vandamme was marching with all speed.



BATTLE OF DRESDEN, LAST OF NAPOLEON'S GREAT VICTORIES. AUG. 1813
On Aug. 27, Napoleon launched his army of 97,000 men against both flanks of the Allies, composed of 200,000 Austrians, Russians and Prussians. Murat's cavalry and Victor's infantry annihilated the Austrian divisions under General Metzko, at Wölfnitz and Lobda, while Ney's columns, on the left, drove the Russians from Seidnitz, Gross Dobritz and Reick. The Allies retreated, having lost 38,000 killed, wounded and prisoners. French losses were 10,000

Napoleon's plan for the 27th was, as usual, simple in its outline. As at Friedland, a ravine separated a part of the hostile line of battle from the rest. The villages west of the Plauen ravine and even Lobda were occupied in the early morning by Gen. Metzko with the leading division of Klenau's corps from Freiberg, and upon Metzko Napoleon intended first to throw the weight of his attack, giving to Victor's infantry and the cavalry of Murat the task of overwhelming the isolated Austrians. The centre, aided by the defences of the Dresden suburbs, could hold its own, as the events of the 26th had shown; the left, now under Ney, with whom served Kellermann's cavalry and the Young Guard, was to attack Wittgenstein's Russians on the Pirna road. Thus, for once, Napoleon decided to attack both flanks of the enemy. His motives in so doing have been much discussed by the critics; Vandamme's movements, it may be suggested, contributed to the French emperor's plan, which if carried out would open the Pirna road. Still, the left attack may have had a purely tactical object, for in that quarter was the main body of the Prussians and Russians, and Napoleon's method was always to concentrate the fury of the attack on the heaviest masses of the enemy, *i.e.,* the best target for his own artillery. A very heavy rainstorm during the night seriously affected the movements of troops on the following day, but all to Napoleon's advantage, for his more mobile artillery, reinforced by every horse available in and about Dresden, was still able to move where the Allied guns sank in mud. Further, if the cavalry had to walk, or at most trot, through the fields the opposing infantry was almost always unable to fire their muskets. "You cannot fire; surrender," said Murat to an Austrian battalion in the battle. "Never," they replied; "you cannot charge us." On the appearance of Murat's horse artillery, however, they had to surrender at once. Under such conditions, Metzko, unsupported either by Klenau or the main army beyond the ravine, was an easy victim. Victor from Lobda drove in the advanced posts and assaulted the line of villages Wolfnitz-Toltschen; Metzko had to retire to the higher ground south-west of the first line, and Murat, with an overwhelming cavalry force from Cotta and Burgstadl, outflanked his left, broke up whole battalions, and finally, in conjunction with the renewed frontal attack of Victor's infantry, annihilated the division. The Austrian corps of Gyulai arrived too late to save it.

Meanwhile Ney on the other flank, with his left on the Pillnitz road and his right on the Grosse Garten, had opened his attack. The Russians offered a strenuous resistance, defending Seidnitz, Gross Dobritz and Reick with their usual steadiness, and Ney was so far advanced that several generals at the Allied headquarters suggested a counter-attack of the centre by way of Strehlen, so as to cut off the French left from Dresden. This plan was adopted, but, owing to various misunderstandings, failed of execution. Thus the Allied centre remained inactive all day, cannonaded by the Dresden redoubts. One incident only, but that of great importance, took place here. The tsar, the king of Prussia, Schwarzenberg and a very large headquarter staff watched the fighting from a hill near Räcknitz and offered an easy mark to the French guns. In default of formed bodies to fire at, the latter had for a moment

ceased fire; Napoleon, riding by, half carelessly told them to reopen, and one of their first shots, directed at 2,000 yards range against the mass of officers on the sky-line, mortally wounded Gen. Moreau, who was standing by the emperor Alexander. A council of war followed. The tsar was for continuing the fight; Schwarzenberg, however, knowing the exhaustion of his troops decided to retreat. As at Bautzen, the French cavalry was unable to make any effective pursuit.

DRESDNER BANK, German Bank was established in Dresden in **1872** by a founders' syndicate headed by Consul Eugen Gutmann taking over the banking house of M. Kaskel in Dresden.

The Office in Berlin, which is now the head office of the bank, was established in **1881.** The bank disposed in **1928** of a capital (including open reserves) of **132** millions of Reichsmarks. It is one of the group of leading German banks, known as the "D-Banks," because their names begin with D.

Besides branches in about 80 places throughout Germany the *Dresdner Bank* maintains branches at Danzig, Bucharest and at three places in Poland. The bank has further an agency at Amsterdam and a special representative in New York. The *Deutsch-Südamerikanische Bank* (*Banco Germanico de la America del Sud)* and the *Deutsche Orientbank* are affiliated institutions of the *Dresdner Bank.* Through its Board of General Managers, the *Dresdner Bank* is represented on the Boards of Administration of most of the important German industrial and commercial concerns with which it maintains very close business relations.

The bank undertakes every kind of banking business both in Germany and foreign countries. It opens current, checking and deposit accounts, executes orders for the purchase and sale of shares and bonds at any Stock Exchange; grants covered and clean credits; receives securities for safe custody; opens commercial credits and issues travellers' letters of credit; provides facilities for every description of oversea-business; advises as to trade openings in all parts of the world; furnishes credit information; forms syndicates and issues or negotiates loans for corporations, municipalities and countries. In fact the bank is concerned with all branches of modern banking organization and is equipped to deal with every banking service.

It is particularly well equipped for transactions in foreign exchange, by reason of the large number of its foreign correspondents. (C. HR.)

DRESS (from the Fr. *dresser,* to set out, arrange, formed from Lat. *directus,* arranged, *dirigere,* to direct, arrange), a substantive of which the most usual meaning is that of clothing or costume in general, or, specifically, the principal outer garment worn by a woman. The verb "to dress" has various applications which can be deduced from its original meaning. It is thus used not only of the putting on of clothing, but of the preparing and finishing of leather, the preparation of food for eating, the application of cleansing and healing substances or of bandages, to a wound, the drawing up in a correct line of a body of troops, and, generally, adorning or decking out, as of a ship with flags. In the language of the theatre the "dresser" is the person who looks after the actor's wardrobe and assists him in the changing of his costumes.

INTRODUCTION

The subject of dress in its currently accepted meaning of clothing is of far wider application than appears at first sight. To the average man there is a distinction between clothing and ornament, the first being regarded as that covering which satisfies the claims of modesty, the second as those appendages which satisfy the aesthetic sense. This distinction, however, does not exist for science, and indeed the first definition involves a fallacy of which it will be as well to dispose forthwith.

Modesty is not innate in man, and its conventional nature is easily seen from a consideration of the different ideas held by different races on this subject. With Mahommedan peoples it is sufficient for a woman to cover her face; the Chinese women would think it extremely indecent to show their artificially compressed feet, and it is even improper to mention them to a woman; in Sumatra and Celebes the wild tribes consider the exposure of the knee immodest; in central Asia the finger-tips, and in Samoa the navel are similarly regarded. In Tahiti and Tonga clothing might be discarded without offence, provided the individual were tattooed; and among the Caribs a woman might leave the hut without her girdle but not unpainted. Similarly, in Alaska, women felt great shame when seen without the plugs they carried in their lips. Europeans are considered indelicate in many ways by other races, and a remark of Peschel is to the point: "Were a pious Mussulman of Ferghana to be present at our balls and see the bare shoulders of our wives and daughters, and the semi-embraces of our round dances, he would silently wonder at the long-suffering of Allah who had not long ago poured fire and brimstone on this sinful and shameless generation." Another point of interest lies in the difference of outlook with which nudity is regarded by the English and Japanese. Among the latter it has been common for the sexes to take baths together without clothing, while in England mixed bathing, even in full costume, is even now by no means universal. Yet in England the representation of the nude in art meets with no reproach, though considered improper by the Japanese. Even more striking is the fact that in civilized countries what is permitted at certain times is forbidden at others; a woman will expose far more of her person at night, in the ballroom or theatre, than would be considered seemly by day in the street; and a bathing costume which would be thought modest on the beach would meet with reprobation in a town.

Modesty therefore is highly conventional, and to discover its origin the most primitive tribes must be observed. Among these, in Africa, South America, Australia and so forth, where clothing is at a minimum, the men are always more elaborately ornamented than the women. At the same time it is noticeable that no cases of spinsterhood are found; celibacy, rare as it is, is confined to the male sex. It is reasonable, therefore, to conclude that ornament is a stimulus to sexual selection, and this conclusion is enforced by the fact that among many comparatively nude peoples clothing is assumed at certain dances which have as their confessed object the excitation of the passions of the opposite sex. Many forms of clothing, moreover, seem to call attention to those parts of the body of which, under the conditions of Western civilization at the present day, it aims at the concealment; certain articles of dress worn by the New Hebrideans, the Zulu-Xosa tribes, certain tribes of Brazil and others, are cases in point. Clothing, moreover—and this is true also of the present day—almost always tends to accentuate rather than to conceal the difference between the sexes. Looking at the question then from the point of view of sexual selection it would seem that a stage in the progress of human society is marked by the discovery that concealment affords a greater stimulus than revelation; that the fact is true is obvious,--even to modern eyes a figure partially clad appears far more indecent than a nude. That the stimulus is real is seen in the fact that among nude races flagrant immorality is far less common than among the more clothed; the contrast between the Polynesians and Melanesians, living as neighbours under similar conditions, is striking evidence on this point. Later, when the novelty of clothing has spent its force, the stimulus is supplied by nudity complete or partial.

One more point must be considered: there is the evidence of competent observers to show that members of a tribe'accustomed to nudity, when made to assume clothing for the first time, exhibit as much confusion as would a European compelled to strip in public. This fact, considered together with what has been said above, compels the conclusion that modesty is a feeling merely of acute self-consciousness due to appearing unusual, and is the result of clothing rather than the cause. In the words of Westermarck: "The facts appear to prove that the feeling of shame, far from being the cause of man's covering his body, is, on the contrary, a result of this custom; and that the covering, if not used as a protection from the climate, owes its origin, at least in a great many cases, to the desire of men and women to make themselves mutually attractive."

PRIMITIVE DRESS

Primitive adornment in its earliest stages may be divided into

three classes; first the moulding of the body itself to certain local standards of beauty. In this category may be placed head-deformation, which reached its extreme development among the Indians of North-West America and the ancient Peruvians; foot-constriction as practised by the Chinese; tooth-chipping among many African tribes; and waist-compression common in Europe at the present day. Many forms of deformation, it may be remarked in passing, emphasize some natural physical characteristic of the people who practise them. Secondly, the application of extraneous matter to the body, as painting and tattooing, and the raising of ornamental scars often by the introduction of foreign matter into flesh-wounds (this practice belongs partly to the first category also). Thirdly, the suspension of foreign bodies from, or their attachment to, convenient portions of the body. This category, by far the largest, includes ear-, nose- and lip-ornaments, head-dresses, necklets, armlets, wristlets, leglets, anklets, finger- and toe-rings and girdles. The last are important, as it is from the waist-ornament chiefly that what is commonly considered clothing at the present day has been developed.

Setting aside for the moment the less important, historically, of these, nearly all of which exist in Western civilization of the present day, it will be as well to consider that form of dress which is marked by the greatest evolution. It is generally supposed that man originated in tropical or subtropical latitudes, and spread gradually towards the poles. Naturally, as the temperature became lower, a new function was gradually acquired by his clothing, that of protecting the body of the wearer. Climate then is one of the forces which play an important part in the evolution of dress; at the same time care must be taken not to attribute too much influence to it. It must be remembered that the Arabs, who inhabit an extremely hot country, are very fully clothed, while the Fuegians at the extremity of Cape Horn, exposed to all the rigours of an antarctic climate, have, as sole protection, a skin attached to the body by cords.

Dr. C. H. Stratz divides clothing climatically into two classes: tropical, which is based on the girdle (or, when the attachment is fastened round the neck, the cloak), and the arctic, based on the trouser. This classification is ingenious and convenient as far as it goes, but it seems probable that the trouser, which also has the waist as its point of attachment, may itself be a further development of the girdle. Certainly, however, in historical times the division holds good, and it is worthy of remark that one of the points about the northern barbarians which struck the ancient Greeks and Romans most forcibly was the fact that they wore trousers. Amongst the most northerly races the latter garb is worn by both sexes alike; farther south by the men, the women retaining the tropical form; farther south still the latter reigns supreme. No distinct latitude can be assigned as a boundary between the two forms, from the simple fact that where migration in comparatively recent times has taken place a natural conservatism has prevented the more familiar garb from being discarded; at the same time the two forms can often be seen within the limits of the same country; as, for instance, in China, where the women of Shanghai commonly wear trousers, those of Hong-Kong skirts. The retention by women in Europe of the tropical garb can be explained by the fact that her sphere has been mainly confined to the house, and her life has been less active than that of man; consequently the adoption of the arctic dress has been in her case less necessary. But it is noticeable that where women engage in occupations of a more than usually strenuous nature, they frequently don male costume while at their work; as, for instance, women who work in mines (Belgium) and who tend cattle (Switzerland, Tirol). The retention of the tropical pattern by the Highlanders is due directly to environment, since the kilt is better suited than trousers for walking over wet heather.

Another factor besides climate which has exerted a powerful influence on dress—more perhaps on what is commonly regarded as "jewellery" as distinct from "clothing"—is superstition. Doubtless many of the smaller objects with which primitive man adorned himself, especially trophies from the animal world, were supposed to exert some beneficial or protective influence on the wearer, or to produce in him the distinguishing characteristics attributed to the object, or to the whole of which the object was a part. Such objects might be imitated in other materials and by successive copying lose their identity, or their first meaning might be otherwise forgotten, and they would ultimately exercise a purely decorative function. Though this factor may be responsible for much, or even the greater part, of primitive "jewellery," yet it does not seem likely that it is the cause of all forms of ornament; much must be attributed to the desire to satisfy an innate aesthetic sense, which is seen in children and of which some glimmerings appear among the lower animals also.

BABYLONIAN AND ASSYRIAN COSTUME

c. 3000–2000 **B.C.**—In Sumerian days (3000–2000 B.C.) Babylonian men wore a fringed garment of wool, known to us generally by the name of the kaunakes (a graecized form of the classical period): the wool seems to have been unspun, and probably the garment consisted merely of natural locks without the hide. It has been conjectured that kaunakes of feathers were also worn. One shoulder was generally covered by this garment, the other left bare, but a long and heavy cloak, open in front, was often worn. The feet were bare. Men and women both wore their hair equally long. Men dressed it in a catogan or chignon at the back, often with the addition of two plaited tails crossed at the back beneath the chignon and with their ends fastened over the forehead. Women had rather more elaborate chignons, sometimes three, one at the back and two at the sides. Priests had their heads shaven and performed certain rites stark naked, as also did the kings and great men, who on these occasions wore their hair down their backs. Beards were occasionally worn. Large hats with brims indicated a mark of dignity, and were worn by gods and kings. Gods had them adorned with horns. Later on we find the kings and important personages wearing a turban consisting of a round cap with a thick band around it. A tunic, sometimes sleeved, and long robes also came in. Warriors wore conical copper helmets, like the mediaeval bassinet, and carried shields and spears; a king could wear a gold helmet made in imitation of his own headdress (tomb at Ur) and use golden swords and javelins. Copper breast-plates may also have been used. Feet were generally bare; but in later days in Assyria sandals and elaborate high boots were worn. A cylinder-seal of stone was carried, fastened to a great pin with lapis lazuli and round gold head, and used to fasten the garment. It was also used as a stiletto, if needed. Large-knobbed walking-sticks were always carried. Herodotus correctly describes the seal and stick carried by every Babylonian. Daggers had often gold and lapis hilts, sometimes even gold blades in early times. In later days the well-known Assyrian "Tiara" with its spike was worn by the kings; the bull-horn headdress was given to gods. The heavily ornamented robes of the Assyrian period are well-known; the enormous earrings and necklaces, the elaborately curled hair and beards of the Assyrian have been familiar to us since the days of Layard. The war-gear of the later period shows, of course, the development from copper to bronze and then to iron weapons, the helmet taking the characteristic Assyrian peaked form, and in the 7th century it is crowned with the Graeco-Carian crest, adopted from the West. Great round shields were carried and hauberks worn of metal plates or scales sewn on leather.

We have so few representations of Babylonian or Assyrian women, other than goddesses (who wear long flounced robes) that it is almost impossible to say much of their costume. In the early period one sees them wearing a modification of the men's kaunakes, with hair rather more elaborately dressed than the men's (see above) and ornamented with nodding balls or flowers of gold and lapos on a comb-like ornament that was stuck into the catogan with a sharp-ended shank. Later on they wore a shapeless robe, with the hair usually "down." Assyrian women wore earrings of great length and weight like the men's, and other adornments like theirs. The Ur excavations have shown that the Sumerian women of 2,000 years before already used "vanity-cases" of gold, with tweezers, earpick and head-scratcher complete.

The Persians wore as court-dress a modification of the Assyrian gear, including the tiara and curled hair and beard. Their native headdress was a "Phrygian" hood, sometimes worn with a veil or scarf across the mouth to keep the dust out, like the *litham* of the Tuareg. Small felt hats, square-topped or round, were worn as their descendants are to this day; a waisted tunic and gaily coloured pyjama-trousers, confined at the ankle, were characteristic of the Persian male costume, so far as it was not influenced by that of Mesopotamia.

In later times in Persia we find the Sassanian kings wearing a development of the old Persian dress, with high tiaras and many chaplets and necklaces of beads, earrings, etc. The hair was worn very bushy, over the shoulders; this was characteristic of the men. We know little of what the Persian women wore.

MINOAN COSTUME

The Bronze Age in Greece.—From the contemporary representations of the men and women of the Bronze age in Greece we can gather a very good idea of their costume. The men wore a very scanty dress, considering the fact that in winter and in the mountains everywhere in Greece the climate is sametimes cold. It consisted principally of a waistcloth tightly folded round the loins, sometimes with the addition of a conspicuous special sheath or codpiece for the penis, and confined at the waist by a large and very tight belt. Naturally the Cretans have unusually small waists, a characteristic of the race to this day. This seems, judging by the universal testimony of the statuettes and wall-paintings, to have been artificially accentuated from youth by tight belting, so that the men appear with waists like wasps. It even seems probable that in the case of the young men the belt was of metal, riveted on in boyhood, and retained till manhood, so that the young men had waists artificially constricted to the size of those of small boys. In middle age it would seem that this ring was removed, and the body eventually assumed a normal form. Statuettes of older men show them as somewhat obese. The women often wore the same constricting belt when young. In form it was generally bevelled. Over the tight waistclout was worn a kilt, in court dress apparently ornamented by a hanging fringe of network (Knossos frescoes, etc.). This kilt, sometimes with the sheath showing, is carefully represented in the Egyptian wall-paintings of the Keftian ambassadors to Egypt in the time of the XVIIIth Dynasty (see EGYPT). It was gaily ornamented with zigzag and other patterns, thus contrasting vividly with the white kilt of the Egyptians. Sometimes this kilt is of considerable length, reaching to the calf of the leg; at other times it, or a development of the waistclout resembling our bathing-drawers or shorts, is lengthened and so full as to resemble the voluminous *βράκαις* of the modern Cretan and Greek islander, which may indeed be derived from it in direct descent. In cold weather and doubtless by older men a cloak was worn, resembling the modern Cretan capote somewhat, but with a heavy fringed lower border. This has been regarded as a sacral garment, but without much reason. In Greece proper the addition was made (due perhaps to a colder climate in winter) of a shirt or chiton with short sleeves: this is never seen in Crete. On the feet either sandals were worn, often with bands round the calf of the leg exactly resembling puttees, or high boots like those still universally worn in thorny and stony Crete, of soft white leather. The arms and neck were decorated with bracelets and necklaces of gold or silver, or stone and kyanos (glass heads). Then, next to the narrow waist, the most characteristic note of Minoan male costume. the hair, was evidently worn at its full natural length. Occasionally it is seen cut short, but this would seem to be so only in the case of mourning men and priests; the latter seem to have worn long robes, confined at the waist, like those worn by the priestesses, and usually white. Normally the men wore the hair unshorn, and falling loose to the waist or below it: on the top of the head it was done up into fantastic knots or curls (horns) which were carefully represented by the Egyptian artists as characteristic. Fashion evidently dictated various modifications of this hair-dressing, more or less elaborate. Sometimes part of the hair was piled up in coils on the top of the head, while the rest hung loose about the body (Tylissos figure: Knossos frescoes, etc). Sometimes, in the case of warriors, it was all knotted up in a "bun" or chignon at the top or back of the head like that of a Sikh. At other times it was twisted (plaited?) in a pigtail (Knossos relief vase) or simply tied behind at the neck in 18th century fashion (Vaphio cup) or confined by bands or slides at the top or sides or back (Chieftain vase).

FIG. 1.—PRINCE AND THE WARRIOR; TRIADA WARRIOR VASE, HAGIA

FROM SCHUCHHARDT "SCHLIEMANN'S EXCAVATIONS" (MACMILLAN)

FIG. 2.—DRESS OF A GREEK WARRIOR IN PROCESSION ON WARRIOR VASE. MYCENAE

A fresco (unpublished) in the Ashmolean Museum shows it tied up in three separate bunches, one at the back of the neck, one at the top of the head, and the third over the forehead. Headgear was not common; but we have representations of a broad-brimmed hat, the later Greek *petasos* (Leiden Museum; fig. 4), and of small round caps evidently concealing a topknot. A god (?) can wear a tiara, or is shown wearing a high headdress of peacock (?) feathers (Knossos fresco). Metal helmets of Roman rather than of Greek form, with a domed crown, ear-pieces and with a knob at the top were worn, sometimes with the addition of nodding crests, the forerunners of the λόφοι of later days The hair is sometimes invisible, being evidently knotted beneath the helmet, or is shown falling down the back, when it is worn (gladiators vase). We have representations of cuirasses on the clay tablets, but usually armour does not appear, or was perhaps of a laminated type like that worn by the Philistines, Shardana and other "Peoples of the Sea" in the Mediterranean area at the end of the Bronze age. The shield was of a peculiar double shape like the figure 8, and reached from ankle to neck, replaced by a smaller round shield at the end of the period, which was of non-Minoan (probably central-European—Hellenic) origin. The usual weapons were a rapier-like sword with decorated hilt; though rarely (Mallia) a great broadsword appears (typical of the Philistines and Shardana later, like the round shield and laminated body-armour); daggers; and spear-heads of a peculiar rounded form somewhat resembling the mediaeval Japanese; bows and arrows with barbed metal heads, and slings were also used. The Cretan slingers were always renowned. The "Peoples of the Sea" who overran the Minoan lands at the end of the Bronze age, coming perhaps from Europe, perhaps (or partly) from the Caucasus by sea, wore characteristic headgear of their own, the Philistines a high feathered cap, the Shardana a round helmet with crescent and ball as insignia. They may have shaved their heads or worn short hair, as it is never shown long in the Minoan and the (shorter) early classical Greek (Iron age) fashion. The kilt was common to them as also to the Hittites of Anatolia.

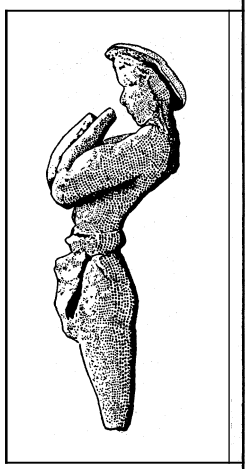
FROM DAVIES, IN "BULLETIN" MET MUS. ART, N Y.

FIG. 3 — MINOANSIN THE TOMB OF USER-AMON, WITH MINOAN BULL-RHYTON AND STANDING BULL

During the early classical period, Greek men wore their hair long, but not so long as the Minoans. Generally reaching the small of the back, it was worn either hanging in loose ringlets (sometimes with a band at the neck), or else braided in two plaits that were wound round the head (we have no instance of this fashion in Minoan times), rolled round a headband, or knotted in a *κρωβύλος* at the back of the head. Short hair did not come into fashion until the second quarter of the fifth century, after the

Persian wars, and then was retained (except, as now, in the case of priests) for 1,000 years, throughout the classical Greek and Roman periods until the fall of the Roman Empire, when the "barbarian" fashion of long hair came in again. A difference between Minoan and classical Greek costume is seen in the fact that the early Greek men often went more or less naked; they habitually exposed their persons in a way that the Minoans never did. We have only one certain representation of a naked Minoan, and he is swimming, arid one doubtful, the "Blue Boy" or saffron-gatherer on a fresco from Knossos. There is none of women (see below). Women's hair in the early Iron age was always worn hanging, in tresses, over the shoulders, sometimes confined at the neck by a band. (For classical Greek dress see section "Greek and Roman.")

Minoan women wore a heavy petticoat-like skirted and flounced garment reaching the ankles and a sort of short-sleeved "zouave" jacket, sometimes with a tight belt like the men. This dress was gaily ornamented with patterned designs. The flounces of the skirt make it resemble curiously the fashionable European skirts of the '70s and '80s.



BY COURTESY OF THE LEIDEN MUSEUM

FIG. 4.—BRONZE FIGURE OF A YOUTH WEARING A PETASOS (HAT)

Breasts were exposed or protected by sheaths. But no representation of a nude woman exists. A cloak with a high "Medici" collar behind is represented. On the head are various forms of headgear, sometimes a horned headdress (Petsofà), sometimes a high blunted conical *polos* (Knossos), sometimes a sort of flat turban. Generally the hair flowed loose, but is always represented as clipped considerably shorter than that of the men, which must have been unshorn from childhood, judging by its length; the hair of the women rarely reaches the waist. It is not often knotted up or entirely concealed beneath the headdress. Bare heads were perhaps rare in the case of the women until the Late Minoan period (c. 1500 B.C.) when we see a court fashion of bare heads with the hair partly knotted behind, partly falling at the sides in comparatively short curls, the fashion much resembling that of the ladies of the courts of Louis XIV. and Charles II., with perhaps a touch of the French Second Empire coiffure associated with the Empress Eugénie (Knossos frescoes). With this golden diadems were often worn, of a type resembling those of classical times (*ibid.*, Mycenae; Tiryns frescoes). Necklaces of gold, lapis and glass of the peculiar Minoan blue (kyanos), were of course worn, and possibly ear-rings by the women. We have only one representation of a man wearing ear-rings, and that is doubtful (cupbearer fresco, Knossos). Egyptian and Asiatic men and women both wore ear-rings and ear-studs, the Egyptians from about 1500 B.C., and not before. Elaborate gold hairpins were used by the Minoan women; golden hairpins of simpler form also by the men, as we see from their discovery with weapons in tombs of men at Mycenae. They would of course be as necessary for the heavy male coiffure as for the women's hair. The women's shoes are rather a doubtful point; probably their feet were usually unshod. Priestesses wore long waisted robes which were also worn by priests, apparently, or temple-musicians of the male sex, as in Lydia. When they participated in the games, as in the religious sport of the bull-leaping (ταυρο-καθάψια) the girls wore the young men's dress of tight belt and waistclout (Knossos fresco, etc.).

Generally we know more of the male costume than the female, owing to the greater number of representations of men, and the fact of their double costume, for war as well as peace. At present it is difficult, except in the case of the women, to confine certain costumes to certain periods; as our knowledge increases it will be possible to do this as accurately as we now can do it in the case of the Egyptians, with our much greater Egyptian material.

The female costume is even more unlike that of classical times than the male, though in the Enrly Iron Greek age women still wore a full skirt tightly confined at the waist, just as the men often wore a tight belt round the waist in the Minoan fashion, but without any clout or sheath.

We have practically no representations of children, so cannot say whether their costume differed in any notable way from that of their elders. An ivory figure of a boy-god is shown with hair long, flowing from beneath his tiara, but much shorter than that of the men. He wears the tight waist-belt. A head of a boy on a sealing has short hair.

EGYPTIAN COSTUME

Until the 18th Dynasty men in the way of costume wore a simple white kilt, which under the 12th Dynasty was often made very high, so that it began almost immediately under the armpits. It was often starched and stiff in the case of persons of some rank. Kings wore more particoioured garments, of the same general type; in archaic days unconventional clothes were apparently worn by them, which later fell out of use. In early days the natural hair was worn long, and the kings kept it in a linen bag of characteristic shape, to exclude the dust, with a pigtail behind, which in later times was retained as a specifically royal headdress, pigtail and all, although the head was really shaved and a short wig worn. Wigs were probably introduced very early, and it may well be imagined that the discomfort of thick and long hair in the Egyptian climate conduced to their invention. We certainly find them in use as early as the Old Kingdom, and a fringe of false hair was found in a 1st Dynasty tomb at Abydos. Under the 4th and 5th Dynasties a short wig of curls cut step-wise was popular; wigless heads are rare. Under the 11th, we have at the British museum two companion figures of a noble wearing each a different type of kilt, and one a short wig, the other a skullcap. Under the 12th Dynasty the hair was kept shorn close to the skull rather than shaved, and the wig was of a longer and very conventional type; men are often represented without it. Under the 13th Dynasty the wig grows longer still, and either it (or possibly the natural hair?) is dressed in three masses, one over each shoulder, the third down the back, something like contemporary female fashion (see below), but not plaited.

Under the 18th Dynasty the long natural hair was commonly worn again, sometimes simply parted in the middle and combed down over the shoulders, but far more usually surmounted by a short wig, so that we see the natural hair falling in front of the ears to the level of the chin or shoulder, while the short artificial wig above it is cut off diagonally across the ears, and forms a square fringe of curls in front. Many men however undoubtedly shaved the head, as of old, and wore nothing but a wig, usually imitating the combed wig and long hair fashion, the shoulder-locks being stiff curls as artificial as the rest. In the Ramesside period all men of position appear to have shaved the head and to have worn wigs of this type; priests now usually wear no wig. This fashion now became universal. Under the Bubastites the "step" form, which had continued sporadically since the time of the Old Kingdom, came in again generally. Under the Saites at first a modification of the Ramesside wig, later a full rounded form was usual besides the archaistic "step" form. Under the Ptolemies and Romans Egyptian men seem to have generally dispensed with wigs, appearing always with carefully shaven crowns. Boys at all times preserved the ancient juvenile fashion of shaving only part of the head, generally the left side, and wearing a single thick plait of their own hair over the right ear, hanging below the shoulder; wigs were an attribute of manhood. Royal princes of mature age wore an imitation of this lock to indicate their filial relationship to the king; and a particular rank of priest wore it combined with a short wig over the rest of the scalp,

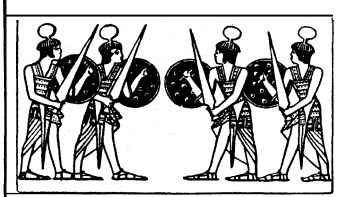

FIG. 5.—SHARDANA GUARDS WITH BROADSWORDS

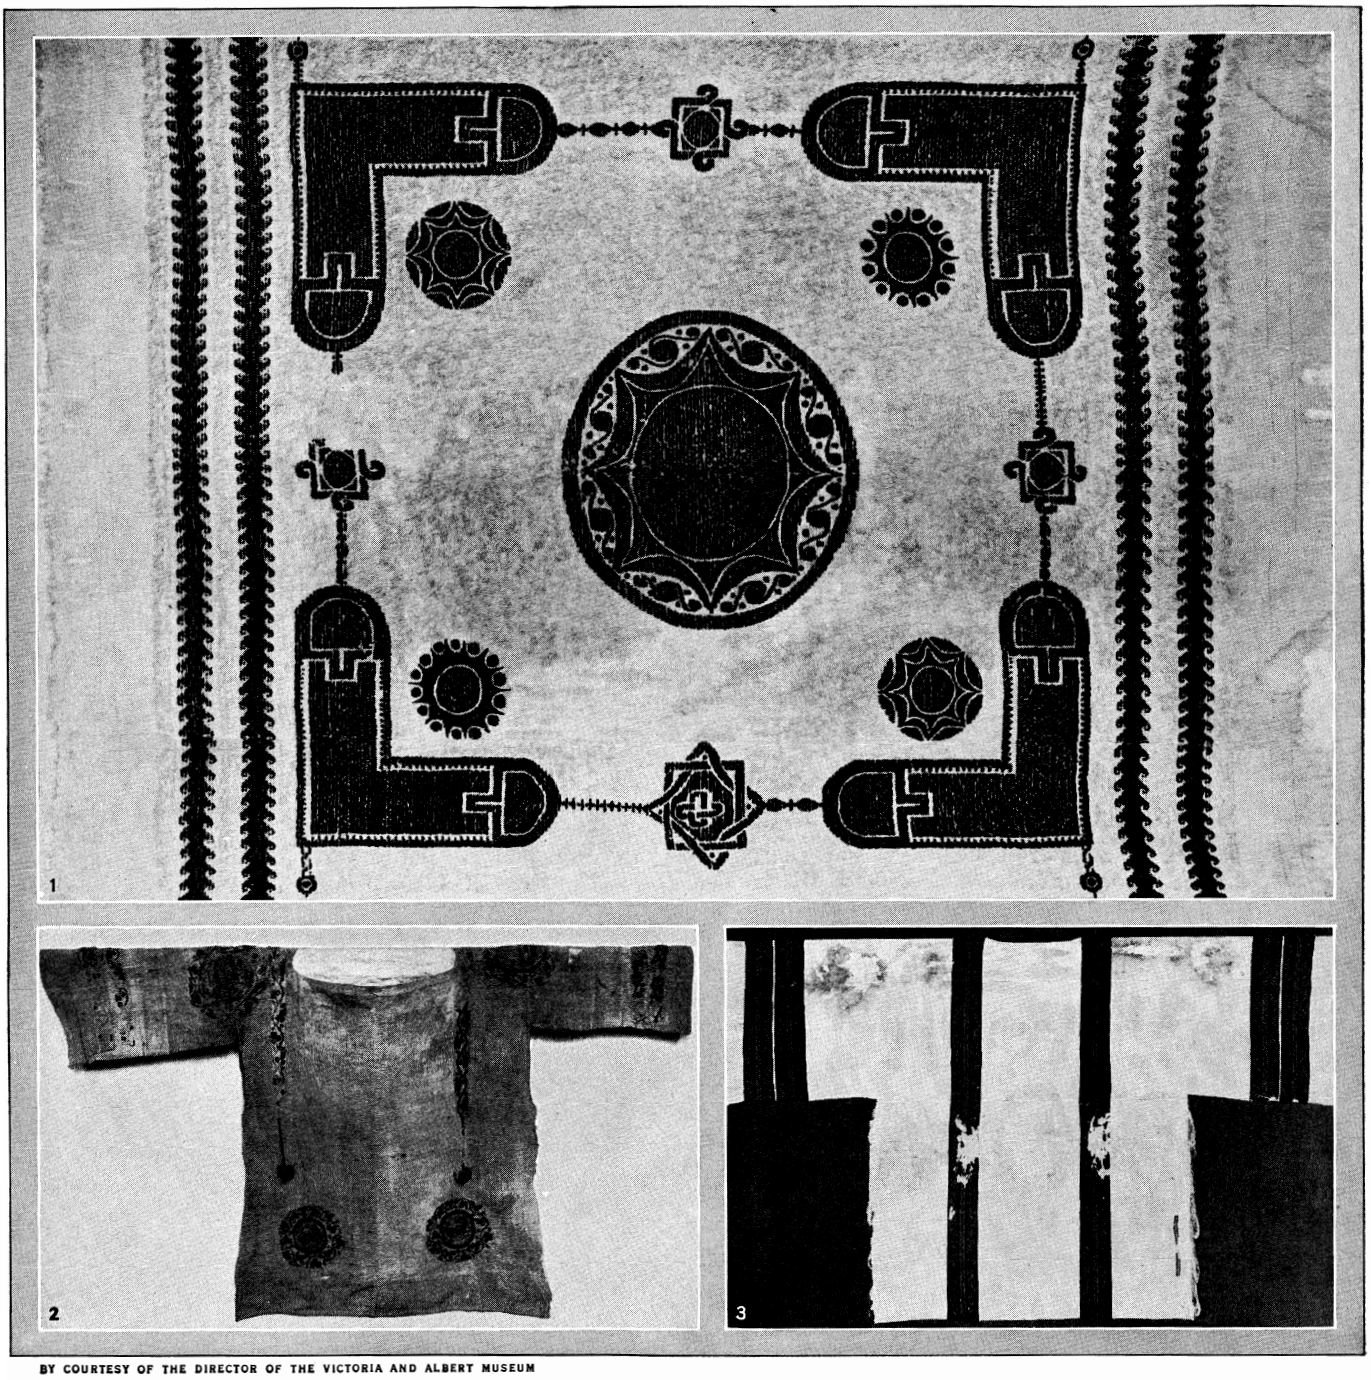
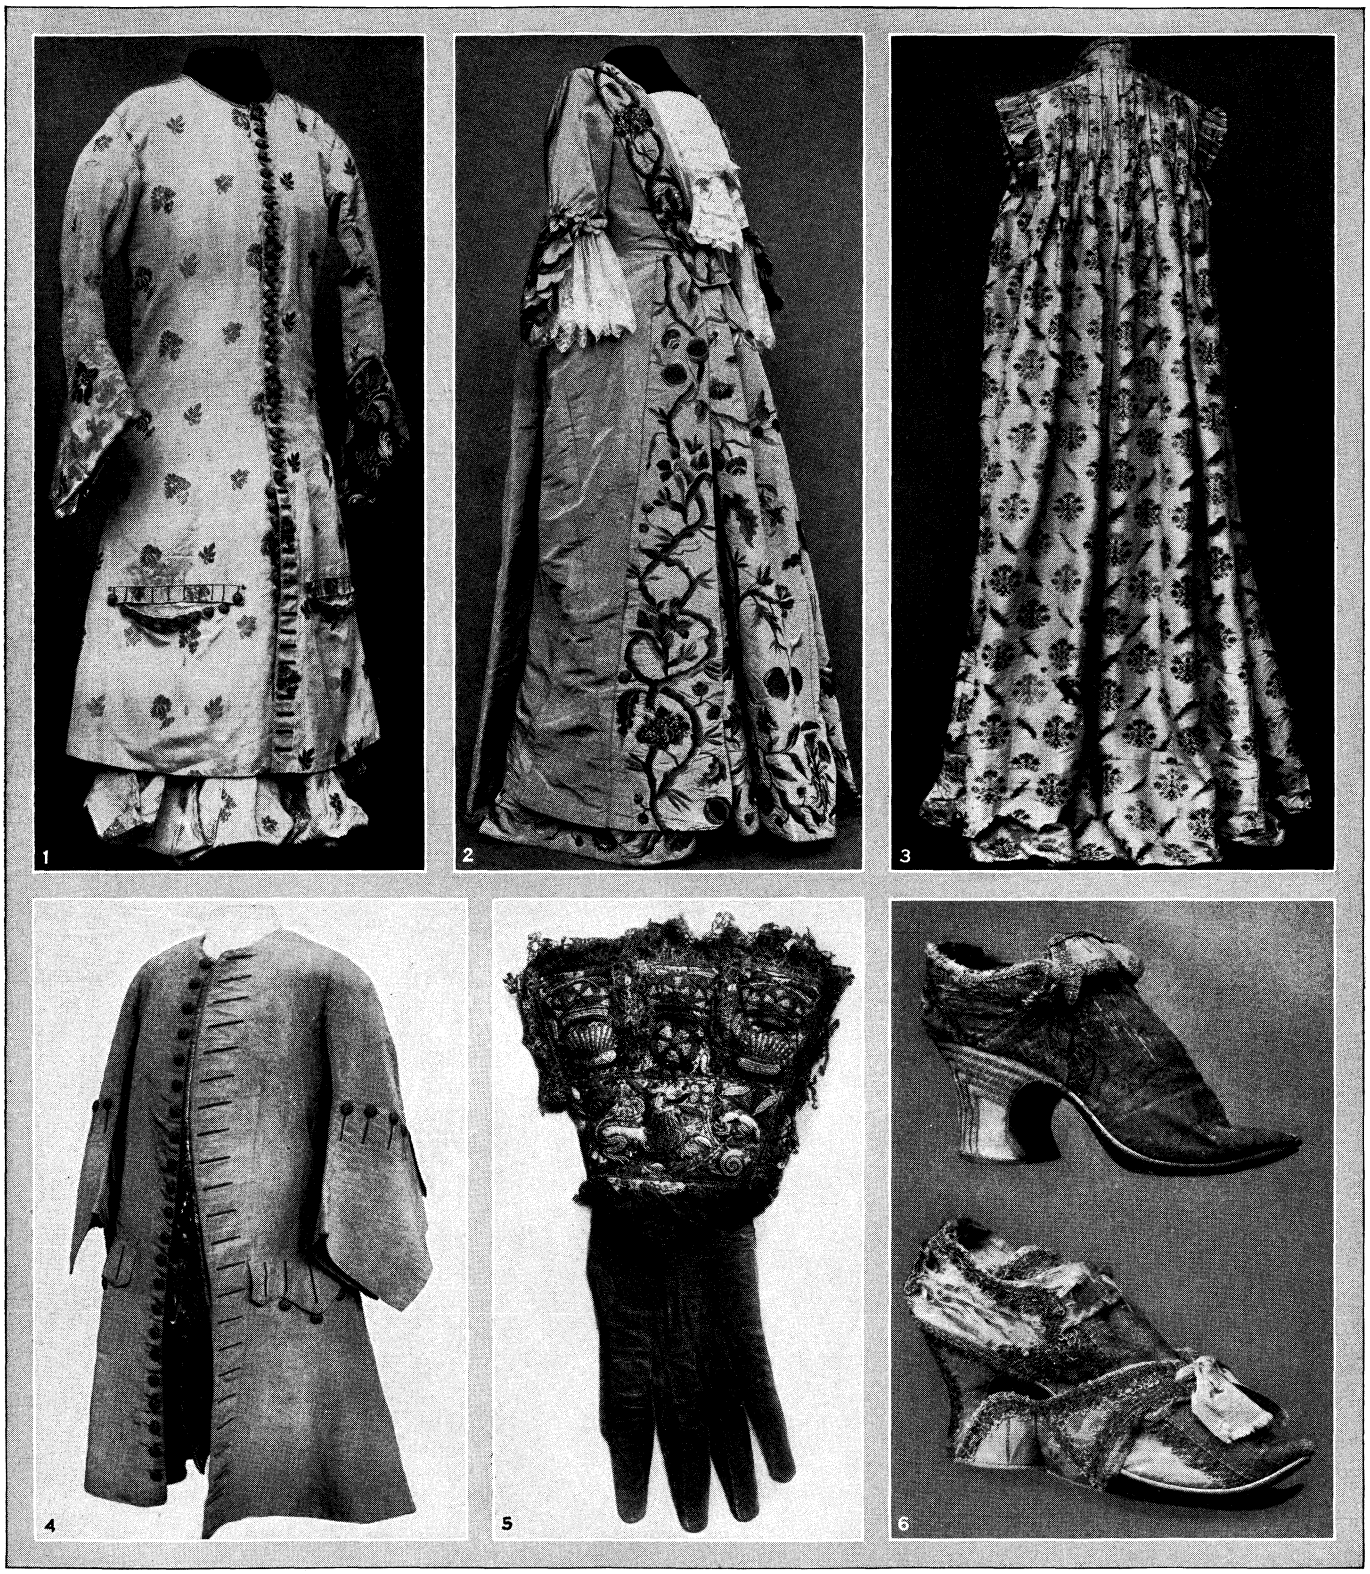


BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM

TUNICS AND CLOAK, LATE EGYPTIAN

1. Cloak from Egypt, Graeco-Roman period, 3rd or 4th century B.C. It is of linen cloth, faced with inter. woven loops in linen and purple wool, and oblong in shape. It served also as a shroud for the dead
2. Child's linen tunic from Akhmim, Egypt, 4th or 5th century B.C. The tapestry-woven ornaments are in purple wool and linen thread
3. Man's linen tunic from Akhmim, Egypt, 3rd or 4th century B.C. The two purple stripes, indicating the rank of Roman senator, and the double sleeve-bands are tapestry woven in purple wool and undyed linen

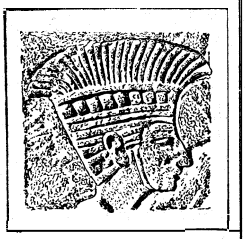
DRESS



ENGLISH DRESS, 16TH TO 18TH CENTURY

1. Coat and trunks (1681) made for Sir Thomas Isham's wedding, but never worn. The drab-coloured silk brocade is woven in silver-gilt thread and cream-coloured silk
2. Lady's dress and petticoat (early 18th century), of coffee-coloured silk, embroidered with coloured silks
3. Back of lady's dress, Elizabethan (1558–1603). The silk brocade is woven in colours on a cream-coloured ground and slashed
4. Man's coat, early 18th century
5. Glove, said to be of Henry VIII.'s era, but possibly of James I.'s, as suggested by the style of decoration and the alternating thistle of Scotland and rose of England. The satin cuff, embroidered with coloured silks, silver-gilt thread and seed pearls, is fringed with gold and silver lace
6. Shoe and clog (early 18th century), silk damask and brocaded front

through a hole in which the plait emerged, as a religious vestment. Caps, or hats, except occasionally a light skull-cap, were not worn till Roman days. Peasants habitually wore their natural hair more or less long, and usually worked naked or with but a close-fitting waist clout, as they do to-day. Under the 18th Dynasty men's dress became more elaborate *(see* ART); over the waist clout or kilt a long linen robe was worn, carefully fluted or gauffred, depending from iust below the navel, while-a cape-or semi-sleeved jacket of similar material covered the shoulders. Necklaces were worn more commonly than before, and such things as bangles, while ear-rings or ear-studs were now introduced from Asia and were worn after the middle of the dynasty as ordinarily by men as by women. The studs (of rosette shape) were large and made a great hole in the lobe, which is always indicated in the statuary of this time, and found on the mummies. Later on, after the 20th Dynasty, these great ear-studs were no longer worn by men, and after the 22nd women also seem to have given them up. But small ear-rings were certainly worn by men as well as by women under the Saites, though the piercing of the lobe necessary ior them was not noticeable enough to be represented in the statues. Shoes, or sandals of reed or palm-fibre were now usual for the better classes; earlier the feet had always been bare.



BY COURTESY OF SIR F. PETRIE AND OF THE TRUSTEES OF THE BRITISH MUSEUM

FIG. 6.— THEHEADDRESS OF A PHILISTINE

The elaborate dress of the 18th Dynasty persisted with little alteration till Ptolemaic times, although under the Saites men are often represented archaistically as wearing only the kilt, as under the Old Kingdom. In Roman times a new fashioned garment with *dagged* borders leaving one shoulder bare, was introduced. The royal crown proper , which remained the same from the 1st Dynasty till Roman times, was composed of two parts, the upper, white, for Upper Egypt, and , red, for Lower Egypt. A peculiar blue royal helm, was introduced under the 18th Dynasty.

Women.—The early dress of women was a close-fitting garment, often blue, with a yoke over the shoulders and a "hobble" skirt. Wigs were early worn over the natural hair which is shown parted in the middle beneath it in a 4th Dynasty statue in the British Museum. Except under the 13th Dynasty, when the men's coiffure was as long as that of the women, the women's wigs were always longer than the men's. Under the 12th the hair, real or false, was worn in a peculiar style, in two masses, bound with gold. and turned up and outwards at the ends on-the breasts. These masses were mostly of small plaits. This coiffure continued till the 18th Dynasty, when it was succeeded by a more flowing coiffure of plaits and curls. Certainly women sometimes had shaven heads beneath their wigs like the men, but the natural hair was no doubt commonly worn long by them, whereas it never was by the men after the pre-dynastic period except possibly under the 13th and certainly under the 18th Dynasty. Towards the end of the 18th Dynasty fashionable women took to exposing their shaven polls, which they never had done before, dropping the use of the wig altogether. Queen Nefertiti wore a high cap or *polos* on her shaven crown, with *infulae* or ribbons hanging from it behind, but her daughters are represented with shaven, and what is more, deformed skulls; it is evident that the practice of rlongating the female skull in childhood rather on the style of the Botocudos Indian of Brazil, the Incas or the Solomon Islanders, was fashionable at the 'Amarna period. This fashion seems not to have persisted for any length of time, but the royal women certainly continued to shave their heads, and go without wigs, in order to wear certain headdresses with convenience, for a long time afterwards. The female mummies of this and later time usually exhibit a mixture of real and false hair when the "hair" is not wholly a wig. But one woman, an unknown person buried in the tomb of Amenhotep II., has very long natural hair. Small girls often wore part of their natural hair plaited at the side to signify youth like the boy's sidelock, or even often had their heads partially shaved in complete imitation of the boys. The older tight dress which we see represented till the end in the case of goddesses, gave way under the 18th Dynasty to a more gracious costume of gauffred linen, on much the same lines as that of the men, but of a more flowing and robe-like character. Particoloured robes are worn by queens. Necklaces, ear-studs, sandals, etc., are the same as the men's, though the women do not wear sandals so often as the men. This general costume continued till the end, when colours came in; in the late Roman period elaborately-patterned caped or shawled garments were worn. Women often seem to have worn a lily on their heads, and both sexes at festivals were fond of placing a lump of highly scented unguent on the head, which is carefully represented in the tomb-paintings and stelae. In Roman times women (and men at feasts) wore large wreaths; Greek costume was then no doubt largely worn by both sexes. Otherwise only the queens wore anything in the way of a headdress *(see* above). (H. R. H.)

FROM "MONUMENTI ANTICHI" BY PERMISSION OF THE DIRECTOR OF THE REAL' ACCADEMIA DEI LINCEI

FIG. 7.— SIDE OF THE PAINTED POTTERY LARNAX FROM CRETE

GREEK AND ROMAN

Sources of information about the dress of the ancient Greeks and Romans are to be found in their literature, their sculpture and their painted vases. Existing examples, though mostly provincial and late in origin, are also of some historical interest. In primitive times, among both the Greeks and Romans one voluminous cloak was thought sufficient dress for a man, and even in later times it was the only garment regarded as indispensable. A tunic or shift was nevertheless worn by men, women and children. At first it appears to have been sleeveless, but individual fancy and variations due to colonization or conquest caused much diversity in apparel. Among the Romans the tunic was often ornamented. The *tunica palmata* was worn at triumphs. Men of senatorial rank wore a tunic with a double stripe in purple down the front (*tunica laticlavia*). Knights had a narrow stripe from each shoulder downwards (*tunica angusticlavin).* In this latter form the tunic went into common use. A man's linen tunic of Graeco-Roman times from Egypt has the two purple stripes as well as double sleeve-bands. Other tunics found in Egypt were more richly adorned. One for a child has in addition a roundel on each shoulder, and two others both on front and back. In course of time the simple slit for thrusting the head through was shaped or cut away in front. Two tunics were sometimes worn; as time passed (and probably always among the peasantry) no other garment was considered necessary.

The cloak, worn over the tunic, varied much at different times and places. Among the Greeks it usually took the form of a large oblong cloth wrapped about the body so as to envelop it from the neck to the ankles. The Romans used a similar garment, known as the *pallium.* But the distinctive Roman cloak was the toga, a large cloth in the form of the segment of a circle (rather less than a semi-circle) worn with the straight side uppermost. One end came forward over the left shoulder reaching nearly to the ground. The garment was then passed round the back, over (or under) the right arm, and across the front, the other end being thrown over the left shoulder to fall behind. There were variations in manner of wearing and in shape according to time and place. The toga was laid aside when there was work to be done. In later times it became a ceremonial garment, gradually losing its amplitude until it was no more than an ornamental band worn over the shoulder by certain officials. A few shreds of men's and women's garments, too incomplete to betray their form, have been excavated at various times from Greek graves of the 3rd to the 5th century B C. in the Crimea. They are chiefly of wool, though linen has been found *(see* TEXTILES AND EMBROIDERIES). Though apparently Greeks and Romans both favoured undyed wool for garments, these specimens from the Crimea

are mostly coloured (generally purple or green). Some are plain or striped; others have woven, embroidered or painted designs. The ornamentation includes deities, figures on horseback, chariots, birds, vines, honeysuckle and scrolls.

In Graeco-Roman Egypt the cloak is oblong, and often of ample dimensions. It is variously ornamented, with figures, animals, birds, fishes, trees, plants, foliage and conventional patterns. The Roman cloak was put to a variety of uses. It might be spread over a bed or couch or laid on the floor. It served also as a shroud for burial.

Those found in Egypt have all been used at last for enveloping the dead. The tunic and the cloak were the chief garments of Greek and Roman times, but various others were also worn in different places and on particular occasions. One among them, the chlamys, may be mentioned. It was a kind of short mantle or scarf, apparently more ornamented (as a rule) than the large cloak.

In shape it seems to have been either a narrow oblong or the segment of a circle. The garments of the Greek and Roman women were more voluminous than the men's, but otherwise they did not differ greatly in classical times. Instead of the toga, women wore the stola, with the *pallium* over it. Men often went barefooted, but leather or wood sandals and buskins were worn. Women wore shoes, and carried fans and parasols. Knitted socks, and knitted or netted caps, hair-nets and bags have been found in abundance in Egypt. Caps of fur and leather, and broad-brimmed hats, were worn on occasion. Brooches, clasps and girdles were used, especially by the women, but the skill of the wearer in adjusting the cloak seems to have been chiefly relied on for keeping it in position.

MEDIAEVAL AND MODERN

The tunic and cloak, which were the principal garments worn in Greek and Roman times, continued to hold their place, with modifications, for many centuries. As the tunic became the chief garment, it was sometimes elaborately decorated. One early Christian writer speaks of people wearing garments on which animals, forests, mountains or huntsmen were figured, while on others were biblical scenes. Late pagan and early Christian garments, found in Egypt, have ornamentation of this nature.

Mediaeval. — At the time of the Norman conquest of England the dress of men and women consisted of a couple of tunics and a loose cloak. The chief innovation was the tight "chausses" or hose enveloping the legs; in classical antiquity trousers were a barbarian garb. From the two tunics were evolved the jackets, pourpoints, jupons, jerkins and doublets of later times, and from the short cloaks the various over-garments, often taking fanciful shapes in the middle ages. Patterned materials were often used, though apparently not quite so much as they were afterwards. It is probable that the initials and devices personal to the wearer, seen in the 14th and 15th centuries, were for the most part of embroidery. They might occur once on the sleeve or shoulder, or they would be powdered over the whole garment. The large painted portrait of Richard II. of England in the sanctuary at Westminster Abbey shows his robe powdered with crowned R's, and presumably the letters sometimes to be seen on the dresses of unidentified individuals in paintings and tapestries had a personal significance. Another portrait of this king, on the celebrated diptych in the possession of the earls of Pembroke at Wilton, shows his mantle covered with crouching harts. The white hart was his personal badge. and again it explains other instances of such devices, though it should be remembered that fanciful representations of this kind formed part of the general repertory of the pattern-designer in mediaeval times. By the middle of the 15th century, rich velvets, with variations of the lobed "Gothic" pattern, often inwrought with gold thread, were much used for costume among the well-to-do.

Only a summary statement of the changes which dress went through during the middle ages and later times can be given here. The following outline has more particular reference to England, but generally speaking it holds good for western Europe, and (where applicable) to America. Some developments might occur earlier in France or Italy, where many fashions originated, and they would tend to survive later in the north.

What may be described as "tailoring," as distinct from draping, comes into notice about the end of the 13th century. Garments then begin to be shaped more to the body, leaving less liberty of adjustment to the wearer. In the latter part of the 14th century "dagging" (the cutting of the edges of the garments into fanciful shapes) takes an exaggerated form, which it keeps for half a century or more.

For head-coverings the plain white wimple began to give way, towards the end of the 14th century, to elaborate head-dresses — the horned, the mitre, the turban — culminating in the fantastic steeple head-dress or "hennin" of the later 15th century, from France. In the 14th century men wore a kind of hood turned sideways on the head. This was followed by a closefitting cap which, towards the third quarter of the 1 jth century, was heightened so as to resemble the Turkish "fez" after which it became lower and flatter.

Shoes, which in early times were for the most part of fur or leather, tied by thongs round the instep or ankles, gradually took form with sole and uppers approximately more or less to the shape of the foot, until in the 14th century a tendency to bring the toes to a sharp point is noticeable. In the later years of this century the uppers were sometimes pierced in fanciful shapes Chaucer refers to this practice when he speaks of the priest Absalon having "Paul's windows carven on the shoes." Shoes with Gothic tracery over the instep were shown in the wall paintings representing King Edward III. and members of his family, formerly in St. Stephen's chapel at Westminster. At the end of the century the shoes of Richard II. are covered with quatrefoils and discs. The "Cracowe" or "poulaine," from Poland, with pointed toes of greatly exaggerated length, then followed, until at the end of the 15th century the fashion ran to the opposite extreme.

16th and 17th Centuries. — In the first half of the 16th century took place the meeting of the French and English kings at the "Field of the Cloth of Gold." This phrase only reflects general tendencies of the time, when fashionable men's clothes were loaded with jewels, and they are said to have spent their fortunes upon their clothes. Early in the 16th century the hose were divided into stockings (bas-de-chausses) and trunk-hose (*haut*-de-chausses). The trunk-hose went through various phases, looser or tighter, shorter or longer, following caprice rather than any progressive evolution.

The slitting of men's sleeves at the elbow or shoulder, to display the garment underneath, was not unusual in the 15th century, but "slashing" in small parallel cuts is a feature of the next century. By the time of Charles I. the slashes became long slits, sometimes extending for practically the whole length of the sleeves, before disappearing altogether. In the latter half of the 16th century men's garments began to be "bombasted" with cotton-wool, hair or sawdust. They form a contrast to the dress of Van Dyck's sitters a few years later. The air of elegant refinement, which must have been due in some degree to the dress itself, is so noticeable in this artist's portraits, that far on in the following century painters would endeavour to recapture some of this glamour by representing their sitters in similar garb. Women's farthingales, in the latter half of the 16th century, extended their skirts to very ample size. The euphuism of the time is reflected in dress, and exaggerated conceits form the subject of embroidery. In a portrait of Queen Elizabeth in the possession of the marquis of Salisbury at Hatfield house, her cloak is embroidered all over with human eyes and ears which, with a serpent on the sleeve, betokened the vigilance and wisdom of the wearer. A more restrained type of ornamentation, chiefly used for linen garments, such as tunics and men's and women's caps, was done entirely in black silk thread. Hence it gained the name of blackwork. It is said to have been brought to England by Catherine of Aragon. Naturalistic flowers were a favourite motive, but badges, rebuses, book-illustrations of enigmatic import, and all kinds of fanciful conceits were also included. As time went on, richness was added by the use of heavy gold thread for stems and other details, and later in the century bright colours replaced the black.

WOMEN'S DRESS, 18TH AND 19TH CENTURIES

1. Lady's dress of Chinese painted silk, England. The period is the second half of the 18th century
2. An American 19th century dress (1810), of checked blue silk
3. An American 18th century dress, "Robe a la Française," of flowered yellow silk
4. Late Victorian dress, England (1880), made of silk with flounces of tassel trimming
5. Gold gauze dress of the era of George IV. (1820–30)
6. Victorian dress, England (*c.* 1865–70). This evening gown of silk gauze shows the polonaise and the fringe trimming of the period

In this form, chiefly for floral patterns, it survived well into the 17th century.

The development of the frill at the neck into the great starched and pleated ruff, with its supporting standard, is a noticeable feature of the time. Completely encircling the neck at first, towards the end of the 16th century it was sometimes worn open in front. Soon afterwards it was replaced by the falling collar, but the encircling ruff and the open ruff were still worn well into the 17th century, as so many Dutch portraits bear witness.

Brims are added to men's caps early in the 16th century, and modifications rapidly succeed one another. In the second half of the century men and women wore higher and stiffer head-dresses. The 17th century brings in the "steeple" hat, and then the leather hat with broad brim and feathers. The broad-toed shoe with parallel slits or slashes is followed by a shoe in which the tilting at the heel begins. A solid corked sole comes first, then a space is cut through under the instep, to be followed by a separate heel-piece.

Children's portraits show that it was customary to dress boys and girls, even those of a tender age, very much in imitation of their elders.

About 1660 an important change took place in men's garments, when coat and vest were first evolved as distinct garments in France. This fashion was carried to England by Charles II. At first the vest was long, reaching to the knees and sleeved. The coat was slightly longer.

The coat and waistcoat of the present day are directly descended from these garments.

The trunk-hose are full, though very soon after they might have been worn narrower, anticipating the buckled knee-breeches of the 18th century. About this time, instead of the natural hair falling to the shoulders, men took to wearing the large periwigs so characteristic of the portraits of Louis XIQ. and his contemporaries; at the end of the century they tower over the brow, giving added height to the wearer. Cravats, often of rich lace, now replace the falling collar. A notable fashion originating in France took its name from the battle of Steinkerque, fought in 1692. The French officers dressing in haste, it is said, tied their fine lace cravats loosely about their necks. This fashion spread to other countries, both for men and women, and lasted some years.

Women's skirts were full at this time, and bodices were laced in front, sometimes with an embroidered stomacher. Hat-brims were now cocked, developing at the end of the century into the three-cornered hat.

Muffs were carried both by men and women in the 17th century, and in various forms they continued in use by women well into the present century. Gloves first became conspicuous in the 16th century, when they were often elaborately embroidered and sometimes embellished with pearls and jewels as well. In the 17th century, when the frill at the wrist gave place to the turned-back linen cuff, large gauntlets were added to the gloves, giving scope for embroidery in the style of the time. A pair of gloves was a customary gift at the New Year, and pains were taken to render them worthy of acceptance. Such gloves were usually of leather, but subsequently various lighter materials were used, and gloves might reach beyond the elbow when sleeves were short.

18th Century.— At the beginning of the 18th century the skirts of men's coats had become fuller and the sleeves had wide cuffs. The sleeved waistcoat was shortened, and at times it was richly embroidered. In course of time the sleeves disappear. As the century advances a distant approximation to the frock-coat of later times is discernible, but the materials continue to be rich. Velvet, often woven in tiny diaper patterns, was much used. When the material was plainer, elaborate embroidery in silk, often embellished with glass pastes and spangles, was usual for fashionable dress. During the course of the century, the skirts of the coat and the corners of the waistcoat were cut away in front, reducing the form more nearly to that of morning-dress of the present day.

Embroidery was used for ladies' dresses, especially for the underskirts rendered visible by the open front of the dress. The silk brocades of Lyons or Spitalfields, with floral patterns in bright colours, came into use. Indian dyed or embroidered cottons, and Chinese painted silks, witnesses to the growing commerce between the maritime nations of Europe and the far east, were made into dresses, causing much searching of heart among weavers at home, who succeeded in getting restrictive enactments put into force. Towards the middle of the century skirts became very ample, being supported by very wide hoops.

The sack or sacque, a loose dress falling straight from the shoulders, continued in use during the greater part of the century. It had originated about 30 years earlier, when Pepys's wife "first put on her French gown called a sac." Later dresses, too, came from France. A letter of the year 1715 from Sarah, duchess of Marlborough to Lord Stair, ambassador at Paris, is still extant—asking him to obtain "two pair more of bodys and a night-gown" for her, and a manteau and petticoat for her grandchild. In the latter half of the 18th century women wore their hair, or wigs, dressed high above the head and powdered, and again men's wigs became larger, but they were already doomed, and Pitt's powder tax of 1795 practically put an end to them.

19th Century.— By the opening of the 19th century, the change in men's outlook had swept away much of the overloaded finery of the past and garments more supple and better suited for active life came into use. Men's coats are cut away in front in a manner resembling the modern dress-coat, the lapels are large and the collar is high and deep. Waistcoats are short and cut square. Knee-breeches are lengthened into the modern trousers. The cocked hat of the 18th century is replaced by the top-hat. The old full dress, moreover, gradually gives way to what we now call the lounge suit, used more and more for all occasions.

Women's dress at the opening of the century is marked by a graceful simplicity, with high waist and low neck. A lower waist and puffed sleeves follow. Meanwhile skirts were widening, until the "crinolines" took their most exaggerated form shortly after the middle of the century. Then followed various adaptations of 18th century styles. About 1880 the projecting "bustle" at the back was in full popularity. Fringes, trimmings, flounces and long trains were in use during the latter part of the century.

FAR EASTERN

The appearance, customs and personal characteristics of Chinese, Japanese and Koreans are distinctly different, and this has consequently brought about dissimilarities in the dress. Only within the last few decades when European costumes have to some extent been adopted, has there been any tendency to uniformity in style.

China.—All classes in China wear a *san* (jacket) and *koo* (trousers), the combination being similar to the Western pyjamas. There are three kinds of each—the single, the lined and the wadded with cotton, to suit the season of the year. To the *san* is attached a narrow collar-band. The *ma kua* is the ordinary jacket with loose sleeves for the common people, and the *baishin,* a sort of vest, is worn over it. The *po* is a long gown and the *qua* a larger and longer *ma kua.* The *po kua* is the official full dress of men, while the *lung po,* or dragon gown, was worn by the emperor at State ceremonies. There are several other gowns in use—the *Chang san* in summer, *chiao* in spring and autumn and *taminou* in winter. When it is very cold the *pipao,* or fur coat, takes the place of the *taminou.* The *to pang,* another kind of overcoat of silk or fur, is worn by the wealthy.

There are all kinds of coats embroidered with dragons, moons, stars, hills, mountains, waters and flowers. Each design has its peculiar symbolism; frequently it is a Buddhistic emblem or the representation of some philosophical concept, such as the "waves of eternity." The mandarins were specially privileged to wear

gold-embroidered clothes, and sometimes the emperor granted the nine orders of mandarins the distinction of wearing a peacock feather on the hat.

Red is a symbol for happiness, and thus we find the bride wearing an elaborate gown of red; the tassel on the top of men's hats and the cord on their *queues* are red.

Japan.—In A.D. 283 two women weavers were sent from Korea to Japan to teach the making of figured silks and brocades. The *ho,* or ceremonial garment of the Japanese emperor and nobles, has an ancient origin; the Chinese seamstresses came to Japan, about A.D. 300 and made this with silk imported from China. Emperor Yuryaku (A.D. 457–479) reformed the national dress and, in the reign of Emperor Suiko (A.D. 593), rank was signified by distinctive head-gear, a custom imitated from that of the Chinese Tang dynasty (A.D. 618–906). Costumes were evolved for civilians, ecclesiastics and the militia, differing in colour, patterns, the length of sleeves and the style of hairdressing.

The *kasane,* or loose tunic, was worn with a short lower garment called the *akome.* The *hakama* was a loose skirt reaching only a few inches below the knees over the *shita-gutsu,* or socks. The whole style of head-gear was called *suberakashi. Kammuri,* a ceremonial headdress, was secured by *kanjashi,* or pins and the *yeboshi,* or cap, was worn over it.

The ladies always wear the *kimono,* a loose gown with a neck-piece called an *eri,* and long sleeves, the garment being fastened by a belt. Since the Heian period (794–1159) women have in general dispensed with the *hakama,* and to-day the female dress for social occasions consists of an underskirt, two or three outer garmects and a *haori,* or interlined silk coat, over the upper part. The *obi,* a belt about 3 yd. long and 10 in. wide, winds about the figure.

Men in rural districts are barefooted, seldom wear *zori* or the wooden clogs called *geta,* and in the hot season they wear almost no clothing. The common-jacket and trousers of cotton crêpe, blue or white in colour, a large grass hat called *kaza* and straw *zori* are the ordinary dress.

Korea.—Among the six departments of the Korean Government was the board of rites, whose duty was to regulate, describe and govern the ceremonial code of polite society, including dress. Koreans dressed according to their class, and in each class distinct costumes were used by those of different ages.

A *chugori* (jacket) and *baji* (trousers) are worn by all classes. The *tooroomaki,* a long flowing tunic, goes over these to anywhere between the knees and ankles; the higher the man's position, the more garments he wears. All these are of varying thickness to suit the weather. Women's *chugori* do not descend to the waist, leaving space for a waist-band, or *huridi,* which is embroidered and woven by hand. (Y. K.)

MODERN

The evolution of modern feminine dress, corresponding closely to the emancipation of women at the beginning of the 20th century, provides one of the most captivating pages in the history of modern civilization. One often considers ridiculous the fashions of other days, but one has only to live the past over impartially to understand that all changes in fashion are rungs in a ladder leading to an inconstant ideal.

Fashions of 1900–28.—In 1900 one could not breathe freely for dust raised by skirts. Women wore frilled underclothes unknown to-day. The body was imprisoned in a corset that pushed the bust forward and the lower part of the body out behind. The hair was dressed so as to follow the movement of the body. The neck was stiffened by a collar with whalebone stays. The sleeves. bodice and hat were trimmed with puffs and frills, details that at first view appeared useless but that helped to conceal the twisted line of the body. This silhouette remained without appreciable change up to 1905 when a step back to fin *de siècle* fashions occurred. Sleeves were again puffed at the top, bodices were shaped to a point in front and the complicated dresses were covered with a profusion of puffs and frills. The hat was perched on the side of the head above a display of hair extravagantly curled; it was frequently trimmed with a cluster of feathers, a mode of delicate hat-trimming that, changing place very often, lasted until 1914. In 1907 a slight Greek influence was felt in the soft materials often draped; tunics with points made heavy by tassels. The high collar made almost its last appearance. In 1909 a collar that freed the neck was popular. During the same year the short skirt appeared for the first time in the 20th century; a short skirt, however, that would have seemed very long in 1929. Enormous hats were loaded with huge, falling feathers. Already the silhouette was being slightly straightened; the bust was less bent and the body a little less deformed by the corset.

So far the few progressive changes in costume were the straightening of the silhouette and the freeing of the neck. They prepared the way for the *directoire* fashions which, already having made a few timid appearances, began to reign definitively in 1910. A bloom of delicate and varied colours was obtained during this period by concealing the dress beneath a transparent tunic of a different shade. Two years later, in 1912, under the influence of a few Russian ballets, the *directoire* began to *orientalize* itself. Trouser-skirts appeared, heads were turbaned and dresses of bright colours were trimmed with gold embroidery, pearls and diamonds. This fashion, taken from the theatre, could not last long, but by its boldness it had thoroughly changed taste; there was no more turning back to the past—the development of fashion traced new ways. It is since 1912 that dresses have no longer hidden the elegant woman's feet and that she has matched the colour of her shoes and dress. The oriental influence transmitted by the theatre became, in 1913, dazzling. The trouser-skirt persisted next to the skirt tightly draped round the legs; it was surmounted by a short and puffed tunic which very often took the shape of a small crinoline. One has only to compare the silhouettes of 1913 and 1900 to understand that the development of fashion was at its highest point, that the past had been forgotten. In the history of modern fashion the years 1912–14 are quite characteristic. The enormous influence of the theatre can be noticed. It attained its development about this time.

The period from 1914–20 is the least notable in the history of fashion. In 1914 the tight skirt surmounted by a wide and much longer tunic could still be seen. The following year the narrow skirt was suppressed and the tunic alone remained. From this period there is no general line of fashion; wide crinoline skirts were worn as well as tightly draped dresses with long trains. The year 1917 alone created a specific line in this period of revolution in fashion. It produced the *barrel dress* which was not seen the following year but which, nevertheless, for some time afterwards, left its traces in a draped movement, recalling draperies of the *paniers* of the 18th century. From 1914–20 there was nothing worthy of entry in the history of fashion; the theatres giving no new styles, old styles were recalled.

The New Line.—Still novelty was sought and in 1921 the new line—the low waist was found. At the same time the skirt was lengthened slightly. The hair, drawn away from the forehead, formed a high chignon often held by a Spanish comb. The Spanish influence made itself felt, not only in combs and headdress, and for a time women draped themselves in Spanish shawls, very often using these in place of evening cloaks. In 1923 the low-waist dress was transformed into a straight dress called the *tube dress,* and from this was born the costume—the straight and short dress—which was generally unchanged to 1929.

At its birth in 1924 it was quite simple; so much so, indeed, that it demanded equal simplicity in dressing the hair, which women began to cut like men. Dresses being simple in shape and trimming, the feminine costume tended to fall into a dreadful dullness. Feminine elegance was saved by research in accessories and by the use of new materials. Fashion began to demand matching not only the dress, coat and hat, but scarves, gloves, shoes and handbags also; the large dressmaking firms began to make false jewels to match models, and even to make perfumes to agree with the lines and colours of their models. The seeking of harmony in the smallest details proceeded further, appearing in the make-up which in days gone by was used simply to correct faults of nature.

Many new materials were created in the last few years. Embroideries on plain materials gave way to printed materials ready for the making of the dress. New furs, feathers, kid, lizard and snake skins appeared on dresses. (R. DE T.-E.)

Fashions from 1928 on.—With the arrival of 1928, the sil-

TRENDS IN WOMEN'S DRESS IN 1931

1. Pajamas were becoming increasingly popular for home wear. Some, as in the figure on the left, because of the fullness of the trouser leg, gave the illusion of being a skirt

2. A Chanel velveteen dress with dramatic puff sleeves. An example of the spiral treatment in evening wear in 1931

houette introduced a "flutter" to its hem line. The uniformity which had nearly reached a banal monotony during the preceding years changed during 1928 to a silhouette with a great deal of movement. The hem line began to dip in back until it almost reached the floor—particularly in evening gowns. During the day, the "sports" feeling, which had continually increased during each successive year, became even more marked. Physical exercise and intelligent diet had given the athletic figure of the modern woman a slender, active look; and rhythm had taken the place of heartiness. The hip line remained moulded—with a flat front and back—while the waist line, above, was felt rather than defined. The longer line of the dresses in back succeeded in giving the feeling of grace and slenderness which had been very much lacking during the recent years. Hats which had completely covered the forehead and eyebrows were beginning to show them again. The introduction of what was known as "ensemble" became even more important in 1928 for daytime wear.

By 1929 the hat showing the forehead had arrived. The hemline continued to remain just below the knees in front, and flowing to the floor in back. For evening, peplums over bouffant editions of the silhouettes appeared—made of taffeta and faille. Day clothes remained approximately the same as the preceding year. The hard silhouette of 1925 and 1926 was completely overthrown. The subtle beginning of the higher waist line and longer skirt line was, bit by bit, insinuating itself into being. Sports clothes became longer—four inches below the knee being the popular length. Trains on evening gowns appeared, giving even greater grace to costumes—but the skirt remained short in front. Clothes were again becoming complicated—almost fussy. The uniform sort of costume of 1925 was forgotten.

Confusion began with the introduction of the very first long skirts. Women became bewildered. They trailed these long skirts through the streets in the daytime. However, in the course of time, the novelty of the long skirt—so confusing to them at first—was gradually adjusted, and it assumed its proper place—which was for evening. The daytime skirt was worn seven or eight inches below the knee. Tea gowns and pajamas for entertaining at home were popular. A softer treatment for bobbed hair ruled. By 1930 the long skirt had at last a sure foothold. The young so called "flapper" had become submerged. She had greeted as a new and exciting experience the feel of a long skirt swishing about her ankles—an experience which she had never felt. Her coats were fitted at the waist; her slouch became dignified rhythm; and legs and knees were completely things of a recent past. Actually beauty of line began to appear. A Greek feeling appeared—a flowing from hip to floor for evening. Evening wraps became much longer—many of them reaching to the floor. The classical Greek line became the edict. "Brittle" lines—both for evening and day—assumed a flowing movement. These last ten months were the most confusing for both women and dressmakers in ten years. The complete and revolutionary change of after-war severity had been one of turmoil and re-adjustment.

1931 ushered in a very graceful and flattering era of spiral treatments in evening dresses. These dresses clung to the figure and the women of 1931 suggested the classical figures on a Greek frieze. The pajama had become overpoweringly popular. During the summer at the watering places of the world the pajama was worn almost continuously, both for daytime and evening. Sometimes the evening pajama—because of the fullness of the trouser leg—gave the illusion of being a skirt. The motion picture had begun its powerful influence, and women were dramatizing their clothes far more than they ever had before. Dramatic clothes were no longer seen only on the actress. Ladies in the audience were equally exciting in their dress and frequently more so than their fasourite star. Inhibitions about colour were being abolished. Gaiety, undoubtedly a reaction from the drabness of more recent years, became the exciting gesture of the day. The financial crisis had caused a rather clever pseudo bravado. It was considered chic to be poor. Wealth was changing hands. Many of the smart women of the day were financially curtailed. Fewer clothes were in once overflowing wardrobes. This seemed to give an added impulse to inventive designers, and each month new ideas were offered. Fashion, unlike in its earlier history, changed almost fortnightly. The continual desire for something new, partly because of promotion in the great shops of the world, and because of the variety of ideas in the cinema and dressmaking houses, made a perpetual fireworks of ideas and variety of design during these latter years.

1932 introduced the pill-box hat, the beret, and the sporty felt. All of these had great popularity. Hats tilted over the left eye. Women remained slim and straight. The evening gown with a high neck in front, the low back, and long sleeves became ever present, even on those occasions when, several years before, only the lowest décolleté would have been correct. A casual look—a gracious look—was the keynote. Gradually a masculine note crept in. Mannish suits were worn for daytime; sport coats were adapted from various masculine sources; and evening clothes displayed a definite masculine trend. It was the beginning of the tailored evening mode.

The year of 1933 found the straight silhouette with a mannish feeling still in great favour. High necks predominated both for evening and day. An elongated "fish tail" appeared on a great many evening gowns, giving a narrow slender look to the lady of the day. What was known as "the dinner suit" appeared, and this tailored interpretation of a thoroughly masculinized dinner dress was worn most conspicuously by the chic woman. Jewels played a very important part with evening clothes—gold jewellery, huge and massive bracelets with a barbaric African feeling.

For daytime, hats suggested the "Cossack," or a modified form of the "fez." During the latter part of the year feathers—ostrich and other varieties—were of great importance. Trailing boas and short capes of feathers added grace and beauty to simple evening gowns. There was an ever increasing interest in shoulder treatments. Shoulders began to play an important part in the trend of fashion. Evening gowns displayed huge ruffled puff sleeves—a mode introduced by a motion picture which became international and returned to America again from Paris. Dinner hats were worn with dinner and theatre dresses. These dresses had a slender moulded look with a broad shoulder treatment.

1934 continued to bewilder its ladies by confusing them with odd materials. Silk was woven to look like wool; materials were made to look like glass; velvet became almost a soft fur. Attempts were made to shorten the evening gown. This was only mildly successful. A few appeared, but the evening dress remained graceful and dignified. A Victorian feeling was introduced in necklines, and a peasant influence found its way into evening gowns with huge spreading skirts and full sleeves. These were charming and becoming.

Fringe appeared, falling gracefully from shoulder and hip to floor. Romantic dresses full from the waist to the floor appeared. The picturesque dress which had been dormant for years became important and youthful as well.

Day clothes continued with a Russian Cossack influence, and also were adapted from the romantic men's costumes of the eighteenth century. Box suits were popular with younger women. Tunics appeared on day clothes and evening gowns. Trains for evening were longer than ever and slits in the skirts gave freedom of movement. Clothes had a gallantry, a dash, and a great deal of movement. Women had assurance and wore their clothes with knowledge and a feeling of freedom.

The silhouette also encouraged the revival and adaptation of fashions of 1910. This rather florid, but amusing era, was reconstructed with a simplified modern treatment. The clinging body flaring into a series of frothy flounces below the knee dominated the scene. The shoulder continued being the object of rejuvenation, arid also swirled into flounces in the form of short capes both double and single of layers of chiffon, organdie, or velvet.

Amusing details were introduced for sport and beach. Rope was applied to linen pocketbooks, made into bracelets with wooden ornaments, and used as dress trimming. Blouses and entire dresses were made of interestingly woven string. Cellophane was woven into wool and made into street dresses. Evening gowns were made of light weight wools and linens. All of these things were revolutionary and contradictory. It became a

year of inventiveness—a year of rather eccentric innovations.

1935 continued to emphasize the swagger gallantry in dress. It also ushered in great collars and foolish hats. For once in the history of fashion, the ridiculous was worn with serious acceptance. As we glance over the pages of fashion history it is not uncommon to be highly amused at some of the eccentricities of a past, but rarely do we recognize this humour as we go about wearing the costume of the present. 1935, however, proved an exception. The millinery of the day was often completely mad. Fantastic bonnets were worn, pancakes of velvet or straw, flaring into points or wings as if a bird had lighted on our ladies' heads. In fact, humour appeared everywhere.

Drapery appeared again with a 1913 feeling. Ladies preferred to return to a gracious pre-war style of dressing—particularly in their evening clothes. Everywhere one heard of the draped silhouette. An East-Indian influence appeared, suggested by the dresses worn by the wife of a visiting East-Indian potentate. These modern dresses were made with the Indian sari attached, which was thrown over the head and fell to the feet. The classical influence also continued, developing a sweeping back full of dignity and grace. Quaint and rather ultra-sophisticated very feminine clothes appeared, inspired by Dresden figures and Eugénie portraits. It was the revival of a romantic era treated in a modern way. It became amusing and charming at the same time.

The Italian exhibition of art in Paris influenced both the designers of clothes and materials throughout the world; and thirteenth, fourteenth, and fifteenth century Madonnas became modern ladies as seen through modern eyes. A military treatment crept into day clothes, "frogs" across the coat fronts, braid, broad shouldered short jackets, small felt hats with showers of black coq feathers giving the illusion of Italian army officers. These things were probably inspired by the war clouds over Italy and Ethiopia. A mediaeval influence and an Italian Renaissance influence were strongly felt in evening clothes. These period influences were always approached and adapted in a contemporary manner giving them an extremely modem viewpoint. A feeling of great luxury and extravagance, particularly in the use of furs appeared to be a foremost thought in 1935. Silver fox skins were used in a most prodigious manner, being made into entire short coats for day and great capes for evening. (G. AD.)

DRESSER, in furniture, a form of sideboard. The name is derived from the Fr. dressoir, a piece of furniture used to range or *dresser* the more costly appointments of the table. The appliance is the direct descendant of the credence and the buffet, and is, indeed, a much more legitimate inheritor of their functions than the modern sideboard, which, as we know it, is practically an 18th-century invention. It developed into its present shape about the second quarter of the 17th century, and has since then changed but little. As a piece of movable furniture it was made rarely, if at all, after the beginning of the 19th century until the revival of interest in what is called "farmhouse furniture" at the very beginning of the 20th century led in the first place to the construction of many imitation antique dressers from derelict pieces of old oak, and especially from panels of chests, and in the second to the making of avowed imitations. The dresser conformed to a model which varied only in detail and in ornament. Its simple and agreeable form consisted of a long and rather narrow table or slab, with drawers or cupboards beneath and a tall upright closed-in back arranged with a varying number of shallow shelves for the reception of plates; hooks for mugs were often fixed upon the face of these shelves. Towards the end of the 17th century small cupboards were often added to the superstructure The majority of these dressers were made of oak, but when, early in the Georgian period mahogany came into general use, they were frequently inlaid with that wood; holly and box were also used for inlaying, most frequently in the shape of plain bands or lines. A peculiarly effective combination of oak and mahogany is found in the dressers, as in other "farmhouse furniture," made on the borders of Staffordshire and Shropshire. The excellence of the work of this kind in that district and in the country lying west of it may perhaps explain the expression "Welsh dresser." which is now no more than a trade term, not necessarily suggestive of the place of origin, but applied to all dressers of this type. In Europe, they are most frequently found in the houses of small yeomen and substantial farmers, into which fashion penetrated slowly.

In the United States, the term dresser is more commonly applied to a piece of bedroom furniture consisting of a chest of drawers, or bureau, with a mirror attached—a sort of dressing-table. This application has no doubt been brought about by its use as a convenience in dressing or attiring one's self.

DRESSING STATION, a military term for the place where wounded are collected and attended to by the medical personnel of a field ambulance. It is thus normally next in rear of the "first-aid," or "regimental aid post."

DRESS MANUFACTURING. No phase in the history of dress is more remarkable than that which has been witnessed in the opening of the 20th century. Class distinctions, in so far as they are indicated outwardly by dress, have disappeared. It is not easy to detect differences of degree among the great bulk of the people. Partly, this is due to the spread of democratic ideas and institutions. Cheap means of transport, for example, bring all classes together. The intermixing produces similarity in style of attire. Partly, also, the cause is economic. There are more wage-earners, at better rates of pay. There has been a tremendous increase in the number of women wage-earners. Every one has more money available to spend on dress.

Mass-Production of Clothes.—A not less important cause is the mass-production of clothing. This both created a demand and developed in response to it. That section of the public of modest means who would have been slow to leave their clerical blue-serge, their homespun, their corduroys and large feathers—the mark of their occupation or class—have been educated into buying copies of the garments worn by the better-to-do, copies produced under the factory system by the hundred thousand. The men's ready-made clothing industry is a phenomenon; in the women's trade, dress everywhere has been completely revolutionized. Thirty years ago the woman of means had recourse exclusively to the dressmaker, the sempstress, the ladies' tailor. The latest fashions from Paris were reproduced for her by them, from actual models brought over or illustrated in the fashion journals. It was all hand process and slow, and "the latest" never percolated through to the mass of the female population. Then arose the trade movement which was to alter all this. It had actually begun in Germany two or three decades earlier, and was bound up with the improvements then being made in textile machinery and with the state of employment. A number of retail shopkeepers dealing in dress materials and articles of clothing found employment for their workers by starting the manufacture of "stock size" garments when orders for made-to-measure clothes were scarce. They were so successful and the service proved so popular that establishments were opened solely for this branch of manufacture. Factories were started in the provinces. Nearly the whole of the trade at first was confined to mantles, the basic and staple garment from which this now remarkable industry has grown.

The German Industry.—In the '70s the industry in Germany was well-established and important. In Berlin alone some 60 firms catered for it, and already were turning their attention from the home to the foreign market. The value of the total output in 1871 reached 30 million marks, and the number of workers employed, amounting to some 35,000, exceeded the number of those engaged in any other German industry at the time. In 1875 Great Britain bought three million marks' worth; in 1876 double that quantity; and two years later ten million marks' worth, the rate of importation thereafter steadily increasing until in 1897 the purchases reached a figure in excess of 88 million marks.

From that date Germany has been losing her monopoly of the world's markets. Almost every one of the chief importing countries—Great Britain, the United States, Austria, Italy, Switzerland, Holland, the Scandinavian countries—began to offer competition. Manufactories, one by one, were quickly opened; and although the German industry continued to grow, for only the "fringe" of the needs of the women of the world had yet been touched, manufacturers in other countries set themselves steadily

to supply the wants of the home consumer. They were handicapped on the score of prices, for the longer experience, lower wages, and higher organization of the Germans told heavily against them, but in another respect they had an advantage.

The German standard models were in the main not specially well-adapted to the non-German market. The women of Germany are heavier in build — "stockier" — than their sisters in the principal importing countries, and although the German manufacturers were quick to appreciate this and to modify the cut accordingly, still it was a compromise and benefited the maker on the spot who made exclusively for, and knew precisely, the needs of his own womenkind.

Growth of American and British Costume Trade — The industry abroad began to get into stride, particularly in the United States and the United Kingdom. For the latter, 1897 appears to have been the pivot year, for, after spending on German mantles no less than 88 million marks, British consumers bought from the same source in 1898 only 65.3 million marks' worth, while in 1899 the drop was bigger still — to 28.4 millions. The decline in subsequent years was in smaller ratio, but steady, until the World War, when the cutting off of supplies from Germany stimulated manufacturers elsewhere to supplant entirely the products of that country, not only at home but in foreign markets. After the War German "ready-mades" began very slowly to regain their former markets, the volume of imports from that country into the United Kingdom, *e.g.*, being valued at about half a million pounds sterling; the actual figure ten years after the outbreak of hostilities (1924) — as shown by the Board of Trade official import and export list classification of women's and girls' outer garments of woven fabrics: (a) costumes, dresses, coats, skirts and the like, and (b) mantles and cloaks — was £345,806.

Machine-made Clothes. — Concurrently with the rise of the industry throughout the world, manufacturing processes underwent remarkable development, and it may be said that there are now few figures and tastes which cannot be suited from the up-to-date manufacturer's stock. The style, fit and finish of even the cheapest "lines" have come to be a technical triumph. Costly and elaborate machinery and processes enable garments to be turned out markedly superior to the bulk of the old-time dressmaker's or hand-tailored product, and quality for quality (speaking of material) at about half cost. The term "mantle," originally in general use, by which was understood in the main a loose-fitting coat or cloak, usually sleeveless and worn over the dress, is becoming obsolete. It is still in some use, as broadly denoting the industry, but in England manufacturers prefer to be identified with the "coat and costume" and in America with the "cloak and suit" trade, in order to get away from a word which associates the product too closely with the early German cheap trade. The coat, deriving from the mantle, is now important, but the costume and suit, the complete dress consisting of coat and skirt, are the basis of the industry.

The trade owes much, however, in connection with the devising and perfecting of scientific, speedy and efficient processes of production to America. American manufacturers set a standard of excellence in this field, in the making of apparel, both for men and women, for all the world to follow. They were the first to realize the great possibilities of the trade and to determine to remove from it the deserved reproach which hitherto had attached to "ready-mades" and all too often had signified '(slop made." They saw that it need only be a question of research, organization and patient improvement of mechanical processes to enable their factories to turn out garments to suit the figure, purse and taste of every conceivable type and class of wearer, and it is well recognized now that in the United States, above all countries, the woman shopper can walk into a store and in the majority of cases be supplied from an immensely assorted stock with a costume or dress which not only exactly meets her fancy as regards fashion, material, colour and accessories, but fits her elegantly, no matter how widely she may diverge from the average or "stock" size.

Height, Width and Girth. — Quite in the early days of the garment industry in the United States steps began to be taken to allow for every variation of the human frame, in height, width, posture and girth, the requisite fullness or reduction of material and measurement being provided, in their minute differences, by no chance or rule-of-thumb methods but on a scientifically-based system of anthropometric variation — such as, for example, that propounded by the late Dr. Henry Wampen to the effect that, in the case of abnormal figures, height or depth quantities are to be calculated from a scale based on the height of the figure, while width quantities are to be based on the breast circumference.

In comparison, the manufacturers of other countries were slow to realize how much the future success of the trade depended upon their ability to cater for the almost infinite series of gradations in the human figure, with the result that for a long time, as in England, the chief customers for "ready-mades" were those of "stock size" proportions rather than those not of the average. Seeking to meet all requirements, the United States took the lead, and still retains it, so far as bulk production on the biggest scale is concerned, and to its enterprise in this particular section of the industry is due to no small extent the fact that American women are among the most smartly-dressed of any women in the world.

American methods of production in both the women's and men's ready-to-wear trade, involving 50 or more principal separate processes, hand and mechanical, and numerous minor operations, American methods of subdivision of labour, and also the types of plant used in the States, are now models for the apparel industry in all countries. It is difficult to estimate the precise extent of the trade in America, as the census returns associate together manufacturers in related branches of trade. Taking as some guide the corporation income tax returns which the United States authorities have published in recent years, we find that in 1924 the number of corporations in the women's and children's clothing and suit industry was put at 1,664, and that they paid tax on profits of $8,210,038. As the figure 1,664 is the fourth highest, in regard to the number of corporations engaged per industry, in a list taken from a report obtained for the purpose of this article, it is clear that the American cloak and suit trade, comprising private firms in addition to corporations, constitutes a very important part of the manufacturing activities of the United States as a whole.

English Styles. — There is a certain demand for English styles in women's costumes in the United States. In 1926 the purchases of such garments from the U.K. amounted to £59,330; the U.K. in return purchasing in 1925 (last available figures) £15,771 worth of U.S. costumes, etc.

To return to the trade of the United Kingdom, women's ready-to-wear garments of the category under discussion are bought principally from (in addition to Germany, figures for which have already been given) France, Belgium, Switzerland, Austria, the Netherlands, Italy and Czechoslovakia. In 1924 the British imports from France were valued at £3,087,000.

In estimating values, also, the course of the French franc since the World War needs to be borne in mind, together with the low cost of labour as compared with that of the United Kingdom.

In 1926 the British exports of fabric garments were worth £1,890,000. The British colonies and dominions are by far the best customers of the British costume manufacturer. As to the geographical distribution of the trade in the United Kingdom, London is an important centre as regards both manufacturing and distribution. For wholesale distribution, the earliest and still a considerable centre is St. Paul's churchyard, Cannon street, Friday street and Old Change, London. At the manufacturing end, the industry is also firmly established in a number of provincial towns and areas, including Manchester (where a speciality is the raincoat and waterproof), Leeds, Glasgow, Bristol, Birmingham and Bradford. (C. J. S.)

DREUX, a town of north-western France, capital of an arrondissement in the department of Eure-et-Loir, 27 m. N.N.W. of Chartres by rail. Pop. (1936) 12,387. Dreux was the capital of the Gallic tribe of the *Durocasses.* In 1188 it was taken and burnt by the English; and in 1562 Gaspard de Coligny, and Louis I., prince of Condé, were defeated there by Anne de Montmorency and Francis, duke of Guise In 1593 Henry IV. captured the town. It was occupied by the Germans in Oct. 1870,

was later evacuated, and again taken, on Nov. 17, by General von Tresckow. In the 10th century Dreux was the chief town of a countship, which Odo, count of Chartres, ceded to King Robert. Later, Louis VI. gave it to his son Robert, whose grandson Peter of Dreux, younger brother of Count Robert III., became duke of Brittany by nis marriage with Alix, daughter of Constance of Brittany by her second husband Guy of Thouars. By the marriage of the countess Jeanne II. with Louis, viscount of Thouars (d. 1370), the Capetian countship of Dreux passed into the Thouars family. In 1377 and 1378, however, Perronelle and Marguerite, two of the three co-heiresses of Jeanne, sold their shares of the countship to King Charles V. Charles VI. gave it to Arnaud Amanien d'Albret, but took it back in order to give it to his brother Louis of Orléans (1407); later he gave it back to the lords of Albret. Francis of Cleves laid claim to it in the 16th century as heir of the d'Albrets of Orval, but the parlement of Paris declared the countship to be crown property. It mas given to Catherine de' Medici (1539), then to Francis, duke of Alençon (1569); it was pledged to Charles de Bourbon, count of Soissons, and through him passed to the houses of Orléans, Vendbme and Condé. Dreux stands on the Blaise, which there divides into several arms. It is overlooked from the north by a hill with a ruined mediaeval castle, within the enclosure of which is a gorgeous chapel, begun in 1816 by the dowager duchess of Orléans and completed by Louis Philippe. It contains the tombs of the Orléans family, chief among them that of Louis Philippe, whose remains were removed from England to Dreux in 1876. The sculptures on the tombs and the stained glass of the chapel windows are masterpieces of modern art. The older of the two hbtels de ville of Dreux was built in the early 16th century, chiefly by Clément Métezeau, whose father, Thibault, was the founder of a famous family of architects, natives of the town. It is notable for the carvings of the façade and for the staircase. The church of St. Pierre is Gothic and contains good stained glass and other uorks of art. Dreux is the seat of a subprefect. Among the public institutions are tribunals of first instance and of commerce. There is also a well-known sanitarium The manufacture of boots and electric fittings and metal-founding are carried on. and there is also a trade in wheat and poultry. (X.)

Battle of Dreux (1562).—The battle of Dreux was the first regular engagement of the Huguenot Wars in France, and it was fought on Dec. 19, 1562. Henry II., king of France, was accidentally killed at a tourney in 1559, and was succeeded by his ten year old son, Charles IX., whose mother, Catherine de' Medici, claimed the right to conduct the government. On March 1, 1562, the duke of Guise massacred 60 Huguenots at Vassy and the leaders of the reformed faith, Condé and Admiral de Coligny, appealed to the Queen but received no satisfaction. War now began, the Huguenots being declared rebels. As they were vastly in the minority they sought assistance from England and Germany, obtaining promises of money from the first, and 9,000 reiters and landsknechts from the second. Leaving d'Andelot and his 9,000 Germans at Orléans, in November, Condé made a dash for Paris, but found Guise and Saint-André already there. To gain time to collect her forces, the Queen-mother made overtures for peace, but as no result was reached, on Dec. 10 Condé moved on Chartres, the royal army following and threatening Orléans. Condé now wished to counter-march on Paris, but Coligny persuaded him to move into Normandy and join hands with an English force which had landed there. Thus it came about that the army marched on Dreux. There the Huguenots found their road blocked, and though inferior in numbers were compelled to accept battle, for as Coligny said: "We must now look to our hands to save us, not to our feet." On each side the left wing was victorious. In all some 6,000 were killed or wounded, and though no true decision was gained the royalists held the field. Marshal Saint-André and the duke of Nevers were killed on the royalist side, and Condé was taken prisoner. After the battle Coligny withdrew his men in good order to Beaugency. The forces engaged were approximately 4,000 horse and 8,000 infantry on the side of the Huguenots, and 3,000 horse and 13,000 infantry on that of the royalists.

See Kervyn *de* Lettenhove, *Les Huguenots et les Gueux* (1885); Aumale, *Hist. des Princes de Condt pendant les XVI^me^ et XVII^me^ siècles* (1864); *The Cambridge Modern History,* vol. iii. (1904).

(J. F. C. F.)

DREW, the name of a family of American actors. JOHN DREW (1827–1862) was born in Dublin and made his first New York appearance in 1846. He played Irish and light comedy parts with success in all the American cities, and was manager of the Arch street theatre in Philadelphia. He visited England in 1855, and Australia in 1859; he died in Philadelphia. His wife, LOUISE LANE DREW (1820–1897), was the daughter of a London actor, and in 1827 went to America, appearing as the Duke of York to the elder Booth's Richard III., and as Albert to Edwin Forrest's William Tell. After this she starred as a child actress, and then as leading lady. She had been twice married before she became Mrs. Drew in 1850. From 1861 to 1892 she had the management of the Arch street theatre in Philadelphia. In 1880 she toured with Joseph Jefferson in his elaborate revivals of *The Rivals,* playing Mrs. Malaprop to perfection. She had three children, John, Sidney and Georgiana, wife of Maurice Barrymore (1847–1905), and mother of Lionel, Ethel and John Barrymore, all actors.

The eldest son, JOHN DREW (1853–1927), began his stage career under his mother's management in Philadelphia as Plumper in *Cool as a Cucumber,* March 22, 1873; and after playing with Edwin Booth and others, became leading man in Augustin Daly's company in 1879. His association with this company, and with Ada Rehan as the leading lady, constituted a brilliant period in recent stage history, his Petruchio being only one, though perhaps the most striking, of a series of famous impersonations. In 1892 he left Daly's company, and began a career as a "star," appearing among other plays in *A Marriage of Convenience, One Summer Day, Richard Carvel, Much Ado About Nothing, The Will, The Circle* (1921–23), *School for scandal* (1923), *Trelawney of the Wells* (1925–26–27). He died in San Francisco (Calif.), July 9, 1927, while on tour.

See Moses, *Famous Actor-Families in America* (1906); Winter, *Wallet of Time* (1913).

DREWENZ, a river of Germany, a right-bank tributary of the Vistula. It rises on the plateau of Hohenstein in East Prussia, 5 m. S.W. of the town of Hohenstein. After passing through the lake of Drewenz (7 m. long), it flows south-west through flat marshy country, and forms, from just below the town of Strassburg to that of Leibitsch, a distance of 30 m., the frontier between East Prussia and Poland. After a course of 148 m. it enters the Vistula from the right, a little above the fortress of Thorn.

DREWS, ARTHUR (1865–1935), German philosopher. was born on Nov. 1 at Utersen, Holstein, and was educated at Munich, Berlin, Heidelberg and Halle. From 1898 he was professor at the polytechnic academy in Karlsruhe. His contributions to the critical appreciation and history of philosophy are *Die deutsche Spekulation seit Kant* (1893); *Kants Naturphilosophie* (1894); *Das Ich als Grundproblem der Metaphysik* (1899); *Das Lebenswerk E. V. Hartmanns* (1907); *Nietzsches Philosophie* (1904); *Plotin* (1908); *Die Philosophie im 19. Jhr.* (1912); *Gesch. des Monismus im Altertum* (1913). His support of concrete monism and an ultimate Being devoid of consciousness and personality is best seen in his *Die Religion als Selbstbewusstsein Gottes* (1906); *Der Monismus* (1908) and *Freie Religion* (3rd ed., 1921).

DREXEL, ANTHONY JOSEPH (1826–1893), American banker, was born in Philadelphia (Pa.) Sept. 13, 1826. He was the son of Francis M. Drexel (1792–1863), founder of the banking-house of Drexel and Co. Anthony, with his brothers Francis and Joseph, succeeded to the control of the business, and organized the banking-houses of Drexel, Morgan and Co., New York, and of Drexel, Harjes and Co., Paris. In 1864 with George W. Childs he purchased the Philadelphia *Public Ledger,* and with him in 1892 founded the Printers' Home for union men at Colorado Springs. In 1891 he founded and endowed the Drexel institute of Art, Science and Industry in Philadelphia. He died at Carlsbad, Germany, June 30, 1893.

DREYER, JOHN LOUIS EMIL (1852–1926), Danish astronomer, was born at Copenhagen on Feb. 13, 1852, and was educated in his native town. In 1874 he became astronomer at

the earl of Rosse's observatory at Birr Castle, Ireland. He remained in Ireland, holding the post of assistant astronomer at the Royal Observatory, Dunsink, from 1878 to 1882, and of director of the observatory at Armagh from 1882 until he retired in 1916. Dreyer's work in astronomy falls into two groups—his observations on nebulae and on the motion of stars, and his work on the history of astronomy. His astronomical observations were started at the Rosse observatory, where the telescope was particularly suitable for his purposes, and continued at Dunsink and Armagh. Dreyer is the author of a number of papers on nebulae and stars, and of *Second Armagh Catalogue of 3,300 Stars* (1886). His "New General Catalogue of Nebulae and Clusters of Stars," published in the *Memoirs* of the Royal Astronomical Society (1888), with supplements in 1895 and 1908, is a standard work. He was particularly interested in the work of Tycho Brahe, and wrote *Tycho Brahe,* a *Picture* of *Scientific Life and Work in the 16th century* (1890), and prepared a complete edition of Tycho Brahe's work, *Tycho Brahe Opera Omnia.* The first volume was published in 1913; ten volumes appeared before Dreyer's death, and the remaining four were complete in manuscript. Dreyer held many academic honours. He died on Sept. 14, 1926.

DREYFUS, ALFRED (1859–1935), French soldier, was born on Oct. 9, 1859, the son of a Mulhouse manufacturer. After studying at the *école polytechnique,* he entered the army as a lieutenant of artillery. He became a captain in 1889, passed through the *école supérieure de la guerre* (staff college), and received an appointment in the Ministry of War. His name is famous because of the judicial error of which he was the victim, which was repaired only after an agitation which disturbed France for many years and aroused deep feeling all over the world. During the summer of 1894, an anonymous letter abstracted from the German embassy was communicated to the Ministry of War. It had been addressed to the military attaché, Col. von Schwarzkoppen. This letter known as the *bordereau,* or schedule, because it had originally been written as a covering letter to certain military memoranda, enumerated the documents which its writer hoped to send to Schwarzkoppen. A French officer was evidently betraying his country. It happened unfortunately that the writing of the *bordereau* was like that of Dreyfus. Suspicion fell upon him, and he was arrested on Oct. 15. He always maintained his innocence, but by reason of the similarity of the hand-writing, appearances were against him. Actual evidence was, however, extremely scanty. For this reason, Gen. Mercier, the minister of war, placed before the members of the court-martial secret documents, utterly valueless as evidence, but which could not fail to impress them. This was done unknown to the prisoner and his counsel, the famous M. Demange, and the fact did not leak out until several years later. On Dec. 22, 1894, Alfred Dreyfus was unanimously found guilty and condemned to detention for life in a fortified area. On March 15, 1895, he was interned on Devil's island, one of the archipelago of the Safety islands off the coast of Guiana. His family never ceased to believe in his innocence. His brother, Mathieu Dreyfus, convinced a terrible judicial error had been committed, strove incessantly to have the case reviewed. This could not be done, however, unless some new facts were brought to light.

An official at the Ministry of War, entirely unconnected with the Dreyfus family, made the necessary discovery. Col. Picquart was the head of the information branch which had to do with the affairs of the secret service. In March 1896 he became possessed of the fragments of an express letter which Col. von Schwarzkoppen, the German military attaché, had torn up unsent, and thrown into the waste-paper basket. It had been found by a French agent. This express letter, known as the *"petit bleu"* was addressed to a French officer, Maj. Esterhazy, and proved that he was in the pay of Schwarzkoppen. On making enquiry Picquart found that Esterhazy led a dissipated life and was heavily in debt. He then discovered that the *bordereau,* wrongly attributed to Dreyfus, was in Esterhazy's hand-writing. Convinced that Dreyfus was innocent and Esterhazy guilty, he laid his information before his superior officers, Gen. de Boisdeffre and Gen. Gonse, the chief and deputy chief of the general staff. They, however, still convinced of Dreyfus' guilt, and unwilling to have the matter reopened, forbade him to pursue his enquiries, and when he said he could not die with such information undisclosed, had him transferred to a distant part of Tunisia. About that time, Col. Henry, the deputy director of the information branch, brought forward a letter apparently from Col. Panizzardi, the Italian military attaché. Dreyfus was referred to in it in terms which, had it been genuine, would have left no doubt of his guilt. The letter was, however, a forgery, and the discovery of this fact led to the first revision of the case. Col. Picquart, before starting for Africa, had told the whole story to his friend the lawyer, M. Leblois. Leblois discussed it with Scheurer-Kestner, a well known politician who was vice president of the senate. He became convinced of Dreyfus's innocence, and began to agitate in his favour. At the same time (Nov. 1897) Mathieu Dreyfus had by the merest chance come to realize that the writing of the *bordereau* was that of Esterhazy. On Nov. 15, 1897, he wrote to the minister of war accusing Esterhazy of the crime for which his brother had been condemned. The general staff was unwilling to own that a mistake had been made. Esterhazy was formally court-martialled, but his acquittal was secured. At the same time a press campaign of extraordinary violence broke out against those who were working for the revision of the 1894 sentence. They were represented as traitors to their country. Col. Picquart was thrown into prison on the pretext that he had communicated confidential papers to a civilian (M. Leblois). The cause of Dreyfus had, nevertheless, gained many supporters, especially in intellectual circles. Georges Clemenceau and Francis H. Pressensé in the newly founded *l'Aurore,* and Yves Guyot, Joseph Reinach and others in the *Siècle* set on foot an agitation which did not cease till justice had been done. On Jan. 13, 1898, two days after Esterhazy's acquittal, Zola published in *l'Aurore* under the title *"J'accuse"* the famous open letter to the president of the republic, in which he denounced the efforts which were being made to stifle the truth. At the instance of the Ministry of War, proceedings were taken against him. The case was heard in February. His lawyers, Labori and Albert Clemenceau, brother of the statesman, called many witnesses to the innocence of Dreyfus and convinced a large section of the public. But opinion on the whole was still unfavourable. Zola was condemned to a year's imprisonment. He later took refuge in England for a time.

As the call for revision grew more and more insistent, Cavaignac, minister for war in Brisson's cabinet, tried to arrest it by reading aloud in the chamber on July 7, 1898, the alleged letter from Panizzardi which had been brought forward by Col. Henry some months before. Soon after, however, on Aug. 30, it was made clear that it had been forged by its seeming discoverer, who was arrested and committed suicide in his cell at Mt. Valérien. This decided the Government to lay the demand made by Mme. Dreyfus for revision of the original sentence before the court of appeal. After months of enquiry, the court annulled the sentence of 1894 and ordered a new trial before a court-martial at Rennes. Little by little the cause of Dreyfus was gaining ground. Loubet, who became president of the republic on the death of Felix Faure in Feb. 1899, was favourably inclined to it, as was also the cabinet of Waldeck Rousseau, which came into power in June. But feeling still ran high, especially in military circles. Dreyfus was brought back from Guiana. The new trial lasted a month. On Sept. 9, 1899, the court-martial at Rennes by five votes to two delivered an incoherent judgment by which Dreyfus was found guilty with extenuating circumstances, and condemned to ten years' imprisonment. This amazed the general public. On Sept. 19 the Government decided to pardon Dreyfus. He was immediately set at liberty, and after a short stay at Geneva, settled in Paris. At the end of 1903 further facts which came to light led to a demand for a second hearing by the court of appeal, and a further long and detailed enquiry. On July 12, 1906, the court of appeal finally quashed the sentence of 1894. Dreyfus was completely rehabilitated. A Government measure reinstating him in the army with the rank of major of artillery was immediately passed. He was employed for a year in a military office at St. Denis near Paris and resigned in July 1907. In June 1908, on the

occasion of the transfer of the ashes of Zola in the Pantheon, an anti-Semite journalist, Gregori, fired two shots at him, one of which wounded him slightly. He re-entered the army during the World War, was promoted lieutenant-colonel in 1918, and shortly afterwards an officer of the Legion of Honour. After that he lived in retirement until his death in Paris, July 12, 1935.

BIBLIOGRAPHY.—Dreyfus's letters written in captivity have been published under the title *Lettres d'un Innocent (1898)*. His memoirs entitled *Cinq années de ma vie* appeared in 1901. The shorthand reports of the various trials have been published (some by the Libraire Stack of Paris and others by the *Ligue des Droits de E'homme). See* also Joseph Reinach, *Histoire de l'affaire Dreyfus (7* vols., 1901–1911); Theodore Reinach, *Histoire sommaire de l'affaire Dreyfus* (1924); and an anti-Dreyfusite work by Dutrait-Crozon, *Précis de l'affaire Dreyfus* (1909). (P. B.)

DRIBURG, a town and spa of Germany, in Prussian Westphalia, pleasantly situated on the Aa and the railway Soest-Hoxter-Berlin. Population 3,000. **It** has glass manufactures. It is celebrated for its saline-ferruginous springs, discovered in 766, and since 1779 largely frequented in summer. In the vicinity are the ruins of Iburg, a castle destroyed by Charlemagne in 775, and bestowed by him upon the bishopric of Paderborn.

DRIESCH, HANS (1867–1941), German biologist and philosopher, was born on Oct 28, 1867, at Kreuznach. After studying at Hamburg, Freiburg, Munich and Jena, he travelled in the Far East, and from 1891 to 1900 worked in the zoological station of Naples. He then settled in Heidelberg where in 1909 he became privat-docent and in 1911 professor of philosophy. In 1920 he was made professor at Cologne and in 1921 at Leipzig. Driesch brgan as a disciple of Haeckel but through the influence of G. Wolff and W. Roux came to support a dynamic vitalism.

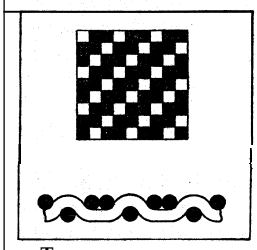
His doctrine that the functions of protoplasm cannot be explained mechanically was the outcome of experiments on the blastula of the sea-urchin, which showed that any fragment cut at random always gave a complete embryo and on the restitution of animal parts. From these he concluded that the organism must be a harmonious equipotential system possessing a vital individualizing entelechy which works through the matter with a view to the whole. He also maintained that instinct and action are inexplicable mechanically. His anti-mechanism in the psychological sphere is seen in his *Leib und Seele* (Leipzig, 1920. Eng. trans. with a full bibliography of his works, 1927). His other important works are *Analytische Theorie der organischen Entwicklung* (Leipzig, 1894); *Science and Philosophy of the Organism* (Gifford Lectures, 1907–8); *History and Theory of Vitalism* (1914); *The Problem of Individuality* (1914); *Wissen und Denken* (Leipzig, 1919); *The Crisis in Psychology* (Princeton Lectures, 1925). He died in Leipzig in Apr. 1941.

DRIFFIELD (officially Great Driffield), urban district, Buckrose parliamentary division, East Riding of Yorkshire, England. It is 19½ m. N. of Hull, with which it is connected by a navigable canal. Population of urban district (1938) 6,258. The town is served by the L.N.E. railway and is a junction for several branch lines. It is a market town, the centre of an agricultural district, and manufactures oil-cake. The town is rich in historical associations and has an excellent museum.

DRIFT: *see* GLACIAL PERIOD.

DRILL. In military science, the word *drillen* was used in Dutch, German and Danish from the 17th century for training in military exercises and was adopted into English in the same sense. The origin of the application seems to be in the primary sense of "to turn round," from the turning of the troops in their evolutions and from the turning of the weapons in the soldiers' hands. Drill is, formally, the preparation of soldiers for their duties in war by the practice or rehearsal of movements in military order and the handling of arms; and, psychologically, the method of producing in the individual soldier habits of self-control and of mechanically precise actions under disturbing conditions, and of rendering the common instinctive will of a body of men, large or small, amenable to the control of, and susceptible to a stimulus imparted by its commander's will. *(See* ARMY; INFANTRY; ROMAN ARMY.)

In textiles, drill is the name of a fabric made in both linen and cotton, and commonly bleached and finished stiff. The word is a shortened form of "drilling," from the German *drillich,* or "three-threaded," and is so named because the weave originally used in its construction is what is termed the three-leaf twill, nine repeats of which appear in the accompanying figure, while immediately below the design is an intersection of all the nine threads with the first pick. It is essentially a warp-faced fabric; that is, the upper surface is composed mostly of warp threads. In the figure it will be seen that two out of every three threads appear on the surface, and, by introducing a greater number of threads per inch than picks per inch, the weft is made to occupy a still more subordinate position so far as the upper surface of the cloth is concerned. Although the weave shown is still extensively used in this branch, there are others, *e.g.,* the four-thread and the five-thread weaves, which are employed for the production of this cloth. Large quantities of drill are shipped to the Eastern markets and to other subtropical centres. It is also used for military tropical uniforms, and for jackets, overalls, etc.



TWO DRILL DESIGNS
Three-leaf twill, a warp-faced fabric

In agriculture, a furrow in which seed may be sown is known as a drill. The word is somewhat doubtful in origin. It may be the same as an obsolete word "drill," to trickle, flow in drops, also a small stream or flow of water, a rill, and is possibly an altered form of "trill." Drill is also the name of an agricultural machine used for sowing seed or distributing manure *(see* CULTIVATING MACHINERY). *(See* also AGRICULTURE: AGRICULTURAL MACHINERY: SOWING.)

DRILL, *Papio leucophoeus,* **a** large baboon inhabiting the coast of Guinea. It is smaller and less fierce than its relative, the mandrill, and is further distinguished by the black colour of the bare face.

DRILLING, PETROLEUM. Modern automatic rotary drilling has supplanted to a remarkable extent former methods of cable tool or "rod and drop tool" systems. (For details of this, as well as other methods of boring, *see* BORING.) It is the extension and perfection of automatic drilling that has been responsible for the opening up of oil pools at greater and greater depths. Electric drive for both rotary and cable tool drilling has become common practice, whereas in the early 1920s it was an innovation and experimental. Before automatic machinery could be put to work on so complex and difficult an operation as deep-well drilling there was required the development of specially designed motors, Erst applied to well pumping, field water supply, pipe-straightening machines, cutting and threading machines, and finally to drilling. Rotary drilling required the development of adjustable speed motors and reduction gears of new type, and cable tool drilling, the development of an electric drive and control designed to give motion for drilling; power and high speed for pulling tools. bailing and setting casing, and slow speeds for ramming bits. With the first successful electric rotary deep-well drilling operation in California in 1923, a new era in drilling technique, based on automatic operation and simplicity of complete control, began. To see these modern plants in operation, drilling to depths of from 5,000ft. to 10,000ft. or even 15,000ft., is to get the full effect of the contrast between them and Drake's first steam-driven rig in 1859 or the first crude rotary operation at Spindletop. Texas, in 1901. Steel derricks tower 122ft. to 178 feet. Every step of raising the bit, unscrewing and screwing up again the lengths of steel tubing joined for a mile or more, is under control from the derrick floor.

On the derrick floor is an array of instruments resembling the instrument board of a power plant or of an aeroplane. A gyroscope compass determines whether the hole is being bored straight. Before its use there were cases of crooked holes drifting many hundreds of feet from the point vertically under the well site. Crooked holes meant trouble, delay, often loss of the well. An ingenious camera also is put to the same use as the gyroscope, taking photographs in the darkness far down in the well. It is the

only eye the production engineer has for seeing where he is travelling. Another instrument is the weight indicator, which shows the weight on the bit. The driller always watches it carefully, for it was found that there is some relation between the weight on the bit and the deflection of the hole, and that the deflection could be reduced by permitting less weight to rest on the bit when drilling. At frequent intervals the engineer in charge of the drilling operation consults charts of recordings from these various instruments.

In every modern operation similar contrasts from the old days are noted, whether the field be steam, Diesel, or electrically drilled. Improved devices for core drilling make it possible to obtain, for laboratory study, complete sections of the rocks and sands penetrated. In rotary drilling intensive studies of drilling fluids have resulted in compounds that greatly aid in the control of wells and the prevention of blow-outs. Methods of completing wells are greatly improved. It is important, in modern practice, to conserve gas pressure in an underground reservoir. Cementing methods are applied that seal off the gas sands underlying oil sands, so to conserve gas pressure. It is important also to case or cement off encroaching water from penetrated strata. Effective methods are applied to prevent water flooding by use of casing perforation, opposite oil zones only, leaving water zones cemented off. The major units for drilling—derricks, boilers, and pumps—are all of much heavier design. All tubular goods and drilling tools have reached a standard of strength and reliability consistent with the demands made upon them for deeper drilling. Failure of equipment, once a common occurrence, is rare. Wells may be drilled safely to depths exceeding 10,000ft., not as an unusual, but as an every-day occurrence.

As compared with 10 or 15 years before, well depths commercially reached in 1938 more than doubled. See Table I.

TABLE I.—Deepest Tests and Deepest Producing Wells, by Years

Year	Deepest Drilled Depth, Ft.	Deepest Producing Depth, Ft.	Year	Deepest Drilled Depth, Ft.	Deepest Producing Depth, Ft.
1938	15,004	13,206	1928	8,523	8,523
1937	12,786	11,302	1927	8,046	7,591
1936	12,786	9,950	1926*	8,046	7,591
1935	12,786	9,836	1925	.....	7,591
1934	11,377	9,710	1924	7,319	.....
1933	10,585	9,710	1909	5,660	.....
1932	10,585	9,710	1900	2,800	.....

(L. M. F.)

DRINK BILL. In Great Britain, this term has for many years been applied to an annual statement issued up to 1909 by the late Dr. Dawson Burns and since that date by George B. Wilson (in annual letter to the press, usually reproduced in substance in the Alliance Year Book, edit. by G. B. W. and published by the United Kingdom Alliance, London), showing the annual expenditure on and consumption of alcoholic liquors in the United Kingdom; since 1923 in Great Britain. The statement is based on the quantities of beer, spirits and wine retained for home consumption in Great Britain in the calendar year, as shown in the trade returns issued by the customs and excise, and does not include exports or re-exports of such liquors. The unit taken for beer is the 36 gal. barrel as sold. The number of such barrels is larger than the corresponding number of standard barrels which formerly were the unit of taxation. The materials which produce 1,000 standard barrels of 1,055° specific gravity before fermentation in 1938, in fact produced 1,344 selling barrels. The unit taken for spirits is the proof gallon. Spirits are, however, sold on the average at 30° under proof, or 142·8 selling gallons for every 100 proof gallons, so that the total gallons of liquid actually consumed as spirits in 1938 were not 10,098,000 as stated below but 14,420,000 gallons, or the equivalent of about 864 million bottles of whisky. The Drink Bill for 1938:—

Liquors	Consumption	Retail cost £
	(000's omitted)	
British spirits at 130s. per proof gal.	8,922	57,993
Other ditto	1,176	7,644
	10,098	65,637
Beer at 132s. per bulk barrel (including Irish imports)	24,861	164,080
Wine at 30s. per gallon	14,890	22,335
Cider, British Wines, etc.	.....	5,000
		£257,050
Per head		£5·11·6

The expenditure and consumption were about:

	England, Wales	Scotland
Expenditure	£234,716,000	£22,339,000
Per head	£5·14·0	£4·9·6
Spirits per head (proof gallon)	0·20	0·37
Beer per head (bulk gallons)	20·7	8·1
Absolute alcohol per head (gallons)	1·07	0·65

Of the absolute alcohol consumed about 12½% was taken in spirits, 78% in beer, and the balance in wine, etc.

The liquor taxation (duties and licences) collected in 1938 was about £109,400,000, or 42½% of the total Drink Bill.

The following figures compare the taxes on liquor and licences with the total tax revenue of the United Kingdom (Great Britain and N. Ireland since 1923):—

Year	Taxes on liquor and licences	Total tax revenue	Percentage borne by liquor taxation
	£	£	
1839	16,208,000	49,033,000	33·0
1899–1900	41,686,000	108,496,000	38·4
1919–1920	133,873,000	998,960,000	13·4
1938–1939	111,604,000	896,415,000	12·5

The use of industrial alcohol has greatly increased. In 1925 it was 7,529,000 proof gallons, but in 1938, 54,428,000 gallons. About two-thirds of the spirits annually distilled are now used for non-dutiable purposes. (*See* PROHIBITION; TEMPERANCE.)

(G. B. W.)

DRINKING VESSELS. Nature provided the primitive man with various forms of drinking vessels, such as the coco-nut, the gourd, eggs of the larger birds, shells and even the human skull, many of which have been of such practical use that they have lasted to the present day. The first artificial drinking vessels were so similar to those used for food, that it is difficult to make a definite line of distinction. The races of the Neolithic and Bronze ages furnished vessels of pottery of a beaker-like form, and later prehistoric times produced vessels of gold, bronze and other materials which seem to have been used as drinking vessels. A specimen, resembling an early Victorian tea-cup on a high foot, was found by Schliemann in his exploration of the superimposed cities of Troy. It is of clay, but similar forms found at Tiryns and Mycenae are of gold. Schliemann was especially interested in a tall, trumpet-shaped cup with two earlike loop handles; a sauce-boat shaped vessel of gold, made with a lip for pouring or drinking at each end, and with two loop handles; and others of gold, silver and electrum, three of which were shaped like 18th-century coffee cups without handles.

Gothic and Scandinavian Types.—The practice of burying with the dead warrior any property that he might need has preserved to our day the actual vessels in use by the pagan northmen who pervaded northern Europe from the 4th century onward. Among the belongings surrounding one Saxon chieftain were five cows' horns and four glass cups. The horns were 2 ft. long, and richly mounted at the mouth and at the point with silver bands embossed and gilt. The glasses were of a trumpet shape, with a

small foot, while the sides were ornamented with tubes bent downward and open on the inner side, so that the liquid would fill them. Another type was a simple cone of glass, sometimes ornamented with an applied spiral glass thread, or festoons of white glass imbedded in the body of the vessel. Still a third form was that of the "tumbler," a plain cup or bowl widely expanded at the mouth and with a rounded base, so that it could only be set down when empty. There are in the museums many other contemporary varieties, plain cylindrical goblets, generally with ornamental glass threads on the outside, and a more usual type has an orange-shaped body with a wide, plain mouth. In Belgium, France and Germany the same types occur, also additional forms that do not occur in England—one of which is a drinking glass in the shape of shunting horn with glass threads forming an ornamental design on the outside. These glass drinking vessels were popular, but a large number of small pottery vessels were found, and in one grave at Broomfield, in Essex, two small wooden cups were found. Horns as drinking vessels retained their popularity at all times, actual horns being supplanted later by horn-shaped vessels.

Church Vessels.—The drinking vessel possessing the most established history is doubtless the chalice of the Christian Church. Upon early Christian tombstones are found such vessels. apparently with a symbolic intention. But it is not until about the 6th century that the sacred vessels assumed a definite form. From that time date the lost golden chalices of Monza, representations of which still exist in that city; and the famous chalice of Gourdon in the Bibliothèque Nationale in Paris is probably of about the same time. All of these are two-handled with a vase-shaped body supported on a high base. Two glass vases of exactly this two-handled form are in the Slade collection at the British Museum, and may well have been chalices. This form seems to have been succeeded by a goblet with straight lines and without handles. Then came the rounded cup-shaped bowl as seen in the well-known Kremsmunster chalice. An interesting silver vessel, probably a chalice, found at Trewbiddle, in Cornwall, is in the British Museum. It is a plain semi-oval, and dates from the 9th century. The 13th century chalice was usually a broad, shallow cup, on a conical base. These gradually became taller, with a bowl smaller in proportion, so that in the 17th century both the civil and religious vessels had lost all sense of true artistic proportions. In Britain chalices ceased to be used in the English church in the reign of Edward VI. and were replaced by communion cups. The chalices of the early centuries were made of various materials. glass being more practicable, with gold and silver as preferences when they could be obtained.

Mediaeval Vessels **for Common** Uses.—Wooden vessels, of which mazer bowls seem to have predominated, were commonly used in the 14th, 15th and 16th centuries. In the latter century they began to take on elaborate mountings, and then, as other materials came into use among the wealthy, they began to lose their popularity. Crystal, agate and other hard stones, ivory and Chinese porcelain, were all in use, as well as the precious metals. Of the cups that are preserved in the British Museum, the royal gold cup of the kings of England and France is of interest. It is of nearly pure gold with a broad bowl and a high foot, the cover pyramidal. The subjects represented on its ornamentation are scenes from the life of St. Agnes, in two rows, one on the cover and one outside the bowl; on the foot are the symbols of the four Evangelists, and around the base a coronal of leaves alternating with pearls; the cover originally had a similar adjunct, but it has unfortunately been cut away. Its history has been traced from the time when it was made, about 1380, to the present time.

16th–18th Century Types.—Drinking vessels of the 15th and 16th centuries were of so many shapes, materials and decorations that most every type can be placed in that period. There were all sorts of adaptations, such as the ostrich egg mounted on elaborate silver, the coco-nut used in the same way and Chinese and other Oriental wares turned into cups and vases of various forms. Actual horns, provided with feet so as to serve as standing cups, were quite common. The elegant natural curve of the horn, often mounted with great richness, added still to the charm of the vessel. German silversmiths made many vessels in the forms of animals, the head generally removable so as to form a small cup. Stags, lions, bears and various birds are often found. **A** common type of Switzerland and South Germany was that of a figure of a peasant, generally in wood, carrying on his back a large basket, which edged with silver formed the drinking cup. A curious fancy was to make cups in the form of a globe. These are of historic value, because they show the state of geographical or astronomical knowledge at the time.

Glass cups were not common in England until the 16th century, Venice having practically a monopoly of the supply. The relations of Venice with the East were of so intimate a character that the earlier forms of Venetian glasses were nearly identical with those of the Mohammedan East. This period saw various kinds of wine glasses and goblets with enamelled and lace designs; tankards, practical but seldom graceful; beakers, resembling our modern tumblers and a common type among the Arabians.

In the 17th and 18th centuries a great impetus was given to the production of curious drinking vessels, not in the sense of supplanting the many varieties of the past, but as an interesting innovation. Cups of leather, generally in the form of a lady's shoe, were common. Flagons, or "black jacks" were also of leather. The material that lent itself to a greater possibility in the field of art was that of pottery. In England at various potting centres a great number of cups called "tygs" were made. These were large mugs with three or four handles, so that the cup could be passed from one to another. Some of these have quaint devices and inscriptions. "Puzzle jugs" afforded a good deal of amusement at this time. They were jugs with open-work around the neck, and a variety of spouts, only one of which led to the liquid. The Chinese still cling to the rhinoceros horn as an object of somewhat archaic form, believing it to be an antidote for poison. The beautiful amber hue and the thickness of the horn, together with the various carved decorations, make it a vessel of unusual interest. Tea-cups with no handles, and much thinner than coffee cups, were made in China in the 18th century.

The 19th and 20th centuries have seen the manufacture and use of most every form of drinking vessel that the ancient and mediaeval times produced, after changing the shapes and materials only as a matter of commercial interest. Glass is the most widely used material, being cheaper and more practicable, while clay is a better material when it comes to retaining heat or cold. *(See* also GLASS; POTTERY AND PORCELAIN; SILVERSMITHS' AND GOLDSMITHS' WORK.)

DRINK TRAFFIC: *see* LIQUOR LAWS.

DRINKWATER, JOHN (1882–1937), British poet, playwright and critic, born at Leytonstone, Essex, June 1, 1882, and educated at the Oxford high school. After 12 years' work as an insurance clerk, he devoted himself to theatrical enterprise, and became manager and producer to the Pilgrim Players, who developed into the Birmingham Repertory Theatre Co. His first volume of poems appeared in 1906 and his first play, *Cophetua* (in verse), in 1911. He subsequently published several volumes of verse, critical studies on *William Morris* (1912), *Swinburne* (1913) and others, and several plays, of which *Abraham Lincoln* (1918) was produced with great success both in London and in the United States. Among his later plays were the "chronicle dramas" *Oliver Cromwell* (1921), *Mary Stuart* (1922) and *Robert E. Lee* (1923), each of which was performed in London. In 1923 his *Collected Poems* (2 vol.) were published, and in 1925 *The Muse* in *Council,* a collection of essays, and his *Collected Plays* (2 vol.). In 1925 *The Pilgrim of Eternity: Byron—a Conflict,* a prose work, made its appearance. His autobiography appeared in two volumes, *Inheritance* (1931) and *Discovery* (1932). He wrote prolifically in the last years of his life, but none of his later work was of particular importance. He died March 25, 1937.

DRIP, DRIP-MOULD or **DRIPSTONE:** *see* HOOD MOULD.

DRIVER, SAMUEL ROLLES (1846–1914), English divine and Hebrew scholar, was born in Southampton on Oct. 2, 1846. He was educated at Winchester and New college, Oxford,

He was a fellow (1870) and a tutor (1875) of New college, and in 1883 succeeded Pusey as regius professor of Hebrew and canon of Christ Church He was a member of the Old Testament revision committee (1876–84) and examining chaplain to the bishop of Southwell (1884–1904). He died on Feb. 26, 1914. Dr. Driver devoted his life to the study, both textual and critical, of the Old Testament. Among his numerous works are commentaries on the books of the Old Testament. His *Introd. to the Literature of the Old Test.* (1897, 9th ed., 1913) became a standard work, and exercised great influence on younger scholars. His other most important work in Hebrew scholarship is to be found in his contributions to the Oxford *Heb. and Eng. Lexicon of the O.T.* (1906). A bibliography of his works is given in appendix B to Cooke's edition of *Ideals of the Prophets* (1915).

DRIVER'S INSURANCE: *see* INSURANCE, MISCELLANEOUS.

DRIVING, a word used in a restricted sense for the art of controlling and directing draught animals from a coach or other conveyance or movable machine to which they are harnessed for the purpose of traction (from "to drive"; *i.e.* generally to propel, force along or in, a word common in various forms to the Teutonic languages). This has been an occupation practised since domesticated animals were first put to this use. In various parts of the world a number of different animals have been, and still are, so employed; of these the horse, ox, mule and ass are the most common, though their place is taken by the reindeer in northern latitudes, and by the Eskimo dog in arctic and antarctic regions. The driving of each of these requires special skill, only to be acquired by practice combined with knowledge of the characteristics peculiar to the several animals employed.

Under all these different conditions driving is a work of utility, of economic value to civilized society. But from very early times driving, especially of horses, has also been regarded as a sport or pastime. This probably arose in the first instance from its association with battle. In the earliest historical records, such as the Old Testament and the Homeric poems, the driver of the chariot fills a place of importance in the economy of war; and on his skill and efficiency the fate of kings, and even of kingdoms, must often have depended. The statement in the Book of Kings that Jehu the son of Nimshi was recognized from a distance by his style of driving appears to indicate that the warrior himself on occasion took the place of the professional charioteer; and although it would be unsafe to infer from the story that the pleasure derived from the occupation was his motive for doing so, the name of this king of Israel has become the eponym of drivers. Among the Greeks at an equally early period driving was a recognized form of sport, to the popularity of which Horace afterwards made allusion. Racing between teams of horses harnessed to war-chariots took the place occupied by saddle-horse racing and American trotting races *(see* HORSE-RACING) in the sport of modern times. The element of danger doubtless gave pleasurable excitement to chariot racing and kept alive its association with incidents familiar in war; just as at a later period, when the institution of chivalry had given the armed knight on horseback a conspicuous place in mediaeval warfare, the tournament became the most popular sport of the aristocracy throughout Europe.

Driving as it is practised to-day for pleasure without profit, and without the excitement of racing, is of quite modern development. Oliver Cromwell, indeed, met with a mishap in Hyde Park while driving a team of four horses presented to him by the count of Oldenburg, which was the subject of more than one satirical allusion by contemporary royalist writers; but two things were needed before much enjoyment could be found in driving, apart from utility. These were the invention of carriages on springs, and the construction of roads with smooth and solid surface. The former did not come into general use till near the end of the 18th century, and it was about the same period that the engineering skill of Thomas Telford and the invention of John London Macadam combined to provide the latter. The influence on driving of these two developments was soon apparent. Throughout the 18th century stage-coaches, ponderous unwieldy vehicles without springs, had toiled slowly over rough and deeply rutted tracks as a means of communication between different parts of Great Britain; but those who made use of them did so as a matter of necessity and not for enjoyment. But by the beginning of the 19th century the improvement in carriage-building and road-construction alike had greatly diminished the discomfort of travel; and interest in driving for its own sake grew so rapidly that in 1807 the first association of amateur coachmen was formed. The two principal driving clubs in recent times have been the Four-in-Hand and Coaching Clubs. The former was founded in 1854 by the then duke of Beaufort, and such was its popularity that the club could not entertain a quarter of the applications for membership. In 1870 therefore the Coaching Club was formed with the duke of Beaufort as president. The meets of these two clubs in Hyde Park were in pre-war days a great feature of the London season, and on two or three occasions the Coaching Club mustered more than 30 coaches. The Four-in-Hand Club after an existence of over 70 years was dissolved in 1926, but the Junior Club in 1927 continued to be well supported, and in this year some 10 to 12 members drove their drags to the three meets which were held. The club at this time numbered 41 members.

Road-coaching has for long been a popular pastime amongst horsemen in the British Isles. Following the supersession of the stage-coaches by railways an important revival of coaching was initiated in 1866, and up to the time of the World War there were numerous well-appointed stage-coaches running daily in and out of London, notably on the Brighton and Portsmouth roads. On July 13, 1888, J. Selby, the well-known professional coachman, performed his celebrated feat of driving the "Old Times" coach from London to Brighton and back in 7hrs. and 50mins. This drive worked out at an average pace of 13·79m. per hour, horses being changed so smartly that with 8 teams and 14 changes the latter took altogether only 6mins. 12secs. Since the war, owing to economic conditions and the great increase in motor traffic most of these coaches have been compelled to come off the road, but in 1927 the "Old Berkeley" and "Venture" coaches, running respectively to Boxhill and Hampton Court had successful seasons *(see* COACHING).

In modern driving, one, two or four horses are usually employed. When a greater number than four is put in harness, as in the case of the state equipages of royal personages on occasions of ceremony, the horses are not driven but are controlled by "postillions" mounted on the near-side horse of each pair. When two horses are used they may either be placed side by side, in "double harness," which is the commoner mode of driving a pair of horses, or one following the other, in a "tandem." Four horses, or "four-in-hand," are harnessed in two pairs, one following the other, and called respectively the "leaders" and the "wheelers."

Though it is a less difficult accomplishment to drive a single horse than a tandem or four-in-hand, or even a pair, it nevertheless requires both knowledge and the skill that practice alone confers. The driver should have some knowledge of equine character, and complete familiarity with every part of the harness he uses. and with the purpose which each buckle or strap is intended to serve. The indefinable quality known in horsemanship as "good hands" is, partly at least, the result of learning the correct position for the arm and hand that holds the reins. The reins are held in the left hand, which should be kept at about the level of the lowest button of the driver's waistcoat, and near the body though not pressed against it. The driving hand should never be reached forward more than a few inches, nor raised as high as the breast. The upper arm should lie loosely against the side, the forearm horizontal across the front of the body, forming a right angle or thereabouts at the elbow-joint, the wrist bent inwards, and the back of the hand and knuckles facing outwards towards the horses. In this position the three joints of the arm form a kind of automatic spring that secures the "give" to the movement of the horse's mouth which, in conjunction with firmness, is a large part of what is meant by "good hands." But this result is only obtained if the reins be also held with the proper degree of bearing on the bit. What the proper degree may be depends greatly on the character of the horses and the sever-

ity of the bit. Pulling horses must be restrained by a strong draw on their bits, such as would bring other animals to a standstill. But under no circumstances, no matter how sluggish the horses are, should the reins be allowed to lie slack. The driver should therefbre always just "feel his horse's mouth" as lightly as possible; he then has the animal well under control in readiness for every emergency, while avoiding such a pull on the mouth as would cause a high-spirited horse to chafe and fret.

These principles are common to all branches of the art of driving, whether of one, two or four horses. When they are observed no great difficulty confronts the coachman who is content with single or double harness, provided he has acquired the eye for pace and distance, and the instinctive realization of the length of the carriage behind him, without which he may suffer collision with other vehicles, or allow insufficient room in turning a comer or entering a gateway. For before he can have had the practice by which alone this knowledge is to be gained, the beginner will have learnt such elementary facts as that his horses must be held well in hand going down hill and given their heads on an ascent, and to be sparing in the use of the hand-brake, with which most modern carriages are provided. This apparatus is most useful in case of emergency, or for taking weight off the carriage on a really steep descent; but the habit which too many coachmen fall into of using the brake on every trifling decline should be avoided. Its effect is that the horses are continually doing collar-work, and are thus deprived of the relief which ought to be given them by occasional light pole or shaft work instead.

Tandem and Four-in-hand.—When the ambition of the amateur coachman leads him to attempt a tandem or four-in-hand he enters on a much more complex department of the art of driving. In the first place he has now four reins instead of two to manipulate, and the increase of weight on his hand, especially when four horses are being driven, requires considerable strength of wrist to support it without tiring. It is of the first importance, moreover, that he should know instinctively the position in his hand of each of the reins, and be able automatically and instantaneously to lay a finger on any one of them. The driver who has to look at his reins to find the off-side leader's rein, or who touches the near-side wheeler's in mistake for it, is in peril of a catastrophe. It is therefore essential that the reins should be correctly disposed between the fingers of the left hand, and that the driver should as quickly as possible accustom himself to handle them automatically. The coachman should take the reins in his hand before mounting the box-seat, as otherwise his team may make a start without his having the means to control them. It is customary to hitch the reins, ready for him to take them on or through the off-side terret (the ring on the pad through which the rein runs) of the wheeler—the off-side wheeler in four-in-hand. Standing on the ground beside the off-side wheel of his carriage, ready to mount to the box-seat, the coachman, after drawing up his reins till he almost feels the horses' mouths, must then let out about a foot of slack in his off-side reins, in order that when on his seat he may find all the reins as nearly as possible equal in length in his hand. The reins should then be transferred to the right hand disposed as they will be in the left when ready to start, but one finger lower down; the first finger will then be free to hold on to the footboard in mounting the box. When replaced in the left hand after mounting, the leaders' reins should be separated by the forefinger, and the wheelers' by the middle finger. The near-leader's rein will then be uppermost of the four, between the forefinger and thumb; then between the forefinger and middle finger are two reins together—the off-leader's and the near-wheeler's in the order named; while at the bottom, between the middle and third fingers, is the off-wheeler's rein. It will be found that held thus the reins spread immediately in front of the hand in such a way that each several rein, and each pair of reins—two near-side, two off-side, two wheelers', or two leaders'—can be conveniently manipulated; and the proficient driver can instinctively and instantaneously grasp any of them he chooses with his right hand without having to turn his eyes from the road before him to the reins in his hand. Having seated himself on the bolt and transferred the reins, thus disposed, from the right to the left hand, the coachman should shorten them till he just feels his wheelers' mouths and hold back his leaders sufficiently to prevent them quite tightening their traces. Then, when he has taken the whip from its socket in his right hand, he is ready to start. This is an operation requiring careful management, to secure that leaders and wheelers start simultaneously; for if the leaders start first they will be drawn up sharp by their bits. The moment it is desired to start, the team should be given their heads and the "office" to start by the coachman at once easing his left hand. When once started a further adjustment of the reins is usually necessary. The driver should see that his team is going straight. If the leaders and wheelers are not exactly on the same line, this or that rein must be shortened or lengthened as the case may require; and it is to be noticed that as the near-wheeler's and off-leader's reins lie together between the same fingers, a simultaneous shortening or lengthening of these two reins will usually produce the desired result. With rare exceptions, reins should be shortened or lengthened by pushing them back or drawing them forward with the right hand in front of the driving hand, and not from behind it. As soon as the team is in motion the leaders may be let out till they draw their traces taut; but draught should be taken off them on falling ground or while rounding a corner. In rounding a comer a loop of the leaders' rein, on the side to which the turn is to be made, is taken up by the right hand and placed under the left thumb. This "points the leaders," who accordingly make the required turn, while at the same time the right hand bears lightly on the reins of the opposite side, to prevent them making the turn too sharply for safety to the coach behind them. When the turn is made the driver's left thumb releases the loop and the team returns to the straight formation. A circumstance useful to bear in mind is that the swingle-bars are wider than the maximum width of the coach; consequently the driver knows that provided the team and coach are going straight, wherever the bars can pass through with safety—and as they are before his eyes the calculation is easy—the coach will safely follow.

The Use of **the** Whip.—A necessary part of driving four horses or tandem is the proper use of the whip. The novice, before beginning to drive, should acquire the knack—which can only be learnt by practical instruction and experiment—of catching up the thong of the whip on to the stick by a flick of the wrist. Practice and considerable dexterity are required in using the whip on the leaders without at the same time touching, or at all events, alarming or fretting, the wheelers. The thong of the whip should reach the leaders from beneath the swingle-bar. This demands skill and accuracy, especially when striking the near leader, but no coachman is competent to drive four horses until he is able to touch with the whip any particular horse that may require it, and no other.

Essential as is proficiency in the use of the whip when driving four horses, it is even more imperative for the driver of tandem. For in four-in-hand the leaders act in some measure as a restraint upon each other's freedom of action, whereas the leader in tandem is entirely independent and therefore more difficult to control.

In the usual method of harnessing a tandem the lead traces draw direct from the wheeler's trace buckles. They should never be attached to the shafts, as this is a dangerous practice. The above method entails a considerable length of trace, and a trace-bearing-strap passing over the leader's loins is a necessity. Another method consists in having two swingle-bars similar to those used in four-in-hand, by means of which the leader's traces can be reduced to the same length as those of the wheeler.

A tandem, owing to the greater freedom of the leader from control, requires in a sense more delicate handling than a four-in-hand, but the latter supplies the coachman with problems of greater difficulty, and so of greater interest, if only for the reason that he has to deal with the various temperaments of four horses instead of only two, while the weight on the hand is obviously more severe, and a heavy coach load entails extra precautions for safety, especially in driving down hill. In Great Britain the coach-and-four is the more popular.

DROBISCH, MORITZ WILHELM (1802–1896), German philosopher and mathematician, was born on Aug. 16, 1802, in Leipzig, where he became professor of mathematics in 1826, professor of philosophy in 1842 and where he died on Sept. 30, 1896. He regards logic, whose business is the establishment of the general laws of thought, as a formal science independent of psychology. Religion is, for him, the expression of man's desire to escape from the impulses of nature to a divine being whose existence is better demonstrated by the ethical than the teleological proof. Drobisch's support of Herbart appears in his *Beiträge zur Orientirung über Herbart's System der Philosophie* (1834) and in *Neue Darstellung der Logik* (1836). He also wrote *Grundlehren der Religions-philosophie* (1840); *Empirische Psychologie* (1842); *Quaestionum mathematico-psychologicarum spec. I.–V.* (1836–39) and *Über die mathematisclze Bestimmung der musikalischen Intervalle* (1846).

See Neubert, *M. W. Drobisch* (Leipzig, 1902).

DROESHOUT, MARTIN, engraver, born in 1601 and baptized in London on April 26, 1601, was son of Michiel Droeshout and probably the pupil of his father and elder brother John, both engravers. Martin's title to fame is his engraved portrait of William Shakespeare (signed *Martin Droeshout sculpsit*), which appeared in the precious first folio edition of Shakespeare's plays printed in London in 1623. The engraver was only 15 years old at the time of Shakespeare's death and the portrait was therefore not done from life. (*See* SHAKESPEARE PORTRAITS.) Martin Droeshout's later work is superior to this portrait. We may mention his portraits of John Howson, Bishop of Durham, and of John Donne. He also illustrated Captain John Smith's "True Travels" (1630).

DROGHEDA (drŏch'ĕ-dă), municipal borough and seaport, on the southern border of Co. Louth, Eire, on the river Boyne, about 4 mi. from its mouth in Drogheda bay, and 31½ mi. N. by W. from Dublin by rail. Pop. (1936), 14,494.

The earliest notices call the town Inver-Colpa or the Port of Colpa; the present name signifies "The Bridge over the Ford." A synod was convened here in 1152 by the papal legate, Cardinal Paparo; in 1224 was founded a Dominican friary, of which there are still remains; and in 1228 the two divisions of the town received separate incorporation from Henry III. In 1412, Henry IV. granted a charter authorizing the combination of the two towns. In the reign of Edward III. Drogheda was classed with Dublin, Waterford and Kilkenny as one of the four staple towns of Ireland. Richard II. received in its Dominican friary the submissions of O'Neal, O'Donnell and other chieftains of Ulster and Leinster. The right of coining money was bestowed on the town, and several parliaments were held there, including one in 1495, when Poyning's laws were enacted. In the civil wars of 1641 the place was besieged by O'Neal, but was relieved. In 1649 it was captured by Cromwell and the inhabitants brutally massacred. In 1690 it was garrisoned by King James's army, but after the battle of the Boyne it surrendered without a struggle. Drogheda ceased to be a parliamentary borough in 1885, and a county of itself in 1898.

From the close of the 12th century, and for some time after the Reformation, the primates of Ireland lived in Drogheda. Its proximity to Dublin, the seat of government and of the Irish parliament, induced them to prefer it to *Ardmacha inter Hibernicos.* Near Drogheda, in later times, was the primate's castle and summer palace at Termonfeckin, some ruins of which remain.

The ancient fortifications of Drogheda have disappeared save that St. Lawrence gateway remains almost perfect, and there are ruins of the West or Butler gate. St. Peter's chapel formerly served as the cathedral of the modern Roman Catholic archbishopric of Armagh. There was formerly an archiepiscopal palace in the town, built about 1620; and the Dominicans, the Franciscans, the Augustinians, the Carmelites and the Knights of St. John had monastic establishments. Of the Dominican monastery (1224) there still exists the Magdalen tower; while of the Augustinian abbey of St. Mary d'Urso (1206) there are the tower and a pointed arch. There is a blue-coat school, founded about 1727; present buildings, 1870. The industrial establishments comprise cotton, flax and flour mills, sawmills, tanneries, salt and soap-works, breweries, chemical manure, engineering works and the big cement works, one of the largest of its kind in the world. The town is the headquarters of the valuable Boyne salmon-fishery. A brisk sea trade is carried on in agricultural produce.

DROHOBYCZ, a Polish town in the province of Lwow, capital of a district which contains the largest oilfield in Poland. Pop. (1931), 32,622. Oil was first found at Boryslaw and Tustanowice in 1904, and reached its highest production in 1909. Drohobycz has a factory of mineral oil, the largest oil refinery in Poland, and is connected by pipe lines with the chief wells. It also produces mineral gas, gasoline and ozokerite. Russian troops conquered Drohobycz in Sept. 1939 and it fell to Germany in 1941.

DROIT, a legal title, claim or due; a term used in English law in the phrase *droits of admiralty,* certain rights or perquisites assigned by the Crown to the lord high admiral. (*See* also WRECK.) The most important of these in modern times consisted of ships and goods captured in port in time of war; others were flotsam, jetsam, ligan, treasure, deodand, derelict within the admiral's jurisdiction; all fines, forfeitures, ransoms, recognizances and pecuniary punishments; all sturgeons, whales, porpoises, dolphins, grampuses and such large fishes, with the share of some prizes—such shares being afterwards called "tenths," in imitation of the French, who gave their admiral a *droit de dixième.* The droits of admiralty were definitely surrendered to the Crown by Prince George of Denmark, when lord high admiral of England in 1702. In prize law droits of admiralty are distinguished from droits of the Crown which, before 1914, were granted to the captors of ships and cargoes captured at sea by duly commissioned ships of war. (*See* H. C. Rothery, *Prize Droits,* being *A Report to H.M. Treasury on Droits of the Crown and of Admiralty in Time of War* [1915]; also the *Law Quarterly Review,* vol. xxxii., p. 38, and the Naval Prize Act, 1918; also Holdsworth, *History of English Law,* vol. i. pp. 559–561.)

The term *droit* is also used in various legal connections (for French law, *see* FRENCH LAW), such as the *droit* of angary (*q.v.*), the *droit d'achat* (right of pre-emption) in the case of contraband (*q.v.*), the feudal *droit de bris* (*see* WRECK), the *droit de régale* or ancient royal privilege of claiming the revenues and patronage of a vacant bishopric, and the feudal droits of seigniory generally.

DROIT ADMINISTRATIF. French administrative law may be described as that section of law which establishes the different administrative organs of the State and defines their powers as regards individuals. It will thus be noticed at once that there is a very close connection between French constitutional and administrative law since in the former the general plan of the operation of the powers inherent in the State is set out whereas in the latter the various organizations by which these powers are enforced are detailed, or—in another phrase—in constitutional law are to be found the principles whose application is enacted through the channels of administrative law.

France is for administrative purposes divided into "départements" which are subdivided into "arrondissements." The latter are again subdivided into "cantons" with a further subdivision into "communes." These different administrative divisions are

not, however, of equal importance. The "départements" and the "communes" are at the same time electoral constituencies, administrative units and so-called "personnes morales." The "arrondissements" are neither "personnes morales" nor administrative units. The "cantons" are neither legal nor administrative units although they elect a councillor to the conseil *général* and to the conseil *d'arrondissement*. The "communes" form an administrative centre of great activity.

"Droit administratif" is, therefore, concerned with the general interests of the State, the regional interests of the "départements" and the local interests of the "communes," although for reasons of economy it is often enforced by the same agents as in the case of the "préfet" of a "département" who is at the same time an agent of the State and of the "département."

There are several classes of administrative organs, the authorities entrusted with the execution of administrative decisions ("prefets" and "sous-prefets"), mayors, deliberative councils, which must be subdivided into deliberative councils proper, namely, those who have power to take executive decisions (conseil *général*, conseil *d'arrondissement* and conseil municipal) and consulting councils (conseil de *préfecture*, conseil d'e'tat), and finally administrative tribunals entrusted with jurisdiction.

The acts of administrative authority are fundamentally divided into two classes, acts of authority proper or, as they are sometimes called, unilateral administrative acts, by means of which the administration orders or prohibits some action by the subject of its administration, as for instance the order of a mayor prohibiting processions in the territory of his commune, and acts of administration proper by means of which the administrative authorities ensure the safeguard of the property of "personnes morales administratives" and enforce contracts, the nature of these acts being from a legal point of view the same as those of a private citizen. Appeals against acts of so-called authority proper are, however, within the jurisdiction of the administrative tribunals, whereas disputes arising out of acts of so-called administration proper are tried before the ordinary judicial tribunals.

Acts of authority proper are subdivided into "actes individuels" and "actes réglementaires." "Actes individuels" are those concerning a particular individual in connection with a defined object. "Actes réglementaires" are those by which the administrative authority imposes certain restrictions on a body of individuals. The right to do "actes réglementaires" is entrusted as regards the whole State to the president of the republic, as regards the "départements" to the "préfets" and as regards the "communes" to the mayors. This subdivision of acts of authority proper is important as regards jurisdiction, for only "actes individuels" can be appealed against before the ordinary administrative tribunals. The sole means of attacking an "acte réglementaire" is before the conseil *d'état* which may order it to be cancelled as ultra vires.

Private individuals are protected against officials by their power of prosecution before the Criminal Courts in certain cases (Art. 166–195, Crim. Code) and their right of bringing an action before the ordinary judicial tribunals where an official is personally liable, as the responsibility for acts done by an official is only assumed by the administration in cases where the fault is inherent in the service, and thirdly by appeal to the administrative tribunals.

It is true that in case of tort French citizens can only sue officials of the State in their official capacity in the ordinary courts when the act complained of is alleged to have been committed "with malice," and that in the absence of "malice" the private citizen must seek his remedy before an administrative tribunal. It is, however, interesting to compare generally the rights of a French citizen with those of a British subject who, in dealing with State officials or civil servants, finds that he is, in many cases, powerless owing to the immunity these persons enjoy as regards the consequences of acts done in their official capacity. French Administrative Law may be said to be based on the recognition of the fact that the State, regarded as a "personne morale," has two distinct entities, and that in its politic capacity it is a "person" who is responsible for the torts of its servants as well as for contracts made by them on its behalf, and that consequently it may be sued, if not in the ordinary courts, before the administrative tribunal whose existence consequently constitutes a protection for the subject against arbitrary decisions of individuals acting officially, whereas English jurisprudence, as already stated, regards acts done by officials or servants of the Crown still on the mediaeval assumption that as "the king can do no wrong" and "the State is the king," it is not responsible for the torts of its servants. This comparison between the English and French system of jurisprudence may be further emphasized by a consideration of the fact that the French administrative tribunals are real tribunals, acting independently of the executive, whose functions and powers are defined in the Code *Administratif*, whereas under the English rule of law Government departments often exercise *in* camera, and without an oral hearing of the applicant, semi-judicial functions under Statutory Powers which, in practice, confer on them the power of judging their own cause without appeal.

Only cases in which a definite right has been violated can be heard before the administrative tribunals; where private interests only are concerned appeal can be made only to representatives of the administration, following the hierarchical order upwards. As regards the cases which come before the administrative tribunals these are divided into four classes: first, those in which the tribunal examines the matter as regards both law and fact, and decides if a decision is to be upheld or replaced by another; secondly, those in which the tribunal has to decide if any administrative act was ultra vires, in which case it quashes the decision; thirdly, those in which the tribunal is called upon to interpret the scope and intention of an administrative act; and, fourthly, those in which the tribunal has power to impose a penalty in cases where public property has been encroached upon, or a legal usufruct of public utility unobserved. It must be noticed that this last class of case constitutes an infraction of the rule that every illegal act of any kind, the commission of which entails a penalty, falls within the provisions of the Penal Code and must be tried before the ordinary judicial tribunals.

The fundamental principle of the separation of the judicial and administrative authorities was enacted by the law of Aug. 24, 1790, sec. 2 Art. 13 which enacts that the judges may not in any may interfere with the operations of the administrative corps, or summon before them administrators to answer for acts done in carrying out their proper duties. This principle has been so far developed that if during the course of an action before the ordinary judicial tribunals a question arises which might prejudice a decision of the administrative tribunals, the hearing must be suspended pending a decision by the latter. In cases, however, of "expropriation" on grounds of public utility, in which a decision must be given by the judicial tribunal, the latter may refuse to make an order if all the legal formalities required have not been duly carried out by the administrative authorities.

Finally certain matters which should, according to their nature, be brought before the judicial tribunals have by law been allotted to administrative tribunals, *e.g.*, questions arising out of the contracting for public works, the sale of any part of the national domain and the declaration of the State as a debtor.

Administrative tribunals are divided into tribunals of first instance and those of appeal. The mayor and the council of the prefecture always constitute tribunals of first instance. The "prefets" and the competent minister constitute sometimes tribunals of first instance and sometimes tribunals of appeal. The conseil d'e'tat is in principle an appeal tribunal, although in certain cases it is a court of first and last instance, and even a court of cassation. The *cour des comptes* except in one instance is a court of first and last instance. These tribunals are also subdivided into tribunals competent to hear and determine all matters which have not been specially reserved, and special tribunals for the trial of the latter class of cases.

Ordinary tribunals are in the first instance that of the competent minister and in the second instance the conseil d'e'tat. Special tribunals for the hearing of general cases are the council of the prefecture. the "prefet," the "sub prefet" and the mayor.

Special tribunals with special functions are those of the *cour des comptes*, the maritime prefects, the council of public instruction, the tribunals with jurisdiction concerning the issue of coinage,

that of the sanitary police, that for excess values and that for the colonies.

Administrative judges are removable, with the exception of those of the *cour des comptes.* (F. No.)

DROITWICH, market town and municipal borough, Evesham parliamentary division, Worcestershire, England, 5½ mi. N.N.E. of Worcester, and 126 mi. N.W. from London by the G.W.R., but served also by the L.M.S.R. Pop. (1938) 4,662. Area 2.7 sq.mi. It stands on the river Salwarpe, a tributary of the Severn, being connected with the latter by canal. There are three parish churches, St. Andrew, St. Peter and St. Michael, of which the first two are fine old buildings in mixed styles. The principal occupation is the manufacture of the salt obtained from the brine springs or *wyches,* to which the town probably owes its name and origin. The springs also give Droitwich a considerable reputation as a health resort. There are Royal Brine baths (with a clinic), St. Andrew's baths and a private bath hospital. Owing to the pumping of the brine there is a continual subsidence of the ground, detrimental to the buildings, and new houses are mostly built in the suburbs. In the pleasant well-wooded district surrounding Droitwich the most noteworthy points are Hindlip Hall, 3 mi. S., where (in a former mansion) conspirators in the Gunpowder Plot defied search for eight days (1605); and Westwood. a fine hall of Elizabethan and Carolean date on the site of a Benedictine nunnery, 1 mi. west of Droitwich, which offered a retreat to many royalists during the commonwealth.

A Roman villa, with various relics, has been discovered here. but it is doubtful how far the Romans made use of the brine springs, which are also mentioned in several charters before the conquest. At the time of the Domesday survey all the salt springs belonged to the king, who received a yearly farm of £65, but the manor was divided between several churches and tenants-in-chief. The burgesses of Droitwich (*Wic, Saltwic, Wich, Drightwich*) are mentioned in the Domesday survey. The town is first called a "burgus" in the pipe roll of 1155–56, but the burgesses did not receive their first charter until 1215, when Ring John demanded a fee-farm of £100. The payment of the fee-farm gradually lapsed in the 18th century. In mediaeval times Droitwich was governed by two bailiffs and twelve jurats. Queen Mary granted the incorporation charter in 1553–54 under the name of the bailiffs and burgesses. James I in 1625 granted fuller charter, which remained the governing charter until the Municipal Reform act. King John's charter granted the burgesses a fair on May 9, to last for eight days, but Edward III in 1330 granted instead two fairs, on Dec. 29 and Oct. 28 and three days after. Queen Mary granted three new fairs. In recent times fairs were held in June and December, but these have lapsed and now none is held. James I changed the market day from Monday to Friday.

DRÔME, a department of south-east France, formed of parts of Dauphiné and Provence, and bounded on the west by the Rhone, which separates it from Ardkche, north and north-east by Iskre, east by Hautes-Alpes, south-east by Basses-Alpes and south by Vaucluse; area 2,533 sq.mi ; pop. (1936) 267.281. Drôme is watered by tributaries of the Rhone, including the Iskre in the north, the DrBme in the centre and the Aygues in the south, flowing from spurs of the Alps westwards to the alluvial plains on the left bank of the Rhone. North of the Drôme lie the Vercors and the Royans, a region of forest-clad north to south ridges. South of that river the mountain system is intersected everywhere by torrents. In the east of the department the mountains of the Dévoluy reach 7,890 ft. North of the Iskre a district of low hills stretches to the limits of the department in the Valloire, its most productive portion. The climate, except in the valleys bordering the Rhone, is cold, and winds blow incessantly. Snow lies on the mountain-tops during the greater part of the year.

The agriculture of the department is moderately prosperous. The main crops are wheat, grown chiefly on the banks of the Isère and Rhone, oats and potatoes. Large flocks of sheep feed on the pastures in the south; cattle-raising is carried on principally in the north-east. Good wines, among which the famous Hermitage growth ranks first, are grown on the hills and plains near the Rhone and DrBme. Fruit culture is much practised. Olives and figs are grown in the south; the cultivation of mulberries and walnuts is more widely spread. The rearing of silkworms in Drôme is very important. The Montélimar district is noted for its truffles. Mineral products include lignite, blende, galena, calamine, freestone, lime, cement, potter's clay and kaolin. Brick and tile works, potteries and porcelain manufactories exist in several localities. Industries comprise flour-milling, distilling, wood-sawing, turnery and dyeing. The chief textile industry is the preparation and weaving of silk, which is carried on in a number of towns. Woollen and cotton goods are also manufactured. Leather working and boot-making, carried on on a large scale at Romans, are important, also the manufacture of machinery, hats, confectionery and paper. Drôme exports fruit, nuts. oil. cheese, wine, wool, live stock and its manufactured articles; the chief import is coal. It is served by the Paris-Lyon railway, and the Rhone and Iskre furnish over 100 m. of navigable waterway. The canal de la Bourne, the only one in the department, is used for purposes of irrigation only. Drôme is divided into the arrondissements of Valence, Die and Nyons, comprising 29 cantons and 378 communes. The capital of the department of Drôme is Valence, the seat of a bishopric of the province of Avignon. The department forms part of the académie (educational division) of Grenoble, where its court of appeal is also located. and of the region of the XIV army corps (Lyons).

Besides Valence, the chief towns of the department are Die, Montélimar, Crest and Romans. Nyons is a small industrial town with a mediaeval bridge and remains of ramparts. Suze-la-Rousse is dominated by a fine chbteau with fortifications of the 12th and 14th centuries; in the interior the buildings are in the Renaissance style. At St. Donat there are remains of the palace of the kings of cisjuran Burgundy; though but little of the building is of an earlier date than the 11th century, it is the oldest example of civil architecture in France. The churches of Léoncel, St. Restitut and La Garde-Adhémar, all of Romanesque architecture, are also of antiquarian interest. St. Paul-Trois-Chbteaux, an old Roman town, once the seat of a bishopric, has a Romanesque cathedral. At Grignan there are remains of the Renaissance château where Madame de Sévigné died. At Tain there is a sacrificial altar of A.D. 184.

DROMEDARY, a name for swift riding camels (q *v.)* of the Arabian (one-humped) or the Bactrian (two-humped) species.

DROMICEIDAE: *see* **EMU.**

DROMORE, a market town of Co. Down, Ireland, on the Upper Lagan, 17½ mi. S.W. of Belfast by rail. Pop. of urban district (1926), 2,229. The bishopric here grew out of an abbey of Canons Regular attributed to St. Colman in the 6th century and was united in 1842 to Down and Connor. The town and cathedral were wholly destroyed during the insurrection of 1641, and the present church was built by Bishop Jeremy Taylor in 1661. Remains of a castle and earthworks are to be seen, together with a large rath, or encampment, known as the Great Fort. The town gives its name to a Roman Catholic diocese. Manufacture of linen is the chief industry.

DROMOS, the open air passage, enclosed between stone walls, leading down to the entrance of Greek "beehive" tombs.

DRONE, in music, the bass pipe or pipes of instruments of the bagpipe type, having no lateral holes and therefore giving out the same note without intermission as long as there is wind in the bag, thus forming a continuous pedal, or drone bass. The drone pipe has, instead of a mouthpiece, a socket fitted with a beating reed, and inserted into a stock or short pipe immovably fixed in an aperture of the bag. The Greek classics allude to the existence of a pipe with a drone, either of the arghool or the bagpipe type.

DRONFIELD, a town and urban district of Derbyshire, England, 6 mi. S. of Sheffield, on the L.M.S. railway. Pop. (est. 1938) 6,609. Area, 5.4 sq mi. It is on the river Drone, a tributary of the Rother. There are extensive foundries. Spades, shovels, reaping hooks, sickles and scythes are made. Coal is mined in the neighbourhood. The church of St. John the Baptist, with a lofty spire, is a good example of Decorated work, with

Perpendicular additions.

DRONGO or King Crow, an Old World group of birds of the family *Dicruridae;* the plumage is usually black and the tail forked. The drongos inhabit Africa, south-eastern Asia and the Malayan region to Australia. The largest genus, *Dicrurus*, includes the black drongo (D. ater), the ashy drongo (D. longicaudatus), and the white-bellied drongo. Drongos are mimicked by three species of drongo-cuckoos (*Surniculus*), which lay their eggs in the drongos' nests.

DROP FORGING. Drop forging is the production in quantity of articles in metal by means of a falling weight forcing the heated material into a die. It is only within the last 60 years or so that drop forging as it is known to-day has been practised. Since the beginning of this century great development has taken place owing to the growth of the motor industry and the increasing demand for mechanical transport. An enormous number of the parts of an automobile are now drop forged, *e.g.,* the engine crankshaft, connecting rods, bearing caps, tappets, rockers, valves, flywheels, gears, actuating forks, couplings, levers and lever brackets. On the chassis. the front axles, back axle casings, swivels, stub axles, wheel hubs, steering levers, brake levers, pedal levers and plates, differential gears and pinions, brake shoes and brackets are all made by this method, even small articles such as wind-screen pillars, wing-nuts and stainless door-handles being made under the drop hammer. The development of aviation finds much employment for drop forging in connection with propeller hubs, crankshafts, connecting rods, valves, brackets, gears, etc. Great accuracy is demanded for this work, both for weight and strength; very fine limits are imposed, and the forgings are subjected to severe tests by the Aeronautical Inspection Directorate. Many other industries use drop forged articles, common products being scissor blanks, surgical instruments and heavy gears for railway work.

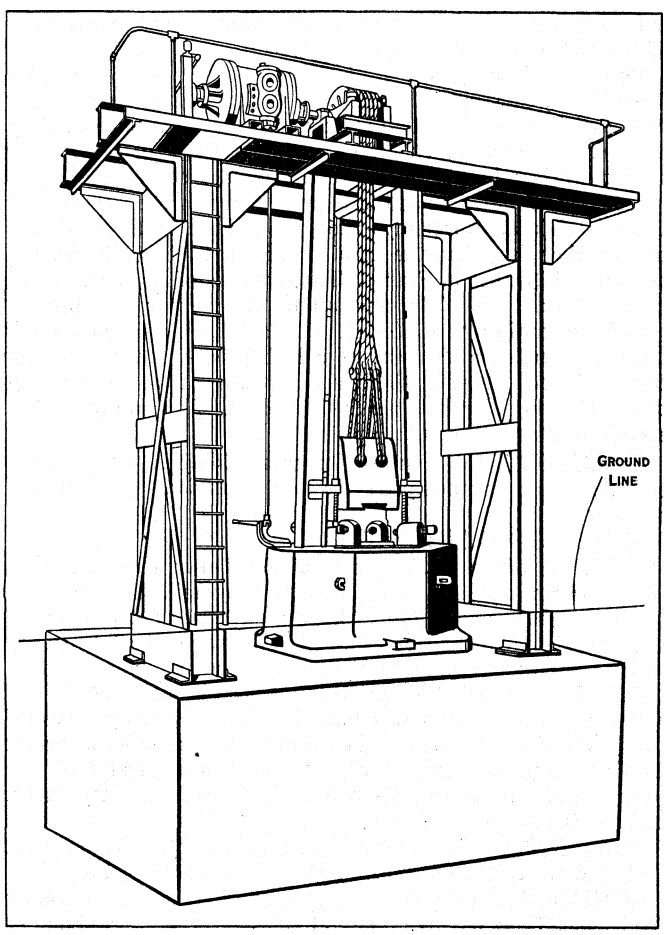

FIG. 1.— DIAGRAM OF TYPICAL DROP HAMMER WITH STEAM LIFTER
Weighing anything from 1 cwt. to 4 tons, the anvil being at least 15 times as heavy, the hammer or "tup" is raised by lifting arms operated by steam power. Guide rods fixed in the anvil control its fall

Drop forging is essentially a moulding operation, the metal being worked with the aid of machines at a sufficient heat to bring it to a plastic condition, but never to the molten condition necessary for the production of castings. Drop forged articles are frequently confused with castings, but the manufacturing process is entirely different.

The hammer used in drop forging operations consists of a forged or cast block of steel, commonly called the "tup" and weighing anything from 1 cwt. to 3 or 4 tons, which is lifted to a height and then allowed to fall or "drop" on to the anvil block by its own weight. The fall is controlled by guide rods or slides bolted to, or fixed in, the anvil block. The lifting apparatus varies in detail, but in its essentials consists of pulleys exerting a variable friction pull on a belt connected with the tup, manipulated with cords or levers usually by hand (fig. 1). The hammers mostly used in Great Britain are those delivering a gravitation blow by a falling weight impinging on an unyielding anvil, but steam hammers are also used, where the tup is attached to a piston rod and propelled downwards and lifted up by means of steam or compressed air. The anvil receives the whole of the energy delivered by the hammer whenever a blow is struck except the small amount absorbed in compressing the stamping, and therefore the ratio of the weight of the hammer to the weight of the anvil block is of great importance; a minimum ratio of 15 to 1 is usual, *i.e.,* a 1 ton hammer will have a 15 ton anvil block and so on.

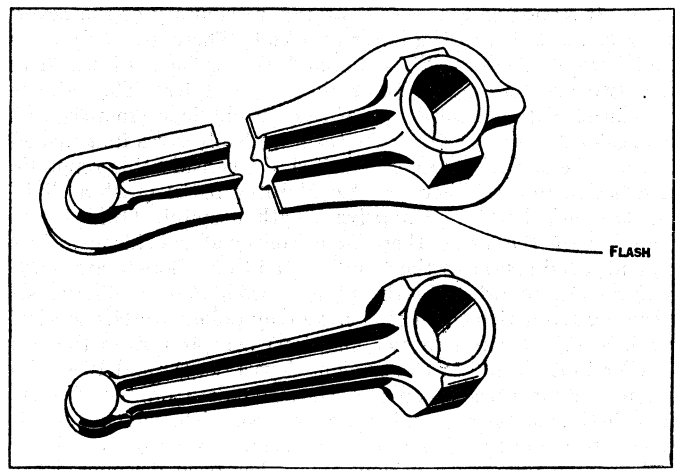

FIG. 2.— DROP-FORGED ROD BEFORE AND AFTER FLASH HAS BEEN REMOVED
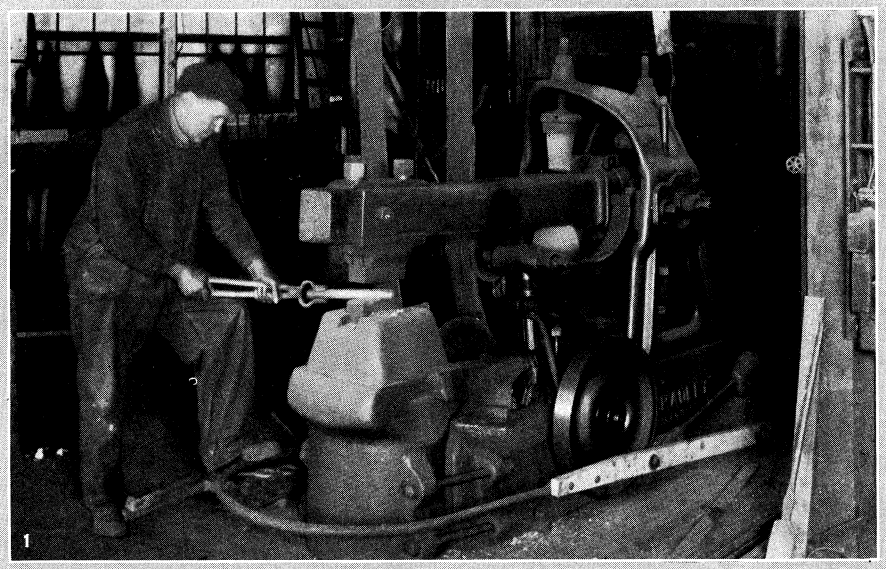
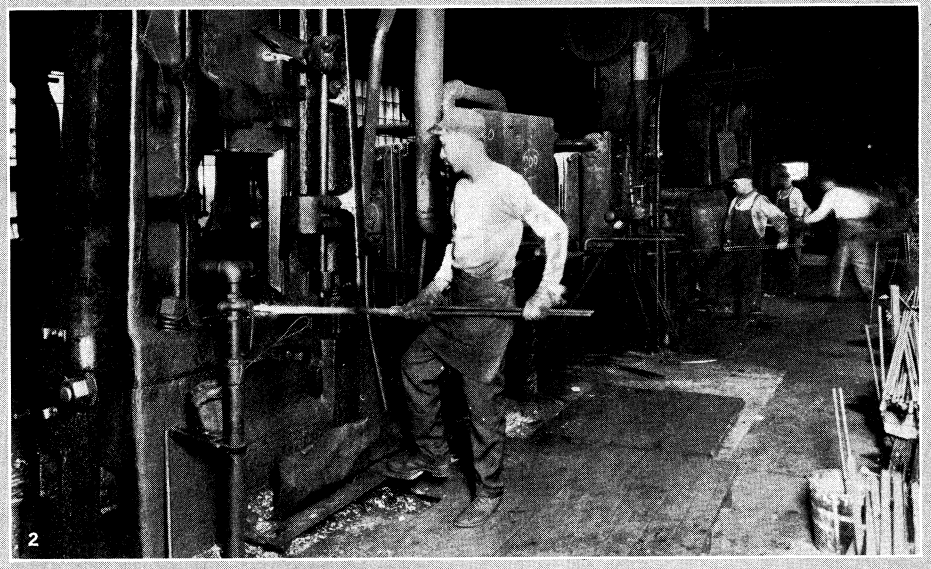
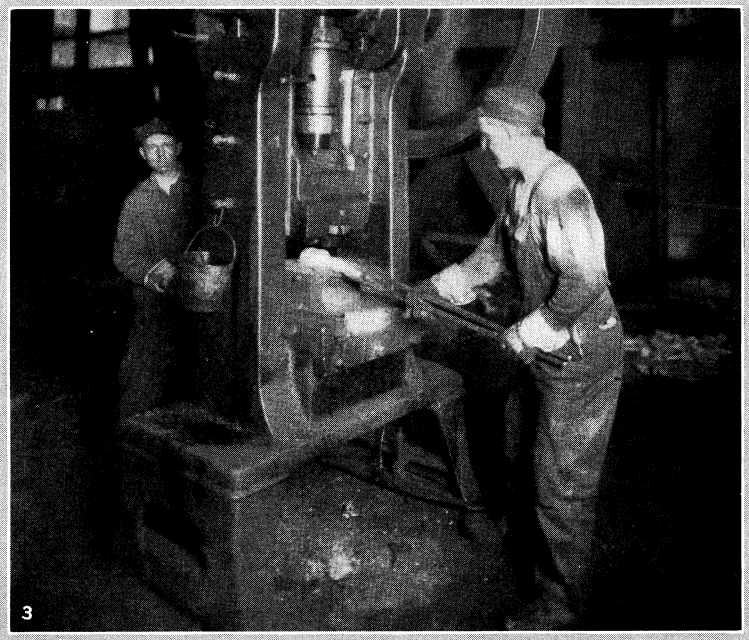
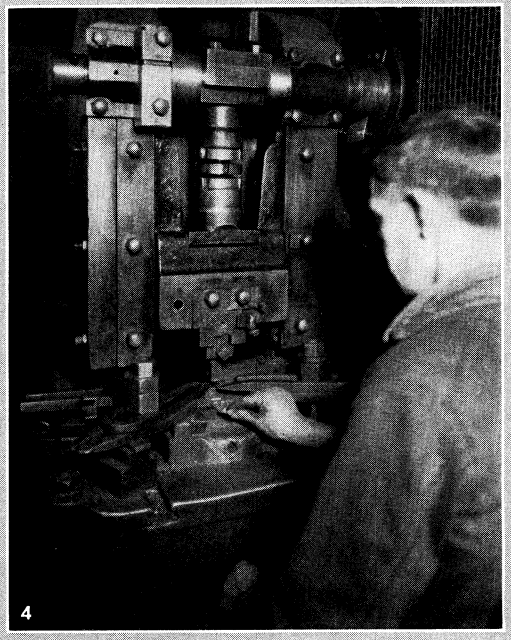
When the metal is being forged, a certain amount, known as the "flash," is pressed out at junction of dies (upper figure). It is removed by trimming tools, and the finished forging is then ready for machining (lower figure)

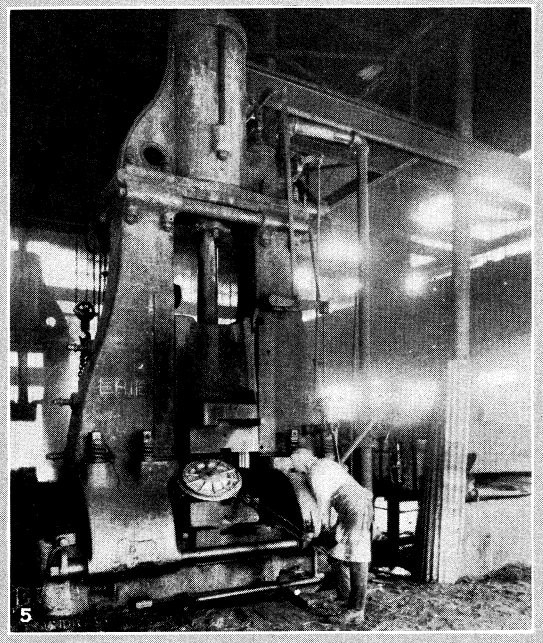
Die Block.—For the manufacture of a drop forged article, impressions are sunk in two die blocks to the exact shape and size of the pattern required. Careful attention is paid to the cutting of these dies which are frequently of a very intricate pattern; very expensive steel is usually employed and highly skilled workmen are engaged. One die is fixed in the tup and the other is fixed on to the anvil block by means of poppet pins or keys; the metal to be forged, which has previously been heated in an adjacent furnace to a malleable condition, is placed between these dies, and several blows in quick succession are struck by the hammer, thus forcing the metal evenly into the die impressions. The number of blows required must be gauged with some accuracy by the stamper; too few blows will not obtain uniform strength in the forging, while too many will shorten the life of the dies. A certain quantity of metal is extruded at the point where the two dies meet, and this surplus metal, called the "flash" or "fin," is removed on completion of the forging operation by means of a pair of trimming tools fixed in a press; one of these tools resembles the pattern of the article required and the other is made hollow to the outline of the pattern at the point of the flash (fig 2). The forging, placed in the press, is forced through the hollow tool by the solid one and the flash is cut off, the forging being subsequently returned to the hammer for one more blow to correct any possible distortion or bending which may have taken place during the trimming operation.











BY COURTESY OF (1) C. C. BRADLEY AND SON, INC., (2) THE CHAMBERSBURG ENGINEERING COMPINY. (3) E. W. BLISS COMPANY, (4) THE KILBORN AND BISHOP COMPANY, (5) THE ERIE FOUNDRY COMPANY

DROP–FORGING HAMMERS AND TRIMMING PRESSES

1. Trip hammer forger; a substitute for sledge hammer
2. Board drop hammer; lifts by power, drops by gravity
3 and 4. Trimming presses: 3, hot trimming; 4, cold trimming
5. Steam drop hammer; force of each blow under direct control of operator

On the completion of the forging operation, the forgings are usually subjected to heat treatment to relieve the metal of any strains set up during stamping and also to render it most suitable for machining operations should these be required. Heat treatment is an integral part of the manufacture and is carried out by highly experienced workmen; perfect control and knowledge of temperature is vital, as the necessary strength and hardness can only be obtained if the treatment is correct.

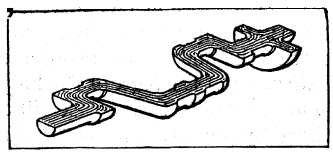


FIG. 3.—DROP-FORGED CRANK-SHAFT. SHOWING GRAIN ARRANGED TO FOLLOW CONTOUR OF CRANK-SHAFT

All wrought metals have in a marked degree "grain" or "fibre" and great care has to be taken in forging to see that the grain is worked into a position parallel to the principal stresses likely to occur in the article to be forged. Grain must never be allowed to run transversely to the axis of the greatest bending stress (fig. 3). This is one of the great advantages of drop forgings over castings. In a casting, where the metal is melted down and poured into a mould, the structure becomes crystalline and not fibrous; but in a drop forging, always made from bars or billets which have the grain running longitudinally, very careful attention is paid to the disposition of this grain, so that if there is a bending stress it goes across the longitudinal grain and not between it.

Drop forgings are made in many metals; besides the various alloy steels, stainless steels and iron, brass, yellow metal, cupro-nickel, aluminium, duralumin, magnesium, etc., are used. Considerable progress has been made with the forging of these light allovs. Some of them are exceedingly difficult to forge, and the greatest accuracy in gauging the forging temperatures is required.

(K. R. C.)

IN THE UNITED STATES

Drop forging is divided into four classes, dependent on the type of machine used. They are: (1) trip hammer forging; (2) drop hammer forging; (3) upsetting; and (4) press forging.

Trip hammer forging is done with a power-driven sledge hammer so arranged that successive blows strike in exactly the same place. The helve type of trip hammer consists of (1) a base or anvil on which there is held a die; and (2) an arm or helve fixed at one end, the other end of which is mechanically raised and lowered. On the moving end of the helve there is fastened a second die which strikes against the die held on the anvil. Another type of helve hammer makes use of an auxiliary ram between the helve and the upper die. The ram operates between vertical guides and is loosely connected to the helve. The advantages of a trip hammer are the rapidity with which it delivers its blows and the ease with which the operator can instantly change the force of the blow from zero to the maximum of the machine. Typical examples of the type of forgings made by this process are the various types of chisels, punches and picks.

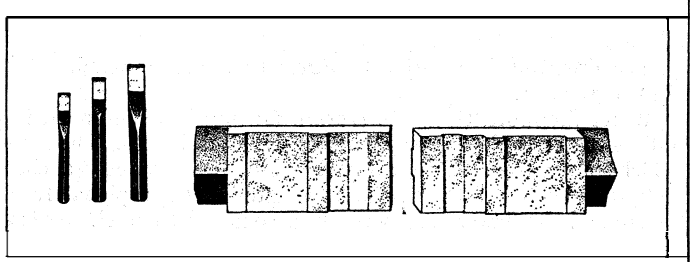

FIG. 4.— TRIP HAMMER DIES FOR FORGING COLD CHISELS. SHOWING THREE SIZES OF CHISELS PRODUCED IN SUCH DIES

Fig. 4 shows a typical pair of trip hammer dies used to forge cold chisels. This pair of dies is designed to forge three sizes of chisels.

Drop hammer forging is that branch of the forging industry which utilizes a machine called a drop hammer. A drop hammer consists of a base, a hammer or ram which strikes the base and which travels vertically between side guides, and the overhead mechanism for lifting the hammer and releasing it. In the board drop hammer (Plate I. fig. 2), a board, generally of maple, raises the ram. The lower end of the board is fastened to the upper portion of the ram and the upper end of the board travels between two rolls which revolve in opposite directions. Automatic mechanism is provided so that the rolls alternately squeeze the board and, revolving, lift it. The rolls are then spread apart, allowing the ram to fall. The steam drop hammer (Plate I. fig. 5) utilizes a steam cylinder for the lifting mechanism, the piston rod taking the place of the board and the ram being fastened to the lower

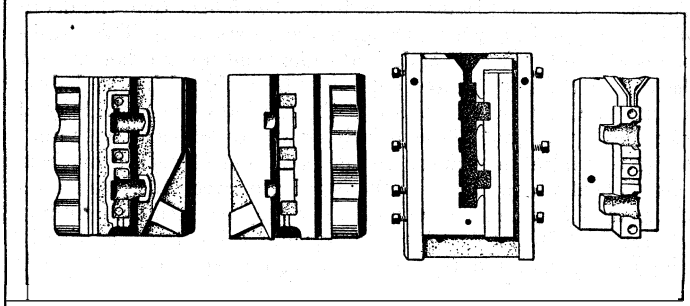

FIG. 5.— FORGING AND TRIMMING DIES FOR A CROSSHEAD SUPPORT FORGING

end of the piston rod. The air drop hammer is fundamentally the same as the steam hammer, but uses compressed air instead of steam.

For forging with the drop hammer there is used a set of tools known as forging dies, which are blocks of steel used in pairs. The dies are cut or dug out so that when the two cut-out blocks are put face to face, the hollow included between them has the exact shape of the forging which they are designed to produce. (See fig. 5.) One of the dies is solidly fastened to the base or anvil, while the other is fastened to the lower end of the ram. The overhead mechanism of a drop hammer is automatic. The hammer travels to the top of its stroke and is released, causing the die block fastened to it to strike against the one on the base, after which the ram is instantly raised. The operation of drop forging consists of heating any suitable metal to a temperature at which it is malleable, placing it on the lower die block and allowing the upper die block to fall on it repeatedly, forcing the metal into the shape defined by the sunk or cut-out portion of the dies. The making of drop forgings can be considered as divided into (1) the making of the dies and (2) the production of the forgings.

Die Making.— In making dies it must be remembered that it is not possible to forge all shapes. No hole or depression in a drop forging may be larger at the bottom than at the top, although it may be smaller. In actual practice it must be slightly smaller by an amount equal to the "draft," as the angle at the side of every depression is called. No surface of a drop forging may be parallel to the path of travel of the dies, but must depart from parallelism by an amount not less than the draft angle and in the direction which will make all parts of the forging smaller at the bottom of the impression in each die than at the top. The usual draft angle in drop forging is 7°.

It is possible to forge many different kinds of materials, among them being iron, copper, certain of the brasses, bronze, aluminium, monel metal, nickel and a great number of alloys of these and similar metals. By far the greatest number of forgings are made from steel and its alloys. Typical examples are wrenches, pliers, chisels, hammers, parts of machines of all kinds and automobile connecting rods, crank shafts, manifold flanges and clevis bolts. The die design is influenced by the quantity which is to be made at one setting of the dies as well as by the quantity eventually wanted. Dies may be so designed as to make two or more forgings at once, later to be cut apart by trimming. Since metal is forged while hot and shrinks in cooling, that fact must be allowed for when making dies. All forging dies are made larger than the size which the piece is to be when cold, by an amount equal to the shrinkage. The cutting of die blocks proceeds in several stages, each designed to the end that the final or finishing stage will produce the exact forging wanted.

After the finishing cut is made and the impression is completed,

the accuracy of the work is tested by placing the two die blocks face to face and pouring melted lead into the impression and allowing it to harden; afterwards, this lead cast which has the shape of the desired forging is examined. The quantity of forgings which one pair of dies will produce varies from perhaps 100 pieces under the worst to perhaps 500,000 under the best conditions. The normal life for steel pieces lies between 10,000 and 40,000.

Upsetting is done with a drop hammer by making a hole in the bottom die and placing in the hole a bar longer than the depth of the hole and allowing the upper die to strike it. This mushrooms the end. When it is desired to have an upset other than at the end of the bar the lower die may be designed in two halves so that one may be removed and the forging taken out. Special machines embodying these principles are called upsetters, bulldozers or forging machines. In the operation of such a machine a bar is heated and placed in the opening between the two halves of a pair of gripping dies, one of which may be fixed or both may be movable. The two halves of the die come together tightly gripping the bar and then the ram is forced against the end, upsetting it and also forcing the metal to fill any shaped impression which may be in the gripping dies. The ram then returns and the gripping dies open for the operator to remove the piece.

Press forgings are made in toggle joint or hydraulic presses using dies in the same general manner as in the drop hammer method, the difference being that a slow push is used instead of the quick, heavy blow of a ram. Presses are also used for sizing forgings, taking the place of cold striking in a drop hammer. *(See* PRESSES and PRESSWORK.) (H. K.)

DROPSY, the name given to a collection of serous fluid in all or any of the cavities of the body, or in the meshes of its tissues. Dropsy of the subcutaneous connective tissue is termed *oedema* when it is localized and limited in extent; when diffuse it is termed *anasarca;* the term *oedema* is also applied to dropsies of some of the internal organs, notably the lungs. *Hydrocephalus* signifies an accumulation of fluid within the ventricles of the brain or in the arachnoid cavity; *hydrothorax,* a collection in the pleural cavities; *hydropericardium,* in the pericardium; *ascites,* in the peritoneum.

Dropsy (excluding "epidemic dropsy," for which *see* below) is a symptom and not a specific disease, being the exaggeration of a normal condition. Fluid, known as lymph, is continually passing through the capillary walls into the tissues, and in health this is removed as fast as it is exuded, in one or more of three ways; part is used in the nutrition of the tissues, part is returned to the general circulation by the veins, and part by the lymphatics. Any accumulation constitutes dropsy and is a sign of disease, though not a disease in itself. The serous effusions due to inflammation are not included under the term dropsy. A dropsical fluid varies considerably in composition according to its position in the body, but only slightly according to the disease which has given rise to it. Its specific gravity ranges betwen 1,008 and 1,018; the mineral salts present are the same in amount and kind as those of blood and do not vary with the position of the exudation. The quantity of albumin, however, depends much on the position of the fluid, and slightly on the underlying disease. In oedema the fluid contains only traces, whereas a pleural or peritoneal effusion is always highly albuminous. Also an effusion due to heart disease contains more albumin than one due to kidney disease. In appearance the fluid may be colourless, greenish or reddish from the presence of blood pigment, or yellowish from the presence of bile pigment; transparent or opalescent or milky from the presence of fatty matter derived from the chyle.

The simplest cause of dropsy is purely mechanical, blood pressure being raised beyond a certain point owing to venous obstruction. This may be due to thrombosis of a vein as in phlegmasia dolens (white leg), retardation of venous circulation as in varicose veins, or obstruction of a vein due to the pressure of an aneurism or tumour. Cardiac and renal dropsy are more complicated in origin, but cardiac dropsy is probably due to diminished absorption, and renal dropsy, when unassociated with heart failure, to increased exudation. But the starting-point of acute renal dropsy, of the dropsy sometimes occurring in diabetes, and that of chlorosis is the toxic condition of the blood. For accounts of the various local dropsies *see* HYDROCEPHALUS; ASCITES; LIVER; etc. General dropsy, or dropsy which depends on causes acting on the system at large, is due chiefly to diseases of the heart, kidneys or lungs, occasionally to lardaceous disease, more rarely still to diabetes or one of the anaemias.

The natural tendency of all heart diseases is to transfer the blood pressure from the arteries to the veins, and, so soon as this has reached a sufficient degree, dropsy in the form of local *oedema* begins to appear at whatever may be the most dependent part of the body—the instep and ankle in the upright position, the lower part of the back or the lungs if the patient be in bed—and this tends gradually to increase till all the cavities of the body are invaded by the serous accumulation. The diseases of the lungs which produce dropsy are those which obstruct the passage of the blood through them, such as emphysema and fibrosis, and thus act precisely like disease of the heart in transferring the blood pressure from the arteries to the veins, inducing dropsy in exactly a similar manner. The dropsy of renal disease is dependent for the most part on an excess of exudation, due largely to an increase of arterial and cardiac tension. This in its turn produces arterial thickening and cardiac hypertrophy, which, if the case be sufficiently prolonged, brings about a natural removal of the fluid. In kidney cases, in the absence of cardiac disease, the dropsy appears first about the loose cellular tissue surrounding the eyes.

For the treatment of dropsy the reader is referred to the articles on the diseases of which it is a symptom. Briefly, tapping of the abdomen or puncture of the legs are resorted to in severe cases. Dehydration by diet may be valuable when the dropsy is other than renal. And there is the routine treatment by drugs, purgative, diaphoretic and diuretic as the symptoms of the case may demand.

Differing from the preceding is *epidemic dropsy,* the first recorded outbreak of which occurred in Calcutta in the year 1877. It disappeared during the hot weather of the following year, only to recur over a wider area in the cold months of 1878 to 1879, and once again in the cold of 1879 to 1880. Since then only isolated cases have been recorded in the immediate neighbourhood of Calcutta, though epidemics have broken out in other places. At thk end of 1902 an outbreak occurred in the Barisal gaol, Bengal, in which nearly one-third of the cases ended fatally. Dropsy was an invariable feature, and was either the first symptom or occurred early. The lower limbs were first affected, trunk and upper limbs later in severe cases, the face very rarely. It was accompanied by pyrexia, gastro-enteritis, deep-seated pains in limbs and body, and burning and pricking of the skin. Various rashes appeared early in the attack, while eczema, desquamation and even ulceration supervened later. Anaemia was very marked, giving rise in Mauritius to the name of acute anaemic dropsy. Death was often sudden, resulting chiefly from cardiac and respiratory complications. Probably it is a vitamin-deficiency disease akin to beri-beri.

DROPWORT, in botany, the common name for *Filipendula ulmaria* (family Rosaceae), found in dry pastures. It is a perennial herb, with much-divided, radical leaves and an erect stem, 2 to 3 ft. high, bearing a loose terminal inflorescence of small white flowers.

The dropwort is a native of Europe and Asia, introduced in North America.

Water dropwort, *Oenanthe crocata* (family Umbelliferae), is a tall, herbaceous plant growing in marshes and ditches. The stem, which springs from a cluster of thickened roots, is stout, branched, hollow and 2 to 5 ft. high; the leaves are large and pinnately divided, and the flowers are borne in a compound umbel, the long rays bearing dense, partial umbels of small white flowers. The plant, which is very poisonous, is often mistaken for celery.
