American Historical and Philosophical Writer. Sometime History Tutor at Harvard University. Author of *The American Revolution; The Beginnings of England;* etc.
GRANT, ULYSSES SIMPSON (in *part).*

J. F. C. F. Major General John F. C. Fuller
Military Assistant to Chief of Imperial General Staff (retired). Chief General Staff Officer, Tank Corps, 1917–8. Author of *Tanks in the Greut War; The Reformation of War; Sir John Moore's System of Training; The Dragon's Teeth; Empire Unity and Defence;* etc. GAUGAMELA; GRANICUS, BATTLE OF THE.

J. Fn. Jack Fulton, B.S.
Managing Editor of *Golfing* and *Golfdom.* GOLF.

J. G. D. Captain J. G. Dollman
Assistant Keeper, Department of Zoology, Natural History Museum, South Kensington. GAME RESERVES *(in part).*

J. G. R. John George Robertson, M.A., Ph.D.
Professor of German Language and Literature, University of London, 1903–33. Author of *History of German Literature; Schiller after a Century;* etc.
GERMAN LITERATURE; GOETHE, J. WOLFGANG VON; etc.

J. H. John Hilton, M.A.
Professor of Industrial Relations, University of Cambridge. Director of Statistics, Ministry of Labour, London, 1919–31.
GENTLEMEN'S AGREEMENTS.

J. H. D. J. H. Driberg
Author of *The Lango, A Nilotic Tribe of Uganda.* GANDA.

J. H. Hes. John Henry Hessels, M.A.
Author of *Gutenberg; An Historical Investigation.*
GLOSS AND GLOSSARY *(in part).*

J. H. McG. James Howard McGregor, M.A., Ph.D.
Professor of Zoology, Columbia University, New York. Author of various papers on Reptilian and Primate Palaeontology.
GORILLA.

J. H. R. John Horace Round, M.A., LL.D.
Late Historical Adviser to the Crown. President, Essex Archaeological Society, 1916–21. Author of *Feudal England; Peerage and Pedigree.* GEOFFREY DE MONTBRAY.

J. I. P. John Isaac Platt, M.Sc., F.G.S.
Lecturer in Geology, University College of Wales, Aberystwytb.
GLACIER.

J. L. My. J. L. Myres, O.B.E., M.A., D.Sc., F.B.A., D.Litt.
Wykeham Professor of Ancient History and Fellow and Librarian of New College, Oxford, 1910–39. General Secretary, British Association for the Advancement of Science, 1919–32. Author of *The Dawn of History; The Political Ideas of the Greeks; Who Were the Greeks;* etc. GORTYNA.

J. L. W. Jessie L. Weston, Litt.D.
Author of *Arthurian Romances.*
GAWAIN; GRAIL, THE HOLY; GUENEVERE.

J. No. John Nolen, Ph.B., A.M., Sc.D.
Former Landscape Architect, Cambridge, Mass. Author of *City Planning; New Ideals in the Planning of Cities, Towns and Villages.* GARDEN CITIES *(in part).*

J. S. B. John Sutherland Black, M.A., LL.D.
Assistant Editor, 9th Edition, *Encyclopædia Britannica.* Joint Editor of *The Encyclopædia Biblica.* GIBBON, EDWARD *(in part).*

J. S. F. Sir John Smith Flett, K.B.E., M.A., D.Sc.
Director, Geological Survey of Great Britain and Museum of Practical Geology, 1920–35. Formerly Lecturer on Petrology in Edinburgh University. GLAUCONITE; GREISEN.

J. T. S. James Thomson Shotwell, Ph.D., LL.D.
Director, Division of Economics and History, Carnegie Endowment for International Peace, New York.
GOLDEN ROSE *(in part).*

J. Wa. James Walker
Advocate of the Scottish Bar. Author of *Intestate Succession in Scotland.* GROUND RENT *(in part).*

J. W. C. John William Cobb, C.B.E., B.Sc., F.I.C.
Livesey Professor Emeritus of Coal, Gas and Fuel Industries in the University of Leeds. GAS MANUFACTURE *(in part).*

J. W. H. James Wycliffe Headlam-Morley, C.B.E.
Assistant Director, Political Intelligence Department of the Foreign Office, 1918–20. Member of the Political section of the British Delegation to the Peace Conference at Paris, 1919. Author of *The History of Twelve Days; The Issue; The German Chancellor and the Outbreak of War;* etc. GERMANY *(in part).*

J. W. L. J. W. Luce, A.B.
Production Manager, The Fleischmann Distilling Corporation, New York. GIN *(in part).*

J. W. Y. John W. Young, Ph.D.
Former Professor of Mathematics, Dartmouth College, Hanover, N. H. President of Mathematical Association of America. Author of *Projective Geometry; Fitndamental Concepts of Algebra and Geometry.* GEOMETRY *(in part).*

K. A. Eck. Karl August Eckhardt
Professor in the Faculty of Law, University of Gottingen.
GERMANIC LAWS, EARLY *(in part).*

K. K. K. Krumbacher
Late Professor of Greek Language and Literature in the University of Munich. GREEK LITERATURE *(in part).*

M. L. M. Max L. Moorhead, **M.A.**
Assistant in History, University of California. GUATEMALA *(in part).*

M. Pa. Rev. Mark **Pattison, LL.D.**
Late Rector of Lincoln College, Oxford.
GROTIUS, **HUGO** *(in part).*

N. A. C. Nelson **Antrim** Crawford, M.A.
Editor-in-Chief of *Household Magazine,* Topeka, Kans. Formerly Director of Information, United States Department of Agriculture, Washington. Co-Author of *Agricultural Journalism.* Formerly lecturer, Graduate School of Agriculture, Washington, D.C. GRANGE, THE.

N. E. C. Norman E. Crump
Statistical Correspondent to the *Financial Times,* London. Member of the Council of the Royal Statistical Society. Joint-Author of *Clare's A. B. C. of the Foreign Exchanges.* GULDEN.

N. G. G. Nicholas G. Gedye, O.B.E., **B.Sc., M.Inst.C.E.**
Consulting Civil Engineer. Formerly Chief Engineer, Tyne Improvement Commission. Served B.E.F. Lt. Colonel (Late R.E.). Acting Director, Civil Engineer-in-Chief's Department, Admiralty. Chief Civil Engineer for Docks, Harbours and Inland Waterways, Ministry of Transport, 1919–21.
GRAVING **DOCK;** GROYNE.

O. B. **Oswald** Barron, F.S.A.
Editor of *The Ancestor,* 1902–5. GENEALOGY *(in part);* GIRDLE.

O. J. **Otto** Jespersen, **Ph.D., Hon.Litt.D., LL.D.**
Professor of English in the University of Copenhagen, 1893–1925. Formerly Corresponding Fellow of British Academy. Formerly Member of Academies of Copenhagen, Oslo, Lund, Helsingfors and Ghent. Author of *Growth and Structure of the English Language; A Modern English Grammar; Language, Its Nature, Development and Origin; The Philosophy of Grammar;* etc.
GRAMMAR.

P. F. K. Percy F. Kendall, **M.Sc.**
Formerly Professor of Geology, Leeds. Author of many geological articles. GLACIAL PERIOD.

P. G. Percy Gardner, **Litt.D., LL.D., F.S.A.,** F.B.A.
Professor of Classical Archaeology, University of Oxford, 1887–1925. Professor Emeritus since 1925. GREEK ART.

P.G.H.B. P. G. H. Boswell, O.B.E., D.Sc., F.R.S., F.G.S., A.R.C.S.
Emeritus Professor of Geology in the University of London. George Herdman Professor of Geology in the University of Liverpool, 1917–1930. Author of *Books on Sedimentary Rocks; Sands for Glassmaking.* GRAVEL OR PEBBLE BEDS; GREYWACKE.

P. G. R. Paul G. Redington
Chief of the Biological Survey of the United States Department of Agriculture, 1927–1942, Washington. GAME LAWS *(in part).*

P. La. Philip Lake, M.A., E.G.S.
Lecturer in Physical and Regional Geography in Cambridge University. Formerly of the Geological Survey of India. Author of *Monograph on British Cambrian Trilobites.* Translator and Editor of Kayser's *Comparative Geology.* GERMANY *(in part).*

P. Leb. **Phileas** Lebergue
Greek correspondent of *Le Mercure de France* under the name of Demetrius Asteriotis. GREEK LITERATURE *(in part).*

P. McC. Primrose **McConnell, B.Sc.,** F.G.S.
Author of *Diary of a Working Farmer;* etc.
GRASS AND GRASSLAND (in *part).*

P. Re. Paul Reboux
Directeur Littéraire, *Les Editions de Laurier,* Paris.
GASTRONOMY.

R. B. Hr. Robert B. Harper
Vice-President in charge of Research and Testing, The Peoples Gas Light and Coke Company, Chicago.
GAS MANUFACTURE (*in part*).

R. C. Bd. Robert Cecil Bald, M.A., LL.B., Ph.D.
Professor of English, Cornell University since 1937.
GREAT BRITAIN (*in part*).

R. C. J. Sir Richard Claverhouse Jebb, O.M., LL.D., D.C.L.
Public Orator, Cambridge University, 1869–75, and Professor of Greek, 1889–1905. Author of *Translations into Greek and Latin;* etc. GREEK LITERATURE (*in part*).

R. D. Ca. R. D. Carmichael, A.B., Ph.D.
Dean of the Graduate School, University of Illinois, Urbana, Ill.
GEOMETRIES, FINITE.

R. G. H. Ralph George Hawtrey, F.B.A.
Assistant Secretary to the Treasury, London. Author of *Currency and Credit;* etc. GREAT BRITAIN (*in part*).

R. H. Ra. Robert Heron Rastall, Sc.D., P.G.S.
University Lecturer in Economic Geology and Fellow of Christ's College, Cambridge. Member of Council of the Geological Society, 1915, and Mineralogical Society, 1918. Attached to War Office, 1915–9. Author of *Geology of the Metalliferous Deposits.*
GEOLOGY.

R. J. Mi. R. J. Milbourne, M.Inst.C.E.
Member of the Council and Chairman (1928–9) of the Society of British Gas Industries. Author of *Gasholder Design and Construction.* GASHOLDERS.

R. McK. Roderick MacKenzie, M.A.
Fereday Fellow of St. John's College, Oxford, and Assistant Editor of the 9th Edition of Liddell and Scott's *Greek-English Lexicon.* GREEK LANGUAGE (*in part*).

R. N. B. Robert Nisbet Bain
Late Assistant Librarian, British Museum. Author of *Scandinavia: The Political History of Denmark, Norway and Sweden, 1513–1900;* etc.
GEDYMIN (*in part*); GODUNOV, BORIS F.; GOLOVIN, FEDOR; etc.

R. P. Bs. Robert Preston Brooks, Ph.D.
Dean, College of Business Administration, University of Georgia. Director, Institute of Public Affairs, University of Georgia. Member Georgia Fact Finding Commission and author of its studies on Taxation. Director, Institute for Study of Georgia Problems. Author of *A History of Georgia; The Agrarian Revolution in Georgia.* GEORGIA.

R. P. G. D. Roderick Peter George Denman, M.A., A.M.I.E.E.
Assistant in the National Museum of Science, London.
GRAMOPHONE (*in part*).

R. Pr. Robert Priebsch, Ph.D.
Professor of German Language and Literature in the University of London, 1902–31. Author of *Deutsche Handschriften in England;* etc. GERMAN LANGUAGE.

R. R. Sir Richard A. Studdert Redmayne, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E.
Past President, Institute of Mining and Metallurgy. Hon. Member, Surveyors' Institute. H.M. Chief Inspector of Mines, 1908–20. Author of *The British Coal Industry during the* War. GOB.

R. Rs. R. Ross
Ministry of Agriculture and Fisheries, London.
GREAT BRITAIN (*in part*).

R. Sch. Robert Schmidt
Director of the Schlossmuseum in Berlin. Author of *Das Glas; Möbel; Brandenburgische Gläser; Chinesische Keramik;* etc.
GLASS (*in part*).

R. U. S. R. U. Sayce, M.A.
Lecturer in Material Culture and Physical Anthropology, University of Cambridge. Formerly Lecturer, Natal University College, Pietermaritzburg, Natal. GRAAFF REINET; GRAHAMSTOWN.

R. W. B. R. W. Burgess, B.A., Ph.D.
Member of American Mathematical Society, American Statistical Association; etc. GRAPHIC METHODS IN MATHEMATICS.

R. W. Rd. Robert W. Richardson, Ph.D.
Chief Social Science Analyst, Co-ordinator of Inter-American Affairs, Washington, D. C. GUAYAS OR EL GUAYAS.

S. A. C. Stanley Arthur Cook, Litt.D., D.D.
Regius Professor of Hebrew, Cambridge, 1932–38. Lecturer in Hebrew and Syriac, Gonville and Caius College, Cambridge. Editor, Palestine Exploration Fund, and Co-editor of the *Cambridge Ancient History.* Author of *Religion of Ancient Palestine;* etc. GENEALOGY (*in part*); GENESIS; GIDEON (*in part*).

S. B. F. Sidney B. Fay, Ph.D., Litt. D., L. H. D.
Professor of History, Harvard University and Radcliffe College, Cambridge, Mass. Author of *Origins of the World War* (2 vols.); etc. GERMANY (*in part*).

S. C. Sir Sidney Colvin, M.A.
Literary and Art Critic. Late Slade Professor of Fine Art, Cambridge University. GIORGIONE (*in part*); GIOTTO (*in part*).

S. G. Stephen Lucius Gwynn
President of the Irish Literary Society since 1932. Author of *Irish Books and Irish People;* etc. GRIFFITH, ARTHUR.

S. H. M. Sydney Herbert Mellone, M.A., D.Sc.
Examiner in Philosophy, Universities of St. Andrews, 1899–1902; London, 1902–6; Edinburgh, 1907–10; in Psychology, Edinburgh, 1913–6. Lecturer in the University of Manchester, 1911–21. Author of *The New Testament and Modern Life; The Price of Progress and other Essays;* etc. GNOSTICISM.

S. Pe. Selig Perlman, Ph.D.
Professor of Economics, University of Wisconsin, Madison, Wisconsin. GENERAL STRIKE (*in part*).

S. R. G. Samuel Rawson Gardiner
English Historian. Sometime editor of the *English Historical Review.* Author of *Student's History of England; Prince Charles and the Spanish Marriage;* etc.
GEORGE I. (*in part*); GEORGE II.; GEORGE IV. (*in part*).

S. T. H. W. Captain S. T. H. Wilton, R.N. (retired)
Late Assistant Director of Naval Ordnance, Admiralty, London.
GREAT BRITAIN (*in part*).

S. W. C. Sydney W. Cole, M.A.
University Lecturer in Medical Chemistry, Cambridge.
GELATIN.

T. A. Thomas Ashby, D.Litt., F.B.A., F.S.A., Hon.A.R.I.B.A.
Formerly Director of the British School at Rome. Author of *Turner's Visions of Rome; The Roman Campagna in Classical Times; Roman Architecture.* Revised and completed for press a *Topographical Dictionary of Ancient Rome* (by the late Prof. J. B. Plattner). Author of numerous archaeological articles.
GELA; GROTTAFERRATA.

T. A. H. Thomas Anderson Henry, D.Sc.
Director, Wellcome Chemical Research Laboratories, London.
GLUCOSIDES, NATURAL.

T. A. S. T. A. Stephenson, D.Sc.
Professor of Zoology, University of Cape Town. GRAPTOLITES,

T. B. Sir Thomas **Barclay, LL.B., Ph.D.**
Vice-President, International Law Association. Author of *International Law and Practice;* etc. GUERRILLA *(in part).*

T. *D.* Thomas **Dillon,** M.A., **D.Sc.**
Professor of Chemistry, University College, Galway. Formerly Assistant to Professor of Chemistry, University College, Dublin. GUMS.

T. E. La. Colonel T. E. Lawrence
Formerly Research Fellow of All Souls, Oxford. Assistant in the British Museum's excavation of Carchemish, 1910–4. Author of *The Seven Pillars of Wisdom; Revolt in the Desert.*
GUERRILLA, *Guerrilla Warfare.*

T. F. H. Talbot F. Hamlin, B.A., **B.Arch.**
Instructor in the History of Architecture, Columbia University, New York. Author of *The Enjoyment of Architecture; The American Spirit in Architecture.*
GOTHIC ARCHITECTURE; GOVERNMENTAL ARCHITECTURE.

T. G. S. Thomas **G. Shearman**
Author of *The Single Tax; Natural Taxation; Distribution of Wealth.* GEORGE, HENRY.

T. H. M. Thomas Hunt Morgan, M.S., **Ph.D., LL.D.**
Professor of Biology, California Institute of Technology. Author of *Evolution and Adaptation; Heredity and Sex; Mechanism of Mendelian Heredity;* etc. GENE.

T. H. R. Theodore H. Robinson, M.A., D.D.
Professor of Semitic Languages, University College, Cardiff.
GIDEON *(in part).*

T.K.R. Sir Thomas Kirke Rose, **D.Sc.,** A.R.S.M.
Chemist and Assayer of the Mint, 1902–26. President, Institution of Mining and Metallurgy, 1915–6. Author of *The Metallurgy of Gold; The Precious Metals;* etc.
GOLD MINING AND METALLURGY.

T. P. H. Thomas P. Hilditch, **D.Sc.,** F.I.C.
Campbell Brown Professor of Industrial Chemistry (Oils, Fats and Waxes) in the University of Liverpool. GLYCERINE.

T. P. Ma. Thomas P. Martin, A.M., **Ph.D.**
Library of Congress, Washington. Formerly Associate Professor of History, Boston University. GREEN, DUFF.

T. S. Thomas Seccombe, M.A.
Formerly Lecturer in History, East London and Birkbeck Colleges, University of London. Stanhope Prizeman, Oxford, 1887. Assistant Editor of *Dictionary of National Biography,* 1891–1901. Author of *The Age of Johnson;* etc. GILBERT, SIR W. S.

T. S. R. Tyler Stewart Rogers, **B.Sc.**
Technical Director, Owens-Corning Fiberglas Corporation, Toledo, Ohio. Author of *Plan Your Home to Suit Yourself.*
GLASS FIBRES.

V. R. B. Victor R. Boswell, M.S., **Ph.D.**
Principal Horticulturist and Assistant Head of Division of Fruit and Vegetable Crops and Diseases, Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C. GARLIC.

W. A. P. W. Alison Phillips, M.A., **Litt.D.**
Lecky Professor of Modern History, Dublin University, 1914–39. Contributor to the *Cambridge Modern History;* etc.
GERMANY *(in part);* GREEK INDEPENDENCE, WAR OF; etc.

W. B. D. William Bell Dinsmoor, S.B.
Professor of Archaeology, Columbia University, New York, and American School at Athens. Co-author of *The Architecture of Ancient Greece;* etc. GREEK ARCHITECTURE.

W. B. Pn. Wheeler B. Preston
Author and publicist.
GIBRALTAR *(in part);* GREAT BRITAIN *(in part).*

W. C. B. T. W. C. B. Tunstall, M.A.
Civilian Lecturer, Royal Naval College, Greenwich. Author, *The Book of Naval Adventures; William Pitt, Earl of Chatham;* etc. GRAND ALLIANCE, WAR OF THE *(in part).*

W. D. La. Walter Davis Lambert, A.M.
Mathematician, United States Coast and Geodetic Survey. Author of *The Effect of the Change of Spheroid on the Mapping of a Region;* etc. GEODESY.

W. D. M. William Diller Matthew, A.M., **Ph.D.,** F.R.S.
Former Professor of Palaeontology and Director, Museum of Palaeontology, University of California, Berkeley, Calif. Author of various scientific treatises on fossil vertebrates. GLYPTODON.

W. E. Cx. Warren E. Cox
Former Art Editor, *Encyclopædia Britannica.* GOTHIC ART.

W. F. C. William Feilden Craies, M.A.
Late Barrister-at-Law, Inner Temple and Lecturer on Criminal Law, King's Cullege, London. Editor of Archbold's *Criminal Pleading* (23rd ed.). GAME LAWS *(in part).*

W. G. M. Walter George **McMillan,** F.C.S., M.I.M.E.
Formerly Secretary of the Institute of Electrical Engineers and Lecturer on Metallurgy, Mason College, Birmingham. Author of A *Treatise on Electro-Metallurgy.* GRAPHITE *(in part).*

W. Gr. William Graham, P.C., M.A.
Former M.P. for the Central Division of Edinburgh. Member of the Royal Commission on Income Tax, 1919. Financial Secretary to the Treasury, 1924. Author of *The Wages of Labour;* etc.
GENERAL STRIKE *(in part).*

W. H. Ch. William Henry Chamberlin
Former American Correspondent in the Soviet Union, the Far East and France. Author of *Japan Over Asia,* etc.
GILBERT AND ELLICE ISLANDS; GUAM.

W. Tho. Wallace Thompson, **B.Sc., Litt.D.**
Former Editor-in-Chief of *Ingenieria Internacional,* New York. Fellow of the Royal Geographical Society. Author of *The People of Mexico; Trading with Mexico; The Mexican Mind; Rainbow Countries of Central America.* GUIANA *(in part);* etc.

X. Initial used for anonymous contributors.

ENCYCLOPEDIA BRITANNICA

VOLUME 10

GAME TO GUN-METAL

GAME, a word which in its primary and widest significance means any amusement or sport, often combined in the early examples with "glee," "play," "joy," or "solace." It is a common Teutonic word, in O.E. *gamen,* in O.H.G. *gaman.* For "game," from the legal aspect, and the laws relating to its pursuit see GAME LAWS. The athletic contests of the ancient Greeks (ἀγῶνες) and the public shows (*ludi*) of the arena and amphitheatre of the ancient Romans are treated below (GAMES, CLASSICAL); the various forms of modern games, indoor and outdoor, whether of skill, strength or chance, are dealt with under their specific titles. A special use ("gaming" or "gambling") restricts the term to the playing of games for money, or to betting and wagering on the results of events, as in horse-racing, etc. (see GAMING AND WAGERING). *See* also CHILDREN'S GAMES.

GAME LAWS, statutes which regulate the right to pursue and take or kill certain kinds of wild animals. For game laws in the U.S. see page 3. In Great Britain by common law wild animals were only property when reduced into possession by being killed or captured. Hence statutes were required to protect sporting rights. Royal rights were protected by special laws (see FOREST LAWS), but where royal rights do not exist the right to take or kill wild animals is incidental to the ownership or occupation of the land on which they are found. In England the chief statutes are the Night Poaching Acts, 1828 and 1841, Game Act, 1831, Poaching Prevention Act, 1862, Ground Game Acts, 1880 and 1906, and acts for the protection of wild birds, of which the latest is the Protection of Lapwings Act, 1928.

Pursuit of game on another's land without his consent is a trespass for which the pursuer is civilly liable, although when deer or hares are hunted with hounds or greyhounds there is no criminal liability. In other cases trespassers may be prosecuted, but the game taken by a trespasser belongs to him unless it was both started and killed on the land of the one owner, when it belongs to such owner. Even so the killing and taking it away as part of one continuous act is not larceny (R. v. Townley, 1871, L.R.1C. C.R. 315). The young of wild animals, before they can fly or run away, belong to the owner of the land on which they are.

Classification of Animals.—Wild animals are classified for purposes of sport in England as follows:—(I) Beasts of royal forest (hart and hind, boar, wolf and all beasts of venery); (2) beasts of chase (a forest in the hands of a subject) and park (an enclosed chase), viz., buck and doe, fox, marten and roe; (3) beasts of warren (roe, hare, rabbit, partridge, pheasant, woodcock, quail, rail and heron); (4) game as defined by the Night Poaching Act, 1828, and the Game Act, 1831, *i.e.,* pheasant, partridge, black game, grouse or red game, bustard and hare (in France game includes everything eatable that runs or flies); (5) wild fowl not mentioned above; *e.g.,* duck, snipe, plovers; (6) other wild birds, protected by the Wild Birds Protection Acts.

Rights of chase, park and free warren depend on Crown grant or prescription founded on lost grant. Free warren is quite different from ordinary warrens, in which hares or rabbits are bred by the owner of the soil for sport or profit. Ground game in such warrens is protected under the Larceny Act, 1861, s. 17, as well as by the game laws. In manors, the lord by his franchise had the sporting rights over the manor, but at the present time this right is restricted to the commons and wastes of the manor, the freehold whereof is in him, and does not extend to enclosed freeholds nor as a general rule to enclosed copyholds, unless at the time of enclosure the sporting rights were reserved to him by the Enclosure Act or award (*Sowerby* v. *Smith,* 1873, L.R. 8 C.P. 514). The Game Act 1831 gives lords of manors and privileged persons certain rights as to appointing gamekeepers with special powers to protect game within the district over which their rights extend (ss. 13, 14, 15, 16). The game laws in no way cut down the special privileges as to forest, park, chase or free warren (1831, s. 9), and confirm the sporting right of lords of manors on the wastes of the manor (1831, s. 10). On lands not affected by these rights, the right to kill or take game is presumably in the occupier. On letting land the owner may, subject to the qualifications hereinafter stated, reserve to himself the right to kill or take "game" or rabbits or other wild animals concurrently with or in exclusion of the tenant. Where the exclusive right is in the landlord, the tenant is not only liable to forfeiture or damages for breaches of covenants in the lease, but is also liable to penalties on summary conviction if without the lessor's authority he pursues, kills or takes any "game" upon the land or gives permission to others to do so (1831, s. 12). In effect he is made criminally liable for game trespass on lands in his own occupation, so far as relates to game, but not if he takes rabbits, snipe, woodcock, quails or rails.

The net effect of the common law and the game laws is to give the occupier of lands and the owner of sporting rights over them the following remedies against persons who infringe their right

to kill or take wild animals on the land. A stranger who enters on the land of another to take any wild animals is liable to the occupier for trespass on the land and for the animals started and killed on the land by the trespasser. He is also criminally liable for game trespass if he has entered on the land to search for or in pursuit of "game" or woodcock, snipe, quail, landrails or rabbits. If the trespass is in the daytime the penalty may not exceed 40s., unless five or more persons go together, in which case the maximum penalty is £5. If a single offender refuses his name or address or gives a false address to the occupier or to the owner of the sporting rights or his representatives or refuses to leave the land, he may be arrested by them, and is liable to a penalty not exceeding £5, and if five or more concerned together in game trespass have a gun with them and use violence, intimidation or menace, to prevent the approach of persons entitled to take their names or order them off the land, they incur a further penalty up to £5.

If the trespass is in search or pursuit of game or rabbits in the night-time, the maximum penalty on a first conviction is imprisonment with hard labour for three months; on a second, imprisonment, etc., for six months, and the offender may be put under sureties not to offend again for a year after a first conviction or for two years after a second conviction. For a first or second offence the conviction is summary, subject to appeal to quarter sessions, but for a third offence the offender is tried on indictment and is liable to penal servitude (three–seven years) or imprisonment with hard labour (two years). The offenders may be arrested by the owner or occupier of the land or their servants, and if the offenders assault or offer violence by firearms or offensive weapons they are liable to be indicted and on conviction punished to the same extent as in the last offence. In 1844 the above penalties were extended to persons found by night on highways in search or pursuit of game. If three or more trespass together on land by night to take or destroy game or rabbits, and any of them is armed with firearms, bludgeon or other offensive weapon, they are liable to be indicted and on conviction sentenced to penal servitude (3–14 years) or imprisonment with hard labour (two years). By "day" time is meant from the beginning of the first hour before sunrise to, the end of the first hour after sunset. It is illegal and severely punishable, however, to set traps or loaded spring guns for poachers, whereby any grievous bodily harm is intended or may be caused even to a trespasser, so that poachers can be prevented only by personal attendance on the scene of their activities; and the provisions of the game laws above stated are, so far as concerns private land, left to be enforced by private enterprise without the interference of the police, with the result that in some districts there are scenes of private nocturnal war. Even in the Night Poaching Act, 1844, which applies to highways, the arrest of offenders is made by owners, occupiers or their game-keepers. The police were not given any direct authority as to poachers until the Poaching Prevention Act, 1862. In all cases of summary conviction for poaching an appeal lies to quarter sessions. In all cases of poaching the game, etc., taken may be forfeited by the court which tries the poacher.

	England and Scotland	Ireland
Hare	March 1 to July 31	March 1 to July 31
Red deer (male)	None	Jan. 1 to June 9
Fallow deer	None	Sept. 29 to June 10
Pheasant	Feb. 2 to Sept. 30	Feb. 2 to Sept. 30
Partridge	Feb. 2 to Aug. 31	Feb. 2 to Aug. 31
Black game	Dec. 10 to Aug. 20*	Dec. 10 to Aug. 20
Grouse or red game	Dec. 10 to Aug. 12	Dec. 10 to Aug. 12
Quail and landrail	March 1 to Aug. 1	Jan. 10 to Sept. 19
Ptarmigan	Dec. 10 to Aug. 12†	Dec. 10 to Aug. 20
Bustard (wild turkey)	March 1 to Sept. 1‡	Jan. 10 to Sept. 1
Snipe, teal, widgeon, wild duck, woodcock and all other kinds	March 1 to Aug. 1§	March 1 to Aug. 1

*Sept. 1 in Devon, Somerset and New Forest.
†Scotland only.
‡England only.
§Also in certain districts under Wild Birds Protection Orders. Lapwings are also protected by the Protection of Lapwings Act, 1928.

Close Time.—Within periods known as "close time," and in England and Ireland on Sundays or Christmas Day, it is illegal to kill game. The present close times are in table in col. 1.

Licences.—The right to kill game is conditional on the possession of a game licence, subject to certain exceptions (Hares Acts, 1848, Game Licences Act, 1860). A licence is not required for beaters and assistants who go out with holders of a game licence. The licence is granted by the Inland Revenue Department. The issue is regulated by the Game Licences Act, 1860, as amended by the Customs and Inland Revenue Act, 1883. The licences now in use are of four kinds:—

Those taken out after July 31—	
To expire on the next July 31	£3 0 0
To expire on the next Oct. 31	2 0 0
Those taken out after Nov. 1—	
To expire on the next July 31	2 0 0
Those taken out for any continuous period of 14 days specified in the licence	1 0 0

In the case of gamekeepers in Great Britain for whom the employer pays the duty on male servants, the annual licence fee is £2, but the licence extends only to lands on which the employer has a right to kill game. A licence granted either in Great Britain or in Northern Ireland is effective throughout the United Kingdom; but not in the Irish Free State.

The sale of game when killed is also subject to statutory regulation. Gamekeepers may not sell game except under the authority of their employer (1831, ss. 17, 25). Persons who hold a full game licence may sell game, but only to persons who hold a licence to deal in game. These licences are annual (expiring on July 1), and are granted in London by justices of the peace, and in the rest of England by the council of the borough or urban or rural district in which the dealer seeks to carry on business (1831, s. 18; 1893, c. 73, s. 27), and a notice of the existence of the licence must be posted on the licensed premises. A licence must be taken out for each shop. Certain persons are disqualified for holding the licence (1831, s. 18). The licensed dealer may buy British game only from persons who are lawfully entitled to sell game. Conviction of an offence under the Game Act, 1831, avoids the licence (s. 22). The local licence must also be supplemented by an excise licence for which a fee of £2 (£3 in the Irish Free State) is charged.

Deer are not within the definition of game but to hunt or kill deer in enclosures in forests, chases or purlieus, or in enclosed land where deer is usually kept, or after a previous conviction to hunt or kill deer in the open parts of a forest, is a felony, and certain minor provisions are made as to arrest by foresters, forfeiture of venison unlawfully possessed and for unlawfully setting traps for deer. These enactments do not prevent a man from killing on his own land deer which have strayed there (Threlkeld v. Smith, 1901, 2 K.B. 531). In Scotland the unlawful killing of deer is punished as theft.

Damage to Crops by Game.—At common law the owner of land with sporting rights, and his sporting tenants, must use the reserved rights reasonably. They are liable for any damage wilfully or unnecessarily done to the crops, etc., of the occupier, such as trampling down standing crops or breaking hedges or fences, but not for damage done by game bred on the land or frequenting it in the ordinary course of nature. Modern legislation has greatly increased the rights of the occupiers. As regards hares and rabbits the occupier's rights are regulated by the Ground Game Act, 1880. The occupier has the right to kill and take hares and rabbits on the land. The right cannot be divested by contract, but where apart from the act the right to kill game on the land is vested in a person other than the occupier, such person has a right concurrent with the statutory right of the occupier to take hares and rabbits on the land. The act does not extend to common lands nor to lands over which rights of grazing or pasturage for not more than nine months in the year exist. The mode of exercise of the occupier's right is subject to certain limitations.

On moorland and unenclosed lands (which are not arable and do not consist of detached portions of less than 25 ac.) the occupier may between Sept. 1 and March 1 kill and take ground game; but between Sept. 1 and Dec. 10 firearms may not be used (1880,

s. 1 [3]; 1906, s. 2). In the case of such lands the occupiers and the owners of the sporting rights may between Sept. 1 and Dec. 10 make and enforce for their joint benefit agreements for taking the ground game. The Agricultural Holdings Act, 1906 (operating from 1909) deals, inter *alia,* with damage to crops by deer and winged game, but does not apply to damage by hares or rabbits. The tenant of agricultural land without the right to kill is entitled to compensation for damage to his crops exceeding 1s. per acre over the area affected if caused by game (s. 2). The right of the tenant is indefeasible.

Scotland and Ireland. — By the law of Scotland all men have right and privilege of game on their own estates as a real right incident thereto, which does not pass by an agricultural lease except by express words, or in the case of ground game by the act of 1880. The landlord is liable to the tenant for damage done to the surface of the lands in exercise of his right to the game and also for extraordinary damage by over-preserving or over-stocking. Night poaching is punished by the same act as in England, and day poaching by an act of 1832 and the act of 1882. The provisions of the act of 1832 as to game trespass by day apply also to deer, roe, rabbits, woodcock, snipe, rails and wild duck; but in other respects closely resemble those of the English act of 1831.

The common law as to game is the same for Ireland as for England. The game laws of Ireland are contained partly in acts passed prior to the union (1698, 1707, 1787 and 1797), partly in acts limited to Ireland, and as to the rest in acts common to the whole United Kingdom which continue in force both in Northern Ireland and in the Irish Free State.

Night poaching in Ireland is dealt with by an act of 1826. Trespass on lands in pursuit of game to which the landlord or lessor has by reservation exclusive right is summarily punishable under an act of 1864, which includes in the definition of game, woodcock, snipe, quails, landrails, wild duck, widgeon and teal. Under the Land Act, 1881, the landlord of a statutory holding may at the commencement of the term subject to the Ground Game Acts retain and exercise the exclusive right of taking "game" as above defined.

A game licence is not required for taking or killing rabbits. But in other respects the law as to game licences and licences to deal in game is the same as in Great Britain.

See Oke's ***Game Laws*** (5th ed., 1912); Nolan, ***Sporting Rights*** (1914). (W. F. C.; F. G.)

UNITED STATES AND CANADA

The United States established game laws for the protection of game rather than the granting of exclusive hunting or fishing rights to any persons. As early as 1623 the Plymouth Colony passed a law declaring all hunting and fishing to be free, except on private property. No class legislation exists. Possession of game by killing belongs, subject to limitations of the State law, to him who kills or catches, not, as in England, to the landowner on whose property such game may be caught or bagged. During the season of reproduction, wild game and fish may not be molested.

The U.S. Department of Agriculture has as one of its functions the conservation and protection of wild game and migratory birds. Among the most important enactments are the Migratory Bird Treaty Act, passed in 1918, and the Lacey Act, passed in 1900. The treaty act protects species that pass between the United States and Canada, and the Lacey Act regulates interstate commerce in game and controls the importation of foreign animals and birds, preventing illicit interstate traffic in game, and excluding injurious species of foreign birds and animals. The Federal migratory bird law may be further restricted by State legislation. Each State has intricate and detailed laws of its own, often conflicting with those of another State.

The Migratory Bird Treaty Act, growing out of a convention between the United States and Great Britain signed in 1916, has resulted in greatly co-ordinated State laws relating to migratory game birds, and has given to the Department of Agriculture power to regulate within certain limits the capture, possession and disposition of migratory birds. Fundamental items found in such enactments include the abolition of spring shooting, suspension of sale and the prescription of definite, reasonable, daily bag limits, while, by the terms of the treaty, open seasons are restricted to a period not exceeding three and one-half months in any one year between Aug. 15 and March 10.

Particularly important for the protection of game is the establishment of adequate breeding and resting grounds. Increasing commercial developments have made serious inroads upon the natural breeding and resting grounds of all wild life; drainage of marshes and lakes has been one means of destroying large water areas suitable for the production of game. To offset this destruction of natural reproduction areas, the Government has set aside reservations, which either directly or indirectly protect wild life. (See GAME **RESERVES.**) There are administering agencies in national parks and other reservations to protect, incidentally, wild life. These include: the National Park Service, the Forest Service, the Bureau of Fisheries, the Bureau of Lighthouses and the War and Navy Departments. Under the Bureau of Biological Survey are 80 game and bird reservations, all of which are bird refuges and five of them are stocked with big game. Additions to the number are made from year to year.

Federal and State laws alike allow the capture of game for propagation purposes under permit. Various restrictions govern the sale of game raised in captivity, additional licences and fees being required. In some States traffic in such game is legal, and the game may be sold for food or scientific purposes. The Federal regulations allow shooting of such game only in the open season of the State in which it is killed, provided migratory fowl raised in captivity shall have had removed, before attaining a certain age, a portion of the web of one foot.

The first general game law in Alaska was enacted in 1902 and revised in 1908, though adequate provision for conservation in Alaska, particularly of game and land fur-bearing animals, came only in 1925, when the Alaska game law was passed. This created a commission of five resident members, one of whom is the chief representative of the Bureau of Biological Survey in Alaska, and provides for fuller protection of wild life. Eskimos and Indians are at liberty to hunt game at any time for the use of themselves and their immediate families for food and clothing.

Common to nearly all States are the following provisions: hunting licences are required, with the fee for residents much lower than for non-residents; in many States licences on private property are not required by owners, while trespassing on another's property without permit is forbidden; no fishing licences are needed in some States by minors under 16 to 18 years of age; and in others minors under 17 may hunt without a licence if accompanied by a holder of a general licence. There are strict regulations for selling protected game. Possession of game taken out of the State is usually subject to local laws, but possession of migratory birds is restricted to the open season and the first 10 or 15 days of the closed season. In a few States reports must be made within a limited time to the State commissioner of game, stating the number and kind of game killed, and in several States the commissioner may close or open a season either because of depleted stocks or of depredations by game on crops.

In a few States aliens are not permitted to hunt or to own firearms, but special cases are excepted by the commissioners upon the payment of a large fee. Special privileges are accorded soldiers, veterans of the Indian, Civil and World Wars in six States and in the Territory of Alaska to native-born Indians and Eskimos. In New York State none but licensed Indians may hunt on Indian reservations.

Canada. — The Dominion of Canada has a general law prohibiting the export of deer carcasses, wild turkey, quail, partridge, prairie fowl and woodcock. The Migratory Birds Convention Act is supplemented by regulations similar to those governing the Migratory Bird Treaty Act in the United States. Full text of the regulations will be found in an annual publication by the commissioner of national parks of Canada, Ottawa.

Each province makes its own laws and regulations for hunting game. All non-residents must have licences, the cost of such

licences varying in amount according to the kind of game; residents' fees are lower, and in Manitoba no licence is required of a resident hunting on his own property. There are special regulations for guides, and, in the case of hunting big game, in Manitoba and Saskatchewan the costume worn by the hunter must be white. The licencee is required to report the number of big game and game-birds killed.

The laws governing the sale of game vary in all the provinces; in Ontario, some native game may be sold; in Nova Scotia, little game except rabbits in a certain season; in Prince Edward island all game lawfully killed (except migratory birds) may be sold; the same is true of Quebec, birch or spruce partridge being excepted also; New Brunswick forbids the sale of all game except that a licensed hunter may sell moose or deer lawfully killed by him; in Alberta, only heads of big game may be sold under special sale fees.

The export of all protected game is prohibited except in Yukon and Quebec; geese and brant in Prince Edward island; special permits, however, may be obtained from the commissioner. Deer raised on private lands may be exported; all birds so raised must be killed by other means than shooting, and so tagged before they can be sold. Most of the provinces allow game raised in captivity to be bought, sold and exported for propagation purposes.

For open seasons on game for the United States, Canada, Newfoundland and Mexico, for bag limits and possession, and regulations regarding sale and interstate transportation of game, see bulletins issued annually by State and Provincial game commissioners and Farmers' Bulletins on game laws, compiled by the U.S. Department of Agriculture. Minor exceptions in individual States and Provinces may be found by consulting the game laws published by each. (X.)

Game Protection in the U.S.—The game of the United States is in danger of extinction. This is due to the American system of "free shooting" for every citizen, the dictation of killing laws and regulations by the killers themselves, the reluctance of the killing majority to give up its killing "rights" so long as any game remains. For 50 years the laws of the United States have permitted wasteful killing of game. Even in 1928 many open seasons were 50% too long, and many bag limits 40% too high. All States save Pennsylvania and New Jersey tolerate the extra-deadly automatic and pump shotguns, the use of live decoys and the baiting of ducking waters. Along with these blunders are to be reckoned the loss of natural cover and food, exposure to natural enemies, the severity of extra hard winters and now the scourge of the hunting automobile. The net loss of marshes and lakes by drainage as a factor in waterfowl decrease has been much exaggerated, and so has the disappearance of heavy timber. Much harm was wrought during the six years from 1921 to 1927 by the policy of the eastern promoters of a certain public-shooting-grounds bill in opposing constructive Federal legislation while failing to enact their own measure. Unfortunately the American machinery for the destruction of American game is now so vast, so varied and so uncontrollable, its momentum is so great, that it is a question whether it will be possible to curb its power, or reverse it before the end of the game supply is reached.

All the game of the United States is divisible into two groups—killable and protected. The former includes the shreds and patches of about 25 species of birds, deer and black bear in quite a number of States, elk in three States, mountain sheep in Wyoming, white goats only in Idaho and Washington, and occasionally moose in Maine and Wyoming. Fugitive grizzly bear exist in five or six States, and black bear in probably 20 States. Of the original stock of big game in the United States not more than 2% remains. In a few States cotton-tail rabbits are abundant; but squirrels are scarce nearly everywhere, and the raccoon is to be found in a few places only.

The killable upland game birds are down to the diseased and vanishing ruffed grouse, the pinnated, sharp-tailed and sage grouse, all weakly and hopelessly hanging on in less than one-half of their former States. The wild turkey's area of extermination is large, and soon the guns will destroy the remainders of that gorgeous bird. The bob-white quail has disappeared from 14 of the 35 States it once inhabited and is rapidly being exterminated in the others. In California the steadily growing scarcity of native quail is causing much alarm. It needs real protection rather than "more water." The efforts made to breed the bob-white in captivity have served only to prove the futility of such efforts.

Prairie-chicken hunting is dead in nine States, sage grouse in seven, wild-turkey hunting is banned in 14 States, and from Maine to Minnesota the ruffed grouse seems to be disappearing. The woodcock and snipe still are killable; but they are so rare that their pursuit is ethically quite wrong and generally fruitless. All other shore birds have become so scarce that now all of them are protected at all times. The ducks, brant and Canada goose, to a total of about ten species, are more or less abundant in a few spots in nine States, but are absent from about five-sixths of the great area they once inhabited in good numbers. The areas of practical extinction seem to be steadily widening. Twenty-six States have felt compelled by waterfowl scarcity to reduce their bag limits on waterfowl about 40% below the Federal Government's regulations. For official information regarding the extinction of game hunting in each of the 48 States and Canada, see Game Laws of *1927–28,* published by the U.S. Department of Agriculture.

The class of "protected" species includes all the "game" mammals and birds that are living in sanctuaries where they can never be hunted or killed. Any game "preserve" that permits the hunting and killing of any of its wild inhabitants for "sport" is distinctly not a sanctuary, and for it the term "game preserve" is a misnomer that never should be employed.

The numerous and costly efforts that have been made by many States in importing tender foreign quail to restock their lifeless game "areas" usually have been disappointing. In another ten or 15 years, unless drastic action is taken, the killable game of the United States will be so completely gone that the sport of game hunting will be as dead as buffalo hunting. The sizes of the 48 State armies of game destroyers stagger the imagination. The story is told by the annual hunting licences. For example, Pennsylvania and New York each turn out annually over 600,000 hunters. The small State of New Jersey has 155,567 hunters; the large State of California has 252,017. In the autumn of 1926 the grand total of licensed hunters taking the field in the United States was 5,183,353. They were carried to their greatly expanded hunting-grounds, in quick time, by perhaps 2,000,000 automobiles. All their guns are breech-loading and rapid-fire. Of their shotguns, about 85% are of the super-deadly choke-bore, automatic and "pump" pattern, spraying out either five or six charges of shot without removal from the shoulder. The gunpowder used is of extra strength and super-deadliness. These hunters are assisted by guides, dogs, boats, blinds, decoys, baited waters and other devices to take unfair advantage of the helpless game. Game birds are constantly harassed in flight and while trying to feed or rest, by the booming guns, plus the warfare of the predatory birds and mammals that sportsmen call "vermin." For the disappearance of game during the 30 years ending in 1928 the hunter himself is fully 90% to blame. See also NATIONAL PARKS. (W. T. H.)

Measures for Game Protection.— The protection of wild life involves several elements, outstanding among which are the insurance of adequate habitat (see GAME RESERVES); the enactment and enforcement of wise conservation laws (see above); the control of both predatory animals and birds of prey; the remedying of conditions productive of diseases and parasites in breeding and feeding areas of wild life; the proper disposal of surpluses from the annual increase; and the cultivation of a proper attitude of mind on the part of sportsmen and the public generally toward game protection.

Of first importance in measures for game protection is provision for refuge areas, where wild birds and other species can feed, breed and rest undisturbed by man. In the United States, the rapid development of the once wild portions of the country has taken from many of the birds and mammals large areas of their former haunts. Because of this, a great responsibility devolves upon the public agencies of the State and Federal Governments charged with the protection and maintenance of the wild

life to do everything possible to re-establish in part at least these lost homes. Refuges that have been established in the United States have been effective in saving from threatened extinction such noble game animals as the buffalo, elk, antelope and the mountain sheep. The Upper Mississippi River Wild Life and Fish Refuge, which comprises large areas of low lands extending approximately 300 m. down the Mississippi river from Wabasha, Minn., is beginning to serve well not only for the conservation of the waterfowl that come to this region in abundance but for the increase of such water-using animals as the beaver and muskrat. Several of the States have established refuges for waterfowl and also for upland birds, and a few of the Federal refuges set aside by executive order include marshland areas that serve various species of wild fowl and valuable fur animals.

Next in importance to the maintenance of refuge areas for game-protection purposes is the existence of adequate game laws, and both State and Federal Governments have made long strides in this respect. These laws deal with the limitations on the number of birds or animals that may be taken in a given period, definitions of proper open seasons on game, prohibition of the sale of game and of the use of devices of great destructiveness heretofore employed in hunting, requirements of reports to public agencies on the number and kind of animals and birds taken under licences issued, and the institution of an appropriate method of tagging in connection with big game and important fur-bearers to ensure that the animals have been legally taken and may be lawfully transported. More and more noticeable is the tendency among public agencies to plan their enforcement programme to suit the needs of the birds or animals that are to be protected rather than to agree to a setting of seasons and limits that might be classed as political expedients. Many of the State game commissions—and in the Federal Government, the Bureau of Biological Survey—by legislative act have been given broad authority to handle promptly and by regulation such restrictions as are deemed to be necessary for the welfare of the birds and animals involved.

Another important factor in game protection is that which has to do with the control of predatory animals and birds of prey. The Federal Government and many of the States are spending considerable sums to reduce the numbers of such predacious animals as the wolf, coyote, mountain lion and the bobcat. As a result of the campaign waged against the coyote by the Federal Government and its co-operators in the Western States the deer have increased rapidly, and the antelope, the very existence of which seemed to be threatened, is coming back because of the lessening of damage done to fawns by this predator. Attention is now being given in many quarters to the control of such birds of prey as the goshawk, the sharp-shinned and Cooper hawks, and the magpie and crow, which are locally injurious to beneficial birds. Control measures for the welfare of game animals and birds are necessary also in connection with the diseases and parasites to which they are subject when concentrated on natural feeding and breeding areas or on game preserves. Maladies such as that known as alkali poisoning develop among wild ducks and other species that are limited by the advancement of farming operations to waters that become in effect death-traps for the birds. Measures that have been undertaken to remedy these adverse conditions include the building of dikes for impounding fresh waters, a notable example of which is furnished in the Federal Bear River Migratory Bird Refuge, on the marshes at the north end of Great Salt Lake, Utah, a concentration area for the wild fowl of many surrounding States.

Just as there may be over-enthusiasm in other welfare activities, so may measures for game protection reach a stage that threatens danger to the very species sought to be protected. Such a danger arises when either refuge or non-refuge areas of limited size become so overstocked that the available food supply is no longer adequate for their support. Game conservation in such cases has demanded the disposal of the surplus, when it cannot be cared for by an extension of needed facilities. In many cases the surplus has been disposed of by transplanting elsewhere, as in the case of buffalo and elk from fenced preserves and deer from open areas, and in others it has been necessary for the welfare of the main stock to utilize part of the surplus as food or for other purposes.

One other element in the game-protection programme may be briefly stated as that of a proper attitude of mind by the sportsmen of the country toward the wild life. There are too many poachers, market hunters and night shooters; but the true sportsmen obey the game laws and urge by precept and otherwise such observance on their fellows, and there are now in the United States many noted organizations of sportsmen, bird lovers and other conservationists who are zealously working to bring about better protection for the beneficial forms of the bird and animal life of the country. (P. G. R.)

GAME RESERVES. The great forest areas oi Sussex and Hampshire, preserved by the early Norman kings, may be regarded as one of the forerunners of the modern game reserve. The game, however, was in this case preserved solely for hunting purposes, and not, as in the modern reserves, preserved for the sake of the game itself. Game preservation for the sake of sport has been carried on in Europe for many hundreds of years, but it is only comparatively recently that the idea of the modern game reserve has been evolved. These reserves are seen at their best in North America, Africa and the Far East. Canada and the United States are at present well ahead of the rest of the world in game preservation, but the reserves of Africa, the Malay Peninsula, and Australia are not far behind those of the New World in importance and organization. In Canada there are 13 areas put apart as national parks, comprising a total area of 8,900 sq.m., and in the United States some 8,456 sq.m. are devoted to this purpose. In addition, some 45,500 sq.m. are set aside in Canada as reserves. These national parks are visited by large numbers of people and the financial support thus obtained is very considerable. The game reserves of Africa and other parts of the Old World, where game still abounds, are not supported in a similar fashion, since the number of European visitors to the reserves is limited. The most popular of the African reserves is the new national park of the dominion of South Africa, known as the Kruger National park; this reserve is attracting a large number of visitors and its popularity is steadily increasing. The Kruger National park had its origin in a game sanctuary founded by President Kruger in 1898; it was then known as the Sabi reserve, occupying the country between the Crocodile and Sabi rivers near the boundaries of Portuguese East Africa. After the South African War this area was considerably enlarged, the reserve extending from the Crocodile river in the south, all along the Portuguese boundary to the Limpopo and the Rhodesian border in the north, and from the Portuguese boundary in the east nearly as far as the Drakensberg in the west, a total area of zoom. by 60 miles. In 1926 the Union Government decided to make this reserve into a national park where the fauna of the country may be preserved for all time. The extent of this park as it exists to-day is about 22om. by 4om., the park extending from Komatipoort in the south along the Portuguese East African border to the junction of the territories of the Union, Rhodesia, and Portuguese East Africa on the Limpopo. Elephants are still to be found in this reserve, inhabiting the country around the Letaba and Tendi rivers, the animals wandering as far north as the Shingwedsi, and southwards to the Olifants rivers. In addition, considerable numbers of migrants from Portuguese territory have latterly made their appearance between the Shingwedsi and Limpopo rivers. A few specimens of the black rhinoceros *(Rhinoceros [Diceros] bicornis)* remain, and giraffe are reported to be increasing in numbers. Zebra, eland, kudu, roan and sable antelope, waterbuck, impala, Reedbuck, bushbuck, duiker, steinbuck, klipspringer and blue wildebeest are also to be met with within the confines of the park. In addition warthogs and bushpigs are found in all suitable localities and the hippopotamus lives in all the larger rivers. Buffaloes, which in 1902 were represented by only about a dozen individuals, are now fairly numerous in the area between the Sabi and Crocodile rivers. The number of lions is steadily decreasing and the leopard is getting, year

by year, a rarer animal. The reserve also serves as a sanctuary to a great variety of bird life.

Similar reserves exist in Zululand, where in the Umfolozi reserve the Southern white rhinoceros (Rhinoceros *simus simus*) has its last home. In the Mkuze reserve the Nyala (or Inyala) is found in fair numbers, together with impala, kudu, waterbuck, and other large and medium-sized antelopes. In these Zululand reserves it has been suggested that the shortage of food supply, which has had a very serious effect on certain species, was due in part to the presence of vast numbers of zebra and blue wildebeest (or brindled gnu); possibly the shooting of the larger carnivora within the reserves has upset the balance of nature.

In Northern Rhodesia there are three game reserves (1) Mweru Marsh reserve (2,500 sq.m.); (2) Kafue reserve (3,500 sq.m.); and the Victoria Falls reserve (80 sq. miles). The Mweru Marsh Reserve is situated between Lake Mweru and the southern end of Lake Tanganyika; it is especially designed for the protection of elephants. In addition, it contains hippopotamus, eland, kudu, situtunga, sable and roan antelopes, buffalo, and some of the smaller antelopes, such as duikers and oribis. Pelicans and flamingoes and many other types of bird life abound. The Kafue reserve is situated in the western half of the colony, the Kafue river running through the reserve from north to south. Elephants are occasionally found, and reports have been received of the occurrence of the black rhinoceros in this reserve. The majority of the large and medium-sized antelopes found in the colony are to be met with. The Victoria Falls reserve is a narrow strip of country, about 40m. long, bordering the north side of the Zambesi river; the function of this reserve is to protect such animals as still survive in the neighbourhood of the Victoria Falls.

In Central Africa there is the newly-formed national park at Kivu, in the eastern Belgian Congo, and the Birunga volcanoes lying to the north-east of Lake Kivu have been proclaimed a sanctuary for the eastern gorilla (Gorilla gorilla *beringei*). Numerous other game reserves exist in Uganda, the Sudan, Kenya Colony, Tanganyika Territory and Nyasaland. In Tanganyika Territory there are 11 different reserves, varying in size from about 240 to 2,600 sq. miles. The most important of these is the so-called Selous reserve on the Rufiji river; this is the main elephant refuge of Tanganyika Territory. The Kilimanjaro and Meru reserves are also of importance as including much dense forest country. In the Kilimanjaro forest area, in addition to numerous elephants, there occur such animals as Abbots Duiker (*Cephalophus* spadix) and the black and white Colobus monkey (Colobus *caudatus*). This reserve occupies the high forest zones and alpine meadow areas of the mountain.

In Kenya Colony there are two large reserves, the Northern game reserve (25,000 sqm.) extending from Nyiro, south-east of Lake Rudolf, nearly as far as Lake Baringo in the south, with an approximate width of about 60m., and the Southern game reserve occupying a large part of the Masai reserve, stretching from Nairobi in a south-easterly direction for upwards of 160m., the total area included in the reserve being about 15,000 sq. miles. In the Northern reserve a number of desert forms occur, such as Waller's gazelle or gerenuk (Lithocranius *walleri*) and a variety of dik-diks (Rhynchotragus *kirki, smithi,* etc.). In addition, elephant, rhinoceros, hippopotamus, giraffe (G. *reticulata*), buffalo, eland, kudu, lesser kudu, beisa, topi, hartebeest, waterbuck, impalla, two forms of Grant's gazelle, Thomson's gazelle, klipspringer, Grevy's zebra, Grant's zebra, steinbuck, reedbuck and a variety of small duikers, together with a number of ostriches, inhabit this reserve. In the Southern reserve most of these forms also occur; the giraffe is, however, the Masai type (G. *tippelskerchi*), the zebra, Burchell's zebra, and the oryx, the fringed-eared oryx (Oryx *callotis*). Lions, leopards and cheetahs are also fairly frequently met with.

In Uganda the Semliki reserve contains elephants, buffaloes, waterbucks, kobs, and a variety of duikers. The Bunyoro game reserve contains numbers of elephants, but its area is far too limited for any real use as a general reserve. Other natural Uganda sanctuaries are the Budongo forest and Bugoma forest in Bunyoro, the Kibale and Butara forests in Toro, the sleeping sickness areas of Kabula and Mawogola on the Ankole-Masaka border, southern Busoga, and the uninhabited areas of north Bulamezi, Buruti, and north-east Singo. In the Sudan there is a large game reserve situated between the White and Blue Niles and the Sobat river. In Nigeria there are four game reserves, one in the northern and three in the southern provinces. The northern reserve is situated in the Bornu province and contains most of the game animals to be found in the northern provinces; this area contains an adequate supply of water and grazing and is sufficiently large to function as a game sanctuary. The land around certain towns within this reserve is excluded from the reserve for a radius of 5 miles. In the southern provinces the best of the reserves is bounded on the west, south, and east by the Gwate creek; the other two reserves, the Orle river reserve, and the Anambra river reserve are not so suited for the purposes of game preservation.

In Asia the principal game reserves are in the Federated Malay States, Burma, and Ceylon. In Negri Sembilan there is a reserve of 68,000 ac. situated on the Serting river. The country here is mostly low-lying with a few hills; a large part of it is covered with heavy forest and contains elephant, seladang, sambar, tapir, tiger, and large numbers of small game and birds. In Pahang there are three reserves, (1) the Krau reserve of 130,000 ac.; (2) the Gunong Tahan reserve totalling some 360,000 ac.; and (3) the Sungei Lui reserve (42,500 acres). These reserves contain most of the species of big and small game found in Malaya except the Javan rhinoceros (*Rhinoceros sondaicus*). In Burma the area set aside for reserves is at present by no means extensive, but more and larger reserves will probably be formed in the near future. The five reserves are (1) the Pidaung sanctuary (260½ sq.m.) containing elephant, bison, sambar, hog-deer, tiger, leopard and bear; (2) the Kahilu reserve (200 sq.m.), containing the very rare Javan rhinoceros; (3) the Sheve-U-Daung sanctuary (81 sq.m.), which contains some specimens of the Sumatran rhinoceros (R. *sumatrensis*); (4) the Maymyo sanctuary (49 sq.m.); and (5) the Moscos islands (19 sq.m.), contain Sambar and a variety of smaller game animals and birds.

In Ceylon one of the most important reserves is the game sanctuary of the Southern province; it comprises the extreme eastern division of the Hambantota district situated between the Yala and Kumbukkan rivers. In area this sanctuary is about 150 sq.m., and the entry into it can only be obtained on permission of the forest officers. It abounds in large and small game, sambar and the spotted deer being very abundant, and elephants, leopards, bears, and pigs are also to be met with. Another type of reserve in the Southern province is the resident sportsman's reserve, which adjoins the game sanctuary on the west. During the open season it is possible for the resident sportsman (of not less than six months' residence) to shoot in this reserve on licences to be obtained from the revenue officer of the district. The game in this reserve, although increasing in numbers, is not nearly so abundant as it is in the sanctuary. A similar sportsman's reserve has been formed in the Eastern province, with an area of about 300 sq.m., bounded on the east by the sea and the west by the Uva province boundary; in the north it extends as far as the Pottuvil-Mupane road, and southwards reaches Kumbukkan Oya. Most of this reserve is bush country, with some large lagoons surrounded by park lands. Elephants are sufficiently numerous to be a nuisance to sportsmen after smaller game, and sambar and spotted deer are numerous. A sportsman's reserve is also maintained in the province of Uva; the reserve is situated in the southern part of the province and is open to resident sportsmen only.

In India the forests are frequently divided up into shooting blocks, usually of large size, one block being reserved as a game sanctuary. The formation of large game reserves, such as exist in Africa, is not possible in India, and to a large extent the game must be protected by shooting licences and the such small sanctuaries as may be formed in the centres of the game country.

In Australia there are a great number of reserves for the

preservation of native game. In Western Australia alone some 42 reserves have been formed for the protection of bird-life and the smaller marsupials. The national park of 3,349 ac. is situated at Swan View, about 14m. E. of Perth; grey kangaroos and some of the smaller marsupials are found in this park. In Queensland there are also a large number of game sanctuaries, including about 40 island reserves. The national parks of Victoria, some 12 in number, serve to protect and preserve many rare birds and small marsupials. The largest of these parks is Wilson's promontory of over 100,000 ac. and contains large numbers of the more common native animals. Mt. Buffalo is another important reserve of 25,980 ac.; it contains a number of interesting birds but not many mammals. The Grampians forest is another fine sanctuary in which kangaroos and wallabies are found. These forest reserves have practically no inhabitants, but are accessible to the public by roads or tracks; with the exception of Mt. Buffalo and Wilson's promontory, there are no hotels or rest-houses. In addition to these national parks there are also about 180 reserves in Victoria, in many of which the platypus and other rare mammals thrive, and the kangaroo and wallaby find plenty of shelter in the forests. Tasmania has a fine narionai park of 38,500 ac. in the south-central part of the island, and over 160,000 ac. are maintained as a game reserve in the region of Lake St. Clair, Lincoln. These two sanctuaries will ensure that the fast disappearing fauna of the island will be preserved for future generations. The national park includes the Mount Field range and adjoining country; the altitude varies from 500 to 4,721 ft. above sea-level, so that the fauna and flora of this region is both varied and interesting. Among the larger mammals Bennett's wallaby (*Macropus bennetti)* is to be met with on the higher levels, and the smaller Rufous wallaby inhabits the scrub. Ringtail and brush phalangers are fairly common, and kangaroo rats and marsupial mice (*Dromicia*) occur. These latter, on account of their small size and nocturnal habits, are not often seen. Wombats are common on the Broad river valley and on the open moors. The marsupial cats (Dasyurus) are found fairly frequently, and the Tasmanian devil and marsupial wolf (*Thylacinus cynocephalus*) are possibly also inhabitants of this area. The platypus is to be found in the lakes and the spiny anteater is also a native of the park. A large percentage of the Tasmanian birds are to be found within the boundaries, including specimens of the great wedge-tailed eagle. This national park, unlike so many of the reserves of Africa and elsewhere, is fairly easy to get to; trains run from Hobart to National park every week-day, and in the summer months a Sunday service is maintained.

In New Zealand the national parks are chiefly maintained for the preservation of bird-life, and there are no native game animals. The parks are eight in number, of which the biggest are the Sounds National park, Tongariro, and Arthur's Pass. Tongariro, in the North island, is remarkable for its beautiful scenery, containing within its boundaries the volcanic peaks of Ruapshu, Tongariro, and Ngarurhoe. Another North island park embraces the volcano known as Mt. Egmont. The most famous parks in the South island are the Sounds or Fiordland, and Tasman park (97,800 acres). The former park is noted for its sounds, or fiords, and the latter for the inclusion of Mt. Cook, the highest peak in the dominion. All these parks function as valuable reserves for the preservation of the native fauna and flora. The deer which have been introduced into New Zealand are not protected in these national parks, as the damage resulting from these animals is so serious that it has been found necessary to take steps to reduce their numbers.

In Africa the game reserves are usually in charge of the game warden, assisted by assistants and honorary game wardens. There are also employed a number of native scouts. The staff, in addition to looking after the reserves, have to keep the large carnivora in check; a troublesome task in certain of the East African reserves. The staff of the Game Department in Kenya Colony consists of a game warden and four assistants; in addition there are 39 honorary game wardens whose powers are similar to those of the game warden, the game ordinance, stating that "Game warden includes assistant game warden and honorary game warden." In certain special cases, such as permits for export of game trophies, authority is vested only in the game warden. In addition there are a number of scouts, and valuable information is often received from casual natives. Honorary game wardens also give much assistance in the Federated Malay States. (J. G. D.)

THE UNITED STATES

The term "game preserve," instead of "game reserve," is used in the United States. In its strictest sense it is limited to areas set aside for the protection of those species of wild mammals and birds that are defined by law or commonly hunted as "game." This is in contrast with the use of the term in England in connection with "shooting preserves." In its broadest sense, as here used, it is applied to Federal, State, municipal and private reservations where killing or disturbance of wild life is prohibited. True game reservations are those established primarily for the protection of wild animals or birds, but such areas as national and State parks, national monuments and military and other reservations are of almost equal importance to the wild life forms, although their protection is incidental.

Established in 1872, the Yellowstone National Park, famous for its scenic beauties, is one of the most important big-game sanctuaries in the United States, and protection and perpetuation of its wild life is of very general interest. The elk of the park have been the subject of numerous Federal, State and other conservation measures. The Elk Refuge, situated near Jackson, Wyo., with a present (1929) area of 4,225 ac., was established in 1912 to provide forage in winter for a herd of about 10,000 animals largely from the park region. Facilities for the winter care of big-game animals of the Yellowstone region are also being extended by the acquisition of areas in Montana north of the boundary of the park. Another example of an extensive area important in protecting wild life is found in Mount McKinley National Park, Alaska, the home of caribou and mountain sheep.

Five executive departments administer reservations on which wild life is protected, as follows: The Department of Agriculture, bird refuges and game preserves; the Department of the Interior, national parks, reclamation and irrigation projects and certain national monuments; War and Navy Departments, military reservations; Department of Commerce, Afognak and Pribilof, or Fur-Seal, island reservations, Alaska.

The Bureau of Biological Survey of the U.S. Department of Agriculture, the chief Federal agency studying the distribution, habits and economic status of wild life, has under its charge 80 bird refuges and game preserves. These have been established by executive orders, the first signed by President Roosevelt on March 14, 1903, and by special acts of Congress. Five of the refuges are primarily preserves for buffalo, elk, deer, mountain sheep and antelope, and include the National Bison Range in Montana, Sullys Hill Game Preserve in North Dakota, Wind Cave Game Preserve in South Dakota, Niobrara Reservation in Nebraska and the Elk Refuge in Wyoming. Two others, the Upper Mississippi River Wild Life and Fish Refuge, and the Bear River Migratory Bird Refuge, Great Salt Lake, Utah, are of special importance to migratory birds. Most of the other refuges were established for the benefit of non-game species. The Forest Service of the Department of Agriculture administers a number of Federal refuges for big game in national forest areas, the more important being the Wichita in Oklahoma, the Grand Canyon in Arizona and the Pisgah in North Carolina.

Most of the States, and in some instances counties or municipalities, have dedicated areas to the conservation of wild animal and bird life. These refuges range from State lands, as in Alabama, where they are set aside as "forest reserves and game refuges," to those in some States acquired by purchase, those established on private premises by contract with the owners, or, as in California, where refuge districts are defined and closed to hunting by State law. The refuge system in several States has been greatly aided by donations of private lands. More than 237,000 ac. have been added to the State refuges in Louisiana by gifts of private areas.

In Pennsylvania, numerous refuges ranging from 1,200 to 3,000 ac. in extent, are established in the midst of several thousand acres of State-controlled forest and other areas. Fire lanes are cleared and each refuge is marked by a single strand of wire high enough to permit free access of game. The surplus animals from the protected area restock the surrounding region. Many States in the West have designated extensive areas within Federal forest reserves as State game refuges, particularly in Wyoming, Montana, Idaho, Utah and California. The authority of the several States to locate refuges on Federal, State or private lands is contrasted with that of the Federal Government which is restricted to the public domain and areas specially acquired. In a number of States authority to establish refuges by regulation has been conferred upon State game officials, and what are in effect refuges are created by law or by regulation, closing local areas to hunting or to the taking of particular kinds of game. A few States have entered a comparatively new field by acquiring areas where the public may hunt waterfowl or other game during the open season. Louisiana, since 1921, has operated Pass-a-l'Outre, a 60,000 ac. marsh and water area in Plaquemines parish as a public shooting ground. In Utah a special area for public shooting is under operation by the State. Reelfoot lake, Tenn., and the Susquehanna flats, at the head of Chesapeake bay, Md., are in effect public shooting areas. Pennsylvania has maintained areas open to public shooting surrounding her State refuges for big game. The Adirondack region and the Catskill park in New York also may be mentioned as public hunting areas for big game.

Municipal preserves in some sections have proved highly attractive to wild life. Among the best known of these are Lake Merritt, at Oakland, Calif.; the preserve at Daytona, Fla.; and Cook county park, at Chicago. What may be termed "private" game preserves are virtually numberless. They may range from the premises of the farmer or landowner posted against public hunting, to those where extensive developments and improvements have been made for attracting bird and animal life and insuring its subsequent protection and care.

Organizations of sportsmen and conservationists, as well as interested individuals, also establish and maintain sanctuaries for wild life. The so-called "duck" clubs having shooting areas have set aside in many instances portions of their holdings as inviolate sanctuaries. The extent to which such areas have passed into private control has brought about a serious condition from the viewpoint of the unattached hunter. The acquiring of marsh and water areas by individuals or clubs has often saved such areas to the wild fowl. Warden service, feed and even water has been supplied to render these preserves attractive to waterfowl, and in some cases sustenance is provided for a much greater number of the birds than the members kill. At some clubs also game keepers and breeding plants are maintained that produce for liberation more birds than are annually taken there. Private quail-shooting preserves, some ranging from 10,000 to 20,000 ac., chiefly on leased lands, are maintained in some States in the South.

(F. L. EA.)

GAMES, CLASSICAL. 1. *Public* Games.—The public games of Greece (ἀγῶνες) and Rome (Ludi) consisted in athletic contests and spectacles of various kinds, generally connected with and forming a part of a religious observance. Probably no institution exercised a greater influence in moulding the national character, and producing that unique type of physical and intellectual beauty which we see reflected in Greek art and literature, than the public contests of Greece (see ATHLETE; GLADIATORS; ATHLETIC SPORTS).

The earliest games recorded are those at the funeral of Patroclus. Greek games were in their origin connected with religion; either, as here, a part of the funeral rites, or else instituted in honour of a god, or as a thank-offering. Each of the great contests was held near some shrine or sacred place and is associated with some deity or mythical hero. It was not before the 4th century that this honour was paid to a living man (see Plutarch, Lysander, 18). The games of the Iliad and those of the Odyssey at the court of Alcinous show at what an early date the distinctive forms of Greek athletics—boxing, wrestling, putting the weight, the foot and the chariot race—were determined.

The Olympian games were the earliest, and to the last they remained the most celebrated of the four national festivals. Olympia was a naturally enclosed spot in the plain of Elis. There was the grove of Altis, in which were ranged the statues of the victorious athletes, and the temple of Olympian Zeus with the chryselephantine statue of the god, the masterpiece of Pheidias. There Heracles (so ran the legend which Pindar has introduced in one of his finest odes), when he had conquered Elis and slain its king Augeas, consecrated a temenos and instituted games in honour of his victory. A later legend, which probably embodies historical fact, tells how, when Greece was torn by dissensions and ravaged by pestilence, Iphitus enquired of the oracle for help, and was bidden restore the games which had fallen into desuetude; and there was, in the time of Pausanias, suspended in the temple of Hera at Olympia, a bronze disc whereon were inscribed, with the regulations of the games, the names of Iphitus and Lycurgus. From this we may safely infer that the games were a primitive observance of the Eleians and Pisans, and first acquired their celebrity from the powerful concurrence of Sparta. The sacred armistice, or cessation of all hostilities during the month in which the games were to be held, is also credited to Iphitus.

In 776 B.C. the Eleians engraved the name of their countryman, Coroebus, as victor in the foot race, and thenceforward we have an almost unbroken list of the victors in each succeeding Olympiad or fourth recurrent year. For the next 50 years no names occur but those of Eleians or their next neighbours. After 720 B.C. we find Corinthians and Megareans, and later still, Athenians and extra-Peloponnesians. Thus what at first was nothing more than a village feast became a bond of union for all the branches of the Doric race, and grew in time to be the national festival. It survived even the extinction of Greek liberty, and had nearly completed 12 centuries when it was abolished by the decree of the Christian emperor, Theodosius, in the tenth year of his reign.

Let us attempt to call up the scene which Olympia in its palmy days must have presented as the great festival approached. Heralds had proclaimed throughout Greece the "truce of God." Those white tents belong to the Hellanodicae, or ten judges of the games, chosen one for each tribe of the Eleians. They have been here already ten months, receiving instruction in their duties All, too, or most of the athletes must have arrived, for they have been undergoing the indispensable training in the gymnasium of the Altis. But along the "holy road" from the town of Elis a motley throng is crowding. Conspicuous in the long train are the θεωροί or sacred deputies, clad in their robes of office, and bearing with them in their carriages of state, offerings to the shrine of the god. There is no lack of noted visitors. A feature of the mediaeval tournament and the modern racecourse is wanting. Women might indeed compete and win prizes as the owners of teams, but all except the priestesses of Demeter were forbidden, matrons on pain of death, to enter the enclosure.

At daybreak the athletes presented themselves in the Bouleuterium, where the judges were sitting, and proved by witnesses that they were of pure Hellenic descent, and had no stain, religious or civil, on their character. Laying their hands on the bleeding victim, they swore that they had duly qualified themselves by ten months' continuous training in the gymnasium, and that they would use no fraud or guile in the sacred contests. Thence they proceeded to the stadium, where they stripped to the skin and anointed themselves. A herald proclaimed, "Let the runners put their feet to the line," and called on the spectators to challenge any disqualified by blood or character. If no objection was made, they were started by the note of the trumpet, running in heats of four, ranged in places assigned by lot. The foot-race was only one of 24 Olympian contests which Pausanias enumerates, though we must not suppose that these were all exhibited at any one festival. Till the 77th Olympiad all was concluded in one day, but afterwards the feast was extended to five.

The order of the games is for the most part a matter of conjecture, but, roughly speaking, the historical order of their institution was followed. We will now describe in this order the

most important.

(1) The Foot-race.—For the first 13 Olympiads the δρόμος, or single lap of the stadium, which was zooyds. long, was the only contest. The δίαυλος, in which the course was traversed twice, was added in the 14th Olympiad, and in the 15th the δόλιχος, or long race, of 7, 12, or, according to the highest computation, 24 laps, about 2⅔m. in length. We are told that the Spartan Ladas, after winning this race, dropped down dead at the goal. There was also, for a short time, a race in heavy armour, which Plato highly commends as a preparation for active service. (2) Wrestling was introduced in the 18th Olympiad. The importance attached to this exercise is shown by the very word palaestra, and Plutarch calls it the most artistic and cunning of athletic games. The practice differed little from that of modern times, save that the wrestler's limbs were anointed with oil and sprinkled with sand. The third throw, which decided the victory, passed into a proverb, and struggling on the ground, such as we see in the famous statue at Florence, was not allowed, at least at Olympia. (3) In the same year was introduced the πένταθλον (pentathlon), a combination of the five games enumerated in the well-known pentameter ascribed to Simonides: ἅλμα, ποδωκείην, δίσκον, ἄκοντα, πάλην. Only the first of these calls for any comment. The only leap practised seems to have been the long jump. The leapers increased their momentum by means of ἁλτῆρες or dumb-bells, which they swung in the act of leaping. (4) The rules for boxing did not differ greatly from those of the modern ring (see PUGILISM), and the chief difference was in the use of the caestus. This, in Greek times, consisted of leather thongs bound round the boxer's fists and wrists; and the weighting with lead or iron or metal studs, which made the caestus more like a "knuckle-duster" than a boxing-glove, was a later Roman development. The killing of an antagonist, unless proved to be accidental, not only disqualified for a prize, but was severely punished. The use of earguards and the comic allusions to broken ears, not noses, suggest that the Greek boxer did not hit out straight from the shoulder, but fought windmill fashion. In the *pancratium,* a combination of wrestling and boxing, the use of the caestus, and even of the clenched fist, was disallowed. (5) The chariot-race had its origin in the 23rd Olympiad. Of the hippodrome, or racecourse, no traces remain, but from the description of Pausanias we may infer that the dimensions were approximately 1,600ft. by 400ft. Down the centre there ran a bank of earth, and at each end of this bank was a turning-post round which the chariots had to pass. "To shun the goal with rapid wheels" required both nerve and skill, and the charioteer played a more important part in the race than even the modern jockey. Pausanias tells us that horses would shy as they passed the fatal spots. The places of the chariots were determined by lot, and there were elaborate arrangements for giving the drivers a fair start. The large outlay involved excluded all but rich competitors, and even kings and tyrants eagerly contested for the victory. Chariot-races with mules, with mares, with two horses in place of four, were successively introduced. Races on horseback date from the 33rd Olympiad. Lastly, there were athletic contests of a similar kind for boys, and a competition of heralds and trumpeters, introduced in the 93rd Olympiad.

The prizes were at first, as in the Homeric times, of some intrinsic value, but after the 6th Olympiad the only prize for each contest was a garland of wild olive. The successful athlete received, in addition to the honours, very substantial rewards. A herald proclaimed his name, his parentage and his country; the Hellanodicae took from a table of ivory and gold the olive crown and placed it on his head, and in his hand a branch of palm; as he marched in the sacred revel to the temple of Zeus, his friends and admirers showered in his path flowers and costly gifts, singing the old song of Archilochus, τήνελλα καλλίνικε, and his name was canonized in the Greek calendar. Fresh honours and rewards awaited him on his return home. If he was an Athenian he received, according to the law of Solon, 500 drachmae, and free rations for life in the Prytaneum; if a Spartan, he had as his prerogative the post of honour in battle. Poets like Pindar, Simonides and Euripides sung his praises, and sculptors like Pheidias and Praxiteles were engaged by the State to carve his statue. And there were well-attested instances of altars being built and sacrifices offered to a successful athlete. An Olympian prize was regarded as the crown of human happiness. Cicero, with a Roman's contempt for Greek frivolity, observes with a sneer that an Olympian victor receives more honours than a triumphant general at Rome, and tells the story of the Rhodian Diagoras, who, having himself won the prize at Olympia, and seen his two sons crowned on the same day, was addressed by a Laconian in these words:—"Die, Diagoras, for thou hast nothing short of divinity to desire." Alcibiades, when setting forth his services to the State, puts first his victory at Olympia, and the prestige he had won for Athens by his magnificent display.

The Pythian games originated in a local festival held at Delphi, anciently called Pytho, in honour of the Pythian Apollo, and were especially devoted to musical competitions. The date at which they became a Panhellenic ἀγών (so Demosthenes calls them) cannot be determined, but the Pythiads as a chronological era date from 527 B.C., by which time music had been added to all the Panhellenic contests. Now, too, these were held at the end of every fourth year; previously there had been an interval of eight years. The prize was a chaplet of laurel.

The *Nemean* games were biennial and date from 516 B.C. They were by origin an Argive festival in honour of Nemean Zeus, but in historical times were open to all Greece, and provided the established round of contests, except that no mention is made of a chariot-race. A wreath of wild celery was the prize.

The *Isthmian* games, which were held on the Isthmus of Corinth in the first and third years of each Olympiad. Their early importance is attested by the law of Solon which bestowed a reward of 100 drachmae on every Athenian who gained a victory. The festival was managed by the Corinthians; and after the city was destroyed by Mummius (146 B.C.) the presidency passed to the Sicyonians until Julius Caesar rebuilt Corinth (46 B.C.). They probably continued to exist till Christianity became the religion of the Romah empire. The Athenians were closely connected with the festival, and had the privilege of *proedria,* the foremost seat at the games, while the Eleans were absolutely excluded from participation. The games included gymnastic, equestrian and musical contests. The prize was a crown, at one time of parsley (or wild celery); later of pine. The importance of the Isthmian games in later times is shown by the fact that Flamininus chose the occasion for proclaiming the liberation of Greece, 196 B.C.

The Ludi Publici of the Romans, as in Greece, were intimately connected with religion. At the beginning of each civil year it was the duty of the consuls to vow to the gods games for the safety of the commonwealth, and the expenses were defrayed by the treasury. Thus, at no cost to themselves, the Roman public were enabled to indulge at the same time their religious feelings and their love of amusement. Their taste for games naturally grew till it became a passion, and under the empire games were looked upon by the mob as one of the two necessaries of life. The aediles who succeeded to this duty of the consuls were expected to supplement the State allowance from their private purse. Political adventurers were not slow to discover so ready a road to popularity, and what at first had been exclusively a State charge, was taken up by men of wealth and ambition. A victory over some barbarian horde, or the death of a relation, served as the pretext for a magnificent display. But the worst extravagance of private citizens was eclipsed by the reckless prodigality of the Caesars, who squandered the revenues of whole provinces in catering for the mob of idle sightseers on whose favour their throne depended. But though public games played as important a part in Roman as in Greek history, and must be studied by the Roman historian as an integral factor in social and political life, yet, regarded solely as exhibitions, they are comparatively devoid of interest.

It is easy to explain the different feelings which the games of Greece and of Rome excite. The Greeks, at their best, were actors, the Romans, from first to last, were spectators. It is true that even in Greek games the professional element played a

large and ever-increasing part. As early as the 6th century B.C. Xenophanes complains that the wrestler's strength is preferred to the wisdom of the philosopher, and Euripides, in a well-known fragment, holds up to scorn the brawny, swaggering athlete. But, what in Greece was a perversion and acknowledged to be such, the Romans not only practised but held up as their ideal. No Greek, however high in birth, was ashamed to compete in person for the Olympic crown. The Roman, though little inferior in gymnastic exercises, kept strictly to the privacy of the palaestra; and for a patrician to appear in public as a charioteer is stigmatized by the satirist as a mark of shameless effrontery.

For the Roman world, the circus was at once a political club, a fashionable lounge, a rendezvous of gallantry, a betting ring, and a playground for the million. Juvenal, speaking loosely, says that in his day it held the whole of Rome; but there is no reason to doubt the precise statement of P. Victor, that in the Circus Maximus there were seats for 350,000 spectators.

Of the various *Ludi Circenses* it may be enough here to give a short account of the most important, the *Ludi Magni* or *Maximi.*

Initiated, according to legend, by Tarquinius Priscus, the *Ludi Magni* were originally a votive feast to Capitoline Jupiter, promised by the general when he took the field, and performed on his return from the annual campaign. They thus presented the appearance of a military spectacle, or rather a review of the whole burgess force, which marched in solemn procession from the capitol to the forum and thence to the circus, which lay between the Palatine and Aventine. First came the sons of patricians, mounted on horseback, next the rest of the burghers ranged according to their military classes, after them the athletes, naked save for the girdle round their loins, then the company of dancers with the harp and flute players, next the priestly colleges bearing censers and other sacred instruments, and lastly the simulacra of the gods, carried aloft or drawn in cars. The games themselves were fourfold:—(I) the chariot race; (2) the *ludus Troiae;* (3) the military review; and (4) gymnastic contests. Of these only the first two call for any comment. (1) The chariot employed in the circus was the two-wheeled war car, at first drawn by two, afterwards by four, and more rarely by three horses. Originally only two chariots started for the prize, but under Caligula we read of as many as 24 heats run in the day, each of four chariots. The distance traversed was 14 times the length of the circus or nearly 5m. The drivers were divided into companies, distinguished by colours, whence arose the factions of the circus which assumed such importance under the later emperors. In republican times there were two factions, the white and the red; two more, the green and the blue, were added under the empire, and for a short time in Domitian's reign, there were also the gold and the purple. Even in Juvenal's day party spirit ran so high that a defeat of the green was looked upon as a second Cannae. After the seat of empire had been transferred to Constantinople these factions of the circus were made the basis of political cabals, which frequently resulted in sanguinary tumults, such as the famous Nika revolt (A.D. 532), in which 30,000 citizens lost their lives. (2) The *Ludus Troiae* was a sham-fight on horseback, in which the actors were patrician youths. A description of it will be found in the 5th Aeneid. *(See* also CIRCUS.)

The two exhibitions we shall next notice, though occasionally given in the circus, belong more properly to the amphitheatre. *Venatio* was the baiting of wild animals, who were pitted against one another or against men—captives, criminals or trained hunters called *bestiarii.* The first certain instance on record of this amusement is in 186 B.C., when M. Fulvius exhibited lions and tigers in the arena. The taste for these brutalizing spectacles grew apace, and the most distant provinces were ransacked by generals and proconsuls to supply the arena with rare animals—giraffes, tigers and crocodiles. Sulla provided for a single show 100 lions, and Pompey 600 lions, besides elephants, which were matched with Gaetulian hunters. Julius Caesar enjoys the doubtful honour of inventing the bull-fight. At the inauguration of the Colosseum 5,000 wild and 4,000 tame beasts were killed, and to commemorate Trajan's Dacian victories there was a butchery of 11,000 beasts. The *naumachia* was a sea-fight, either in the arena, which was flooded for the occasion by a system of pipes and sluices, or on an artificial lake. The rival fleets were manned by prisoners of war or criminals, who often fought till one side was exterminated. In the sea-fight on Lake Fucinus, arranged by the emperor Claudius, 100 ships and 19,000 men were engaged.

But the special exhibition of the amphitheatre was the *munus gladiatorium,* which dates from the funeral games of Marcus and Decimus Brutus, given in honour of their father, 264 B.C. It was probably borrowed from Etruria, and a refinement on the common savage custom of slaughtering slaves or captives on the grave of a warrior or chieftain. Nothing so clearly brings before us the vein of coarseness and inhumanity running through the character of the Roman as his passion for gladiatorial shows. Only after the conquest of Greece we hear of their introduction into Athens, and they were then admitted rather out of compliment to the conquerors than from any love of the sport. In spite of numerous prohibitions from Constantine downwards, they continued to flourish even as late as St. Augustine. To a Christian martyr, if we may credit the story told by Theodoret and Cassiodorus, belongs the honour of their final abolition. In the year 404 Telemachus, a monk who had travelled from the East on this sacred mission, rushed into the arena and endeavoured to separate the combatants. He was instantly despatched by the praetor's orders; but Honorius, on hearing the report, issued an edict abolishing the games. *(See* GLADIATORS.)

Of the other Roman games the briefest description must suffice. The *Ludi Apollinares* were established in 212 B.C., and were annual after 211 *B.C.,* consisting mainly of theatrical performances. The *Megalenses* were in honour of the great goddess, Cybele, instituted 204 B.C., and from 191 B.C. celebrated annually. Under the empire the festival assumed a more orgiastic character. Four of Terence's plays were produced at these games. The *Ludi Saeculares* were celebrated at the beginning or end of each *saeculum,* a period variously interpreted by the Romans themselves as 100 or 110 years.

Private Games.—There is quite naturally a much closer resemblance between the pursuits and amusements of children than of adults. Homer's children built castles in the sand, and Greek and Roman children alike had their dolls, their hoops, their skipping-ropes, their hobby-horses, their kites, their knuckle-bones and played at hopscotch, the tug-of-war, pitch and toss, blind-man's bluff, hide and seek, and kiss in the ring, or at closely analogous games. Games of ball were popular in Greece from the days of Nausicaa, and at Rome there were five distinct kinds of ball, and more ways of playing with them. It is strange that we can find in classical literature no analogy to cricket, tennis, golf or polo, and though the *jollis* resembled our football, it was played with the hand and arm, not with the leg. Cock-fighting was popular both at Athens and Rome, and quails were kept and put to various tests to prove their pluck.

Under indoor games we may distinguish games of chance and games of skill. *Tesserae,* marked with pips like modern dice, were evolved from the *tali,* knuckle-bones with only four flat sides. The old Roman threw a hazard and called a main, just as did Charles Fox. The vice of gambling was lashed by Juvenal.

The primitive game of guessing the number of fingers simultaneously held up by the player and his opponent is still popular in Italy where it is known as "morra."

Athena found the suitors of Penelope seated upon cowhides and playing at πεσσοί, which was a form of draughts, an invention ascribed to Palamedes. In its earliest form it was played on a board with five lines and with five pieces. Later we find eleven lines, and a further development was the division of the board into squares.

Duodecim scripta, as the name implies, was played on a board with 12 double lines and approximated very closely to our backgammon. There were 15 pieces on each side, and the moves were determined by a throw of the dice; "blots" might be taken, and the object of the player was to clear off all his own men. Lastly must be mentioned the *Cottabus* (*q.v.*), a game peculiar to the Greeks, and with them the usual accompaniment of a wine party. In its simplest form each guest threw what was left in his cup

into a metal basin, and the success of the throw, determined partly by the sound of the wine in falling, was reckoned a divination of love. For the various elaborations of the game, Athenaeus and Pollux must be consulted.

GAMETE, in biology the name given to the special cells set apart in most plants and animals for sexual reproductive purposes. (See SEX.) They are usually of two kinds: (1) the ovum, which is large, stationary and heavily laden with food-materials (yolk); and (2) the spermatozoon or (in plants) spermatozoid, which is small, actively motile and, in all animals except the Arthropoda (insecis, spiders, crabs, etc.) and nematode worms, consisting of a head of nuclear material (see NUCLEUS) and a long vibratile tail. In the higher plants (conifers and flowering plants) and in many fungi, this element is much modified (see PLANT), but in most of the lower plants the spermatozoid closely resembles the animal spermatozoon. In some Algae (*q.v.*), both gametes are spermatozoon-like; and in certain Algae and Protozoa the whole organism acts as a gamete. The two gametes, in all the above cases, fuse to form a zygote, which develops into the adult organism. An organism producing ova is said to be female, one producing spermatozoa, male: one producing both, hermaphrodite. (See SEX, HEREDITY, CYTOLOGY, HERMAPHRODITE, EMBRYOLOGY.)

GAMETOGENESIS, in embryology, the name given to an abnormal form of egg fertilisation due to the entrance of a number of spermatozoa into the ovum instead of one as in normal fertilisation. A corresponding number of male pronuclei are formed, and the subsequent development, if it takes place at all, is abnormal. The spermatozoa and ova are called the gametes. In the Arthropoda, selachians, amphibians and mammals the reproductive organs can admit of several spermatozoa normally entering the ovum, but of these only one forms a male pronucleus, the rest being absorbed. See EMBRYOLOGY, HEREDITY, SEX.

GAMING AND WAGERING. At common law no games were unlawful, but early legislation in England (1388, 1409, 1477 and 1541) sought to restrict games in the interests of archery. The early Stuarts encouraged manly sports, but Puritan agitation secured the Sunday Observance Act, 1625, which prohibited most sports and pastimes on Sunday. Cock-fighting and the setting of other animals to fight are offences against the Prevention of Cruelty to Animals Acts. Other games have been declared illegal chiefly because of their tendency to promote gambling. Such games include ace of hearts, pharaoh (faro), basset and hazard (1738), passage and all games with dice (1739), roulette or rolypoly (1744), lotteries (except under the Art Unions Act, 1846), rouge et *noir,* baccarat-banque (1884), *chemin-de-fer* (1895) and all card games which are not games of mere skill.

Wagering has received a great deal of attention from parliament, but at common law an action would lie to enforce a wager. In 1845 a general Gaming Act was passed by which all agreements by way of gaming or wagering are null and void and no action lies to recover money, even from a stakeholder, alleged to be won upon any wager. Until the Gaming Act, 1892, however, agents who paid lost bets were able to recover the amounts paid from their principals.

Betting on Horse Races.—In England, although football matches and greyhound racing are also responsible for much betting, the general public bets chiefly on horse races. A large number of people make a living from the habit. Special editions of the evening papers are published giving "tips" and the odds quoted by the "bookmakers" or professional betting men, who by laying money against a number of horses and by shrewdly regulating the odds according to their knowledge and information and the desire of the public to support certain horses rather than others, usually manage to grow rich, while in the long run the backer of horses almost always loses money. On the more important races betting begins weeks or even months before the event. The odds are governed largely by the public demand, and if a great many people bet on the one horse the price shortens until in many cases instead of laying money against a horse a bookmaker takes odds, *i* e., agrees to pay in the event of the horse winning a smaller sum than he will receive if it loses. Bookmakers employ many agents and touts on commission.

The Betting act, 1853, rendered liable to punishment keepers of places for the purpose of any person betting with persons resorting thereto, and the Licensing act, 1872, penalized licensed persons who allowed their houses to be used in contravention of the 1853 act. The act only applied to ready-money betting and to places used for betting with persons physically resorting thereto, so that bets by letter, telegram or telephone did not fall within its penalties. The 1853 act made it an offense to advertise a betting house, and an 1874 act imposed penalties on persons advertising illegal betting.

Street betting was penalized by the Metropolitan Streets act, 1867, the Vagrancy act, 1873, and by-laws made by local authorities. These measures were found to be inadequate and in 1906 the Street Betting act was passed. Severe penalties were imposed on anyone frequenting or loitering in a street or public place (other than a racecourse or adjacent ground on a race day) for the purpose of betting or settling bets. Police constables might arrest for such an offense without warrant. It was obvious, however, to anyone passing along the back streets of London or any large town that the act was habitually broken.

By the Finance act, 1926, bookmakers were required to take out a license and a betting tax was imposed. Evasion of the tax was so flagrant, however, that for the first time the use of the totalizator or pari-mutuel system was authorized in England. This system, under which the whole sum staked on the horses in any race (less authorized deductions) is divided among the backers of the winning horses, had been in use on all French racecourses since 1866 and is in general use abroad. By the Racecourse Betting act, 1928, the Betting act, 1853, did not apply to any approved racecourse or any act done thereon on a day when horse races, but no other races, take place thereon, and totalizators might be lawfully set up and operated thereon by the Racecourse Betting Control board, set up under the act, or any person authorized by them. It was, however, made an offense to have a betting transaction, whether by the totalizator or not, with a person apparently under the age of 17, whether such person was betting for himself or placing a bet for another person, unless it was proved that such person was at the time 17 or over.

Lotteries.—Lotteries, or the determining of prizes by lot, were used in the entertainments and festivals of Roman emperors, of the feudal and merchant princes of Europe and of Louis XIV's court. In the Italian republics of the 16th century the lottery principle was applied to encourage the sale of merchandise. The institution became very popular in France and gradually assumed, despite the protest of the *parlements,* an important place in the government finance. In 1776 the biggest lotteries were merged in the *Loterie Royale,* and all private lotteries were suppressed. This lottery was suppressed in 1836 but in 1844 lotteries were authorized for the assistance of charity and the fine arts. Lotteries were suppressed in Belgium in 1830, Sweden in 1841 and Switzerland in 1865, but they are still common in many continental countries. The most important in the world is the Christmas "gordo" at Madrid, and the most popular has been the Irish sweepstakes (see below). Lotteries were also made illegal in Alaska (1899), Hawaii (1900) and Puerto Rico (1902).

Although lotteries were declared illegal in England by the act of 1698, which declared them a public nuisance, they continued to flourish by authorization of the government. From 1709 to 1824 the government annually raised large sums by lotteries. From 1793 to 1824 the yield averaged £346,765 annually. The prohibition of lotteries in general acts did not affect lotteries

established or specially authorized by statute, but now the only lotteries which would be legal are those complying with the stringent conditions of the Art Unions act, 1846. The activity of parliament indicates the extent of the evil. The Act of 1698 was followed by a numerous succession of acts, culminating in the Betting and Lotteries Act of 1934. In 1802 the definition of lottery was extended to include little-goes and any game or lottery not authorized by parliament, drawn by dice, lots, cards, balls or by numbers or figures or by any other way, contrivance or device whatsoever. Raffles and sweepstakes come within this definition and are illegal, and many devices by newspapers and tradesmen to attract customers by offering prizes have been suppressed. Thus to sell goods with the benefit of a chance of securing a prize, or with the promise of a prize, the value or nature of which depends on chance is an offense even though full value be given for the purchase price. Similarly a competition, the result of which depends on chance, is illegal. If, however, the result depends on skill, the competition is not a lottery, and organizers of competitions have been ingenious in keeping within the letter of the law while offering the public all the excitement of a lottery. The advertisement of foreign or illegal lotteries was forbidden in 1836 and 1844 and, if detected, tickets in and advertisements of foreign lotteries are treated by the customs as prohibited goods.

Irish Sweepstakes.—Best known of the many lotteries has been the Irish Hospital Sweepstakes which, until terminated by the war in 1940, collected £60,870,000 in 10 yrs. Although sanctioned by Eire and based on Britain's three outstanding horse races (the Grand National, Derby and Cesarewitch), more than half of the tickets were sold in the United States and its possessions. Irish hospitals benefited, over the 10-yr. period, by approximately £14,000,000. The sweepstake's huge drum—a ticket-mixing machine from which the lucky numbers were drawn—became one of Dublin's main sight-seeing attractions. Until liquidated in 1940, Irish Hospitals' Trust, Ltd., had the largest payroll of any firm in Eire with the exception of Guinness brewery.

Gambling in Stocks and Shares or in commodities falls within the Gaming acts, but buying or selling by way of speculation is not penalized in any may unless the shares or stock of a joint stock banking company are being bought or sold, when the provisions of Leeman's act, 1867, must be observed. The test is whether, although the transaction is in form commercial, the real intention of the parties is to make a mere wager on the price of the shares or commodity at a date fixed by the contract. The form, however, of all bargains on the stock exchange is calculated and intended to preclude people from setting up a Gaming act defense, as a contracting party is entitled to call for delivery or acceptance of the stocks or shares named in the contract. But in many cases dealings with "outside stockbrokers" or "bucket shops" have been held to be mere wagers although the contracts purported to give the right to demand delivery or acceptance. The courts may examine into the true nature of a transaction.

In Scotland the courts refuse to try actions on wagers. The acts of 1710, 1835, 1906 and 1922 extended to Scotland, as did the Lottery acts, except that of 1698. The 1853 act was extended to Scotland in 1874, and wide powers to suppress gaming houses, street betting, lotteries and gaming are conferred by the Burgh Police act, 1892 and 1903. The weight of judicial opinion is that the Gaming act, 1845, does not apply to Scotland. In Ireland the law is substantially as in England but the provisions for a betting tax did not apply to the Irish Free State (Eire) and the 1928 act did not apply to Ireland. It is the custom in Northern Ireland, however, to pass legislation which closely follows that in England. In 1923 the Irish Free State passed an act in the terms of the Gaming act, 1922, repealing s. 2 of the Gaming act, 1835.

(F. G.; X.)

NORTH AMERICA

Except for horse racing, almost all forms of gaming and wagering became illegal in the United States. Several states sanctioned dog racing, and more or less open gambling was permitted in several others, but only the wagering on horses gained wide legality in the United States. By 1943, 22 states allowed betting on horse races under the pari-mutuel system, and each had set up its racing commission to regulate the various tracks. There were more than 50 major horse-racing tracks in the United States in that year, and several averaged daily receipts of almost $2,000,000 during their month's meetings. Dog racing was confined principally to the eastern United States, with Miami, Fla., and Boston, Mass., the chief centres.

Lotteries were permitted in some states as late as 1890, when the last authorized lottery passed with the demise of the famous Louisiana lottery. Tickets on the Irish Sweepstakes, however, were widely sold throughout the United States during the 1930s, and numerous modified forms of lottery, usually in the name of charity, were allowed. Despite the fact that all forms of gaming with cards, dice, roulette wheels or other mechanical devices were forbidden, they continued to be carried out surreptitiously throughout the country generally.

Canada closely followed the United States in its gambling habits; but its horse racing passed largely under dominion, rather than provincial, control. Canada in 1943 had more than a dozen major tracks, principally in Montreal and Toronto. Mexico, with the most pliable of wagering laws on the continent, came to share with Cuba the distinction of being the centre of winter racing for North America.

Horse Racing.—Of all forms of betting in the United States, horse racing attracts by far the greatest number of bettors and resulted in the creation of many large syndicates for such a purpose. Dozens of newspapers, "dope sheets" and "tip" tabloids developed for, and because of, the interest in horse racing. An elaborate, nationwide news service, informing its clients of jockeys, scratches and odds, was in existence until it was barred by the U.S. government in the late 1930s.

The syndicates assumed control of large groups of betting establishments, or "bookie shops," in the major cities. Several syndicates were offsprings of prohibition-day gangs, and their tactics were not unlike those employed in the control of liquor dispersement. Powerful influences were built up by these syndicates, and in some cases hundreds of thousands of dollars were expended by them in order to secure the election of state or city officials known to be favourable to the retention of legislation permitting betting on horse racing or favourable to the allowance of the illegal "bookie" to operate. The race track operators themselves also formed their own lobby groups in order to retain legalized horse racing or, in some states, to bar legislation permitting dog racing to interfere with the "sport of kings."

The 22 states which allowed horse racing in 1943 and had commissions set up for regulation of the tracks were: Arkansas, California, Delaware, Florida, Illinois, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Nebraska, Nevada, New Hampshire, New Jersey, New York, Ohio, Oregon, Rhode Island, South Dakota, Washington and West Virginia. The mutuel system, or some modification of it, came into general use throughout the United States and Canada. In the mutuel system the bettor places his money on the horse he favours. The money bet on all entries is then divided, less the percentage to the track management and to the state, among those who placed money on the entries who finished first, second and third. Most of the larger tracks are equipped with totalizators—machines which compute the number and amounts of bets staked on a race and reveal such figures to the betting public on a huge board placed at the finish line.

An established percentage of each wager makes up the "take"—part of which goes to the track and part of which usually goes to the state. Several states, the most noteworthy being Michigan and Kentucky, decided not to take a percentage of the pari-mutuel handle but to charge the track a daily license fee. Michigan allowed the track 7½% of the pari-mutuel gross; Florida, on the other hand, allowed the state 8% of the pari-mutuel and the track 15%.

Many times the amount of money wagered by those in attendance at race tracks is bet daily at various "bookies" in practically all cities. The "book" sometimes consists of a cigar-store counter and again may be a large, ostentatious room, heavily

carpeted and elaborately furnished. The bookmaker, who is of course operating surreptitiously, may, if he finds he has received more bets than he wishes to handle, "lay off" through an agent at the track. Also, the huge sums bet by gambling syndicates go into the betting machines at the track through a representative who, more skilled in rapidly computing odds than the average racegoer, waits until he can determine a close approach to the exact odds and then bets the money for his syndicate.

An important, although often overlooked, phase of betting is the "breakage." Some tracks "break" on 5 cents and others on 10 cents—that is, the track retains the few cents which might be over the nickel or dime payoff. Thus, if the pari-mutuel calls for a $5.63 price on a horse, the track actually would pay the ticket-holders $5.60 and retain the extra 3 cents for itself. Tracks with a 10 cent payoff can figure on approximately a $4\frac{1}{2}$ cent "breakage," while the 5 cent payoff will usually return about 2 cents per ticket. Although insignificant to the individual bettor, "breakage" at U.S. tracks daily amounts to a small fortune.

Before the pari-mutuel system was employed nationally, betting at many of the tracks was done with individual bookmakers. The bookmaker would estabiish odds on the vanous entries, accept wagers on them at his quoted prices, and re-arrange the odds according to how each horse was backed by those placing bets with him. Until the legalizing of racing in New York and the establishment of the pari-mutuel system, the tracks at New York City were the last stronghold of the bookmaker.

In the dissemination of information on racing, both to the public and to professional gamblers, thousands of persons and elaborate systems are employed. The compilation of charts showing past performances of all entries is gathered daily at a tremendous expense. These charts are published by racing newspapers except where such publication is forbidden by state law. Then, too, an army of "clockers" or timers watch the daily training and performances of race horses at the various tracks. This information goes to two sources: to professional gamblers and syndicates for their own information, and to "handicappers," employed by newspapers to make selections of probable winners for the following day's racing. The network of telegraph wires used to convey this information from the various tracks rivals in magnitude those of the great press services which bring the world's news to the newspapers. Gambling syndicates have their own leased wires, running direct from the tracks into their headquarters, so that they do not have to share their information with anyone else.

The handling of bets at all dog racing tracks is on the same basis as at the horse racing tracks, but has not the ramifications of the latter.

Lotteries or Pools.—Various forms of lotteries or pools also are played daily by hundreds of thousands in the larger cities, especially among the smaller gamblers. "Policy" and other lotteries which pay on terminal numbers of daily bank clearings, United States treasury balance and sales of shares on the stock exchange, attract them. Agents for these pools are widespread. It may be a woman or girl who daily canvasses bettors in her immediate neighbourhood or among her circle of friends, or the keeper of a little delicatessen or candy store who will accept the pennies of children from a nearby school. And the aggregate wagered daily in these small sums constitutes a tremendous total.

The numbers game proved one of the more popular means of gambling, especially among Negroes. Bets as small as 5 cents are taken and the payoff is 100 to 1 or $5 for the 5-cent wager. The bettor selects 3 numbers ranging from 1 to 78. Each day 24 different numbers are selected—from 1 to 78—and those whose 3 numbers are among the 24 are winners.

Professional Baseball.—Major league baseball proves another medium for the gambler, both large and small. The practice of oral betting among those at the game—whether the next pitch will be a strike or a ball or a hit or an out, etc.,—was greatly curbed, but there still remained other forms of baseball gambling. Betting commissioners daily offer odds on each game in the major leagues, such odds being computed on the relative strength of the contending teams and the rival pitchers. After the "Black Sox" scandal of 1919, when several members of the Chicago White Sox accepted money from a gambling syndicate to "throw" a world's series, baseball itself revealed no taint of gambling.

College Football.—Each week during the autumn months the larger cities are flooded with cards challenging the public to select three or more teams from Saturday's schedule and to back such selections with anything from 25 cents up. If all 3 teams win, the bettor collects 4 for 1. His payoff grows proportionately larger to the number of winners he names. A tie or loss for any one of his selectees, however, means he has lost the bet. The odds, needless to say, are heavily in favour of the bet-taker.

Slot Machines.—Slot machines and other mechanical devices, while usually illegal, are allowed in some sectors. The slot machine is especially found in private and semi-private clubs. The same is true of punchboards, which award money or merchandise to those who punch winning numbers from the holes in the board. Keno or Lotto is permitted in some sections and is sometimes used to raise money for churches and schools.

GAMMA RAYS (usually written y-Rays) are electromagnetic radiations of very high frequency emitted by certain radioactive bodies (*see* RADIOACTIVITY). These radiations possess wave lengths of less than $\frac{1}{10}$ Angstrom unit or 10^{-10} of a centimeter. They mark the present upper limit of the spectrum of electromagnetic radiations. (*See* X-RAYS, NATURE OF.) The various interesting properties possessed by these rays are chiefly due to their extremely high frequency.

GAMUT, a term in music used to mean generally the whole compass or range of notes possessed by an instrument or voice (from the Greek letter *gamma,* used as a musical symbol, and *ut,* the first syllable of the mediaeval hymn, *Sanctus Johannes*). Historically, however, the sense has developed from its stricter musical meaning of a scale (the recognized musical scale of any period). originating in the mediaeval "great scale," of which the invention has usually been ascribed to Guido of Arezzo (*q.v.*) in the 11th century. The whole question is somewhat obscure, but, in the evolution of musical notation out of the classical alphabetical system, the invention of the mediaeval gamut is more properly assigned to Hucbald (d. 930). In his system of scales the semitone was always between the and and 3rd of a tetrachord, as G, A, ♭ B C, so the ♮ B and ♯ F of the second octave were in false relation to the ♭ B and the ♮ F of the first two tetrachords. To this scale of four notes G, A, ♭ B, C were subsequently added a note below and a note above which made the hexachord with the semitone between the 3rd and 4th both up and down, as F, G, A, ♭ B, C, D. It was at a much later date that the 7th, our leading note, was admitted into a key, and for this the first two letters of the last line of the above-named hymn "Sanctus Johannes" would have been used, save for the notion that as the note Mi was a semitone below Fa, the same vowel should be heard at a semitone below the upper Ut, and the syllable Si was substituted for Sa. Long afterwards the syllable Ut was replaced by Do in Italy, but it is still retained in France; and in these two countries, with whatever others employ their nomenclature, the original Ut and the substituted Do stand for the sound defined by the letter C in English and German terminology. The literal musical alphabet thus accords with the syllabic:

A	B	C	D	E	F	G
La,	Si,	Ut or Do,	Re,	Mi,	Fa,	Sol.

In Germany a remnant of Greek use survives. A was originally followed in the scale by the semitone above, as the classical Mesē was followed by Paramesē, and this note, namely ♭ B, is still called B in German, English ♮ B (French and Italian Si) being represented by the letter H. The gamut which, whenever instituted, did not pass out of use until the 19th century, regarded the hexachord and not the octachord, employed both letters and syllables, made the former invariable while changing the latter according to key relationship, and acknowledged only the three keys of ***G, C*** and F. (*See,* also, under MUSICAL NOTATION.)

GANDA, a Bantu tribe of east equatorial Africa. The Hamitic invaders, while remaining the light-skinned aristocracy, have been much more absorbed by the local Bantu who form the

peasantry. Apart from this distinction of skin colour there is not much to distinguish the aristocracy from the peasantry (*bakopi*) in physical appearance, though there is in speech, and class distinction is no longer an ethnic one. Hair is thick and woolly and is kept short, and the Ganda alone among the surrounding Bantu tribes do not mutilate their persons in any way. Bracelets of iron, copper and ivory are worn but otherwise the people are not addicted to personal adornment. They cover the whole body from chest to ankles with robes of bark-cloth, the manufacture of which is an important industry. They live in large circular huts, divided by many partitions and thatched with unusual care and skill. The walls and partitions are covered with a characteristic reed-work, and every home of importance has attached to it a series of neatly-kept courtyards surrounded by high fences of reed-work. A number of these residences surrounded by luxuriant gardens go to form a loose settlement, of which the market place is the conspicuous feature. The houses of the peasantry are simpler, of smaller dimensions and of ruder structure. Broad roads, carried over swamps by solid causeways, radiate from the capital to the villages of chiefs.

The Ganda are skilled watermen and maintain a large flotilla of war canoes. Their canoes are in remarkable contrast to the dug-outs of most of their neighbours, their keel, false prow and sewn boards suggesting an Indonesian origin. Their weapons consist of thrusting spears, a club which is used for war and executions, an oval shield of wickerwork with a central boss of wood or iron. Children use bows and arrows. They manufacture good pottery and artistic mats, and have a variety of musical instruments including the xylophone, flutes, harps, horns and drums. The drums of the *kabaka* are a tribal property and each is individually named, special drummers being detailed by chiefs for monthly duty.

Though they keep the usual domestic animals (their cattle being mostly of the short-horned, humped variety), they are essentially agriculturalists, the banana and sweet potato being the staple crop though a few cereals are also raised. All Iand except the clan burial grounds is the property of the *kabaka,* and individual holdings which are cultivated by a man's wife are granted him by his chief or directly by the king, or *kabaka.*

The clans are totemic and exogamous, have each certain social and political functions and are graduated in social status and prestige by various factors which are not constant. Certain clans are debarred from presenting a prince as candidate to the throne. Clans and their subdivisions have their separate estates *(butaka)* which are the clan burial grounds in charge of clan functionaries called *bataka,* who among other duties have to select the male and female life servants of the *kabaka.* Inheritance is patrilineal and the heir is one of the sons of the deceased, who is selected after the funeral by his brothers and sisters. Wives are not inherited but live as widows (with considerable licence) in separate huts built for them by the heir. Polygyny is usual, and blood-brotherhood is a widely practised institution.

Society is elaborately organized on a feudal system, at the centre of which is the *kabaka* who exercises direct and absolute rule. He is assisted by three ministers, the *katikiro* or chief executive, the *mulamuzi* or chief justice and *nzuwanika* or treasurer, and a variety of lesser officials including his naval and military commanders-in-chief. These ministers are also members of the *lukiko* or council, which consists of the chiefs of the 20 *saza* or counties into which the country is divided, together with three notables for each county and six additional men of importance for the kingdom—all nominated by the *kabaka.* The functions of the *lukiko* are judicial, administrative and advisory. Each county is in charge of a chief appointed by the *kabaka* who assigns him estates on appointment, but neither these nor the chieftainship are hereditable and are held solely at the *kabaka's* pleasure. The counties are subdivided into approximately ten districts each called *gombolola* under district chiefs subordinate to the county chiefs, and these district chiefs have a varying number of petty headmen or *miruka* under them. The peasants are tenants-at-will of the landholders, to whom they owe allegiance and service, including the maintenance of roads, personal labour, taxes and military obligations. Through all the hierarchy of chieftainship the same state and similar functionaries are maintained as at the royal court, and judicial procedure prescribes that with certain exceptions trials shall start at the lowest court and reach the *lukiko* by a series of appeals or commitments. The *kabaka's* mother has a very important position in the constitution.

Their religion combines ancestor worship with the worship of a number of natural phenomena, such as *Kiwanuka* the lightning, *Musisi* the earthquake. *Kazoba* the firmament was the nearest approach to a high god, but such a conception is probably subsequent to Mohammedan and Christian influence and is not earlier than the comparatively modern deity *Katonda.* There is a caste of priests and diviners called *Banzandwa,* and virgins were dedicated as brides to the nature deities.

See E. Hornell, "Indonesian Culture in East Africa" (in *Man,* i., 1928); Sir H. H. Johnston, *The Uganda Protectorate* (1902); J. Roscoe, *The Baganda* (1911). (J. H. D.)

GANDAK, a river of northern India. It rises in the Nepal Himalayas, flows south-west until it reaches British territory, where it forms the boundary between the United Provinces and Bengal for a considerable distance and falls into the Ganges opposite Patna. A snow-fed stream, its floods endanger the surrounding plains, lying at a lower level than its banks; it is accordingly embanked.

The LITTLE GANDAK rises in the Nepal hills, enters Gorakhpur district about 8 m. west of the Gandak, and joins the Gogra just within the Saran district of Bengal.

The BURHI (or old) GANDAK also rises in the Nepal hills, and runs roughly parallel to and east of the Gandak, of which it represents an old channel, passing Muzaffarpur, and joining the Ganges nearly opposite to Moughjr. Its principal tributary is the Baghmati, which rises in the hills north of Kathmandu, flows southward through Tirhut, and joins the Burhi Gandak close to Rusera.

GANDERSHEIM, a town of Germany in the *Land* of Brunswick, in the deep valley of the Gande, 48 mi. S.W. of Brunswick. Pop. (1933) 2,787. The convent church *(Stiftskirche)* contains the tombs of famous abbesses, and the famous abbey (now occupied by provincial government offices) dates from the 11th century.

There are manufactures of linen, cigars, aluminum and wire in the town.

The abbey of Gandersheim was founded by Duke Ludolf of Saxony in 856. His own daughter Hathumoda was the first abbess and under her successor, Louis III granted a privilege, by which the office of abbess was to continue in the ducal family of Saxony as long as any member was found competent and willing to accept the same. Otto III gave the abbey a market, a right of toll and a mint. The abbey was ultimately recognized as holding its fief directly from the emperor, and the abbess had a vote in the imperial diet. The conventual estates were of great extent, and the elector of Hanover and the king of Prussia were among its feudatories. Protestantism was introduced in 1568 and the last Roman Catholic abbess died in 1589; but Protestant abbesses were appointed to the foundation, and continued to enjoy their imperial privileges till 1803, when Gandersheim was incorporated with Brunswick. Gandersheim is famous for its literary memorials; Hroswitha, the Latin poet, was a member of the sisterhood in the 9th century; and the rhyming chronicle of Eberhard of Gandersheim is probably the earliest historical work in Low German.

GANDHARVA, (1) in Vedic Hindu mythology a celestial spirit of the highest sky, though in the *Avesta* he was a dragon-like monster, *Gandarewa,* dwelling in the sea, the abode of the white Haoma *(see* SOMA). But he was soon multiplied into a class of minor deities with various collective functions. Gandharva's union with the Apsaras (*q.v.*) typifies marriage, and they are parents of the first men *(see* YAMA). He is also a herbalist. Later, the Gandharvas preside over battles, the most popular being Tumburu, the "tambour" who leads them to watch those of men. They have their own breed of horses, their own land, located on both sides of the Indus, suggesting Gandhara, while Takshila and Pushkalavata were in Gandharva-desa and Gandhāra-desa respectively. But Gandharva-nagara,—"town" is some-

times spoken of as a real city or as only a mirage. (2) In Hindu law a *gandharva* marriage is informal, based on mutual consent.

See A. A. Macdonell, **Vedic** *Mythology,* and E. *W.* Hopkins, *Epic Mythology,* Strasbourg, **1897** and 1915.

GANDHI, MOHANDAS KARAMCHAND (1869–), Hindu nationalist leader, was born at Porbandar (Kathiawar, India) of a Bania family with official traditions. At the age of 19 he went to London, studied for a time at University college, and was called to the bar by the Inner Temple. Soon after starting practice in the Bombay High Court he was called, in 1893, on professional business, to South Africa, where he threw himself at once into a long and bitter struggle for the liberties of the Indian settlers in that country. He became leader of the opposition to a variety of measures taken by the local authorities to discourage Asiatic immigration and to limit the rights of citizenship available to Asiatics already resident.

It was in the course of this movement that his conception of resistance without violence developed; he relinquished his large income as an advocate, and founded a colony for his compatriots on Tolstoian lines near Durban. As the price he paid for his championship of the Indians' grievances, besides being more than once arrested and imprisoned he suffered frequent indignities at the hands of opponents. This neither checked his energies nor deterred him from rendering service of marked loyalty to the Government on three occasions; for he raised and commanded a Red Cross unit in the Boer War, he organized a plague hospital when the epidemic broke out in Johannesburg, and he led a stretcher-bearer party in the suppression of the Natal revolt of 1908. At last in 1914 a commission of inquiry into the Indian discontent recommended the removal of several of the worst injustices against which Gandhi had striven; and he felt justified in closing down his activities in South Africa and returning to India. There a wider field of political protest awaited him; and he was soon at work organizing, in connection with the home-rule movement, resistance to the British Government by "soul force" and non-cooperation.

In Jan. 1919 there were published two bills (subsequently known as the Rowlatt Acts) giving the Government emergency powers for dealing with revolutionary crimes and conspiracies; these had followed the proposals of a responsible commission which had investigated the subject, and the powers they conferred were safeguarded by elaborate protections against abuse. But Gandhi declared them to be an insult, intended to discredit the Indian people on the eve of ostensible political reforms, and he denounced the bills as instruments of oppression. He instituted a campaign of Satyagraha (literally, insistence on truth) or non-violent disobedience to unjust laws in the first instance, enlarging if necessary into disobedience to any law and complete non-cooperation with the Government. Spreading rapidly, the agitation burst into violence in the Punjab and elsewhere, with results which shocked Gandhi into a temporary suspension of his civil disobedience. Later in the year, he formed common cause with the Indian Mohammedans of the Khilāfat party, aggrieved by the terms of peace which Great Britain was offering to Turkey; and in July 1920 he proclaimed a general campaign of "non-violent non-cooperation." Its points were the boycott of Government service, of the new legislatures and of the courts of law; the surrender of all public offices; and the withdrawal of children from Government schools; to which were subsequently added boycott of foreign goods and the adoption of the spinning-wheel as an emblem of economic independence.

The agitation spread rapidly. The unlettered people who saw his earnestness and asceticism, and heard his simple eloquence, regarded him as a saint, and invested him with the title of Mahatma, or Great Soul. By 1921 Gandhi was at the zenith of his power. The National Congress, sitting at Christmas of that year, delegated its full authority to him, and empowered him to appoint his own successor. But signs of change were now appearing. The unrest into which the non-cooperation movement had plunged the country culminated in a series of grave outrages, some of a racial character, of which the Moplah outbreak was the worst, and others directed against the agencies of law and order. Gandhi met them by personal penances. and by repeated postponements of the date on which he had foretold that India would be liberated from British rule. But he had generated forces which he had no power to recall or control, and plain people were getting alarmed at the consequences. Muslim support was being deflected from him by the encouragement which Lord Reading's Government was giving to Islamic sentiment over Turkey; and his closest adherents were embarrassed by his frequent changes of policy. Consequently, when he was arrested in March 1922 and put on trial for conspiring to spread disaffection with a view to overthrowing the government of the country, the coup evoked little excitement. Gandhi pleaded guilty, accepted responsibility for all that had happened and invited "the highest penalty that can be inflicted upon me for what in law is a deliberate crime and what appears to me to be the highest duty of a citizen."

Condemned to six years' simple imprisonment, he was released in Jan. 1924 after an operation in gaol for appendicitis, and the rest of his sentence was unconditionally remitted. He came back to a party which had chosen other leaders, and was soon to reverse his policy of boycotting the administration. Esteemed and consulted though he continued to be by his oid followers, he was no longer a power to sway the masses; at the end of 1925 he announced his intentions of retiring from the world for a year; and his more recent incursions into politics have been ineffective. The nationalist movement was switched on to lines more familiar to western constitutional usage. But Gandhi's economic nostrums were unpractical and he gave way to unexpected bursts of intolerance, as when he described the British government of India as "satanic."

He renewed his agitation in Jan. 1930, urging civil disobedience by violation of the salt excise laws. He was arrested and interned at Poona on May 5. (ME.)

In Jan. 1931 Gandhi was released from prison. In the same year his conversations with the viceroy led to the Delhi Pact; and later he took part in the Round Table Conference in London. In 1933 he was again imprisoned for a short time, being released owing to the danger of his self-imposed fasting to his health.

See Romain Rolland, *Mahatma Gandhi* (1924); *C.* **F.** Andrews, *Mahatma Gandhi's Ideas* (1929).

GANDÍA, a seaport of eastern Spain in the province of Valencia; on the Gandía-Alcóy and Alcira-Denia railways. Pop. (1930) 14,009. The town is on the left bank of the Alcóy or Sérpis, which drains a rich and densely populated plain. The river enters the Mediterranean at the small harbour of Gandia (El Grao), 3 m. N.E. Among the ancient buildings are the Gothic church, the college founded by the director-general of the Jesuits (1510–1572), and the palace of the dukes of Gandia. The town manufactures leather, silk, velvet and ribbons, and exports fruit and imports coal, timber and flour.

GANDO, an emirate of British West Africa, in the N.W. part of the protectorate of Nigeria, and west of the Niger river. The state was established, c. 1819, on the death of Othman Dan Fodio, the founder of the Fula empire, and its area and importance varied considerably during the 19th century, several of the Fula emirates being regarded as tributaries, while Gando itself was more or less dependent on Sokoto. Gando in the middle of the century included both banks of the Niger at least as far north-west as Say. The districts outside the British protectorate now belong to France. Treaty relations with the British were entered into in 1884 and in 1903 the part assigned to the British sphere by agreement with France came definitely under the control of the administration in Nigeria. Gando is now included in the province of Sokoto. The chief town is Gando, situated on the Sokoto, the first considerable affluent of the Niger from the east, about 60 m. S.W. of the town of Sokoto.

GANESHA or **GANESH,** in the post-Epic Hindu mythology, eldest son of Siva and Parvati. His name means leader of (Siva's) attendants; he is a creator of obstacles and as such came to be placated for their removal. Depicted with an elephant's head, to symbolize his sagacity, he is the god of worldly wisdom; and is invoked on the first page of every book, especially in ledgers, as he bestows prosperity in trade. He is worshipped all over

India, especially in the south, and is affected by six sects, under his six titles, Mahā-Ganapati, etc. These hold him, not Siva, to be the real first cause and the Hairamba Ganapatiyas are taxed with unedifying rites.

See Hastings, E.R.E., vi., Edinburgh, 1913, *s.v.* GANAPATIYAS.

GANESH DATTA SHASTRI, SHRI JAGADGURU (1861–), Indian philosopher, was born on July 12, 1861. He was educated at the Oriental college. Lahore, and Punjab university, and in 1882 became a teacher. He held professorships of Sanskrit at Forman Christian college (1886–1907), Government college and Oriental college (1908–17). In 1917 he was appointed senior professor of Sanskrit and theology at Sanstan Dharam college, Lahore. In 1926 he was invested by the Government of India with the highest Sanskrit title of *Mahāmahopādhyāya;* he is the first Punjabi on whom this title has been conferred.

His publications include: Sanskrit-Hindi and Sanskrit-English-Hindi dictionaries; *Shāstriyasiddhānta* (1909); *First Book of Hindi Language; Bhagavadgita* (the Song Divine, 1926), various manuals on religious teaching, and articles on philosophical, religious and social subjects.

GANGES (GANGA), a great river of northern India, formed by drainage of the southern Himalayas. It rises in the Garhwal state, its lower course focusses the river system of Bengal, and it falls into the Bay of Bengal after a course of 1,500 m. It issues, under the name of the Bhagirathi, from an ice cave at the foot of a Himalayan snow-bed near Gangotri, 10,300 ft. above sea-level.

During its passage through the southern spurs of the Himalayas it receives the Jahnavi from the north-west, and subsequently the Alaknanda, after which the united stream takes the name of the Ganges. Deo Prayag, their point of junction, is a celebrated place of pilgrimage, as is also Gangotri, the source of the parent stream. At Sukhi it pierces through the Himalayas, and turns south-west to Hardwar, also a place of great sanctity. It proceeds by a tortuous course through the districts of Dehra Dun, Saharanpur, Muzaffarnagar, Bulandshahr and Farukhabad, in which last district it receives the Ramganga. Thus far the Ganges has been little more than a series of broad shoals, long deep pools and rapids, except during the melting of the snows and throughout the rainy season. At Allahabad, however, it receives the Jumna, a large river, which rises also in the Himalayas farther west. The combined river winds east by south-east through the United Provinces, receiving the Gumti and the Gogra at consecrated spots. But the tongue of land at Allahabad, where the Jumna and the Ganges join, is the true Prayag, or place of pilgrimage, to which hundreds of thousands of devout Hindus repair to wash away their sins in the sacred river. Here the great festival called the Maghmela is held.

Shortly after passing the holy city of Benares the Ganges enters Behar, and after receiving the Sone from the south, passes Patna, and is joined by the Gandak, which rises in Nepal. Farther east it receives the Kusi, and then, skirting the Rajmahal hills, turns sharply southward, passing near the ruined city of Gaur. The delta begins 220 m. in a straight line, or 300 by the windings of the river, from the Bay of Bengal. The main channel takes the name of the Padma or Padda, and proceeds in a south-easterly direction, past Pabna to Goalanda, above which it is joined by the Jamuna or main stream of the Brahmaputra. The vast confluence receives further additions from the hill country to the east, and forms a broad estuary known as the Meghna, which enters the Bay of Bengal near Noakhali. This estuary, however, is only the largest and most easterly of a great number of mouths or channels. The most westerly is the Hooghly, which receives the waters of a number of distributary channels that start from the parent Ganges above Murshidabad. Between the Hooghly on the west and the Meghna on the east lies the delta. Its northern angle consists of rich and fertile districts, such as Murshidabad, Nadia, Jessore and the 24 Parganas. But towards its southern base, resting on the sea, the country sinks into a series of swamps, intercepted by a network of channels. This waste is known as the Sundarbans, from the *sundari* tree, which grows in abundance in the seaboard tracts.

The most important channel of the Ganges for commerce is the Hooghly (*q.v.*), on which stands Calcutta, about 90 m. from the mouth. Beyond this city the navigation is conducted by native craft. Below Calcutta important boat routes through the delta connect the Hooghly with the eastern branches of the river.

The catchment basin of the Ganges is bounded north by a length of about 700 m. of the Himalayan range, south by the Vindhya mountains, and east by the ranges which separate Bengal from Burma; area 432,480 sq, m. The average fall from Allahabad to Benares is 6 in. per mile; from Benares to Calcutta, between 4 and 5 in.; from Calcutta to the sea, 1 to 2 in. Great changes take place from time to time in the river-bed. Extensive islands are thrown up, and attach themselves to the mainland, while the river deserts its old bed and seeks a new channel. it may be many miles off. Many decayed or ruined cities attest such changes in ancient times.

The Ganges is crossed by six railway bridges on its course as far as Benares; and there is another at Sara in Eastern Bengal.

The UPPER GANGES CANAL and the LOWER GANGES CANAL, with headworks at Hardwar, are the two principal systems of perennial irrigation in the United Provinces. They include j68 m. of main canals, and irrigated 1,316,000 acres in 1920. New headworks have more lately been completed.

GANGOTRI, a celebrated place of Hindu pilgrimage, in the Himalayas. It is situated in the state of Tehri-Garhwal in the United Provinces, on the Bhagirathi, the chief head-stream of the Ganges, and contains a small temple about 20 ft. high, in which are images representing Ganga, Bhagirathi and other figures of mythology. The bed of the river adjoining the temple is divided off by the Brahmans into three basins, where the pilgrims bathe. One of these portions is dedicated to Brahma, another to Vishnu and the third to Siva. The pilgrimage to Gangotri is considered efficacious in washing away sin and ensuring eternal happiness. The water taken from this sacred spot is exported by pilgrims to India and sold at a high price. The elevation of the temple above the sea is 10,319 ft.

GANGPUR, a feudatory State of India, in the province of Bihar and Orissa. The country is for the most part an undulating plain, broken by detached ranges of hills. The rivers are the Ib and the Brahmani, formed here by the union of the Sankh and the South Koel. The State possesses considerable mineral resources. A large coalfield also extends into it; deposits of manganese ore were first worked in 1908, and the output in 1921 was a little under 20,000 tons of ore; dolomite and limestone quarries are also worked. The State has been opened up by the Bengal-Nagpur railway, which runs through it for about 70 miles. Area, 2,492 sq m.; pop. (1931) 356,674; estimated revenue, Rs.6,66,000.

GANGRENE, a synonym in medicine for mortification (*q.v.*), or a local death in the animal body due to interruption of the circulation by various causes.

GANGSTER, a member of a group or gang operating in the overcrowded sections of any large American community and participating in criminal practice for financial gain. Originally the gangster was hardly more than a rowdy—the product of indolence and drink—who started on a career of idleness and petty thievery. Joining a gang, he learned the tactics of gang warfare, struggling with fists and stones to help his gang gain supremacy over other rival groups. Early in the present century the gangster became the paid agent of the unscrupulous politician of the period, who was quick to recognize his value in carrying out his schemes without incrimination. Gang weapons changed during this time to clubs and blackjacks, and the gangster became a recognized element in the lower strata of big city life. Drug traffic and later silk and fur stealing became popular outlets for his energies. In labour unrest he became a notable factor. The employment of gunmen to help foment labour troubles, the hiring of strong-arm men by the employers to protect "scabs" and by the unions to intimidate and maltreat the strike-breakers is a chapter in the history of labour conditions. These professional "sluggers" used their dull periods for more peaceful diversions, such as picking pockets and snatching purses. When pistols came into general use the element of terror in gang methods increased.

The argot of gangdom is distinctive. A "cold meat party" is a gathering of gangsters to pay tribute to a comrade who has been "rubbed out" (killed). "Packing a rod" is carrying a gun, and electrocution, the fate which is potentially the meed of every gangster, is known as "baking" or "frying." A "gun Moll" is a woman who carries the weapons of a gangster, a "stool pigeon" an agent who is in the paid employ of an influential leader and who acts as his confidential aide in all delicate commissions. His position is particularly dangerous since he is open to overtures from hostile factions and his services can usually be bought by the highest bidder.

See F. H. Allport, *Social Psychology* (Boston, 1924); C. E. Merriam, *New Aspects of Politics* (Chicago, 1925); P. H. Furfey, *The Gang Age* (1926); F. M. Thrasher, *The Gang* (1927); and H. Asbury, *The Gangs of New York* (1928).

GANILH, CHARLES (1758–1836), French economist and financial writer, was born at Allanche (Cantal) on Jan. 6, 1758 He was educated for the profession of law and practised as *avocat*. During the revolutionary period he played an active part in public affairs, for which he suffered imprisonment, and under Napoleon he held several public offices. He died in 1836. Ganilh is best known as the defender of the mercantile school in opposition to the views of Adam Smith and the English economists. He wrote *Essai politique sur le revenue des peuples de l'antiquité, du moyen âge,* etc. (1808); *Des systèmes d'economie politique* (1809); *The'orie d'economie politique* (181j); *Dictionnaire analytique de l'économie politique* (1826).

GANIVET, ANGEL (1865–1898), Spanish essayist and novelist, was born at Granada. He entered the diplomatic profession and was appointed consul at Antwerp, Helsingfors (where he published in 1896 his first book *Granada la Bella*) and Riga. Ganivet shows a brilliant power of evocation in the novels *La Conquista del reino de Maya . . .* (1897) and *Los Trabajos del infatigable creador Pio Cio* (1898). His best work lies, however, in the field of the essay—in the *Idearium español* (1897), where, a:, in the *Epistolario* (1904), his original and suggestive thought has free play.

GANJA, a town in the Azerbaijan A.S.S.R., in 40° 43' N. and 46° 20′ E., altitude 1,446 ft., on a northern spur of the Armenian plateau above the valley of the Kura river. Pop. (1926) jj,510, mainly Tatars and Armenians. Its position on the railway has facilitated wine, liquorice and textile manufactures, including wool, cotton and silk. Calico mills constructed in 192j have 66,000 spindles. It is the outlet for the copper mines of Kedabek and the sulphur pyrites of Chigari-dzor. Manganese is found in the district, which has cotton plantations, vineyards (those of the German colony being specially noted), fruit gardens and a silkworm breeding industry. Beekeeping is profitable The town is very old, and changed hands between Persians, Khazars and Arabs even in the seventh century. Later it was captured by Mongols, Persians, Georgians and Turks. In 1804 it became Russian and was known as Elisavetpol until the formation of the Azerbaijan S.S.R. when it resumed its original name. In 1826 the Russians under Paskevich defeated a Persian attack on the town. Amidst the ruins of old Ganja, 4 miles distant, is the "Green Mosque" and the beautiful mosque of the Persian Shah Abbas (1620) is in the modern town. The Persian poet, Shah Nizam (Nizam-ed-Din), was born here in 1141 and his grave is said to be in the vicinity. There is a marked contrast between the newer quarters, and the winding, narrow unhealthy ancient streets, with their low-roofed, windowless huts.

GANJAM, district, British India, in the extreme north-east of the Madras Presidency. It has an area of 8,383 sq.m., largely mountainous and rocky, but interspersed with open valleys and fertile plains, with groves of trees. The mountainous tract known as the Maliyas, or chain of the Eastern Ghats, has an average height cf about 2,000 ft. The hilly region, formerly the agency of Ganjam, is now included with the agencies of Vizagapatam and Godavari in one administrative division. The chief rivers are the Rushikulya, the Vamsadhara and the Languliya. Sea and river fisheries occupy many people. The hilly region abounds in forests.

Ganjam formed part of the ancient kingdom of Kalinga. The inaccessible country long kept the rising Mohammedan power at bay; and it was only a century after the first invasion of Orissa that a Mohammedan governor was sent to govern the Chicacole Circars, including the present district of Ganjam. In 1753 Chicacole and the Northern Circars were made over to the French. In 1759 Masulipatam was taken by an English force sent from Bengal, and the French were compelled to abandon Ganjam and their other factories in the north. In 1765 the Northern Circars (including Ganjam) were granted to the English by imperial firman, and in August 1768 an English factory was founded at Ganjam, protected by a fort. The British found the district difficult to rule at first. In 1816 Ganjam was overrun by the Pindaris; and in 1836 occurred the Gumsur campaign, when the British first came into contact with the aboriginal Kondhs, and suppressed their practice of human sacrifice.

In 1931 the pop. of the district was 2,411,619. It suffered severely from famine in 1919, and also from cyclones on two occasions. The principal crops are rice, other food grains, pulse and oil seeds; 46% of the cultivated land is under irrigation and fish is caught and cured. Salt is evaporated, as a government monopoly, along the coast. Sugar is refined at Aska. A considerable trade is conducted at the ports of Gopalpur and Calingapatam, which are only open roadsteads. The district is traversed throughout by the East Coast railway (Bengal-Nagpur system). The headquarters station is Berhampur; the town of Ganjam occupied this position till 1815, when it was found unhealthy, and its importance declined.

GANNET, or SOLAN GOOSE, *Sula bassana,* a large sea-bird. It breeds in enormous numbers in certain stations in the north Atlantic (of which the Bass Rock in the Firth of Forth, and Bird Rock in the Gulf of St. Lawrence, are the most famous), arriving about the end of March and leaving again in the autumn. During the non-breeding season it ranges over the whole of the north Atlantic.

The plumage in both sexes is white, with the outer edge of the wing black and some bare patches of dark blue skin round the eye. The young are clad in brown, white-tipped feathers. The nest is a shallow depression, usually in a mass of grass and seaweed. The single egg is white, and the young are hatched blind and naked. Striking mutual courtship ceremonies are performed. The gannet feeds on fish, which it obtains by plunging into the water with closed wings, often from a considerable height. Fishermen tow a board with a herring painted on it below the surface of the water; the bird dives, strikes the board and breaks its neck.

The most remarkable structural features of the gannet are the closed nostrils, the aborted tongue and the system of subcutaneous air-spaces, which communicate with the lungs, and can be filled or emptied at will. These latter probably break the force of its plunge.

In the southern hemisphere are two smaller forms, *S. capensis* of South Africa and *S. serrator* of Australia, while the tropical boobies, comprising four species, also belong here. One, *S. variegata,* from Peru, retains its spotted plumage throughout life and is one of the guano birds.

To the same genus belong the boobies, including the booby gannet (S. *leucogastra*) of tropical and subtropical seas throughout the world, and Brewster's booby (S. *brewsteri)* on the Pacific coast of North America.

GANODONTA or **TAENIODONTA,** an extinct group of clawed mammals of the North American Eocene. They include two families, the Stylinodontidae, which resemble the sloths in certain characters of teeth, skull and feet, and the Conoryctidar, with a less distinct resemblance to the armadillos. In *Stylinodon* of the later Eocene the teeth are high-crowned, rootless, columnar oval prisms like those of the sloths, but retain an enamel covering, the skull is short-faced, deep-jawed, small-brained, limbs short and stout, pelvis deep, tail massive, fore foot of digging type with large compressed claws. The Conoryctidae of the Paleocene are more primitive, with unreduced tritubercular teeth and related in skull and skeleton to primitive Insectivora. The affinities of

the group are uncertain. It is regarded by Osborn and Matthew as a side-branch from primitive edentate stock paralleling the ground-sloths.

GANOID, a name applied to fishes with rhombic bony scales covered on the outer surface with a layer of ganoine, a vitreous substance. It is now known that ganoid scales differ considerably in structure, and that the ganoids are not a natural group. Most fishes with ganoid scales are extinct, but the gar-pikes (*Lepidosteus*) survive in the fresh-waters of North America, and the Polypteridae in the rivers of Africa. (See FISHES.)

GANS, EDUARD (1797–1839), German jurist, was born at Berlin on March 22, 1797, of Jewish parents. He studied law first at Berlin, then at Göttingen, and finally at Heidelberg, where he attended Hegel's lectures, and became thoroughly imbued with the principles of the Hegelian philosophy. In 1826 he was appointed professor in the Berlin faculty of law. His great work is Erbrecht *in* weltgeschichtlicher *Entwicklung* (1824, 1825, 1829 and 1835). The liberality of his views, especially on political matters. drew upon Gans the displeasure of the Prussian Government, and his course of lectures on the history of the last 50 years (published as Vorlesungen *über d.* Geschichte d. letzten *fünfzig* Jakre, Leipzig, 1833–34) was prohibited. He died at Berlin on May 5, 1839.

GANSBACHER, JOHANN BAPTIST (1778–1844), Austrian composer, was born in 1778 at Sterzing in Tirol. He was a pupil of the celebrated Abbé Vogler and later during his second stay with Vogler, then (1810) living at Darmstadt, formed a close friendship with Weber and Meyerbeer. His own numerous compositions have been long since forgotten.

GANYMEDE, son of Tros (or Laomedon), king of Troy. Because of his surpassing beauty (his name, if Greek at all, may mean "glad in brightness"), he was carried off by the gods, or Zeus, or, according to a later myth, the eagle of Zeus or the god himself in eagle shape, to serve as cup-bearer (Homer, Iliad, v. 265, xx. 232; Horace, Odes, iv. 4. 1; Ovid, Met., x. 155). In compensation, Zeus gave his father a stud of immortal horses (or a golden vine, Lesches, *Ilias* parva, frag. 6). From fairly early times (Theognis, 1,345 6th century B.C.), and perhaps especially among Dorians (a Cretan variant makes Minos the ravisher, Athenaeus 601 E; cf. Plato, Laws, 636 C), his kidnapper was supposed to have a homosexual passion for him, hence the connotation which Catamitus, the popular Latin form of his name, had and has. As divine cup-bearer, he was apparently credited with making the Nile rise (Pindar, frag. 282, von Christ), and was later identified with the constellation Aquarius (pseudo-Eratosthenes, catast., 26).

See especially Weizsacker-Drexler in Roscher's Lexikon, *s.v.*

GAO, a town of French West Africa, the chief town of a circle, in the colony in the French Sudan, on the left bank of the Niger, 400 m. by river below Timbuktu. Pop. (1933), 5,307. The present town dates from the French occupation in 1900; of the ancient city there are scanty ruins, the chief being a truncated pyramid, the remains of the tomb (16th century) of Mohammed Askia, the Songhoi conqueror, and those of the great mosque. The city of which the French settlement is the successor was founded by the Songhoi, probably in the 7th or 8th century, and became the capital of their empire. In the 14th century Gao was conquered by the king of Melle, and its great mosque was built (*c.* 1325) by the Melle sovereign Kunkur Musa on his return from a pilgrimage to Mecca.

In the 15th century the Songhoi regained power and Gao attained its greatest prosperity in the reign of Askia. It did not enjoy the commercial importance of Jenné nor the intellectual supremacy of Timbuktu, but was the political centre of the western Sudan for a long period. On the break up of the Songhoi power the city declined in importance. It became subject in 1590 to the Ruma of Timbuktu, from whom it was wrested in 1770 by the Tuareg, the last named surrendering possession to the French. A Frenchman, D'Isalquier (*q.v.*) spent some years in Gao in the early 15th century. In modern times it was reached by Mungo Park (1805) and by Heinrick Barth (1875). It is now the Niger terminus for trans-Saharan motor traffic. From Gao upwards the Niger is navigable for over 1,000 miles.

See F. Dubois "La région de Gao" (*L'Afrique françaises* [1909]).

GAOL or **JAIL,** a prison (*q.v.*). The two forms of the word are due to the parallel dual forms in Old Central and Norman French respectively, jaiole or *jaole,* and *gaiole* or *gayolle.* The form "gaol" still commonly survives in English, and is in official usage, *e.g.,* "gaol-delivery"; the spelling "jail" is used in America.

GAŌN (plur. *Geōnim*). The transition from ancient to mediaeval Judaism was accomplished by four successive groups of rabbis (of whom the *Geōnim* were the last), whose teaching safeguarded tradition and whose advice or decisions were often invoked far beyond the limits of their schools or communities. With the end of the *Geōnim* centralized authority in Judaism passed away and gave place to congregationalism. The age of codification succeeded and the general acceptance of codes prevented local autonomy from drifting into sectarianism. The invention of printing finally stereotyped the last code (Joseph Caro's *Shulḥan 'Arūkh, q.v.*) and retarded development. The four groups were:—

I. The *Tannā'im* (sing. *Tannā,* or teacher, from Aramaic Tend, he taught; the root corresponds to the Hebrew *Shanah,* hence Mishnah) were the scholars whose teaching is recorded in the Mishnah (see TALMUD). The last *tannā'im* belong to three generations (a) A.D. 70–100. Representative name, Johanan ben Zaccai who, leaving the beleaguered Jerusalem, founded a school at Jamnia in Judaea and saved Judaism from perishing with the Temple. (b) 100–130. Representative name 'Aqiba (*q.v.*) who died a martyr in the fight for freedom against Hadrian. (c) 130–160. Representative name, Judah the Prince, compiler of the *Mishnah.* The schools moved to Galilee (Usha, Sepphoris).

II. *Amorāīm,* lit. speaker, the spokesman of a *Tannā,* who repeated his discourses. But after the *Mishnah* was compiled the 'Amora became an independent teacher. The age of the *Amorāīm* lasted from the 2nd to the 5th centuries and their work was the Gemara. In 350 the Palestinian schools decayed and were succeeded by the Babylonian schools at Nehardea, Sura and Pumbeditha. Representative names, Rab (or Abba Arika, 175–247), Samuel (180–257) who arranged the calendar, and Ashi (352–427) who, with Rabina (d. 499), may be said to have compiled the Talmud.

III. The *Saboraim* (properly *Ṣebhōrā'ē,* plu. of *Ṣābhōrā,* a reasoner) during the 6th century effected slight supplementary work. It was an era of persecution and creative thought was hampered. The Gaōn Sherira enumerates 12 *Saboraim.*

IV. The *Geōnim* (*Gaōn*=Excellency, probably for *Geōn Ya'aqōbh,* Ps. xlvii. 5) from the end of the 6th to the 11th centuries effected the transference of the centre of Judaism from Asia to Europe. The Gaōnate was civilly subject to the Exilarch but throughout the diaspora enjoyed a wide authority. Their *Responsa* are of great importance and they standardized the liturgy. Among the great *Geōnim* may be mentioned Sherira (ben Hanina of Pumbeditha, d. 1000), author of the famous circular letter addressed to Jacob ben Niṣṣim of Kairowan in which the history of the Talmudic and Gaonate periods is set forth; Amram (ben Sheshna, of Sura, d. 875), the first authority to arrange a complete domestic and synagogal liturgy; and Sa'adia (*q.v.*) of Sura (892–942) who fought Karaism (see KARAITES), translated the scriptures into Arabic, compiled a dictionary and was a master of philosophy. The last *Geōnim* of Sura and Pumbeditha were Samuel ben Hofni (d. 1034) and Hai (d. 1038) respectively.

BIBLIOGRAPHY.—*See* the relevant articles in Jew. Encycl. and Hastings, Encycl. Rel. *and* Eth. (where lists of Tannā'im and Geōnim are given). J. Mann's Jews in Egypt and Pulestine (Oxford, 1922) is a mine of information about details of the Gaonate. For general readers the histories of H. Graetz (Philadelphia, 1891), of Margolis and Marx (ib. 1927) and I. Abrahams (Short *Hist.* of **Jew.** Lit., 1906), will be found useful. Benjamin of Tudela, who travelled in 1165, speaks of the Gaonate (**Eng.** trans. by M. Adler, see pp. 39 sqq. Lond., 1907).

GAP, capital of the French department of Hautes-Alpes, 122 mi. by rail from Marseille. Pop. (1936) 10,860. It is the *Vapincunt* of the Romans founded by Augustus about 14 B.C. In 1232 most of the region passed from Provence by marriage to the

dauphins of Viennois. The town itself, however, remained under the rule of the bishops until 1512, when it was annexed to the crown of France. It was sacked by the Huguenots in 1567 and 1577, and by the duke of Savoy in 1692. It was the birthplace of the reformer Guillaume Farel (1489–1565), who first preached his doctrines there about 1561–62. Gap is built at a height of 2,418 ft. on the right bank of the Luye. The 17th century cathedral has been entirely reconstructed (1866–1905). The former prefecture contains scientific and archaeological collections and many mss. from the monastery of Durbon. The episcopal see of Gap, now in the ecclesiastical province of Aix-en-Provence, is first mentioned in the 6th century, and in 1791 was enlarged by the annexation of that of Embrun. Gap is a thermal spa. The industries include tilling, sawmilling, corn milling and the making of gloves and confectionery.

GAPAN, a municipality of the province of Nueva Ecija, Luzon, Philippine Islands, almost directly south of Cabanatuan, the provincial capital. Pop. (1939) 23,324 (a gain of 9,707 since 1918), of whom 11,480 were males, and 1 white. It is surrounded with a fertile rice-producing country and with forests containing hardwood and is a commercial centre of some importance. Of its inhabitants aged 6 to 19, inclusive, 41·2% attended school, and of those 10 years old and over 61·2% were reported as literates. Principal vernaculars are Tagalog and Pnmpango.

GAPON, GEORGII (1870–1906), Russian orthodox priest and revolutionary, known as "Father Gapon." At one time he was an agent of the secret police, and was associated with the notorious Zubatov in Moscow.

He became Zubatov's agent in St. Petersburg (Leningrad) to organize a workers' movement under police supervision; the movement soon got beyond the power of the police and came under socialist leaders. Gapon led the unarmed crowd to present a petition to the tsar at the Winter palace (Jan. 22), when the soldiers fired on the crowd. Gapon vanished, but he was tracked by the revolutionaries and murdered, at Terioki, Finland, on April 11, 1906.

GARANA: *see* GUARANA.

GARARISH, a semi-nomadic tribe of Semitic origin, on the right bank of the Nile from Wādi Halfa to Merawi. Many are agriculturists; they claim kinship with the Ababda, but are more Arab than Beja.

GARASHANIN, ILIYA (1812–1874), Serbian statesman, was born on Jan. 28, 1812, at Garasha (Kragujewac). In 1836 Prince Milosh appointed him a colonel and commander of the then just organized regular army of Serbia. In 1842 he was called to the position of assistant to the home minister, and from that time until his retirement from public life in 1867 he was repeatedly minister of home affairs. He rendered great services to his country as minister for foreign affairs. He sought to replace the Russian protectorate over Serbia by the joint protectorate of all the great powers of Europe. In 1853 he opposed co-operation with Russia against Turkey and the western powers. His anti-Russian views led Prince Menshikov, while on his mission in Constantinople, 1853, peremptorily to demand his dismissal. Nevertheless his personal influence in the country secured the neutrality of Serbia during the Crimean War. It was due to Garashanin that France proposed to the peace conference of Paris (1856) that the old constitution, granted to Serbia by Turkey as suzerain and Russia as protector in 1839, should be replaced by a more modern and liberal constitution, framed by a European international commission. But the agreement of the powers was not secured. Garashanin induced Prince Alexander Karagcorgevich to convoke a national assembly, which had not been called to meet for ten years. The assembly was convoked for St. Andrew's Day 1858, but its first act was to dethrone Prince Alexander and to recall the old prince Milosh Obrenovich.

When after the death of his father Milosh (in 1860) Prince Michael ascended the throne, he entrusted the premiership and foreign affairs to Iliya Garashanin. The result of their policy was that Serbia was given a new, although somewhat conservative, constitution, and that she obtained, without war, the evacuation of all the fortresses garrisoned by the Turkish troops on the Serbian territory, including the fortress of Belgrade (1867). Garashanin was preparing a general rising of the Balkan nations against the Turkish rule, and had entered into confidential arrangements with the Rumanians, Bosnians, Albanians, Bulgarians tnd Greeks, and more especially with Montenegro. But the execution of his plans was frustrated by his sudden resignation (at the end of 1867), and by the assassination of Prince Michael a few months later (June 10, 1868). Although he was a Conservative in politics, and as such often in conflict with the leader of the Liberal movement, Yovan Ristich, he certainly was one of the tblest statesmen whom Serbia had in the 19th century.

His son, NILUTIN GARASHANIN (1843–1898), entered parliament in 1874. He was minister of the interior (1880–83), and prime minister (1884–87). In 1894 he became ambassador in Paris, where he died on March 7, 1898.

GARAT, DOMINIQUE JOSEPH (1749–1833), French writer and politician, was born at Bayonne on Sept. 8, 1749. After practising as an advocate at Bordeaux, he came to Paris, and became a contributor to the *Encyclopédie méthodique* and the *Mercure de France.* He gained a reputation by an *éloge* on Michel de L'Hôpital in 1778, and was three times crowned by the Academy for *éloges* on Suger, Montausier and Fontenelle. In 1785 he became professor at the *Lycée.* When deputy to the states-general in 1789, he served the papular cause by his narrative of the proceedings of the Assembly contributed to the *Iournal de Paris.* He played an undignified part in politics, and became a tool in the hands of others. Danton made him minister of justice on Oct. g, 1792, and entrusted to him what he called the *commisison affreuse* of communicating to Louis XVI. his sentence of death. In 1793 Garat became minister of the interior. Though himself uncorrupt, he acquiesced in corruption in his subordinates. At last, disgusted with the excesses which he was unable to control, he resigned (Aug. 15, 1793). On Oct. 2 he was arrested for Girondist sympathies but soon released. He escaped further molestation owing to the friendship of Robespierre, whose literary *amour-propre* he had flattered. On the 9th Thermidor, however, he took sides against Robespierre, and on Sept. 12, 1794 he was named by the Convention as a member of the executive committee of public instruction. In 1798 he was appointed ambassador to Naples, and in 1799 became a member, then president, of the Council of the Ancients. After the revolution of the 18th Brumaire he was chosen a senator by Napoleon and created a count. During the Hundred Days he was a member of the chamber of representatives. He was a member of the Institute of France from 1803 until the restoration of Louis XVIII. He died at Ustaritz near Bayonne on April 25, 1833. His elder brother Dominique (1735–1799) was also a deputy to the states-general.

The works of Garat include, besides those already mentioned, *Considérations sur la Rdvolution Française* (1792); *Mémoires sur la Rdvolution, ou exposé de ma conduite* (1795); *Mdmoires sur la vie de M. Suard, sur ses écrits, et sur le XVIIIe siècle* (1820). For the history of Garat's tenure of the ministry, *see* police reports of Dutard, in W. A. Schmidt's *Tableaux de la Révolution Française* (3 vols., Leipzig, 1867–70).

GARAT, PIERRE-JEAN (1764–1823), French singer, nephew of Dominique Joseph Garat, was born in Bordeaux on April 25, 1764. Gifted with a voice of exceptional timbre and compass he was the favourite singer of Marie Antoinette, to whom he gave lessons. At the beginning of the Revolution he accompanied Rode to England, where the two musicians appeared together in concerts. He returned to Paris in 1794 but fell under suspicion, was imprisoned for a short time, and then left Paris for Hamburg. He gained a great reputation in all the capitals of Europe, and retained his voice for a long period. He was a keen partisan of Gluck in opposition to Handel. On the institution of the Paris Conservatoire he became its first professor of singing, and had many famous pupils.

See Bernard Miall, *Pierre Garat* (1913).

GARAY, JANOS (1812–1853), Hungarian poet and author, was born on Oct. 10, 1812, at Szegszárd. In 1834 he brought out at Pest an heroic poem, in hexameters, under the title *Csatár.* After this he issued in quick succession various historical dramas, among which the most successful were *Arbócz, Országh* Ilona and

Báthori Erzsébet—the first two published at Pest in 1837 and the last in 1840. Garay removed in 1838 to Pressburg, where he edited the political journal *Hirnök* (Herald). He returned to Pest in 1839, and in 1842 was admitted into the Kisfaludy Society, of which he became second secretary. He published a collection of his poems (1843); *Tollrajzok* (Sketches with the Pen, 1845); *Arpádok* (1847), a collection of ballads; *Balatoni Kagyldk* (Shells from the Balaton Lake) (1848), lyrics; *Frangepán Kristófné* (Christopher Frangepan's Wife) (1846), a poetical romance; and, his last and most famous work, an historical poem in 12 cantos, with the title *Szent László* (Saint Ladislaus) (Eger, 1852). Garay was professor of Hungarian language and literature to the University of Pest in 1848–49. After about four years' illness he died on Nov. j, 1853, in great want.

A collective edition of his poems was published at Pest the year after his death by F. Ney (2nd ed. 1860), and several of his poems were translated by Kertbeny. See *Garay Jdnos Összes költeményei* (2nd ed., Pest, 1860); and *Dichtungen von Johann Garay* (2nd ed., Vienna, 1856).

GARBLE, originally a mediaeval commercial term in the Mediterranean ports, meaning to sort out, or to sift merchandise, such as spices, etc., in order to separate what was good from the refuse; hence to select the best of anything. Similarly a "garbler" was an official appointed to sort out, or test the work of those who had sorted, the spices or drugs offered for sale in the London markets. In this sense the word is obsolete, but by inversion, or rather perversion, "garble" now means to sort out or select, chiefly from books or other literary works, or from public speeches, some portion which twists, mutilates or renders ineffective the meaning of the author or speaker.

GARBORG, ARNE EVENSEN (1851–1924), Norwegian writer, was born on Jan. 25, 1851, at Thime. He joined the movement for the creation of a Norwegian literary language based on the *landsmaal* or peasant dialect derived from old Norsk, in place of the Dano-Norwegian literary medium. He wrote a series of novels deeply penetrated by religious feeling. In 1895 he wrote a cycle of lyric poems in the *landsmaal, Haugtussa* (1895), which describe a young girl's belief in the supernatural. He also translated the *Odyssey* (1918) and a selection from the *Mahabharata* (1921), and, for representation at the *landsmaal* theatre, which he and his wife had founded, Holberg's classical comedy, *Jeppe paa Berget* (1921). His collected works, *Skrifter i samling,* began to appear in 1908. Garborg died on Jan. 14, 1924, at Asker.

See Erik Lie, *Arne Garborg* (1914).

GARÇÃO, PEDRO ANTONIO JOAQUIM CORREA: *see* CORREA GARÇÃO, PEDRO ANTONIO JOAQUIM.

GARCIA (DEL POPOLO VICENTO), MANOEL (1775–1832), Spanish tenor singer and composer, was born in Seville on Jan. 22, 1775. At 17 he made his début on the stage at Cadiz, in an operetta which included songs of his own composition. He had already a considerable reputation as a composer of light operas and as an operatic singer when he appeared in Paris in 1808, in Paer's opera *Griselda.* At Naples later he created some famous rbles in Rossini's operas, and sang them until 1816 when he visited London and Paris. Between 1819 and 1823 he lived in Paris, singing in *Il Barbière, Otello, Don Giovanni,* etc., and producing some operas of his own—he wrote about 100 in all—of which *La Morte di Tasso* was the most important. But his greatest work was done as a teacher of singing in London and Paris. Of his principles and method he left an account in his *Metado di Canto,* the substance of which was subsequently incorporated by his son Manoel in his admirable *Traité complet* de *l'art du chant* (1847). He died in Paris on June 2, 1832.

His son, Manoel Garcia (1805–1906), who celebrated his hundredth birthday in London on March 17, 1905, was born at Madrid, and as a teacher became no less famous than his father. He was a professor at the Paris Conservatoire (1830–48), at the Royal Academy of Music, London (1848–95), and will be remembered, it is safe to say, so long as the art of singing is studied, as the inventor of the laryngoscope.

See M. Sterling Mackinlay, *Garcia the Centenarian and his Times* (London, 1908).

GARCIA DE LA NUERTA, VICENTE ANTONIO (1734–1787), Spanish dramatist, published an unsatisfactory collection of Spanish plays entitled *Teatro Español* (1785–86), and various dramas, of which only *Raquel* now survives.

GARCÍA DE PAREDES, DIEGO (1466–1534), Spanish soldier and duellist, born at Trujillo, Estremadara. He served in his youth in the war of Granada; after killing a relative, Ruy Sanchez de Vargas, in a street fight, he fled to Rome, where he took service as a soldier of Pope Alexander VI., then in conflict with the barons of the Romagna. A personal quarrel resulting in a murder obliged him to pass over to the enemy. By his daring and strength he won the admiration and trust of the Colonnas, as also of Gonzalo de Córdoba. He took part in the wars between Ferdinand V. of Aragon and Louis XII. on the frontier of Navarre, and once against the Turks on the Danube till 1530. His countrymen, crediting him with feats of fabulous strength, made him the hero of many Miinchausen-like stories of personal prowess. He was killed at a jumping-match at Bologna in 1534; his body was carried to Trujillo and there buried in the church of Santa Maria Mayor in 1545.

GARD, a department in the south of France, part of the old province of Languedoc. Pop. (1936) 395,299. Area 2,271 sq.mi. It is bounded N. by the departments of Lozkre and Ardbche, E. by the Rhone, which separates it from Vaucluse and Bouches-du-Rhbne, S. by the Mediterranean, S.W. by Hérault and W. by Aveyron. Gard is divided into three sharply-defined regions. The tree-clad Cévennes, with their deep and fruitful valleys, occupy the north-west, reaching a height of 5,120 ft. on the frontier of Lozkre. The Garrigues, a dry, hilly limestone region stretches south from the Cévennes over about half the department, and grows cereals, vine and olive. The southern coastal plain is unhealthy because it has numerous lagoons and marshes, but it comprises the best arable land and vineyards in Gard.

Besides the Rhone and the Ardkche, the principal rivers are the Cèze, Gard, Vidourle and Hérault. They all rise in the Cévennes, and the Ckze and the Gard feed the Rhone, the lower Vidourle forming the southwest boundary of the department. The Hérault rises, and flows for a short part of its course, in the west of Gard. The upper course of the river Gard is in mountain gorges, and melting snows often cause disastrous floods. Near Remoulins it is crossed by a celebrated Roman aqueduct—the Pont du Gard. The canal de Beaucaire extends from the Rhone at Beaucaire to Aigues-Mortes, which communicates with the Mediterranean at Grau-du-Roi by means of the Grand-Roubine canal.

The climate is warm in the south-east, colder in the north-west; it is rather changeable, and rain-storms are common. The cold and violent north-west wind known as the mistral is its worst drawback. Les Fumades (near Allbgre) and Euzet have mineral springs. The chief grain crops are wheat and oats. Rye, barley and potatoes are also grown. Gard is famed for its cattle, its breed of small horses, and its sheep, yielding very fine wool. In the rearing of silk-worms it ranks first among French departments. The principal fruit trees are the olive, mulberry and chestnut. The vine is extensively cultivated and yields excellent red and white wines. The department is rich in minerals, namely coal, iron, lime, lignite, asphalt, zinc, lead and copper, for the most part situated in the neighbourhoods of Albs and La Grand'-Combe and Le Vigan. Much salt is obtained from the coastal marshes. The fisheries are productive. Manufactures include silk, of which Alks is the chief centre, cotton and woollen fabrics, hosiery, carpets, ironware, hats (Anduze), gloves, paper, leather, earthenware and glass. There are important metallurgical works, the chief of which are those of Bessèges. The exports of Gard include coal, lignite, coke, asphalt, building-stone, iron, steel, silk, hosiery, wine, olives, grapes and truffles.

The department is served by the P.L.M. railway. It is divided into the arrondissements of Nimes, Alks and Le Vigan, with 40 cantons and 353 communes. The chief town is Nimes, which is the seat of a bishopric of the province of Avignon and of a court of appeal. Gard belongs to the 15th military region (Marseilles), and to the académie (educational division) of Montpellier. Nîmes, Alks, Uzès, Aigues-Mortes, Beaucaire, Saint-Gilles,

Bessèges, La Grand'-Combe and Villeneuve-lès-Avignon are the principal towns. Opposite the manufacturing town of Pont-St.-Esprit the Rhone is crossed by a fine mediaeval bridge more than 1,000 yd. long built by the Pontiff brethren. Le Vigan, an ancient town with several old houses, carries on silk-spinning.

GARDA, LAKE OF, the most easterly and the most extensive of the Lombard lakes (the *Lacus Benacus* of the Romans), surpassed in the Alpine region only by those of Geneva and Constance. The lake is now divided between the provinces of Verona, Brescia and Trento. Its broad basin orographically represents the southern portion of the valley of the Adige, though that river now flows through a narrow trench which is separated from the lake by the long narrow ridge of the Monte Baldo (7,277 ft.). The lake is fed by the Sarca at its north end, while at the southern extremity of the lake the Mincio flows out, on its way to join the Po. The area is about 143 sq.m., length $32\frac{1}{4}$ m., greatest breadth about 10 m., height of surface above sea-level 216 ft. and the greatest depth 1,135 feet. Its upper northern end is narrow, but between Garda (east) and Salb (west) the lake expands gradually into a nearly circular basin. Owing to this conformation the lake is much exposed to sudden and violent winds. The steep grey limestone crags of Monte Baldo, on the eastern side of the lake, contrast strongly with the rich vegetation on the western and southern shores. The portion of the western shore that extends from Gargnano to Salb is the most sheltered and warmest part of the region, so that not merely does it resemble one continuous garden (producing lemons, figs, mulberries and olives) but is frequented in winter. The lovely promontory of Sermione (anc. Sirmio) at the southern end of the lake, has also an extremely luxuriant vegetation. It was a favourite residence of Catullus; but the large ruins of a Roman villa on the promontory belong to the imperial period, while there are also remains of the Lombard period, and a fine castle of the Scaligers. At the south end of the lake are the towns of Peschiera ($14\frac{1}{4}$ m. by rail from Verona on the east) and of Desenzano ($17\frac{1}{2}$ m. by rail from Brescia on the west), which are $8\frac{3}{4}$ m. distant from each other. There is a regular steamer service from these two towns. On the west shore of the lake are Salb, Maderno, Toscolano (a place important in the early history of the printing press), Gargnano and Limone, while the rugged east shore can boast only of Bardolino and Garda. At the northern end of the lake is Riva.

GARDELEGEN, a town in Prussian Saxony. Germany, on the main Berlin-Hanover railway. Pop. (1939) 12,062. Gardelegen was founded in the 10th century, and on the neighbouring heath Margrave Louis I. of Brandenburg gained, in 1343, a victory over Otto of Brunswick. It has a Romanesque church. and a hospital founded in 1285. There are considerable manufactures, notably agricultural machinery and buttons, and its beer has a great repute.

GARDEN, MARY (1877–), American operatic singer, was born at Aberdeen, Scotland, on Feb. 20, 1877. At the age of six she was brought to the United States. In 1888 her family settled in Chicago, where her early musical training was received. She went to Paris in 1896, and studied under Trabadello, Chevallier and Fougère. She made her début at the Opéra Comique, Paris, April 3, 1900, in the title rôle of Louise. Her first appearance in the United States was at New York in the title rôle of Thais, Nov. 2j, 1907. In 1910 she became a member of the Chicago Civic Opera company, assuming, among others, the parts of Salomé, Thai's, Mélisande and Louise. She was general director of the Chicago Opera Association in 1921–22. In 1927 she sang in *Pelléas et Mélisande* in Geneva, Switzerland; also in Paris in the opera *Resurrection.*

GARDEN, the ground enclosed and cultivated for the growth of fruit, flowers or vegetables (see HORTICULTURE). From the fact that Epicurus (*q.v.*) taught in the gardens at Athens, the disciples of his school of philosophy were known as *οἱ ἀπὸ τῶν κήπων*—those from the gardens (Diog. Laertius x. 10); and Cicero (De *finibus* v. 1, 3, and elsewhere) speaks of the Horti *Epicuri* (the gardens of Epicurus). Thus as the "Academy" refers to the Platonic and the "Porch" (*στοά*) to the Stoic school, so the "Garden" is the name given to the Epicurean school of philosophy For Garden Planning, see LANDSCAPE ARCHITECTURE.

GARDEN CITIES, a term first used in 1869 by A. T. Stewart in connection with the development of an estate on Long Island, N.Y., are to be distinguished from "garden suburbs" which are, generally, merely suburbs with specially restrictive by-laws of an industrial city. (See TOWN AND CITY PLANNING and SOCIAL ARCHITECTURE.) The idea of a garden city, that is, a unit planned as a whole, was due to Sir Ebenezer Howard, who, in a book entitled Tontorrow (London 1898), outlined a scheme for the building of a new model town to be called "Garden City." The publication of this book led to the formation of the Garden Cities Association in 1899 and to the establishment of Letchworth, the first garden city, in 1903, and Welwyn, the second, in 1920. The main features of Howard's scheme were (1) the purchase of a large area of agricultural land within a ring fence; (2) the planning of a compact town upon it surrounded by a wide rural belt; (3) the town to accommodate population and industry; (4) the town to be limited in extent and never to encroach upon the rural belt; (5) the land values arising from the population to belong to the community that created them.

Howard based his scheme upon the admitted need for a remedy for the evils of the congestion of towns and the depopulation of the countryside. He pointed out the obvious facts that towns grew because people were attracted to them, and people left the country districts because they did not like them. The country must be made attractive, he said, and that can be done by establishing there the magnet of town-life. A form of town which combined the undoubted social and economic advantages of towns with the undoubted benefits of the country would be superior to existing towns and would draw population to it. The new town would be limited in extent because (1) it is possible, he considered, to get everything that is required in a town of about 30,000, while improved means of transportation would enable those who wished to do so to travel to the big city, and because (2) the inhabitants of the rural belt should be kept in close touch with town-life and rural interests should form part of the town's economy. If such towns were scattered over the country there would, he believed, be an end to rural depopulation and the overcrowding of the great towns would cease.

The "garden city" was to be created by a private corporation which would raise money on loan, lay out the town, construct the roads, drainage, public services, etc., and let the land on revisible leases, the rents increasing with the growth of population. Howard showed that the reasonable rents that could be got would be amply sufficient to pay a return on the expenditure, leaving a considerable surplus. The rents, moreover, were to be "rate-rents," that is to say were to include such charges on property as were normally required to meet the expenditure of the local authority.

Unearned Increment of the Community.— Howard contended that his scheme was practicable for two main reasons. The first was that by purchasing land at agricultural value and then bringing a large population to it the increment in land value would be sufficient to provide a substantial economic foundation. The "unearned increment," created by increase of population in any particular place had hitherto invariably gone into private pockets; in his scheme it would be retained for the community. That the amount of this "unearned increment" in general was great was well known. Proposals for taxation of land values were attempts to get possession of it. Howard's scheme secured it for the community as it arose. His second main reason was that there was a tendency for industry to leave the congested cities and to seek rural surroundings. Manufacturers were establishing their works on the outskirts of towns and even in country villages, because they found the costs and conditions of working in the cities too onerous. This tendency, Howard declared, should be organized. There should be a concerted movement of industry from the over-burdened cities to the new free towns, the garden cities.

Howard's proposals came at a time when there was an increasing public interest in industrial housing. In the garden cities houses could be provided for the working classes under the best possible conditions both as to cost and surroundings. Many of

those who were interested in the housing question were therefore attracted to the garden city idea. In 1898 when Howard put forward his scheme there was no public interest in England in town-planning; but the advantages of planning a town in advance of building it were appreciated and gave additional point to Howard's contentions. The housing and town-planning movements of the 20th century thus became closely associated with the garden city movement, and the influence of that movement upon them was profound, but the specific proposals for garden cities and the general ideas on which they were based were by no means expressed in the housing and town-planning activities that gained momentum in the early part of the century in England and reached their height in the years immediately after the World War.

Letchworth and Welwyn.—These are the only examples of garden cities in the world, though the municipal city of Wythenshawe, near Manchester, started in 1929, is virtually a third.

Letchworth was established in 1903 as the first garden city on Sir Ebenezer Howard's plan. An area of 3,822 acres (afterwards increased to 4,552 acres) was purchased 35 miles from London and within 2½ miles of the old market town of Hitchin, in Hertfordshire. A joint stock company, called First Garden City Ltd. was formed to carry out the enterprise, with an authorized capital of £300,000, the dividend on which was limited to 5% per annum. A plan was prepared for a town of about 32,000 inhabitants, with distinct areas for houses, shops and factories and a surrounding rural belt. Development was started in 1904. The company constructed the roads, drainage system, water, gas and electricity supplies. In 1928 the town had a population of about 14,000 with 80 industries, principally engineering works, but including corset-making, printing, book-binding, etc.

On the formation of the scheme the First Garden City, Ltd., made a public issue of share capital but only a small part was taken up and the undertaking was mainly financed by mortgages, loans and debentures. Interest has been paid on the bulk of the capital since the start; in 1913 a small dividend was paid on the share capital; in 1928 a start was made to pay off the accumulated arrears of dividend on the shares.

Howard's scheme of revisible rents and rate-rents was found impracticable at Letchworth, the land being let on ordinary building leases for 99 years. Rates are levied by the local authority as in other towns. The growth of the town has been slow, less than half the ultimate population having been reached after 25 years

The second garden city was started after the war in 1920, when Welwyn Garden City was formed. This second scheme was initiated by a joint stock company with an authorised share capital of £250,000 entitled to a dividend not exceeding 7% per annum.

Welwyn, 20 miles from London, is a few miles north of Hatfield on the London and North Eastern Railway main line. The estate consists of 2,383 acres, on which a town of 40,000 has been planned with a small rural belt. When purchased the estate was completely rural and the company has constructed the roads, drainage, water, electricity and other supplies. In 1928 the town had a population of 7,000 with a number of industries, including engineering, breakfast foods, cinema studios, printing, etc.

The promoters of the scheme have had to contend with the difficulties of the post war period, and development has been slower than was anticipated. The public issue of shares in 1920 was not successful and the scheme has been financed by debentures and loans. The company was granted loans from the Public Works Loan Board for approved capital expenditure under the provisions of the Housing Act 1921. This has brought the scheme to some extent under the supervision of the Ministry of Health. Interest on borrowed money has been paid from the start, but no dividend has yet been declared on the share capital.

The features of Welwyn are its consistent architectural development, site planning, public gardens, and absence of small shops. Being near to London a large proportion of the population is engaged in business there; but the site is well adapted for industrial purposes and industrial development is likely to be accelerated. As at Letchworth land is let on building lease (but for 999 years) and rates are levied as in other towns. The company however undertakes certain public services (*e.g.* sewage disposal) at its own expense, and provides funds for education, sport, etc.

BIBLIOGRAPHY.—Ebenezer Howard, *Garden Cities of Tomorrow* (1903); C. B. Purdom, *The Garden City* (1913); *Town Theory and Practice* (ed. by C. B. Purdom, 1923); C. B. Purdom, *The Building of Satellite Towns* (1925).

The United States has no "garden city" like Letchworth or Welwyn, England, and no development of the "garden village" as complete and significant as Port Sunlight or Bourneville, but it has had many "industrial housing schemes" carried out during the period of the garden city movement in England and some suburban developments that resemble the "garden city." These developments are of great variety in origin, and extent and merit. Most of the industrial developments had some sort of general plan or layout. In some it was the typical American gridiron, and in many other cases it did not show great skill or merit. In only a few, even of the best, was there more than a street scheme. The average of these developments in the United States would show below 12 houses to the gross acre—probably not more than six—with lots averaging at least 50 ft. in width by more than 100 ft. in depth. It is somewhat doubtful if an examination of the American schemes would disclose any element of co-operative or public ownership which is English in character rather than American, and yet in many industrial villages the land has been sold at a low price and without speculative profit. While there was no legal or definite limit to the return from the invested capital, many of the industrial enterprises were conducted often at a financial return lower than that recognized as a reasonable rate. The higher class suburban developments accept no such limitation. *See* SOCIAL ARCHITECTURE. (J. No.)

GARDENIA, a genus of evergreen shrubs and trees of the madder family (Rubiaceae), containing about 50 species, natives of the warmer parts of the old world.

Several are grown in greenhouses for their handsome, sweet-scented white flowers, which are developed singly at the end of a branch or in the leaf-axils and are funnel- or salver-shaped, with a long tube.

The double forms of *Gardenia jasminoides* (China), the Cape-jasmine, or gardenia of the florists, are among the most beautiful and highly perfumed of any in cultivation. Gardenias are readily propagated by cuttings.

They require plenty of heat and moisture in the growing season, and must be kept free from insects by frequent syringing.

GARDENING: *see* HORTICULTURE.

GARDINER, JAMES (1688–1745), Scottish soldier, was born at Carriden in Linlithgowshire, on Jan. 11, 1688. The circumstances of his death (Sept. 21, 1745) are described in Sir Walter Scott's *Waverley*. In his early years he was reckless and profligate. but in 1719 a vision of Christ on the Cross led to his conversion, and from that time he lived a life of great devoutness.

See P. Doddridge, *Life of James Gardiner* (1747, often reprinted).

GARDINER, SAMUEL RAWSON (1829–1902), English historian, son of Rawson Boddam Gardiner, was born near Alresford, Hants. He was educated at Winchester and Christ Church, Oxford, where he took a first class in *literae humaniores*, and became a fellow of All Souls (1884) and Merton (1892). For some years he was professor of modern history at King's college, London. Gardiner, who was himself a descendant of Cromwell and Ireton, is the historian of the Puritan revolution, and has written its history in a *History of England from the Accession of James I. to the Outbreak of the Civil War, 1603–1642* (10 vols., 1863–82); *History of the Great Civil War, 1642–1649* (4 vols., 1886); and *History of the Commonwealtlr and Protectorate, 1649–1660* (3 vols., 1894–1903). His researches in public and private collections of manuscripts at home, and in the archives of Simancas, Venice, Rome, Brussels and Paris, were indefatigable. In his judgments of men and their actions he is unbiassed, and his appreciations of character exhibit a remarkable fineness of perception and a broad sympathy. Throughout his work he gives a prominent place to everything which illustrates human progress in moral and religious, as well as political conceptions, and specially to the rise and development of the idea of religious toleration, finding his authorities not only

in the words and actions of men of mark, but in the writings of obscure pamphleteers, whose essays indicate currents in the tide of public opinion.

Gardiner's style is clear and unadorned; he appeals constantly to the intellect rather than to the emotions, and is seldom picturesque, though in describing a few famous scenes, such as the execution of Charles I., he writes with pathos and dignity. Among the most noteworthy of his separate works are: *Prince Charles and the Spanish Marriage* (2 vols., 1869); *Outline of English History* (1st. ed. 1887, later ed. 1919); *Constitutional Documents of the Puritan Revolution, 1625–1660* (1st ed., 1889; 3rd ed., 1906); *Student's History of England* (2 vols., 1st ed. 1890–91; later ed. 1920); *What Gunpowder Plot Was* (1897); *Oliver Cromwell* (1901). He edited collections of papers for the Camden Society, and from 1891 was editor of the *English Historical Review*.

See H. B. Learned, *Samuel Rawson Gardiner* (1902); R. G. Usher, "Critical study of the historical method of S. R. Gardiner," in *Washington University Studies*, vol. iii., part ii., no. i. (1915).

GARDINER, STEPHEN (1493?–1555), English bishop and lord chancellor, was born at Bury St. Edmunds, the son of a cloth merchant. He was educated at Trinity Hall, Cambridge, and became doctor of civil lam in 1520, and of canon law in the following year. About 1525 he was made secretary to Cardinal Wolsey whom he accompanied on his important diplomatic mission to France in 1527. Next year Gardiner was sent by Wolsey to Italy with Edward Fox, provost of King's college, Cambridge, to promote the business of Henry's divorce from Catherine of Aragon. Though he failed to procure the desired decretal commission, Gardiner by his great intrepidity, won from Clement his consent to a general commission for Campeggio and Wolsey to try the cause in England. This, as Wolsey saw, was quite inadequate and he again instructed Gardiner to press the pope to send the desired decretal on, even if the latter was only to be shown to the king and himself and then destroyed. At last the pope gave what was desired on the express conditions that Campeggio was to show it to the king and Wolsey and no one else, and then destroy it, the two legates holding their court under the general commission. In 1529 Gardiner was sent again to Italy, but this time the pope would make no further concessions, or promise not to revoke the cause to Rome.

Gardiner's services, however, were fully appreciated. He was appointed the king's secretary. He had been already some years archdeacon of Taunton, and the archdeaconry of Norfolk was added to it in March 1529, which two years later he resigned for that of Leicester. In 1530 he was sent to Cambridge to procure the decision of the university as to the unlawfulness of marriage with a deceased brother's wife, in accordance with the new plan for settling the question without the pope's intervention. In this he succeeded, though not without a good deal of artifice. In Nov. 1531 the king rewarded him with the bishopric of Winchester, vacant by Wolsey's death. In 1532, nevertheless, he displeased the king by the part he took in the preparation of the famous "Answer of the Ordinaries" to the complaints brought against them in the House of Commons.

His next important action was not so creditable; for he was "assistant" to Cranmer as counsel for the king, when the archbishop, in the absence of Catherine, pronounced her marriage with Henry null and void on May 23, 1533. Immediately afterwards he was sent to Marseilles, where an interview between the pope and Francis I. took place in September, of which event Henry stood in great suspicion, as Francis had hitherto maintained the justice of his cause. At this interview Bonner intimated the appeal of Henry VIII. to a general council in case the pope should proceed to sentence against him. This appeal, and also one on behalf of Cranmer presented with it, were drawn up by Gardiner. In 1535 he and other bishops were called upon to vindicate the king's new title of "Supreme Head of the Church of England." The result was his celebrated *De vera obedientia*, the ablest of all the vindications of royal supremacy, reprinted in 1537 by the Swiss reformers. In the same year he had a dispute with Cranmer about the visitation of his diocese He was also employed to answer the pope's brief threatening to deprive Henry of his kingdom. During the next few years he was engaged in various embassies in France and Germany until 1538 when, owing to Cromwell's mistrust, he was replaced as ambassador in Paris by Bonner. In 1539 he took part in the enactment of the severe statute of the Six Articles, which led to the resignation of bishops Latimer and Shaxton and the persecution of the Protestant party. In 1540, on the death of Cromwell he was elected chancellor of the University of Cambridge. A few years later he attempted to fasten a charge of heresy upon Archbishop Cranmer in connection with the Act of the Six Articles; and but for the intervention of the king would probably have succeeded. Though he had supported the royal supremacy, Gardiner objected to the religious doctrines of the Reformation. He had to contend with frequent storms of royal indignation; but the king had need of him quite as much as he had of Cranmer; for Gardiner, even under royal supremacy, was anxious to prove that England had not fallen away from the faith, while Cranmer's authority as primate was necessary to upholding that supremacy. Thus Gardiner and the archbishop maintained opposite sides of the king's church policy; and though Gardiner was encouraged by the king to put up articles against the archbishop for heresy, the archbishop could always rely on the king's protection.

Under Edward VI. Gardiner was completely opposed to the policy of the dominant party both in ecclesiastical and in civil matters. The religious changes he objected to both on principle and on the ground of their being moved during the king's minority, and he resisted Cranmer's project of a general visitation. His remonstrances, however, were met by his committal to the Fleet, and the visitation of his diocese was held during his imprisonment. Though soon released, it was not long before he was called before the council, and, refusing to give them satisfaction, was thrown into the Tower, where he remained for over five years. His bishopric was given to Poynet, a chaplain of Cranmer's and bishop of Rochester. On Mary's accession, Gardiner was restored to his bishopric, and as lord chancellor, set the crown on the queen's head at her coronation. He also opened her first parliament and for some time was her leading councillor.

He was now called upon, in advanced life, to undo not a little of of his early work—to vindicate the legitimacy of the queen's birth and the lawfulness of her mother's marriage, to restore the old religion, and to recant what he had written touching the royal supremacy. It is said that he wrote a formal retraction of his *De vera obedientia* which is no longer extant. As chancellor he negotiated the queen's marriage treaty with Philip, to which he shared the general repugnance, though he could not oppose her will. In executing it, however, he provided that the Spaniards should in nowise interfere in the government of the country. After the coming of Cardinal Pole, and the reconciliation of the realm to the see of Rome, he still remained in high favour. He no doubt approved of the act, which passed the House of Lords while he presided there as chancellor, for the revival of the heresy laws. Neither is there any doubt that he sat in judgment on Bishop Hooper, and on several other preachers whom he condemned to be degraded from the priesthood. But he endeavoured to save the lives of Cranmer and Northumberland, and much as he was maligned by opponents, there are strong evidences that his natural disposition was humane and generous. In May 1553 he went to Calais as one of the English commissioners to promote peace with France; but their efforts were ineffectual. In Oct. 1555 he again opened parliament as lord chancellor, but soon fell ill and died at Whitehall on Nov. 12. He was buried in Winchester cathedral.

Besides his conspicuous statesmanship and legal ability, Gardiner possessed a learning in divinity far from commonplace. His part in the drawing up of doctrinal formularies in Henry VIII.'s time is not clear; but at a later date he wrote tracts in defence of the Real Presence against Cranmer, some of which, being written in prison, were published abroad under a feigned name. Controversial writings also passed between him and Bucer, with whom he had several interviews in Germany, when he was there as Henry VIII.'s ambassador. A friend of learning he took great interest in promoting the study of Greek at Cambridge. He was, however, opposed to the new method of pronouncing the language intro-

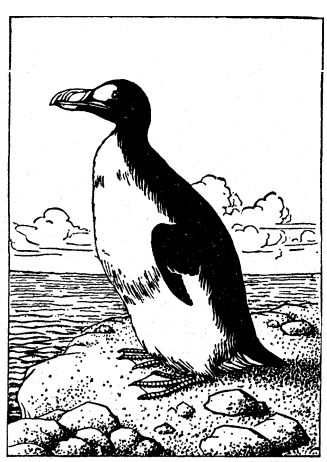
duced by Sir John Cheke, and wrote letters to him and Sir Thomas Smith upon the subject, in which, according to Ascham, his opponents showed themselves the better critics, but he the superior genius. His house was spoken of by Leland as the seat of eloquence and the special abode of the muses.

For a list of Gardiner's writings and general bibliography, *see* the article in the *Dict. Nat. Biog. See* also *J. A.* Muller, *Stephen Gardiner and the Tudor Reaction (1926).*

GARDNER, PERCY (1846–1937), English classical archaeologist, was born in London, and was educated at the City of London school and Christ's college, Cambridge (fellow, 1872). He was Disney professor of archaeology at Cambridge (1880–87), and professor of classical archaeology at Oxford (1887–1925). Gardner was a fellow of the British Academy and of other learned societies in many foreign countries. Among his works are: *Types* of *Greek Coins* (1883); *A Numismatic Commentary on Pausanias* (with *F.* Imhoof-Blumer, 1887); *New Chapters in Greek History* (1892), an account of excavations in Greece and Asia Minor; *Manual of Greek Antiquities* (with F. B. Jevons, 2nd ed. 1898); *Grammar of Greek Art* (1905); *Principles of Greek Art* (1913); *New Chapters in Greek Art* (1926); and a number of works on theological and ecclesiastical subjects.

His brother, ERNEST ARTHUR GARDNER (1862–1939), educated at the City of London school and Caius college, Cambridge (fellow, 1885), was director (1887–95) of the British School at Athens, and later became professor of archaeology at University college, London, and dean of the university. His publications include: *Introduction to Greek Epigraphy* (1887); *Catalogue of the Vases in the Fitzwilliam Museum, Cambridge* (1897); *Ancient Athens* (1902); *Handbook of Greek Sculpture* (1905); new and enlarged ed. (1915); *The Art of Greece* (1925), etc.

GARDNER, a city among the hills of northern Worcester county, Massachusetts, U.S.A., 60m. W. by N. of Boston, at an altitude of 1,200ft. It is served by the Boston and Maine railroad. The population was 16,971 in 1920 (32·7% foreign-born white) and was 20,206 in 1940 by the federal census. The outstanding industry is the manufacture of chairs, dating from 1805. Other important products are baby carriages, children's vehicles, oil stoves, range burners, silverware, timeclocks, woodworking machinery and reed, fibre and upholstered furniture. The aggregate factory output in 1940 was valued at $19,276,949. The city maintains a system of supervised playgrounds, a public bath-house and swimming pool. Gardner was formed in 1785 from parts of four other towns, and was named after Colonel Thomas Gardner (1724–75), who was mortally wounded at the battle of Bunker Hill. It was chartered as a city in 1923.



GREAT AUK (ALCA IMPENNIS) KNOWN ALSO IN THE HEBRIDES, WHICH IT FREQUENTED, AS THE GAREFOWL

GAREFOWL, also known as Great Auk *(Alca impennis)*, a large flightless sea-bird, now extinct. Slightly smaller than a tame goose, it resembled its relative the razorbill *(A. torda)* in appearance, but a large patch of white occupied nearly all the space between the bill and the eye, while the bill itself bore eight or more transverse grooves. Owing to the small size of the wings, the bird was unable to fly.

It is a mistake to suppose that this bird had a high northern range. It bred in Iceland and on islands off Newfoundland, where the French fishermen used both the bird and its eggs for food. Enormous numbers were killed, the birds being driven up a plank into the hold of the vessel *(see* Ritchie, *Animal Life in Scotland).* It became extinct about 1844. The egg resembled that of the razorbill in shape and colour, but was larger. *(See* AUK.)

GARFIELD, JAMES ABRAM (1831–1881), twentieth president of the United States, was born on Nov. 19, 1831 in a log cabin in the little frontier town of Orange, Cuyahoga county, Ohio. His early years were spent in the performance of such labour as fell to the lot of every farmer's son in the new states, and in the acquisition of such education as could be had in the district schools held for a few weeks each winter. But life on a farm was not to his liking, and at 16 he left home and tramping across the country to Cleveland, Ohio, sought employment from the captain of a lake schooner. But the captain drove him from the deck, and, wandering on in search of work, he fell in with a canal boatman who engaged him. During some months young Garfield served as bowsman, deck-hand and driver of a canal boat. An attack of the ague sent him home, and on recovery, having resolved to attend a high school and fit himself to become a teacher, he passed the next four years in a hard struggle with poverty and in an earnest effort to acquire an education; worked as a teacher, a carpenter and a farmer; studied for a time at the Western Reserve Eclectic Institute at Hiram, Ohio, and finally entered Williams College. On graduation, in 1856, Garfield became professor of ancient languages and literature in the Eclectic Institute at Hiram, and within a year rose to be its principal.

Soon afterwards he entered political life. In the early days of the Republican party, when the shameful scenes of the Kansas struggle were exciting the whole country, and during the campaigns of 1857 and 1858, he became known as an effective speaker and ardent anti-slavery man. His reward for his services was election in 1859 to the Ohio senate as the member from Portage and Summit counties. When the "cotton States" seceded, Garfield appeared as a warm supporter of vigorous measures, and when the call came for 75,000 troops, at once offered his services to the governor, and became lieutenant-colonel and then colonel of the 42nd Ohio Volunteers, recruited largely from among his former students. He served in Kentucky, was promoted to the rank of brigadier-general of volunteers early in 1862; took part in the second day's fighting at the battle of Shiloh, served as chief of staff under Rosecrans in the Army of the Cumberland in 1863, fought at Chickamauga, and was made a major-general of volunteers for gallantry in that battle. In 1862 he was elected a member of Congress from the Ashtabula district of Ohio, and, resigning his military commission, took his seat in the House of Representatives in Dec. 1863. In Congress he joined the radical wing of the Republican party, advocated the confiscation of Confederate property, approved and defended the Wade-Davis manifesto, and was soon recognized as a hard worker and ready speaker. Capacity for work brought him places on important committees and his ability as a speaker enabled him to achieve distinction on the floor of the House and to rise to leadership. The year 1874 was one of disaster to the Republican party. The greenback issue, the troubles growing out of reconstruction in the South, the Crédit Mobilier and the "Salary Grab," disgusted thousands of independent voters and sent a wave of democracy over the country. Garfield himself was accused of corruption in connection with the Crédit Mobilier scandal, but the charge was never proved. A Republican convention in his district demanded his resignation, and re-election seemed impossible; but he defended himself in two pamphlets, "Increase of Salaries" and "Review of the Transactions of the Crédit Mobilier Company," made a village-to-village canvass, and was victorious. In 1876 Garfield for the eighth time was chosen to represent his district; and afterwards as one of the two representatives of the Republicans in the House, he was a member of the Electoral Commission which decided the dispute regarding the presidential election of 1876. When, in 1877, James G. Blaine was made a senator from Maine, the leadership of the House of Representatives passed to Garfield, and he became the Republican candidate for speaker. But the Democrats had a majority in the House, and he was defeated. Hayes, the new president, having chosen John Sherman to be his secretary of the treasury, an effort was made to send Garfield to the United States Senate in Sherman's place. But the President needed his services in the House, and he was not elected to the Senate until 1880.

The time had now come (1880) when the Republican party must nominate a candidate for the presidency. General Grant had served two terms (1869–77), and the unwritten law of custom condemned his being given another. But the "bosses" of the Republican party in three great states—New York, Pennsylvania and Illinois—were determined that he should be renominated. These men and their followers were known as the "stalwarts." Opposed to them were two other factions, one supporting James G. Blaine, of Maine, and the other John Sherman, of Ohio. When the convention met and the balloting began, the contest along these factional lines started in earnest. For 28 ballots no change of any consequence was noticeable. Though votes were often cast for ten names, there were but two real candidates before the convention, Grant and Blaine. That the partisans of neither would yield in favour of the other was certain. That the choice therefore rested with the supporters of the minor candidates was manifest, and with the cry "Anything to beat Grant!" an effort was made to find some man on whom the opposition could unite. Such a man was Garfield. His long term of service in the House, his leadership of his party on its floor, his candidacy for the speakership, and his recent election to the United States Senate, marked him out as the available man. Between the casting of the first and the 33rd ballot, Garfield, who was the leader of Sherman's adherents in the convention, had sometimes received one or two votes and at other times none. On the 34th he received 17, on the next 50, and on the next almost the entire vote hitherto cast for Blaine and Sherman, and was declared nominated. During the campaign Garfield was subject to violent personal abuse; the fact that he was alleged to have received $329 from the Crédit Mobilier as a dividend on stock led his opponents to raise the campaign cry of "329," and this number was placarded in the streets of the cities and printed in flaring type in partisan newspapers. The forged "Morey letter," in which he was made to appear as opposed to the exclusion of the Chinese, was widely circulated and injured his candidacy in the West. That the charges against Garfield were not generally credited, however, is shown by the fact that he received 214 electoral votes to his opponent's 155. He was inaugurated on March 4, 1881.

On July 2, while on his way to attend the commencement exercises at Williams College, the new president was shot in a Washington railway station by a disappointed office-seeker named Charles J. Guiteau, and on Sept. 19, 1881, he died at Elberon, New Jersey, whither he had been removed on the 6th. He was buried in Cleveland, Ohio, where in 1890 a monument was erected by popular subscription to his memory.

In 1858 Garfield had married Miss Lucretia Rudolph, by whom he had seven children.

BIBLIOGRAPHY.—President Garfield's writings, edited by Burke A. Hinsdale, were published at Boston, in 1882; *The Life* and Letters of James A. Garfield, by Theodore Clarke Smith in 1925.

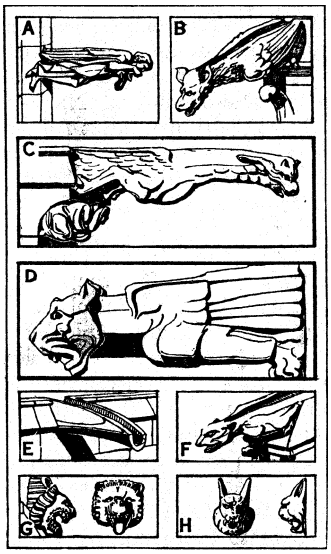
GARFIELD, a rapidly growing industrial city of Bergen county, New Jersey, U.S A., on the Passaic river, 12 mi. N.W. of Kew York city. It is served by the Erie railroad (and for freight also by the Susquehanna) and by motor-coach lines. The population was 19,381 in 1920 (44% foreign-born white, largely from Italy. Hungary and Poland) and was 28,044 in 1940 by the federal census. It has extensive woollen and worsted mills, and various other manufacturing industries, with an aggregate output in 1939 valued at $28,034,895. The city was founded in 1881; incorporated as a borough in 1898, and as a city in 1920. Between 1900 and 1920 the population increased over 450%.

GAR-FISH, a genus of fishes (*Belone*) found in most temperate and tropical seas, and recognized by their long, slender, compressed and silvery body, and by their jaws being produced ioto a long, pointed, bony and sharply-toothed beak. About 50 species are known, some attaining a length of 4 or 5ft. One species is common on the British coasts, and is well known by the name of "long-nose." The green bones deter many people from eating this wholesome food. The skipper (Scomberesox) and half-beak (*Hemirhamphus*), in which the lower jaw only is prolonged, are fishes akin to the gar-pikes.

GARGANEY, or SUMMER-TEAL, *Anas querquedula,* is one of the smallest of the ducks and is a summer visitant to England, where it breeds in the east Norfolk Broads. Slightly larger than the common teal (*A.* crecca), the male has a nutmeg-brown beard and a white line behind the eyes. The female resembles the hen teal, but possesses no wing spot. In Ireland and Scotland the garganey is rare. It has not a high northern range, and its appearance in Norway and Sweden is casual. It is nowhere common in Europe, but ranges far to the eastward in Asia, and yearly visits India in winter in enormous numbers. They nest very frequently in reed-beds.

GARGANO, MONTE (anc. Garganus Mons), a massive mountainous peninsula projecting eastward from the north coast of Apulia, Italy, and belonging geologically to the opposite Dalmatian coast; it was indeed separated from the rest of Italy by an arm of the sea as late as the Tertiary period. It is of the same character as the Carso, being composed of fractured calcareous rock, and has numerous superficial and subterranean cavities. The highest point (Monte Calvo) is 3,465 ft. above sea-level. The oak forests for which it was renowned in Roman times have entirely disappeared except in three sections, and have left the soil dry and stony. Monte Sant' Angelo (*q.v.*) is the principal town.

See Beltramelei, *Il* Gangano (Bergamo, 1907) well illustrated.



A, B, C, E, F, FROM VIOLLET-LE-DUC; D, 'THE AMERICAN ARCHITECT": G, FROM FLETCHER. "HISTORY OF ARCHITECTURE ON THE COMPARATIVE METHOD" (BATSFORD)

GARGOYLES

Ancient: G, Greek; H, Roman; Gothic: E, French undecorated; C and F, Notre Dame, Paris (*c.* 1225); B, the Ste. Chapelle Paris (*c.* 1250); A, St. Urbain, Troyes (*c.* 1290); Modern: D, Farmers Loan and Trust Building, New York City (Starrett and Van Vleck, architects)

GARGOYLE,. in architecture, a decorated water spout. Although technically speaking the term applies to the carved lions of classic cornices, or to the terra-cotta spout, such as those found frequently in Pompeii, in general usage the word has become restricted to the grotesque, carved spouts of the middle ages, and is even, incorrectly, applied to other: grotesque beasts, such as the *chimères* that decorate the parapets of Notre Dame at Paris. The gargoyle of the developed Gothic period is usually a grotesque bird or beast sitting on its haunches on the back of a cornice moulding and, in order to throw the water far from the building, projecting for several feet.

GARHWAL, a district of British India, in the Kumaon division of the United Provinces. Pop. (1931) 533,885; area 5,612 sq.m. It consists almost entirely of rugged mountain ranges running in all directions, and separated by narrow vallevs which in some cases become deep gorges or ravines. The onlv level portion of the district is a narrow strip of waterless forest between the southern slopes of the hills and the fertile plains of Rohilkhand. The highest mountains are in the north, and embrace some of the most stupendous of the snow-clad giants, the principal peaks being Nanda Devi (25,661 ft.), Kamet (25,413), Trisul (23,382), Badrinath (23,210), Dunagiri (23,181) and Kedarnath (22,853). The Alaknanda, one of the main sources of the Ganges, receives with its affluents the whole drainage of the district. At Devaprayag the Alaknanda joins the Bhagirathi, and thenceforward the united streams bear the name of the Ganges. Cultivation is principally confined to the immediate vicinity of the rivers, which are employed for purposes of irrigation. Tradition has it that Garhwal originally consisted of 52 petty chieftainships, each chief with his own independent fortress (garh), that 500 years ago, one of these chiefs, Ajai Pal, reduced all the minor principalities under his own sway, and founded the Garhwal king-

dom. He and his ancestors ruled over Garhwal and the adjacent state of Tehri, in an uninterrupted line till 1803, when the Gurkhas invaded Kumaon and Garhwal, driving the Garhwal chief into the plains. They in turn were defeated by the British in the war with Nepal in 1814, when Garhwal and Kumaon were converted into British districts, and the Tehri principality was restored to a son of the former chief. Since annexation, Garhwal has rapidly advanced in material prosperity. Two battalions of the Indian army (the 39th Garhwal Rifles) are recruited in the district, which also contains the military cantonment of Lansdowne. Grain and coarse cloth are exported, and salt, borax, live stock and wool are imported, the trade with Tibet being considerable. The administrative headquarters are at the village of Pauri, but Srinagar and Kotdwara are the chief marts. Transport is laborious, and the people are simple and attractive.

GARIBALDI, GIUSEPPE (1807–1882), Italian patriot, was born at Nice on July 4, 1807. He entered the Sardinian navy, and, with a number of companions on board the frigate "Euridice," plotted to seize the vessel and occupy the arsenal of Genoa at the moment when Mazzini's Savoy expedition should enter Piedmont. The plot being discovered, Garibaldi fled, but was condemned to death by default on June 3, 1834. Escaping to South America in 1836, he was given letters of marque by the state of Rio Grande do Sul, which had revolted against Brazil, and after a series of victorious engagements, passed into the service of Uruguay. In Montevideo, he formed the Italian Legion, with which he won the battles of Cerro and Sant' Antonio in 1846, and assured the freedom of Uruguay. He returned to Italy upon receiving news of the incipient revolutionary movement, and landing at Nice on June 24, 1848, placed his sword at the disposal of Charles Albert. He formed a volunteer army 3,000 strong, but shortly after the defeat of Custozza had to flee to Switzerland. Proceeding thence to Rome, he was entrusted by the Roman republic with the defence of San Pancrazio against the French, where he gained the victory of April 30, 1849. During May he dispersed the Bourbon troops at Palestrina, Velletri and elsewhere, and after the fall of Rome started on his wonderful retreat through central Italy pursued by the armies of France, Austria, Spain and Naples. He escaped to Ravenna, then to Piedmont, and ultimately to America from whence he returned to Italy in 1854, and purchased the island of Caprera on which he built his home. On the outbreak of war in 1859 he was in command of the Alpine infantry, defeating the Austrians at Casale on the 8th of May, crossing the Ticino on the 23rd of May, and, after a series of victorious fights, liberating Alpine territory as far as the frontier of Tirol.

Returning to Como to wed the countess Raimondi, by whom he had been aided during the campaign, he was apprised, immediately after the wedding, of certain circumstances which caused him to abandon that lady and to start for central Italy. Forbidden to invade the Romagna, he returned to Caprera, where with Crispi and Bertani he planned the invasion of Sicily. Assured by Sir James Hudson of the sympathy of England, he began active preparations for the process which ended in the making of Italy. He reached Marsala on May 11, 1860, landed under the protection of the British vessels "Intrepid" and "Argus," and on the following day his dictatorship was proclaimed at Salemi. On the 15th the Neapolitan troops were routed at Calatafimi, on the 25th Palermo was taken, on the 6th of June 20,000 Neapolitan regulars were compelled to capitulate, on July 20, Messina fell and on Aug. 21, the battle of Reggio was won. On Sept. 7, Garibaldi entered Naples, and a month later, routed the remnant of the Bourbon army 40,000 strong on the Volturno. On Nov. 7, Garibaldi accompanied Victor Emmanuel during his solemn entry into Naples, and on the morrow returned to Caprera.

Indignant at the cession of Nice to France and at the neglect of his followers by the Italian government, he returned to political life. Elected deputy in 1861, his anger against Cavour found violent expression, until Cavour's successor, Ricasoli, enrolled the Garibaldians in the regular army. While marching on Rome in the following year, he was taken prisoner at Aspromonte on the 27th of August. Liberated by an amnesty, Garibaldi returned once more to Caprera amidst general sympathy, and in 1864 was enthusiastically received in London. On the outbreak of war in 1866 he assumed command of a volunteer army and on the 3rd of July he defeated the Austrians at Monte Saello, on the 7th at Lodrone, on the 10th at Darso, on the 16th at Condino, on the 19th at Ampola, on the 21st at Bezzecca, but, when on the point of attacking Trent, he was ordered by General Lamarmora to retire. His famous reply "Obbedisco" ("I obey") has often been cited as a classical example of military obedience to a command destructive of a successful leader's hopes, but documents now published (cf. *Corriere della sera,* Aug. 9, 1906) prove that Garibaldi had for some days known that the order to evacuate the Trentino would shortly reach him. As early as the 16th of July Crispi had been sent to warn Garibaldi that, owing to Prussian opposition, Austria would not cede the Trentino to Italy, and that the evacuation was inevitable. Hence Garibaldi's laconic reply. He returned to Caprera to mature his designs against Rome, which had been evacuated by the French in pursuance of the Franco-Italian convention of September 1864. In 1867, he prepared to enter papal territory, but was arrested at Sinalunga by the government and conducted to Caprera. He escaped to Florence, and, with the complicity of the second Rattazzi cabinet, entered Roman territory at Passo Corese on the 23rd of October. Two days later he took Monterotondo, but on Nov. 2nd, his forces were dispersed at Mentana by French and papal troops. Recrossing the Italian frontier, he was arrested at Figline and taken back to Caprera. In 1870 he formed a fresh volunteer corps and went to the aid of France, defeating the German troops at Chatillon, Autun and Dijon. Elected a member of the Versailles assembly, he resigned his mandate in anger at French insults, and withdrew to Caprera until, in 1874, he was elected deputy for Rome. Popular enthusiasm induced the Conservative Minghetti cabinet to propose that £40,000 with an annual pension of £2,000 be conferred upon him but the proposal was refused by Garibaldi. Upon the advent of the Left to power, however, he accepted both gift and pension. He died at Caprera on June 2, 1882, one of the greatest masters of revolutionary war.

Vecchi, *La Vita e La Geste di Garibaldi* (Bologna, 1910) and *A.* Luzio, *Garibaldi, Cavour, Verdi* (Turin, 1924)

GARIBALDI, GIUSEPPE (1879–), Italian general, eldest son of Gen. Ricciotti Garibaldi and grandson of the Liberator, was born at Melbourne, July 29, 1879. He fought under his father in the Greco-Turkish War in 1897, and served in the South African War, subsequently leading an adventurous life in South and Central America and in the Balkans. On the outbreak of the World War he raised an Italian Legion of 14,000 men, which fought on the side of France in the Argonne. In 1915 Garibaldi returned to Italy, and on Italy's entry into the War he enlisted as a volunteer. He was soon afterwards commissioned, being given command of a battalion, and served with distinction in the IV. Army. He returned to the French front in March 1918 in command of the famous Brigata Alpi, and in June was promoted brigadier-general. He resigned his command in June 1919 and gave up his commission in Feb. 1920. He became opposed to the Fascist Government and in the autumn of 1924 was involved in an anti-Fascist agitation organised by the *Ztalia libera* Association. Deciding, however, that the movement had no chance of success, he departed for New York to devote himself to business.

GARIN LE LOHERAIN, French epic hero. The 12th century *chanson de geste* of Garin le Loherain is one of the fiercest and most sanguinary narratives left by the *trouvères.* This local cycle of Lorraine, which is completed by Hervis de Metz, Girbers de Metz, Anséis, fils de Girbert and Yon, is obviously based on history, and affordsa picture of the savage feudal wars of the 11th and 12th centuries. The cycle relates three wars against hosts of heathen invaders In the first of these Charles Martel and his faithful vassal Hervis of Metz fight by an extraordinary anachron-

ism against the Vandals, who have destroyed Reims but are defeated in a great battle near Troyes. In the second Hervis is besieged in Metz by the "Hongres." In the third Thierry, king of Moriane, sends to Pippin for help against four Saracen kings. He is delivered by a Frankish host, but falls in the battle. Hervis of Metz was the son of a citizen to whom the duke of Lorraine had married his daughter Aelis, and his sons Garin and Begue are the heroes of the *chanson* which gives its name to the cycle. The dying king Thierry had desired that his daughter Blanchefleur should marry Garin, but when Garin prefers his suit at the court of Pippin, Fromont of Bordeaux puts himself forward as his rival and Hardré, Fromont's father, is slain by Garin. The rest of the poem is taken up with the war that ensues between the Lorrainers and the men of Bordeaux. Blanchefleur becomes the wife of Pippin, while Garin remains her faithful servant. He is slain after avenging the murder of his brother. The remaining songs continue the feud between the two families. According to Paulin Paris, the family of Bordeaux represents the early dukes of Aquitaine, the last of whom, Waifar (745–768) was slain by Pippin the Short, king of the Franks; but the *trouvères* had in mind no doubt the wars which marked the end of the Carolingian dynasty.

See *Li Romans de Garin le Loherain,* ed. P. Paris (1833); *Hist. litt. de la France,* vol. xxii. (1852); J. M. Ludlow, *Popular Epics of the Middle Ages (186;)*; F. Lot, *Etudes d'htstoire du moyen âge* (1896); F. Settegast, *Quellenstudien zur gallo-romanischen Epik* (Leipzig, 1904). A complete edition of the cycle was undertaken by E. Stengel, the first volume of which, *Hervis de Mes* (Gesellschaft für roman. Lit., Dresden), appeared in 1903.

GARLAND, HAMLIN (1860–1940), American writer, was born at West Salem, Wis., Sept. 14, 1860. His early celebrity was due in large part to his rebellion against the idyllic interpretations of rural life then current; and his *Main-Travelled Roads* (1891), *Other Main-Travelled* Roads (1910), and *Prairie Folks* (1893), written in a mood of intense resentment, remain among the most bitter indictments of the farm in American fiction. Yet his fondness for the unbroken prairie made his Son *of the Middle Border* (1917) and *Trail-Makers of the Middle Border* (1926) fascinating revelations of the lure of free land, of the epic movement of peoples that in a few decades swept the border line of civilization from the Alleghenies to the Pacific. The former book is an admirable record of his boyhood in Wisconsin, Minnesota, and Iowa, his brief homesteading in Dakota, and his early literary struggles in Boston. *A Daughter of the Middle Border* (1921) records his and his family's later experiences, chiefly in and near Chicago, a city which in *Crumbling Idols* (1894) he celebrated but which he left for New York city.

GARLAND, JOHN, JOHANNES DE GARLANDIA (c. 1195–*c.* 1272), Latin grammarian and poet, was born in England of noble family. He studied at Oxford under a certain John of London, and about 1202 went to Paris where he had Allan of Lille as a teacher. He himself taught at Paris until 1229 when he went to the new university of Toulouse. In 1232 or 1233, Garland had to fly from Toulouse on account of religious troubles with the Albigensians. The rest of his life was spent at Paris in writing and teaching. His *Compendium Grammatice* and his *Liber de Constructionibus,* both important for a knowledge of mediaeval Latin, are still unedited, but his *Dictionarius,* a Latin vocabulary, was edited in 1857 by T. Wright, who also published fragments of the *Poetria* (1841), since edited in full by G. Mari (Milan, 1892 and Erlangen, 1902). The best known of Garland's poems are *De triumphis ecclesiae* (ed. T. Wright 1856), books iv–vi giving a detailed account of the Albigensian crusade in the south, and *Epithalamium beatae Mariae Virginum,* still in ms. The *De Mysteriis ecclesie* was ed. by F. G. Otto (Giessen 1842) and the *Morale scolarium,* which covers such topics as general behaviour, table manners, virtue, and the defense of the pope against simony, by L. J. Pactow (Berkeley, California, 1927) who in his introduction gives an account of the life and works of Garland.

GARLIC, *Allium sativum,* a bulbous perennial plant of the family Liliaceae, indigenous apparently to southwest Siberia. It has long, narrow, flat, obscurely keeled leaves, a deciduous spathe, and a globose umbel of whitish flowers, among which are small bulblets. The bulb, which is the only part eaten, has membranous scales, in the axils of which are 10 or 12 cloves, or smaller bulbs. From these new bulbs can be procured. The bulb has a strong and characteristic odour and an acrid taste, and yields an offensively smelling oil. This, when garlic has been eaten, is evolved by the excretory organs, the activity of which it promotes. From the earliest times garlic has been used as an article of diet, principally in small amounts as a flavouring. In the United States about 16,000,000 lb. is grown annually (1932–41), chiefly in the states of California, Texas and Louisiana.

GARLIC-MUSTARD (*Alliaria officinalis*), a plant of hedge-banks, low woods and waste grounds, called also hedge-garlic, Jack-by-the-hedge and sauce-alone. It is an erect, somewhat branching biennial or perennial herb, 2 ft. to 3 ft. high, of the mustard family (Cruciferae), native to Europe and temperate Asia and naturalized in North America from Quebec and Ontario to Virginia. The long-stalked, coarsely-toothed leaves emit, when crushed, a garlic-like odour. The plant bears white flowers.

GARMISCH-PARTENKIRCHEN, a resort town in Upper Bavaria, Germany, on the edge of the Bavarian Alps and under the shadow of the Zugspitze, the highest mountain in Germany. It lies S.W. of Munich in one of the valley highways leading to the Brenner pass to Italy and is on the railway from Augsburg to Innsbruck. Pop. (1939) 19,096.

GARNEAU, FRANÇOIS-XAVIER (1809–1866), Canadian historian, the son of a working man, was born in Quebec. He entered a notary's office when about 1 j, himself becoming a notary in 1830. In 1831 he visited England, studying English institutions. Returning to Canada in 1833, he was appointed translator to the chamber of Lower Canada, and from 1844–64 was secretary to the city of Quebec. His *Histoire du Canada* (1845–48) treats of the history of all the French colonies in North America, strongly anti-British in tone. He also published *Voyage en Angleterre et en France* (1855).

GARNER, JOHN NANCE (1868–), vice-president of the United States, was born in a log cabin in Red River county, Texas, Nov. 22, 1868. After some schooling, including one term at Vanderbilt university, he studied law and was admitted to the bar, starting practice at Clarksville, Texas. He served two terms in the Texas legislature, 1898–1902. He was elected a Democratic representative in congress in 1902 and continued as such for 30 years. After being successively Democratic whip and leader in the house he was elected speaker in 1931. In 1932 he was a candidate for the Democratic nomination for president. He released his delegates in favour of F. D. Roosevelt. Garner himself was then nominated for vice-president and was elected. Four years later he was again nominated for the vice-presidency and again was elected with F. D. Roosevelt.

GARNET or **GARNETT, HENRY** (1 j j5–1606), English Jesuit, was born at Heanor, Derbyshire, educated at Winchester and afterwards studied law in London. Having become a Roman Catholic, in 1575 he joined the Jesuits in Italy, and in 1587 was made superior of the English province. Fearless and indefatigable in carrying on his propaganda and in ministering to the scattered Catholics, even in their prisons, Garnet is remembered for his connection with the Gunpowder plot for which he suffered death. On June 9,1605, Garnet was asked by Catesby whether any undertaking which should involve the destruction of the innocent together with the guilty was lawful. Garnet answered in the affirmative, giving as an illustration the fate of persons besieged in time of war. Afterwards, however, he admonished Catesby against intending the death of "not only innocents but friends and necessary persons for a commonwealth," and showed him a letter from the pope forbidding rebellion. According to Sir Everard Digby, Garnet, when asked the meaning of the brief, replied "that they (meaning the priests) were not to undertake or procure stirs, but yet they would not hinder any, neither was it the pope's mind they should, that should be undertaken for Catholic good. . . . This answer, with Mr. Catesby's proceedings with him and me, gave me absolute belief that the matter in general was approved, though every particular was not known." A few days later, according to Garnet, the Jesuit, Oswald Tesemond, known as Greenway, informed him of the whole plot "by way of confession," but he urged

Greenway to do his utmost to prevent its execution. Garnet's conduct in now keeping the plot a secret has been a matter of considerable controversy not only between Roman Catholics and Protestants, but amongst Roman Catholic writers. He appears to have taken no decisive steps to prevent the crime, and his movements immediately prior to the attempt were certainly suspicious. In September, shortly before the expected meeting of parliament on Oct. 3, Garnet organized a pilgrimage to St. Winifred's Well in Flintshire, which included Sir Everard Digby, Rokewood, John Grant and Robert Winter. During the pilgrimage Garnet asked for prayers "for some good success for the Catholic cause at the beginning of parliament." After his return he went to Coughton where it had been settled the conspirators were to assemble after the explosion. On Nov. 6, Bates, Catesby's servant and one of the conspirators, brought him a letter with the news of the failure of the plot. On the 30th Garnet addressed a letter to the government in which he protested his innocence. On Dec. 4, Garnet and Greenway were, by the confession of Bates, implicated in the plot. In company with another priest, Oldcorne *alias* Hall, Garnet hid himself, but at last on Jan. 30, 1606, surrendered and was taken up to London. Examined by the council on Feb. 13, he refused to incriminate himself. Subsequently, Garnet and Oldcorne having been placed in adjoining rooms and enabled to communicate with one another, their conversations were overheard on several separate occasions and considerable information obtained. Garnet at first denied all speech with Oldcorne, but later on March 8, confessed his connection with the plot. He was tried at the Guildhall on the 28th.

In the eyes of the law, Garnet was guilty of misprision of treason, *i.e.*, of having concealed his knowledge of the crime, an offence which exposed him to perpetual imprisonment and forfeiture of his property. His trial, like many others, was influenced by the political situation, the case against him being supported by general political accusations against the Jesuits as a body, and with evidence of their complicity in former plots. The prisoner himself prejudiced his cause by his numerous false statements, and by adhering to the doctrine of equivocation. He was declared guilty, and executed on May 3, 1606. He acknowledged himself justly condemned for his concealment of the plot, but maintained to the last that he had never approved it. Garnet's name was included in the list of the 353 Roman Catholic martyrs sent to Rome from England in 1880. His *aliases* were Farmer, Marchant, Whalley, Darcey, Meaze, Phillips, Humphreys, Roberts, Fulgeham, Allen. Garnet was the author of a letter on the Martyrdom of Godfrey Maurice, *alias* John Jones, in Diego Yepres's *Historia particular de la persecucion de Inglaterra* (1599); a *Treatise of Schism;* a translation of Canisius' *Summa of Christian Doctrine* (1622) ; a treatise on the Rosary; a Treatise of Christian Renovation (1616).

AUTHORITIES.—On the question of Garnet's guilt, see *A True and Perfect Relation of the whole Proceedings against . . . Garnet a Jesuit and his Confederates* (1606, repr. 1679), the official account, but incomplete and inaccurate; *Apologia pro Henrico Garneto* (1610), by the Jesuit L'Heureux, under the pseudonym Endaemon-Joannes, and R. GARNET, in mineralogy a closely related group of silicate minerals. The name is from Lat. *granatum,* a pomegranate, in allusion to the resemblance of the crystals to the seeds of this fruit in shape and colour. Garnets were worn as beads in ancient Egypt, and have been extensively used as gem stones. The modern carbuncle is a deep-red garnet (almandine) cut *en cabochon,* or with a smooth convex surface frequently hollowed out at the back in consequence of the depth of colour, and sometimes enlivened with a foil. Though not extensively employed by the Greeks as a material for engraved gems, it was much used by the Romans of the empire. Flat polished slabs of almandine or "precious garnet" are found inlaid in mosaic work in Anglo-Saxon and Merovingian jewellery.

The garnets form a well defined group of orthosilicates of the general chemical formula $3R''O{\cdot}R'''_2O_3{\cdot}3SiO_2$ in which R″=Ca, Mg,Fe″,Mn″ and R‴=Al,Fe‴,Cr‴, while silicon in some varieties is partly replaced by titanium. The following pure species are recognized: Grossular, $3CaO{\cdot}Al_2O_3{,}3SiO_2$; Pyrope, $3MgO{\cdot}Al_2O_3{\cdot}3SiO_2$; Almandine, $3FeO{\cdot}Al_2O_3{\cdot}3SiO_2$; Spessartine, $3MnO{\cdot}Al_2O_3{\cdot}3SiO_2$; Andradite, $3CaO{\cdot}Fe_2O_3{\cdot}3SiO_2$; Uvarovite, $3CaO{\cdot}Cr_2O_3{\cdot}3SiO_2$. Melanite, Iwaarite and Schorlomite are varieties of andradite containing significant percentages of titanium; Mn″, Y, and Zr appear rarely as minor constituents. Most garnets, however, prove on analysis not to be strictly any one of these minerals, but isomorphous mixtures of two or more of the end members, the particular R″or R″ being partly replaced by other metals of the same type.

All garnets crystallize with cubic symmetry, usually in rhombic dodecahedra (110), or trapezohedra (211) or in a combination of the two. The hexoctahedron is found in some combinations, but the octahedron and cube forms are rare. An imperfect cleavage or parting parallel to the dodecahedron obtains, but is seldom observed in thin sections of garnet crystals. The hardness is variable, 6.5 to 7·5, the lime-alumina garnet being the softest. Density varies from 3.4 to 4.3 according to the composition. The refracting power is high, varying with the composition, thus:—

	N	D
Grossular	1·735	3·530
Pyrope	1·705	3·510
Almandine	1·830	4·250
Spessartine	1·800	4.180
Andradite	1·895	3·750
Uvarovite	1·840	3·420

The refraction of andradite increases with increase in titanium content, a schorlomite or melanite from Kuusamo, Finland, with 18·98% To, having a refractive index of 2·01.

Being cubic, garnets are normally singly refracting or isotropic, but the calcium garnets (grossular, andradite, melanite and uvarovite) are frequently birefringent, a fact which led Mallard to conclude that the garnets are really anorthic crystals with close approximation to cubic symmetry. Klein has referred the pseudocubic garnets to four structural types in which uniaxial and biaxial subindividuals interpenetrate, forming the octahedral, dodecahedral, trapezohedral, and topazolitic structures, distinguished in polarized light by the manner in which the garnet crystals break up into doubly refracting sectors. No complete explanation of anisotropism in the garnet group of minerals is however yet available. Some of the zoned grossular and andradite garnets show a succession of isotropic and anisotropic shells.

Most of the garnets melt incongruently and break up into other compounds among which anorthite, monticellite, pyroxene, melilite, spinel and iron oxides have been recognized. From dry melts, spessartine and melanite have been crystallized while grossular has been synthesized under pressure by reaction of calcium orthosilicate and aluminium chloride. Ferriferous garnets fuse to a magnetic globule.

Almandine (precious garnet), the iron-aluminium garnet, derives its name by corruption from *alabandicus,* the name given by Pliny to a stone found at Alabanda, a town in Asia Minor. It is usually of a deep red colour inclining to purple and shows a characteristic absorption spectrum consisting of three bands. The mineral is used considerably in jewellery. The home of almandine in igneous rocks is in the granite-gneisses particularly those of Archaean age, and in the dynamically metamorphosed argillaceous sediments—mica schists, para-gneisses and granulites. In areas of progressive dynamic metamorphism, the entry of almandine in these latter rocks marks a definite grade of metamorphosis, the mineral being generated from chlorite and quartz. Almandine frequently alters to chlorite and pseudomorphs of this mineral are common in mica schists. Noteworthy localities for large and well crystallized almandines are the schists of the St. Gotthard, the Zillerthal, and Fort Wrangell in Alaska.

Pyrope, the magnesium-aluminium garnet, is named from the Greek πυρωπός (fiery eyed) in allusion to its deep red colour. Here are classed those garnets sometimes referred to as Bohemian garnet, Cape ruby and rhodolite. A pyrope of typical blood red colour is the common garnet of jewellery. It is distinguished from the red almandine by lower refraction and density. Pure pyrope is unknown in nature, the most magnesian type yet examined containing 75 molecular % of this constituent. The pure mineral would doubtless be colourless, the rich colour of the naturally occurring pyrope being due to one or more of the contained metals iron, manganese or chromium. Dry melts of the composition of pyrope crystallize at atmospheric pressure to an assemblage consisting of forsterite, cordierite and spinel, and it is probable that pyrope is formed in nature only under high pressures. The magnesian garnets occur only in eclogites, peridotites and serpentines resulting from the alteration of olivine-rich rocks. Noteworthy localities for their occurrence are Zoblitz and Greifendorf in Saxony and Meronitz in Bohemia, where they are derived from serpentines. In North America they occur in peridotites in Kentucky, New Mexico and other localities. The Kimberlite pipes of the South African diamond fields contain in the "blue ground" irregular or rounded crystals of blood-red to brown pyrope (the so-called Cape ruby) examples of which have been found enclosing crystals of diamond. These garnets are primary crystals of an igneous eclogite (griquaite) or peridotite. Pyrope weathers usually to chlorite, but in the serpentines it is frequently found surrounded by a fibrous rim composed largely of amphibole, pyroxene and a spinellid mineral. This fibrous crust is frequently referred to as Kelyphite (Gr. κέλυφος a nut shell). Though not always of the same constitution, a magnesian amphibole is a common constituent together with spinel or picotite. In most cases it is probably a reaction rim due to magmatic resorption. The production of amphibole and spinel by mutual reaction of pyrope and olivinic liquid may be represented as follows:

$$Mg_3Al_2Si_3O_{12} + Mg_2SiO_4 \rightarrow MgAl_2O_4 + 4MgSiO_3$$

The resulting products have a distinctly greater molecular volume, and it is probable that a reaction of this type sets in during the intrusion of pyrope-bearing peridotites to higher levels in the crust.

Grossular, the lime-alumina garnet, is named from Lat. *grossularia*, a gooseberry, in allusion to the common pale green colour of its crystals. Here are classed the calcium garnets known as cinnamon stone, hessonite, romanzovite and succinite. When pure the mineral is colourless or white but it is frequently pale green, amber, red, or even emerald green from the presence of chromium. The red variety (cinnamon stone, chiefly from Ceylon) is often confused with zircon (hyacinth) from which it is readily distinguished by its much lower specific gravity. Grossular melts incongruently and an assemblage consisting of anorthite, wollastonite and gehlenite is obtained from its dry melts. Typically a metamorphic mineral, it occurs only in unmetamorphosed igneous rocks when these have been contaminated by lime-rich inclusions. It occurs as a subordinate constituent of some saussurites and rarely as a metasomatic or pneumatolytic product in altered serpentines. The characteristic home of grossular however is the thermally altered calcareous sediment where it accompanies other lime-rich minerals such as scapolite, idocrase and wollastonite. In regional metamorphism it is developed in similar rocks, but it is noteworthy that in these occurrences the garnets are frequently isotropic, unlike those of contact rocks. Noteworthy localities for its occurrence in fine crystals are in the Ala valley (Piedmont) where it occurs in hyacinthine dodecahedra together with diopside and idocrase, an assemblage common in mineral collections, in contact limestones at Monzoni, in ejected limestone blocks at Vesuvius, and in Elba developed in yellow octahedra.

Spessartine, the manganese-aluminium garnet (from Spessart, Bavaria, where it occurs in red trapezohedra in granite) is usually of red, brownish-red or yellow colour. The crystal form is commonly trapezohedral (211). This mineral, or a spessartine-rich almandine, is of widespread distribution. It occurs in granites and pegmatites and as a pneumatolytic product in cavities or lithophysae of acid lavas. In hornfelses and crystalline schists derived from manganiferous, argillaceous and quartzose sediments it is a characteristic mineral. In the crystalline schists, in areas of progressive metamorphism spessartine may be generated at an early stage, entering into the constitution of phyllites Lefore biotite is synthesized. Noteworthy localities for its occurrence are in granite at Aschaffenburg (Spessart), in the cavities of rhyolites near Simpson (Utah) and Nathrop (Colorado). In the whetstones of the Ardennes minute isotropic spessartine (or spessartine with considerable percentages of the grossular molecule) forms colourless or reddish-yellow dodecahedra, often in great abundance. Fine large trapezohedra of spessartine are recorded from numerous localities in the central provinces of India, where they form constituents of important manganese ore deposits.

With andradite, calcium ferric garnet—named after J. B. d'Andrada who first examined it—are included the garnets known as allochroite, aplome, colophonite, demantoid, jelletite and topazolite. The common colour of andradite is brown, but green, yellow and wine colours are not infrequent. The grass green demantoid is used as a gemstone and possesses high refractive and dispersive power. Andradite is a typical metamorphic mineral, but is found also in igneous rocks which have assimilated fragments of limestone. It is a characteristic constituent of andradite skarns, metasomatic rocks arising at the contacts of limestones and acid plutonic rocks such as granites and quartz diorites. The iron content of the andradite is largely provided by the solutions emanating from the cooling igneous intrusion. Noteworthy localities for andradite in Europe are the contact aureoles of the Devonian igneous intrusions of the Oslo region, and Arendal. In North America andradite contact zones are frequently the home of important ore deposits of iron and copper, *e.g.*, the copper ore occurrences of Conception del Oro (Mexico) and the Clifton-Morenci district (Arizona). Melanite, Iwaarite and Schorlomite are titaniferous andradites of entirely different geological mode of occurrence. They are practically limited to intermediate and basic alkaline igneous rocks. These garnets are usually black, dull or resinous and in thin section dark brown, often zoned with shells of varying titanium content. In schorlomite titanium is present, not only replacing silicon but also as Ti_2O_3. It occurs in the nepheline syenites of Magnet Cove (Arkansas) and in the leucitophyre of Horberig, Kaiserstuhl. The original Iwaarite found in the ijolite of Iwaara, Finland, contains as much as 25% TiO_2. Titanium rich melanites occur in the alkaline and ultra-alkaline igneous rocks, nepheline syenites, ijolites, borolanites, leucitophyres, phonolites, etc., noteworthy localities for their occurrence being Loch Borolan (Assynt), the Kaiserstuhl, Fen district (Norway), Kola Peninsula, Magnet Cove, Port Cygnet (Tasmania) and other alkaline provinces.

Uvarovite, named in honour of the Russian minister, Count Uvarov, is a rare emerald-green calcium-chromium garnet known in altered serpentines and metamorphosed limestones, in the first named rocks in cavities associated with chromite at Bisersk in the Northern Urals and also on Skyros and in limestones in Tasmania and at Orford (Canada). Crystals of uvarovite usually show anomalous birefringence.

An isomorphous mixture of grossular, almandine and pyrope forms the red garnet common in dynamically metamorphosed igneous rocks of the dolerite-gabbro group—amphibolites, hornblende schists and pyroxene rocks. The almandine molecule is dominant. In the amphibolites the garnets show a range of pyrope content from 9–28 molecular %, and an average grossular content of 24%. (C. E. T.)

GARNETT, RICHARD (1835–1906), English librarian and author, son of the learned philologist Rev. Richard Garnett (1789–1850), priest-vicar of Lichfield cathedral and afterwards keeper of printed books at the British Museum, was born at Lichfield. He was educated at home and at a private school, and in 1851, just after his father's death, entered the British Museum as an assistant in the library. In 1875 he rose to be superintendent of the reading-room, and from 1890 to 1899, when he retired, he

was keeper of the printed books. In 1895 he was made a C.B. In the history of the British Museum library his place is second only to that of Panizzi. Besides introducing the "sliding press" in 1887 he was responsible for reviving the publication of the general catalogue, the printing of which, interrupted in 1841, was resumed under him in 1880, and gradually completed. He married (1863) an Irish wife, Olivia Narney Singleton (d. 1903); his son Edward (1868–1937), a well-known author, married Constance Black, known under her married name as the translator of the works of Turgeniev, Tolstoy and other Russian authors.

Dr. Garnett's chief publications in book-form were: in verse, *Primula* (1858), *Io in Egypt* (1859), *Idylls and Epigrams* (1869, republished in 1892 as A *Chaplet from the Greek Anthology), The Queen and other Poems* (1902), *Collected Poems* (1893); in prose, biographies of Carlyle (1887), Emerson (1887), Milton (1890), Edward Gibbon Wakefield (1898); a volume of remarkably original and fanciful tales, *The Twilight of the Gods* (1888); a tragedy, *Iphigenia in Delphi* (1890); A *Short History of Italian Literature* (1898); *Essays in Librarianship and Bibliophily* (1899); *Essays of an Ex-librarian* (1901). He was an extensive contributor to the *Encyclopædia Britannica* and the *Dictionary of National Biography,* editor of the *International Library of Famous Literature,* and co-editor, with E. Gosse, of the elaborate *English Literature: an illustrated Record.* This list represents only a small part of his published work.

GARNIER, CLEMENT JOSEPH (1813–1881), French economist, was born at Beuil (Alpes Maritimes) on Oct. 3, 1813. He studied at the Ecole de Commerce, Paris, of which he became secretary and finally a professor. In 1842 he founded with Gilbert-Urbain Guillaumin (1801–64) the Société d'Economie Politique; and in 1846 he organized the Association pour la Liberté des Echanges. He also helped to establish and edited for many years the *Journal des économistes* and the *Annuaire de l'économie politique.* Of the school of *laissez faire,* he was engaged during his whole life in the advancement of the science of political economy, and in the improvement of French commercial education. In 1873 he became a member of the Institute, and in 1876 a senator for the department in which he was born. He died in Paris on Sept. 25, 1881. Of his writings, the following are the more important: *Traitk d'économie politique* (1845), *Richard Cobden et la Ligue* (1846), *Traitk des finances* (1862), and *Principes du population* (1857).

GARNIER, GERMAIN, MARQUIS (1754–1821), French politician and economist, was born at Auxerre on Nov. 8, 1754. He was educated for the law, and obtained the office of *procureur* to the Châtelet in Paris. On the calling of the states-general he was elected as one of the *députés suppléants* of the city of Paris, and in 1791 administrator of the department of Paris. After Aug. 10, 1792, he withdrew to the Pays de Vaud, returning to France in 1795. Two years later he was among the candidates for the Directory; in 1800 he was prefect of Seine-et-Oise. At the Restoration, he received a peerage, became minister of State and member of privy council, and in 1817 was created a marquis. He died at Paris on Oct. 4, 1821. His literary reputation depends chiefly on his later works on political economy, especially his admirable translation, with notes and introduction, of Smith's *Wealth of Nations* (1805) and his *Histoire de la monnaie* (2 vols., 1819), which contains much sound and well-arranged material.

GARNIER, JEAN LOUIS CHARLES (1825–1898), French architect, was born in Paris on Nov. 6, 1825, and died on Aug. 3, 1898. He was the son of a wheelwright and studied drawing and mathematics at the Petite Ecole de Dessin. He then entered the atelier of Lebas. Passing the entrance examination of the Ecole des Beaux Arts in 1842, he studied there in the evening, supporting himself by working by day in the offices of Viollet-le-Duc and other architects. In 1848 he won the *Grand Prix de Rome* and went to the Villa de Medicis. His principal works were the measured drawings of the Forum of Trajan and the temple of Vesta in Rome and the temple of Serapis at Pozzuoli. Garnier's other works include the imperial academy of music, the casino at Monte Carlo, the Bischoffsheim villa at Bordighera, the Hotel du Cercle de la Librairie in Paris and his tombs for the musicians Bizet, Offenbach, Massé and Duprato. In 1874 he was elected a member of the Institute of France.

See L. G. B. P. Larroumet, "La vie de Charles Garnier," in *L'Ami des Monuments Français,* xviii., 65, 224; xix., 18 (1904–05).

GARNIER, MARIE JOSEPH FRANÇOIS [FRANCIS] (1839–1873), French officer and explorer, was born at St. Étienne on July 25, 1839. He entered the navy, and after voyaging in Brazilian waters and the Pacific he obtained a post on the staff of Admiral Charner, who from 1860 to 1862 was campaigning in Cochin-China. After some time spent in France he returned to the East, and in 1862 he was appointed inspector of the natives in Cochin-China, and entrusted with the administration of Cho-lon, a suburb of Saigon. At his suggestion the marquis de Chasseloup-Laubat sent a mission to explore the valley of the Mekong. Garnier accompanied Captain Doudart de Lagrée on this expedition. From Kratie in Cambodia to Shanghai 5,392 m. were traversed, and of these 3,625 m., chiefly of country unknown to European geography. The area was surveyed with care, and the positions fixed by astronomical methods, most of the observations being taken by Garnier himself. Volunteering to lead a detachment to Talifu, the capital of Sultan Suleiman, the sovereign of the Mohammedan rebels in Yunnan, he successfully carried out the dangerous enterprise. When shortly afterwards Lagrée died, Garnier conducted the expedition in safety to the Yang-tsze-Kiang, and thus to the Chinese coast. The preparation of his narrative, after his return to France, was interrupted by the Franco-German War, and during the siege of Paris he served as principal staff officer to the admiral in command of the eighth "sector." Returning to Cochin-China he found the political circumstances of the country unfavourable to further exploration, turned to China, and in 1873 followed the upper course of the Yang-tsze-Kiang to the waterfalls. He was next commissioned by Admiral Dupré, governor of Cochin-China, to found a French protectorate or a new colony in Tongking. On Nov. 20, 1873 he took Hanoi, the capital of Tongking, and on the 21st of December he was slain in fight with the Black Flags. His chief fame rests on the fact that he originated the idea of exploring the Mekong, and carried out the larger portion of the work.

The narrative of the principal expedition appeared in **1873,** as *Voyage d'exploration en Indo-Chine effectué pendant les années 1866, 1867 et 1868, publié sous la direction de M. Francis Garnier, avec le concours de M. Delaporte et de M. M. Joubert et Thorel* (2 vols.). An account of the Yang-tsze-Kiang from Garnier's pen is given in the *Bulletin de la Soc. de Géog.* (1877). His *Chronique royale du Cambodje,* was reprinted from the *Journal Asiatique* in 1872. See *Ocean Highways* (1874) for a memoir by Colonel Yule; Petit, *Francis Garnier* (1885) and Hugh Clifford, *Further India,* in the Story of Exploration series (1904).

GARNIER, ROBERT (*c.* 1545–*c.* 1600), French tragic poet, was born at Ferté Bernard (Le Maine). He published his first work while still a law-student at Toulouse, where he won a prize (1565) in the *jeux floraux.* It was a collection of lyrical pieces, now lost, entitled *Plaintes amoureuses de Robert Garnier* (1565). After some practice at the Parisian bar, he became *conseiller du roi* in his native district, and later *lieutenant-ge'ne'ral criminel.*

In his early plays Garnier was a close follower of the Senecan school. His pieces in this rhetorical manner are *Porcie* (published 1568, acted at the hôtel de Bourgogne in 1573), *Cornklie* and *Hippolyte* (both acted in 1573 and printed in 1574). His next group of tragedies — Marc-Antoine (1578), *La Troade* (1579), *Antigone* (acted and printed 1580) — shows an advance on the theatre of Etienne Jodelle and Jacques Grévin, and on his own early plays, since the rhetoric is accompanied by some action.

In 1582 and 1583 he produced his two masterpieces *Bradamante* and *Les Juives.* In *Bradamante,* which alone of his plays has no chorus, he cut himself adrift from Senecan models, and sought his subject in Ariosto, the result being what came to be known later as a tragi-comedy. The dramatic and romantic story becomes a real drama in Garnier's hands, though even there the lovers, Bradamante and Roger, never meet on the stage. The contest in the mind of Roger supplies a genuine dramatic interest. *Les Juives* has for its theme the story of the barbarous vengeance of Nebuchadrezzar on the Jewish king Zedekiah and his children. This tragedy, although almost entirely elegiac in conception, gains

unity by the personality of the prophet. Faguet says that of all French tragedies of the 16th and 17th centuries it is, with *Athalie,* the best constructed with regard to the requirements of the stage. Actual representation is continually in the mind of the author; his drama is, in fact, visually conceived.

The best edition of his works is by Wendelin Foerster (Heilbronn, 4 vols., 1882–83). A detailed criticism of his works is to be found in Emile Faguet, *La Tragédie française au XVIe siècle* (1883, pp. 183–307).

GARNIER-PAGÈS, LOUIS ANTOINE (1803–1878), French politician, was born at Marseilles on Feb. 16, 1803. His brother ETIENNE (1801–1841) was secretary of the society *Aide-toi, le ciel* t'aidera, under the Restoration, supported the revolution of July and sat in the Chamber of Deputies from 1831 until his death. Louis Antoine fought on the barricades in 1830, and after his brother's death was elected to the Chamber. He was a leading spirit in the affair of the reform banquet fixed for Feb. 22, 1848. He was a member of the provisional government of 1848, and was named mayor of Paris. On March 5, he was made minister of finance, and incurred great unpopularity by the imposition of additional taxes. He was a member of the Constituent Assembly and of the Executive Commission. Under the Empire he was conspicuous in the republican opposition and opposed the war with Prussia, and after the fall of Napoleon III. became a member of the Government of National Defence. Unsuccessful at the elections for the National Assembly in 1871, he retired into private life, and died in Paris on Oct. 31, 1878. He wrote *Histoire de* la *révolution* de *1848* (8 vols., 1860–1862); *Histoire de* la *commission exécutive* (1869–1872); and *L'Opposition* et *l'empire* (1872).

GARNISH: see ATTACHMENT; EXECUTION; BANKRUPTCY.

GARO HILLS, a district of British India, in the Assam valley division of Assam. Area 3,152 sq.m. Pop. (1931) 190,911. It takes its name from the Garos, a tribe of Tibeto-Burma origin, by whom it is almost entirely inhabited. The Garos are probably a section of the great Bodo tribe, which at one time occupied a large part of Assam. In the 18th century they were a terror to the inhabitants of the plains below their hills. The early period of British rule is a record mainly of raids by the Garos, followed by blockades of the hills. At last in 1866 a British officer was posted among the hills with a small police force. This step was effective in putting a stop to raids till 1871–72, when further outrages were committed by some independent Garos. It was decided to annex their territory. A police force marched through the hills; the heads taken in the raids were surrendered and there were no further disturbances.

The district consists of the last spurs of the Assam hills, which here run down almost to the bank of the Brahmaputra, where that river debouches upon the plain of Bengal and takes its great sweep to the south. The administrative headquarters are at Tura, where the American Baptist mission maintains a branch. Coal in large quantities and petroleum are known to exist in the hills. Nomadic cultivation is practised, *i.e.,* patches of forest are burnt and cleared with the axe and crops are grown among the ashes. These patches are cultivated for a few years and then left, fresh areas being cleared in the same way. Nearly half of the cotton grown in Assam is raised by the Garos: it is remarkable for a short staple and woolly fibre, which has led to its being mixed with wool for carpet making.

The Garos are an Assam tribe of the Bodo group which seems to have migrated from the direction of Bhutan, but probably absorbed some pre-existing local stock (wavy and even curly hair is frequent); the existing culture suggests Indonesian affinities. A Tibeto-Burmese language is spoken; the tribe is related to the Rabhas, Kacharis and Tipperas.

Villages are built on river banks, the houses raised on piles; land is communal and cultivation shifting, rice and cotton being grown. Garos are good fishermen but indifferent hunters Distension of the ear is practised. There are a dozen sub-tribes with varying customs and dialects, but all are divided into matrilineal clans. Marriage is exogamous and polygamous and the proposal comes from the woman, who, if accepted, lives for a time in the bridegroom's house on probation, but this system is subject to compulsory cross-cousin marriage coupled with a rule by which a man must marry his wife's father's widow, who is in such cases the husband's father's sister, actual or classificatory. Such a wife takes precedence of her daughter married before her. A man's sister's son, called his *nokrom,* stands therefore in intimate relationship to him, as the husband of one of the daughters and ultimately of his widow and the vehicle through which his family's interest in the property of his wife is secured for the next generation, for no male can inherit property.

The dead are buried, followed by various forms of secondary disposal including urn burial, burial by water and sometimes by special treatment of the frontal bone. Head-hunting (*q.v.*) used to be practised, enemy skulls being kept in the latrines, and there are faint traces of cannibalism and human sacrifice in the past. Religion is generally animistic, but provides a benevolent creator and a sort of vague ancestor worship with soul figures of wood or stone, probably phallic, and a fertility cult which involves the sacrifice of an imitation horse. They believe in the reincarnation of the soul. (See also ASIA: Ethnology; HEAD-HUNTING; LYCANTHROPY; METEMPSYCHOSIS.)

See A. Playfair, *The* Garos (1909).

GARONNE (Lat. *Garumna*), a river of south-western France, rising in the Maladetta group of the Pyrenees and flowing in a wide curve to the Atlantic ocean. It is formed by two torrents, one of which has a subterranean course of 2½ m., disappearing in the sink known as the Trou du Taureau ("bull's hole") and reappearing at the Goueil de Jouéou. After a course of 30 m in Spanish territory, during which it flows through the fine gorge, the Vallée d'Aran, the Garonne enters France in the department of Haute Garonne through the narrow defile of the Pont du Roi, and at once becomes navigable for rafts. At Montréjeau it receives on the left the Neste, and encountering at this point the vast plateau of Lannemezan turns abruptly east, flowing in a wide curve to Toulouse. At Saint Martory it gives off the irrigation canal of that name. At this point the Garonne enters a fertile plain, and supplies the motive power to several mills. It is joined on the right by various streams fed by the snows of the Pyrenees. Such are the Salat, at whose confluence river navigation begins, and the Arize and the Ariège (both names signifying "river")

From Toulouse the Garonne flows to the north-west, now skirting the northern border of the plateau of Lannemezan which here drains into it by the Save, Gers and Baïse. On its right the Garonne receives its two chief tributaries, the Tarn, near Moissac, and the Lot, below Agen; afterwards it is joined by the Drot (or Dropt), and on the left by the Ciron. Between Toulouse and Castets, 33½ m. above Bordeaux, the river is accompanied at a distance of from ½ m. to 3 m. by the so-called "lateral canal" of the Garonne, constructed in 1838–56. This canal is about 120m. long. From Toulouse to Agen the main canal follows the right bank of the Garonne, crossing the Tarn on an aqueduct at Moissac, while another aqueduct carries it across the Garonne at Agen. It has a fall of 420 ft. and over 50 locks. The carrying trade upon it is chiefly in agricultural produce and provisions, building materials, wood and industrial products. At Toulouse the canal connects with the Canal du Midi, which runs to the Mediterranean.

After passing Castets the Garonne begins to widen out considerably to about 650 yd. at Bordeaux, its great commercial port. From here it flows between two flat shores to the Bec d'Ambès (15½ m.), where, after a course of 357 m., it unites with the Dordogne to form the vast estuary known as the Gironde. The peninsula lying between these two great tidal rivers, the entre-deux-mers ("between two seas"), is famous for its wines. The drainage area of the Garonne is nearly 33,000 square miles. Floods are of common occurrence, and descend very suddenly. The most disastrous occurred in 1875. 1856 and in 1770, when the flood level at Castets attained the record height of 42½ ft. above low-water mark.

GAR-BIKE (Lepidosteus) a genus of fishes with four, or perhaps more, species in the rivers of North and Central America, with elongate body covered with hard rhombic scales, with the jaws produced, and with strong conical teeth. Fishes with ganoid scales of the same structure were abundant in Mesozoic times,

but *Lepidosteus* is not known before the Eocene. In the bill-fish or long-nosed gar *(L. osseus)* the jaws are exceedingly long and slender, in other species shorter and broader. The alligator gar of Cuba, Mexico and the southern States, reaches a length of 10 ft. These are piscivorous fishes, of sluggish habits, but very voracious. The name gar or garfish is also given to the Belonidae, fishes of warm seas, slender and with long jaws, but with thin cycloid scales, and not related to the gar-pikes.

GARRET, properly a small look-out tower built on a wall, and hence the name given to a room on the top storey of a building, the sloping ceiling of which is formed by the roof.

GARRETT, JOÃO BAPTISTA DA SILVA LEITAO DE ALMEIDA, VISCONDE DE ALMEIDA-GARRETT (1799–1854), perhaps the greatest Portuguese poet since Camoens, was born in Oporto; but the French invasion of Portugal drove the family to the Azores, and Garrett made his first studies at Angra. Going to the University of Coimbra in 1816 he soon earned notoriety by the precocity of his talents and his fervent Liberalism. His tragedy *Lucrecia* was played there in Feb. 1819, and he also wrote *Merope* and a great part of *Cato*, all these plays belonging to the so-called classical school. Leaving Coimbra with a law degree, he proceeded to Lisbon, and on Nov. 11, 1822, married D. Luiza Midosi; but the alliance proved unhappy and a formal separation took place in 1839.

The reactionary movement against the Radical revolution of 1820 reached its height in 1823, and Garrett had to leave Portugal by order of the Absolutist ministry then in power, and went to England. He became acquainted with the masterpieces of the English and German romantic movements during his stay abroad.

Imbued with the spirit of nationality, he wrote in 1824 at Havre the poem *Camões*, which destroyed the influence of the worn-out classical and Arcadian rhymers, and in the following year composed the patriotic poem *D. Branca*. He was permitted to return to Portugal in 1826, and thereupon devoted himself to journalism. His defence of Liberal principles brought him three months' imprisonment and when D. Miguel was proclaimed absolute king on May 3, 1828, Garrett had again to leave the country. He spent the next three years in and about Birmingham, Warwick and London. Sailing in Feb. 1832, he disembarked at Terceira, whence he passed to S. Miguel, then the seat of the Liberal government. Here he became a co-operator with the statesman Mousinho da Silveira, and assisted him in drafting those laws which were to revolutionize the whole framework of Portuguese society. In his spare time he wrote some of the beautiful lyrics afterwards collected into *Flores sem Fructo* (1845). He took part in the expedition that landed at Mindello on July 8, 1832, and in the occupation of Oporto. Early in the siege he sketched out, under the influence of Walter Scott, the historical romance *Arco de Sant' Anna* (1845–51).

In 1834–35 he served as consul-general and *charge' d'affaires* at Brussels, later the government employed him to draw up a proposal for the construction of a national theatre, and a school of dramatists and actors arose under his influence. To give them models, he proceeded to write a series of prose dramas, choosing his subjects from Portuguese history. He began in 1838 with the *Auto de Gil Vicente* and followed this up in 1842 by the *Alfageme de Santarem*, and in 1843 by *Frei Luiz de Sousa*, one of the few great tragedies of the 19th century, a work as intensely national as *The Lusiads* and written in a restrained and beautiful prose.

Entering parliament in 1837, Garrett soon made his mark as an orator. He brought in a literary copyright bill, which, when it became law in 1851, served as a precedent for similar legislation in England and Prussia. He wrote about this time the drama *D. Filippa de Vilhena* (1840), founded on an event in the revolution of 1640. In July 1843 an excursion to Santarem resulted in a prose masterpiece *Viagens na minha terra*. He took no part in the civil war that followed the revolution of Maria da Fonte. He spent much of the year 1850 in finishing his *Romanceiro*, a collection of folk-poetry of which he was the first to perceive the value; and in June 1851 he was created a viscount. In 1852 he became for a short time, minister of foreign affairs. In 1853 he brought out *Folhas Cahidas*, a collection of short poems exquisite in form. He died on Dec. 9, 1854, and on May 3, 1903, his remains were translated to the national pantheon, the Jeronymos at Belem, where they rest near to those of Herculano and Camoens. As poet, novelist, journalist, orator and dramatist, he deserves the remark of Rebello da Silva: "Garrett was not a man of letters only but an entire literature in himself."

Besides his strong religious faith, Garrett was endowed with a deep sensibility, a creative imagination, rare taste and a singular capacity for sympathy. He was first and always an artist. His artistic temperament explains his many-sided activity, his expansive kindliness, his seductive charm, especially for women, his patriotism, his aristocratic pretensions, his huge vanity and dandyism and the ingenuousness that absolves him from many faults in an irregular life. From his rich artistic nature sprang his profound, sincere, sensual and melancholy lyrics, the variety and perfection of his scenic creations, the splendour of his eloquence, the truth of his comic vein, the elegance of his lighter compositions. The complete collection of his works comprises 24 volumes.

Prestage, "The Visconde de Almeida Garrett" in the *Oxford and Cambridge Review* (1911), pp. 89–114. *Frei Luiz de Sousa* was translated by E. Prestage under the title *Brother Luiz de Sousa* (1909). (E. P.; A. B.)

GARRICK, DAVID (1717–1779), English actor and theatrical manager, was descended from a good French Protestant family named Garric or Garrique of Bordeaux, which had settled in England on the revocation of the Edict of Nantes. His father, Captain Peter Garrick, who had married Arabella Clough, the daughter of a vicar choral of Lichfield cathedral, was on a recruiting expedition when his famous third son was born at Hereford on Feb. 19, 1717. Captain Garrick, who had made his home at Lichfield, in 1731 rejoined his regiment at Gibraltar. This kept him absent from home for many years, during which letters were written to him by "little Davy," acquainting him with the doings at Lichfield. On his father's return from Gibraltar, David, who had previously been educated at the grammar school of Lichfield, was sent with his brother George to the "academy" at Edial just opened in June or July 1736 by Samuel Johnson, the senior by seven years of David, who was then 19. This seminary was, however, closed in about six months, and on March 2, 1737, both Johnson and Garrick left Lichfield for London—Johnson, as he afterwards said, "with twopence halfpenny in his pocket," and Garrick "with three-halfpence in his." Johnson, whose chief asset was the ms. tragedy of *Irene*, was at first the host of his former pupil, who, however, before the end of the year went to live at Rochester with John Colson (afterwards Lucasian professor at Cambridge). Captain Garrick died about a month after David's arrival in London. Soon afterwards, his uncle, a wine merchant at Lisbon, having left David a sum of £1,000, he and his brother entered into partnership as wine merchants in London and Lichfield, David taking up the London business. The concern was not prosperous, and before the end of 1741 he had spent nearly half of his capital.

His passion for the stage completely engrossed him; he tried his hand both at dramatic criticism and at dramatic authorship. His first dramatic piece, *Lethe*, or *Aesop in the Shades* was played at Drury Lane on April 15, 1740; and he became a well-known frequenter of theatrical circles. His first appearance on the stage was made in March 1741, *incognito*, as harlequin at Goodman's Fields, Yates, who was ill, having allowed him to take his place during a few scenes of the pantomime entitled *Harlequin Student*, or *The Fall of Pantomime with the Restoration of the Drama*. Garrick subsequently accompanied a party of players from the same theatre to Ipswich, where he played his first part as an actor under the name of Lyddal, in the character of Aboan (in Southerne's *Oroonoko)*. On Oct. 19, 1741 he made his appearance at Goodman's Fields as Richard III. and gained the most enthusiastic applause. Among the audience was Macklin, whose performance of Shylock, early in the same year, had pointed the way along which

Garrick was so rapidly to pass in triumph. On the morrow the latter wrote to his brother at Lichfield, proposing withdrawal from the partnership. Meanwhile, each night had added to his popularity on the stage. The town, as Gray (who, like Horace Walpole, at first held out against the *furore)* declared, was "horn-mad" about him. Before his Richard had exhausted its original effect, he won new applause as Aboan, and soon afterwards as Lear and as Pierre in Otway's *Venice Preserved,* as well as in several comic characters (including that of Bayes). Glover ("Leonidas") attended every performance; the duke of Argyll, Lords Cobham and Lyttelton, Pitt and others praised the new actor. Within the first six months of his theatrical career he acted in 18 characters of all kinds, and from Dec. 2, he appeared in his own name. Pope went to see him three times during his first performances, and pronounced that "that young man never had his equal as an actor, and he will never have a rival." Garrick's farce of *The Lying Valet,* in which he performed the part of Sharp, was at this time brought out with so much success that he ventured to send a copy to his brother.

His fortune was now made, and while the managers of Covent Garden and Drury Lane resorted to the law to make Giffard, the manager of Goodman's Fields, close his little theatre, Garrick was engaged by Fleetwood for Drury Lane for the season of 1742. In June of that year he went over to Dublin. He was accompanied by Margaret (Peg) Woffington, of whom he had been for some time a fervent admirer. From Sept. 1742 to April 1745 he played at Drury Lane, after which he again went over to Dublin. Here he remained during the whole season, as joint-manager with Sheridan, in the direction and profits of the Theatre Royal in Smock Alley. In 1746–47 he fulfilled a short engagement with Rich at Covent Garden, his last series of performances under a management not his own. With the close of that season Fleetwood's patent for the management of Drury Lane expired, and Garrick, in conjunction with Lacy, purchased the property of the theatre, together with the renewal of the patent; contributing £8,000 as two-thirds of the purchase-money. In Sept. 1747 it was opened with a strong company of actors, Johnson's prologue being spoken by Garrick, while the epilogue, written by him, was spoken by Mrs. Woffington. Garrick was surrounded by many eminent players, and he had the art, as he was told by Mrs. Clive, "of contradicting the proverb that one cannot make bricks without straw, by doing what is infinitely more difficult, making actors and actresses without genius." The naturalness of his acting fascinated those who, like Partridge in *Tom Jones,* listened to nature's voice, and justified the preference of more conscious critics. To be "pleased with nature" was, as Churchill wrote, in the *Rosciad* (1761), to be pleased with Garrick. For the stately declamation, the sonorous, and beyond a doubt impressive, chant of Quin and his fellows, Garrick substituted rapid changes of passion and humour in both voice and gesture, which held his audiences spellbound. Garrick's French descent and his education may have contributed to give him the vivacity and versatility which distinguished him as an actor; and nature had given him an eye, if not a stature, to command, and a mimic power of wonderful variety. The list of his characters in tragedy, comedy and farce would be extraordinary for a modern actor of high rank; it includes not less than 17 Shakespearian parts. As a manager he did good service to the theatre and signally advanced the popularity of Shakespeare's plays, of which not less than 24 were produced at Drury Lane under his management. Many of these were not pure Shakespeare; and he is credited with the addition of a dying speech to the text of *Macbeth.* On the other hand, Tate Wilkinson says that Garrick's production of *Hamlet* in 1773 was well received at Drury Lane even by the galleries, "though without their favourite acquaintances the gravediggers." Among his published adaptations are an opera, *The Fairies* (from *Midsummer Night's Dream)* (17jj); an opera *The Tempest* (1756); *Catherine and Petruchio* (1758); *Florizel and Perdita* (1762). But not every generation has the same notions of the way in which Shakespeare is best honoured. Few sins of omission can be charged against Garrick as a manager. but he refused Home's *Douglas,* and made the wrong choice between *False Delicucy* and *The Good Natur'd Man.* For the rest, he purified the stage of much of its grossness, and introduced a relative correctness of costume and decoration unknown before. To the study of English dramatic literature he rendered an important service by bequeathing his then unrivalled collection of plays to the British Museum.

After escaping from the chains of his passion for the beautiful but reckless Mrs. Woffington, Garrick had in 1749 married Mademoiselle Violette (Eva Maria Veigel), a German lady who had attracted admiration at Florence or at Vienna as a dancer, and had come to England early in 1746, where her modest grace and the rumours which surrounded her created a *furore.* Garrick, who called her "the best of women and wives," lived most happily with her in his villa at Hampton, acquired by him in 1754, whither he was glad to escape from his house in Southampton street. To this period belongs Garrick's quarrel with Barry, the only actor who even temporarily rivalled him in the favour of the public. In 1763 Garrick and his wife visited Paris, where they were cordially received and made the acquaintance of Diderot and others at the house of the baron d'Holbach. Grimm extolled Garrick as the first and only actor who came up to the demands of his imagination; and it was in a reply to a pamphlet occasioned by Garrick's visit that Diderot set forth the views expounded in his *Paradoxe sur le comédien.* After some months spent in Italy, where Garrick fell seriously ill, they returned to Paris in the autumn of 1764 and made more friends, reaching London in April 1765. Their union was childless, and Mrs. Garrick survived her husband until 1822. Her portrait by Hogarth is at Windsor castle.

Garrick practically ceased to act in 1766, but he continued the management of Drury Lane, and in 1769 organized the Shakespeare celebrations at Stratford-on-Avon. Of his best supporters on the stage, Mrs. Cibber, with whom he had been reconciled, died in 1766, and Mrs. (Kitty) Clive retired in 1769. Garrick sold his share in the property in 1776 for £35,000, and took leave of the stage by playing a round of his favourite characters—Hamlet, Lear, Richard and Benedick, among Shakespearian parts; Lusignan in *Zara,* Aaron Hill's adaptation of Voltaire's *Zaire;* and Kitely in his own adaptation of Ben Jonson's *Every Man in his Humour,* Archer in Farquhar's *Beaux' Stratagem;* Abel Drugger in Ben Jonson's *Alchemist;* Sir John Brute in Vanbrugh's *Provoked Wife;* Leon in Fletcher's *Rule a Wife and have a Wife.* He ended the series, as Tate Wilkinson says, "in full glory" with "the youthful Don Felix" in Mrs. Centlivre's *Wonder* on June 10, 1776. He died in London on Jan. 20, 1779. He was buried in Westminster Abbey at the foot of Shakespeare's statue.

In person, Garrick was a little below middle height; in his later years he seems to have inclined to stoutness. The extraordinary mobility of his whole person, and his power of as it were transforming himself at will, are attested by many anecdotes and descriptions, but the piercing power of his eye must have been his most irresistible feature. The most discriminating character of Garrick, slightly tinged with satire, is that drawn by Goldsrnith in his poem of *Retaliation.* Garrick was often happy in his epigrams and occasional verse, including his numerous prologues and epilogues. He had the good taste to recognize, and the spirit to make public his recognition of, the excellence of Gray's odes at a time when they were either ridiculed or neglected. His dramatic pieces, *The Lying Valet,* adapted from Motteux's *Novelty Lethe* (1740), *The Guardian, Linco's Travels* (1767), *Miss in her Teens* (1747), *Irish Widow,* etc., and his alterations and adaptations of old plays, which together fill four volumes, evinced his knowledge of stage effect and his appreciation of lively dialogue and acting. He was joint author with Colman of *The Clandestine Marriage* (1766), in which he is said to have written his famous part of Lord Ogleby.

Garrick's *Private Correspondence* (published in 1831–32 with a short memoir by Boaden, in 2 vols. 4to), which includes his extensive *Foreign Correspondence* with distinguished French men and women, and the notices of him in the memoirs of Cumberland, Hannah More and Madame D'Arblay, and above all in Boswell's *Life of Johnson,* bear testimony to his many attractive qualities as a companion and to his fidelity as a friend.

BIBLIOGRAPHY.—A collection of unprinted Garrick letters is in the Forster library at South Kensington. A list of publications of all kinds for and against Garrick will be found in R. Lowe's *Bibliographical History of English Theatrical Literature* (1887). The earlier biographies of Garrick are by Arthur Murphy (2 vols., 1801) and by the bookseller Tom Davies (2 vols., 4th ed., 1805), the latter a work of some merit, but occasionally inaccurate and confused as to dates; and a searching if not altogether sympathetic survey of his verses is furnished by Joseph Knight's valuable *Life* (1894). Percy Fitzgerald's *Life* (2 vols., 1868; new edition, 1899) is full and spirited, and has been reprinted, with additions, among Sir Theodore Martin's *Monographs* (1906). *See* also C. Gaehde, *David Garrick als Shakespeare-Darsteller*, etc. (1904); Mrs. Parsons' *Garrick, and his Circle* and *Some unpublished Correspondence of David Garrick* ed. G. *P.* Baker (Boston, Mass., 1907) and F. A. Hedgcock, *A cosmopolitan actor, David Garrick and his French friends, etc.* (1912).

As to the portraits of Garrick, *see* W. T. Lawrence in *The Connoisseur* (April 1905). That by Gainsborough at Stratford-on-Avon was preferred by Mrs. Garrick to all others. Several remain from the hand of Hogarth, including the famous picture of Garrick as Richard *III.* The portraits by Reynolds include the celebrated "Garrick between Tragedy and Comedy." Zoffany's are portraits in character. Roubiliac's statue of Shakespeare, for which Garrick sat, and for which he paid the sculptor 300 guineas, was originally placed in a small temple at Hampton, and is now in the British Museum.

GARRISON, WILLIAM LLOYD (1805–1879), the American anti-slavery leader, was born in Newburyport (Mass.), on Dec. 10, 1805. His parents were from the British province of New Brunswick. The father, Abijah, a sea captain, drank heavily and deserted his home when William was a child, and it is not known whether he died at sea or on land. The mother, whose maiden name was Lloyd, is said to have been a woman of high character, charming in person and eminent for piety. She died in 1823. William had little education but made the most of his opportunities. He was set to learn the trade of a shoemaker, first at Newburyport, and then, after 1815, at Baltimore (Md.). Then he was apprenticed to a cabinet-maker (at Haverhill, Mass.), but ran away. In Oct. 1818, when he was 14, he was indentured to Ephraim W. Allen, proprietor of the Newburyport *Herald,* to learn the trade of a printer. He soon became an expert compositor, and after a time began to write anonymously for the *Herald.* His communications won the commendation of the editor, who had not at first the slightest suspicion that he was the author. He also wrote for other papers with equal success. His skill as a printer won for him the position of foreman, while his ability as a writer was so marked that the editor of the *Herald,* when temporarily called away from his post, left the paper in his charge.

The printing-office afforded him an opportunity to increase his meagre education. He was enthusiastic about liberty; the struggle of the Greeks to throw off the Turkish yoke enlisted his sympathy; and at one time he seriously thought of entering the West Point academy and fitting himself for a soldier's career. His apprenticeship ended in 1826, when he began the publication of a new paper (actually the old one under a new name), the *Free Press,* in his native place. The paper, whose motto was "Our Country, our Whole Country, and nothing but our Country," was an intellectual force, but was too radical for Newburyport, and the enterprise failed. Garrison then went to Boston, where, after working for a time as a journeyman printer, he became the editor of the *National Philanthropist,* the first journal established in America to promote the cause of total abstinence from intoxicating liquors; but a change in the proprietorship led to his withdrawal before the end of the year. In 1828 he established the *Journal of the Times* at Bennington (Vt.), to support the re-election of John Quincy Adams to the Presidency of the United States. This paper also died within a year. In Boston he had met Benjamin Lundy (*q.v.*), who had for years been preaching the abolition of slavery. Garrison had been deeply moved by Lundy's appeals, and after going to Vermont he showed the deepest interest in the slavery question. Lundy was then publishing in Baltimore a small monthly paper, *The Genius of Universal Emancipation,* and he went to Bennington and invited Garrison to join him in the editorship. His mission was successful.

Garrison first accepted Lundy's views of gradual emancipation, but soon changed to total and immediate freedom for slaves when he joined Lundy in Baltimore in 1829. Lundy believed that the negroes, on being emancipated, must be colonized somewhere beyond the limits of the United States; Garrison held that they should be emancipated on the soil of the country, with all the rights of freemen. Garrison saw that it would be idle to expose and denounce the evils of slavery, while responsibility for the system was placed upon former generations, and the duty of abolishing it transferred to an indefinite future. His demand for immediate emancipation fell like a tocsin upon the ears of slaveholders. The *Genius,* when it became a vehicle for this dangerous doctrine. was feared and hated. Baltimore was then one of the centres of the domestic slave trade, and upon this traffic Garrison heaped the strongest denunciations. He was prosecuted for libel by the owner of a slave-carrying vessel, was fined $50, and, in default of payment, committed to gaol.

John G. Whittier interceded with Henry Clay to pay Garrison's fine and thus release him from prison. Clay responded favourably, but before he could act Arthur Tappan, a philanthropic merchant of New York, contributed the necessary sum and set the prisoner free after an incarceration of seven weeks. The partnership between Garrison and Lundy was then dissolved by mutual consent, and Garrison resolved to establish a paper of his own, in which he could advocate the doctrine of immediate emancipation and oppose the scheme of African colonization. He first proposed to establish his paper at Washington, in the midst of slavery, but on returning to New England and observing the state of public opinion there, he came to the conclusion that little could be done in the South while the non-slaveholding North was lending her influence for the sustenance of slavery. He determined, therefore, to publish his paper in Boston, and set himself to the task of awakening an interest in the subject by lectures in some of the principal cities and towns of the North. In Boston, then a great cotton mart, he tried in vain to procure a church or vestry for the delivery of his lectures, until a body of infidels under the leadership of Abner Kneeland (1774–1844), proffered him the use of their small hall. He accepted it gratefully, and delivered (in Oct. 1830) three lectures, in which he unfolded his principles and plans.

On Jan. 1, 1831, without capital and without a subscriber, he and his partner, Isaac Knapp (1804–43), issued the first number of the *Liberator,* avowing their "determination to print it as long as they could subsist on bread and water, or their hands obtain employment." Its motto "Our country is the world—our countrymen are mankind," shows his changed viewpoint. The paper in addition to favouring abolition, attacked war, alcoholic liquors and tobacco, and assailed freemasonry, capital punishment, and imprisonment for debt. The editor, in his address to the public, uttered the words which have become memorable as embodying the whole purpose and spirit of his life: "I am in earnest—I will not equivocate—I will not excuse—I will not retreat a single inch—and I will be heard." For many months Garrison and his partner made their bed on the floor of the room in which they printed their paper, and where Mayor Harrison Gray Otis of Boston, in compliance with the request of Governor Robert Y. Hayne of South Carolina, "ferreted them out." Otis decided, however, that the paper could not be suspended. In the same year (1831), $5,000 reward was offered for Garrison's arrest and conviction under the laws of Georgia. The *Liberator,* though in constant financial difficulties, exerted a mighty influence, and lived to record not only President Lincoln's proclamation of emancipation, but the adoption of an amendment to the Constitution of the United States for ever prohibiting slavery.

Garrison was a pacifist, and sought the abolition of slavery by moral means alone. He knew that the National Government had no power over the system in any State, though he thought it should bring its moral influence to bear in favour of abolition. His idea was to combine the moral influence of the North, and pour it through every open channel upon the South. To this end he made his appeal to the Northern churches and pulpits, beseeching them to bring the power of Christianity to bear against the slave system, and to advocate the rights of the slaves to immediate and unconditional freedom. When they did not respond, he denounced them, and by 1840 had become very unorthodox. The first society organized under Garrison's auspices, and in accordance with his

principles, was the New England anti-slavery society in Jan. 1832. The same spring Garrison issued his *Thoughts on African Colonization,* in which he showed from official documents that the American colonization society was organized in the interest of slavery, and that in offering itself as a practical remedy for that system it was guilty of deception. Garrison was deputed by the New England anti-slavery society to visit England for the purpose of counteracting the influence there of agents of the colonization society. He went in the spring of 1833, and was received with great cordiality by British abolitionists. He took home with him a "protest" against the American colonization society signed by Wilberforce, Zachary Macaulay, Samuel Gurney, William Evans, S. Lushington, T. Fowell Buxton, James Cropper, Daniel O'Connell and others.

Garrison's visit to England enraged the pro-slavery people, and when he returned in September with the "protest" against the colonization society, and announced that he had engaged the services of George Thompson as a lecturer against American slavery, there were fresh outbursts. The American anti-slavery society was organized in December of that year (1833), the declaration of its principles coming from Garrison's pen. The activities of this society and Thompson's lectures aroused such fury that, in the autumn of 1835, Thompson was compelled to return secretly to England. He had announced that he would address the women's anti-slavery society in Boston, and a mob gathered. Not finding him, it seized Garrison and dragged him through the streets until he was rescued, and protected in the gaol until he could leave the city in safety.

The abolitionists of the United States were a united body until 1839–40 when division occurred. Garrison countenanced the activity of women in the cause, even appointing them as lecturing agents; moreover, he believed in the political equality of the sexes, to which a strong party was opposed upon social and religious grounds. His attack on the churches caused dissent. Many believed that Garrison injured abolitionism by causing it to be associated in men's minds with these unpopular views on other subjects. These differences led to the organization of a new national anti-slavery society in 1840, and to the formation of the "Liberty Party" (*q.v.*) in politics *(see* BIRNEY, JAMES G.). The two societies sent their delegates to the world's anti-slavery convention in London in 1840, and Garrison refused to take his seat in that body, because the women delegates from the United States were excluded. The discussions of the next few years served to make clearer than before that the Constitution of the United States supported slavery; and Garrison came to the conclusion that its pro-slavery clauses were immoral, and that it was therefore wrong to take an oath for its support. Because of this, Garrison burned the Constitution, denouncing it as "a covenant with death and an agreement with hell." He chose as his motto, "No union with slaveholders," and thereafter worked for peaceful disunion. When in 1861 the Southern States seceded from the Union and took up arms against it, he saw clearly that slavery would perish in the struggle and that the Constitution would be purged of its pro-slavery clauses. He therefore ceased to advocate disunion, and devoted himself to hastening the inevitable event. His services at this period were recognized and honoured by President Lincoln and others in authority, and the whole country knew that the agitation which resulted in the abolition of slavery was largely due to his uncompromising spirit and indomitable courage.

In 1865 at the close of the war, he declared that, slavery being abolished, his career as an abolitionist was ended. He counselled a dissolution of the American anti-slavery society, insisting that it had become *functus officiis,* and that whatever needed to be done for the protection of the freedmen could best be accomplished by new associations formed for that purpose. The *Liberator* was discontinued at the end of the same year, after an existence of 35 years. He visited England for the second time in 1846, and again in 1867, when he was received with distinguished honours, public as well as private. In 1869 he became president of the Free Trade League, advocating the abolition of custom houses throughout the world. In 1877, he again visited England, and declined every form of public recognition. He died in New York on May 24, 1879, in the 74th year of his age, and was buried in Boston, after a most impressive funeral service, four days later. In 1843 a small volume of his *Sonnets and other Poems* was published, and in 1852 appeared a volume of *Selections from his Writings and Speeches.*

Garrison's son, WILLIAM LLOYD GARRISON (1838–1909), was a prominent advocate of the single tax, free trade, woman's suffrage, and of the repeal of the Chinese Exclusion Act, and an opponent of imperialism. Another son, WENDELL PHILLIPS GARRISON (1840–1907), was literary editor of the New York *Nation* from 1865 to 1906.

BIBLIOGRAPHY.—The great authority on the life of Garrison is the thorough and candid work of his sons, W. P. and F. J. Garrison, *William Lloyd Garrison, 1805–1879; The Story of his Life told by his Children (4* vols., 1885–89). See *Garrison: an Outline of his Life* (1879), and *William Lloyd Garrison and his Tinzes (1880)* by Oliver Johnson, a prominent abolitionist and intimate friend of Garrison. Goldmin Smith's *The Moral Crusader; a Biographical Essay on William Lloyd Garrison (1892)* is a brilliant sketch. J. J. Chapman's *Garrison* (1913) is valuable for its picture of the abolition movement; Lindsay Swift, *William Lloyd Garrison* (1911), is a reliable biography though it is too eulogistic; Edward Channing, *A History of the United States* (vol. v. and vi., 1905–25), and Ellis Paxson Oberholtzer, *A History of the United States since the Civil War* (1917–26) give the relation of Garrison to the history of his time.

GARROTTE, an appliance used in Spain and Portugal for the execution of criminals *(see* CAPITAL PUNISHMENT). "Garrotting" is the name given in England to a form of robbery with violence which became rather common in the winter of 1862–63. An act of 1863, imposing the penalty of flogging in addition to penal servitude for this offence, had the effect of stopping it almost entirely.

GARSHIN, VSEVOLOD MIMHAILOVICH (1855–1888), Russian author, was born in the government of Ekaterinoslav in Feb. 1855, the son of a retired army officer. From his childhood he had a nervous temperament, and in 1872 he was put under restraint for a year. In 1874 he entered the High School of Mines at St. Petersburg (now Leningrad), but on the outbreak of the Russo-Turkish War (1877) he enlisted as a private in an infantry regiment. Wounded in Aug. 1878 he was invalided home; from that time he suffered from frequent attacks of melancholia, and in 1887 he tried to commit suicide by throwing himself down some stone steps, broke his leg, and died in a hospital on March 24, 1888. Many of his best known stories, *The Signal* (1912); *The Coward, Mad Love,* or *An Artist's Dream* (1889); *The Red Flower* (1883); *Attalea Princeps* and *That which was Not* have been translated into English. His *Four Days,* written while he was lying wounded at Kharkov, created a great sensation.

GARSTANG, JOHN (1876–), British archaeologist, born in Blackburn, was educated at Blackburn Grammar School and Jesus College, Oxford. From 1897 onward he directed excavations on various Roman sites in Britain (Ribchester, Richborough, etc.), in Egypt, and in Nubia. In 1902 he became honorary reader in Egyptian archaeology, at Liverpool University, and in 1907 professor of the methods and practice of archaeology. In the same year he led an expedition to Asia Minor and North Syria. He also conducted excavations on the Hittite site of Sakje-Genzi (1908 and 1911), ancient Meroë (Sudan) (1909–14), and Askalon, (1920–21). During the World War (1915–19) he served voluntarily as liaison officer for the medical services. From 1919–26 he held the post of director of the British School of Archaeology in Jerusalem, and from 1920–26 that of director of the department of antiquities of the Government of Palestine.

He has published many books on the results of his researches, including *The Third Egyptian Dynasty* (1911); *Roman Ribchester* (1911); *A Short History of Ancient Egypt* (with Prof. Newberry, 1911); *The Land of the Hittites* (1911); *Notes to an Index of Hittite Geographzrul Names* (1923); *The Hittite Empire* (1929).

GARSTIN, SIR WILLIAM EDMUND (1849–1925), British engineer, was born in India on Jan. 29, 1849. He was educated at Cheltenham and King's college, London, and in 1872 entered the Indian Public Works department. In 1885 he was transferred to Egypt, and in 1892 became inspector-general of

irrigation and under-secretary of State for Public Works. He proved himself an indefatigable worker, and by his efforts extensive areas were reclaimed in Egypt and the Sudan. Among his greatest works were the Asyut barrage and the Aswan reservoir. In addition, it was due to him that the White Nile was cleared of sudd, thus rendering possible free navigation between Khartoum and Gondokoro. He was created K.C.M.G. in 1897 and G.C.M.G. in 1902. In 1907 he was appointed British Government director of the Suez Canal company. During the World War he devoted himself to Red Cross work in England, being created G.B.E. in 1918. He died in London on Jan. 8, 1925.

GARSTON, seaport, Wavertree parliamentary division, Liverpool borough, Lancashire, England, on the Mersey, 6 m. S.E. of Liverpool. Pop. (1931) 17,262. The docks of the L.M.S. railway company, with over a mile of quayage are specially equipped for shipping coal.

GARTH, SIR **SAMUEL** (1661–1719), English physician and poet, entered Peterhouse, Cambridge, in 1676, graduating B.A. in 1679, and M.A. in 1684. He took his M.D. and became a member of the College of Physicians in 1691. In 1697 he delivered the Harveian oration, in which he advocated a scheme for providing dispensaries for the relief of the sick poor as a protection against the greed of the apothecaries. In 1699 he published a mock-heroic poem, *The* Dispensary, in six cantos, ridiculing the apothecaries and their allies among the physicians.

GARTOK, a trade-market of Tibet, situated on the bank of the Indus on the road between Shigatse and Leh, to the east of Simla. In accordance with the Tibet treaty of 1904, Gartok, together with Yatung and Gyantse, was thrown open to British trade. In winter it consists of only a few dozen people whose houses stand in the midst of a bare plain. In summer, however, all the trade between Tibet and Ladakh passes through this place.

GARUT, a district in the residency of Priangan, in Java, Netherlands Indies, the seat of an assistant resident, and a native regent. It is Sundanese territory, has a population of 670,870, and is the centre of a well-cultivated region, noted for its tea, rubber and chinchona plantations, but is better known as one of the most beautiful health resorts of Java. Situated at a height of 2,300 ft. above sea-level, the town (pop. 24,219) is very charmingly laid out. The district forms a plateau, around which are grouped magnificent mountains, some volcanoes, with mountain lakes, hot springs and other wonders of nature. Among the most interesting excursions are the crater of the Papandayan, a volcano still active, which blew out the greater part of one side of a mountain in 1772, killing thousands of people and destroying much of the surrounding countryside; the Kawah Kamodyan, a most interesting collection of pools of boiling mud, geysers and fumaroles; the Telega Bodas, or White lake, situated amidst charming forest scenery; the Kawah Manut, or Bird's Crater; the lakes of Bagendit and Leles, and the hot springs of Chipanas; the lake of Pendjalu; and Mount Chikorai. The district was occupied by the Japanese in March 1942. (E. E. L.; X.)

GARVIE, ALFRED ERNEST (1861–) English divine, was born on Aug. 29, 1861 at Zyrardów, Russian Poland; he was educated privately in Poland and at George Watson's College, Edinburgh. He studied for a year at Edinburgh University (1878–79), and after four years in business in Glasgow, spent eight years in study at Glasgow and at Oxford. He was appointed in 1903 a professor at Hackney and New Colleges, London, becoming in 1907 principal of New College. In 1922 he was appointed principal of Hackney College, and from 1924 onward held both posts until his retirement in 1933.

His numerous publications include: *The Ritschlian Theology* (1899); *Handbook* of *Christian Apologetics* (1913); *The Christian Doctrine of the Godhead* (1925); and *The Preachers of the Church* (1926).

GARY, ELBERT HENRY (1846–1927), American jurist and business man, was born on Oct. 8, 1846, and brought up on his father's farm, near Wheaton, Ill. He attended public school and Wheaton college, and studied law in the office of his uncle, Col. Vallette. He graduated in 1867 from the Union College of Law, which became the law department of the University of Chicago, and later of Northwestern university, Chicago. In 1869 he began his law practice in Chicago. In 1874 he organized the Gary-Rheaton bank, of which he was president. He was elected judge of Du Page county in 1882 and again in 1886. During this period he also frequently held court in Chicago, Cook county, and occasionally presided over important cases in other counties throughout the State of Illinois. He was three times elected president of the town of Wheaton, and on its becoming a city in 1890 served as mayor for two terms.

Until 1898 he practised law in Chicago and became a leader and authority in corporation law and insurance matters. He was president of the Chicago Bar Association in 1893–94. In time he became general counsel and a director in a number of large railroads, banks and industrial corporations, including steel and wire companies. He early saw the advantages of combination in business. In 1891 he was one of the organizers of the Consolidated Steel and Wire Company. In 1898, upon the organization of the Federal Steel Company, with the financial backing of J. P. Morgan and Company, he became its first president and retired from legal practice. This company was merged in 1901 in the U.S. Steel Corporation, which was then organized with a capital stock exceeding $1,000,000,000, then by far the largest industrial corporation in the world. He was elected chairman of the executive committee and later chairman of the board of directors and of the finance committee, and continued to be chief executive officer during 26 years of remarkable development of the steel industry and growth of the corporation.

The steel mills and town of Gary, Ind., were laid out in 1906 by the U.S. Steel Corporation, and later named in his honour. The site was then a waste of sand dunes. Twenty years later Gary had grown, following the plans and large investments of the Steel Corporation, under Judge Gary's direction, to be a beautiful city of 100,000 people, with a splendid school system and with enormous and varied mills for the manufacture of iron and steel products. Equally important and beneficent developments were similarly carried out under E. H. Gary's leadership in other parts of the country, including those at Birmingham, Ala., Pittsburgh, Pa., and Duluth, Minn. As chairman of the Steel Corporation, he advocated and established many pioneer measures for the welfare of the employees of industrial corporations, including stock ownership by them and participation in profits, high wages and safe, sanitary and pleasing surroundings. He was always a strong advocate and a firm upholder of the "open shop." During his chairmanship the seven-day week and the 12 hour day for labour in the steel mills were abolished. (J. A. FA.)

GARY, a city of Lake county, Ind., U.S.A., at the southern end of Lake Michigan, 25 mi. S.E. of Chicago. It is on federal highways 12 and 20 and is served by the Baltimore and Ohio, the Michigan Central, the New York Central, the Pennsylvania, the Nickel Plate, the South Shore (electric) and the Wabash railways, two industrial belt railroads and by lake steamers. The population in 1920 was 55,378, of whom 5,299 were Negroes and 16,460 were foreign-born white; and was 111,719 in 1940 by federal census.

Gary is a creation of the United States Steel corporation, which in 1905 bought a tract of 8,000 ac. there. The site consisted of barren sand dunes and swampy meadows, crossed by the Grand Calumet and the Little Calumet rivers. In 1941 the city had an assessed valuation of $135,000,000; 210 mi. of improved streets, 1j mi. of boulevards, 155 mi. of water mains, 31 mi. of streetcar track and a fleet of motor buses, 100 mi. of sewers, 4 mi. of bathing beach, and 696 ac. of public parks, golf courses and playgrounds. A city-planning commission was appointed in 1919, and the city plan (adopted in 1924 and revised in 1933) includes a comprehensive zoning system, and the "Gary Gateway," providing for a civic centre.

A modern sewage treatment plant and intercepting sewers were completed in 1940 at a cost of $4,818,000.

The industries (chiefly subsidiaries of the United States Steel corporation) represent an investment of several hundred million dollars, and include the largest steel works, tin-plate mills, rail mill and cement works in the world.

The schools of Gary provide academic instruction 48 weeks in the year; physical training 52 weeks, on six and a half days each

week. William A. Wirt (1874–1938), the first superintendent of schools, taking advantage of his unique opportunity for experimentation, worked out a system known among educators as the "work-study-play plan" or "platoon plan," and it has been adopted, with more or less modification, in many cities.

Gary was chartered in 1906, and was named after Elbert H. Gary (1846–1927), chairman of the board of directors of the Steel corporation. At the first federal census (1910) after the founding of the city, the population was 16,802, and in the following decade it increased more than threefold. The original area had grown to 41·37 sq.mi. by 1941. At the beginning of the nation-wide strike of steel workers in 1919 (Sept. 22) the walk-out in Gary was almost complete. The city was occupied on Oct. 7 by federal troops, who were not withdrawn until the strike was called off, on Jan. 7, 1920.

For an account of the public school system, *see* F. P. Bachman and R. Bowman, ***The*** Gary *Public Schools* (1918).

GAS, a general term for one of the three states of aggregation of matter; also more specifically applied to coal-gas, the gaseous product formed in the destructive distillation of coal or other carbonaceous matter (*see* below, section *Gas Manufacture;* for gas engines *see* INTERNAL COMBUSTION ENGINES).

The Gaseous State.—Matter is studied under three physical phases—solids, liquids and gases, the latter two being sometimes grouped as "fluids." The gaseous fluid with which we have chiefly to do is our atmosphere. Though practically invisible, it appeals in its properties to other of our senses; thus we feel it in its motion as wind, and observe the dynamical effects of this motion in the quiver of the leaf or the motion of a sailing ship.

The practically obvious distinction between solids and fluids may be stated in dynamical language thus: Solids can sustain a longitudinal pressure without being supported by a lateral pressure; fluids cannot. Hence any region of space enclosed by a rigid boundary can be easily filled with a fluid, which then takes the form of the bounding surface at every point of it. But here we distinguish between fluids according as they are gases or liquids. The gas will always completely fill the region, however small the quantity put in. Remove any portion and the remainder will expand so as to fill the whole space again. On the other hand, it requires a definite quantity of liquid to fill the region. To quote Sir Oliver Lodge: "A solid has volume and shape; a liquid has volume, but no shape; a gas has neither volume nor shape."

It is necessary to distinguish further between a gas and a "vapour." The latter possesses the physical property stated above which distinguishes a gas from a fluid, but it differs from a gas by being readily condensible to liquid, either by lowering the temperature or moderately increasing the pressure. The study of the effects of pressure and temperature on many gases led to the introduction of the term "permanent gases," to denote gases which were apparently not liquefiable; but with improved methods these gases have been liquefied and even solidified, thus rendering the term meaningless. (*See* LIQUEFACTION OF GASES.) "Perfect gas" is applied to an imaginary substance in which there is no frictional retardation of molecular motion, *i.e.,* one which obeys Boyle's law. (*See* PHYSICS.)

The study of gases may be divided into two main branches: the physical and the chemical. The former investigates essentially general properties, such as the weight and density, the relation between pressure, volume and temperature (piezometric and thermometric properties), calorimetric properties, diffusion, viscosity, electrical and thermal conductivity, etc., and generally properties independent of composition. These subjects are discussed in the articles DENSITY; THERMOMETRY; .CALORIMETRY; DIFFUSION; HEAT, *Conduction of;* and CONDENSATION OF GASES. The latter has for its province the preparation, collection and identification of gases, and the volume relations in which they combine; in general it deals with specific properties. The historical development of the chemistry of gases—pneumatic chemistry—is treated in the article CHEMISTRY; the technical analysis of gaseous mixtures is treated under CHEMISTRY, *Gas Analysis.* Connecting the experimental study of the physical and chemical properties is the immense theoretical edifice termed the kinetic theory of gases. This subject, which is discussed in the article MOLECULE, has for its purpose, (1) the derivation of a physical structure of a gas which will agree with the experimental observations of the diverse physical properties, and (2) a correlation of the physical properties and chemical composition.

GAS COAL: *see* COAL AND COAL MINING.

GASCOIGNE, GEORGE (*c.* 1535–1577), English poet, eldest son of Sir John Gascoigne of Cardington, Beds, was born probably between 1530 and 1535. He was educated at Trinity college, Cambridge, and became a member of Gray's Inn in 1555. His escapades were notorious; he was imprisoned for debt, and was obliged to sell his patrimony to pay the debts contracted at court. He was M.P. for Bedford in 1557–58 and 1558–59, but when he presented himself in 1572 for election at Midhurst he was refused on account of his bad reputation. He married the wealthy widow of William Breton, thus becoming step-father to the poet, Nicholas Breton. Fighting in the Low Countries in 1572 he was driven by stress of weather to Brill, which had just fallen into the hands of the Dutch. He obtained a captain's commission, and fought in the campaigns of the next two years. Taken prisoner after the evacuation of Valkenburg by the English troops, he was sent to England in the autumn of 1574. He dedicated to Lord Grey of Wilton the story of his adventures, *The Fruites of Warres* (printed in the edition of 1575) and *Gascoigne's Voyage into Hollande.* In 1575 he had a share in devising the entertainments provided for Queen Elizabeth at Kenilworth and Woodstock. Most of his works were actually published during the last years of his life, after his return from the wars. He died at Bernack, near Stamford, where he was the guest of George Whetstone, on Oct. 7, 1577.

Gascoigne acknowledged Chaucer as his master, and differed from the earlier poets of the school of Surrey and Wyatt chiefly in the added smoothness and sweetness of his verse. His poems were published in 1572 during his absence in Holland with the title *A hundreth Sundrie Floures bound up in one small Posie . . .* followed in 1575 by an authorized edition, *The Posies of G. G. Esquire . . .* (not dated). This edition contains as preface a treatise on prosody, apparently the earliest in English, "Certayne Notes of Instruction concerning the making of verse or ryme in English."

Gascoigne was a pioneer in many directions. In 1576 he published *The Steele Glas,* sometimes called the earliest regular English satire. Although this poem is Elizabethan in form and manner, it is written in the spirit of *Piers Plowman.* Gascoigne begins with a comparison between the sister arts of Satire and Poetry, and under a comparison between the old-fashioned "glas of trustie steele," and the new-fangled crystal mirrors which he takes as a symbol of the "Italianate" corruption of the time, he attacks the amusements of the governing classes, the evils of absentee landlordism, the corruption of the clergy, and pleads for the restoration of the feudal ideal.

> Againe I see, within my glasse of Steele
> But foure estates, to serve each country soyle,
> The King, the Knight, the Pesant, and the Priest.
> The King should care for al the subjects still,
> The Knight should fight, for to defend the same,
> The Pesant, he shoulde labor for their ease,
> And Priests shuld pray, for them and for themselves.—
> (Arber's ed. p. 57.)

His dramatic work belongs to the period of his residence at Gray's Inn, both *Jocasta* (of which Acts i. and iv. were contributed by Francis Kinwelmersh) and *Supposes* being played there in 1566. *Jocasta* is a literal version of Lodovico Dolce's *Giocasta,* which was derived probably from the *Phoenissae* in the Latin translation of R. Winter. *Supposes,* a version of Ariosto's **I.** *Suppositi,* is an early and excellent adaptation of Italian comedy, and "the earliest play in English prose acted in public or private." Udal's *Ralph Roister Doister* had been inspired directly by Latin comedy; *Gammer Gurton's Needle* was a purely native product; but *Supposes* is the first example of the acclimatization of the Italian models that were to exercise so prolonged an influence on the English stage. A third play of Gascoigne's, *The Glasse of Government* (published in 1575), is a school drama of the "Prodi-

gal Son" type, familiar on the Continent at the time, but rare in England.

Gascoigne's works not already mentioned include: "G.G. in commendation of the noble Arte of Venerie," prefixed to *The Noble Art of Venerie or Hunting* (1575); *The Complaynte of Phylomene*, bound up with *The Steele Glas* (1576); *The Droomme of Doomes-day* (1576), a prose compilation from various authors, especially from the *De contemptu mundi* of Pope Innocent III., printed with varying titles, earliest ed. (1470?); *A Delicate Diet for daintie mouthde Droonkardes* . . . (1576), a free version of St. Augustine's *De ebrietate*. *The Posies* (1572) included *Supposes, Jocasta, A Discourse of the Adventures of Master F[erdinando] J[eronimi]*, in imitation of an Italian novella, a partly autobiographical *Don Bartholomew of Bath*, and miscellaneous poems. *The Whole Workes of G.G.* . . . appeared in 1587. In 1868–70 *The Complete Poems of G.G.* . . . were edited for the Roxburghe Library by W. C. Hazlitt. In his *English Reprints* Prof. E. Arber included *Certayne Notes of Instruction, The Steele Glas* and the *Complaynt of Philomene*. *The Steele Glas* was also edited for the *Library of English Literature*, by Henry Morley, vol. i. p. 184 (1889). A new edition, *The Works of George Gascoigne* (The Cambridge English Classics, 1907, etc.) is edited by Dr. J. W. Cunliffe. *See* also F. E. Schelling, *The Life and Writings of George Gascoigne* (Publications of the Univ. of Pennsylvania series in Philology, vol. ii. No. 4, 1894); C. H. Herford, *Studies in the Literary Relations of England and Germany in the Sixteenth Century*, pp. 149–164 (1886), and "Gascoigne's Glasse of Government," in *Englische Studien*, vol. ix. (Halle, 1877, etc.).

GASCOIGNE, SIR WILLIAM (c. 1350–1419), chief justice of England in the reign of Henry IV. Gascoigne practised as an advocate in the reigns of Edward III. and Richard II. On the banishment of Henry of Lancaster Gascoigne was appointed one of his attorneys, and soon after Henry's accession to the throne was made chief justice of the court of king's bench. After the suppression of the rising in the north in 1405, Henry eagerly pressed the chief justice to pronounce sentence upon Scrope, the archbishop of York, and the earl marshal Thomas Mowbray, who had been implicated in the revolt. This he absolutely refused to do, asserting the right of the prisoners to be tried by their peers. Although both were afterwards executed, the chief justice had no part in the transaction. The oft-told tale of his committing the prince of Wales to prison is unauthentic, though it is characteristic of Gascoigne's independence. Gascoigne appears to have been removed from his post or resigned soon after the accession of Henry V. He died in 1419, and was buried in the parish church of Harewood in Yorkshire.

GASCONY (WASCONIA), an old province in the south-west of France. It takes its name from the Vascones, a Spanish tribe, which in 580 and 587 crossed the Pyrenees and invaded the discrict known to the Romans as Novempopulana or Aquitania tertia. Basque, the national language of the Vascones, took root only in a few of the high valleys of the Pyrenees, such as Soule and Labourd; in the plains Latin dialects prevailed, Gascon being a Romance language. In the 7th century the name of Vasconia was substituted for that of Novempopulana. The Vascones readily recognized the sovereignty of the Merovingian kings, but in reality they remained independent. They even appointed national dukes, against whom Charlemagne had to fight at the beginning of his reign. Finally Duke Lupus II. made his submission in 819, and the Carolingians were able to establish Frankish dukes in the country. After the death of Duke Arnaud in 864 the history of Gascony falls into the profoundest obscurity. In the feudal period Gascony comprised a great number of countships (including Armagnac, Bigorre, Fézensac, Gaure and Pardiac), viscountships (including Béarn, Lomagne, Dax, Juliac, Soule, Marsan, Tartas, Labourd and Maremne) and seigneuries (*e.g.*, Albret, etc.).

During the Hundred Years War Gascony was a battle-field for the forces of England and of France. The French seized the duchy, but, aided by the rivalry between the powerful houses of Foix and Armagnac, Edward III. was able to recover it, and by the treaty of Bretigny in 1360 John II. recognized the absolute sovereignty of England therein. Handed over as a principality by Edward to his son, the Black Prince, it was used by its new ruler as a base during his expedition into Spain, in which he received substantial help from the Gascon nobles. The renewal of the war between England and France, which took place in 1369, was due in part to a dispute over the sovereignty of Gascony, and during its course the whole of the duchy save a few towns and fortresses was lost; but the victories of Henry V. in northern France postponed for a time the total expulsion of the foreigner. This was reserved for the final stage of the war and was one result of the efforts of Joan of Arc, the year 1451 witnessing the capture of Bayonne and the final retreat of the English troops from the duchy.

The French kings, especially Louis XI., managed to restore the royal authority in the duchy, although this was not really accomplished until the close of the 15th century when the house of Armagnac was overthrown. It was by means of administrative measures that these kings attained their object. Gascony was governed on the same lines as other parts of France and from the time of Henry IV., who was prince of Béarn, and who united his hereditary lands with the crown, its history differs very slightly from that of the rest of the country. The Renaissance inspired the foundation of educational institutions and the Reformation was largely accepted in Béarn, but not in other parts of Gascony. The wars of religion swept over the land, which was the scene of some of the military exploits of Henry IV., and Louis XIV. made some slight changes in its government. As may be surmised the boundaries of Gascony varied from time to time, but just before the outbreak of the Revolution they were the Atlantic Ocean, Guienne, Languedoc and the Pyrenees, and from east to west the duchy at its greatest extent measured 170 miles.

At the end of the ancien *régime* Gascony was united with Guienne to form a great military government. After the division of France into departments, Gascony, together with Béarn, French Navarre and the Basque country, formed the departments of Basses-Pyrénées, Landes, Hautes-Pyrénées and Gers. Parts of Gascony also now form arrondissements and cantons of the departments of Lot-et-Garonne, Haute-Garonne, Aribge and Tarn-et-Garonne.

GASHOLDERS. As the manufacture of gas must be maintained at an approximately even rate throughout the 24 hours, while the rate of consumption varies considerably at the different hours of the day, it is necessary to provide storage for the gas produced during the periods of minimum demand, and also to provide against any temporary breakdown in the manufacturing plant. In the early days of the gas industry the vessel in which the gas was stored was known as a "gasometer," as this vessel had to serve the dual purpose of storing and measuring the amount of gas made. With the advent of the station meter in the year 1820 for measuring the volume of gas, the name of "gasholder" was adopted, but even now in Great Britain journalists and others invariably use the technically obsolete word "gasometer."

The capacity of the gasholder should be equal to at least 75% of the maximum daily output. There are now four distinctive types of gasholders: (1) frame guided, (2) spirally guided, (3) dry or tankless, (4) spherical. The frame guided and spirally guided holders may have one or more lifts, the one lift type being known as a single lift holder, and the other as a telescopic gasholder, the latter type being generally adopted for economic reasons. The movable vessel in which the gas is stored is known as the floating gasholder. The steel structure which guides the floating holder as it ascends or descends is termed the guide framing, and is erected round the circumference of the steel or brick tank which contains the water for sealing the sides of the floating gasholder, thus preventing the escape of gas. Gas is admitted into the holder by means of an inlet pipe which passes through the bottom of the tank, and extends to a height of about 6 in. above the water level; another similar pipe is provided as an outlet for the gas to the district mains; both pipes being con-

trolled by slide valves.

The telescopic form of holder (fig. 1) consists of two or more lifts, which work or slide inside one another, much in the same way as an ordinary telescope. The inner or first lift is constructed to a certain diameter, according to the capacity required, and the diameter of each succeeding lift is increased by about 2 ft., whilst the depth of each lift would be constant, and equal to about one-fifth the diameter. In order to secure a gas-tight joint between

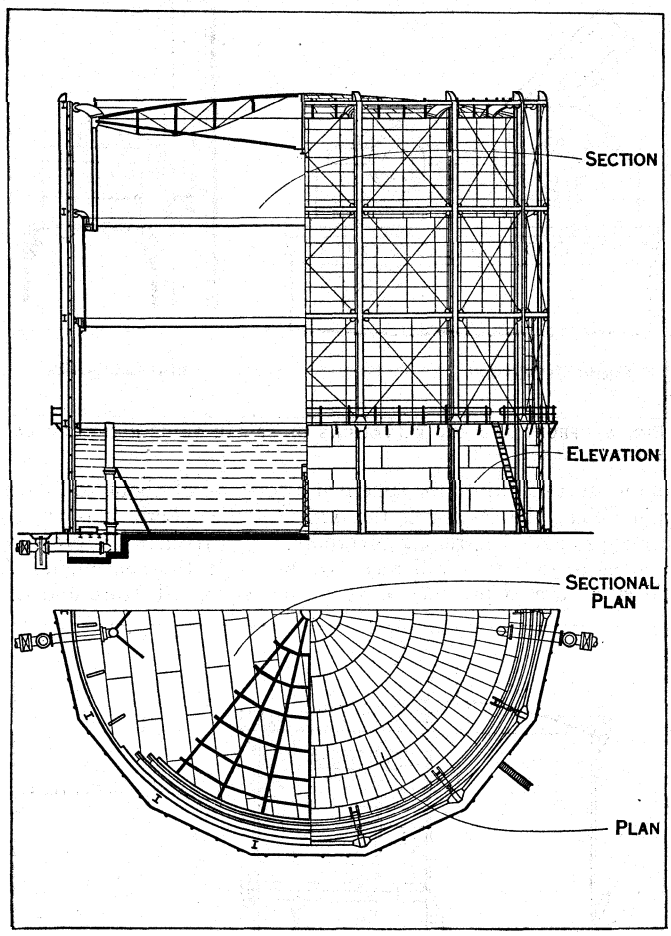

FIG. 1.— ELEVATION AND SECTIONAL PLAN OF TELESCOPIC GASHOLDERS
This type consists of two or more lifts working into each other on the telescopic principle. The diameters of the lifts decrease by 2 ft., the depths remaining constant

the lifts as they leave the tank, the bottom row of sheeting of the inner lift is prepared with a channel cup about 18 in. deep, whilst the top row of sheeting of the adjcining lift is fitted with an inverted channel cup, usually termed the "dip" (fig. 2). As the inner lift rises out of the water in the tank, the channel cup engages with the dip, thus making a gas-tight water-sealed joint between the lifts. Each succeeding lift is fitted with a dip at the top, and a cup at the bottom. with the exception of the final or outer lift, which is provided with a dip at the top only, and a strong angle steel curb at the bottom. The crown of the holder is dome-shaped, and when at rest in the tank, is either supported by a trussed steel roof forming part of the inner lift, or upon a permanent steel or timber framing erected in the tank. The sheeting of the sides and crown of the holder is about $\frac{1}{8}$ in. thick, with the exception of the rows of sheets adjoining the cup and dip, and also the junction between the crown and sides of the inner lift, which are much thicker, in order to allow for extra wear and strain at these points. The tank may be constructed in brick, concrete or steel. Brick and concrete tanks are usually constructed by excavating the ground and building up the sides of the tank, so that the top of same finishes about 6 in. above the ordinary ground level. Water-tightness is obtained by encasing the bottom and side walls of the tank in a layer of clay puddle, or by coating the inside surface of the tank walls with cement. Steel tanks are usually erected on a flat bed of concrete, laid at a foot or so below the normal ground level, the sides being formed of a number of tiers of steel plates varying in thickness to suit the pressure due to the depth of water in the tank. Steel tanks are much less costly than either brick or concrete tanks, and can be much more quickly erected.

Frame Guided **Gasholders.**—These consist of a series of columns or standards fixed at equal distances round the circumference of the tank, which are connected together by one or more tiers of horizontal girders or struts, and a series of diagonal bracing rods, thus forming a continuous tie all round. The guide framing may be carried up to the full height of the holder when fully inflated, or to the top of the second lift only, thus allowing the inner lift to run clear of the guide framing, which is then known as a "flying lift." Channel guide runs are fixed to the inner face of the standards, to form a pathway for the guide rollers—which are attached to the crown and the dip of each lift—to work up and down for the purpose of guiding the gasholder and enabling it to withstand the overturning force of the wind. The underside of each cup is fitted with a corresponding number of radial rollers. which run in channel guides fixed to the inside of the next adjoining lift; the bottom curb of the outer lift is also fitted with similar rollers working in channel guides fixed to the sides of the tank.

Spirally Guided **Gasholders.**—The floating lifts of a spirally guided gasholder (fig. 3) are practically the same in construction

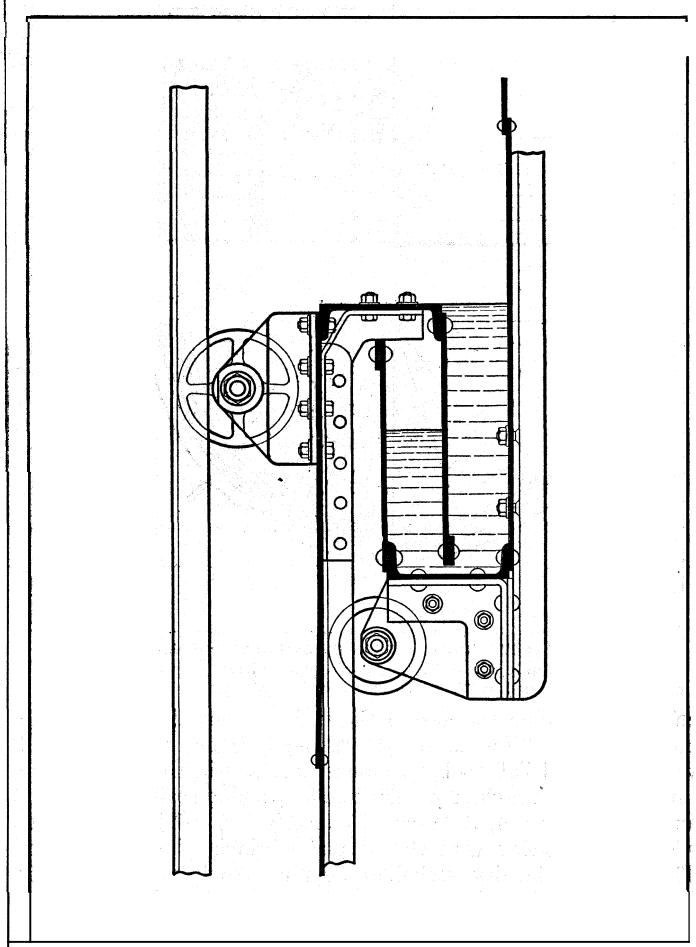

FIG. 2.— CROSS-SECTION OF THE "CUP AND DIP." WHICH MAKES THE CONNECTION BETWEEN THE TWO LIFTS AND FORMS THE HYDRAULIC SEAL

as the frame guided holder, with the exception that a number of double flanged rails, inclined at an angle of 45° are secured to the side sheeting of each lift at equal distances round the circumference. The spiral guides run between a corresponding number of sets of rollers (fig. 4) mounted in adjustable carriages, secured to the dips of the holder and top curb of the tank. The action of

the holder in rising or falling is comparable with the action of a coarse threaded screw, and the spiral motion thereby imparted to the floating vessel is sufficient to maintain the holder in a level condition, and enables it to resist the overturning force produced by the wind. This form of holder costs from 10 to 15% less than the frame guided holder.

Dry **Gasholders.**—In this type of holder (fig. 5) the tank with its water content is dispensed with, thereby greatly reducing the cost of foundations. The tankless gasholder consists of a cylindrical steel plate tower, within which a horizontal disc or piston moves up or down, receiving or expelling the gas. The piston is guided in its vertical movement by a system of rollers, travelling up or down the inner sides of the steel cylinder. The periphery or outer edge of the piston is lubricated and maintained gas-tight by means of several layers of moulded rubber packing rings, which

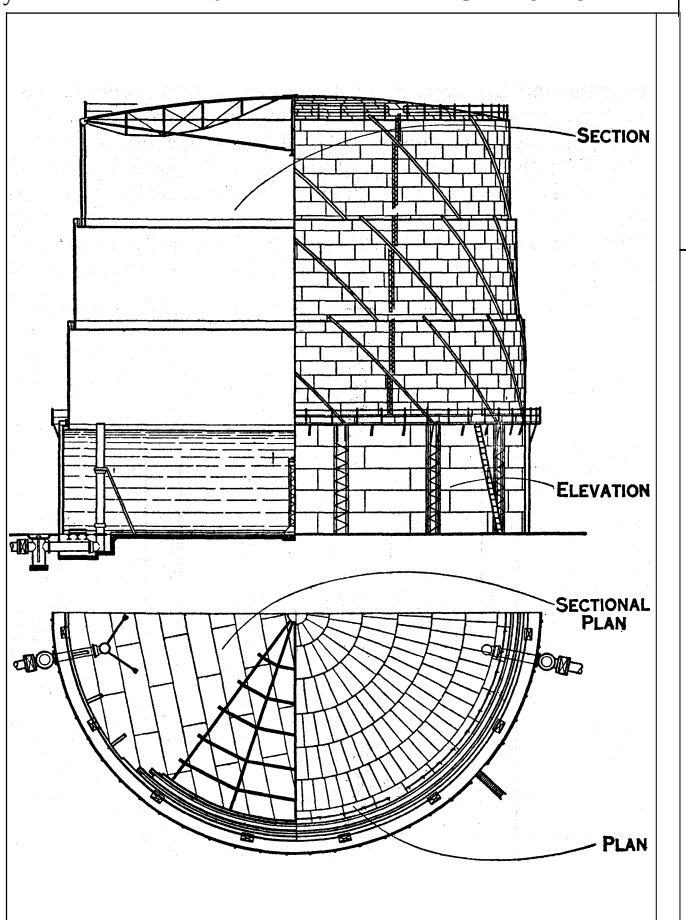

FIG. 3.— THE ELEVATION AND FLAN OF SPIRALLY GUIDED GASHOLDER
The construction differs from the telescopic type in having a number of double-flanged rails, inclined at 45°, secured to the side sheeting of each lift

effectively confine the gas to the underside of the piston. The interior of the tower above the piston is freely accessible, well ventilated, and lighted by openings provided in the sides of the tower above the highest gas level. The packing seal, guide rollers and lubricators can, therefore, be readily inspected at any time, without interfering with the normal working of the gasholder. The roof of the dry gasholder does not enclose the gas—this being the function of the moving piston—and is only required to perform the duty of sheltering the moving piston from rain, snow and dust.

Another type of dry gasholder consists of a polygonal steel tower, with movable piston, similar in construction to that previously described, but in this design the periphery of the piston is maintained gas-tight by means of a light gas-tar of moderate viscosity, contained in an annulus formed on the outer edge of the piston. As this seal is not absolutely tar-tight, a small quantity of tar escapes and flows to the bottom of the cylinder, where it is collected in a series of chambers, and is pumped up again by a number of automatically controlled electric pumps, to the top of the tower.

Spherical **Gasholders.**—This type (fig. 6) is principally used for storing gas under pressure. It is a plain sphere of simple construction, usually about 50 ft. in diameter, formed of steel plates about $\frac{9}{16}$ of an inch thick. The gas to be stored is forced by a

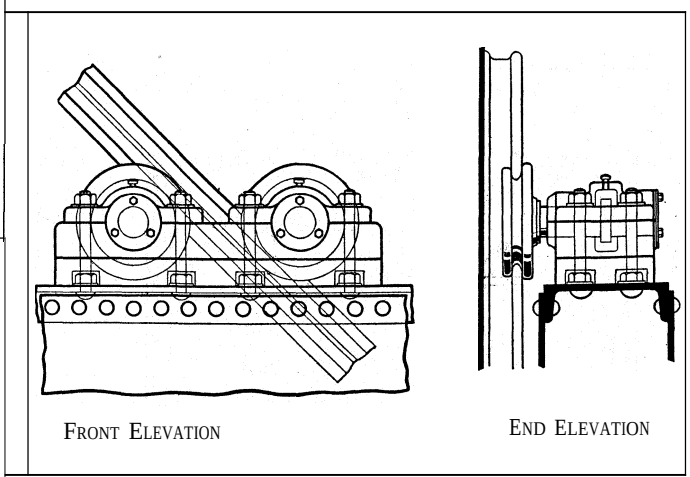

FIG. 4.— FRONT AND END ELEVATIONS OF SPIRAL GUIDE RUN BETWEEN SET OF ROLLERS

compressing plant into the sphere at a pressure of about 50 lb. per sq.in. When the gas leaves the outlet of the sphere, it is passed through suitable controlling governors, which reduces the pressure to such an extent as will meet the needs of the consumers. A sphere filled at a pressure of 50 lb. per sq.in. will store and de-

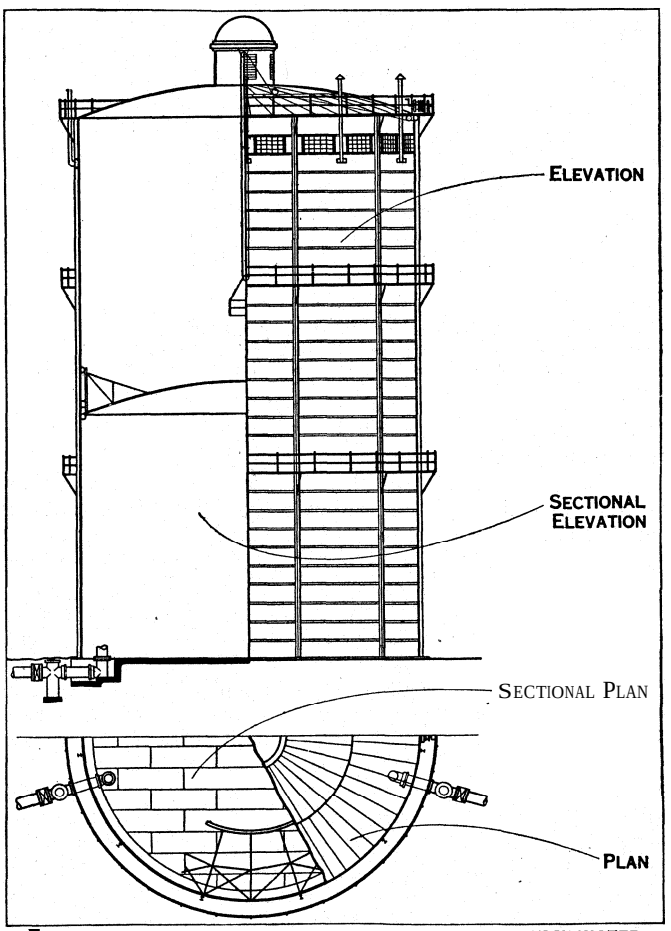

FIG. 5.—DRY GASHOLDER IN WHICH WATER TANK IS ELIMINATED
In this type of holder a great reduction in foundation costs is effected. The holder consists of a cylindrical steel tower in which a horizontal piston moves up and down, receiving or expelling the gas

liver about 33 times its cubical content at the lower pressure required in the distributing mains.

GAS IN WARFARE: see CHEMICAL WARFARE.

GASKELL, ELIZABETH CLEGHORN (1810–1865), English novelist and biographer, was born on Sept. 29, 1810, in a house in Lindsay row, Chelsea, London; now 93 Cheyne walk. Her father, William Stevenson (1772–1829), had been successively Unitarian minister, farmer, boarding-house keeper for students at Edinburgh, editor of the Scots Magazine, and contributor to the *Edinburgh* Review before he received the post of keeper of the records to the Treasury, which he held until his death. His first wife, Elizabeth Holland, died a month after her daughter, Elizabeth, was born, and the babe was taken to Knutsford, Cheshire, to be adopted by her maternal aunt, Mrs. Lumb. Thus her childhood was spent in the environment idealized in Cranford. From 1824 to 1826 Elizabeth went to school at Stratford-on-Avon, from 1827 to 1829 she lived in London with her father and his second wife; and after two winters at Newcastle-on-Tyne in the family of William Turner, a Unitarian minister, and a third in Edinburgh, she married, on Aug. 30, 1832, William Gaskell, minister of the Unitarian chapel in Cross street, Manchester, and from 1846 to 1853 professor of English history and literature in Manchester New college. They lived first in Dover street, then in Rumford street, and finally, in 1850, at 84 Plymouth grove.

Mrs. Gaskell and her husband thought to emulate George Crabbe and write the annals of the Manchester poor, but only one poetic "sketch" appeared (*Blackwood's Magazine,* 1837). In 1844, while they were visiting North Wales, their infant son died, and to distract Mrs. Gaskell from her sorrow her husband suggested a long work of fiction. Hence Mary Barton, a Tale of Manchester Life was begun. It was published in 2 vols., 1848; its appeal for neighbourly love, its dramatic power and humour winning for the author the friendship of Carlyle, Landor and Dickens. Dickens asked her, in 1850, to contribute to his new magazine, Household Words, and here the whole of Cranford appeared at intervals from Dec. 1851 to May 1853, exclusive of one sketch, reprinted in the "World's Classics" edition (1907), that was published in All the Year Round for Nov. 1863. *Cranford* is an English classic. It is a picture of Knutsford indeed, but a work of imagination that has a place in literature beside the much earlier work of Jane Austen. In Ruth (1853) Mrs. Gaskell again presents Knutsford, thinly disguised, and the little Unitarian chapel in that town. North and South, a powerful tale of the industrial revolution, first published serially in *Household* Words, was separately published in 1855.

Then came—in 1857—the Life of Charlotte Bronte, in two volumes. Two years earlier Miss Bronte had begged her publishers to postpone the issue of her own novel, *Villette,* in order that her friend's Ruth should not suffer. This biography, by its vivid presentation of the tragic story of the three Bronte sisters, gave its author a place among English biographers.

In 1863 Mrs. Gaskell published her last long novel, *Sylvia's* Lovers, a romantic tale of Whitby smugglers and the press-gang riots. In the same year a one-volume story, A Dark Night's Work, and Cousin Phyllis and other Tales, appeared.

Mrs. Gaskell died on Nov. 12, 1865, at Holyburn, Alton, Hants, and was buried in the graveyard of the Knutsford Unitarian church. Her unfinished novel, Wives and Daughters, was published in 2 vols. in 1866.

See J. A. Payne, *Mrs Gaskell and Knutsford* (and ed., 1905); E. H. Chadwick, *Mrs. Gaskell* (and ed., 1913, with bibliography); and Gerard DeWitt Sanders, *Elizabeth Gaskell* (1930).

GAS LIGHT AND COKE COMPANY. This London public utility company, working under Act of Parliament, had in 1938 an issued capital of over £47,000,000, and employed 25,000 men and women whose interest in the company under its co-partnership scheme was approximately £1,000,000. The company was granted a royal charter in 1812.

In 1870 the City of London and Great Central companies were amalgamated with the old chartered company, and from then onwards the company's position has been consolidated by further amalgamations, the last two being with the Southend Company and the Brentwood Company in 1932.

In the early years gas was used almost wholly for lighting. From round about the turn of the century, however, it came rapidly into almost universal use for cooking. Later on, its uses for space heating and water heating were developed. Its most recent adaptation has been for central heating and central hot water supply in offices, blocks of flats and other large buildings, and for industry. In 1929, for example, the annual consumption of gas in the national newspaper offices was 192,000,000 cu.ft.; in 1939 it was over 420 million cubic feet. Stream-lined design, automatic ignition, and the use of coloured finishes are features of modern gas appliances. Between 1934 and 1939 the company's output of gas increased by 4.7 per cent, a most satisfactory increase on so large a turnover.

In 1938, 3,400,942 tons of coal were carbonized and 49,034,014,000 cu.ft. of gas (over 245,000,000 therms) were sold to 1,673,712 consumers and distributed through 6,172 miles of main. The coke made for sale was 1,729,700 tons and the output of coal tar 36,000,000 gallons.

The Gas Light and Coke Company is (1939) associated, through the South-Eastern Gas Corporation Ltd., with the control of 27 other gas companies. The grouping of companies, large and small, makes possible skilled financial control, cheap capital for development, co-ordination of policies, and the employment of specialists. These modern developments have teen responsible for much of the progress of the gas industry. (L.C.M.; X.)

GAS MANUFACTURE. When coal is heated out of contact with air it is resolved into a stable solid residue, known as coke, and volatile matter, the principal constituent of which is gas, known as coal gas. The coke residue may be gasified in steam to make water gas. Coal gas, either alone or mixed with water gas, is distributed in pipes for public supply.

Coal gas has an average heating value of about 500 British Thermal Units per cubic foot and water gas, unless enriched by carburetting (as see below), has a heating value of some 300 B T.U. per cubic foot.

Another kind of gas can be made if air is blown either alone or mixed with steam through a deep hot bed of coal. From half to two-thirds of this gas by volume is made up of the nitrogen contained in the air used for gasification, and the heating value

of such gas is of a much lower order than that of coal gas or water gas on that account, running about 120–160 B.T.U. per cubic foot. This is the form of gaseous fuel mainly used for large industrial furnaces and is known as producer gas.

GAS FOR PUBLIC SUPPLY

The first use made of coal gas was as an illuminant, burning without any previous admixture of air with a yellowish luminous flame. The earliest observation and demonstration of this property has been ascribed to John Clayton and to Jean Pierre Minckelers, but the first practical application on any considerable scale seems to have been made by William Murdock who ran a small experimental plant in 1795, lighted a Soho factory by gas a few years later, and in Feb. 1808 was awarded the Rumford Medal of the Royal Society of London for his invention as described in a paper read before the Society. The Gas Light and Coke Company (*q.v.*) was incorporated in London in 1812.

Low Temperature Carbonization in Iron Retorts.—Murdock's gas making apparatus was an iron retort placed in an inclined position, and heated by a fire burning on a grate below. For a long time, the retorts commonly employed in gas works were made of cast iron, which being charged with the coal to be carbonized, were heated by small coal to a temperature which probably ran from 600–700° C, a much lower temperature than now obtains, as is indicated by the yield of gas, which ran from 6,000–7,000 cu.ft. per ton of coal. Further description will be facilitated by a consideration of the principles involved in the carbonization process, that is the heating of coal out of contact with air.

The essential elementary constituents of a coal are carbon, hydrogen and oxygen, with small quantities of nitrogen and sulphur and some incombustible matter. On heating out of contact with air, the coal fuses more or less and partially decomposes. Gaseous products of decomposition force their way through the plastic mass and give it a honeycombed structure. By the process of decomposition, however, the coal becomes less fusible, until it becomes a porous solid known as coke. Further heating drives off more gas and results in a shrinkage and hardening of the coke. The volatile matter coming away in the early stages is rich in easily condensible tarry matter and gaseous hydrocarbons. At a temperature above 800° C, the volatile matter is principally hydrogen gas.

The following analyses are given to exemplify the composition of coal-gas, tar and liquor.

Gases	High temperature			Low temperature
	Horizontal retorts	Vertical retorts		
		Without	With steam	
Carbon dioxide	2·0	2·2	3·4	4·5
Unsaturated hydrocarbon	3·1	2·3	1·8	3·8
Oxygen	0·5	0·4	0·7	0·2
Carbon monoxide	8·0	10·3	15·1	8·3
Hydrogen	50·6	49·5	49·3	29·1
Methane	28·1	28·5	21·2	49·1
Nitrogen	7·7	6·8	8·5	5·0
	100·0	100·0	100·0	100·0

Tar	Per cent.	Liquor	Grms. per 100 cc.
Water	1·6	Ammonia	1·58
Crude naphtha	2·6	Sulphate as thiocyanate	0·12
Light oils	9·4	Sulphate as sulphide	0·24
Carbolic oil	12·1	Hydrocyanic acid as thiocyanate	0·21
Creosote oil	13·0	Carbon dioxide as carbonate	1·78
Pitch	61·3	Chlorine as chloride	0·36
	100·0	Phenol	0·45
		Pyridine	0·02

Now considering the volatile matter, this is driven off in gaseous form owing to the high temperature, but on cooling down there is a gradual process of condensation. In gas manufacture, the cooling is hastened by washing with water, which also removes ammonia, formed from the nitrogen compounds in the coal. The consequence is that the volatile matter is divided into three portions, two of them liquid but not mixing, because one

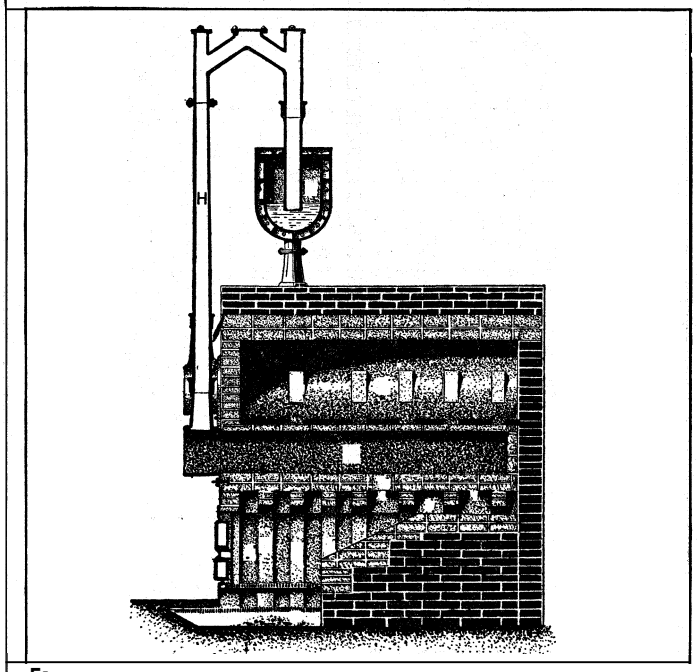

FIG. 1 — SIMPLE SETTING OF A SINGLE RETORT DIRECT-FIRED FROM A GRATE BELOW

is oily, the tar, while the other is the so-called ammonia liquor. The third portion is the gas which, after purification from sulphuretted hydrogen, is ready for distribution.

It will be readily understood that both the quantities and the compositions of the tar, liquor and gas vary according to the nature of the original coal and the conditions of manufacture, particularly the temperature. The low temperature products are those resulting from the first processes of break-down in the coal. The high temperature products contain many of the substances formed by the secondary decomposition of the primary products, brought about by subjecting them to a higher temperature. The difference shows itself very plainly in the gas yield, which is much higher for high temperature working, and in the nature of the gas which contains much more hydrogen and less of the easily decomposable compounds of carbon and hydrogen. The tar is usually smaller in amount for high temperature working and it is characterized by the presence of the so-called aromatic hydrocarbons of the benzene type, which are products of secondary decomposition and are absent from low temperature tars. The increased yield of gas in high temperature working is partly due to the secondary decomposition of some of the more decomposable tar constituents, although it is mainly accounted for by an extensive formation of hydrogen peculiar to high temperature working.

Fire-clay Retorts.—The volume of gas obtainable by working in iron retorts was limited by the properties of this material.

An important advance was made when fire-clay was substituted for iron in the construction of the retorts, because a higher temperature was permissible and further improvement of a radical character followed when, in the heating of these retorts, gas firing and the recuperative principle could be employed.

Recuperative Retorts.—This will be understood from fig. 2, which shows a setting of ⌒-shaped horizontal fire-clay retorts in a setting. They are heated by a gas made by passing air through a deep layer of red hot coke. This gas, meeting hot air immediately under the retorts, burns around them and carbonizes

the coal contained therein. The waste gases, after heating the retorts, do not, however, pass away directly to a chimney, as in the old "direct" firing (fig. 1), but are turned downwards into the recuperator, where they pass along channels in which they are only separated by a thin fire-clay partition from air travelling upwards to meet the gas. By this plan, some of the heat is abstracted from the waste gases and restored to the setting in the air used for combustion. Consequently, less heat leaves the setting, and a higher temperature can be attained accompanied by a fuel economy. This system of carbonization in horizontal recuperative fire-clay retorts rapidly became standard practice, and remains so to a considerable extent. It enabled an average gas yield of 10,000 cu.ft. of gas per ton of coal to be obtained, and lowered the expenditure of fuel required for heating the setting from 25–30% of the weight of coal carbonized to 15–20%.

Although excellent in many ways, the horizontal retort setting as so far described had the disadvantage of requiring heavy labour for hand charging. This drawback has been to some extent neutralized by the use of mechanical charging machines. Other methods were, however, coming forward by which the aid of gravity could be invoked for the moving of the coal and coke during carbonization, and some other advantages secured.

Vertical Retorts.—The simplest form of the vertical retort was one in which the retorts were all set vertically instead of horizontally, as in the past, and, being filled with coal, were heated until the whole of the charge had been carbonized, after which it was withdrawn. This so-called Intermittent Vertical System was patented in England by Bueb in 1904, after previous trial at the Dessau Gas Works. It had the advantage, as compared with the hand-charged horizontal retort setting, of lessening labour and requiring less ground space for a given output. It had also the new characteristic, that the retort could be fully charged, thereby lessening that contact of the volatile matter with red hot coke and the walls of the retort, which make for secondary decomposition. A further advance was made almost at once by the introduction of continuous working into the vertical retort system by which, instead of completing the carbonization of the whole charge before withdrawing any portion of the coke residue, a continuous feed of coal was made to the top of the retort and coke was continuously withdrawn from the bottom by an extracting mechanism.

The principal names associated with this system are Woodall-Duckham, Glover-West and Robert Dempster and Sons, and it has been widely adopted. The idea had been applied with limited success previously by Settle and Padfield. Fig. 3 illustrates a setting of Glover-West retorts which can be taken as typical. The heating gas from the producer passes through apertures,

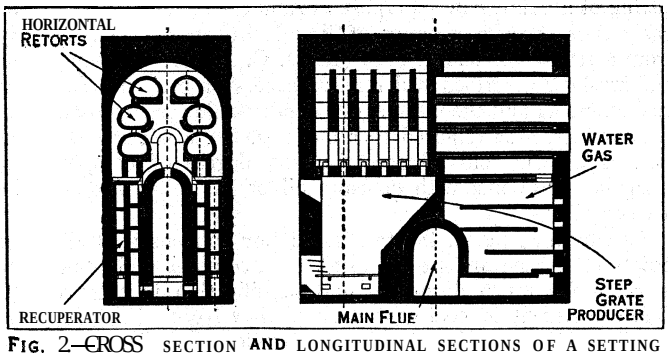

FIG. 2.—CROSS SECTION AND LONGITUDINAL SECTIONS OF A SETTING OF 6 HORIZONTAL RETORTS

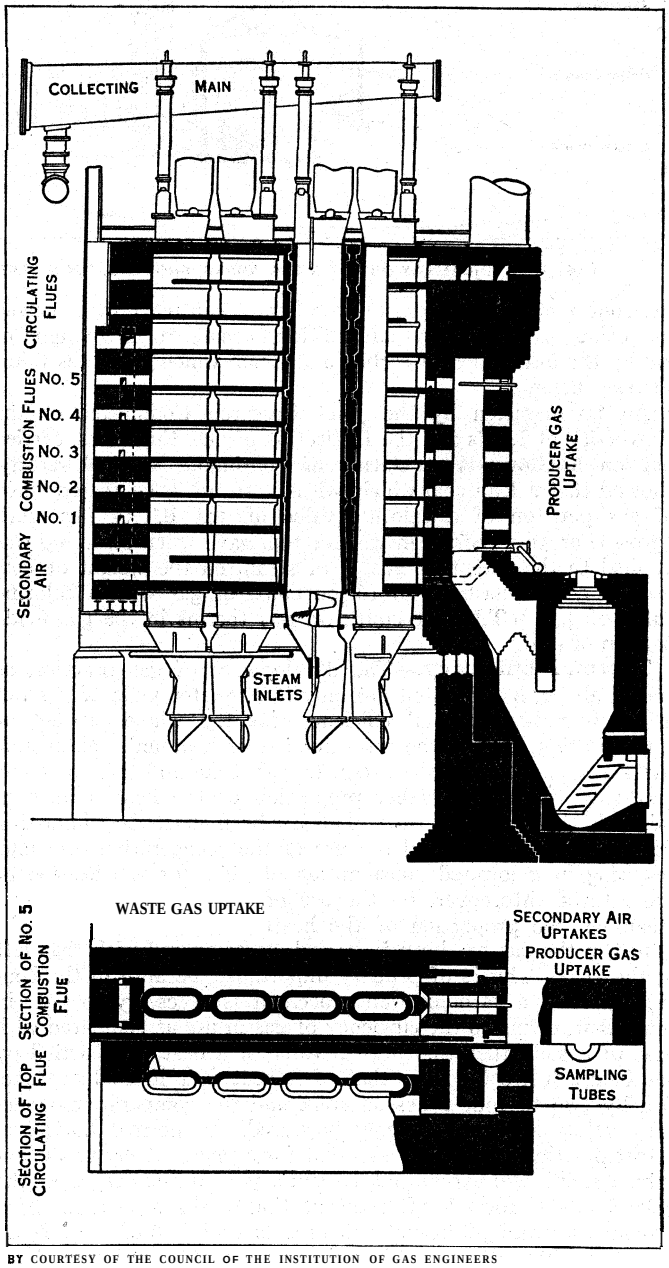
which can be regulated, into heating channels surrounding the retorts. The upper sections are heated by waste gases alone.

The heating quality of the gas is now of paramount importance. As a consequence, the heating value of a gas per cubic foot has become recognized as of more consequence than its illuminating power in "standard candles" and has become the statutory method of defining its quality. The British Gas Regulation Act of 1920 introduced the sale of gas by the therm, a therm being 100,000 B.T.U., and allowed gas companies and authorities to specify the standard quality in B.T.U.'s per cubic foot of the gas they would supply, insistence, however, being rightly made upon the maintenance of that standard as all-important. These alterations in the conditions of manufacture and use, and in legislation, have permitted and encouraged such developments in gas manufacture



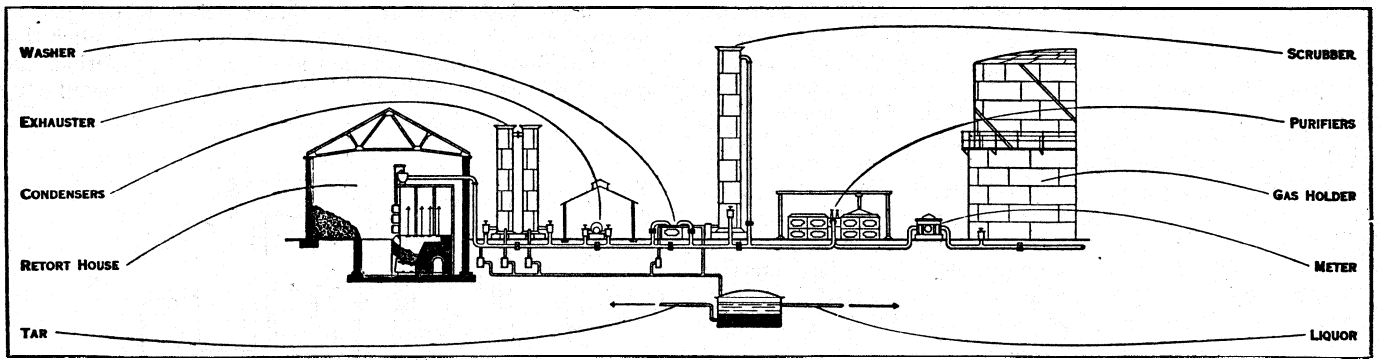
BY COURTESY OF THE COUNCIL OF THE INSTITUTION OF GAS ENGINEERS

FIG. 3.—ASETTING OF 8 VERTICAL GAS RETORTS IN ELEVATION ABOVE, AND IN PLAN BELOW

as make for more complete gasification of coal, *i.e.*, obtaining a larger proportion of its potential heat in the gas made.

Steaming.—One mode of obtaining this result, to which reference has already been made, has been working at a higher temperature. That has demanded special attention to the quality of the refractory materials used in the construction of the retorts and their settings and has led to an increase in the use of silica instead of fire-clay in vital parts subject to the higher temperatures. By such means, higher yields of gas per ton (13,000 ft. per ton) have become common. The gas so made is rich in hydrogen and poorer in illuminating constituents than was commonly supplied previously for lighting purposes and is lower in calorific value, say 500 as against 600 B.T.U. per cubic foot.

Another method of increasing the yield in volume and thermal units has come into use, known as the "steaming" of vertical gas retorts, which is carried out by introducing steam at the base of



BY COURTESY OF J. E. CHRISTOPHER

FIG. 4.—TYPICAL LAY-OUT OF A GAS WORKS. SHOWING. FROM LEFT TO RIGHT, CONSECUTIVE STEPS IN THE PROCESS OF MANUFACTURING

the continuous vertical gas retort where it can react with the red hot coke. By this means an addition is made to the volume of gas by the interaction of carbon and steam which generates water gas (see below).

An investigation by the Joint Research Committee of the University of Leeds and the Institution of Gas Engineers, carried out on a Glover-West setting of continuous vertical retorts, showed that a lean coal which, without steam, gave 10,400 cu.ft. of gas per ton of a calorific value of 544 B.T.U. per cu.ft. (gross), or 56.5 therms in gas per ton, gave when steaming was applied to the extent of 26.4% of steam on the weight of coal used, a yield increased to 16,900 cu.ft. of gas with a calorific value of 447 B.T.U. per cu.ft., or 75.7 therms in the gas made per ton of coal.

Thermal Efficiency — The development of gas practice, as traced above, has resulted not only in a greater yield of gas but in an increased thermal efficiency for the whole process of carbonization, that is the total number of heat units obtainable by the combustion of the products, gas, coke and tar, has come gradually to form a higher proportion of the heat units contained in the coal carbonized. This has been effected by improved design of the setting and the use of the recuperative principle, resulting in a lowered consumption of coke for the heating of the retorts. Moreover, by the use of higher temperatures and steaming, the proportion of the heating value of the coal obtained in the gas has been increased, as compared with that left in the coke. This is of primary importance, because in the consideration of a carbonization process it is necessary to bear in mind that, owing to the efficiency of gas in use as compared with that of a solid fuel, the thermal value of a heat unit carried by gas is much greater than that of a heat unit in coal or coke, usually two to four times as great and the comparative monetary value is correspondingly increased. In normal horizontal retort practice it may be taken that for every 100 heat units contained in the coal carbonized, 24 will appear in the gas, 42 in the coke available for sale after the heating of the retorts has been provided for and 5·6 in tar, which means that 71·6 of the original heat units have been obtained in the available useful products of carbonization. Otherwise expressed the thermal *efficiency* of the carbonization process so conducted is 71·6%, 28·4% having been used and lost in the manufacture. In a more modern installation a higher value would be attained, for example, in the investigation of steaming reported above, the efficiencies of carbonization varied from 80–83%.

Purification of Gas.—As indicated above, the volatile matter driven off from the coal and leaving the retort contains permanent gas and constituents more or less easily condensed or washed from it. Treatment for this purpose is made in a train of apparatus which varies widely in detail but not much in principle. The succession of parts is indicated diagrammatically in fig. 4.

In fig. 1 a so-called "ascension" pipe (H) is shown leading upwards from a horizontal retort, then bending over and dipping below the liquid seal in the so-called hydraulic main, the seal being used to prevent access of air to the main when the retort is opened for charging and discharging. Some cooling occurs in the ascension pipe and condensing of tarry matter. Collecting together of the gas from a number of retorts into a hydraulic main is common practice. Easily condensible constituents come down there and in the following foul main which leads to the condensers. These are vertical pipes of considerable area and the cooling effect of air upon them causes such a lowering of temperature in the gas as to bring down both tar and water, which are gathered from the bases of the condenser pipes. The pipes themselves may be circular or may be made annular, so as to make a sort of chimney up which air will pass the more rapidly because it is warmed by the enclosing gas in the annular space. Water is sometimes used with success instead of air as a condensing medium.

The next stage is the washing or scrubbing of the gas in which more complete cooling of the gas can be secured, and at the same time the dissolving out of soluble constituents carried by the gas. The construction of washers and scrubbers has called for many designs but intimacy of contact between gas and liquid in the scrubber is sought in every case. In the Livesey Washer for example, the gas stream is repeatedly broken up and forced through water by an ingenious device. In the scrubber, as shown in fig. 4, the gas passes up a tower packed with boards, coke, rings or other filling, so arranged as to give a large surface of contact, with the descending current of water or weak liquor which is relied upon to complete the removal of ammonia from the gas.

Another type of scrubber contains slowly revolving disc brushes, the fibres of which are alternately moistened by liquid in the bottom of the scrubber and exposed to the gas current which they are called upon to purify (Holmes, "Standard"). Some use is made in the gas industry of centrifugal washers consisting of a number of superposed chambers in each of which the gas passes through a spray of liquid thrown out centrifugally from a revolving cone or cage (K. H. C. Feld). The condensing and washing described will remove excess of moisture from the gas, ammonia and the more easily condensable tarry constituents. If, however, it is required to remove such volatile tar constituents as benzene and toluene with any degree of completeness, a further scrubbing with creosote oil or gas oil is found to be necessary.

As shown in fig. 4, the tar and liquor condensed at different points of the system are led away to a common well, but there is room for much discretion and modification in this respect. One constituent of coal gas which by law has to be completely eliminated if the gas is to be used for public supply, is sulphuretted hydrogen, and the final process of purification in ordinary practice is to pass the gas through iron oxide purifiers, and thence to gas-holders (see GAS HOLDERS). The purifiers contain hydrated oxide of iron, or similar material spread on grids. The oxide absorbs sulphuretted hydrogen rapidly, becoming converted into sulphide. If, owing to this conversion, the sulphida material no longer operative in absorbing sulphuretted hydrogen, is removed and exposed to air, it is re-oxidized with the formation of free sulphur. If a small amount of air is admitted along with the gas to the purifiers, this re-oxidation will take place in situ, and this is usually done. When the sulphur content of the fouled

oxide has reached some 50%, the material is sold for the making of sulphuric acid. Most of the sulphur in the gas is contained as sulphuretted hydrogen and is removed by this process. There remains, however, a small quantity occurring as carbon bisulphide and not removed by oxide of iron. It has been shown by Carpenter and Evans that by thermal treatment in the presence of a nickel catalyst the carbon bisulphide can be converted into sulphuretted hydrogen, subsequently removed.

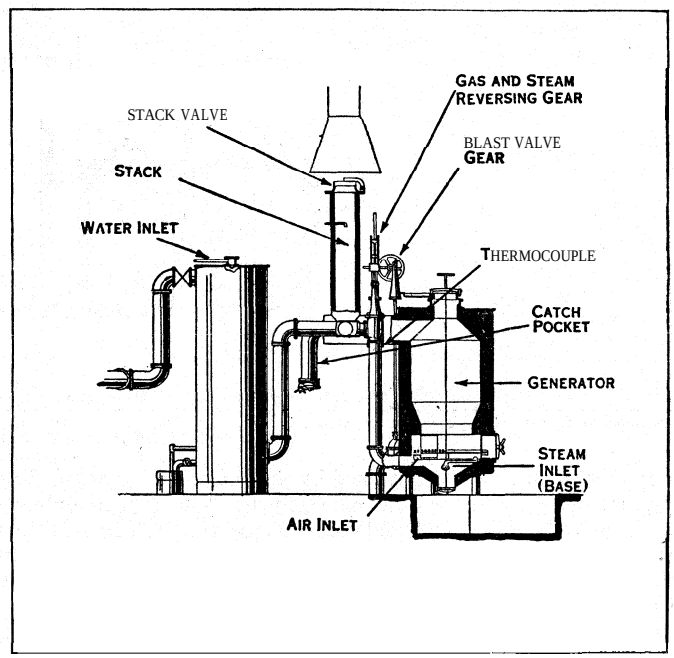
The sulphuretted hydrogen to be removed from the gas is dependent upon the composition of the coal and other factors, but is of the order of 1% and the carbon bisulphide about one-twentieth of this amount or less. Of the same small order of magnitude are cyanogen and naphthalene.

Ammonia. — Liquor containing the ammonia washed out of the gas is either sold as such or used at gas works for the production of ammonium sulphate. When distilled with lime, ammonia is driven off from it and being absorbed in sulphuric acid, forms the sulphate which constitutes a valuable manure. The quantity obtained at gas works usually lies between 20 and 30 lb. of ammonium sulphate per ton. The ammonia yield can be increased by steaming the retorts, but the liquor obtained is usually weaker because of the passage of undecomposed steam from the top of the gas retort into the gas. A weaker liquor has a lower commercial value if it has to be sent away for treatment and has the further disadvantage that after distillation for ammonia the residual liquor is greater in amount.

The direct method of ammonia recovery in which the gas is passed through sulphuric acid for the absorption of ammonia, instead of effecting a separation of the ammonia liquor and distilling it has found little application in gas works.

Tar. — The tar made at gasworks is subjected to a complicated process of distillation, resolving it into fractions which boil over in different temperature ranges, the fractions being afterwards refined. These operations are usually carried out at separate tar distilleries. The average yield of tar by the ordinary gasworks process can be taken as 5% of the weight of coal carbonized. At lower temperatures, more tar is produced and the light oil fraction coming over on distillation is usually greater in volume.

Water Gas. — A limited gasification of coke in steam can be effected in the continuous vertical retort as described above, but the complete gasification of the carbon in coke is carried out in an entirely different type of apparatus, known as a water gas plant. At high temperatures, carbon decomposes steam into hydrogen and carbon monoxide, but with an absorption of heat according to the equation $C+H_2O \rightarrow CO+H_2-29{,}000$ calories. When the temperature of the carbon has been brought down by this absorption of heat, the reaction is altered with the production of carbon dioxide. An equilibrium tends to be established by the catalytic action of the solid carbon (and inorganic ash constituents) so that a ratio $\frac{CO \times H_2O}{CO_2 \times H_2}$ may be established among the gas constituents, the ratio being constant for any one temperature but lowering with the temperature. The reversible reaction occurring $CO+H_2O \rightleftarrows CO_2+H_2$ makes for a higher carbon dioxide content of the gas as the temperature is lowered, and moreover, since the velocity of gasification is rapidly lowered with falling temperature, the gas made with the same rate of steam supply comes to contain more undecomposed steam. Carbon dioxide lowers the calorific value of the gas and the steam requires condensation. The high temperature of the carbon can, however, be restored by stopping the steam and blowing with air which raises the temperature of the fuel bed, generating a producer gas. The industrial process based upon this principle of alternately blowing a bed of coke with steam and air was made by Gillard (1849), Tessie du Motay and Lowe (1873) and called the water-gas process. The plant as illustrated in fig. 5, is that of Messrs. Humphreys and Glasgow. The coke bed is enclosed in a steel casing, lined with fire-brick, and may be blown through the grate below by either air or steam. An arrangement of valves also enables the steam to be introduced above the coke for a "down-run." The exact arrangement and time in the up-run with steam, down-run with steam and blowing with air is varied to suit the fuel and other conditions and constitutes a cycle of operations which is carried out systematically. The coke is blown with steam until, by lowering temperature, the carbon dioxide produced in the water gas is lowering its quality too far. During the steam blow, the water gas made is carried forward to a scrubber, down which water is running and then goes forward to joint the main gas stream of the works for purification from sulphuretted hydrogen. This water gas should have a calorific value

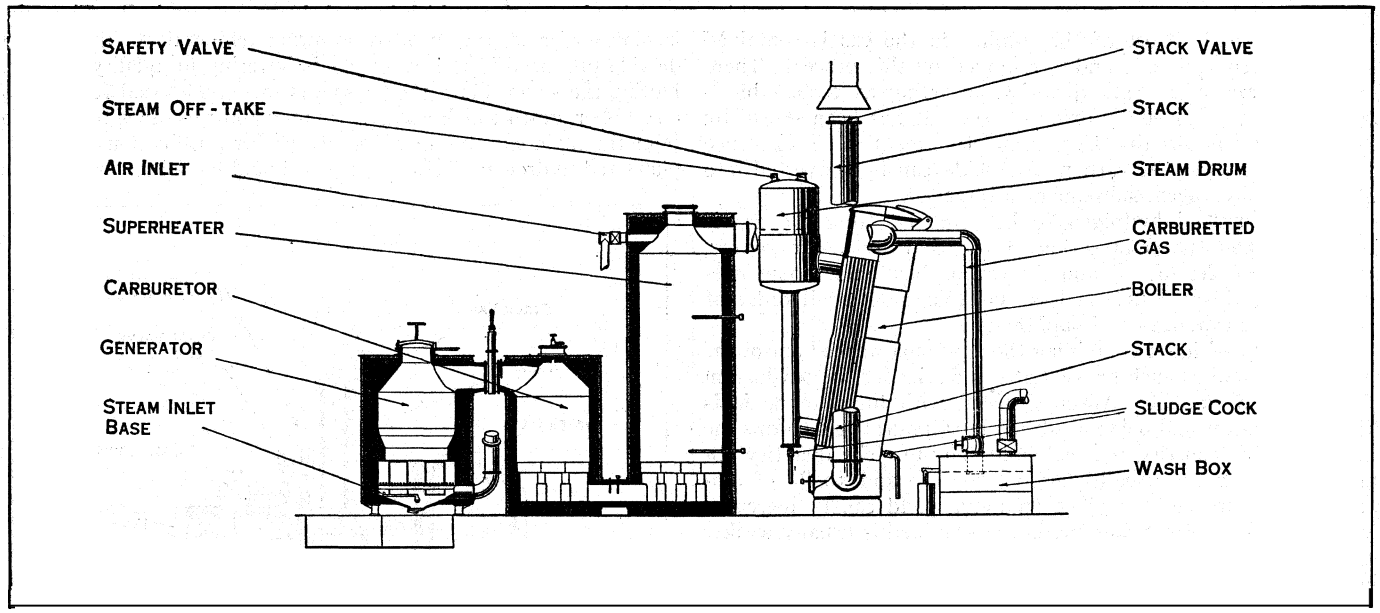


BY COURTESY OF THE INSTITUTE OF GAS ENGINEERS

FIG. 5. — BLUE WATER-GAS PLANT, SHOWING PARTS

of 300 B.T.U. per cu.ft. When the steam blast is replaced by air, in order to restore the high temperature in the fuel bed, the producer gas generated being heavily charged with nitrogen is not allowed to go forward to the scrubber, but is turned to waste up the stack. That continues until a satisfactory high temperature has been re-established in the fuel bed, when steam is again employed. The heaviest thermal loss in the process is that of the potential and thermal heat in the producer gas, but this is being considerably lessened in the most modern plants by the installation of a waste heat boiler. Another means of lessening the same loss is adopted in the Dellwik Fleischer plant, in which, by the use of a thin bed of fuel and a powerful blast of air, regeneration of heat in the fuel bed can be carried out more quickly, more of the carbon being burned to carbon dioxide instead of carbon monoxide, so that more heat is generated in the fuel bed and less leaves the generator as potential heat of combustion in the blow gas. (The steam using stage is known as the "run" and the air using stage as the "blow.")

Carburetted Water Gas. — It has been noted that the water gas made by the process as described above has a calorific value approximating to 300 B.T.U. per foot. It is known as "blue" water-gas and is definitely lower in grade than the coal gas made from retorts. There is a means, however, ready to hand, of increasing the calorific value by utilizing some of the heat in the gases leaving the generator for the purpose of cracking oil, that is converting it into permanent gas, rich in hydrocarbons, and so obtaining a "carburetted" water-gas of enhanced calorific value. Fig. 6 illustrates a Humphreys and Glasgow plant used for this process. The gas from the generator passes through two chambers, a carburettor and a superheater packed with brickwork, which are raised to redness, some air being admitted for the combustion of the "blow" gas therein. The oil is run in from the top of the carburettor and should be such as can be efficiently cracked under the conditions of the process. (In early stages of the development of the plant the oil was run directly upon the coke in the generator, but this was unsatisfactory for various reasons.) In this plant, blue water-gas leaves the generator with a calorific value of 300 B.T.U. per cu.ft., but leaves the superheater enriched by the car-



BY COURTESY OF THE INSTITUTE OF GAS ENGINEERS

FIG. 6.— CARBURETTEDWATER-GAS PLANT AND WASTE HEAT BOILER

buretting to an extent determined by the amount of oil used. The thermal efficiency of the oil cracking in the plant is high, amounting to something like 90% and consequently the thermal efficiency of the carburetted water-gas process is higher than that of the blue water-gas process and increases with the amount of oil used. The extent of carburetting employed is influenced by this factor, by the price of oil and the quality of gas desired. In England, carburetting is usually carried out so far as to bring the carburetted water-gas up to something like the same calorific value as the coal-gas made at the same works, say 500 B.T.U., but in America it has in the past been usually carried much further. It is plain too that blue water-gas, enriched by carburetting to the extent desired, can be used as a means of modifying the calorific value of the mixture of coal-gas and water-gas supplied from a works. The extent to which the coke made in a gas works may be economically gasified and water-gas supplied depends on relative capital and operating costs and the prices of coal, coke and oil. A water-gas plant has the advantage, however, of being able to be put rapidly into full operation and the yield of gas per ton of fuel is high. In tests under working conditions, a blue water-gas plant gave the following results:

Gas in cu.ft. per ton coke to generator		51,000
Calorific value of gas	B.T.U.	305 gross
Composition of gas	Carbon dioxide	3·80
	Unsaturated hydrocarbons	0·05
	Oxygen	0·05
	Carbon monoxide	42·35
	Hydrogen	49·60
	Methane	0·65
	Nitrogen	3·50

A Carburetted Water-Gas Plant gave:—

Carburetted gas in cu.ft. per ton of coke		63,400
Calorific value	B.T.U.	481 gross
Composition of gas	Carbon dioxide	5·2
	Unsaturated hydrocarbons	6·0
	Oxygen	0·4
	Carbon monoxide	34·9
	Hydrogen	
	Methane	
	Nitrogen	4·9

The thermal efficiency of gas production in the carburetted water-gas plant with waste heat boiler, *i.e.*, heat of combustion of gas divided by heat of combustion+heat lost and utilized in carrying out the process, was 67·1 in this test, using 1.85 gals. of oil and 35·32 lb. of coke (dry) for each 1,000 cu.ft. carburetted water-gas made.

In the latest designs of carburetted water-gas plant, the blast steam and hot gas valves are operated automatically. There is a mechanical coke feed, an annular boiler round the generator and a mechanical grate. **A** so-called back run has been introduced into the working during which steam is passed for a time down the superheater, up the carburettor and finally down the generator.

Complete Gasification **and** Other Processes.—The processes so far described are those which have come into general use. Attempts are being made to make gas for public supply by completing the gasification of coal in one process instead of carbonizing it first in retorts and gasifying the coke residue, so far as may be desired, in steam in a separate generator and process. The water-gas process and generator is in some form embodied in all these plants. In the United Gas Improvement Company's plant some constructional modifications of the water-gas generator allow of the use of some coals in it in place of coke. In other plants, a retort is in effect superposed upon a water-gas generator (Tully). In another (Robinson). the working of horizontal gas retorts and water-gas generator is combined so as to discharge coke from the retorts into the generator and to utilize heat from the latter for carbonization. In plant by M. W. Travers, gas is recirculated to the generator after passing through a recuperator (heated by blow-gas) with the object of restoring sufficient heat to complete the carbonization process, both that and the gasification being carried out in the generator. Use is being made in gas works of coke ovens (*q.v.*) heated by producer gas; they are tending to be made narrow with reduced carbonization times. Vertical chambers too are meeting with some success (Otto Pintsch). There is a large amount of gas of approximately the same composition as that made in horizontal retorts available from by-product coke-oven plants, even when the heating of the ovens has been carried out by coke-oven gas. Such gas is being brought into use for public supply where economically advantageous, transmission over long distances being made by pumping.

The newer systems of low temperature carbonization (*q.v.*) are still in the experimental stage and cannot be said to contribute to public supply.

The development of gas manufacture is proceeding largely from a systematic study of the quality of different coals for carbonization and gasification at different temperatures and rates. The influence of the composition and physical properties of coal, such as fusibility and size of particle, the possibilities arising from blending different coals or pre-treating them by washing or preliminary gentle heating are receiving attention, while systematic studies of thermal efficiencies are stimulating the design of apparatus for carbonization and gasification so as to secure higher thermal and chemical yields.

Large manifolds in foreground convey gas and by-products to and from the building

GAS FOR INDUSTRIAL USE

The gas manufactured for public supply finds extensive and increasing applications for industrial heating. Being thoroughly cooled and cleansed it can be controlled with nicety through taps and valves. which makes for convenience, cleanliness and efficiency in use It is a smokeless fuel, and by its use ground space and expenditure on the cost of gas-making apparatus is saved Since, too, such gas is of high calorific value and does not carry into its flame any large proportion of nitrogen or other inert constituents, it can be used for high temperature processes in simple apparatus without the necessity of providing for that pre-heating of the air or gas or both which is a necessity for such high temperature work when the leaner producer gas is employed. The simplest process of gas making is that used in making producer gas, and the great bulk of gasification effected for such purposes as the heating of steel-melting and other large industrial furnaces is conducted on this plan.

Producer **Gas.**—When air is passed through a deep bed of carbon maintained at a high temperature, above 1,000° C, such that complete contact with the carbon is ensured and equilibrium obtained practically the whole of the carbon is obtained as carbon monoxide, according to the equation

$$C+\tfrac{1}{2}\{O_2+4N_2\}\rightarrow CO+2N_2+29{,}000 \text{ calories.}$$

If the temperature is lower, even although the contact is complete and equilibrium is still attained, some carbon will be burned to CO_2 according to the equation

$$C+O_2+4N_2\rightarrow CO_2+4N_2+97{,}000 \text{ calories.}$$

If, however, the high temperature has been maintained and the carbon entirely converted to CO, it is plain that the gas will consist of one-third carbon monoxide and two-thirds nitrogen, and the equation representing its formation may be called the ideal producer gas equation. If this producer gas is collected and burned with air, it will generate heat according to the equation

$$CO+2N_2+\tfrac{1}{2}O_2+4N_2\}\rightarrow CO_2+4N_2+68{,}000 \text{ calories.}$$

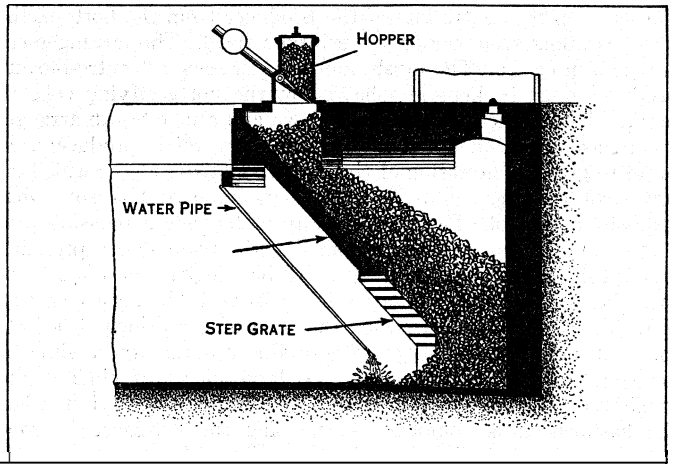
It will be seen that even if the whole of the heat generated in making the producer gas by converting the carbon to CO were lost, sixty-eight ninety-sevenths of the total heat of combustion of carbon to CO_2 would still remain available for use by its combustion of the gas. This large proportion of heat available for the second stage of the combustion of the carbon in burning carbon monoxide to carbon dioxide is the basis of producer gas practice. There are various factors which cause divergence in the composition of producer gas from that of the ideal producer gas equation In the first place, when coal is used as a fuel and is fed down on the fuel bed, it is at once subjected to a process of distillation or carbonization in the current of producer gas ascending from below, made by the action of the blast upon the carbonized fuel Producer gas is so enriched to some extent with hydrogen and hydrocarbons, particularly methane, and the percentage of nitrogen correspondingly diminished. More important, however, is the modification in composition brought about by the steam consequent upon a lowering of the temperature of the fuel bed and the formation of water-gas by interaction with carbon The more steam is used, the lower the temperature and the more carbon dioxide and hydrogen at the expense of carbon monoxide is formed The percentage of nitrogen is further lowered by the admixture with water-gas. Moreover, as the quantity of steam is increased and the temperature decreases. the rate of steam decomposition by the carbon lessens and steam passes through the fuel bed undecomposed. The quantity of steam supplied is best controlled by the temperature of the mixed blast at a point well beyond the introduction of the steam, so as to allow a thorough mixing. The temperature of the blast rises with the proportion of steam. It will be understood that undecomposed steam, which begins to occur in quantity as soon as the saturation temperature of 60° has been exceeded, is an objectionable constituent in the producer gas, since it is thermally useless and would tend to prevent the attainment of high temperatures on combustion on account of its high specific heat. Bone and Wheeler followed changes brought about in the composition and yield of producer gas, by gradually increasing the proportion of steam with results tabulated below. The coal used was washed nut screened over a 1 in. mesh.

Steam saturation, temperature of blast	60°	70°	80°
Percentage composition of gas:			
Carbon dioxide	5 25	9·15	13 25
Carbon monoxide	27 30	21·70	16 05
Hydrogen	16 60	19·65	22.65
Methane	3 35	3·40	3·50
Nitrogen	47 50	46 10	44·55
Total combustibles	47·25	44 75	42·20
Cal value of gas, B T.Us. per cu ft. at 0° and 760 mm. Gross	185 6	177 5	169 5
Cal value of gas, B T.Us. per cu ft. at 0° and 760 mm. net	173 0	163·3	154 3
Yield of gas cu ft at 0°C and 760 mm. per ton of coal	138,250	141,450	147,500
Steam added to blast, lb per lb. of coal	0·45	0·80	1·55
Percentage steam decomposed	87 0	61·0	40·0
Therms in gas per ton of coal (gross)	256 6	251·1	250 0
Weight of steam undecomposed per lb. of coal	0 06	0·31	0·93
Therms in gas / Therms in coal × 100	82 4	80 6	80·3

The two columns "Weight of steam undecomposed per lb. of coal" and "Therms in gas per ton of coal" have been added by the writer.

As the saturation temperature was raised by more steam, the gas composition shows a rise in carbon dioxide from 5 to 13% and a change over from a carbon monoxide producer gas, in which that constituent is dominant to a hydrogen producer gas is explained The nitrogen has fallen and the percentage of total combustibles has also fallen on account of the increase of carbon dioxide, resulting from the lower temperature of the fuel bed. The calorific value of the gas has slightly diminished, but the volumetric yield increased, so that the yield in therms contained in the gas per ton of coal gasified shows little change The weight of steam undecomposed per lb of coal has run up from 0·05 to 0 9 lb. Per ton of coal

Producer Construction.—The development of the apparatus in which the manufacture of producer gas is carried out can now

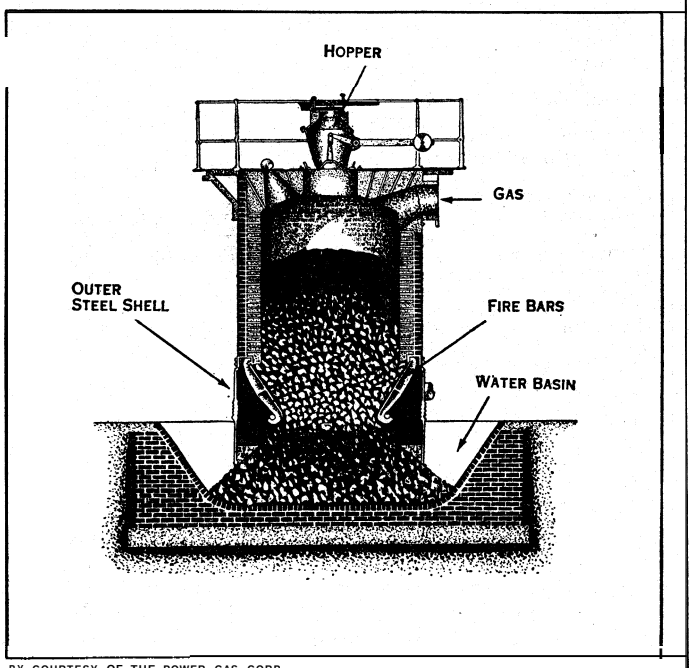


FROM RAMBUSH'S "MODERN GAS PRODUCERS" (BENN BROS.)
FIG. 7.—OLD TYPE PRODUCER WORKING WITH MATERIAL DRAUGHT AND NO BLAST UNDER PRESSURE

be traced. It would appear that the earliest gas producers were deep shafts of brick-work, but the name most closely identified with the successful establishment of the gas producer is that of Siemens, and a diagram of his Producer (1861) is given in fig. 7. It illustrates how the coal falls from the hopper and lies in the producer above the step grate. The producer was connected to a furnace, and the air for gasification was drawn through the fuel bed by natural chimney draft, operative on the furnace, supplemented at times by a syphon effect, induced by the dis-

position of the main between producer and furnace.

Pressure Producers.— More modern conditions have, however, demanded an increased output per unit of space and grate area, and this has been met by putting the producer under positive blast. Such a high rate of working involves a greater tendency to clinker formation, which has been counteracted by the use of steam. Fig. 8 is an example of one of the many gas



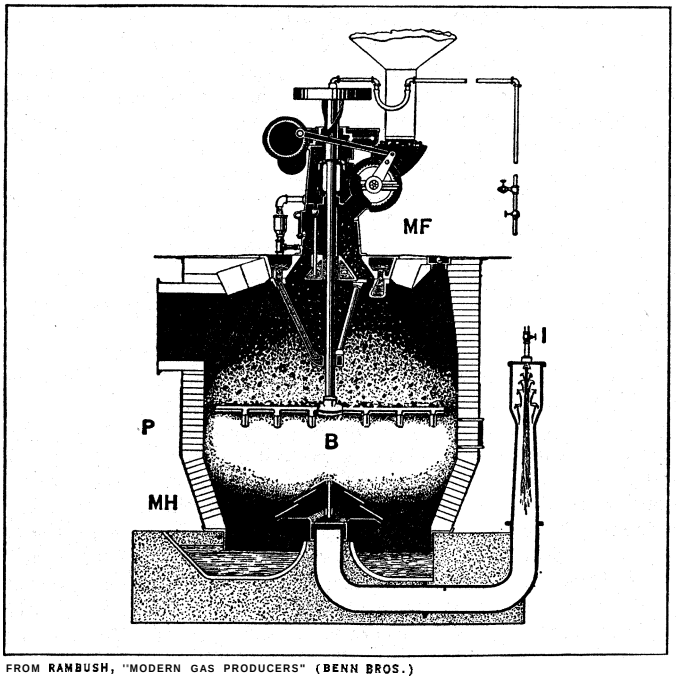
BY COURTESY OF THE POWER GAS CORP.

FIG. 8.— PRODUCER FOR BLOWING WITH AN AIR-STEAM BLAST

producers devised to work under these conditions. It is shown as a steel cylindrical shell, firebrick lined, and dipping into a water lute, which enables a pressure of blast to be maintained without escape, and ashes to be withdrawn through the water as required. The grate bars are shown arranged in a truncated cone, and the air-steam blast is admitted to the space between them and the casing. An alternative to this "side-blowing" is to deliver the blast up the centre line of the producer from the bottom, the blast escaping from under a mushroom head. This arrangement is shown in fig. 10. The mushroom head in such a "centre-blown" producer must be kept in ashes below the hot gasifying coke to prevent its destruction. The side blown and centre blown arrangements are occasionally combined for very wide producers, in order to give a penetration of the blast to all parts of the wide bed, but such combination is not at all common and is somewhat difficult to control. The simplest way of blowing a pressure producer is to use an injector supplied with steam under pressure, which can be easily arranged so as to be adequate in amount for injecting the air and at the same time saturating the blast (fig. 10).

It will be readily understood that one of the principal objects to be attained in the design of a producer is that there shall be no accretion of semi-fused ash into large pieces of clinker, and maximum facility for removing the ash necessarily left when the gasification is complete, so keeping the producer in good working order and minimizing labour. Fig. 9 illustrates one mode of attaining these ends adopted in the Kerperly producer. The central grate used for admission of the blast revolves mechanically in the ash bed, affording little hold for any pieces of clinker or bringing a shearing stress to bear upon them with a disintegrating effect. The outside shell of the producer is lined with fire-brick in the ordinary way in its upper half, but in the lower half is constituted by what is in effect an annular boiler, with no brickwork lining. Clinker cannot form in the same way on the comparatively cold metal surface of such a water jacket as it can on a hot surface of fire-brick, which is itself practically as hot as the coke and ash in contact with it. The steam raised by the annular boiler can be used for the blast. (This combination of mechanical grate and water-cooled sides is also coming into use for water-gas generators.) The ash in the arrangement as shown in fig. 11 is delivered into a water trough below, which provides a seal and a convenient channel from which the ash is automatically scooped. Details differ and a dry revolving base without water seal is sometimes employed. The well-being of a producer depends upon keeping the distribution of the blast and the ascending gas current as uniform as possible across the section of the producer, so as to give satisfactory contact in all parts with the descending fuel. Imperfections in this respect, such as the existence of channels up the bed, have their effect in a deterioration in the quality of the producer gas made, indicated by a rise in temperature of the gas leaving the producer. For this reason, the top of the producer is usually provided with a number of poke holes, through which pokers are periodically inserted by the producer man, for the purpose of keeping the fuel bed level, filling up hollows or channels, and breaking up incipient clinkers. In some of the more modern designs this work has been minimized by the introduction of a mechanical revolving poker. In the form introduced by Talbot, the poker was a central vertical shaft running the whole depth of the producer, with two arms, one revolving near the top of the fuel bed and the other just above the grate in the clinker-forming region. This form of poker was difficult to maintain in action over long periods, and it has been simplified by Talbot and others, as indicated in the diagram of the Chapman mechanical producer in fig. g. There the horizontal arm of the poker is shown revolving near the top of the fuel bed. It is not intended to prevent clinkering of ash, but to keep the top of the fuel bed in good working order.

By-product Producer Plant.— For many purposes, producer gas can be used hot from the producer without further cleaning. Indeed, that is so with the great majority of uses to which producer gas is put. If however the gas is generated for use in the gas engine, which is thermally much more efficient than the steam engine, it must be cleaned and cooled. The most complete system for providing washed clean producer gas, and at the

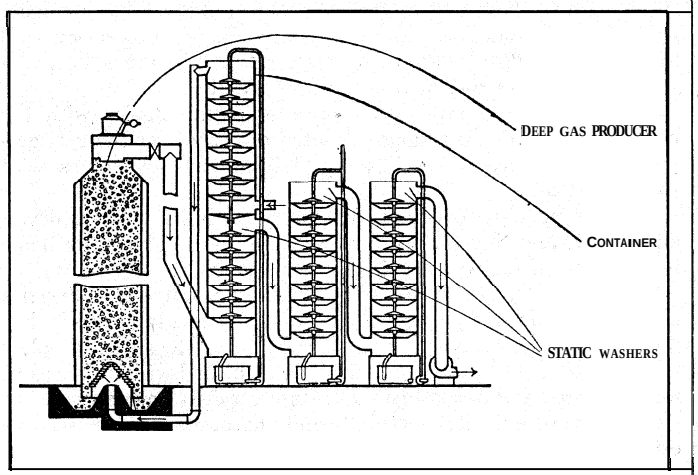


FROM RAMBUSH, "MODERN GAS PRODUCERS" (BENN BROS.)

FIG. 9.— PRODUCER WITH MECHANICAL FEED AND DISTRIBUTOR FOR COAL. AND GRATE REVOLVING IN FUEL BED

same time recovering as ammonia the nitrogen in the coal gasified (to the extent of some go lb. of sulphate of ammonia per ton) is due to the late Dr. Ludwig Mond (1889). The plant he elaborated has been simplified by Lymn and Rambush and is shown in the simplified form in fig. 11. The producer carries a very much deeper fuel bed (say 10 ft. against 5 ft.) than is ordinarily employed, and more steam is employed in the blast, 1 lb. per

ton of fuel gasified, By this means, the temperature of the fuel bed is kept low, and the coal is given a long time of exposure to the ascending gas current, as it gradually descends towards the grate. These conditions favour the production and preservation of ammonia and of low temperature tars. The gas is washed, freed from ammonia, and cooled, by passing in turn through the three Lymn static washers, the ammonia being absorbed



BY COURTESY OF THE POWER GAS CORP

FIG. 10.— DEEP GAS PRODUCER FROM WHICH GAS PASSES THROUGH STATIC WASHERS FOR WASHING. AMMONIA ABSORPTION. AND COOLING

by a solution of ammonium sulphate, maintained slightly acid, and the after-cooling being effected by water. The Lymn washer, which replaced the towers of the original Mond plant, consists of a number of cones fixed to a central shaft, alternating with strips fixed to the outer case of the washer, so that the descending water or liquor is repeatedly forming a falling sheet or shower, through which the ascending gas has to pass. The air blast going to the producer ascends a washer "F," superposed on "C" and is there warmed and moistened by hot water which has been pumped from "C" after abstracting heat from the gas. Gas leaving such a plant is ready for use in furnaces, but centrifugal tar extractors and saw-dust scrubbers are employed in cleaning the gas more thoroughly for use in engines.

The following results have been reported by Lymn (1924) as long-period averages using a Durham coal containing 8·0% of ash:

Gas analysis	Carbondioxide	8·3%
	Carbon monoxide	21·0%
	Hydrogen	20·5%
	Methane	4·9%
	Nitrogen	45·3%
B.T.Us. net to cu.ft.		178
Gas efficiency	Cal. val. of gas (netto) / Cal. val. of coal (netto)	80%
Average gas yield (cu.ft.) per ton of dry fuel gasified		122,000
Average ammonium sulphate yield per ton of dry fuel gasified		90 lb.
Average yield of dry tar per ton of dry fuel gasified		21 gal.
Steam into producer per lb. of dry fuel		1 lb.

When ammonia recovery is not attempted, the process of washing and cooling is simplified. A washed producer gas has advantages for many uses in that its control can be made so much more precise and its subdivision for heating purposes so much more readily effected than with gas straight from the producer. Distribution, moreover, is much simplified, so that for example in south Staffordshire a scheme is in operation for distributing producer gas in pipes over a considerable area. Even in a works it is an advantage to be able to convey the gas in steel or cast-iron mains, which drain themselves of all impurities, rather than firebrick lined conduits, in which tarry and dusty deposits accumulate, necessitating periodical clearances, by burning out, or other methods.

Suction Producers.— Many producer-gas plants are made for power purposes (Dowson, National) and washed producer-gas finds one of its most characteristic applications in the provision of gaseous fuel for isolated gas engine units. In the smallest plants for this purpose, the so-called "suction gas plants," it is the suction stroke of the gas engine which is relied upon to draw air through the fuel-bed of the producer.

The gas on its way to the scrubber passes through a vertical water vaporizer, which provides all the steam required. Water is supplied to the scrubber and the gas passing up it is both cleaned and scrubbed.

Blast Furnace Gas.—The blast furnaces used for the production of pig-iron may be regarded as very deep air-blown gas producers, from which the quality of the gas is lowered to some 90 or 100 B.T.U. per cu.ft., by the oxidation which much of the carbon monoxide undergoes in reducing oxide of iron to the metallic state.

There are some special types of gas producer which have not been described. In one, invented by Dowson, air is drawn in both at the top and bottom of the fuel bed and the gas is collected in nostrils, which open into the producer half way down, where the fuel is red hot. By this means, the amount of tar in the gas is lessened, but the gas of necessity leaves the producer very hot and there are difficuities in keeping the gas exits open for the free passage of gas. In another special type of producer, the ash is run off as a liquid slag. No steam is employed in that case, since a very high temperature is a working necessity, and it may even be necessary to add some flux along with the coal.

BIBLIOGRAPHY.—Among books dealing with gas manufacture are: Alwyne Meade, *Modern Gasworks Practice;* and W. B. Davidson, *Gas Manufacture.* Producer gas is treated of by N. E. Rambush, *Modern Gas Producers;* and Dowson and Larter, *Producer Gas.* More general are Bone, *Scientific Uses oi Coal;* and Haslam and Russell, *Fuels and their Combustion.* The *Transactions of the Institution of Gas Engineers* and *Proceedings of the American Gas Association,* the *Gas Journal* and *Gas World,* are periodicals dealing specially with gas manufacture. (J. W. C.)

GAS SUPPLY IN THE UNITED STATES

In the little more than 120 years since the first gas company was organized in the United States, the gas industry has developed into one of the key industries. It has not only expanded until to-day gas service is known in practically every town but it has also gone through a complete metamorphosis, and from a light-producing industry has emerged as a heat-producing one, selling a service which is rapidly growing in popularity for every kind of domestic and industrial heating. This industry is represented by 429 manufactured gas companies and 805 natural gas companies Eighty-one million people are served. Of the 1,234 plants, 1,174 are privately owned, and 60 are municipal plants owned and operated by cities. While municipal ownership in the gas industry has never been popular in the United States, it is becoming even less of a factor every year.

The First Gas Plants.—Following the discovery of how to make gas from coal and the unparalleled success of gas lighting in one or two European cities, it was in Baltimore that gas lighting got its start in the United States. Although there were a few isolated instances of gas being used by individuals in other cities previously, introduction of gas lights in Rembrandt Peale's museum in Baltimore in 1816 proved to be such a sensation and success that the city council passed an ordinance on June 17, 1816, permitting Peale and others to manufacture gas, lay pipes in the streets and contract with the city for street lighting. The first recorded demonstration of gas in the United States was in Philadelphia in Aug. 1796. The gas was manufactured by M. Ambroise and Company, Italian fireworkers and artists. A few years later, in 1812, David Melville of Newport, R.I., lighted his home and the street in front with gas which he manufactured. He also lighted a factory at Pawtucket and induced the Government to use gas at Beaver Tail lighthouse.

Baltimore, however, was the first city to use gas commercially, and other cities followed her lead. Introduction of gas lighting was not rapid. Since it was a radical change from the common methods of lighting of those days, it was regarded with fear by many people. As many objections were made against it in the United States as had been made in London when introduced there.

Gas was used first for street lighting. Later public buildings were lighted in this way, and a few wealthy citizens also used gas to light their homes. It was not until between the years 1865 and 1875 that the use of gas for home lighting began to make any great progress.

Manufactured Gas — The first authentic recorded use of gas for domestic purposes was about 1830 or 1832, when James Sharp, of Northampton, England, demonstrated the availability of gas for cooking in his own home. It was about the year 1859 when gas started to be used to any extent for cooking in the United States, and this was done chiefly on stoves imported from England.

Much interest was manifested at an exhibit of different types of gas stoves shown at the Centennial Exhibition, held in 1876, in Philadelphia.

Many of the exhibitors used gas stoves in connection with their exhibits.

The latter part of the 19th century saw the gas industry of the United States firmly entrenched as a utility furnishing light to homes and factories, with the domestic cooking business more or less in the nebulous stage. It was at this time, however, that the industry was given a severe blow, probably the worst that has ever been dealt to an industry in the history of American business enterprise. It was the advent of the electric light which caused consternation, and yet it was this same electric light which was responsible for placing the industry in its present place of importance.

In the face of the keen competition the electric light would offer, it was apparent that the gas companies would have to look for other fields to conquer. Today, some 60 years after the invention of the electric light, gas has establish'ed a record for itself as a fuel and both homes and industries use this smokeless fuel for thousands of purposes.

Just at the turn of the 20th century, the industry had the domestic-cooking business as a base load, and soon other fields of heat application were developed, until today there is hardly a heating process, in the home and in any industry, which cannot be and is not being done with gas.

The sales of gas for the year 1937 revealed an increase of about 9,000,000,000 cu.ft. over the total registered for 1936. The sales figure was 351,000,000,000 cu.ft., proportioned as follows:

About 196,000,000,000 cu.ft. for household purposes, 107,400,000,000 cu.ft. for industrial and commercial uses, 45,600,000,000 cu.ft. for house heating, and 2,100,000,000 cu.ft. for miscellaneous purposes.

The use of manufactured gas for commercial and industrial heating applications continues to show phenomenal growth, the amount consumed in 1937 representing 31% of the total sales of manufactured gas for all purposes, or an increase of 7,324,000,000 cubic feet.

Manufactured gas companies now serve 9,949,000 customers. Miles of main total 92,295, invested capital $4,500,000,000, and gross operating revenue $363,000,000.

Natural Gas. — This industry is a large and important business in the United States. The total amount of natural gas produced in 1937 amounted to 2,447,620,000,000 cubic feet. In 1937 there were 7,006,000 consumers of natural gas, who used a total of 1,314,493,000,000 cu ft. of natural gas. The estimated total revenue from such uses was $442,000,000. The State of California has the largest number of consumers of natural gas, followed by Ohio and Pennsylvania.

It is estimated that in 1937 there were 16,005,000 gas ranges, 1,125,000 gas refrigerators, and 735,000 gas-fired central house heating installations in use in the United States. Although gas has been used for cooking to the largest extent, it is only one of the conveniences which are available to the modern American home through the use of gas. Automatic hot water supply is growing in use, and many of the most up-to-date homes have adopted the incinerator as an aid to cleanliness and sanitation. House heating by gas is a development which promises to do more than any other recent achievement to relieve the American home from back-breaking labour exerted merely to provide heat in the house.

Gas house heating is completely automatic — it requires no attention. Cities having natural gas service have used this splendid fuel for house heating and auxiliary heating to the exclusion of all other fuels, but in the manufactured gas territory the premium over coal operation has prevented the general adoption of gas up to this time. This use is growing very rapidly. To eliminate noise, ensure freedom from interference with radio reception, and to provide an ideal method for refrigeration, there has been developed the gas operated automatic refrigerator.

This unit is also available as a combination device with the cabinet type of kitchen range mounted directly over the refrigerator, an appliance which has especial interest for homes with small kitchens.

The completely gas-equipped laundry with its washer, dryer, and ironer, reducing the work of washing and making the home independent of the weather, is also very popular.

In late years, the manufactured and natural gas industries have become, in many respects, substantially one large gas industry, and many communities which were formerly supplied solely with manufactured gases are now being furnished with mixtures of manufactured and natural gases or with straight natural gas.

The combined manufactured and natural gas industry is estimated to represent a total capital investment of close to $5,000,000,000.

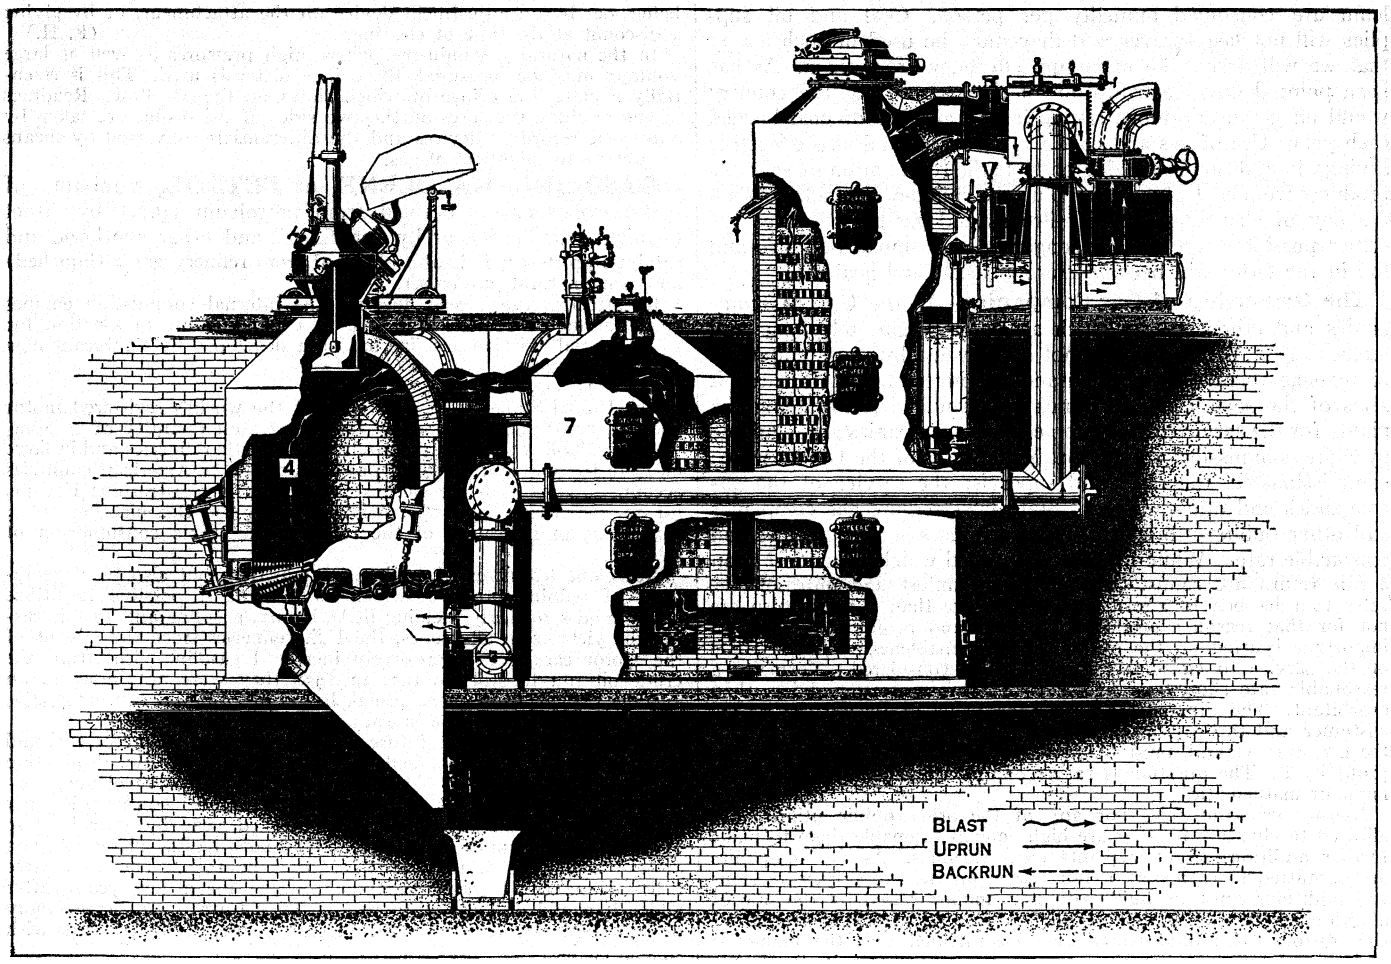
Use **of** Gas. — No true concept of the gas business can be secured without referring to the growing use of this fuel in industry, and the important part it is playing in the manufacturing world. A study of the stocks and bonds listed on the New York Stock Exchange and Curb Market fails to reveal any industry that cannot use gas profitably in some of its manufacturing processes. Yet such a list could be extended by thousands, gas having more than 21,000 uses in industry.

The chief advantages gas offers are as follows: Improvement in quality and economy in manufacture of the product, owing to perfect heat control; marked increased production; fuel storage space eliminated; elimination of capital tied up in fuel investment; elimination of smoke and end of the ash removal nuisance.

The Ford Motor Company plant at River Rouge alone uses approximately 50,000,000 cu.ft. of gas a day. This is enough to supply a city of 5,000,000 population. A typical industrial gas installation will consume as much gas in one day as 500 average homes. Gas is being used extensively for baking bread in large bakeries, making candy, roasting coffee, smoking meat, pasteurizing milk, pressing clothes, singeing cloth and yarn, melting glass and many different kinds of metal, vulcanizing automobile tires, drying clothes and lumber, forging, heating rivets, galvanizing, welding, cutting metal, annealing, hardening and tempering alloy steel, tool dressing, bolt and rivet making, shrinking locomotive tires, heating structural steel for fabrication, bending pipe, plate heating, soft metal melting, aluminium melting, lead refining, silver refining, in treating various metals in ovens and for many other purposes.

While the use of gas for heating homes was started in America but a few years ago, there are today many scores of thousands of installations of central gas-fired units, exclusive of the millions of space heaters in use. It is estimated that Chicago has over 20,000, and other cities boast of more than 1,000 homes that are heated entirely with gas, and in addition natural gas zones with all homes heated by natural gas. Supplying a heating service that is in most localities not so expensive as to be prohibitive, the gas companies are preparing themselves to take on installations at a rate two and three times in excess of what they have in the past. Using gas for house heating one obtains a service entirely automatic in character, free of labour, dirt, smoke, dust and ashes. Recent years have seen the use of gas heating developed in the so-called skyscraper. A large building in Boston, 13 storeys high, 2,175,000 cu.ft. in size, is heated by manufactured gas.

A most important step taken by the gas industry in behalf of its domestic customers was the establishment of a testing laboratory at Cleveland, O., for testing gas appliances. In this manner



FROM THE AMERICAN GAS JOURNAL

FIG. 11.— SECTIONAL VIEW OF A STEERE WATER-GAS MACHINE WITH BACKRUN, CHARGING MACHINE FOR MECHANICAL FUELING. AUTOMATIC GRATES, THREE-WAY BACKRUN VALVE AND WATER SPRAYS IN THE SUPERHEATER FOR MAKING BACKRUN STEAM AND LOW GRAVITY GAS

The arrows indicate the course of the gas-making cycle. Wavy arrows show the blasting, which heats the fuel bed in the generator (4) to gas-making condition. In so doing a producer gas is made which in turn is cansumed as secondary air is admitted in the top of the carburetor (7). This combustion heats the checkerbrick in the carburetor and superheater to proper temperatures for cracking or gasifying the oil which is sprayed into the machine at the top of the carburetor during the uprun. Straight arrows show the path of the uprun and the arrows formed with dashes, the course of the backrun. An ordinary gas-making cycle is: blasting, two minutes; uprun, 1¼ minutes; backrun, 1½ minutes, then a final uprun of ¼ minute

the American Gas Association has met the obligation of the industry to the American people for the safest, most efficient and most economical utilization of its product. The laboratory is financed by a large number of gas companies and manufacturers of appliances, and into it has been built the hopes and aims of the industry to serve the public to the best of its ability. In this laboratory are being tested for the information of manufacturers, gas companies, dealers and the general public, all manner of appliances in which aas is burned for domestic uses.

THE FUTURE OF GAS

The Passing of Coal as Fuel.— Leaders of American industry believe, and are constantly preaching, a coming era of effective conservation of all natural resources and efficient and economical use of the public services. They foresee the time not only when oil will be reserved for purposes of transportation by land and sea and air, but also when the burning of raw fuel of any kind, including coal, will be forbidden. They believe that the necessity for conservation, together with the growing sense of the economic waste and the loss of health and efficiency as a result of smoke, will result in coal being used exclusively as a raw material rather than as fuel. It is believed that perhaps 70% of the potential efficiency of coal is wasted in the average home and anywhere from 25 to 75% in industrial plants. **A** ton of coal used in the manufacture of gas will produce approximately 1,400 lb. of smokeless fuel (coke), 10,000 cu.ft. of gas, 25 lb. of ammonium sulphate, 1½ gal. of benzol, and 10 gal. of tar.

Air Pollution **by** Coal Smoke.— Smoke pollutes the atmosphere, injures the health and destroys property. It is claimed that more persons are devitalized, disabled and poisoned by the impurities contained in smoke-polluted air than by the noxious ingredients in food or water. Density of atmospheric smoke increases pneumonia and causes other illnesses. As smoke diminishes sunlight and increases the humidity during both cold and warm weather, it is certain it exerts an important influence upon the health of all persons who live in a smoky city. The Mellon Institute estimates the annual smoke loss and damage in Pittsburgh is $10,000,000, or almost as much as the city's yearly bill for domestic fuel. Since Chicago has nearly five times the population of Pittsburgh, it is probably a conservative estimate to put the annual cost of smoke damage in that city at $20,000,000, or nearly double that of Pittsburgh. The total volume of air-diluted gases discharged from smoke stacks in Chicago each day amounts to approximately 47,000,000,000 cu.ft., or 58 times as much as the average daily consumption of manufactured gas.

Smokeless Cities Possible.— Conservation of our natural resources, including coal, is one of the big problems of the age. Few people realize the enormous amounts of coal and oil burned every year. Back in the days of the Civil War, roughly 33,000,000 tons of coal were produced annually and the consumption of petroleum, which was then just coming into use, was about ⅔ gal. per caput. Today, about 3.8 tons of coal and 139 gals. of petro-

leum are consumed annually per person. Coal and oil supplies will not last forever and they must be used in such a way that we will derive the maximum efficiency from them. As has been pointed out, electrification of the railroads of the country would effect an enormous ,saving in the amount of coal burned each year. Use of gas and coke for heating would also effect-big savings, in addition to making possible the reclamation of valuable products from coal which now go up the chimney as smoke. When the day of electrification of railroads and gas-heated cities becomes possible there will no longer be any smoke nuisance and life in the cities will become more pleasant and healthful.

The Ownership **of** Gas Companies.— In the U.S. gas companies and other utilities, such as electric light, telephone and street railway companies, are not only owned by those employed to manage them, but by thousands of investors. It is through sales of the securities that funds are provided for building the plants for the service of the people. These companies are regulated by State commissions in practically all States of the Union, which commissions fix the rates and supervise the service of the gas companies and other utilities. State laws require gas companies and other public utilities to render adequate service at just and reasonable rates. While rates thus imposed which afford less than a fair return are confiscatory and hence unjust and unreasonable, rates that happen to afford something more than a fair return are not for that reason exorbitant. Earnings and profits may have an important bearing on the question of reasonableness, but the value of the service to consumers must also be considered. Normally a reasonable rate should be higher than compensatory and less than exorbitant. The difference between the value of the service to the customer and the cost of producing and selling it, including cost of the necessary capital, must be equitably divided so that both parties profit by it. The question is rather one of economics than of arithmetic or mathematics.

Neither gas companies nor any of the other public utilities are allowed to charge rates that are high enough to enable them to make further additions to their plants from earnings. As the companies are permitted to earn only a fair return on the property, extensions and additions must be built with new money raised by the sale of additional securities. These securities are sold after the regulatory commissions have investigated and are satisfied that the money is to be spent for needed improvements. (A. FOR.; R. B. HR.)

GAS METER. The quantity of gas which flows through a pipe is measured either by a dry or a wet meter, the latter being used to a far less degree than the former, although for big station meters the wet system is employed.

Briefly, a *wet meter* has a revolving drum divided into compartments, more than half the drum being submerged in water. The compartments are alternately filled with gas and then emptied during the revolution, and by knowing the cubical capacity of the compartments, the amount of gas passed during a revolution is also known, and can be read by a suitable registering apparatus.

The *dry meter* is a more convenient type registering apparatus for long periods. The principle is derived from the original type of Thomas Glover & Co. Ltd., Edmonton, London, and comprises an arrangement of double bellows, made of Persian sheepskins. These are attached to disks in such a manner, and so connected to valves, that alternate filling and exhausting of the bellows occurs, and the pulsations are transmitted by a train of gearing to the index dials. The simple adjustment of a pin enables the-meter to be set to cbmpare accurately with a standard meter.

GAS METER. THE INDEX IS READ BY TAKING THE FIGURE BEHIND EACH HAND. THUS 874, AND ADDING TWO CIPHERS

Another type is the *votary meter* which is utilized for station registration. The stream of gas passes through a fan wheel, the revolutions of which are communicated to the gearing of the recording mechanism. Special kinds of small meters are constructed also for testing purposes.

On the ordinary meter index there are four dials, a top one showing when a small quantity has passed—say 2ft. or 5ft., and three others as illustrated, from which the reading is taken. The hands of the outer dials move in the direction of the hands of a clock, that of the centre one in the opposite way. In reading, the figure behind each hand is noted, and two ciphers added to the three numbers; thus 8, 7, 4, indicates 87,400 cubic feet.

Prepayment meters are of two classes. In one the prepayment is made to an inspector, who then sets the meter to pass the corresponding value in gas. The other has a coin attachment, the insertion of the coin giving a certain amount of gas, changes in the price of gas being met by an adjustment device on the attachment, or by giving a discount at the time of clearing. (F. H.)

In the natural gas industry, where high pressures as well as large volumes must be measured, the orifice meter is used. This is essentially a plate, the orifice of which slows up the gas flow. Readings of the resulting pressures on the two sides of the orifice are taken by automatic recording devices and the differentials converted by means of tables into cubic feet of gas.

GASOLINE, GASOLENE, or **PETROL,** a mixture of hydrocarbons chiefly derived from petroleum (*q.v.*) by direct (straight) distillation or by "cracking" and other synthetic and catalytic processes; it is also obtained from refinery gases (liquefied) and from natural gas (*q.v.*).

Its principal use is as a fuel for the internal combustion engines (*q.v.*) of motor vehicles, and it is in expanding use in aviation for which special aviation gasoline has been developed by significant new refinery processes.

See PETROLEUM.

The United States, with over 68% of the world's registered motor vehicles, needs and consumes by far the greatest quantity of gasoline, which is supplied practically entirely by domestic refineries and in large measure by domestic crude oil production. Other American countries account for 5.12% of the world's motor vehicle registration; Europe, for 20.9%; Africa, for 1.5%; Asia, for 1.5% and Oceania, for 2.6%; this being an indication of the relative geographic consumption of gasoline.

Not alone by increased crude oil production, but also by development of refining processes which have made it possible to utilize heavy crudes formerly yielding little, if any, gasoline and by increasing the yield from all crudes, the U.S. refineries since the advent of the motor car have progressively increased gasoline yield from the crude oil run to stills so that in 1938 they were obtaining on an average 18.6gal. from every 42-gal. barrel of crude oil run, or 44.2%, as against 10.5gal. or 25% in 1915.

An analysis of probable future **U.S.** consumption of motor fuel and crude oil requirements entailed was made in 1935 by the Production Sub-committee on Future Demand of the American Petroleum Institute. It was shown that the trend of motor fuel consumption per automobile unit had been definitely upward year by year because of greater year-round driving and better roads, having increased from an estimated 525gal. in 1918 to 690gal. in 1935. The committee believed the trend would continue upward for a few years, after which it would decline due to the tendency toward greater economy of operation exemplified by the increasing use of lighter cars with smaller engines and with the further probability of some slight increase in compression ratios and the addition of super-chargers. A probable peak of 730gal. in 1940 was estimated, with the curve downward thereafter to a figure of 670gal. per unit in 1960. It was the opinion of the committee that by 1960 practically all heavy trucks and buses would be propelled by Diesel engines, using Diesel or fuel oil. Analysis of U.S. Bureau of Public Roads reports on consumption of motor fuel revealed that about 90% of all gasoline consumed was consumed by motor vehicles and the balance of 10% went for other uses. On the basis of unit consumption estimates and probable motor vehicle registration, the committee estimated the total future motor fuel demand as follows:

Total Estimated Future Gasoline Demand

(Thousands of U.S. Barrels of 42 Gal. Each)

	For Passenger Cars, Trucks and Buses	For Other Uses	Total
1935	388,800	43,200	432,000
1940	507,492	56,388	563,880
1945	539,910	59,990	599,900
1950	572,913	63,657	636,570
1955	582,444	64,716	647,160
1960	591,741	65,749	657,490

Not all this gasoline would come from crude oil direct, as natural gasoline production averaged about 40,000,000bbl. per year and benzol (from coal) about 2,000,000bbl. per year, and an increase in these sources to 48,000,000bbl. in 1960 was believed probable. The committee estimated that the yield of gasoline from crude oil would be increased and the crude oil requirements to meet the increased future gasoline consumption therefore be proportionately lessened, as shown in the following table:

	Gasoline Yield from Crude Oil (Per Cent)	Crude Oil Requirements (Thousands of Barrels)
1935	43.8	919,500
1940	48.0	1,099,000
1945	51.0	1,104,080
1950	54.0	1,109,800
1955	56.0	1,087,930
1960	58.0	1,071,020

The evident tremendous growth of aviation in military and commercial application which is now in process will undoubtedly greatly increase the proportion of gasoline needed for this purpose, as well as raise estimates of probable future gasoline consumption. Aviation gasoline consumption in the United States totals only about .4% of

the entire gasoline consumed, divided as follows: For commercial aviation, .24% and for the Army Air Corps, National Guard, Bureau of Aeronautics, Navy Department (including Marine Corps), U.S. Coast Guard, and Bureau of Air Commerce .16%.

Gasoline consumed by agriculture in the United States accounts for about 5.53% of the total gasoline consumption, divided as follows: For tractors 4.42% and for other farm uses 1.11%. Highway construction agencies consume 1.03% and other construction operations 1.06%. About .3% is consumed by manufacturing industries; .28% by the U.S. Government; .08% for dry cleaning; .02% by the railroads. Use of gasoline by boats is extensive but only a small percentage of the total gasoline consumed. There are nearly 250,000 motor boats registered in the United States, all fueled by gasoline. These and other marine uses account for about .16% of the total gasoline consumption.

BIBLIOGRAPHY.—American Petroleum Institute, *American Petroleum Industry* (1935) and *Petroleum Facts and Figures* (1939); H. A. Breakey, unpublished thesis, "Motor Fuel Demand in the U.S." *(See* also PETROLEUM: *Bibliography.)* (L. M. F.)

GASOLINE PRESSURE APPLIANCES. These appliances have come into wide and varied use in the United States and in many other countries, and have largely superseded the so-called gas machine making air-gas which came into considerable use earlier in the century. Gas machines are used to some extent, principally in rather large buildings or institutions, in more or less isolated localities where natural or manufactured gas is not available, but for home and other uses they are no longer in wide employment as, in addition to the inroads made by gasoline pressure appliances, "bottled gas" (*q.v.* under PETROLEUM), principally propane, and in some instances mixtures of propane and butane, has made heavy inroads on the market formerly supplied by gas machines and air-gas.

The first step in the development of the use of gasoline for lighting, heating, and cooking was the gas machine, which, using a special "cut" or fraction of natural gasoline, was installed on or near the premises and carburetted air with the vapour of the highly volatile gasoline into so-called air-gas which was piped to stove, lighting fixtures, etc. After the gas machine had been in use a number of years, the method of converting gasoline into a combustible gas was changed and heat was used to gasify the liquid. What was known as the centre generator system was developed. In this, liquid gasoline was ied under pressure to a generator, where through the application of heat it was gasified and conducted through about 1½in. tubing to the various appliances.

The next step was to make each appliance a gas generator in itself. This was known as the hollow wire system, and the gasoline was ied to each individual light through a very small copper tubing. There the application of heat gasified it. Neither of these systems is in common use in the United States today, although in some other countries the hollow wire system is in demand.

The final and present step was the portable lamp, lantern, and stove. Here the unit is complete in itself, the gasoline being under pressure in a fount and generated into gas from the heat of the mantle or burner. The stoves have been developed from a crude stove into a modern range resembling in all ways the modern gas or electric range. Utilization of the many types of gasoline pressure appliances is not alone confined to sections and countries devoid of natural or manufactured gas, but bas been stimulated by the growth of automobile travel, these devices in various forms being used in trailers, for camping and, along the road, by "hot dog" stands. Some idea of the variety of uses made of these burners is given as follows: Poultry-men for incubators and brooders; dairymen, for steaming and sterilizing; stockmen, for stock food cookers and for warming water in stock tanks; show concessions, for "hot dog" stands, lunch counters, candy and popcorn machines; restaurants, hotels, coffee shops, road stands, under hot plates, coffee urns, steam tables and water heaters; barber and beauty shops, to provide hot water; print shops, to melt metal; school laboratories, as an economical means of supplying each student with an individual heating unit for demonstrations and experiments; plumbing, tin and tire shops, for vulcanizing, melting metal, and soldering; doctors and dentists, for heating and sterilizing; miscellaneous uses, for steam boiler;, canning machines, street dining cars, wall paper removers, steamers for beer fountains, road tarring machines, roofer's tar machines, spaghetti mahing machines, candy and doughnut kettles, and clothes and hat cleaning machines. For household use, gasoline pressure appliances include modern ranges, water heaters, floor furnaces, radiant heaters, self-heating irons, lamps. and gas lighting fixtures.

The gasoline used in these appliances is straight-run gasoline. usually the lowest priced gasoline sold by the oil companies. With the increasing use in the United States of tetra-ethyl lead in motor fuels, extending more and more into the lowest straight-run grades, a problem has been presented in eliminating leaded gasoline from this field. Manufacturers have advocated that refiners designate a product for gasoline pressure appliances, and in the meantime the United Laboratories, Wichita, Kan. issue a list of gasolines approved as fuels for gasoline pressure appliances in the United States from which all known leaded brands are eliminated. The estimated fuel requirements to operate gasoline pressure appliances manufactured and sold during 1936 and 1937, based on sales reported by six of the leading manufacturers which are member companies of the United Laboratories, are show-n in Table *I.* (L. M. F.)

TABLE *I.—Estimate of Fuel Required to Operate Gasoline Pressure Appliances Manufactured and Sold During 1936 and 1937 Only, Based on Sales Reported by United Laboratories Metnber Companies*

Type of Appliance	App. total No. of appliances sold in 1936–37 by 6 mfrs.	Aver. fuel rate		Est. av. hrs. used per day	Est. av. hrs. used per year	Est. gal. each uses per year	Est. total gal. used per year
		hrs./gal.	gal./hr.				
Lamps and lanterns	447,651	40·	0·025	1¾	650	16·0	7,162,416
Gasoline irons & blow torches	236,707	33'	0·03	3.2 hrs. wk.	166	5·0	1,183,535
Camp stove?	251,095	7·	0·14		75	10·5	2,636,497
Radiant heaters and/or hot plates	56,752	6·	0·16	5 hrs./day 100 days	500	80·0	4,540,160
Misc. burners	44,510	4·	0·25	3·0	900	225·0	1,112,750
Cook stoves and ranges	204,845	6·0	0·16	3·43	1,250	200·0	41,969,000
Total gallons per year							58,604,358

Authority: United Laboratories, Wichita, Kansas.

GASPARRI, PIETRO (1852–1934), Italian cardinal, was born at Capovalazza de Ussita on May 5, 1852. He received the degree of doctor of philosophy, theology and canonical law after study at the pontificate seminary at Rome, and from 1880 to 1898 was professor of canonical law at the Catholic Institute in Paris. In 1904 Piux X., having decided to codify the canonical law, confided to Gasparri the direction of the work. In 1907 he was made cardinal and in Oct. 1914 Benedict XV. appointed him secretary of state, which office he held throughout the arduous World War period and the almost equally strenuous reconstruction period which followed. He was retained by Pius XI. and in 1926 began negotiations which resulted in the Vatican Treaty. He resigned Jan. 1930, and was succeeded by Cardinal Eugenio Pacelli.

GASPÉ, a peninsula in the Gulf of St. Lawrence and a district in the province of Quebec, Canada. *(See* QUEBEC.)

GASQUET, FRANCIS AIDAN (1846–1929), English Roman Catholic cardinal and historian, was born in London Oct. 5, 1846. He was educated at Downside College, Bath, afterwards becoming superior of the Downside Benedictine monastery (1878–84). Created cardinal in 1914, in 1918 he was appointed prefect of the Vatican archives. Cardinal Gasquet was president of the international commission for the revision of the Vulgate. He carried out extensive researches in English history from mediaeval times to the Reformation. He died in Rome on April 5, 1929.

GASSENDI, PIERRE (1592–1655), French philosopher, scientist and mathematician, was born of poor parents at Champtercier, in Provence, on Jan. 22, 1592. He studied at Digne and at the University of Aix, returning to Digne as a lecturer in theology in 1612. Five years later he took holy orders, and was called to the chair of philosophy at Aix.

After 1628 Gassendi travelled in Flanders and Holland. During this time he wrote, at the instance of Mersenne, his examination of the mystical philosophy of Robert Fludd *(Epistolzca dissertatio in qua praecipua principia philosophiae Ro. Fluddi deteguntur,* 1631), an essay on parhelia *(Epistola de parheliis)*, and some valuable observations on the transit of Mercury which had been foretold by Kepler. He returned to France in 1631, and two years later became provost of the cathedral church at Digne. Some years were then spent in travelling through Provence with the duke of Angoulême, governor of the department. The only literary work of this period is the *Life of Peiresc.* In 1642 he was engaged by Mersenne in controversy with Descartes. His objections to the fundamental propositions of Descartes were published in 1642; they appear as the fifth in the series contained in the works of Descartes. In these objections Gassendi's tendency towards the empirical school of speculation appears more pronounced than in any of his other writings. In 1645 he accepted the chair of mathematics in the Collège Royal at Paris, and lectured for many years with great success. In addition to controversial writings on physical questions, there appeared during this period the first of the works by which he is known in the history of philosophy. In 1647 he published the treatise *De vzta, moribus, et doctrina Epicuri libri octo.* The work mas well received, and two years later appeared his commentary on the tenth book of Diogenes Laertius, *De vita, moribus, et placitis Epicuri, seu Animadversiones in X. librum Diog. Laër.* (Lyons, 1649; last edition, 1675). In the same year the more important *Syntagma philosophiae Epicuri* (Lyons, 1649; Amsterdam, 1684) was published. Gassendi died at Paris on Oct. 24, 1655.

Like Bacon, Gassendi urged the importance of experimental

research, but he added little to our knowledge of physical science. In philosophy he opposed the blind acceptance of Aristotle, revived atomism and advocated an empirical realism. But he was not a consistent empiricist, for while he constantly maintains "that there is nothing in the intellect which has not been in the senses," and that the imaginative faculty is the counterpart of sense, he at the same time admits that the intellect, which he affirms to be immaterial and immortal, attains notions and truths of which sensation or imagination can give us not the slightest apprehension. (*Op.* ii. 383.) He instances the capacity of forming "general notions" and universals, the notion of God and the power of reflection.

The first part of the Syntagma *philosophicum,* which exhibits Gassendi's critical ability, his wide reading, and also his deficiency in speculative power, contains at least one praiseworthy portion, a sketch of the history of the science. It also contends that the true method of research is the analytic, rising from lower to higher notions, though it admits that inductive reasoning, as conceived by Bacon, rests on a general proposition not itself proved by induction. In the second part of the *Syntagma,* the physics, he approves of the Epicurean physics, but rejects the Epicurean negation of God and particular providence, and of an immaterial rational soul, endowed with immortality, capable of free determination, and specially created. The hypothesis of the *calor vitalis* (vital heat), a species of anima *mundi* (world-soul), which is introduced as physical explanation of physical phenomena, does not seem to throw much light on the special problems which it is invoked to solve Nor is his theory of the weight essential to atoms as being due to an inner force impelling them to motion in any way reconcilable with his general doctrine of mechanical causes. In the third part, the ethics, there is little beyond a milder statement of the Epicurean moral code, and a mass of historical quotations. The final end of life is happiness, and happiness is harmony of soul and body (*tranquillitas* animi et *indolentia corporis*).

BIBLIOGRAPHY.—Gassendi's collected works, including his correspondence and a life by Sorbière, were published by Montmort, 6 vols. (Lyons, 1658). An untrustworthy abridgment of his philosophy was given by his friend, the celebrated traveller, Bernier, *Abrégé de la philosophie de Gassendi,* 8 vols. (1678). *See* also Bougerel, *Vie* de *Gassendi* (1737); Damiron, *Mémoire sur Gassendi,* and *Mémoires pour servir à l'histoire de philosophie au XVII^e siècle* (1858); G. S. Brett, *Philosophy of Gassendi* (1908); *P.* F. Thomas, *La Philosophie de Gassendi* (1889); Ritter, *Geschichte der Philosophie,* x.; Feuerbach, *Gesch. d. neu. Phil. von Bacon bis Spinoza,* 127–150; F. *X.* Kiefl, P. *Gassendis Erkenntnistheorie und seine Stellung zum Materialismus (1893);* and Delambre, *Hist. de l'Astronomie,* vol. ii. (1821), for his astronomical contributions.

GAS STOVES. Many kinds of gas-consuming appliances are commonly included under this heading. The main types in general use are the gas-cooker and the gas-fire, and each of these is manufactured in many different forms. Gas-fired water-heaters, radiators, boilers for central-heating purposes, furnaces and many other gas-consuming contrivances are also employed in houses, offices, factories, hospitals, etc.

The Gas-Cooker.—As usually manufactured, the gas-cooker consists of a gas-heated oven, combined with a hot plate provided with boiling burners, and some form of griller. Many years of experiment have brought the appliances to a high degree of efficiency, with the result that they are very freely used. It is estimated that in Great Britain alone there are six to seven million domestic gas-cookers in use. It is claimed for the most modern appliances that with town gas at 9d. per therm (*i.e.,* 100,000 British thermal units), the cooking of a varied menu for a family of six persons may be performed at a cost of less than $\frac{3}{4}$d. per day per person.

Gas-cookers are now frequently made with a very high-grade finish in polished metal and nickel-plated fittings. A specially tough vitreous enamel is used to cover both the interiors and exteriors, including the hotplate, and a new process has been adopted by which the enamel is applied cold to castings and fired afterwards, instead of being sprayed on to hot metal. Expansion and contraction do not affect these enamels, and stains can be removed easily without damage to their surfaces.

Gas-cooker ovens are now often fixed at a higher level than in the past, in some cases on stands raised about 6 inches from the floor, and in others about 2 feet 4 inches above floor level. When the oven is raised to eye level, the hotplate is fixed on the same stand at the side of the oven instead of above it.

Nearly all gas ovens are internally-heated, combustion taking place inside the chamber in which the food is cooked. This practice was investigated on behalf of the Lancet, and the principle declared sound. Externally heated ovens have, ho ever, been made. In internally heated ovens one or two bar burners of bunsen type are fixed at the base. When two burner bars are used they are placed at the sides; when one only is provided it is fixed at the back. The oven has adjustable shelves which make it possible for several articles of food to be cooked at one time.

The metal walls and door are insulated with silicate wool, which is packed between the inner and outer casings. The products of combustion and the vapours arising from the food pass away through an opening, which in some cases is situated at the top of the oven and in others at the bottom.

The thermostat supplied with many gas cooker ovens is provided with a revolving knob and pointer, and a numbered dial. By setting the pointer at the figure required for certain cooking processes the cooking is automatically carried out without the necessity of further attention on the part of the user.

The Hotplate.—The bulk of the cooking for the average household is done on the hotplate, which consists of two or more boiling burners and a griller, with bars above to support cooking utensils. The boiling burners are of two kinds—the "drilled ring" and the "spreading flame," each of which has merits. In some cases, both types are used in the same hotplate. The "drilled ring" burner is usually regarded as the better for slow work—especially when solid materials are contained in the saucepan—whereas for plain boiling work, such as heating water in a kettle, the "spreading flame" burner can be employed with advantage in thermal efficiency. The flames can, in either case, be reduced or increased at will to give a large number of variations of heat between the maximum and the minimum.

The common type of hotplate is of "open" form, the cooking vessels being supported above the burners by relatively slender bars or grids so constructed that, while having the necessary strength, they provide the smallest possible surface contact with the flames of the boiling burners. This ensures the utmost economy in gas consumption, because very little heat is conducted away and wasted through the bars, and with gas at gd. per therm, about 14 pints of water may be boiled for $\frac{1}{2}$d.

In the "enclosed" type of hotplate, the burners are covered by a metal plate or plates upon which the vessels stand. With this type of hotplate the amount of gas used for heating a single vessel is greater than when open bars are used, as some of the heat which is passed to the plate is conveyed to the adjoining metal, upon whose surface other and slower cooking operations may of course be carried on. The closed hotplate also provides a smooth surface on which vessels can readily be manipulated. For this reason this type is sometimes preferred for large-scale cooking operations. When cookers are made with closed tops, some detachable plates are provided for removal to permit a kettle or other vessel to be placed directly over the burner flame to hasten the process of boiling. Alternatively, one or more solid plates are frequently supplied with the more popular open-top hotplates for use when specially slow cooking processes are required.

In the kitchens of works' canteens, hotels, hospitals and institutions, separate appliances are usually provided for the carrying out of the various functions of the domestic gas cooker. Among those in common use for large-scale catering are roasting ovens, table hotplates, fish-fryers, pastry ovens, soup boilers, vegetable steamers, instantaneous water-heaters, Bains Marie grillers and toasters, hot closets and carving tables, incinerators, refrigerators, and bread-baking ovens of various sizes up to those nearly 100 feet long, through which the loaves pass on a continuous travelling web of iron plates supported by chains.

Gas Fires.—The gas fire fundamentally consists of :

(1) A horizontal burner with a number of jets which produce a row of intensely hot but silent flames;

(2) What are known as "radiants," superimposed on these jets to become incandescent when the flames burn within them;

(3) A fire-brick back behind the radiants; and

(4) A canopy capable of conveying to a chimney or flue all the products of combustion, and of creating the necessary movement of air to ensure good ventilation.

The details of burner design include regulating devices whereby the correct size, character and silence of the gas flame can be readily produced, and what is known as a "duplex" tap, by means of which some flames may be extinguished while the remainder keep burning. The user is thus able to obtain the exact amount of heat required at any given time. The radiants are made of refractory material specially prepared so that the fire will reach 90% of its full heating power in about five minutes from the moment of lighting, and will radiate at its greatest intensity two or three minutes later. This is due partly to the form of the fuel and partly to its composition. The radiant is of skeleton form, within which the flame burns. It is as slender in construction as possible. but sufficiently strong to withstand a fair amount of rough handling without becoming fractured. Some gas fires are constructed to accommodate "radiants" which are so designed as to simulate the appearance of a coal or coke-fire when burning. The result is obtained by the blackening of portions of the radiants, which are specially made with a backward curve, and by superimposing upon them a layer of solid pieces of refractory material resembling coke. Another type is made to imitate blazing logs of wood.

As gas does not produce soot and its products of combustion are of a vaporous character, the flue area necessary is much smaller than that for a coal fire. By the use of what are called "economy" blocks, suitable gas fire flues can be constructed within the thickness of the party or external walls, rendering unnecessary the provision of brick chimney breasts. Gas fires are low in running cost. It is said that with gas at 9d. per therm, a room 12′ x 12′ may be heated for an hour, with the fire full on, for 1⅛d., the hourly cost being considerably reduced over a period as the room becomes warm.

GASTEIN, in the province of Salzburg, Austria, a side valley of the Salzach, annexed to Germany in 1938, is renowned for its mineral springs. The valley lies at an elevation of between 3.000 and 3,500 ft. and is traversed by the river Gasteiner Ache and the railway which pierces the Hohe Tauern. The principal settlements in the valley are Bad-Gastein and Hof-Gastein. Bad-Gastein is a very celebrated watering-place situated on a shelf between the upper and lower valleys of the Ache at a height of about 3,300 ft. Its thermal springs have a temperature of 113–120° F, are mineral-bearing and radioactive and used as baths for the treatment of nervous diseases, rheumatoid complaints and senile debility. Their medical value has been known since the 7th century but they were popularized by the visits of Wilhelm I. of Prussia and the Austrian Imperial family. On several occasions, notably during the negotiation of the Austro-German treaty in 1879, the town has been the scene of historic political conferences. It is also celebrated for its magnificent waterfalls, the upper, the Kesselfall (196 ft.) and the lower, the Bärenfall (296 ft.). Population 1,040 Hof-Gastein, the capital of the valley commune, lying at a lower level, is also a spa, the waters being conveyed from Bad-Gastein by a conduit. At one time it was, after Salzburg, the richest place in the province owing to its gold and silver mines, worked from the Roman period onwards until the 17th century, since when they have been disused.

GASTER, MOSES (1856–1939), Rumanian Jewish scholar, was born at Bucharest, and educated at Bucharest university, where he became lecturer in Rumanian language and literature (1881–83). His championship of the cause of persecuted Jews led to his expulsion from Rumania, and he came to England, where he held a lectureship at Oxford in Byzantine and Slavonic languages (1886 and 1891), and was for six years (1890–96) principal of the late Montefiore college at Ramsgate. The Rumanian order, *Bene merenti,* 1st class, was bestowed on him for literary achievements. In 1887 he was appointed chief rabbi of the Sephardi communities of England. He retired in 1919.

His numerous publications include: *History of Rumanian Popular Literature (1883);* new edition of Sephardic Prayer-Book with revised English translation (5 vols., 1901–06); *The Hebrew version of Secretum Secretorum of Aristotle* (1908); *The Samaritan Book of Joshua* (1908); *Example of the Rabbis* **(1924);** many Rumanian translations, and contributions to learned journals.

GASTONIA, a rapidly growing industrial city of North Carolina, U.S.A., in the healthful Piedmont plateau, at an altitude of 825 ft.; 100 mi. E.S.E. of Asheville; the county seat of Gaston county. It is served by federal highways 74, 29 and 321, and by Carolina and Northwestern, Piedmont and Northern (electric), and Southern railways. Population was 21,313 in 1940 (18% Negro and 0.7% foreign-born). The principal industry is textile manufacturing, supplemented by machinery manufacturing and service establishments. The 46 cotton mills had a total in 1940 of 700,000 spindles. Textile products, valued at $35,000,000, include cotton yarns, tire fabric, sewing thread, dress goods, rugs, bedspreads, hosiery, drapery material, etc. The state orthopaedic hospital is there. Gastonia was settled about 1872, incorporated as a town in 1876 and as a city in 1910. It has a council-manager form of government.

GASTRIC AND DUODENAL ULCER. A gastric ulcer is situated towards the centre of the stomach or near the pyloric orifice. It is commoner in the female sex. A duodenal ulcer is situated in the duodenum just beyond the pyloric orifice and chiefly affects men. They are produced by the gastric juice which digests a damaged portion of the lining mucous membrane. The cause of this damage is not usually to be found, but sometimes bacteria conveyed by the blood-stream from some focus of infection, or inflammation of the mucous membrane, are responsible. Rarer causes are the blood poisons resulting from burns of the skin, certain purpuric diseases and anaemias, or Bright's disease. A dilated artery or vein may cause thinning of the overlying mucous membrane and finally ulceration and rupture; blockage of an artery by blood-clot, leading to death of a portion of mucous membrane, is a rare cause. An injury is the rarest cause of all.

An acute ulcer is one recently formed. It is single or multiple, varies in size from that of a split pea to about an inch in diameter, and may be quite superficial or extend right through all the coats of the stomach. Acute ulcers, if treated, heal in about three or four weeks, leaving small scars. Sometimes they gradually extend, become thickened, and adhere to adjacent structures, now constituting chronic ulcers.

Chronic ulcer is usually single, and varies in size from that of a sixpenny piece to an area covering a third of the stomach. The liver or pancreas may be exposed by its erosion; and, by contraction during the healing process, the pyloric orifice or duodenum may be obstructed, or an hour-glass contraction of the stomach produced. Such ulcers heal with great difficulty and frequently remain unhealed for years. At any time during its formation or existence acute or chronic ulcer may erode an artery and cause bleeding; or perforate through the stomach wall, with extrusion of the gastric contents into the body cavity giving rise to general peritonitis or a local abscess.

Distinguishing Characteristics. — An acute ulcer is usually characterized by the sudden vomiting of a large quantity of blood (haematemesis) without any warning whatever. The blood lost may amount to as much as two quarts, although not more than half a pint may be vomited. The patient becomes blanched, almost pulseless, and often unconscious. For a few days subsequently black tarry motions (melaena) due to altered blood are passed. In acute duodenal ulcer melaena and fainting are frequently the only signs of bleeding. Sudden perforation without warning constitutes a second type of case, but it is not very common. The patient is seized with violent pain in the abdomen, vomits, and may collapse. In twenty-four hours the abdomen distends with the onset of peritonitis, the temperature rises, and death occurs in four or five days unless the patient is promptly operated upon. In a third class of case the patient has suffered for a longer or shorter time from the symptoms of indigestion before the above catastrophes occur.

Chronic ulcer is characterized by attacks of pain and vomiting extending over a period of from two to twenty years. The attacks

last a few weeks or months and are separated by intervals, in which the patient is quite free from symptoms, or may suffer from constant dyspepsia (indigestion). The pain, which is usually severe, is situated in the abdomen between the breast-bone and the navel, often covers quite a small area, which is tender to the touch, and may shoot through to the back.

In gastric ulcer it occurs from a half to two hours, and in duodenal ulcer up to seven hours, after food. In each case it may awake the patient during the night. The pain is relieved in most cases by eating food or by alkaline medicine. Vomiting is more common in gastric ulcer and relieves the pain. The remaining symptoms are a feeling of fullness and repeating of wind and sour fluid. The bleeding in chronic ulcer is less profuse than in acute ulcer and commonly consists of dark clots and material like coffee-grounds. Perforation is more common in chronic than acute ulcer and more frequently leads to a local abscess. Stricture of the pylorus gives rise to more severe pain and the vomiting of large amounts at infrequent intervals. **A** chronic ulcer may be seen in many cases by the X-rays.

Treatment. — The treatment of bleeding consists in keeping the patient absolutely at rest in bed with light coverings in a cool and shaded room. Sips of cold water only are allowed by the mouth, feeding being entirely conducted by nutrient enemata. When the melaena has stopped, mouth feeding is commenced and the case then treated as all ulcers should be; that is to say in bed for six weeks, the diet being gradually increased through the stages of milk, eggs, cereals, fish, chicken, vegetables, and meat. When on a full diet, the patient is allowed up, and after convalescence given general instructions as to mode of life and diet. Some alkaline medicine is administered two hours after food to neutralise the acid of the gastric juice, which is the chief factor in preventing the healing of the ulcer. Operation is not resorted to in bleeding, but in the case of perforation it is necessary so that the hole in the stomach or duodenum may be stitched up, as this proceeding holds out the only hope of recovery. Operation is also indicated when the medical treatment of chronic ulcer has failed. The ulcer is either cut out, or, if this is impossible, a short-circuiting operation (gastro-enterostomy) is performed. A new opening is made in the stomach, which is joined to the small intestine below the duodenum. By this means the stomach empties itself rapidly, and a free regurgitation of intestinal contents into the stomach keeps the acidity of the gastric contents low. This operation is more particularly useful if the pylorus is obstructed. Relapse after operation occurs in a certain number of cases.

J., The Surgery of the Stomach,* 1914; Osler, *Principles and Practice of Medicine,* 1917; Carman, *The Roentgen diagnosis of Diseases of the Alimentary Canal* (2nd ed.), 1920; Walton, *The Surgical Dyspepsias,* 1923. (C. Bo.)

GASTRITIS, inflammation of the stomach, in which catarrh, or irritation of its mucous membrane, is the most frequent and most readily recognized sign. This may be acute or chronic and depends upon some local or general condition which induces congestion in the walls of the stomach (see ALIMENTARY CANAL).

Acute Gastritis may arise from various causes. The most intense forms, if the patient live long enough, follow the swallowing of corrosive poisons, such as strong mineral acids or alkalis which extensively destroy the mucous membrane. Other, non-corrosive, poisons cause acute degeneration of the stomach wall (see POISONS). Acute inflammatory conditions may be secondary to zymotic diseases such as diphtheria, pyaemia, typhus fever and others. Gastritis may also be caused by the ingestion of food which has begun to decompose, or may result from eating substances which themselves remain undigested. The symptoms consist in loss of appetite, sickness or nausea, and headache, frontal or occipital, often accompanied with giddiness. The tongue is furred, the breath foetid, and there is pain or discomfort in the region of the stomach, with sour eructations, and frequently vomiting, first of food and then of bilious matter. An attack of this kind tends to subside in a few days, especially if the exciting cause be removed. Sometimes, however, the symptoms recur with such frequency as to lead to the more serious chronic form of the disease.

The treatment bears reference, in the first place, to any known source of irritation, which, if it exist, may be expelled by an emetic or purgative (except in cases due to poisoning). This, however, is seldom necessary, since vomiting is usually present. For the relief of sickness and pain the sucking of ice and counter-irritation over the region of the stomach are of service. Further, internal administration of bismuth or weak alkaline fluids, and along with these, a light milk diet, are usually sufficient to remove the symptoms.

Chronic Gastric Catarrh may result from the acute or may arise independently. It is not infrequently connected with antecedent disease in other organs, such as the lungs, heart, liver or kidneys, and it is especially common in persons addicted to alcoholic excess. In this form the texture of the stomach is more altered than in the acute form, except in the toxic and febrile forms above referred to. It is permanently in a state of congestion, and its mucous membrane and muscular coat undergo thickening and other changes. The symptoms are those of dyspepsia in an aggravated form (see DYSPEPSIA), of which discomfort and pain after food, with distension and frequently vomiting, are the chief; and the treatment must be conducted in reference to the causes giving rise to it. The careful regulation of the diet, in amount, quality, and the intervals between meals, demands special attention. Feeding on artificially soured milk may be useful. Lavage or washing out of the stomach with weak alkaline solutions has been used with success. Bismuth, arsenic, nux vomica, the mineral acids and pepsin are all of use.

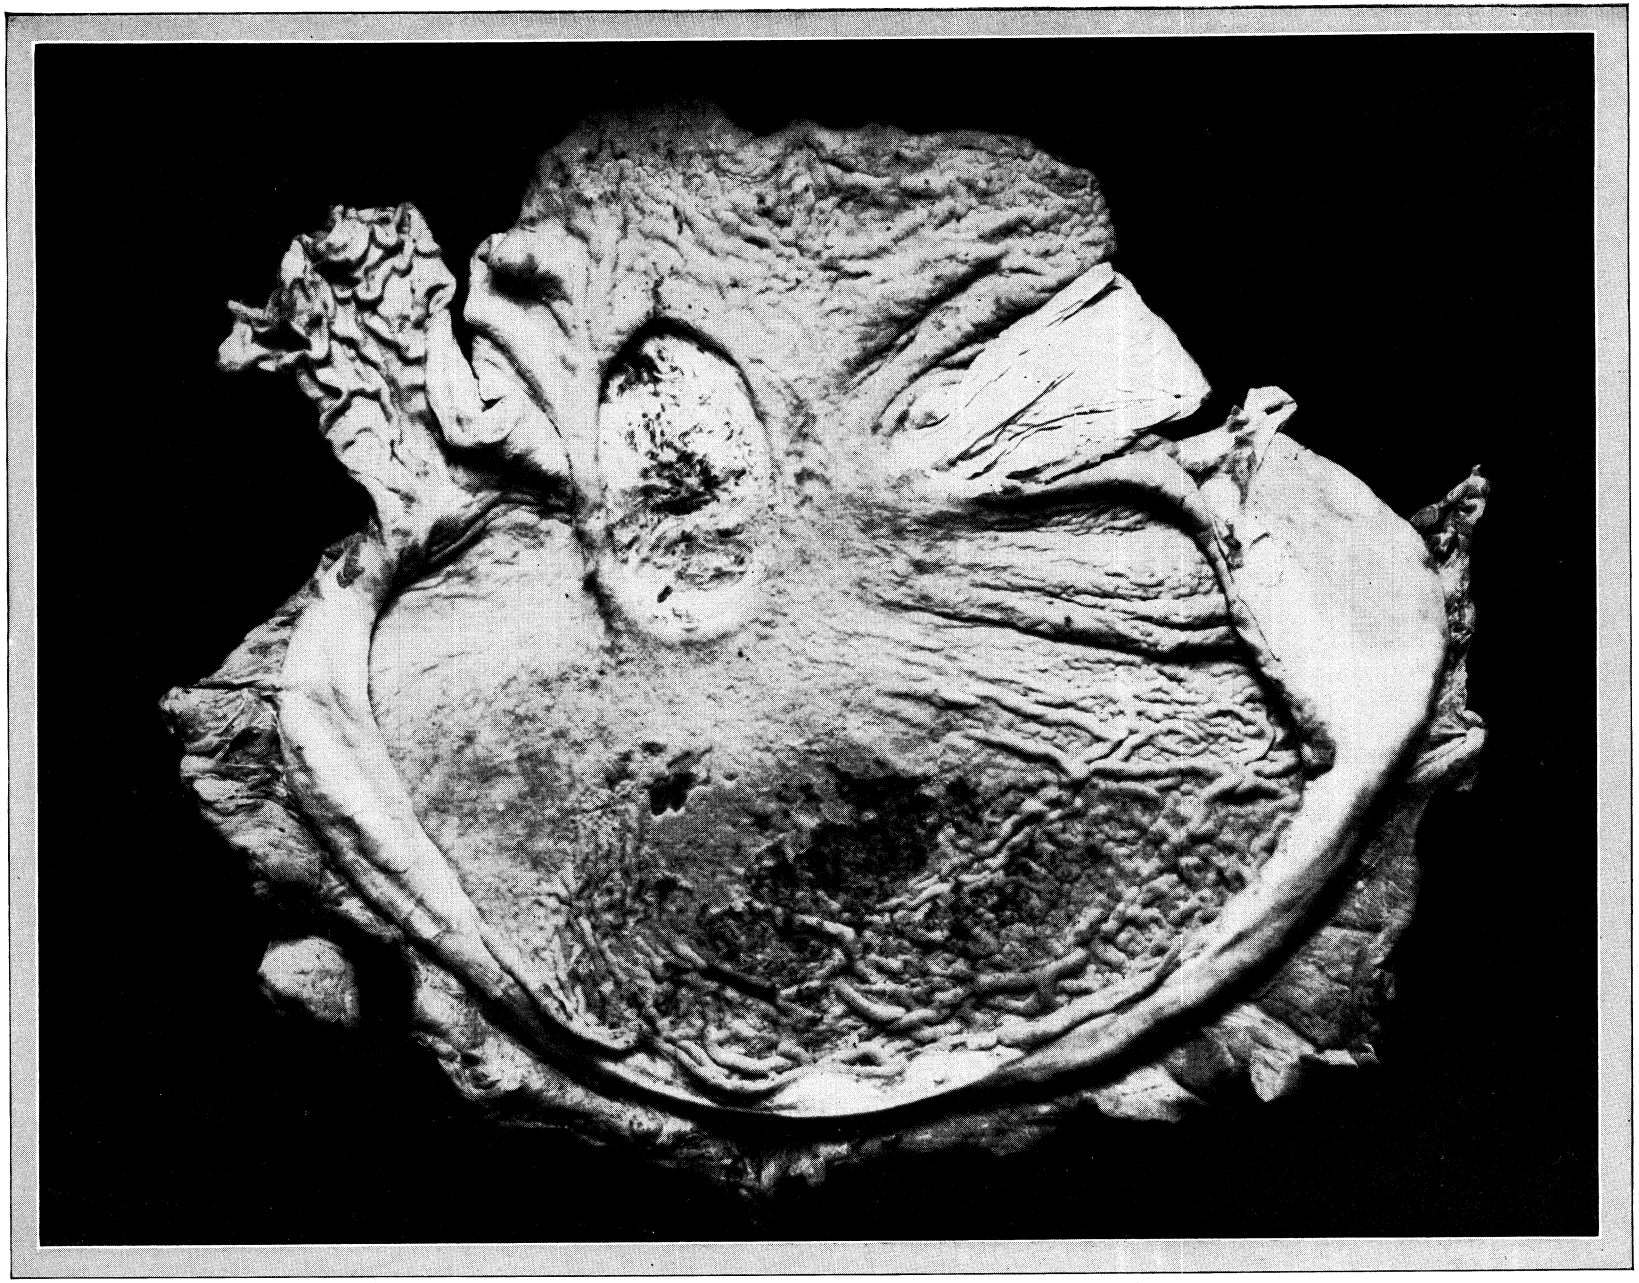
GASTRONOMY, MODERN. Is gastronomy an art or a science? This is a question on which epicures and cooks are at issue. La Rochefoucauld wrote that "eating is a necessity, but eating intelligently is an art." Vauvenargues admitted unhesitatingly that "great thoughts come from the stomach." The doctrine of Epicurus bids us find an agreeable employment for our faculties in the intelligent enjoyment of the pleasures of the table. And finally, to go back still farther, Ecclesiastes himself teaches us that "a man hath no better thing under the sun, than to eat, and to drink, and to be merry. . . ."

Throughout the ages, meals have been made a time of relaxation, comfort and enjoyment. The feasts of the middle ages were, as we know, assemblies of people desperately hungry after long days of hunting in the forests, trained to violent exercise, capable of wearing heavy armour and of doing justice to a prodigious bill of fare.

In the 17th century, the spirit of order, reason and dignity which characterized the literature of the period found a further outlet in the elaborate organization of banquets: these were conducted according to a regular programme, involving a whole series of minute observances. The result was that the guests got nothing but congealed gravy.

The eighteenth century, witty, pugnacious, enthusiastic and volatile, introduced into cookery its elegance, its instinct for pleasure and refinement. But modern cookery really dates from the end of the First Empire, the time of Brillat-Savarin and Carême. It was they who substituted the "made dish" for masses of roast meat, piled in pyramidal form and held together by skewers. These enormous, barbaric accumulations of food were yet another Bastille which the French Revolution overthrew;

Gastronomy **Is** an Art. — It may fairly be said that modern gastronomy is an art, and that Molière talked like a Philistine when he made one of his characters say that "we eat to live, we do not live to eat." It is an art because it demands the co-operation of all the senses. The crispness of fried dishes and pastry is agreeable to the ear. The softness of well thickened sauces and melting foies gras, the succulent freshness of fruit, are pleasant to the touch. Is there anything more delightful to the eye than a dish au gratin, with its captive flavours imprisoned under its golden dome? Do not odours like those of seasonings of herbs, or of truffles, afford the highest possible gratification



FROM BOLTON, "ULCER OF THE STOMACH" (ARNOLD AND CO.)

SADDLE-SHAPED ULCER OF THE SMALL CURVATURE

A dilated stomach with the anterior wall turned back to show a saddle-shaped ulcer of the small curvature, which has become considerably contracted, thereby narrowing the pylorus seen to the left of the ulcer

to the sense of smell? Of the palate there is no need to speak.

It may even be said that gastronomy is a perfect art, for so wide a range of enjoyment could not, in the opinion of the present writer be derived from listening to a symphony, hearing a poem read, or gazing at a beautiful building. Indeed, it would not be unreasonable to maintain, not merely that gastronomy is a perfect art, but that it is the only art which is perfect.

Gastronomy Is a Science.—Unquestionably gastronomy is a science, for it has its laws, its formulas, its fixed processes. Art cannot be taught, whereas the profession of cookery should be preluded by a long apprenticeship. Certain physico-chemical laws have to be observed in the preparation of our food; and cooks often make scientific discoveries without knowing it. Why does red wine go well with roast meat and cheese? Because tannin combines with albuminous substances in a manner propitious to digestion. Why do we eat potatoes fried? Because fats and starch are chemical substances belonging to the same group of hydrocarbonates. Why do me put lemon juice on fried dishes, or in a salad? Because acids attack cellulose and saponify oil, and make them easier to digest.

Likewise, there are culinary processes which are scientific applications of the laws of nature. Roast meat, for example, must be exposed to great heat for a short time in order that a crust may form all over the surface, and then placed in a moderately heated oven and left there as long as possible in order that the bro ned skin may imprison all the juices of the meat and that these, by a slow process, as it were of digestion, may make the flesh tender.

Again, cooks know that a sauce the principal ingredient of which is the yolk of an egg must never be allowed to boil, or else its elements will become disunited: as we say, they will curdle. They know, too, that, if need be, they can be reunited simply by the addition of the yolk of another egg and a little boiling water. If a dish is too salt, add at once a few spoonsful of milk or a little butter. Many practical examples of the kind could be cited.

Cookery Since the World War.—The renewed interest in gastronomy is undoubtedly one of the effects of the World War. For four years millions of men, living as best they could on trench fare, sought solace in the misery of their leisure hours by dreaming of good cheer. For four years, whenever they came out of the line, they revelled in table-cloths, properly served meals, "made dishes" and the savours of which they were deprived. At the same time, men became more appreciative of life and its pleasures—a kind of instinctive protest against the all-pervading menace of death, a parallel to which may be found in the reaction under the Directory after the famine and executions of the Terror.

As people became more genuinely appreciative of good living, the cooking of the big "palace," which hitherto had satisfied their requirements, lost its popularity. Diners would no longer tolerate those dull, stereotyped meals, at which a chicken's breast is cut up into the tiniest fragments, and the sweets—half-melted ices or palsied puddings, as the case may be—have so unspeakably depressing an effect.

The motor-car has made it possible for the traveller to avoid having meals in the large towns where the expresses stop, and to try his luck in the restaurants which are now springing up in ever-increasing numbers in the country round. But the adventure sometimes turns out a misadventure. At many of these restaurants it is always uncertain whether there will be guests or not; the dishes, therefore, are cooked a long time beforehand and kept in tins, to be warmed up when ordered. The unpleasant surprises a guest may experience who has the ill-luck to enter an establishment of this kind which is not presided over by a conscientious *chef*, or a cook careful of her reputation, may easily be imagined.

The Good Restaurant.—Some restaurant-keepers, encouraged by the various gastronomical societies founded in recent times, have, while exploiting modern ideas of comfort, endeavoured at the same time to revive a lost tradition. They provide only good wines, instead of Vouvray ruined by a smell of sulphuric acid, or Bordeaux from Algeria. They do not crowd their guests together like sardines, or furnish the place so expensively that a prohibitive increase of prices is inevitable. They set no store by luxurious interiors lighted with excessive brilliance, where a few solitary individuals dine lugubriously and groups of unoccupied waiters stand about.

A first necessity in a good up-to-date restaurant is a cloak-room the use of which is optional. Think of a bachelor, who has two meals at a restaurant daily, being obliged to pay, from June to October, two hundred francs in cloak-room charges for a straw hat!

In a good restaurant, the tables are well placed, the service is simple and the bill of fare consists of a few dishes only—but the preparation of each dish must be a labour of love, executed with care and patience. No orchestra disturbs the quiet of the place. The head waiter does not insist on your ordering what he himself fancies; the proprietor comes to ask your opinion of the Armagnac and the kirsch served to you. And a delightful surprise awaits you—the bill is moderate. The result is that you leave the restaurant having dined well, your mind at ease, your heart at peace with the world.

The Revival of Cookery.—For some time past a good deal has been heard about new dishes. As a matter of fact, there is hardly a dish which has not been attempted already.

Many people, it is certain, do not know that in the Middle Ages, at the Tour d'Argent, the oldest restaurant in Paris, dormouse pastry, mixed dishes of snakes, porpoise, roast swan and crane stuffed with plums were served to the guests. Nor that Frederick the Great made his coffee with champagne and added mustard to give the remarkable drink a still stronger taste. Nor that, before the war, a cook named Jules Maincave gave to the world fillets of mutton with crayfish sauce, beef cooked in kummel, bananas with Gruyère cheese, sardines with Camembert cheese and herring soup with raspberry jelly.

These last experiments, it must be confessed, are highly unpleasant; for the ingredients in question could not possibly be made to harmonize, any more than cat and dog. Nor is it at all clear how a mixture, for example, of chocolate and red wine could be rendered palatable.

At the same time, it would be a mistake to go to the opposite extreme and content ourselves with the stereotyped dishes turned out by cooks devoid of imagination. When a writer uses hackneyed words—a habit of which journalism affords only too frequent examples—we say that he writes in *cliche's* and that he writes badly. When a painter always paints the same picture over and over again, we are quick to compare him to a photographer lazily taking a succession of proofs from the same negative. Similarly, in the domain of cookery, the most modest dishes should afford a good housewife an opportunity of using her inventive faculty and her intelligence. There is no reason why the culinary fashions of years gone by should immobilize and enslave us, nor why the gastronomists of to-day should be less adventurous, less eager for knowledge than their predecessors who, throughout the ages, have enriched cookery with a stream of new discoveries. We should not abandon hope of improving on first results. We should pay no attention either to dogmatists who accept the existing order of things, repeat and solemnly hand on to posterity what they have heard from their elders, and irrevocably condemn the unknown as a matter of principle, or to those who take fright at an unfamiliar flavour, like children swallowing their first oyster. If men had always acted thus, if no risks had been taken and no experiments made, whereby alone the adventurous instinct learns self-restraint, the range of our enjoyments would to-day be exceedingly limited. We should be no more tolerant of the conservatism of people who will not eat roast chicken unless surrounded by watercress, or veal unless in the company of carrots or peas, or a leg of mutton with anything else than a dish of haricot beans.

What we should aim at doing is to combine with familiar recipes something which, while setting off their good qualities, yet introduces an element of surprise and provides what was wanting in them. We should not hesitate to transform a sauce possessing

its traditional flavour into something more savoury and unexpected. The harmonies which can be obtained from certain combinations of crisp and fatty substances and of watery and farinaceous vegetables, are worth studying.

Here follow a few recipes in the new style of cookery; these will give an idea of the kind of dish which harmonizes with a modern dining-room.

Tomato Tart.—This is a simple, family dish which is sure to be appreciated by old and young alike. Make an open tart of unsweetened pastry. Fill it with a thick *béchamel* (a sauce made of flour and butter) flavoured with cheese, mixed with concentrated tomato essence. Place on this foundation tomatoes which have been cooked in butter flavoured with onion, and stuffed with mushrooms and olives. The tomatoes should have been put in the oven just before being placed in the tart. Then cover the whole with breadcrumbs done with butter to a golden brown, and the tart is ready to be served. It forms a dish of three storeys, and each of them succulent.

Cold Pork with Truffles.—Foie gras flavoured with truffles is excellent; but it seems a pity to mix two decided flavours. Surely it is better to use truffles to give flavour to something which in itself is comparatively tasteless. M. Verdier, ex-manager of the *Maison Dorée*, and one of the greatest chefs of the day, recommends that pieces of raw truffle should be pressed as deeply as possible into a piece of fresh pork. Choose a piece which is close-grained and not too lean. When the pork is inlaid with a sort of mosaic of truffle, roll it, tie it up and roast it. Let it cool in its own fat, and serve it cold the next day with whatever salad is in season

Haricot Beans with Cream Sauce.—School-boys and soldiers learn to hate haricot beans; but they are a vegetable which can be either detestable or delicious according to the way in which they are cooked. If you want to make haricot beans really exquisite, let them soak for twenty-four hours and then boil them very slowly. Meanwhile get ready in a saucepan a spoonful of good *bkchamel*, half a litre of cream, and plenty of grated Gruyére cheese. Put in plenty of pepper and not very much salt. When the sauce has been brought to a creamy consistency, pour it over the haricots after first straining them. Sprinkle the whole with a little grated cheese, and brown lightly in the oven.

If you like you can colour this dish with methylene blue. This is a new idea which has scandalized the whole cooking world. Methylene blue is an absolutely harmless chemical product; in fact it is actually ordered by doctors as a remedy for digestive disorders, so it cannot do anyone any harm. Dissolve in water as much methylene blue as you can put on the point of a knife. You will get water the colour of an African sky. Boil the beans in this water, and they will take on a greenish-blue shade which will astonish your guests.

Lettuce and Orange Salad.—You need to have the soul of a rabbit to eat salad as it is usually served—green leaves slightly lubricated with oil and flavoured faintly acid with vinegar. A salad is only a background; it needs embroidering. To give character to a lettuce salad, cut up slivers of orange rind as small as pine needles, and sprinkle them over the salad. If you want something still more entertaining for your guests, cut up a carrot into equally small slips. This will at once arouse the attention of any gourmet Which is orange and which is carrot, he will wonder. How does the orange come to have a flavour of carrot and the carrot a flavour of orange? You will have given him a real gastronomic entertainment.

Stewed Apples Flavoured with Tangerine.—A dish of stewed apples, rust-coloured and unadorned, is a melancholy sight Yet this economical dish, which is to be found in the least pretentious homes, can be given a very attractive flavour. All that is needed is to put in little pieces of the rind of tangerines, after removing all the white pith. The dish can easily be decorated with slices of tangerine which have first been freed from their pips and soaked in rum.

These dishes are much easier to make than might be thought from the description. They are far less difficult than most of the recipes of high-class cookery, for which strong *bouillon* of meat or fish is usually required. Guests may at first be rather suspicious of their novelty, but the first mouthful will remove their apprehensions, and they will soon be in the proper frame of mind to appreciate the new style of cooking. When an unfamiliar harmony of flavours forms itself on the palate, we should try to analyze the sensation just as we identify the different instruments in an orchestra. This is the right way to train our taste. We shall create new sources of pleasurable sensation, and we may even enrich humanity by fresh progress in the culinary art.

(P. RE)

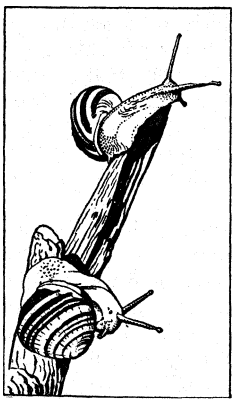
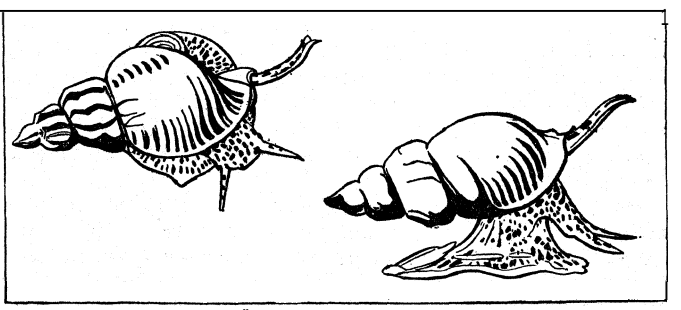
GASTROPODA, a large group of invertebrate animals ranked as a class of the phylum Mollusca and represented by such familiar forms as the limpet, the whelk, the common snail and slug. There is no single English name which can be given to this group. The land and freshwater forms which have shells may all be termed "snails" and the shell-less land forms "slugs," and by a reasonable usage the name "snails" or "sea-snails" may be given to marine gastropoda with shells (whelks, periwinkles, etc.), and the shell-less marine forms (Nudibranchia, etc.) may be called "slugs" or "sea-slugs."



BY COURTESY OF S CROOK
FIG 1.—GARDEN SNAILS CLIMBING

The gastropoda are primarily distinguished from other molluscs by their shell, which is a single structure and is spirally coiled, at least in the larval state. In many gastropoda, however, it is very much modified in the adult and, though it is spiral in a large number of genera, it may lose this appearance and become (*e.g.*) cup-shaped or tubular. In some forms it is covered over by the mantle and degenerate, and it may also be entirely absent. The gastropoda are also distinguished from other molluscs by their asymmetrical organization. The latter is brought about by a process which takes place in larval development, during which the anus and the organs adjacent to the latter are moved forwards ventrally from their originally posterior position and then twisted through 180°, so that they come to lie above and to one side of



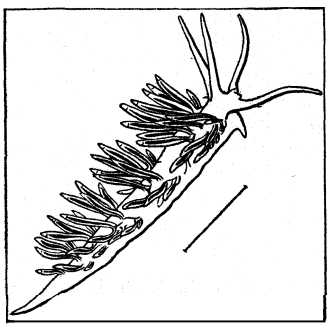
FROM MEHEUT, "ETUDE DE LA MER" (ALBERT LEVY)
FIG. 2.— BUCCINUM UNDATUM

the head. The flexure of the intestine is a phenomenon seen in other molluscs; the twisting or "torsion" of the anal complex is peculiar to gastropods, and it is believed to bring about the asymmetry mentioned above, the chief feature of which is the atrophy or the complete disappearance of the kidney, gill and auricle originally situated on the left side of the body, those of the original right side persisting in a more or less unmodified condition. The clearly defined and well-developed head is likewise distinctive.

The gastropoda constitute the largest class of molluscs and number some 30,000 living species, which range in size from giant

whelk-like forms 2ft. in length, down to minute species of Vertigo barely a millimetre long in the adult state. An enigmatic fossil from the Wealden of Kent (*Dinocochlea* ingens) measuring over 6ft. in length has been described as a fossil gastropod.

In all probability the earliest gastropods were marine animals and they now constitute an important part of the marine fauna. They have also populated fresh water and land, and the familiar Helicidae, the Zonitidae and Bulimulidae are among the largest groups of land invertebrates. In general, their range of habitat is diversified. They are found at very great depths in the sea as well as in the shallower water, and the pelagic gastropods (Pteropoda and Heteropoda) form part of the marine plankton (minute floating organisms). The freshwater and terrestrial gastropoda occupy a great variety of habitats and as a whole are to be reckoned as a very adaptable group, though the need for moisture and lime salts renders them less universally distributed than, *e.g.*, millepedes and Collembola.



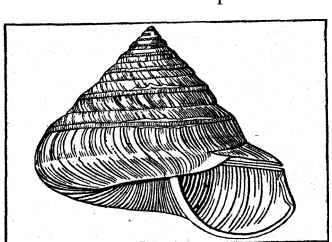
FROM ALDER AND HANCOCK, "BRITISH NUDIBRANCHIATA" (RAY SOCIETY)

FIG. 3.—HERMAEA DENDRITICA

Generally speaking, gastropods are sedentary, inactive animals that rely on their hard shells and unobtrusive habits for protection. The cumbrous shell and the absence of a jointed skeleton render them slow in their movements. On the other hand, they are capable of very considerable muscular exertion and tend to be very tenacious of life. A limited number of genera are more active and mobile and have taken to swimming, climbing and burrowing. Many marine gastropods and the majority of the terrestrial and freshwater forms feed upon plants or on organic débris, and such a diet was no doubt characteristic of the primitive gastropod stock. Several groups, however, have become carnivorous and are modified accordingly in habits and structure.

Classification. — The classification of the gastropoda has undergone many changes in the past. Even at the present time there is no universally accepted system so far as the main subdivisions are concerned, although there is a general measure of agreement as to the composition of certain of the lesser groups.

The class Gastropoda, including the orders Nudibranchiata, Tectibranchiata and Pulmonata, was created by Cuvier in 1795; later he created the Pteropoda as equal in rank with the Gastropoda. In 1812 Lamarck created the group Heteropoda, ranking it also equal with Gastropoda. In 1846–48 Milne-Edwards established the orders Opisthobranchiata and Prosobranchiata. The Pteropoda were held as a distinct class until Pelseneer in 1888 showed their affinities to the Opisthobranchiata.



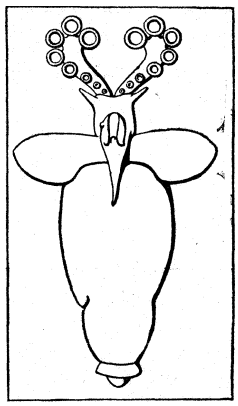
FROM MARTINI AND CHEMNITZ, "CONCHYLIEN-CABINET" (GUSTAV FOCK)

FIG. 4.—PLEUROTOMARIA RUMPHII

The diversity of opinion about the main subdivisions may be taken to imply that any natural groups of these dimensions (sub-classes, orders) that may exist in the class have not yet been made apparent by morphological research. Nevertheless, certain broad groupings are recognized by those authors who in the last two decades have subjected the class to comprehensive treatment.

It will be convenient to contrast three such systems which have been proposed by Pelseneer, Simroth and Thiele respectively. Different as these three schemes appear at the offset, they tend in fact to recognize the same main groupings. For table of systems see top of page 60.

The Streptoneura of Pelseneer contain precisely the same families (limpets, trochids, periwinkles, whelks, etc.) as do the Prosobranchia of Simroth and Thiele. The rest of the class is treated as a single sub-class by Pelseneer. Thiele divides them into two sub-classes (as also seems to be the intention of Hoffman, who is continuing Simroth's treatise in Bronn's Tierreich). But this does not involve any re-arrangement of the contents of Pelseneer's Euthyneura, as the latter are divided into two orders, equivalent in their contents to Thiele's sub-classes. In short, both authors recognize the distinction between the Opisthobranchia and the air-breathing pulmonata. Thiele's promotion of these two groups to the rank of sub-classes is advantageous, however, as it emphasizes the marked structural and bionomic differences between these groups. It is true that they resemble each other in certain distinctive features (*e.g.*, they are hermaphrodite and the visceral complex is detorted) in which they both differ from the Streptoneura. But they are otherwise very clearly defined and have a radically dissimilar evolutionary history.



FROM CHALLENGER, "ZOOLOGY" (H M. STATIONERY OFFICE)

FIG. 5.—SPONGIOBRANCHAEA AUSTRALIS. NOTE THE SUCKERS

Thiele's Archaeogastropoda contain the same families as Pelseneer's Aspidobranchia and Simroth's Scutibranchia. His Mesogastropoda are Pelseneer's Taenioglossa and his Stenoglossa are equivalent to Pelseneer's sub-order of that name. With regard to the status given to these groups Pelseneer's scheme seems at present more rational. While Thiele's elevation of the Stenoglossa to the rank of an order is to some extent justified by the marked specialization of these forms as carnivores and carrion-feeders, it leaves the Taenioglossa, a large and miscellaneous group with too great an appearance of uniformity. Probably Thiele's rating of the Stenoglossa is justifiable, and what is required is a more complete knowledge of the relationships of families constituting the Taenioglossa.

Little can be said concerning the numerous minor divisions. A great deal of work remains to be done in elucidating the constitution and relationships of families, the structure of which is imperfectly known. Many of the minor groups are probably very far from representing natural associations. The work of Pilsbry (1909–28) on the enormous group of land pulmonata has gone a long way towards disentangling the chaotic assemblages originally treated as "Helicidae," "Bulimulidae" and "Zonitidae," and the course of pulmonate evolution is becoming correspondingly clearer to us. But even so, this large and unwieldy order is in need of comprehensive treatment along bionomic as well as morphological lines.

FIG. 6.—TETHYS LEPORINA, SHOWING COWL-LIKE FRONTAL VEIL FORMED FROM ANTERIOR TENTACLES

ANATOMY AND PHYSIOLOGY

The gastropoda are divisible, as we have already seen, into a large number of groups, each distinguished by anatomical and bionomic peculiarities. The significances of these divisions will be easier to grasp, if the main evolutionary tendencies that have been manifested within the class are briefly indicated in advance. The details of gastropod structure and morphology are well described in the standard text-books on this subject, and the description given here consists of a selection of such of the more important modifications as illustrate the main evolutionary changes within the group.

The most primitive of living gastropods are sedentary marine animals which feed upon algae, sea-weeds or organic débris. They creep about by means of a flattened foot and rely for protection on an external shell, which is usually coiled in the adult. Their internal organization, though it is affected

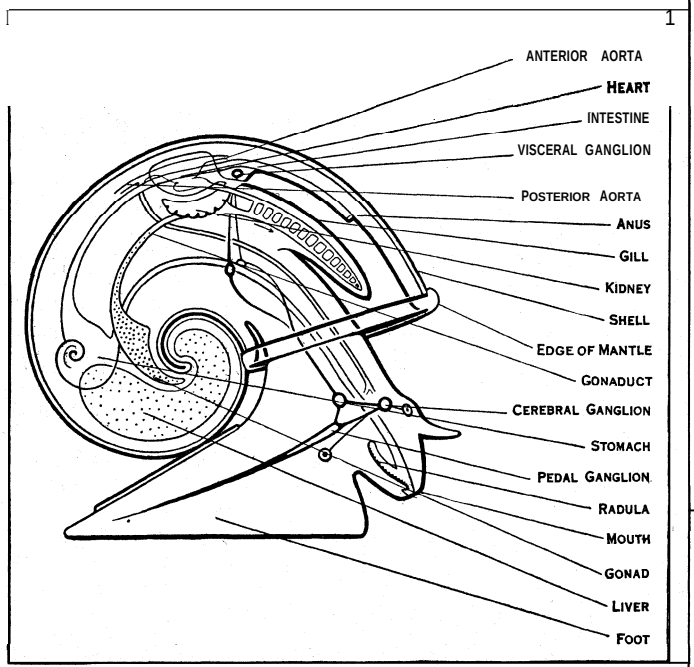
by the "torsion" already mentioned as far as the visceral nervous commissure and alimentary canal are concerned, is still more or less symmetrical. *Pleurotomaria, Fissurella* and *Haliotis* among the Rhipidoglossa exemplify this, type of organization. In the course of evolution the main departures from the latter are as follows: (1) The visceral complex (heart, gills and kidneys) becomes asymmetrical through the atrophy and disappearance of



FROM SPENGEL, "ERGEBNISSE UND FORTSCHRITTE DER ZOOLOGIE" (FISCHER)

FIG. 7.— DIAGRAMO F GASTROPOD ORGANISATIONS

those of the above named organs which are situated on the right side of the adult body. (2) The shell may become internal and degenerate and finally disappear and a secondary external symmetry may be established. **(3) A** terrestrial and air-breathing mode of life has been adopted independently by several groups. (4) A carnivorous or carrion-eating habit has been acquired on several occasions. (5) The creeping mode of progression has been abandoned by certain families in favour of swimming and floating or of a truly sessile (adherent) mode of life.

These by no means exhaust the list of specialization exhibited by the class; but they are the most frequent and lead to the most striking modifications of structure.

External Features and General Organization.— The body of a gastropod is divisible, like that of nearly all molluscs, into four main parts—the visceral sac, the mantle which covers the latter, the head and the foot. The morphological unity of the head and foot has been suggested by Naef, and this subject is discussed in the article MOLLUSCA. The whole animal may be visualized as having an elongate and worm-like body with the head and foot at one end. The greater part of the body is spirally coiled, and the coiled portion (the visceral sac) is sheathed in a fleshy covering, the mantle, which projects as a free fold at the anterior end and hangs down like a skirt around the head and foot. In the cavity thus formed between the mantle and head the function of respiration is normally carried out either by gills or by a lung. In the former case the mantle cavity is largely open to the exterior; in the second the edge of the mantle is adherent to the "neck," a small hole (the pneumostome) being left for the admission of air into the lung. In certain Rhipidoglossa the mantle edge is not complete anteriorly and dorsally, but is interrupted either by a longitudinal slit or a series of holes probably representing a slit, the edges of which have fused.

The mantle secretes a shell which is formed in a single piece and is in most cases spirally coiled. The minute structure of the shell and its chemical composition is described in the article MOLLUSCA. In individual development the shell appears in the embryo as a plate or cap-like rudiment which becomes coiled and grows in size by the deposition of mineral salts round the edge of the open end (aperture). It is likely that the forerunners of the gastropoda had a cap-shaped shell in the adult state.

In the most archaic representatives of the class, however (*e.g. Bellerophon,* among the extinct Cambrian genera and *Pleurotomaria* among living forms) the shell is coiled. It is worthy of note that in *Bellerophon* the shell is not of an elongate or screw-like spiral shape, its coils being all in one plane (planospiral), like

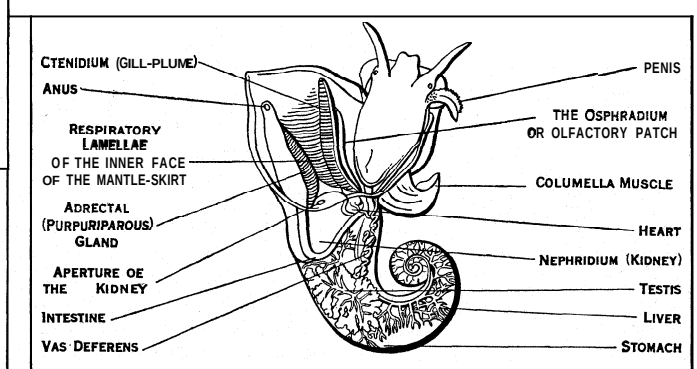


FIG. 8.— MALEOF LITTORINA LITOREA. REMOVED FROM ITS SHELL, SHOWING THE ORGANS ON ITS INNER FACE

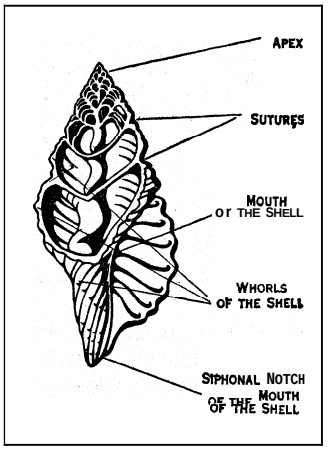
that of the primitive cephalopod *Nautilus.* The modifications of the adult shell are complex and manifold. The general plan and the terminology employed in describing shells are shown in fig. g and the various modifications are described and illustrated in text-books and conchological treatises. It is sufficient here to allude to the most important change that is encountered in the class. The shell, which is to be regarded as primitively spiral, becomes unwound and secondarily cap-shaped in many Streptoneura (Patella, *Capulus*). Furthermore, the edges of the mantle may grow over the shell and cover a large part of its surface. This

condition is found in such genera as *Fissurella, Cypraea,* and Marginella among the Streptoneura and in various Opisthobranchia (*Aplysia*) and Pulmonata (*Vitrina*). The overgrowth of the mantle may be complete and the shell is thus internal and degenerate (Lamellariidae and slug-like Pulmonata). Finally, the shell may disappear entirely (*Titiscania,* many nudibranchs, *Oncidium*). This progressive atrophy of the shell occurs in many groups of gastropods Although it may become of advantage to the animal as allowing it greater freedom of movement, the loss of the shell is to be regarded at least at the offset as an innate tendency of the class and probably of the molluscan phylum as a whole.

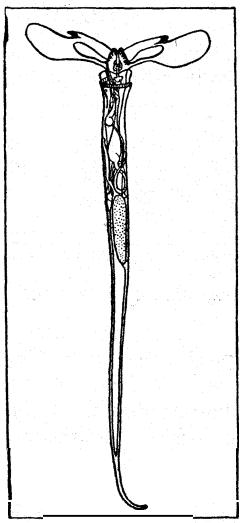


FROM LANKESTER, "TREATISE ON ZOOLOGY" (A & C BLACK)
FIG. 9.—TRITON SHELL, SECTION

The head in the gastropoda is well developed and clearly defined from the rest of the body to which it is connected by a mobile "neck." It is usually provided with sense organs, a snout or muzzle and one or two pairs of tentacles. The foot is a powerful muscular organ. Usually it is rather elongate and has a flat surface suitable for a creeping gait.

Notable modifications of the foot are seen in marine forms which dig in sand (*Natica,* Bullomorpha). These gastropods have the foot transformed into a "digging-shield" shaped like a snow-plough. In heteropods and "pteropods," it is modified for use in swimming.

On the posterior dorsal surface of the foot there is in nearly adult Streptoneura a solid plate, the operculum. When the animal withdraws itself into its shell, this plate by reason of its position and shape remains applied to the aperture of the shell which it closes like a lid. The operculum is absent in nearly all the Euthyneura, but certain terrestrial forms such as the Helicidae secrete a glutinous or calcareous plate over the mouth of the shell when they estivate or hibernate.



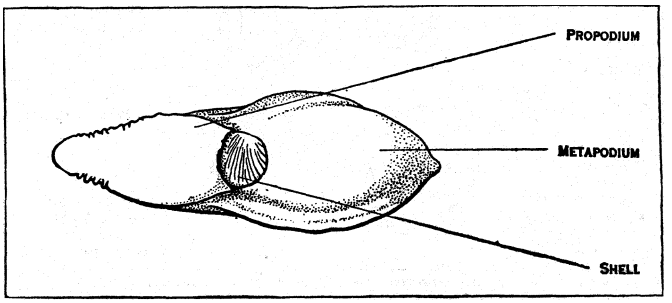
FROM MURRAY AND HJORT, "THE DEPTHS OF THE OCEAN" (MACMILLAN LTD.)
FIG. 10.—CRESEIS ACICULA

The foot often exhibits along its sides a ridge (epipodium) which extends from the head to the posterior extremity The epipodium is well-developed in the Rhipidoglossa and often bears appendages and sense-organs It has been assumed to have a common origin with the funnel of the Cephalopoda. The head and foot are joined to the visceral mass by a narrow and highly mobile "neck." The animal is attached to the shell by the strong columellar muscle, and by the contraction of the latter the animal can withdraw itself into the shell. This muscle is inserted into the columella or axial pillar of the shell (*cf.* fig. 9).

The disposition of the chief external parts having thus been sketched, it will now be convenient to describe how the characteristic gastropod asymmetry is attained. Some details of the internal organization are given below; but it is necessary at this stage to recall the preliminary statement that, while some primitive forms are symmetrically organized, the main parts of the visceral complex (gills, kidneys, etc.) being paired, in most gastropods the organs of the right hand side are atrophied or absent in the adult, and that in the Streptoneura the visceral commissure is twisted into a figure-of-eight. In addition, the spiral winding of the shell and visceral mass has to be accounted for.

Before considering how and in what circumstances this highly characteristic organization was developed in the course of gastropod evolution, it will be best to describe the main organization and metamorphosis of a gastropod larva.

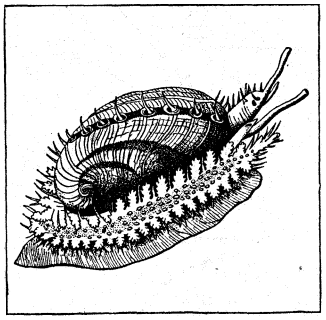
As will be seen in the section on embryology, the larva is symmetrical in the early stages of development, the mouth and the anus lying at opposite ends of the body. At a stage which more or less corresponds with the appearance of the shell, the anus shifts downwards and forwards and ultimately comes to lie below and near the mouth At this stage the mantle cavity is seen as a small space surrounding the anus. Such coiling as the shell may show at this stage is "exogastric," *i.e.,* the coils are situated above



FROM "PROCEEDINGS," MALACOLOGICAL SOCIETY BY COURTESY OF THE COUNCIL
FIG. 11.—SINUM COMPLANATUM

the head and away from the foot. Soon, however, the anus, the mantle cavity and the adjacent parts rotate upwards and come to lie above the head and to the right of the latter. The coils of the shell at the same time roll downwards and assume an "endogastric" position, *i.e.,* they lie over the foot and away from the head. It will be seen that there are two movements involved in this reorganization of the larval symmetry, viz., the ventral flexure of the intestine and the torsion or rotation of the pallial complex up the right side of the body. Though these two changes may be merged into one in individual development they must be carefully distinguished. The ventral flexure is found in the gastropoda, Cephalopoda, Scaphopoda, and Lamellibranchia; torsion is found in the gastropoda alone.

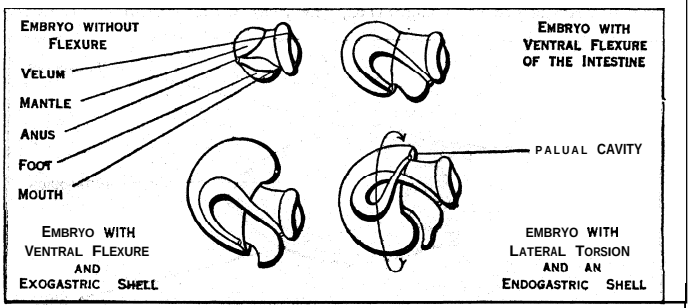
If processes of this kind, which occur in the course of individual development, may be taken to epitomize events which happened during the evolutionary history of the race, then it is to be inferred that metamorphosis is a summary of changes which took place in gastropod evolution. Many theories have been put forward to account for these processes. They agree in attributing great importance to the influence of the spiral shell and the acquisition of a flat and elongate sole. If it is true that the gastropoda are descended from animals with a simple cap-like shell and a relatively small foot, then it seems likely that, as the shell acquired a tubular shape, it became necessary to bring the originally posterior anus and associated organs into a position in which they would not be covered in by the growing shell. Hence the flexure of the intestine, the result of which was to bring the anus near the head. But it plainly could not persist in this position, as the elongation of the foot would tend to drive it backwards. Its rotation up the side of the body, until it came to lie above and to the right of the head, brought it into the most convenient position. It is also likely that the change in the spire of the shell from an exogastric to an endogastric position may have influenced the torsional process. Naef assumes that the animals which gave rise to the primitive gastropods were swimming forms. In such a mode of life the exogastric spire would be no inconvenience. But with the advent of a creeping habit the heavy, forwardly directed shell could no longer maintain its position and would fall on one side. This displacement of the shell would almost inevitably affect the position



FROM LANKESTER, "TREATISE ON ZOOLOGY" (A & C BLACK)
FIG. 12.—HALIOTIS TUBERCULATA

of the pallial complex. The position ultimately taken up by the latter may be explained either as directly due to the displacement of the shell or as an adaptation that placed the pallial complex in a less cramped and restricted situation. It is quite uncertain whether the rotation of the shell or growth of the foot was mast influential in bringing about torsion. It is likely that both contributed.

The foregoing account must not be taken as a description of actual events but of the factors which are likely to have been

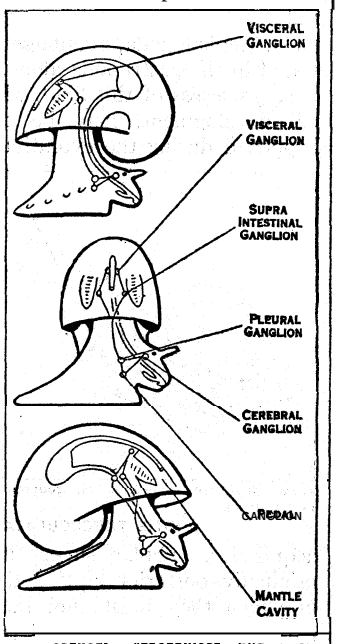


AFTER ROBERT LANKEQTER, "TREATISE ON ZOOLOGY" (A & C BLACK)

FIG. 13.— FOUR STAGES IN THE DEVELOPMENT OF A GASTROPOD SHOWING THE PROCESS OF THE BODY TORSION

concerned in producing flexure and torsion. The spiral winding of the shell and the torsion of the viscera are to be carefully distinguished, as they are probably not causally connected. The main process of torsion, at least in ontogeny, takes place before the spiral winding of the shell and visceral mass is manifest. The cause of the actual asymmetry of the internal organs is not entirely clear. The twisting of the visceral commissure may be due to the effect of the torsion; but the atrophy and reduction of the originally left hand organs is not at first sight referable to the latter. They have been explained as due to the pressure of the shell after it has assumed the endogastric position.

In the Euthyneura the process outlined above tends to be reversed (detorsion). The visceral commissure isuntwisted, the anus and pallial complex in certain forms are carried to the posterior end of the body, and with the loss of the shell a secondary symmetry may be attained. Naef wishes to distinguish between the detorsion of the Pulmonata and that of the Opisthobranchia and to refer them to different causes.



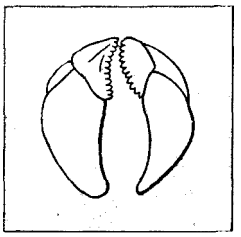
FROM SPENGEL, "ERGEBNISSE UND FORTSCHRITTE DER ZOOLOGIE" (FISCHER)

FIG. 14.— DIAGRAM ILLUSTRATING TORSION IN THE GASTROPOD

INTERNAL ORGANIZATION

The Alimentary System.—The mouth is situated at the anterior end of the head, which is usually snout-like and bent somewhat downwards. In many of the Streptoneura the mouth is at the end of a proboscis which can be thrust out or withdrawn into the cavity of the head. A proboscis is found in certain Taenioglossa (e.g., Natica, *Copulus*), the Rachiglossa and sundry opisthobranchs, notably the Gymnosomata, and is usually associated with a carnivorous diet.

The mouth leads into the buccal, or pharyngeal cavity, which is furnished in most cases with solid cuticular mandibles and a tongue-like organ, the radula, which is beset with numerous rows of teeth and is used for rasping the food. The mandibles are absent in certain forms—Toxoglossa, Helicinidae, heteropods—and are rudimentary in the Rachiglossa. It is uncertain whether the mandibles are to be correlated with a vegetarian diet, but they are without doubt absent or rudimentary in many carnivorous forms. The radula is secreted in a pharyngeal coecum, and is a narrow, ribbon-like organ consisting of a basal membrane supporting a number of rows of teeth usually arranged in two symmetrical sets, one on each side of a median tooth. The number, arrangement, and shape of the teeth are very characteristic and are of great systematic value as they serve to distinguish not only the larger groups (sub-classes, orders, etc.) but also genera and species. The range in the number of teeth is very wide. In some of the Eolids there are only 16 rows each with a single tooth. In *Umbraculum,* on the other hand, there may be as many as 750,000 teeth.



FROM LANKESTER, "TREATISE ON ZOOLOGY (A & C BLACK)

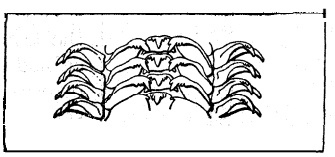
FIG. 15.—MANDIBLES OF JANUS

On either side of the radula are two salivary glands which usually secrete only mucus, though in sundry carnivorous genera they contain an acid which dissolves the hard parts of animals which serve as food.

The oesophagus is generally long and tubular and its inner wall is thrown into numerous folds. In the Stenoglossa it bears a characteristic gland, which in *Conus* and other Toxoglossa constitutes the "poison gland." The portion of the oesophagus adjacent to the stomach is sometimes enlarged to form a muscular "gizzard," the walls of which are lined with teeth or plates.

The stomach is usually thin-walled, but it is lined with a hard cuticle in many genera. It has no digestive function other than that of containing food which is being digested. Digestion is effected by the liver and (when present) the crystalline style. The liver is usually a bilobed organ, the left lobe being larger than the right in most cases. It secretes a digestive ferment which is poured into the stomach by two ducts, and it also has absorptive and excretory functions. The crystalline style is a rod-shaped structure usually of tough, gelatinous consistency, which is either lodged in a special pyloric coecum or lies free in the proximal part of the intestine. It is composed of globulin and, according to Mackintosh, contains an amylolytic enzyme.

The intestine is long or short, according as the animal is herbivorous (e.g., Patella) or carnivorous (e.g., Pterocera). Its inner wall is raised into a prominent ridge, the typhlosole. The anus usually lies on the right side of the body adjacent to the head; but in "detorted" forms it is at the posterior extremity of the body.



FROM "CAMBRIDGE NATURAL HISTORY" (MACMILLAN)

FIG. 16.—RADULA OF VERMETUS

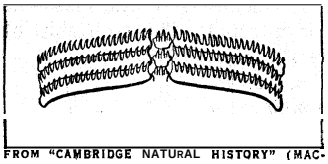
Circulatory and Respiratory Organs.—The blood is usually colourless and contains amoebocytes. Haemoglobin is found in the blood of certain species of Planorbis and haemocyanin in a few genera. The lymphatic tissue is either diffuse or concentrated in a special gland (*e.g.,* in certain Opisthobranchia). The heart is always dorsal in position. It is usually in front of the visceral mass, but it becomes posteriorly situated in some of the Opisthobranchia as the result of complete detorsion and the reacquisition of bilateral symmetry. In the Rhipidoglossa (with few exceptions) it consists of a ventricle and two auricles, but even in this group the left auricle is larger than the right. In *Fissurella* alone are the auricles equal in size. In all other gastropoda there is only one auricle, the left.

There is a well-developed arterial system in nearly all gastropoda. The venous blood, on the other hand, is carried to the gills through a system of irregular cavities that extends between and among the various organs. From these it is carried to the gills either directly or through the kidney by means of a "portal" system.

Respiration is aquatic in the majority of gastropoda and is usually carried out by gills. The latter are expansions of the under side of the mantle and are primitively feather-like structures (ctenidia), a number of delicate vascularized filaments being borne on each side of a central stem in which are situated

two blood-vessels. By one of these the venous blood is carried to the filaments for oxygenation, after which it passes in the other to the heart.

In more specialized gastropoda the gills become comb-like owing to the suppression of the filaments of one side. There are two gills in the more primitive Rhipidoglossa (*Pleurotomaria, Fissurella* and *Haliotis*). In all other gill-bearing forms the topographically left gill alone persists.

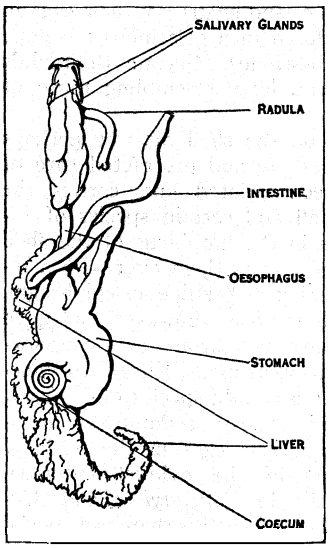


FROM "CAMBRIDGE NATURAL HISTORY" (MACMILLAN)

FIG. 17.—RADULA OF FASCIOLARIA TRAPEZIUM

Although the respiration of the gastropoda is primitively aquatic and is of this nature in the larger part of the class, several important groups have become terrestrial in their habitat and either breathe air or are amphibious. The consequent modifications of the respiratory apparatus are manifold and even among marine forms the normal gills are liable to curious and rather inexplicable modification. The mantle in fact retains to a surprising degree a generalized capacity for discharging the respiratory function and for putting forth respiratory organs not homologous with true gills. Thus respiration from the surface of the mantle may coexist with ctenidial respiration (Heteropoda, Acmaea) or a true gill may be found along with secondarily developed respiratory outgrowths (*Scurria*). The true gill may disappear and be replaced by numerous secondary outgrowths (Patella) or there may be no special branchial organs at all, and respiration is effected by the surface of the mantle (Lepeta).

In the gastropoda which have taken to living on land, the whole mantle-cavity is transformed into a lung. Among certain marine and freshwater Streptoneura there are sundry genera (Littorim, *Cerithium, Hypsobia*) which are accustomed to live out of the water for long periods. Their mantle cavity has an incipient lung-like structure, though the gill is still more or less normally developed. The fully developed lung is formed by the adhesion of the mantle edge to the "neck" and the consequent closure of the mantle cavity which remains in communication with the outer air by a small aperture (the pneumostome). The pulmonate condition has been acquired separately by at least three groups of gastropoda, viz., the Helicinidae among the Rhipidoglossa, the Cyclostomatidae among the Taenioglossa and the Pulmonata among the Euthyneura.



FROM BRONN, "KLASSEN UND ORNUNGEN DES TIERREICHS

FIG. 18.—ALIMENTARY CANAL OF TROCHUS GIBBEROSUS

The **Nervous** System.—Except in certain parasitic forms the nervous system is well developed. It consists of nerve cords, ganglia connected by commissures and sense organs. The various ganglionic centres and commissures are those found in other molluscs, viz., cerebral, pleural, pedal, visceral and stomatogastric. Archaic traits are seen in certain Rhipidoglossa, *e.g.*, the slight differentiation of some of the ganglia in *Pleurotomaria*. The more primitive gastropoda are distinguished by the diffuseness of the system, the various ganglia being separated by fairly long commissures. In certain Taenioglossa and the Stenoglossa, among the Streptoneura, and in the Nudibranchia and Pulmonata, the commissures are shortened and the ganglia are concentrated in the head. The visceral commissure is twisted into a figure-of-eight in all the Streptoneura and in a few Tectibranchia (*Acteon, Bulla,* etc.), but in nearly all the Euthyneura it is untwisted.

The sense organs are eyes, otocysts (organs of balance) and rhinophores or osphradia (olfactory organs). In addition to these organs there are special sensory tracts in various regions of the body which have a less defined and less complex structure.

The eyes are found upon or at the base of the tentacles of the head. They are primitively cup-like invaginations with a pigmented retinal layer, which is thus exposed to the sea water. Such simply constructed eyes are seen in the limpets (Docoglossa). In other Rhipidoglossa the aperture of the cup is still open, though it is very small, and a lens is secreted. In most other gastropoda the aperture is closed by the approximation and fusion of the edges of the original aperture, and a double cornea is formed. The olfactory function is discharged by the osphradia in nearly all aquatic gastropoda. There are two of these organs in such Aspidobranchia as have two gills and in the Docoglossa, and a single osphradium in the rest of the class. They are situated in the mantle-cavity near the gills or gill and are essentially organs for testing the respiratory quality of the water. In structure they may be described as ridges of ciliated epithelium. In terrestrial gastropods the osphradia are replaced by rhinophores which are borne on the tentacles. The organs of balance (otocysts and statocysts) are hollow vesicles lined with ciliated epithelium in which sensory cells occur. They contain hard concretions (otoliths) which impinge on ciliated endings of epithelium and

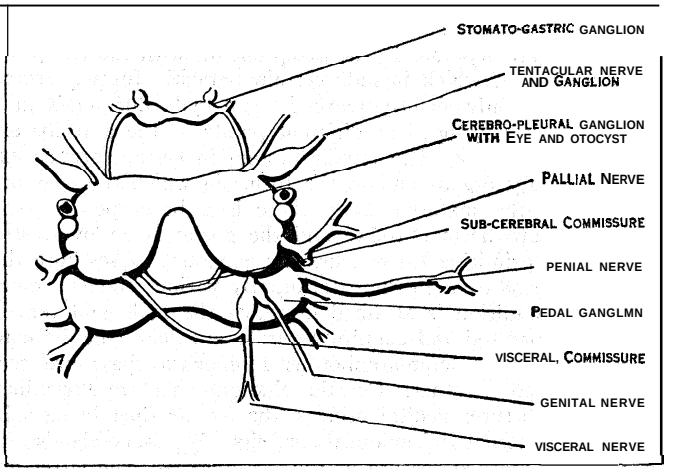
FIG. 19.— NERVOUS SYSTEM OF PATELLA



FROM LANKESTER. "TREATISE ON ZOOLOGY" (A & C BLACK)

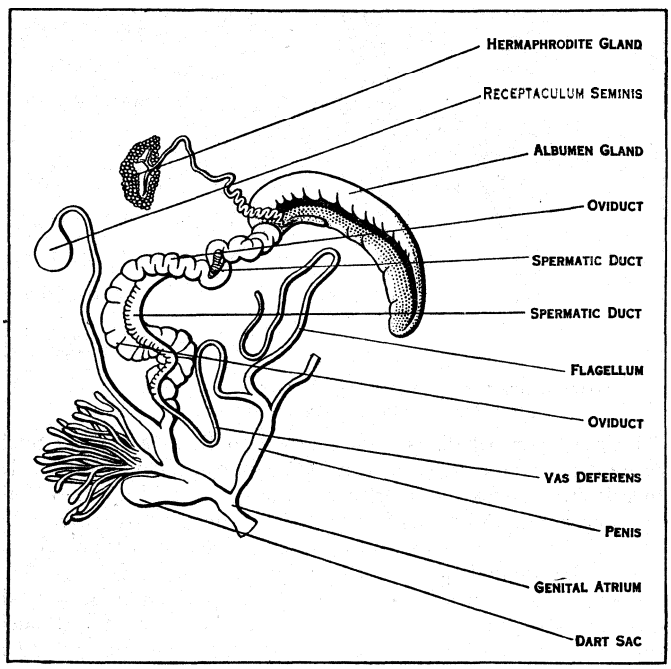
FIG. 20.— NERVOUS SYSTEM OF GONIODORIS

transmit stimuli to the sensory cells. Otocysts are found in the foot in creeping forms; but are sometimes nearer the cerebral ganglia.

Coelom, Renal and Reproductive Systems.—The coelom is represented by the pericardium, kidneys and, theoretically, by the reproductive gland. The latter, however, is a more or less solid or acinous gland, and the cavity from the walls of which it is developed is obliterated in the adult. The kidneys are paired in all the Aspidobranchia, except the Neritacea. In the latter and all other gastropoda the right hand kidney is aborted and, at least in such a form as *Vivipara,* in which its development has been studied, transformed into part of the generative duct.

The functional kidney communicates with the pericardium by a ciliated canal.

In all the gastropoda the gonad or reproductive gland is unpaired. In certain Aspidobranchia it opens into the reno-pericardial canal, as in some of the Lamellibranchia, or into the kidney itself, which thus acts as a gonaduct. In the Neritacea and all other gastropoda there is a separate gonaduct.



FROM MEISENHEIMER, "DIE WEINBERGSCHNECKE"

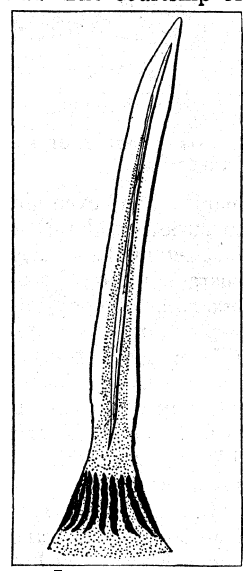
FIG. 21.— REPRODUCTIVE ORGANS OF HELIX POMATIA

The sexes are separate in the Streptoneura with the exception of a few genera, which include certain parasitic forms, Sexual dimorphism is only slightly marked. The male duct ends in a penis which is developed at different points at the anterior extremity of the body. The female system in certain groups exhibits accessory organs and in the forms in which the eggs are incubated in the maternal body there is a brood-pouch. The Euthyneura are hermaphrodite and the gonad is an ovo-testis. In the more primitive Euthyneura the gonaduct passes both the eggs and spermatozoa to the exterior. By various stages a more specialized condition is attained in which the male and female ducts are separated and acquire separate openings (diaulic condition). In the stylommatophorous Pulmonata these are secondarily joined together. Certain Nudibranchia are "triaulic," *i.e.,* they have three genital orifices, the female duct being subdivided into vaginal and oviducal conduits. Accessory glands and organs are a marked feature of the Euthyneura. The latter are usually protandric hermaphrodites, *i.e.,* the spermatozoa come to maturity before the ova. Self-fertilization is not unknown, but usually one individual is fertilized by another. It is worth noting that in one or two cases (Patella, *Crepidula*) among the Streptoneura a change of sex may take place in the same individual and that in sexually differentiated forms hermaphrodite individuals are occasionally found (Acmaea, Lottia, *Ampullaria, Conus*). Parthogenesis (development of the ovum without fertilization) is known in one case (*Paludestrina jenkinsi*).

REPRODUCTION AND DEVELOPMENT

Breeding Habits, Oviposition, Etc.—The breeding habits of very many gastropoda are unknown and in few cases is the life-history from fertilization onwards known in all its details.

In certain primitive Streptoneura the eggs are fertilized externally in the sea water; but in most members of the class the male has a penis and fertilization is internal. The courtship of certain land snails has been carefully studied, and as an example the complex behaviour of the Roman snail (*Helix pomatia*) which has been described by Meisenheimer should be studied. In many land snails courtship is usually accompanied by some act of violent stimulation, usually by means of a calcareous pointed rod (the dart) secreted in part of the male reproductive system.

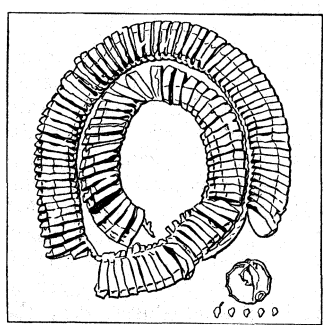


FROM MEISENHEIMER, "DIE WEINBERGSCHNECKE"

FIG. 22.—DART OF HELIX POMATIA

The eggs are usually laid soon after fertilization. They are either deposited singly (*Haliotis,* Gibbula, *Paludestrina*) or in clusters which sometimes form an elaborate "nidus." This may be a simple gelatinous mass (*Limnea*) or a ribbon (certain Opisthobranchia) or a series of horny capsules each containing many eggs may be accumulated in a mass or strung together as a sort of "roulette" (Rachiglossa). The capsules in the latter are formed by a special gland of the foot, a lengthy operation lasting many days. Certain Streptoneura attach their eggs to the external surface of their own shells or those of their neighbours (Paludestrina, some species of Theodoxis, *Capulus*) or deposit them inside the shell (*Vermetus*). *Ianthina* secretes a gelatinous raft on the under surface of which the eggs are suspended. Most of the land snails lay their eggs in holes underground. These are enclosed in a gelatinous envelope (Limax) or in a calcified shell (Helicidae). Certain Bulimulids lay eggs with calcified shells 2–3cm. long, resembling those of birds.

The habit of carrying the eggs on the shell may be perhaps considered as a prelude to more definite and protracted care of the young. *Vermetus,* as has been pointed out, carries the eggs inside the aperture of the shell and certain species of Li*bera* (a pulmonate) places its eggs in the umbilicus of the shell and covers them over with a secretion rather like an epiphragm. There are, however, a good many viviparous or ovoviviparous gastropods, *Vivipari,* Typhobia, a certain species of Melania, and sundry pulmonates incubate their eggs in the terminal part of the oviduct (uterus), while in Tanganyicia and Melania *episcopalis* there is a special brood-pouch which is separate from the oviduct.



FROM "ANIMALS OF ALL COUNTRIES" (HUTCHINSON PERIODICALS)

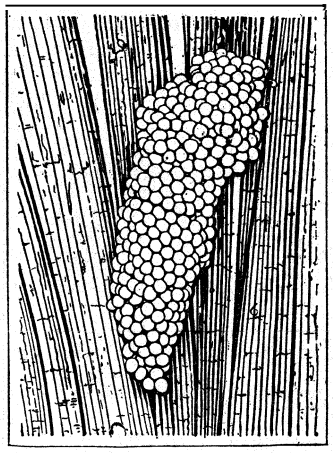
FIG. 23.—EGG CAPSULES OF BUSYCON

The number of eggs varies according to the mode of life and oviposition. *Purpura lapillus* (the dog whelk) deposits up to 150,000 eggs in its capsules and sundry species of Doris lay as many as 600,000. It should be noted that in those Rachiglossa which form capsules containing many eggs some of the latter are devoured by those embryos which emerge first. Interuterine cannibalism has been recorded in the pulmonate Limicolaria. The Pulmonata do not as a rule lay as many eggs as the Streptoneura and Opisthobranchia. Helix *aspersa* deposits up to 100.

Development.— Although the gastropoda display very con-

siderable variation in the adult form, the cleavage of the eggs is more or less the same in all the cases in which it has been studied. Such variation as may have been observed is due to variation in the amount of yolk.

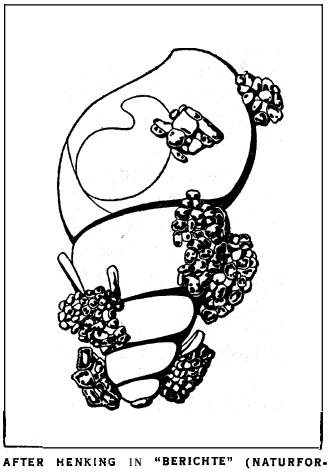
In all gastropoda which have been so far studied cleavage is total and of the type known as spiral. The egg divides into two and then into four cells which are either equal in size (Patella) or approximately equal. A third division then cuts off four small cells (micromeres) from the four original cells (inacromeres). There are now eight cells consisting of a "quartette" of micromeres and the four larger macromeres. The next division gives rise to 16 cells, viz., four more micromeres, which are given off from the macromeres (second quartette) and the products of the sub-division of the first quartette of micronieres. Division proceeds in this way until a cap of numerous micromeres is found lying on top of the four macromeres. In Patella, in which the development is well known, the embryo is at the 32-cell stage radially symmetrical. On the attainment of the 64-cell stage this is replaced by bilateral symmetry.



BY COURTESY OF F. W. BOND

FIG. 24.— EGGS OF THE AMPHIBIOUS SNAIL (AMPULLARIA)

Owing to certain features of the mode of cleavage, it is possible to trace the "lineage" (developmental history) of individual organs back to individual cells or quartettes produced by very early cleavage. This type of research has been a very fruitful source of embryological knowledge, but can only be summarily mentioned here. The micromeres give rise to the ectoderm and its derivatives. the macromeres to endoderm and mesoderm. In Patella gastrulation is by epibole (overgrowth) of the macromeres by the micromeres. At the end of 24 hours the embryo, which up till now has been contained in an egg-membrane, escapes and begins its free-swimming period as a trochophore larva. It is more or less spherical and surrounded by a girdle of long cilia (the prototroch) developed from special trochoblasts.



AFTER HENKING IN "BERICHTE" (NATURFORSCHENDE GESELLSCHAFT)

FIG. 25.—PALUDESTRINA ULVAE CARRYING EGGS COATED OVER BY A LAYER OF SAND-GRANULES

The gut is now developed, the endodermal cells dividing to form the stomach and the mouth and anus arising as ectodermal invaginations. Dorsally, a thickened plate of cells gives rise to the shell-gland, the foot is indicated by two slight prominences on either side of the mid-ventral line, and the mesoderm bands are now formed.

Enlargement of the prototroch to form the *velum* and the growth of the foot characterize the veliger stage. The metamorphosis of the larva has already been described.

The detailed development of the individual organs is not very well known in marine molluscs. We owe the bulk of our knowledge on this subject to the studies of V. Erlanger, Drummond and Tonniges on Vivipara, the pond snail (originally called *Paludina*). The ganglia of the nervous system arise as thickenings of the ectoderm which subsequently become joined together by connectives. The otocysts and eyes are ectodermal invaginations. The pericardium originates as a hollow in the mesoderm and the heart is first seen as a vesicle projecting down from the dorsal wall of the pericardium. The kidneys are tubular extensions of the pericardial cavity; they are joined by ectodermal invaginations which constitute the ureters. The gill appears as a series of folds in the wall of the mantle cavity. The germ cells seem in the first instance to be budded off the pericardial wall and subsequently form a spherical vesicle, the gonad. The kidney of the originally left-hand side forms part of the genital duct.

The origin of the mesoderm in *Vivipara* has been the subject of controversy. (See E. W. MacBride, Text Book of Embryology.)

The account of larval development and organogeny given above is founded very largely upon the study of Vivipara, but it probably represents the course of events in many other gastropods. Departures from this developmental history are mainly of secondary importance, and are due, for example, to the development of special larval organs (*e.g.*, the cephalic vesicle and "podocyst" of Stylommatophora), and the presence of a larger amount of yolk than is usual. The velum is suppressed in oviparous and viviparous forms; but traces of it can be seen in certain of the latter (*Cenia*, some of the Pulmonata). In certain highly modified pelagic larvae the velum is drawn out into extensive lobes (*e.g.*, the Macgillivraya larva of *Dolium*).

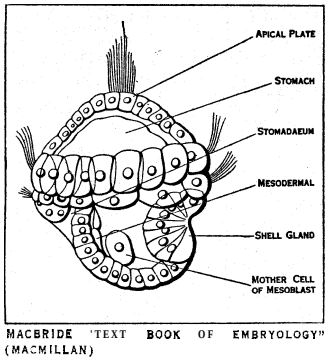
FIG. 26.— EGG CAPSULES OF COMMON WHELK (BUCCINUM UNDATUM)

DISTRIBUTION AND NATURAL HISTORY

The gastropoda have practically a world-wide distribution and are found in the sea, in brackish and fresh water and on land. The marine forms occur in all seas of which the fauna has been examined. In high latitudes they live in the bays and fjords of the Antarctic continent (*e.g.*, in the Ross sea, 77°S.) and off the northern coasts of Greenland and Franz Josef Land. Exactly how far north they occur is uncertain; but in all probability they range right across the north Polar sea. The exclusively marine forms are limited in their distribution by salinity and other environmental factors. But, though it is true that the life-zones that prevent them from invading fresh water and land interpose a strict barrier to their invasion of those habitats, there are certain groups which are intermediate between truly marine forms and those which habitually live in fresh water and on land. The common periwinkle (Littorina litorea) can tolerate very protracted exposure to air (see ANATOMY: Respiratory *Organs*) and the estuaries of most great rivers contain certain forms which can endure daily and seasonal changes of salinity, etc. Similarly, among terrestrial and fresh water gastropods there are forms which are of wide tolerance and live indifferently in water or on land, either being structurally adapted, as in the case of the lung snail (*Ampullaria*) which lives in swamps, and has both a gill and a lung, or having a more or less generalized adaptability (certain species of *Limnea*). Hesse records that an exclusively terrestrial Pulmonate (*Lauria* cylindracea) has taken to living in springs in certain parts of Germany.



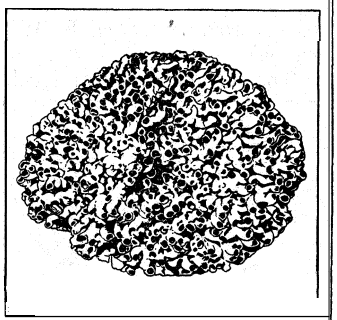
MACBRIDE 'TEXT BOOK OF EMBRYOLOGY" (MACMILLAN)

FIG. 27.— LATERALVIEW OF YOUNG TROCHOPHORE LARVA OF PATELLA COERULEA

The majority of the Streptoneura are marine, but the Helicinidae among the Rhipidoglossa, the Cyclophoridae and Cyclostomatidae among the Taenioglossa have become terrestrial. The members of the genus *Theodoxis* (Neritina) are the only Rhipidoglossa that have invaded fresh water; but many groups of Taenioglossa inhabit the latter, viz., the Viviparidae, Melaniidae, Ampullariidae, Valvatidae, etc. The Stenoglossa are exclusively marine. Among the Euthyneura the Opisthobranchia are likewise a marine group.

The Pulmonata are mainly terrestrial, though certain large families (Planorbidae, Limnaeidae) live in fresh water, and a few (*Amphibola, Siphonaria*) are marine or littoral (Auriculidae).

The horizontal distribution of marine gastropods can only be treated very summarily here. It is sufficient to say that certain main distributional areas can be recognized which have their peculiar and characteristic faunas, the latter being composed of genera and species which are either restricted to those areas or are more frequently found there than elsewhere. For example, in the region between Delagoa Bay and Cape Agulhas, which we may regard as the South African marine province, are found the following genera which occur nowhere else: *Abyssochrysos, Jeffreysiopsis, Alcira, Cynisca, Neptuneopsis* and *Alexandria.* Furthermore, *Bulla Terebra, Ancilla, Patella, Mitra* and *Turritella,* though they occur in other parts of the world, are in this region very richly represented in species, so that South Africa may rightly be considered the metropolis of these genera.

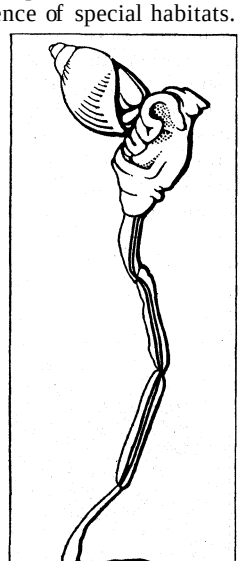


FROM "ANIMALS OF ALL COUNTRIES" (HUTCHINSONS PERIODICALS)

FIG. 28.—SHELL-MASS OF VERMICULUS SPIRATUS, A SESSILE GASTROPOD

The range of individual species is, as in other groups, limited to special areas; but ambiguity as to the precise limits of species makes it difficult to define these areas with exactness in any particular case (*see* SPECIES), while our ignorance as to the opportunities for dispersal and of the physiological constitution and reactions of individual species usually make it impossible to state to what extent the range of species is the expression of a definite constitutional peculiarity.

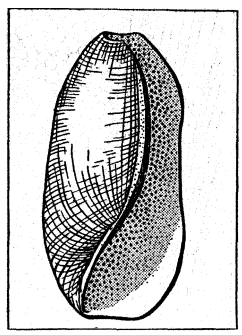
The vertical distribution of marine gastropoda shows a broad grouping of genera according to the preference of special habitats. At the landward limit of marine conditions and often beyond the high-water mark of spring tides are found semi-terrestrial forms, such as the Littorinidae. Well up to high-water mark forms like the marine Pulmonate *Siphonaria* are found, while the limpets (Patellidae) range up to the same level. Between tide marks (littoral zone) are found the Fissurellidae, ormers (*Haliotis*) *Oncidium,* the top shells (*Turbo*) and dog whelks (*Purpura*), as well as those which ascend further beyond the reach of maritime conditions, such as the Littorinidae. Farther down the strand in the shallow water of the Laminarian zone occur a great variety of forms, notably the Nudibranchia. Adaptation to a particular kind of bottom is here of great importance. Burrowing forms, like *Sinum, Natica, Cypraea* and *Bulla* are more frequently found in sand, while the less active creeping forms keep to fronds of *Laminaria* and other seaweeds, the surface of algae, smooth rocks, and the like. *Vermetus,* which is a sessile gastropod with an uncoiled shell, forms irregular masses on rock and coral. *Eulima* and other parasitic forms are found on the external surface or in the body cavity of star-fishes and also in Holothuria. *Magilus* and *Coralliophila* burrow into corals. From the shallow waters downwards the gastropod fauna becomes more sparse. The late W. H. Dall, in his report on the marine gastropoda, obtained by the "Blake" in the gulf of Mexico and the Caribbean sea, gives the following numbers of shallow and deep-water forms: Littoral species, 280; species found down to the edge of the continental shelf (about 100 fathoms) 222; deep water species, 83. Among typical abyssal genera are *Mangilia, Margarita* and *Pleurotoma.* The greatest depth from which a gastropod has been so far taken is 2,845 fathoms (U.S.S. "Albatross" off the coast of Peru).



FROM VOELTZKOW, "REISE IN OSTAFRIKA" (SCHWEIZERBART)

FIG. 29.—MUCRONALIA VARIABILIS, A PARASITIC GASTROPOD SHOWING LONG PROBOSCIS

The forms which have so far been considered are those which in adult life live permanently on the sea bottom. The larvae of very many of these are floating organisms which form part of the marine plankton until they metamorphose into the adult condition. There are, however, three groups and some isolated genera of gastropoda which permanently live floating off the bottom. These are the Heteropoda, an interesting group of Taenioglossa, some of which are curious, highly modified creatures, and the Thecosomata and Gymnosomata. The last two groups, which are sometimes erroneously united into a single group called Pteropoda, form a very large part of the minute plankton of all seas Over 4,000 specimens of *Limacina helicina* were obtained by the "Terra Nova" in a single haul in McMurdo Sound (antarctic). The purple snail *Zantlzina,* which secretes a gelatinous float for its eggs, and the nudibranchs *Phyllirrhoe, Glaucus* and *Scyllaea,* are similarly pelagic, while several tectibranchs such as *Aplysia* and *Tethys* are modified for swimming, though they seem to keep near the bottom.



FROM THE "BULLETIN" OF THE MUSEUM OF COMPARATIVE ZOOLOGY, CAMBRIDGE, MASS

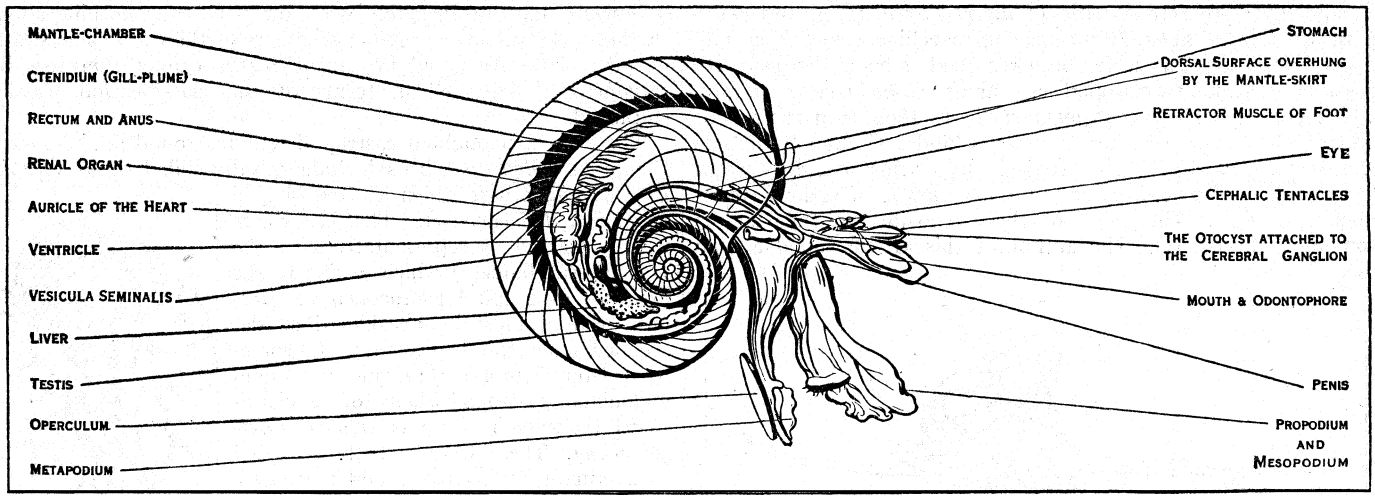
FIG. 30.—SCAPHANDER CYLINDRELLUS

Freshwater gastropoda are omnipresent. They are found in high tarns in the Himalayas, where *Limnea hookeri* has been taken at a height of over 18,000ft. above sea level. *Aplecta hypnorum* reaches as far north as 73° N. in the Taimyr peninsula. The most characteristic and widely spread freshwater gastropoda are members of the *Viviparidae, Melaniidae, Theodoxis, Limnea* and *Planorbis.* They occupy a great variety of habitats—not only rivers, lakes, streams and smaller stretches of water, but also hot springs, torrents, the "trickles" down the faces of cliffs, and marshes. They also invade cattle-troughs, irrigation ditches, water mains and cisterns. As in the case of marine gastropoda, there is some uncertainty as to the precise range and exact habitat of individual species, though in particular areas the habitat of certain species is fairly well defined. *Vivipara vivipara,* the common river snail of the British Isles, prefers slowly-flowing rivers and canals; *Valvata macrostoma* is usually found in marshes and ditches. Pilsbry and Bequaert record the fact that *Limnea natalensis undussomae, Physopsis africana,* and certain species of *Planorbis* prefer open shallow pools of small size. Certain great river systems are occupied by characteristic genera. For example, species of *Cleopafra* and *Lanistes* are peculiar to the Nile drainage area. Other genera are practically cosmopolitan, such as *Unio, Vivipara* and *Limnea.*

The gastropoda which live on land are not so tolerant of external conditions as are certain other groups of terrestrial invertebrates. In Spitsbergen, which on account of divers adverse factors (low winter temperature, etc.) does not sustain a very large and varied animal population, there are no land Mollusca at all, though there are a number of Collembola, Diptera, spiders, mites and other invertebrates.

Extremes of temperature do not as a rule limit the distribution of land gastropoda. Lack of moisture and of lime in the soil on which they live appear to be the most important factors in preventing their spread. In tropical countries lack of shade and suitable places for concealment from excessive heat and light act in a similar way. As a rule they are not found plentifully on "acid" soils. Alkins and Lebour found that of 27 species, 20 were found on rather alkaline soils (pH7·0), 14 tolerated rather more alkaline soils (pH8·0), while only four were found on acid soil (pH5). They are likewise poorly represented in deserts and other dry habitats, although they are not necessarily absent from the latter if there are opportunities for burrowing and a plentiful dew-fall.

Apart from these limitations the terrestrial gastropoda are almost world-wide in distribution A slug *Anadenus* is found at 17,000ft in the Himalayas, and *Chronos sublimis* was taken at

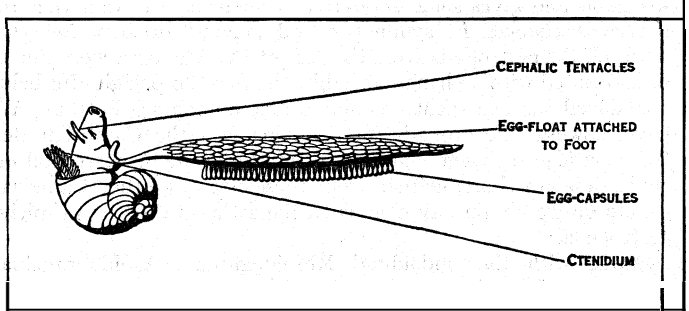


AFTER SOULEYET IN LANKESTER, "TREATISEON ZOOLOGY" (A & C BLACK)

FIG. 31.—OXYGYRUS KERAUDRENI

over 16,000ft. on Mt. Carstenz in New Guinea. Land snails and slugs are found in well-vegetated areas, *e.g.*, woodland, pastures, hedges and banks, jungle, among mosses and lichens and in more arid situations such as cliff faces, rocks and sand dunes. They burrow underground, climb trees and invade houses.

The means by which land gastropoda are dispersed act rather more slowly than those by which marine and freshwater forms are carried about. As a result, land snails and slugs are more



PROM LANKESTER, "TREATISE ON ZOOLOGY" (A & C BLACK)

FIG. 32.— FEMALE JANTHINA WITH EGG FLOAT

localized in their distribution. Extreme cases of such restricted distribution are seen among the Achatinellidae (tree snails) of the Sandwich Islands and the Partulas of Tahiti. Many species of these groups are restricted to single valleys or ridges, and well marked mutational forms are even said to be restricted to a single tree or group of trees.

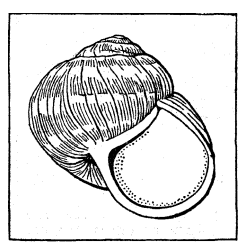
On the other hand, given suitable conditions, dispersal may be to a certain degree facilitated by their habits and constitution. Bartsch has pointed out that the Cerions of the Florida Keys, etc., which can live for four days in sea-water and have the habit of fixing themselves to dead wood during estivation, have probably been transported from island to island after hurricanes which have washed away such timber from the low-lying coastal regions which the Cerions inhabit. The chief continental areas of the world are each characterized by a number of peculiar families and genera, and certain deductions as to former land-connections between such areas may be made. Thus the Achatinidae, Dorcasiinae, Limicolaria, Burton, etc., are exclusively found in Africa and the Bulimulidae, Drymaeus and Borus, in South America. Among the land Mollusca of South America, however, are representatives of the Stenogyridae, a family characteristic of African fauna, and conversely there are Bulimulus-like genera in Africa.

Habits, etc.—The greater number of gastropoda are passive animals of relatively small size and limited powers of locomotion. Usually increase of activity is associated with the carnivorous habit. Their inertia and lack of mobility are compensated by the shell, their more or less obscure appearance and secretive habits, which are their chief defences against enemies. Among marine forms the great power of adhesion manifested by the foot prevents them from being washed away to unfavourable ground, On land the habits of burrowing and entering crevices, of estivation and hibernation are safeguards against climatic excess. Protection against drought is of great importance for animals which require much water. The shelled terrestrial forms are protected against desiccation, and in addition many have the faculty of secreting a covering to the aperture of the shell after they have retired into the latter, The naked forms die very quickly if exposed to very dry air or strong sunlight. Both shelled and naked forms tend to secrete themselves in the daytime and to emerge in the evening or during rainy spells.

Apart from the dependence upon certain necessary external conditions gastropoda seem to be adaptable animals and peculiarly tenacious of life. There are well-authenticated records of land snails which have lived for years without food.

Marine and terrestrial gastropoda have to contend with other hostile forces besides the physical factors of their environment. Marine Mollusca are preyed upon by a variety of enemies. As eggs and larvae they are eaten-by very many vertebrate and invertebrate animals. Fish and sea-birds feed on them in the adult state and whales consume large quantities of the planktonic forms. Birds, carnivorous beetles and small mammals such as rats and mice, take a heavy toll of land snails. Ducks, geese and water beetles feed on pond and river snails.

The gastropoda are vegetable eaters, carnivores or live on organic débris of all kinds. Most Aspidobranchia and Taenioglossa feed on plants, the marine forms browsing on algae. Natica, the Lamellariidae, and the Heteropoda are, however, carnivorous. Natica preys on lamellibranchs, through the shells of which it bores by means of an acid secretion. Captain F. Davis found that the clam Spisulla *elliptica* is persistently preyed upon by Natica *alderi* on the Dogger Bank, about 88% of the clams taken on certain hauls having their shells bored by their enemy. The sessile Taenioglossa, like Vermetus, are plankton-feeders. The Stenoglossa are mainly carnivorous and prey upon other molluscs, or else they feed on carrion. Among the Opisthobranchia the Eolids feed on hydroids, the stinging cells (nematocysts) of which are retained and stored in the dorsal papillae, from which they are discharged when the animal is attacked. The majority of the land Pulmonata feed on green plants, fungi, lichens or vegetable débris. The snail-slug (Testacella) feeds on earth-worms, and *Glandina, Oleacina* and the Streptaxidae are similarly carnivorous.

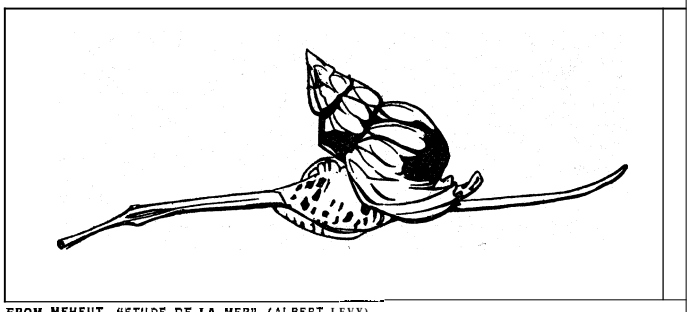


FROM TAYLOR, "MONOGRAPH OF THE LAND AND FRESHWATER MOLLUSCA OF THE BRITISH ISLES"

FIG. 33.—EPIPHRAGM OF HELIX POMATIA

Commensalism is not of such frequent occurrence among gastropoda as it is among Lamellibranchia. A certain number of

Taenioglossa are ectoparasitic (Stilifer, Thyca, etc.), and endoparasitic (*Entoconcha, Entocolax*) upon echinoderms. The only other animal that has so far been recorded as being the host of a gastropod is the stomatopod crustacean *Gonodactylus chiraja,* which harbours *Epistethe* gonodactyli. In their turn gastropods serve as hosts for parasites of various kinds. Certain trematode worms pass part of their life-cycle in marine and freshwater gastropods, and in two cases the association is of serious consequence to man. The effect of these parasites on the snail is sometimes disastrous. The author of this article found a high

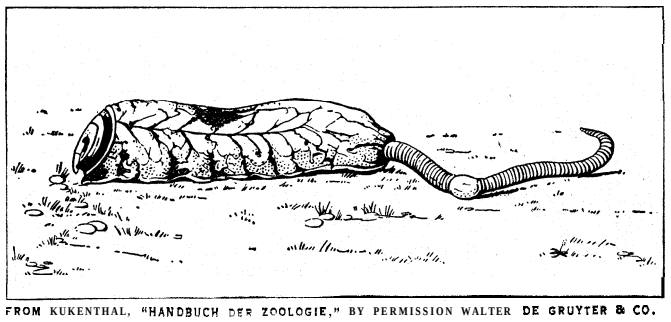


FROM MEHEUT, "ETUDE DE LA MER" (ALBERT LEVY).

FIG 34 — WHELK DEVOURING A PIPEFISH

percentage of a small gastropod *Paludestrina* ventrosa castrated by a trematode which had invaded the reproductive organs of its host. Infection by such parasites is probably high when the parasite passes the rest of its life-cycle in a vertebrate host which preys on the gastropod, as in the case of sea-birds which feed on small water snails in tidal ditches. Certain dipterous flies are parasitic on land snails and several kinds of mites are found on the latter, though it is uncertain if they are actually parasitic.

The gastropoda are protected, as has been stated above, from the attacks of enemies by passive means (their shell and retiring habits). The shell, however, is not always an adequate safeguard from assault. Carnivorous beetles thrust their heads into the aperture and drag the inmate out. Boettger has produced some very interesting and suggestive observations on the relation between attacks of this sort and the development of projections from the sides of the shell-aperture in certain land snails (Otala) which are attacked by carabid beetles. Whether the colour-pattern and sculpture of the shell, which is often very elaborate, are of any protective value is uncertain at present. Observations upon the destruction of the common hedge snails (Cepea) seem to show that birds do not discriminate between the banded and the un-



FROM KUKENTHAL, "HANDBUCH DER ZOOLOGIE," BY PERMISSION WALTER DE GRUYTER & CO.

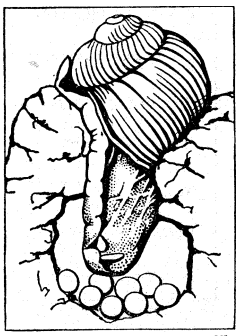
FIG. 35.— TESTACELLA EATING AN EARTHWORM

banded varieties of C. *hortensis* and C. nemoralis. Few positive instances of protective or warning coloration are known, as the habits and enemies of the animals concerned are so imperfectly known. Various species of Cochlicella certainly resemble the seed-pods of the plant on which they mainly feed, and certain Clausilias are sufficiently like leaf-buds; but it is difficult to decide if these resemblances are more than fortuitous. Sundry marine forms which feed on holothurians and tunicates resemble these animals in colour; but again the protective value of the resemblance is uncertain.

PALEONTOLOGY AND EVOLUTION

A great deal is known concerning the fossil remains of gastropod shells; but unfortunately we know practically nothing about the internal structure of extinct members of the class. The status of many interesting and important fossils cannot therefore be satisfactorily discussed in terms of the classification usually employed.

The earliest undoubted gastropod remains found in the Lower Cambrian (*Olenellus*) beds include spirally-coiled shells (Raphistoma) and others which are cup-shaped (*Scenella, Palaeacmea*). The latter are usually treated as representatives of the Docoglossa (limpets) which, owing to the presence of a spiral protoconch (embryonic whorl), must be considered as descended from spiral ancestors. In somewhat later Cambrian horizons are found undoubted gastropod shells of a planospiral (nautiloid) shape (*Cyrtolites,* Bellerophon). These were actually regarded as nautiloids by Deshayes and placed by him in the Cephalopoda. They are now held to be gastropods and have been compared with the pelagic Taenioglossan Atlanta. The slit at the edge of the shell-aperture comparable with that found in the rhipidoglossate *Pleurotomaria,* a genus which appeared in the Silurian (possibly in the Cambrian), justifies the inclusion of *Bellerophon* among the Rhipidoglossa rather than the Taenioglossa. Nevertheless the similarity of their shell to that of the pelagic Atlanta suggests that they were of a swimming or floating habit and gives some support to the theory of Naef that the profound changes in symmetry and general organization that mark off the gastropoda from the rest of the Mollusca were due to or associated with a change of habit, the floating pelagic life being abandoned for one spent creeping about on the sea bottom. We have, however, no grounds for believing that the Cambrian Bellerophontidae represent the most primitive grade of gastropod organization. In short, neither from these nor any other Cambrian genera do we obtain any clue as to the structure of the primitive gastropoda.

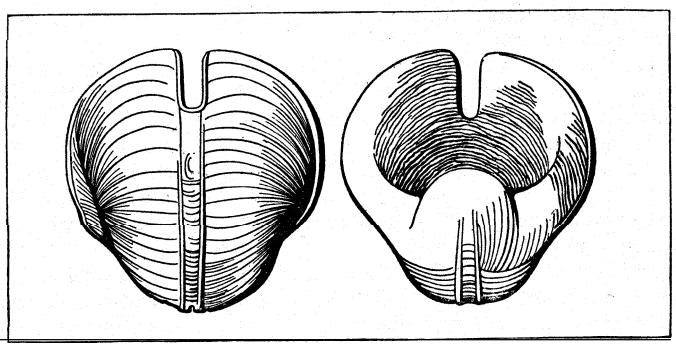


FROM MEISENHEIMER, "DIE WEIN-

G. 36.—OVIPOSITION HELIX POMATIA

Along with the undoubted Rhipidoglossa (Aspidobranchia) above described there are found gastropods which are usually held to be representatives of the *Pectinibranchia.* Stenotheca seems to be related to the Taenioglossan Capulus, and the modern Pyramidellidae are traced to other Cambrian forms.

The Streptoneura are thus well represented in the oldest fossiliferous rocks. In lower and upper Silurian times they increased and many families still flourishing appeared at that epoch, *e.g.,* the



FROM A V ZITTEL, "GRUNDZUGE DER PALAEONTOLOGIE"

FIG. 37.— SHELL OF BELLEROPHON BICARENUS (CAMBRIAN)

Scalaridae, the Capulidae and Turbinidae. Many groups of Rhipidoglossa now extinct reached their developmental climax in mid-Primary times. The Pleurotomariidae, represented at the present day by four very rare species, numbered several hundred species.

Undoubted Euthyneura do not appear until the Carboniferous, when tectibranchs like *Acteon,* etc., are found. With this fact in mind, it is necessary for us to consider briefly one of the most puzzling series of fossils that have been found in Primary rocks.

For a long time certain tubular shells resembling somewhat those of "Pteropods" have been known from Cambrian strata. They have variously been interpreted as thecosomatous pteropods, as cephalopods and tubicolous annelids. Broili (in the last edition of Zittel's *Grundziige der Paliiontologie)* retains them in the gastropoda as an enigmatic class, the Conularida. In 1911 Walcott, in describing the Cambrian fauna of the Burgess shales (British Columbia) figured a species of the genus *Hyolithes,* H. *carinatus,* in which are seen structures somewhat resembling the fins of pteropods. It is not easy, however, to accept these structures as indicative of fins like those of thecosomatous pteropods: and as the shells of these forms are not in themselves sufficient clue to the identity of the animals it is better to accept Broili's verdict. Nevertheless, if these remains are subsequently proved to be those of pteropods, and if the hiatus in time between their appearance and that of the other Opisthobranchia is not merely due to the imperfection of the geological data, then we shall be driven to one of the two very interesting conclusions. It will be necessary to assume either that the Thecosomata were developed directly from the primitive streptoneuran stock and are not from the Opisthobranchia, as is usually believed, or that the Cambrian Thecosomata have nothing to do with modem "Pteropoda," but represent an early essay in pteropod-like specialization.

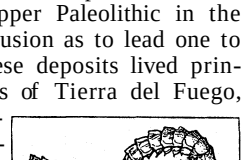
BY COURTESY OF THE SMITHSONIAN INSTITUTE

FIG. 38.—HYOLITHES CARINATUS

The Pulmonata first appear in the Carboniferous. *Dendropupa* and *Anthracopupa,* which seem to be undoubted land pulmonates, referable to the modern family of the Pupidae, are found in the Carboniferous of North America. Undoubted Basommatophora (*Auricula, Linznea, Planorbis)* appear in the Jurassic; but it is by no means certain if the terrestrial Pulmonata actually preceded the fresh-water forms. Since their first appearance in the Carboniferous the Pulmonata, both terrestrial and aquatic, steadily increased through Secondary and Tertiary times until the present day, when they are one of the largest and most highly diversified groups of living animals.

ECONOMIC USES

Although the gastropods are not of outstanding service or disservice to man in any one respect they are of considerable importance in a number of ways. Their chief value is perhaps as an article of diet; for since the earliest stages in man's development they have been used as food. In middle and late Paleolithic deposits in Europe, limpets, periwinkles and top shells occur. In certain "kitchen middens" of the Upper Paleolithic in the west of Scotland they occur in such profusion as to lead one to suppose that the people who formed these deposits lived principally upon these molluscs. The natives of Tierra del Fuego, according to Tylor, used similarly to subsist on various kinds of shellfish, and gastropods of various kinds occur in their middens. At the present day H. Lang (quoted by Pilsbry) states that the Achatinas (large land snails) "are a welcome addition to the food supply of most tribes" in the Belgian Congo, and that their shells "are seen lying on refuse heaps and along the rivers." Among European peoples whelks, periwinkles and ormers are largely consumed; 889 tons of whelks and 3,245 tons of periwinkles were delivered at Billingsgate market, London, in 1922. Though landsnails are only eaten in a few districts in England they are largely used in France, where *Helix pomatia* (the Roman snail) is cultivated on *escargotières* or snail farms.



FROM A PHOTOGRAPH BY HUGH MAIN

FIG 39.— GLOW WORM LARVAE EATING SNAIL

As bait and as the food of edible fishes, birds and whales, gastropods are of substantial indirect value to man.

The shells of gastropoda have been put to a variety of uses by the different races of mankind. The mother-of-pearl obtained from large specimens of *Turbo* and *Haliotis* is imported into Europe for button-making, inlaying and sundry articles of virtu. Among native tribes shells are put to many uses. Those of *Cypraea ntoneta* (the money cowry) are used as currency in Africa and elsewhere, and other species of *Cypraea* are reserved as ornaments for kings and chieftains in the Pacific islands. The left-handed chank *(Turbinella rapa)* is used in the ritual of the god Vishnu in India. Trumpets are still made from *Triton* shells in Africa and the East, just as they apparently were among the early inhabitants of the Mediterranean. The natives of Central Africa use the large shells of various species of *Aclzatina* as drinking-vessels and salt-containers.

The rock-whelk (*Murex*) is no longer fished in the Mediterranean for the sake of the dye which was used in preparing "Tyrian" purple; but species of *Fasciolara* are still employed for obtaining dye by various native races.

Gastropoda are obnoxious to man in at least two important connections. Considerable damage is done to crops by slugs and land snails. *A* small snail *Zonitoides arboreus* causes sugar-cane root disease in Louisiana. Marine gastropods are less obviously obnoxious to man, but one at least in the British Isles has proved itself a troublesome pest of oyster-beds. This is the American slipper limpet (*Crepidula fornicata*), which was accidentally introduced many years ago and has since then multiplied excessively and overruns the oyster beds in south-east England. A more disastrous work is done by those freshwater gastropods which harbour parasites harmful and even fatal to man and one of his more valuable domestic animals. *(a)* In the Middle East, in Japan, various parts of Africa and in South America and the West Indies, species of a trematode, *Schistosoma* (=*Bilharzia*) which cause bladder disease in man, pass part of their life cycle in various species of *Isidora* and *Planorbis. A* focus of this disease has been recently detected in Portugal, where *Planorbis metidjensis* is probably the intermediate host of the parasite. (b) The liver fluke *(Distomum hepaticum)* passes part of its life in the water snail *Linznea truncatula.* Sheep grazing in flooded meadows or near streams become infected with the fluke, which causes "liver-rot."

For the historical treatment of this subject *see* MOLLUSCA.

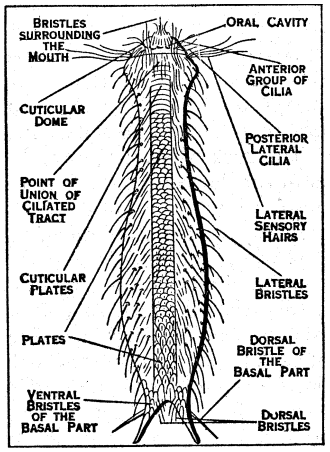
GASTROTRICHA, a small group of fairly uniform animals which live at the bottom of ponds and marshes, hiding amongst the recesses of fresh-water plants and eating organic débris and Infusoria. They vary in size from one-sixtieth to one-

three-hundredth of an inch, and move by long cilia. Two ventral bands of regular transverse rows of cilia are usually found. The head bears some especially large cilia. The cuticle which covers the body is here and there raised into overlapping scales which may be prolonged into bristles. The body, otherwise circular in section, is slightly flattened ventrally. There is a protrusible pharynx armed with eversible recurved teeth. This leads to a muscular oesophagus with a triradiate lumen, which acts as a sucking pump and ends in a funnel-valve projecting into the oval stomach. The nitrogenous excretory apparatus consists of a coiled tube on each side of the stomach, ending internally in large flame-cells. A cerebral ganglion rests on the oesophagus; it is continued some way back as two dorsal nerve trunks. In some species there are eyes. The two ovaries lie at the level of the juncture of the stomach and rectum. The large eggs are laid amongst water weeds. The male reproductive system is little known. The Gastrotricha are hermaphrodite. The group is divided into two sub-orders, the Euichthydina, with a forked tail, and the Apodina, in which the tail is not forked. About 50 species are known. The group shows no clear affinities with any of the great phyla.



FROM ZEITSCHRIFT FUR WISSENSCHAFT,' AFTER ZELINKA (ENGELMANN) GASTROTRICHA (CHAETONOTUS MAXIMUS), A SMALL GROUP OF ANIMALS LIVING AT THE BOTTOM OF PONDS AND MARSHES AND FEEDING ON ORGANIC DÉBRIS AND INFUSORIA. IN SIZE THEY RANGE FROM 1/60 TO 1/300 OF AN INCH

GATCHINA, U.S.S.R.: *see* **TROTSK.**

GATES, HORATIO (1728–1806), American general, was born at Maldon in Essex, England, in 1728. He entered the English army at an early age, and was rapidly promoted. He accompanied Gen. Braddock in his disastrous expedition against Ft. Duquesne in 1755, and was severely wounded in the battle of July 9; he saw other active service in the Seven Years' War. After the peace of 1763 he purchased an estate in Virginia, where he lived till the outbreak of the American Revolution in 1775, when he was named by Congress adjutant-general. In 1776 he was appointed to command the troops which had lately retreated from Canada, and in Aug 1777, as a result of a successful intrigue, was appointed to supersede Gen. Philip Schuyler in command of the Northern Department. In the two battles of Saratoga (*q.v.*) his army defeated Gen. Burgoyne, who, on Oct. 17, was forced to surrender his whole army. This success was, however, due largely to the previous manoeuvres of Schuyler and to Gates's subordinate officers. The intrigues of the Conway Cabal to have Washington superseded by Gates completely failed, but Gates was president for a time of the board of war, and in 1780 was placed in chief command in the South. He was totally defeated at Camden, S.C., by Cornwallis on Aug. 16, 1780, and in December was superseded by Greene, though an investigation into his conduct terminated in acquittal (1782). He then retired to his Virginian estate, whence he removed to New York in 1790, after emancipating his slaves and providing for those who needed assistance. He died in New York April 10, 1806 *See* J. H. Brandow, "Horatio Gates," N.Y. *State Hist. Assoc. Proc.*, vol. iii, pp. 9–19 (1903).

GATESHEAD, municipal, county and parliamentary borough, Durham, England; on the Tyne opposite Newcastle, and on the L.N.E.R. Pop. 117,000 (1938). Area 7 sq mi. The parish church of St. Mary is an ancient cruciform edifice surmounted by a lofty tower; but extensive restoration was necessitated by a fire in 1854 which destroyed a considerable part of the town. Education is provided by a grammar school, a large day school for girls and technical and art schools. Five bridges connect the town with Newcastle-upon-Tyne (*q.v.*). There are large iron works (including foundries and factories for engines, boilers, chains and cables), shipbuilding yards, glass manufactories, chemical, soap and candle works, brick and tile works, breweries and tanneries. The town formerly had a depot of the L.N.E.R., with large stores and locomotive works; its removal to Darlington contributed to the severe effects of the depression of the 1930s felt at Gateshead, where 36% of the working population were unemployed in 1934. Extensive coal mines exist in the vicinity; and at Gateshead Fell are large quarries for grindstones. The county borough was created in 1889 and returns one member to parliament.

Gateshead (Gateshewed) probably grew up during late Saxon times, the mention of the church there in 1080 being the first evidence of settlement. In 1552, on the temporary extinction of the diocese of Durham, Gateshead was attached to Newcastle. but in 1554 was regranted to Bishop Tunstall. During the next century Bishop Tunstall's successors incorporated nearly all the trades of Gateshead, and Cromwell continued this policy. As part of the palatinate of Durham, Gateshead was not represented in parliament until 1832. In 1336 the burgesses claimed an annual fair on St. Peter's Day, and depositions in 1577 mention a borough market held on Tuesday and Friday, but these were apparently extinct in Camden's day, and no grant of them is extant.

GATH, one of the five royal cities of the Philistines. It would seem to be identical with the Kn-tu in the lists of Thuthmose III. and Gimtu (Gintu) of the Tell-Amarna letters. The name occurs several times in the Old Testament, especially in connection with the history of David. Goliath, the Philistine champion, hailed from Gath. Rehoboam is said to have fortified Gath, but Uzziah found it still a Philistine city. Sargon's records show that he took it in 712 B.C. Gath was evidently a place of importance, a walled city (2 Chr. on xxvi. 6), and it is surprising its exact location has been lost since the time of Sennacherib. The *Onomasticon* of Eusebius fixes the site near the road five Roman miles from Eleutheropolis (Beit Jibrin) on the way to Diospolis (Lydda). The Roman road is still traceable and at the place indicated stands Tell es-Sāfi, a small mud village, having near it the mound which marks the site of the Crusaders' castle, Blanchegarde. The village stands on a cliff about 300 ft. high in which are many caves. A fenced city on such an eminence would be remarkably strong, and surprise is naturally felt at its complete disappearance.

The position of the village at Tell es-Sāfi has precluded a complete survey, but the excavations carried out there have, on the whole, proved disappointing and rendered the identification with Gath highly questionable. This and the fact that the sister Philistine cities do not occupy sites naturally strong, but are merely mounds on the plain, make it possible that Gath may yet be found between the coast and the Shephelah. Albright suggests 'Arāk el-Minshiyeh, or rather Ahmad el-'Araini a hill close beside it, as the site of Gath. Tell es-Sāfi he would identify with Makkedah.

See **W. F.** Albright, in ***Bulletin of the American School of Oriental Research,*** 1921 and 1924. (E. Ro.)

GATHAS, the name given to certain chapters of the Zend-Avesta of Zoroaster. It contains the discourses and exhortations of the prophet as well as 17 hymns written in an archaic metre. The language is of considerable antiquity, differing considerably from that ordinarily used in the Avesta. *See* ZEND-AVESTA and ZOROASTER.

GATINEAU, a river of Quebec in Canada, rising in a chain of large lakes due north of 48° N. lat., and continuing southwesterly until it merges into the Ottawa, about one m. below the city of that name. This is one of the main sites of hydroelectric power development in the Dominion. *See* QUEBEC and OTTAWA.

GATLING, RICHARD JORDAN (1818–1903), American inventor, was born in Hertford county (N.C.), Sept. 12, 1818. He assisted in the construction and perfecting of machines for sowing cotton seeds, and for thinning the plants. In 1839 he perfected a practical screw propeller for steamboats, only to find that a patent had been granted to John Ericsson for a similar

invention a few months earlier. He established himself in St. Louis, and taking the cotton-sowing machine as a basis he adapted it for sowing rice, wheat and other grains. The introduction of these machines did much to revolutionize the agricultural system in the country.

Becoming interested in the study of medicine through an attack of smallpox, he completed a course at the Ohio medical college in 1850. In the same year he invented a hemp-breaking machine, and in 1857 a steam plough. At the outbreak of the Civil War he devoted himself at once to the perfecting of fire-arms. In 1861 he conceived the idea of the rapid fire machine-gun which is associated with his name. By 1862 he had succeeded in perfecting a gun that would discharge 350 shots per minute; but the war was practically over before the Federal authorities consented to its official adoption. The invention was adopted by almost every civilized nation. Gatling died in New York city, Feb. 26, 1903.

GATTI-CASAZZA, GIULIO (1869–1940), operatic director, was born at Udine, Italy, Feb. 3, 1869. He was educated at the University of Ferrara and the Royal Superior Naval Academy of Genoa, graduating as an engineer, and studied privately literature, history and music. In 1593 he was made a member of the board of directors of the Municipal theatre and superintendent of the other musical institutions of Ferrara and subsequently (1898) became general artistic and administrative director of the Scala, Milan, remaining there until 1908. Among the singers who appeared under his management were Caruso and Chaliapin. From 1908 to 1935 he was general artistic and administrative director of the Metropolitan Opera. New York. After his retirement he returned to Italy. He died at Ferrara Sept. 2, 1940.

GATTY, MARGARET (1809–1873), English writer, daughter of the Rev. Alexander Scott (1768–1840), chaplain to Nelson, was born at Burnham, Essex, and married in 1839 the Rev. Alfred Gatty, vicar of Ecclesfield, near Sheffield. Mrs. Gatty is remembered for her many admirable books for children, the most famous of which is the *Parables from Nature* (5 vols. 1855–71). As "hunt Judy" of *Aunt Judy's Magazine* she became the personal friend of thousands of her child readers and correspondents.

GATTY, NICHOLAS COMYN (1874–), English composer, was born at Bradfield near Sheffield on Sept. 13, 1874. He was educated privately and at Downing College, Cambridge, and afterwards entered the Royal College of Music, where he studied composition under Stanford. In 1907 he became musical critic to the *Pall Mall Gazette*. For many seasons he acted as musical assistant on the stage at Covent Garden. In 1927 he received the degree of Mus.D. from Cambridge university. He is principally a composer of opera, but has also written: Variations on "Old King Cole" for orchestra; a suite for strings; a setting of Milton's ode: "Fly, envious Time" for chorus and orchestra; three Short Odes (Clough and Shelley); variations and a sonata in G for violin and piano; two sets of piano waltzes, and a number of songs. His operas are: *Greysteel* (unpublished), produced at Sheffield (1906) and *Duke or Devil* (Manchester, 1909), both in one act; *Prince Ferelon*, musical extravaganza in 1 act, produced in 1919 and now established in the repertoire of the "Old Vic." (vocal score published by the Carnegie Trust); *The Tempest* (unpublished), Surrey Theatre, London, 1920; *King Alfred and the Cakes*, and *Macbeth*.

GAUCHOS, a nomadic South American race inhabiting the Argentine Republic and Uruguay of mixed Spanish and Indian descent. They are tall, handsome, strikingly dressed and of great endurance, with a combination of dignity and arrogance in their bearing. Their chief occupation is leather making and ranching, the wild conditions under which they live having made them excellent horsemen, skilled in the use of the lasso and bolas (*q.v.*).

GAUDEN, JOHN (1605–1662), English bishop and writer, reputed author of the *Eikon Basilike*, was born at Mayland, Essex, where his father was vicar. Educated at Bury St. Edmunds and at St. John's college, Cambridge. he seems to have been at Oxford until 1630, when he became vicar of Chippenham. His sympathies were at first with the parliamentary party. He was chaplain to Robert Rich, second earl of Warwick, and preached before the House of Commons in 1640. Apparently his views changed as the revolutionary tendency of the Presbyterian party became more pronounced, for in 1648/9 he addressed to Lord Fairfax *A Religious and Royal Protestation . . .* against the proceedings of the parliament. Under the Commonwealth he faced both ways. At the Restoration he was made bishop of Exeter. He complained to Hyde, earl of Ciarendon, of the poverty of the see, and based claims for a better benefice on a certain secret service, which he explained on Jan. 20, 1661 to be the sole invention of the *Eikon Basilike, Tlze Pourtraicture of his Sacred Majestie in his Solitudes and Sufferings*, put forth within a few hours after the execution of Charles I. as written by the king himself. To which Clarendon replied that he had been before acquainted with the secret and had often wished he had remained ignorant of it. Gauden was advanced in 1662, not as he had wished to the see of Winchester, but to Worcester. He died on May 23 of the same year.

See *Private Correspondence between Chas. I. and Sir Ed. Nicholas* pubd. as vol. v. of the *Memoirs of John Evelyn* (1827); C. Wordsworth, *Who wrote Eikon Basilike?* two letters addressed to the archbishop of Canterbury (1824), and *King* Charles *the First, the Author of Icon Basilikè* (1828); E. J. L. Scott's introduction to his reprint (1880) of the original edition; articles in the *Academy*, May and June 1883, by C. E. Doble; another reprint edit. by E. Almack for the King's Classics (1904); and E. Almack, *Bibliography of the King's Book* (1896) which summarizes etc. the arguments on either side and gives a full bibliography.

GAUDIER-BRZESKA, HENRI (1891–1915), French sculptor, a leading representative of the Vorticist movement which held that the subject-matter of a work of art need not represent or be like anything in nature; only it must be alive with rhythmic vitality. He was born at St. Jean de Braye, Loire, on Oct. 4, 1891. He was the son of Joseph Gaudier, a joiner. After gaining a scholarship he was educated at Bristol college; and was there provided with funds to study art. He went to Nuremberg and Munich and in 1910 returned to France. He henceforth called himself Gaudier-Brzeska. His first commission in sculpture was the statue of Maria Carmi. At the age of 22 he had established his style in the marbles "The Dancer" and "The Embracers." He was killed in a charge at Neuville St. Vaast on June 5, 1915. A memorial exhibition of his work was held at the South Kensington museum, London.

See Ezra Pound, *Gaudier-Brzeska: His Life and Work.*

GAUDY, as a noun, in the sense of rejoicing or feast, a word used of a commemoration dinner at an Oxford college.

GAUGAMELA (ARBELA), BATTLE OF (Oct. 1, 331 B.C.). After his defeat at Issus, Darius assembled a vast horde of men at Babylon. Thence, marching northwards, he crossed to the left bank of the Tigris, and established his magazines and harems at Arbela (Erbil). From Arbela he moved forward to Gaugamela, some 32 miles westwards. Having conquered Egypt, Alexander marched northwards through Palestine, crossed the Tigris at Bezabdi, north of modern Mosul, and, learning of the Persian king's whereabouts, he at once moved forward with a picked force of cavalry. Having located the enemy, he rested his army for four days and fortified his camp. Whilst this was taking place, Darius deployed his army on the plains of Gaugamela, which he converted into a huge parade ground by levelling it. On the fourth night Alexander advanced, but when 3) miles distant from him he called a halt, and assembled his generals. Parmenio suggested that they should encamp where they were, and reconnoitre the ground and the enemy. To this Alexander agreed, and whilst the camp was being fortified, "he took the light infantry and the companion cavalry and went all round, reconnoitring the whole country where he was about to fight the battle." On his return he called together a conference at which he discussed what he had seen, and urged upon his generals the importance of the immediate execution of orders. Whilst the soldiers were resting, Parmenio came to Alexander's tent and suggested a night attack. This proposal Alexander refused to consider, his reason (more probable than the story of his disdaining such craft) being that in the approaching battle he had planned to deliver a decisive blow, and he knew well the difficulties coincident with night operations. Having rejected this advice, Alexander drew up his army. The phalanx was marshalled in

the centre, the right wing consisting of its three right divisions, the hypaspists, the agema and the Companion cavalry; the left wing of the remaining three divisions of the phalanx, the Grecian cavalry and the Thessalian cavalry. Thus far the order of battle was normal. The problem which faced Alexander was very similar to that which confronted Cyrus in Xenophon's account of the battle of Thymbra. Alexander applied the tactics

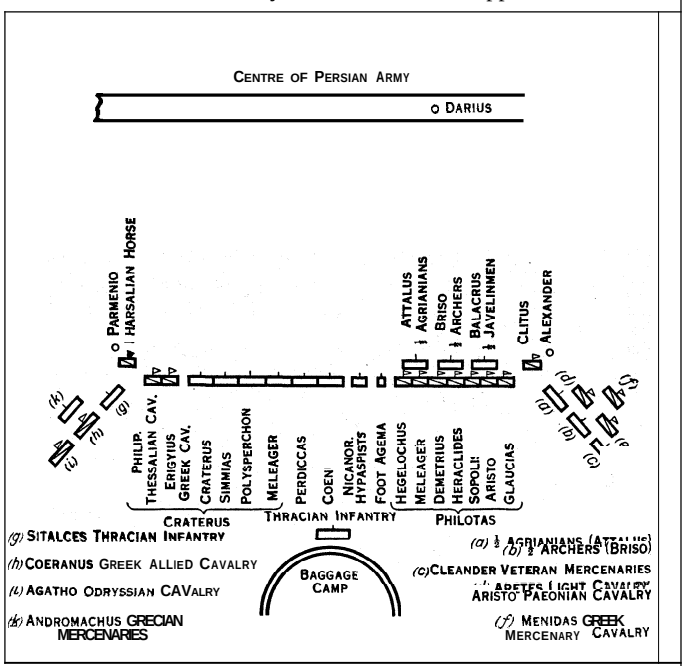

FIG. 1.—DIAGRAM OF BATTLE OF GAUGAMELA (ARBELA), OCT. 1, 331 B C.. SHOWING DISPOSITION OF ALEXANDER'S ARMY UNDER SEPARATE GENERALS

The Greeks numbered 7,000 cavalry and 40,000 foot, while the Persians were probably five times as strong. The battle ended in the complete shattering of the Persian army

made use of at Thymbra. Behind his front he drew up a reserve force consisting of two flying columns; these he posted one behind each wing at an angle to the front, so that they might take the enemy in flank should an attempt be made to turn the wings; or, if this did not take place, then they were to wheel inwards and reinforce the main army. In front of the Companion cavalry he posted half the Agrianians, archers and javelin-men to oppose the charge of the Persian chariots. The baggage guard consisted of Thracian infantry. In all Alexander's army numbered 7,000 cavalry and 40,000 foot, the Persians were, in all probability, about five times as strong. This order of battle should be kept clearly in mind, for, as it will be seen, it was through Alexander's ability to develop his tactics from it that he won the battle.

The Battle.—The initiative was taken by Alexander. He advanced, not directly on the Persians, but towards their left, and so compelled Darius to move on to the unlevelled ground. Darius, fearing that his chariots would become useless, ordered his left-wing cavalry to ride round Alexander's right and halt him. Alexander met this attack with his light cavalry, and a general cavalry engagement took place. Then Darius launched his chariots, but they never got home, as the charioteers were shot down by the light infantry in front of the Companion cavalry. The Persian left was now unmasked and in some confusion, whereupon Alexander wheeled round the Companion cavalry and with the four right divisions of the phalanx he led them towards the gap formed in the Persian front by the advance of their cavalry, and made straight for Darius. This cavalry charge, closely supported on its left by the dense array of bristling pikes in echelon, smote such terror into Darius that he fled the field. Meanwhile the Persian cavalry on Alexander's original right, finding their rear threatened took to flight, and the Macedonians, following up the fugitives, slaughtered them. The left wing, on account of the diagonal march, was in rear of the right, and the impetuous advance of Alexander appears to have created a gap between it and the right wing. Through this gap the Indian and Persian cavalry burst, and advanced towards the baggage camp. While this action was in progress, the Persian cavalry on Darius's right wing rode round Alexander's left wing and attacked Parmenio in flank. Parmenio, now completely surrounded, sent a messenger to Alexander informing him of his critical situation. He received this message whilst he was pursuing the fragments of the Persian left wing, and at once wheeled round with the Companion cavalry, and led them against the Persian right. The Persian cavalry, who were now falling back, finding their retreat menaced, fought stubbornly. "They struck and were struck without quarter" but were routed by Alexander. The pursuit was now taken up, and was continued until midnight, when a forced march was made on Arbela. About 32 miles were covered, but in vain, for Darius made good his escape. Arrian states that the Persians lost 300,000 in killed and Alexander only 100, and 1,000 horses. These figures are obviously unreliable.

Tactics.—This battle was not won by reckless courage but by audacity tempered by a wonderful grasp of what the enemy intended to do, and how his actions could be turned to advantage. This is clearly seen if the diagrams are studied. The order of battle is the normal one, but out of it is developed a very different type of attack to those of the battles of Granicus and Issus. Alexander is never obsessed by past successes, also he never invents what may be called experimental attacks. What he does is to measure up his antagonist and to act accordingly: First he seeks information; this is the foundation of his security, for in spite of his audacity security is always the foundation of his offensive action. Once he has made up his mind he distributes his force economically; his order of battle consists of a protective left and an offensive right, and in his right he concentrates his punch. Having secured his plan, he rapidly moves towards the Persian left flank, not only to get beyond the level ground, but to prevent a double envelopment, and to increase the distance between his left

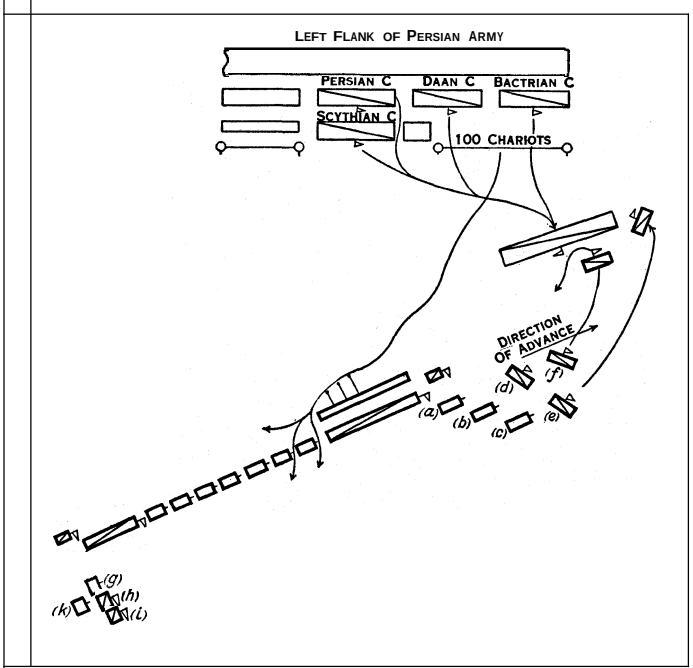

FIG. 2.—ALEXANDER'S FIRST ATTACK ON THE PERSIAN EXTREME LEFT

This manoeuvre compelled Darius to uncover his left centre, thereby leaving a gap, through which Alexander foresaw he could penetrate the Persian line

and the Persian right. This will enable him to shatter the Persian left before the Persian right can annihilate his own left. Also, if he can only draw the Persian right well inwards, should he be able to smash the enemy's left, he will then be in a position to take their right in reverse. In diagram 2, the position of Darius, the decisive point, is off the plan to the left, yet it is the point Alexander intends to strike. He opens the battle by moving away from it, and so compels Darius to uncover the immediate left flank of his centre. Though now well placed to attack in oblique order the outer flank of the Persian left wing he does not do so, for the

decisive point is not the left wing but the centre. In diagram 3 it will be seen that under cover of his right flying column, he suddenly obliques inwards, and concentrates superiority of force opposite the gap once filled by the Scythian and Persian cavalry. Through this gap he charges at top speed and strikes Darius *in rear*. This charge succeeds, not because the Companion cavalry are advancing at top speed, but because their mobility is developed from the security afforded by the flying column and the phalanx.

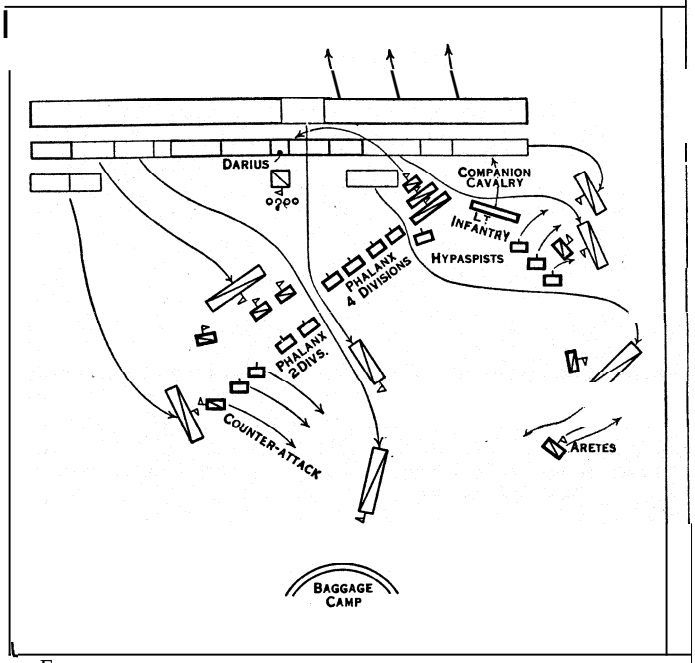

FIG. 3.— DIAGRAM SHOWING PENETRATION TACTICS OF ALEXANDER
By suddenly turning inwards, under cover of his right flying column, Alexander concentrated superior forces in the gap caused by his initial manoeuvre (see fig. 2) and was thus able to take the army of Darius in the rear

The penetration by shock is absolutely successful. Gaugamela is one of the most perfect examples of the tactics of penetration to be found in history.

GAUGUIN, PAUL (1848–1903), French painter, one of the pioneers of the Post-Impressionist movement. He was born in Paris on June 7, 1848, the son of a journalist from Orleans and of a mother partly of Peruvian descent. He spent his childhood in Peru and at Orleans, and after having done his military service in the marines he entered the banking firm of Bertin in Paris in 1871. In 1873 he married Mette-Sophie Gad, a Danish lady. In 1875 he began to spend his free time in painting. Encouraged by his friend, C. Pissaro, he acquired the Impressionist technique. His interest in art took more and more hold of him, and in *1881* he decided to give up his appointment at the bank. His means soon gave out and after an unfortunate attempt to get assistance from his wife's relations at Copenhagen, he separated from her and his children, returning to Paris without means. A period of travel followed. He worked on the island of Martinique (1887–88) and then went to Pont Aven in the Bretagne, where he soon became the leading spirit of a group of painters.

The movement thus started was known as "Synthesism." Gauguin himself was not a theorist. He wished to be rid of all that might intervene between the artist's vision and his canvas; but the other members of the group felt otherwise. Emile Bernard lectured on the synthetic doctrine, Filiger contributed his mediaeval fancies, Sérusier propagated the new ideas; he clarified the vague doctrines of Gauguin. The new tendency is explained by Maurice Denis, one of Sérusier's disciples in Paris; he says: "It was on our reassembling in *1888* that the name of Gauguin was revealed to us by Sérusier, who had just returned from Pont Aven and who allowed us to see not without a show of mystery the lid of a cigar box, on which we could make out a shapeless landscape synthetically designed in violet, vermillion, Veronese green and other unmixed colours, just as they are pressed out of a tube, almost without white in them. 'How does that tree appear to you,' Gauguin had asked—'very green?—Well then use green —the finest green on your palette—and that shadow is rather blue? Do not be afraid to paint it as blue as possible.' " "Thus," continues Denis, "was presented to us for the first time the fruitful conception of the plane surface covered with colours put together in a certain order . . . we learned that every work of art is a transposition, a caricature, the passionate equivalent of a sensation which has been experienced. . . . Gauguin freed us from all restraints which the idea of copying placed on our painter's instinct. . . . Henceforth we aspired to express our own personality. . . . If it was permissible to use vermillion in painting a tree which seemed to us at that moment reddish . . . why not stress even to the point of deformation the curve of a beautiful shoulder, exaggerate the pearly whiteness of a carnation, stiffen the symmetry of boughs unmoved by a breath of air?" *(Theories 1890–1910,* published in 1920.)

Thus Gauguin's ideas were taken up by a group of young students in Paris, which included Bonnard Denis, Ibels, Ranson, Vuillard and Maillol. In *1889* "the school of Pont Aven" moved to Pouldu near by. Their life there and the inn at Pouldu, the rendezvous of artists, which was adorned by Gauguin, was described by Mr. Ch. Chassé in *l'Occident (1903).* In *1888* Gauguin went to Arles to meet his friend, Van Gogh. The two artists had planned to work together, but Van Gogh succumbed to an attack of lunacy and Gauguin left him. *(See* P. Gauguin, *Avant et Aprés.)* Among Gauguin's best work of this period are "Le Christe Jaune," and "La Lutte de l'Ange avec Jacob." He copied Manet's "Olympia," which he considered one of the masterpieces of the age, he etched a portrait of Mallarmé, executed some lithographs and carved reliefs in wood. But in spite of all his efforts his financial position did not improve. His journey to Martinique had inspired him with a love for the tropics and he conceived a plan of going to the South Seas where he could live cheaply and devote himself to his vocation. He sold all his pictures by auction for *9,860* frcs. and went to the island of Tahiti in *1891.* There he lived a simple life with the natives which he described in his autobiographical novel *Noa Noa.*

On his return to Paris he exhibited his paintings at Durand Ruel, but the life in the big city no longer suited him; he left for Tahiti in *1895* never to return. Out there, inspired by his admiration for primitive life, for the luminous colour of the tropical landscape, he produced paintings of great decorative beauty and originality. "L'esprit Veille," "Seule," "Devant la Case," "La Fuite" and "Jours Delicieux" are among his most notable works. They represent the bronzed native Maoris in their surroundings of exotic plants and primitive dwellings. In 1901 he moved to Dominiha on the Marquesas isles. He built himself a house and decorated it with carvings and paintings. The natives treated him as one of their own and he sided with them against the overbearing European representatives of the administration. The end of his life was approaching; he lived in extreme want; in order to pay his taxes he worked in a Government office for 6 frcs. a day; his health was failing. He died on May 9, 1903, and was buried in the Mission cemetery. Victor Ségalen, a navy doctor and writer, who was in the Marquesas isles at the time, gave a vivid and sad account of his end (*Mercure de France,* June 1904).

His last important picture, entitled "D'où venons nous? Que sommes-nous? où allons-nous?" is one of his masterpieces. It was painted under the shadow of an attempted suicide. His description of this work in a letter to his friend, D. de Montfreid, is of interest, as it throws light on his artistic creed. "Before I died I wished to paint a large canvas that I had in mind, and I worked day and night that whole month in an incredible fever. To be sure it is not done like a Puvis de Chavannes, sketch after nature, preparatory cartoon, etc. It is all done straight from the brush on the sackcloth full of knots and wrinkles, so the appearance is terribly rough. . . . I put in it all my energy. a passion

so dolorous, amid circumstances so terrible, and so clear was my vision that the haste of the execution is lost and life surges up. It does not stink of models, of technique, or of pretended rules, of which I have always fought shy, though sometimes with fear. It is a canvas four metres, fifty long and one metre, seventy high. The two upper corners are chrome yellow, with an inscription on the left and my name on the right, like a fresco whose corners are spoiled with age and which is appliqueed upon a golden wall. To the right at the lower end a sleeping child and three crouching women. Two figures dressed in purple confide their thoughts to one another. An enormous crouching figure, out of all proportion and intentionally so, raises its arms and stares in astonishment upon these two, who dare to think of their destiny; a figure in the centre is picking fruit; two cats near a child; a white goat; an idol, its arms mysteriously raised in a sort of rhythm seems to indicate the Beyond. Then, lastly, an old woman nearing death appears to accept everything. . . . She completed the story. . . . It is all on the bank of a river in the woods. In the background the ocean, then the mountains of a neighbouring island. Despite changes of tone the colouring of the landscape is constant—either blue or Veronese green. Where does the execution of a painting commence and where does it end? At that moment when the most intense emotions are in fusion in the depths of one's being, when they burst forth like lava from a volcano . . .? The work is created suddenly, brutally if you like, and is not its appearance great, almost superhuman?"

Gauguin, then, had left Impressionism behind; he had profited by its technique in the use of using colours pure and unmixed; but his work was impregnated with symbolism, his design was expressive, his colour arrangements decorative. His influence on modern art was far-reaching. Besides the school of Pont Aven and the Synthesists, he inspired such artists as Ed. Munch and Toulouse Lautrec. His ideas revolutionized poster design and design in all Arts and Crafts work (Van de Velde, Lemmen, Gallé-Nancy.) His primitive woodcarving and his terra-cotta figure called "Oviri," the Tahitan Diana, was admired by such artists as Picasso and led to the appreciation of negro sculpture. His lithographs and woodcuts opened new fields in the graphic arts.

See Jean de Rotonchamp, Paul Gauguin (1925); Ch. Morice, Paul *Gauguin* (1919); Gauguin's writings: Noa Noa (1924), the manuscript with original illustrations is in the possession of Mr. D. de Montfreid, who also owns the manuscripts of Choses Diverses (1896–97); and of Le *Sourire,* a satirical journal written in Tahiti; Racontars d'un *Rapin* (1902), written on the Marquesas islands, is reproduced for the most part in Rotonchamp's book: Avant et *Après,* published by Charles Morice in Vers *et* Prose (1903); the manuscript was reproduced in facsimile (Leipzig, 1919); Lettres de Paul Gauguin *à* G. D. de Montfreid (1920); The Intimate Journal of P. Gauguin, with a preface by Emile Gauguin (1923); M. Guerin, L'oeuvre Grave' de Gauguin (1927). (I. A. R.)

GAUHATI, a town of British India, headquarters of the Kamrup district of Assam, mainly on the left or south, but partly on the right bank of the Brahmaputra. Pop. (1931) 21,797. Gauhati is the headquarters of the district and of the Brahmaputra Valley division. It is beautifully situated, with an amphitheatre of wooded hills to the south. During the 17th century it was taken and retaken by Mohammedans and Ahoms eight times in fifty years, but in 1681 it became the residence of the Ahom governor of lower Assam, and in 1786 the capital of the Ahom raja. On the cession of Assam to the British in 1826 it was made the seat of the British administration of Assam, and so continued till 1874, when the headquarters were removed to Shillong in the Khasi hills, 67 m. distant, with which Gauhati is connected by an excellent motor road. Two much-frequented places of Hindu pilgrimage are situated in the immediate vicinity, the temple of Kamakhya on a hill 2 m. west of the town, and the rocky island of Umananda in the Brahmaputra. Gauhati is an important centre of river trade, and the largest seat of commerce in Assam. The chief educational institutions are the Cotton Arts college and a law college.

GAUL, GILBERT WILLIAM (1855–1919), American artist, was born in Jersey City (N. J.), on March 31, 1855. He was a pupil of J. G. Brown and L. E. Wilmarth, and he became a painter of military pictures, portraying incidents of the American Civil War. He was elected an associate of the National Academy of Design in 1880, and in 1882 a full academician, and in the latter year became a member of the Society of American Artists. His important works include: "Charging the Battery," "News from Home," "Cold Comfort on the Outpost," "Silenced," "On the Look-out," and "Guerillas returning from a raid." He died in New York, Dec. 21, 1919.

GAUL, Lat. Gallia, the name of the two chief districts known to the Romans as inhabited by Celtic-speaking peoples, (*a*) Gallia *Cisalpina* or *Citerior, i.e.,* North Italy between Alps and Apennines and (b) the far more important Gallia Transalpina or *Ulterior,* usually called Gallia simply, the land bounded by the Alps, the Mediterranean, the Pyrenees, the Atlantic and the Rhine, *i.e.,* modern France and Belgium with parts of Holland, Germany and Switzerland.

(a) Gallia Cisalpina (*q.v.*) was mainly conquered by Rome by 222 B.C.; later it adopted Roman civilization, whence it was often known as "Gnllia Togata"; about 42 B.C. it was united with Italy. Its chief distinctions are that during the later Republic and earlier Empire it yielded excellent soldiers, and that it produced Virgil (by origin a Celt), Livy, Catullus, Cornelius Nepos, the elder and the younger Pliny and other distinguished writers.

(b) Gaul proper first enters ancient history when the Greek colony of Massilia was founded (?600 B.C.). During the Punic Wars it became important to Rome as the highway to Spain (*q.v.*). In 121 B.C. the coast from Montpellier to the Pyrenees (*i.e.,* all that was not Massiliot), with its port of Narbo (mod. *Narbonne*) and its trade route by Toulouse to the Atlantic, was formed into the province of Gallia Narbonensis and Narbo itself into a Roman municipality. Gradually the province was extended north of Massilia, up the Rhone, while the Greek town itself became weak and dependent on Rome. Narbonensis was distinguished from "Gallia Togata" as "Gallia Bracata," from the long trousers (bracae, incorrectly braccae) worn by its inhabitants.

We owe our earliest detailed knowledge of pre-Roman Gaul to the Commentaries of Julius Caesar. Gallia Narbonensis apart, Gaul was at that time divided among three more or less distinct peoples, the Aquitani, the Gauls (who called themselves Celts), and the Belgae. These occupied respectively the south, the centre and the north of the country between the Pyrenees and the Rhine. The tribes were numerous. Prominent among them were the Helvetii, the Sequani and the Aedui in the basins of the Rhone and the Saône; the Arverni in the Cévennes; the Senones and Carnutes in the basin of the Loire; the Veneti and other Armorican tribes between the mouths of the Loire and the Seine. These were all Celts. The Nervii, Bellovaci, Suessiones, Remi, Morini, Menapii and Aduatuci were Belgic; the Tarbelli and others were Aquitani; while the Allobroges inhabited the north of Gallia Bracata, having been conquered in 121 B.C. The ethnological divisions thus set forth by Caesar have been much discussed (see CELT and articles on the chief tribes).

As the result of the Gallic wars (58–51) of Caesar (*q.v.*) the whole of Gaul to the Rhine and the ocean became Roman territory, and in 49 Massilia was annexed. But Roman territory had still to be romanized. Caesar had no time to organize his conquest; this was left to Augustus. As settled by him, and in part perhaps also by his successor Tiberius, Gaul fell into five administrative areas:—

(i.) Narbonensis, that is, the land between Alps, sea and Cévennes, extending up the Rhone to Vienne, is by nature distinct in many ways from the rest of Gaul. It is a sun-steeped southern region, the home of the vine and olive, of the minstrelsy of the Provençal and the exuberance of Tartarin, distinct from the colder and more sober north. Augustus found it already familiar with Roman ways and civilized enough to need no garrison. Accordingly, it was henceforward governed by a proconsul (appointed by the senate) and freed from the burden of troops, while its local government was assimilated to that of Italy. The old Celtic tribes were broken up; instead, municipalities of Roman citizens were founded to rule their territories. Thus the Allobroges now disappear and the *colonia* of Vienna (Vienne) takes their place;

the Volcae vanish, and we find Nemausus (Nîmes). By A.D. 70 the area was "Italia verius quam provincia" (Pliny). The Gauls obviously had a natural bias towards the Italian civilization, and there soon became no difference between Italy and southern Gaul. But, though education spread, the results were somewhat disappointing. Trade flourished; the many towns grew rich and could afford splendid public buildings. But no great writer and no great administrator came from Narbonensis.

(ii.-iv.) Across the Cévennes lay Caesar's conquests, Atlantic in climate, new*to Roman ways. The whole area, often collectively styled "Gallia Comata," from the inhabitants wearing their hair long, often "Tres Provinciae," was divided into three provinces, each under a *legatus pro praetore* appointed by the emperor, with a common capital at Lugdunum (Lyons). The three were: *Aquitania,* reaching from the Pyrenees almost to the Loire; *Lugdunensis,* the land between Loire and Seine, reaching from Brittany in the west to Lyons in the south-east; and *Belgica* in the north. Here also it was found possible to dispense with garrisons, not because the provinces were as peaceful as Narbonensis, but because the Rhine army was close at hand, while the splendid system of roads rendered the movement of troops easy. As befitted an unromanized region, the local government was unlike that of Italy or Narbonensis. Roman municipalities were not unknown, though very few; the local authorities were the magistrates of the old tribal districts. Local autonomy was carried to an extreme, but the policy succeeded. If the Gauls of the Three Provinces, or some of them, revolted in A.D. 21 under Florus and Sacrovir, in 68 under Vindex, and in 70 under Classicus and Tutor *(see* CIVILIS, CLAUDIUS), all five leaders were romanized nobles, with Roman names and Roman citizenship, and their risings were directed rather against the Roman government than the Roman empire. In general, Roman civilization was accepted more or less rapidly; in particular, the worship of "Augustus and Rome," devised by the first emperor as a bond of state religion connecting the provinces with Rome, was eagerly welcomed. It agrees with the vigorous development of this worship that the Three Provinces, though romanized, retained their own local feeling. As late as the 3rd century the cults of Celtic deities (Hercules Magusanus, Deusoniensis, etc.) were revived, the Celtic *leuga* reintroduced instead of the Roman mile on official milestones, and a brief effort made to establish an independent, though romanized, Gaul under Postumus and his short-lived successors (A.D. 259–273). The area was too large and strong to lose its individuality; it was also too rural and too far from the Mediterranean to be romanized as fully and quickly as Narbonensis. Even the Celtic language lingered on in forest districts into the 4th century A.D. Town life, however, grew. The *chefs-lieux* of the tribes became practically, though not officially, municipalities, and many of these towns reached considerable size and magnificence of public buildings. But they attest their tribal relations by their appellations, which are commonly drawn from the name of the tribe and not of the town itself; to this day Amiens, Paris, Rheims, Soissons and others perpetuate the memory of tribes like the Ambiani, the Parisii, the Remi, and the Suessiones Literature also flourished In the latest empire Ausonius, Symmachus, Sidonius, Apollinaris and other Gaulish writers, chiefly of Gallia Comata, kept alive the classical literary tradition, not only for Gaul but for the world.

(v.) The fifth division of Gaul was the Rhenish military frontier, which was organized as two military districts. The northern one was the valley of the Meuse and that of the Rhine to a point just south of Bonn; the southern was the rest of the Rhine valley to Switzerland. Each district was garrisoned at first by four, later by fewer, legions, which were disposed at various times in some of the following fortresses: Vetera (Xanten), Novaesium (Neuss), Bonna (Bonn), Moguntiacum (Mainz), Argentorate (Strasbourg) and Vindonissa (Windisch in Switzerland). At first the districts, being purely military, were called after the garrisons "exercitus Germanicus superior" (south) and "inferior" (north). Later one or two municipalities were founded—the oldest, Colonia Agrippinensis, at Cologne in A.D. 51—and about A.D. 80–90 the two "Exercitus" were turned into the two provinces of Upper and Lower Germany *(see* GERMANY).

These provincial divisions were modified by Diocletian, but without seriously affecting the life of Gaul. The whole country continued Roman and fairly safe from barbarian invasions till after 400. In A.D. 407 a multitude of Franks, Vandals, etc., broke in; Roman rule practically ceased, and the three kingdoms of the Visigoths, Burgundians and Franks began to form. There were still a Roman general and Roman troops when Attila was defeated in the *campi Catalaunici* in A.D. 451, but the general, Aetius, was "the last of the Romans," and in A.D. 486 Clovis the Frank brought Roman rule in Gaul to a final end.

GAULT: *see* CRETACEOUS SYSTEM.

GAUR or **LAKHNAUTI,** a ruined city of British India, in the Malda district of Bengal. The ruins are situated about 8 m. south of English Bazar, the civil station of the district of Malda, and on the eastern bank of an old channel of the Ganges. It is said to have been founded by Lakshman, the Sena king of Bengal, and its ancient name was Lakshmanavati, corrupted into Lakhnauti. Its known history begins with its conquest at the end of the 12th century by the Mohammedans, who retained it as their capital in Bengal for more than three centuries. The seat of government was transferred about 1340 to Pandua (*q.v.*), also in Malda district. When Pandua was in its turn deserted (about 1455), Gaur once more became the capital, but in 1564 owing to a change in the course of the Ganges it was abandoned for Tanda, a place somewhat nearer the main stream. Gaur was temporarily reoccupied by Akbar's general in 1575, when Daud Shah, the last of the Afghan dynasty, refused to submit to the Mogul emperor. This occupation was followed by a virulent epidemic, which depopulated the city and completed its downfall. Since then it has been little better than a heap of ruins, almost overgrown with jungle.

The western side of Gaur was washed by the Ganges, and it was protected both from inundation and from attack by great embankments. Within the space enclosed by these embankments and the river stood the city proper. The city in its prime measured 7½ m. from north to south, with a breadth of 1 to 2 m. The ramparts of the city, which was surrounded by extensive suburbs, still exist; they were works of vast labour, and were on the average about 40 ft. high, and 180 to 200 ft. thick at the base.

Fergusson in his *History of Eastern Architecture* thus describes the general architectural style of Gaur:—"It is neither like that of Delhi nor Jaunpore, nor any other style, but one purely local and not without ccnsiderable merit in itself; its principal characteristic being heavy short pillars of stone supporting pointed arches and vaults in brick." The ruins long served as a quarry for the builders of neighbouring towns and villages, till in 1900 steps were taken for their preservation by the government. The finest ruin in Gaur is that of the Great Golden Mosque, also called Bara Darwaza. or twelve-doored (1526). The Small Golden or Eunuch's mosque has fine carving, and is faced with stone fairly well preserved. The Tantipara mosque (1475–80) has beautiful moulding in brick, and the Lotan mosque of the same period is unique in retaining glazed tiles. The citadel was entered through a magnificent gateway called the Dakhil Darwaza (?1460–74). At the south-east corner was a palace, surrounded by a wall of brick 66 ft. high, of which a part is standing. Near by were the royal tombs. Within the citadel is the Kadam Rasul mosque (1530), which is still used, and close outside is a tall tower called the Firoz Minar (perhaps signifying "tower of victory"). There are a number of Mohammedan buildings on the banks of a great reservoir called Sagar Dighi, including, notably, the tomb of the saint Makhdum Shaikh Akhi Siraj (d. 1357).

See M. Martin (Buchanan Hamilton), *Eastern India,* vol. iii. (1831); G. H. Ravenshaw, *Gaur* (1878); James Fergusson, *History of Indian and Eastern Architecture* (1876); *Reports* of *the Archaeological Surveyor, Bengal Circle* (1900–04).

GAUR *(Bibos gaurus)*, the wild ox of India. The gaur, which extends into Burma and the Malay Peninsula, is the typical representative of an Indo-Malay group of wild cattle characterized by a ridge on the withers, compressed horns, and white legs. The gaur, which reaches a height of nearly 6ft. at the shoulder, is characterized by the forward curve and great elevation of the ridge between the horns. The colour is blackish-grey. Hill-forests are the resort of this species.

GAUS, FRIEDRICH (1881–), German diplomat, born on Feb. 18, 1881, at Brunswick. He became in 1923 director of the legal department in the government, and was concerned in the preparation of German diplomatic documents from the end of the war onwards, but notably in questions of disarmament and of justice. He took part in the Genoa (1922) and London (1924) conferences and acted as legal adviser to the German government in the preparation of the Locarno treaties.

GAUSS, KARL FRIEDRICH (1777–1855), German mathematician and physicist, was born at Brunswick on April 30, 1777. He was the son of a bricklayer and owed his education to the influence of the reigning duke. He went to the Caroline college and later to Gottingen. In 1798 he returned to Brunswick, where he tried to earn his living by teaching privately. When the new observatory at Gottingen was completed in 1807, Gauss became Director and Professor of Astronomy. He practically never left the observatory until he died on Feb. 23, 1855.

Gauss began his mathematical researches at an early age; this early work was incorporated in his *Disquisitiones Arithineticae* (1801) which is a standard work on the theory of numbers. This was followed by a large number of memoirs in pure mathematics. Because of this work he is ranked with Laplace and Lagrange among the three greatest masters of modern mathematical analysis. Amongst other researches in this connection Gauss made extensive use of determinants and imaginaries; he arrived at the method of least squares; observed the double periodicity of elliptic functions; applied vigorous tests on the convergence of an infinite series, and worked out a solution for binomial equations. He wrote on biquadratic residues, and solved the problem of the representation of numbers by binary quadratic forms; he also proved the law of quadratic reciprocity.

Gauss began his magnetic and electrical researches about 1830; his first memoir, *Intensitas vis magneticae terrestris ad mensuram absolutam revocata,* was published in 1833; in this he proposed a system of units based on the units of length, mass and time. He called these units absolute units and the unit of magnetic field has been named the Gauss. With Weber he constructed a magnetic observatory free from iron where they made observations and from which they sent telegraphic messages along a crude line which they erected. In connection with his magnetic measurements, Gauss organized a German Magnetic Union so that magnetic observations were taken at a fixed time at various places in Europe. Gauss and Weber designed the instruments used in these measurements, notably an apparatus for measuring declination and the unifilar and bifilar magnetometers. The union worked from 1834 to 1842, and their results were published in memoirs *Resultate aus den Beobachtungen des Magnetischen Vereins 1836–41* (1837–43). In these memoirs we find the inverse square law and Gauss's theory on earth magnetism; this theory is a mathematical presentation of the distribution of magnetism over the earth's surface rather than a theory to account for the existence of earth magnetism. Gauss applied mathematics to electrostatic and electrodynamic problems; his theories were based on assumptions concerning the position and motion of imponderable electrified particles. He also carried out researches in optics and particularly on systems of lenses. These were publislied in *Dioptrische Untersuchungen* (1840). A memoir on capillary attraction contains a solution of a problem in the calculus of variation and another on attractions treats of the attraction of homogeneous ellipsoids. Gauss took part in geodetic surveys, and wrote two memoirs, *Über Gegenstiinde der hoheren Geodesie* (1841 and 1846). He also wrote a treatise on astronomy, *Theoria motus corporum coelestium* (1809).

See W. Sartorius, *Gauss, zum Gediichtniss* (1856).

GAUTIER, LEON (1832–1897), French literary historian. was born at Hâvre, educated at the Ecole des Chartes, and became successively keeper of the archives of the department of Haute-Marne and of the imperial archives at Paris under the empire. In 1871 he became professor of palaeography at the Ecole des Chartes. He was elected member of the Academy of Inscriptions in 1887, and became chief of the historical section of the national archives in 1893. Léon Gautier rendered great services to the study of early French literature, the most important of his numerous works on mediaeval subjects being a critical text (Tour, 1872) with translation and introduction of the *Chanson de Roland,* and *Les Epopées françaises (3* vols., 1866–67; 2nd ed., 5 vols., 1878–97, including a *Bibliographie des chansons de geste).* He died in Paris on Aug. 25, 1897.

GAUTIER, THEOPHILE (1811–1872), French poet and miscellaneous writer, was born at Tarbes on the 31st of August 1811. He was educated at the grammar school of that town, and afterwards at the College Charlemagne in Paris, but was almost as much in the studios. He very early devoted himself to the study of the older French literature, especially that of the 16th and the early part of the 17th century. This study qualified him well to take part in the Romantic movement, and enabled him to astonish Sainte-Beuve by the phraseology and style of some literary essays which, when barely eighteen years old, he put into the critic's hands. In consequence of this introduction he at once came under the influence of the great Romantic *cénacle,* to which, as to Victor Hugo in particular, he was also introduced by his gifted but ill-starred schoolmate Gérard de Nerval. With Gérard, Petrus Borel, Corot, and many other less known painters and poets whose personalities he has delightfully sketched in the articles collected under the titles of *Histoire du Romantisme,* etc., he formed a minor romantic clique who were distinguished for a time by the most extravagant eccentricity. A flaming crimson waistcoat and a great mass of waving hair were the outward signs which qualified Gautier for a chief rank among the enthusiastic devotees who attended the rehearsals of *Hernani* with red tickets marked "Hierro," performed mocking dances round the bust of Racine, and were at all times ready to exchange word or blow with the *perruques* and *grisâtres* of the classical party. In Gautier's case these freaks were not inconsistent with real genius and real devotion to sound ideals of literature. He began (like Thackeray, to whom he presents in other ways some striking points of resemblance) as an artist, but soon found that his true powers lay in another direction.

His first considerable poem, *Albertus* (1830), displayed a good deal of the extravagant character which accompanied rather than marked the movement, but also gave evidence of uncommon command both of language and imagery, and in particular of a descriptive power hardly to be excelled. The promise thus given was more than fulfilled in his subsequent poetry, which, in consequence of its small bulk, may well be noticed at once and by anticipation. The *Comédie de la mort,* which appeared soon after (1832), is one of the most remarkable of French poems, and though never widely read has received the suffrage of every competent reader. Minor poems of various dates, published in 1840, display an almost unequalled command over poetical form, an advance even over *Albertus* in vigour, wealth and appropriateness of diction, and abundance of the special poetical essence. All these good gifts reached their climax in the *Émaux et camées,* first published in 1856, and again, with additions, just before the poet's death in 1872. These poems are in their own way such as cannot be surpassed. Gautier's poetical work contains in little an expression of his literary peculiarities. There are, in addition to the peculiarities of style and diction already noticed, an extraordinary feeling and affection for beauty in art and nature, and a strange indifference to anything beyond this range, which has doubtless injured the popularity of his work.

But it was not, after all, as a poet that Gautier was to achieve

either profit or fame. For the theatre, he had but little gift, and his dramatic efforts (if we except certain masques or ballets in which his exuberant and graceful fancy came into play) are by far his weakest. It was otherwise with his prose fiction. His first novel of any size, and in many respects his most remarkable work, was *Mademoiselle de Maupin* (1835). Unfortunately this book, while it establishes his literary reputation on an imperishable basis, was unfitted by its subject, and in parts by its treatment, for general perusal, and created, even in France, a prejudice against its author which he was very far from really deserving. During the years from 1833 onwards, his fertility in novels and tales was very great. *Les Jeunes-France* (1833), which may rank as a sort of prose *Albertus* in some ways, displays the follies of the youthful Romantics in a vein of humorous and at the same time half-pathetic satire. *Fortunio* (1838) perhaps belongs to the same class. *Jettatura,* written somewhat later, is less extravagant and more pathetic. A crowd of minor tales display the highest literary qualities, and rank with Mérimée's at the head of all contemporary works of the class. First of all must be mentioned the ghost-story of *La Morte amoureuse,* a gem of the most perfect workmanship. For many years Gautier continued to write novels. *La Belle Jenny* (1864) is a not very successful attempt to draw on his English experience, but the earlier *Militona* (1847) is a most charming picture of Spanish life. In *Spirite* (1866) he endeavoured to enlist the fancy of the day for supernatural manifestations, and a *Roman de la momie* (1856) is a learned study of ancient Egyptian ways. His most remarkable effort in this kind, towards the end of his life, was *Le Capitaine Fracasse* (1863), a novel, partly of the picaresque school, partly of that which Dumas was to make popular, projected nearly thirty years earlier, and before Dumas himself had taken to the style. This book contains some of the finest instances of his literary power.

Yet neither in poems nor in novels did the main occupation of Gautier as a literary man consist. He was early drawn to the more lucrative task of feuilleton-writing, and for more than thirty years he was among the most expert and successful practitioners of this art. Soon after the publication of *Mademoiselle de Maupin,* in which he had not been too polite to journalism, he became irrevocably a journalist. He was actually the editor of *L'Artiste* for a time: but his chief newspaper connexions were with *La Presse* from 1836 to 1854 and with the *Moniteur* later. His work was mainly theatrical and art criticism. The rest of his life was spent either at Paris or in travels of considerable extent to Spain, the Netherlands, Italy, Turkey, England, Algeria and Russia, all undertaken with a more or less definite purpose of book-making. Having absolutely no political opinions, he had no difficulty in accepting the Second Empire, and received from it considerable favours, in return for which, however, he in no way prostituted his pen, but remained a literary man pure and simple. He died on the 23rd of December 1872.

Accounts of his travels, criticisms of the theatrical and literary works of the day, obituary notices of his contemporaries and, above all, art criticism occupied him in turn. It has sometimes been deplored that this engagement in journalism should have diverted Gautier from the performance of more capital work in literature. Perhaps, however, this regret springs from a certain misconception. Gautier's power was literary power pure and simple, and it is as evident in his slightest sketches and criticisms as in *Émaux et camées* or *La Morte amoureuse.* On the other hand, his weakness, if he had a weakness, lay in his almost total indifference to the matters which usually supply subjects for art and therefore for literature. He has thus been accused of "lack of ideas" by those who have not cleared their own minds of cant; and in the recent set-back of the critical current against form and in favour of "philosophic" treatment, comment upon him has sometimes been unfavourable. But this injustice will, beyond all question, be redressed again. He was neither immoral, irreligious nor unduly subservient to despotism, but morals, religion and politics (to which we may add science and material progress) were matters of no interest to him. He was to all intents a humanist, as the word was understood in the 15th century. But he was a humorist as well, and this combination, joined to his singularly kindly and genial nature, saved him from some dangers and depravations as well as some absurdities to which the humanist temper is exposed. As time goes on it may be predicted that, though Gautier may not be widely read, yet his writings will never cease to be full of indescribable charm and of very definite instruction to men of letters. Besides those of his works which have been already cited, we may notice *Une Larme du diable* (1839), a charming mixture of humour and tenderness; *Les Grotesques* (1844), a volume of early criticisms on some oddities of 17th century literature; *Caprices et zigzags* (1845), miscellanies dealing in part with English life; *Voyage en Espagne* (1845), *Constantinople* (1854), *Voyage en Russie* (1866), brilliant volumes of travel; *Ménagerie intime* (1869) and *Tableaux de siège* (1872), his two latest works, which display his incomparable style in its quietest but not least happy form.

There is no complete edition of Gautier's works, and the vicomte Spoelberch de Lovenjoul's *Histoire des œuvres de Théophile Gautier* (1887) shows how formidable such an undertaking would be. But since his death numerous further collections of articles have been made: *Fusains et eaux-fortes* and *Tableaux à la plume* (1880); *L'Orient* (2 vols., 1881); *Les Vacances du lundi* (new ed., 1888); *La Nature chez elle* (new ed., 1891). In 1879 his son-in-law, E. Bergerat, who had married his younger daughter Estelle (the elder, Mmc. Judith Gautier—herself a writer of distinction—was at one time Mme. Catulle Mendès), issued a biography, *Théophile Gautier,* which has been oiten repiinted. With it should be compared Maxime du Camp's volume in the *Grands Écrivains français* (1890) and the numerous references in the *Journal des Goncourt.* Critical eulogies, from Sainte-Beuve (repeatedly in the *Causeries)* and Baudelaire (two articles in *L'Art romantique*) downwards, are numerous. The chief of the decriers is Émile Faguet in his *Études litttraires sur le XIXe siècle.* In 1902 and 1903 there appeared two respectable academic *éloges* by H. Menal and H. Potez. (G. Sa.)

GAUTIER D'ARRAS, French *trouvère,* flourished in the second half of the 12th century. Nothing is known of his biography except what may be gleaned from his works. He dedicated his romance of *Eracle* to Theobald V., count of Blois (d. 1191); among his other patrons were Marie, countess of Champagne, daughter of Louis VII. and Eleanor of Guienne and Baldwin IV., count of Hainaut. *Eracle,* the hero of which becomes emperor of Constantinople as Heraclius, is purely a *roman d'aventures* and enjoyed great popularity. His second romance, *Ille et Galeron,* dedicated to Beatrix, the second wife of Frederick Barbarossa, treats of a similar situation to that outlined in the lay of *Eliduc* by Marie de France.

See the *Oeuvres de Gautier d'Arras,* ed. *E.* Loseth (1890); *Hist. litt. de la France,* vol. xxii. (1852); A. Dinaux, *Les Trouvères* (1833–43).

GAUVAIN, AUGUSTE (1861–1931), French journalist and diplomat, was born at Vesoul Oct. 6, 1861. From 1889 to 1892 he was on the staff of *Le Journal des Débats* and in 1893 became general secretary to the European Commission of the Danube. In 1904 he was appointed French secretary to the Central Office of International Transport at Berne. In 1908 he returned to the staff of *Le Journal des Dkbats* and from that time directed its foreign policy. Gauvain, who became a member of the Academy of Moral and Political Sciences, published verbatim in 14 volumes all his articles in *Le Journal des Dkbats* from 1908 to 1920.

Among his works are: *Les origines de la guerre europtenne* (1915); *L'Europe avant la guerre* (1917); *L'affaire grecque* (1917); *La question Yougoslave* (1918); *L'encerclement de l'Allemagne* (1919).

GAUZE, a light, transparent fabric, originally of silk, and now sometimes made of linen or cotton, woven in an open manner with very fine yarn. It is said to have been originally made at Gaza in Palestine, whence the name. Some of the gauzes from eastern Asia were brocaded with flowers of gold or silver. In the weaving of gauze the warp threads, in addition to being crossed as in plain weaving, are twisted in pairs from left to right and from right to left alternately, after each shot of weft, thereby keeping the weft threads at equal distances apart, and retaining them in their parallel position. The textures are woven either plain, striped or figured; and the material receives many designations, according to its appearance and the purposes to which it is devoted. A thin cotton fabric, woven in the same way,

is known as leno, to distinguish it from muslin made by plain weaving. Silk gauze was a prominent and extensive industry in the west of Scotland during the second half of the 18th century, but on the introduction of cotton-weaving it greatly declined. In addition to its use for dress purposes, silk gauze is much employed for bolting or sifting flour and other finely ground substances. The term gauze is applied generally to transparent fabrics of whatever fibre made, and to the fine-woven wire-cloth used in safety-lamps, sieves, window-blinds, etc.

GAVARNI, PAUL (1804–1866), pseudonym of HIPPOLYTE SULPICE-GUILLAUME CHEVALIER, French caricaturist, born in Paris, Jan. 13, 1804. In 1833 he founded the *Journal des Gens du monde,* and began a series of lithographed sketches, in which he portrayed the striking characteristics, the foibles and vices of the various classes of French society. The letter-press explanations attached to his drawings were short, forcible and highly humorous. The different stages through which Gavarni's talent passed, are well worth being noted. At first he confined himself to the study of Parisian manners, more especially those of the Parisian youth. He was engaged as caricaturist of *Le Charivari.* Many important publications owed a great part of their success to the clever and telling sketches contributed by Gavarni.

Always desiring to enlarge the field of his observations, Gavarni no longer limited himself to such types as the *lorette* and the Parisian student, or to the description of the noisy and popular pleasures of the capital, but turned his mirror to the grotesque sides of family life and of humanity. Whilst showing the same power of irony as his former works, enhanced by a deeper insight into human nature, Gavarni's compositions of this time generally bear the stamp of a bitter philosophy. He returned from a visit to London in 1849 deeply impressed with the scenes of misery and degradation which he had observed among the lower classes of that city. What he had witnessed there became the almost exclusive subject of his drawings, as powerful, as impressive as ever. Most of these last compositions appeared in the weekly paper *L'Illustration.* In 1857 he published in one volume the series entitled *Masques et visages* (12mo.), and in 1869, about two years after his death, his last artistic work, *Les Douze Mois* (1 vol. fol.). Gavarni was much engaged, during the last period of his life, in scientific pursuits. He sent several communications to the Académie des Sciences, and till his death on Nov. 23, 1866, he was eagerly interested in mathematical questions.

Gavarni's *Oeuvres choisies* were edited in 1845 (4 vols. 4to) with letterpress by J. Janin, Th. Gautier and Balzac, followed in 1850 by two other volumes named *Perles et parures;* and some essays in prose and in verse written by him were published by Ch. Yriarte, in 1869. *See* also E. and J. de Goncourt, *Gavarni, l'homme et l'oeuvre* (1873, 8vo); Henri Frantz and Octave Uzanne, *Daumier and Gavarni* (special studio edition 1906). J. Claretie has devoted an essay to Gavarni. *A* catalogue *raisonné* of Gavarni's works was published by J. Armelhault and E. Bocher (Paris, 1873, 8vo).

GAVAZZI, ALESSANDRO (1809–1889), an Italian preacher and patriot, who was born at Bologna on March 21, 1809. He at first became a monk (1825), and attached himself to the Barnabites at Naples, where he afterwards (1829) acted as professor of rhetoric. Driven into exile on account of his liberal views he found refuge in England, where he joined the Evangelical church, and became head and organizer of the Italian Protestants in London. Returning to Italy in 1860, he served as army-chaplain with Garibaldi. In 1870 he became head of the Free Church *(Chiesa libera)* of Italy, united the scattered Congregations into the "Unione delle Chiese libere in Italia," and in 1875 founded in Rome the theological college of the Free Church, in which he himself taught dogmatics, apologetics and polemics. He died in Rome on the 9th day of January 1889.

Amongst his publications are *No Union with Rome* (1871); *The Priest in Absolution* (1877); *My Recollections of the Last Four Popes,* etc., in answer to Cardinal Wiseman (1858); *Orations,* 2 decades (1851).

GAVELKIND, a peculiar system of tenure associated chiefly with the county of Kent, but found also in other parts of England. In Kent all land was presumed to be holden by this tenure until the contrary was proved, but some lands have been disgavelled by particular statutes. It is more correctly described as "socage tenure, subject to the custom of gavelkind." The chief peculiarities of the custom were: (1) A tenant could alienate his lands by feoffment at 15 years of age. (2) There was no escheat on attainder for felony. (3) Generally the tenant could dispose of his lands by will. (4) In intestacy the estate descended to the sons (or, in the case of deceased sons, their representatives) in equal shares: "Every son is as great a gentleman as the eldest son is." Though females claiming in their own right were postponed to males, yet by representation they inherited together with them. (5) A wife was dowable of one-half, instead of one-third of the land. (6) A widower might be tenant by courtesy of one-half without having had any issue, but only so long as he remained unmarried. Gavelkind was, previous to the Conquest, the general custom of the realm, but was then superseded by the feudal law of primogeniture. It was abolished by the Law of Property Act, 1922, and the Administration of Estates Act, 1925.

Irish gavelkind was a species of tribal succession, by which the land, instead of being divided at the death of the holder amongst his sons, was thrown again into the common stock, and redivided among the surviving members of the sept. The equal division amongst children of an inheritance in land is of common occurrence outside the British Isles and is discussed under SUCCESSION. *(See* also INHERITANCE; TENURE.)

See T. Robinson, *On Gavelkind* (1897); Pollock and Maitland, *History of English Law.*

GAVESTON, PIERS (d. 1312), earl of Cornwall, favourite of the English king Edward II., was the son of a Gascon knight, and was brought up at the court of Edward I. as companion to his son, the future king. Early in 1307 he was banished by the king; but he returned after the death of Edward I. a few months later, and at once became the chief adviser of Edward II. Made earl of Cornwall, he received lands and money, and married Edward's niece, Margaret de Clare (d. 1295). He was regent during the king's short absence in France in 1308, and was conspicuous at Edward's coronation. These proceedings and Gaveston's own arrogance aroused the anger and jealousy of the barons. They demanded his banishment; and the king, forced to assent, sent his favourite to Ireland as lieutenant, where he remained for about a year. Returning to England in July 1309, Gaveston showed himself more insolent than ever. In 1311 the king was forced to agree to the election of the "ordainers," and the ordinances they drew up provided *inter alia* for the perpetual banishment of Gaveston, who retired to Flanders, but returned secretly to England at the end of 1311. Soon he was publicly restored by Edward, and the barons had taken up arms. Deserted by the king he surrendered to Aymer de Valence, earl of Pembroke (d. 1324), at Scarborough in May 1312, and was taken to Deddington in Oxfordshire, where he was kidnapped by Guy de Beauchamp, earl of Warwick (d. 1315). He was beheaded on Blacklow Hill near Warwick on June 19, 1312. Gaveston, whose body was buried in 1315 at King's Langley, Herts, left an only daughter.

See W. Stubbs, *Constitutional History,* vol. ii. (Oxford, 1896); *Chronicles of the Reigns of Edward I. and Edward II.,* edited by W. Stubbs. Rolls series (London, 1882–1883); also J. C. Davies, *Baronial Opposition to Edward II.* (1918).

GAVIAL, a fish-eating relative of the crocodile. (See GHARIAL, CROCODILE.)

GAVIIDAE: *see* LOON.

GAVOTTE, properly the dance of the Gavots or natives of Gap, a district in the Upper Alps, in the old province of Dauphiné. It is a dance of a brisk and lively character, somewhat resembling the minuet, but quicker and less stately *(see* DANCE); hence also the use of this name for a form of musical composition.

GAWABRA: *see* ARABS.

GAWAIN, son of King Loth of Orkney, and nephew to Arthur on his mother's side, the most famous hero of Arthurian romance. The first mention of his name is in a passage of William of Malmesbury, recording the discovery of his tomb in the province of Ros in Wales. He is there described as *Walwen qui fuit hnud degener Arturis ex sorore nepos.* Here he is said to have reigned over Galloway; and there is certainly some connection,

the character of which is now not easy to determine, between the two. In the later *Historia* of Geoffrey of Monmouth, and its French translation by Wace, Gawain plays an important and "pseudo-historic" rôle. On the receipt by Arthur of the insulting message of the Roman emperor, demanding tribute, it is he who is despatched as ambassador to the enemy's camp, where his arrogant and insulting behaviour brings about the outbreak of hostilities. On receipt of the tidings of Mordred's treachery, Gswain accompanies Arthur to England, and is slain in the battle which ensues on their landing. Wace, however, evidently knew more of Gawain than he has included in his translation, for he speaks of him as

> Li quens Walwains
> Qui tant fu preudom de ses mains (11. 9057–58);

and later on says

> Prous fu et de mult grant mesure,
> D'orgoil et de forfait n'ot qure
> Plus vaut faire qu'il ne dist
> Et plus doner qu'il ne pramist (10. 106–109).

The English Arthurian poems regard him as the type and model of chivalrous courtesy, "the fine father of nurture," and as Prof. Maynadier has well remarked, "previous to the appearance of Malory's compilation it was Gawain rather than Arthur who was the typical English hero." It is thus rather surprising to find that in the earliest preserved mss, of Arthurian romance, *i.e.,* in the poems of Chrétien de Troyes, Gawain, though generally placed first in the list of knights, is by no means the hero *par excellence.* The latter part of the *Perceval* is indeed devoted to the recital of his adventures at the *Chastel Merveilleus,* but of none of Chrétien's poems is he the protagonist. The anonymous author of the *Chevalier à l'épée* indeed makes this apparent neglect of Gawain a ground of reproach against Chrétien. At the same time the majority of the short episodic poems connected with the cycle have Gawain for their hero. In the earlier form of the prose romances, *e.g.,* in the *Merlin* proper, Gawain is a dominant personality, his feats rivalling in importance those ascribed to Arthur, but in the later forms such as the *Merlin* continuations, the *Tristan,* and the final *Lancelot* compilation, his character and position have undergone a complete change, he is represented as cruel, cowardly and treacherous, and of indifferent moral character. Most unfortunately our English version of the romances. Malory's *Morte d'Arthur,* being derived from these later forms (though his treatment of Gawain is by no means uniformly consistent), this unfavourable aspect is that under which the hero has become known to the modern reader. Tennyson, who only knew the Arthurian story through the medium of Malory, has, by exaggeration, largely contributed to this misunderstanding. Morris, in *The Defence of Guinevere,* speaks of "gloomy Gawain"; perhaps the most absurdly misleading epithet which could possibly have been applied to the "gay, gratious, and gude" knight of early English tradition.

The truth appears to be that Gawain, the Celtic and mythic origin of whose character was frankly admitted by the late M. Gaston Paris, belongs to the very earliest stage of Arthurian tradition, long antedating the crystallization of such tradition into literary form. He was certainly known in Italy at a very early date; Prof. Rajna has found the names of Arthur and Gawain in charters of the early 12th century, the bearers of those names being then grown to manhood; and Gawain is figured in the architrave of the north doorway of Modena cathedral, a 12th-century building. Recent discoveries have made it practically certain that there existed, prior to the extant romances, a collection of short episodic poems, devoted to the glorification of Arthur's famous nephew and his immediate kin (his brother Gaheris, or Gareth, and his son Guinglain), the authorship of which was attributed to a Welshman, Bleheris; fragments of this collection have been preserved to us alike in the first continuation of Chrétien de Troyes *Perceval,* due to Wauchier de Denain, and in our vernacular *Gawain* poems. Among these "Bleheris" poems was one dealing with Gawain's adventures at the Grail castle, where the Grail is represented as non-Christian, and presents features strongly reminiscent of the ancient Nature mysteries. There is good ground for believing that as Grail quester and winner, Gawain preceded alike Perceval and Galahad, and that the solution of the mysterious Grail problem is to be sought rather in the tales connected with the older hero than in those devoted to the glorification of the younger knights. The explanation of the very perplexing changes which the character of Gawain has undergone appears to lie in a misunderstanding of the original sources of that character. Whether or not Gawain was a sun-hero, and he certainly possessed some of the features—we are constantly told how his strength waxed with the waxing of the sun till nocntide, and then gradually decreased; he owned a steed known by a definite name le Gringalet; and a light-giving sword, Excalibur (which, as a rule, is represented as belonging to Gawain, not to Arthur)—all traits of a sun-hero—he certainly has much in common with the primitive Irish hero Cuchullin. The famous head-cutting challenge, so admirably told in *Syr Gawayne and the Grene Knighte,* was originally connected with the Irish champion. Nor was the lady of Gawain's love a mortal maiden, but the queen of the other-world. In Irish tradition the other-world is often represented as an island, inhabited by women only; and it is this "Isle of Maidens" that Gawain visits in *Diu Crone;* returning therefrom dowered with the gift of eternal youth. The Chastel Merveilleus adventure, related at length by Chrétien and Wolfram, is undoubtedly such an "other-world" story. It seems probable that it was this connection which won for Gawain the title of the '[Maidens' Knight," a title for which no satisfactory explanation is ever given. When the source of the name was forgotten its meaning was not unnaturally misinterpreted, and gained for Gawain the reputation of a facile morality, which was exaggerated by the pious compilers of the later Grail romances into persistent and aggravated wrong-doing; at the same time it is to be noted that Gawain is never, like Tristan and Lancelot, the hero of an illicit connection maintained under circumstances of falsehood and treachery. Gawain, however, belonged to the pre-Christian stage of Grail tradition, and it is not surprising that writers bent on spiritual edification found him somewhat of a stumbling-block. Chaucer, when he spoke of Gawain coming "again out of faërie," spoke better than he knew; the home of that very gallant and courteous knight is indeed Fairy-land, and the true Gawain-tradition is informed with fairy glamour and grace.

Loomis, *Celtic Myth and Arthurian Romance* (Columbia Univ. Press, 192 7). (J. L. W.)

GAWAMA'A: *see* ARABS.

GAWLER, a town of Gawler county, South Australia, on the Para river, $24\frac{3}{4}$ m. by rail N.E. of Adelaide. It is one of the most thriving places in the colony, being the centre of a large wheat-growing district; it has also engineering works, foundries, flour-mills, breweries and saw-mills, while gold, silver, copper and lead are found in the neighbouring hills.

GAY, **JOHN** (1685–1732), English poet, was baptized on Sept. 16, 1685 at Barnstaple. On leaving school he was apprenticed to a silk mercer in London, but being weary, according to Dr. Johnson, "of either the restraint or the servility of his occupation," he soon returned to Barnstaple, where he spent some time with his uncle, the Nonconformist minister. He then returned to London, and though no details are available for his biography until the publication of *Wine* in 1708, the account he gives in *Rural Sports* (1713), of years wasted in attending on courtiers who were profuse in promises never kept, may account for his occupations. Among his early literary friends were Aaron Hill and Eustace Budgell. In *The Present State of Wit* (1711) Gay attempted to give an account of "all our periodical papers, whether monthly, weekly or diurnal." To Lintot's *Miscellany* (1712) he contributed "An Epistle to Bernard Lintot," containing some lines in praise of Pope, and a version of the story of Arachne from the sixth book of the *Metamorphoses* of Qvid. Me

was for a short time (1712–14) secretary to the duchess of Monmouth. Swift got him a place as secretary to the ambassador at the Hanoverian court, but before he could take up the post Queen Anne died, and all hope of official preferment was removed with her death.

The dedication of his *Rural* Sports (1713) to Pope was the beginning of a lasting friendship. In 1713 he produced a comedy, The *Wife* of Bath, which was acted only three nights, and *The Fan,* one of his least successful poems; and in 1714 Tlie Shepherd's *Week*, a series of six pastorals drawn from English rustic life, written in ridicule of the Arcadian pastorals of Ambrose Philips, but entertaining on their own account. In 1715, probably with help from Pope, he produced *What d'ye* call it? a dramatic skit on contemporary tragedy, with special reference to Otway's Venice *Preserved.* In 1716 appeared his Trivia, or the Art of Walking the Streets of London, a poem in three books, for which he received several hints from Swift. Trivia has a dry wit and an admirable style; its matter makes it a social-historical document of some importance. In Jan. 1717 Gay produced the comedy of Three *Hours* after Marriage, which was a failure. In this piece he had assistance from Pope and Arbuthnot, but they were glad to have it assumed that Gay was the sole author.

Gay had numerous patrons, and in 1720 he published Poems *on* Several *Occasions* by subscription, realizing £1,000 or more. In that year James Craggs, the secretary of State, presented him with some South Sea stock. Gay, disregarding the prudent advice of Pope and other friends, invested his all in South Sea stock, and lost everything. The shock made him dangerously ill, but his friends came to his assistance. He had patrons in William Pulteney, afterwards earl of Bath, in the third earl of Burlington, who constantly entertained him at Chiswick or at Burlington House, and in the third earl of Queensberry. He was a frequent visitor with Pope, and received unvarying kindness from Congreve and Arbuthnot. In 1724 he produced a tragedy called *The* Captives. In 1727 he wrote for Prince William, afterwards duke of Cumberland, his famous Fifty-one Fables in Verse, for which he naturally hoped to gain some preferment. He refused the situation of gentleman-usher to the Princess Louisa, who was still a child. His friends thought him unjustly neglected by the court, but he had no particular claim on the king's favour, and had already received (1722) a sinecure as lottery commissioner with a salary of £150 a year, and from 1722 to 1729 he had lodgings in the palace at Whitehall.

He certainly did nothing to conciliate the favour of the Government by his next and most famous production, the Beggar's Opera, a lyrical drama produced on Jan. 29, 1728 by Rich, in which Sir Robert Walpole was' caricatured. The part of Polly Peachum was played by Lavinia Fenton, afterwards duchess of Bolton. This piece, which was said to have made "Rich gay and Gay rich," was an innovation, and for a time it drove Italian opera off the English stage. Under cover of the thieves and highwaymen who figured in it was disguised a satire on society, for Gay made it plain that in describing the moral code of his characters he had in mind the corruptions of the governing class. The play ran for 62 nights, though the representations, four of which were "benefits" of the author, were not, as has sometimes been stated, consecutive. Swift is said to have suggested the subject, and Pope and Arbuthnot were constantly consulted while the work was in progress, but Gay must be regarded as the sole author. He wrote a sequel, Polly, the representation of which was forbidden by the lord chamberlain, no doubt through the influence of Walpole. This act of "oppression" proved an excellent advertisement for Polly, which was published by subscription in 1729, and brought its author more than £1,000. The duchess of Queensberry was dismissed from court for enlisting subscribers in the palace. The duke of Queensberry gave him a home, and the duchess continued her affectionate patronage until Gay's death, which took place on Dec. 4, 1732. He was buried in Westminster Abbey. The epitaph on his tomb is by Pope, and is followed by Gay's own mocking couplet:—

> Life is a jest, and all things show it,
> I thought so once, and now I know it.

Acis and *Galatea,* an English pastoral opera, the music of which was written by Handel, was produced at the Haymarket in 1732. The profits of his posthumous opera of Achilles (1733), and a new volume of Fables (1738) went to his two sisters, who inherited from him a fortune of £6,000. He left two other pieces, The Distressed *Wife* (1743), a comedy, and The *Rehearsal* at *Goat*ham (1754), a farce. The Fables, slight as they may appear, cost him more labour than any of his other works. The narratives are in nearly every case original, and are told in clear and lively verse. The moral which rounds off each little story is never strained. They are masterpieces in their kind, and the very numerous editions of them prove their popularity. They have been translated into Latin, French and Italian, Urdu and Bengali. Gay's fame was revived by the three and a half years' run (June 5, 1920 to Dec. 17, 1923) of the Beggar's Opera at the Lyric theatre, Hammersmith.

The two best editions of Gay's Poetical Works are those by J. Underhill (1893) and by J. C. Faber (1926), the latter including Polly and the Beggar's Opera. The Plays and the Poems were edited in the Abbey Classics (1923). The Beggar's Opera was also edited by G. H. McLeod (1906; rev. ed. with music, 1921) and by O. Doughty (1922). See also L. Melville, Life *and* Letters of J. Gay (1921) and W. E. Schultz, Gay's Beggar's Opera, its content, history *and* influence (New Haven, 1923). Gay's Chair (1820), edited by Henry Lee, a fellow-townsman, contained a biographical sketch by his nephew, J. Baller.

GAY, WALTER (1856–1937), American artist, was born at Hingham (Mass.), on Jan. 22, 1856. In 1876 he became a pupil of Léon Bonnat in Paris. He received an honourable mention in the Salon of 1885; a gold medal in 1888, and similar awards at Vienna (1894), Antwerp (1895), Berlin (1896), and Munich (1897). He became an officer of the Legion of Honour and a member of the Society of Secession, Munich. Works by him are in the Luxembourg, the Tate Gallery (London), and the Boston and Metropolitan (New York) Museums of **Art.** His compositions deal mainly with French interiors and French peasant life.

GAYA, a town and district of British India, in the Patna division of Bihar and Orissa, with a station on the Grand Chord line of the East Indian railway. With a population (1931) of 88,005 it is, next to Patna, the most populous town in the province. Gaya is a celebrated place of Hindu pilgrimage, for it is a sacred duty for Hindus to make offerings there for the salvation of their parents and ancestors; it is estimated that no less than 300,000 pilgrims come annually. There are altogether 45 sacred places between (and including) Pretsil hill on the north and Bodh-Gaya on the south, a distance of 15 m., but most are in Gaya itself. The principal shrine is the Vishnupad temple built by the Mahratta princess, Ahalya Bai, in 1787. Others are the rocky temple-crowned hills of Ramsila (372 ft.) and Brahmajuni (450 ft.). The last, which overlooks the civil station, has been identified with the Gayasirsa hill on which Buddha preached.

The DISTRICT OF GAYA, with an area of 4,714 sq.m. and a population (1931) of 2,388,462, consists of a wide plain, with wooded hills along the southern boundary, whence the country falls with a gentle slope towards the north. The hills in the south, which contain scenes of the most picturesque beauty, rise to a height of 2,202 ft. at Durvasarhi and to 1,832 ft. in the Mahabar hills. A long range extends from near Bodh-Gaya north-eastwards, and elsewhere in the open plain, rocky hills occur, either detached or in groups, such as Maher, 1,620 ft.; Kauwadol and the Barabar hills. The northern part of the district is highly cultivated; the portions to the east and west are less fertile; while in the south the country is thinly peopled; and in the jungles covering the hills and the country below them, tigers, leopards, bear and deer are found. The principal rivers are the Son, which marks the boundary between Gaya and the Shahabad, the Punpun and the Phalgu, formed by the junction of two large hill streams, the Nilajan and Mohana. The last three rivers are subject to heavy floods. Agriculture depends largely on artificial irrigation, which is mainly effected by an indigenous system of channels leading from the rivers and storage reservoirs made by building embankments across the lines of drainage. The north-west of the district is irrigated by part of the Son canal system. Mica mines are worked in the south-west of the district, which contains part of the Bihar

mica belt, one of the largest sources of the world's supply. Other industries are the production of shellac, which centres on Imamganj, the weaving of carpets and blankets, notably at Obra, and the manufacture of brass utensils and of black stone-ware, chiefly ornaments sold to pilgrims at Gaya. The district is traversed by the Grand Chord line of the East India railway, the South Behar railway running into the Monghyr district, and a branch line to Patna. Gaya district is singularly rich in ancient sites and has many archaeological remains associated with the early history of Buddhism. Bodh-Gaya, about 6 m. S. of Gaya, is one of the holiest sites of Buddhism. A mound on the Sobhnath hill has been identified with the burial place of Kasyapa, the greatest of Buddha's disciples; the remains of a monastery are in a valley (Hasra Kol) near by, where fine sculptured figures have been found. In the Barabar hills there are rock-cut caves or rooms, in some of which the rock has been wrought to an extraordinary polish. An inscription of Asoka in one group shows they were dedicated to the use of ascetics called Ajivikas. The other group was hewn out of the rock for the use of the same sect by his grandson, Dararatha; they are called the Nagarjuni caves, after a Buddhist teacher of that name who is beiieved to have lived in them in the 2nd century A.D.

GAYAL, a domesticated ox allied to the Gaur (*q.v.*) but distinguished by the more conical and 'straighter horns, and the straight line between them. Gayal are kept by the natives of the hill-districts of Assam, Tenasserim, and Upper Burma.

GAY-LUSSAC, JOSEPH LOUIS (1778–1850), French chemist and physicist, was born at St. Léonard, in the department of Haute Vienne, on Dec. 6, 1778. He entered the École Polytechnique at the end of 1797; three years later he was transferred to the Gcole des Ponts et Chaussées, and shortly afterwards he went to assist C. L. Berthollet in his researches. In 1802 he was appointed demonstrator to A. F. Fourcroy at the École Polytechnique, where subsequently (1809) he became professor of chemistry, and from 1808 to 1832 he was professor of physics at the Sorbonne, a post which he resigned for the chair of chemistry at the Jardin des Plantes. In 1806 he was made an academician. In 1831 he was elected to represent Haute Vienne in the chamber of deputies, and in 1839 he entered the chamber of peers. He died in Paris on May 9, 1850.

Gay-Lussac's earlier researches were mostly physical in character and referred mainly to the properties of gases, vapour-tensions, hygrometry, capillarity, etc. His first memoir, published in 1802, dealt with the expansion of gases. In 1804 the French Academv, desirous of securing some observations on'the force of terrestrihl magnetism at great elevations above the earth, obtained the use of a balloon, and entrusted the task to him and J. B. Biot. In their first ascent from the garden of the Conservatoire des Arts on Aug. 24, 1804 an altitude of 4,000 metres was attained; Gay-Lussac made a second ascent by himself on Sept. 16, when the balloon rose 7,016 metres above sea-level. At this height, he made observations not only on magnetism, but also on the temperature and humidity of the air, and collected several samples of air at different heights. The magnetic observations led him to the conclusion that the magnetic effect at all attainable elevations above the earth's surface remains constant; and on analysing the samples of air he could find no difference of composition at different heights. (For an account of both ascents see *Journ.* de *phys.,* 1804 and BALLOON.) In the same year, in conjunction with Alexander von Humboldt, he read a paper on eudiometric analysis *(Ann.* de *Chim.,* 1805); it contained the germ of his most important generalization, the law of combination by volumes, which was, however, not enunciated in its general form until after his return from a journey through Switzerland, Italy and Germany.

In 1809 his important memoir on gaseous combination was published; in it he pointed out that when gases combine with one another they do so in the simplest proportions by volume, and that the volume of the compound formed bears a simple ratio to that of the constituents (see CHEMISTRY: Physical).

About this time Gay-Lussac's work became more purely chemical. In 1808, he succeeded, with the collaboration of L. J. Thénard, in preparing potassium by the action of red-hot iron on fused potash; the properties of the element were studied and in 1809 he used it for the reduction of boron from boracic acid in 1809. Gay-Lussac carried out some work on chlorine (1809) and iodine (1814) which brought him into direct rivalry with Humphry Davy. He considered "oxymuriatic acid" (chlorine) to be a compound, whereas Davy saw no reason to suppose that it contained oxygen and regarded it as an element, a view which Gay-Lussac was reluctantly compelled to accept.

In 1810 Gay-Lussac published a paper which contains some classic experiments on fermentation, a subject to which he returned in a second paper published in 1815. At the same time he was working with Thénard at the improvement of the methods of organic analysis, and by combustion with oxidizing agents, first potassium chlorate and subsequently copper oxide, he determined the composition of a number of organic substances. His last great piece of pure research was on prussic acid. In a note published in 1811 he described the physical properties of this acid, but he said nothing about its chemical composition till 1815, when he described cyanogen as a compound radicle, prussic acid as a compound of that radicle with hydrogen alone, and the prusslates (cyanides) as compounds of the radicle with metals. The proof that prussic acid contains hydrogen but no oxygen was a most important support to the hydrogen-acid theory, and completed the downfall of Lavoisier's oxygen theory; while the isolation of cyanogen was of equal importance for the subsequent era of compound radicles in organic chemistry.

As a result of his success as an investigator Gay-Lussac's services as a technical adviser became in great demand. He had been a member of the consultative committee on arts and manufactures since 1805; he was attached to the "administration des poudres et salpêtres" in 1818, and in 1829 he received the lucrative post of assayer to the mint. His services to industry included his improvements in the processes for the manufacture of sulphuric acid (1818) and oxalic acid (1829); methods of estimating the amount of real alkali in potash and soda and for estimating the available chlorine in bleaching powder by a solution of arsenious acid; directions for the use of the centesimal alcoholometer published in 1824 and specially commended by the Institute; and the elaboration of a method of assaying silver by a standard solution of common salt. Among his research work of this period may be mentioned the improvements in organic analysis and the investigation of fulminic acid made with the help of Liebig, who gained the privilege of admission to his private laboratory in 1823–1824.

The most complete list of Gay-Lussac's papers is contained in the Royal Society's *Catalogue of Scientific Papers,* which enumerates 148, exclusive of others written jointly with Humboldt, Thénard, Welter and Liebig. Many of them were published in the *Annales de chimie,* which after it changed its title to *Annales de chimie et physique* he edited, with Arago, up to nearly the end of his life; but some are to be found in the *Mémoires d'Arcueil* and the *Comptes rendus,* and in the *Recherches physiques et chimiques,* published with Thénard in 1811.

GAZA, THEODORUS (c. 1400–1475), one of the Greek scholars who were the leaders of the revival of learning in the 15th century, was born at Thessalonica. On the capture of his city by the Turks in 1430 he fled to Italy. During three years spent in Mantua he learned Latin from Vittorino de Feltre, supporting himself meanwhile by teaching Greek, and by copying mss. In 1447 he became professor of Greek in the new university of Ferrara, to which his fame soon attracted students from all parts of Italy. He had taken some part in the councils which were held in Siena (1423), Ferrara (1438), and Florence (1439), with the object of bringing about a reconciliation between the Greek and Latin Churches; and in 1450, at the invitation of Pope Nicholas V., he went to Rome, where he was for some years employed in making Latin translations from Aristotle and other Greek authors. After the death of Nicholas (1455), Gaza removed to Naples, where he enjoyed the patronage of Alphonso the Magnanimous for two years (1456–58). Shortly afterwards he was appointed by Cardinal Bessarion to a benefice in Calabria, where he died about 1475. His Greek grammar (in four books), written in Greek, first printed at Venice in 1495, and afterwards partially translated by Erasmus in 1521, although in many respects defective, especially in its syntax, was for a long time the lead-

ing text-book. His translations into Latin were very numerous.

See G. Voigt, *Die Wiedevbelebung des klassischen Altertums* (1893), and article by C. F. Bahr in Ersch and Gruber's *Allgemeine Encyklopädie*. For *a* complete list of his works, *see* Fabricius, *Bibliotheca Graeca* (ed. Harles), x.

GAZA, the most southerly city of the Philistine Pentapolis, separated from the sea by 3 m. of sand dunes. It was a centre where ancient trade routes met, and through it passed the frankincense from Arabia on its way to the Mediterranean world. It is now the first town on the railway from Egypt to Palestine and since 1922 capital of the southern province of Palestine. The town is well supplied with water. Before World War I it was a prosperous town with good bazaars, a considerable manufacture of black pottery, and a growing export trade in barley. It was more than half destroyed by the war, and the population, although somewhat replenished immediately after the war, dwindled away northward in search of sustenance. The small harbour of Gaza (El-Mineh) is used mainly for the export of grain. The anchorage is seven fathoms. The only industry is provided by about 100 primitive looms on which is made coarse cloth for Bedouin cloaks. The population (1940) was 21,300.

History.— The Egyptian monarch, Thutmose III. (c. 1500 B.C.) found in Gaza a convenient base for operations against Syria. Gaza's king was a vassal of the Pharaohs in the Tell Amarna period about a century later. Joshua's victories brought him to its neighbourhood but not within its walls. It was one of the strongholds from which the Philistines harassed Israel; and Gaza, famous for the worship of Dagon and Derketo, was the scene of Samson's glorious death. Solomon and Hezekiah gained a footing here without being able to retain it. Her traffic in slaves evoked the curse of Amos. In 735 B.C. Tiglath-Pileser made it tributary to Assyria. Gaza coquetted with Egypt and received condign punishment from Sargon. In the three centuries following it was bandied between Babylon and Egypt. Gaza resisted Alexander the Great only to be broken and made a "desert." From the third to the first centuries B.C. Egyptian, Syrian and Jewish armies fought for its possession. The Romans made Gaza into an important place (named Minoa) and Augustus presented it to Herod. New Gaza was built on another site in the first century A.D. Although it showed itself ill-disposed to accept Christianity, a Christian community settled here early, and the Philemon, to whom St. Paul addressed a letter, was said to have been its first head.

In A.D. 634 it surrendered to Omar's troops, and since Hashim the great-grandfather of the Prophet was buried here became a sacred Muslim city. In the 12th century the crusaders found it almost desolate. Baldwin III. erected a fortress (1149) but after Hattin Gaza surrendered. The Khwarismians inflicted a painiul defeat here on the Christian and Saracen armies whom dire necessity drove into a strange and fleeting alliance. In the 16th century the Turks crushed the Mamelukes here and Egypt lay open to Salim I. Gaza fell to Bonaparte (1799). Three battles were fought at Gaza during World War I—the first, March 26–27; and the second, April 19, 1917, in which Gen. Sir Archibald Murray failed to take and hold the city; and the third in November of the same year when Gen. Allenby secured its evacuation by breaking through the Turkish line at Beersheba. The town was much ruined and the mosques damaged.

Battles of Gaza, 1917.—Gaza forms the natural "gate" into Palestine from Egypt by the coast route. Thus when in 1917 the British Government decided to change their operations for the defence of the Suez Canal into an offensive against the Turkish forces in Palestine, Gaza formed the obvious initial objective. Rut the first and second direct attacks, on March 26 and April 17–19, failed, and it was not until the autumn that Gaza fell as a result of Allenby's indirect move, first against Beersheba and then against the weak centre of the Turkish front between Beersheba and Gaza. For a description of these operations, which culminated in the capture of Jerusalem, see PALESTINE, OPERATIONS IN.

GAZALAND, a district of Portuguese East Africa. Formerly indicating a large region between Delagoa bay and the Pungwe river, the name is now confined to the lower Limpopo district. The modern territory of Gaza, part of the district of Lourenço Marques, is 73,584 sq.km. in extent, comprising 5 sub-districts. It is one of the chief recruiting grounds for negro labour in the Transvaal gold mines. The region derives its name from the Swazi chief Gaza, a contemporary of Chaka, the Zulu king. Refugees from various clans oppressed by Dingaan (Chaka's successor) were welded into one tribe by Gaza's son Manikusa, who took the name of Sotchangana, his followers being known generally as Matshangana. Between 1833 and 1836 Manikusa made himself master of the country as far north as the Zambezi and captured the Portuguese posts at Delagoa bay, Inhambane, Sofala and Sena, killing nearly all the inhabitants. The Portuguese reoccupied their posts, but held them with great difficulty, while in the interior the Matshangana continued their ravages unchecked, depopulating large regions. Manikusa died about 1860, and his son Umzila established himself in independence north of the Manhissa river as far as the Zambezi and inland to the continental plateau, a position he maintained till his death (c. 1884). His chief rival was a Goanese named Gouveia, who came to Africa about 1850. Having obtained possession of a *prazo* in the Gorongoza district, he ruled there as a feudal lord while acknowledging himself a Portuguese subject. Portugal's hold on the coast had been more firmly established at the time of Umzila's death, and Gungunyana, his successor, was claimed as a vassal, while efforts were made to open up the interior. This led in 1890–91 to collisions on the borderland of the plateau with the newly established British South Africa Company, and to the arrest by the company's agents of Gouveia, who was, however, set at liberty and returned to Mozambique via Cape Town. An offer made by Gungunyana (1891) to come under British protection was not accepted. In 1892 Gouveia was killed in a war with a native chief. Gungunyana maintained his independence until 1895, when he was captured by a Portuguese force and exiled. He died in 1906. With the capture of Gungunyana opposition to Portuguese rule largely ceased. Later a considerable number of Europeans settled in Gazaland, devoting themselves chiefly to the cultivation of the sugar-cane, rice and maize. The chief town is Chai Chai (Vila Nova de Gaza), a port on the Limpopo.

See G. McCall Theal, *History of South Africa since 1795,* vol. v. (1908); Eric Walker, *A History of South Africa* (1928).

GAZELLE, the name given to a group of antelopes forming the genus *Gazella* (see ANTELOPE).

GAZETTE, a name given to news-sheets or newspapers having an abstract of current events (see NEWSPAPERS).

GAZZANIGA, GIUSEPPE (1743–1818), Italian composer, was born at Verona in 1743 and studied under Niccola Porpora, Niccola Piccinni and Antonio Sacchini. One of the most prolific and popular composers of the time, he wrote some fifty operas, including *Il* Convitato *di* Pietro, La Locanda, *L'Italiana* in Londra and La *Dama* Incognita, besides a number of cantatas and oratorios.

He was chapel-master at the cathedral of Crema, where he died in 1818.

GBANDI, a people of Liberia west of the Loma or Toma, with whom (and with the Kpelle) (*q.v.*) they have many affinities.

See D. Westermann, *Die Kpelle, ein Negerstamm in Liberia* (1921).

GBE, a people physically and socially resembling the Kpelle, living in Liberia north of the Krumen folk and speaking an idiom akin to the Krumen dialects.

GDYNIA, a Polish seaport and naval base, on the bay of Gdynia, opening out into Danzig bay, on the Baltic. It is 12 mi. N.W. of Danzig, with which it is connected by railway. The Polish Government in building a railway to the port passing over territory entirely Polish, had also a scheme for a canal to the port from a convenient point on the Vistula, thus tapping the whole waterway system of Poland.

In 1924, when the port of Danzig proved insufficient for Poland's overseas trade, the Polish state decided to build another

port in the bay of Gdynia, at that time a small fishing village. In ten years the port of Gdynia became one of the largest harbours in Europe.

The construction of the port of Gdynia, which began in 1924, had reached the following stage in 1938: the length of the breakwaters was 3,948 metres (2 miles), of the wharves 12,867 metres (more than 7 miles), the greatest depth, 12 metres (39 feet). The whole harbour covered an area of 1,010 hectares (2,495 acres), of which the water space occupied 33 j hectares (827 acres). The length of railway tracks was 222 kilometres (138 miles), the area covered by warehouses over 50 acres. Gdynia's overseas goods traffic in 1938 reached 9,173,438 tons (10,167 tons in 1924 and 7,191,913 tons in 1934). Pop. (1939) 120,000 (1,300 in 1921 and 34,400 in 1931). Occupied by Germany in World War II.

GEAR, an outfit, applied to the wearing apparel of a person, or to the harness and trappings of a horse or any draft animal, as riding-gear, hunting-gear, etc.; also to household goods or stuff. The phrase "out of gear," though now connected with the mechanical application of the word, was originally used to signify "out of harness" or condition. The word is also used of apparatus generally, and especially of the parts collectively in a machine by which motion is transmitted from one part to another by a series of cog-wheels, continuous bands, etc. *(See* BICYCLE; MECHANICS; MOTOR VEHICLES; POWER TRANSMISSION; STEAM ENGINE.)

GEAR-CUTTING MACHINES: *see* MACHINE-TOOLS.

GEBER or **JABIR,** more fully Abii Mūsā Jābir ibn Ḥayyān, was the most celebrated chemist of mediaeval times. There is reason to believe that he belonged to the famous South Arabian tribe of Al-Azd, some members of which settled in the town of Kūfa shortly after its foundation by the Caliph Omar in A.D. 638. Jābir's father, Ḥayyān, was a druggist in Kūfa and an ardent supporter of the ʿAbbasid family, at that time plotting to secure the caliphate. It is probable that Jābir was born at the town of Tus (near the present Meshed) in the year A.D. 721 or 722, while his father was in Persia as an ʿAbbasid agent. Shortly afterwards, Ḥayyān was arrested and executed by 'Umayyad officers, and the younger Jābir was sent to Arabia, where he studied under Harbi at Himyari. As a youth, Jābir attached himself to the sixth Shi'ite Imām, Jaʿfar al-Ṣādiq, from whom he probably obtained his first introduction to occultism, though perhaps not to alchemy itself. He is said to have afterwards joined the Sufi order, then recently founded by Abū Hāshim of Kiifa (died A.D. 777–778). In later life, Jābir became a friend of Hārūn al-Rashid's powerful ministers the Barmakides, and, according to tradition, shared their banishment from Baghdad in A.D. 803. Retiring to Kiifa, he spent the rest of his life in obscurity, though one authority maintains that he survived until the accession of the Caliph Al-Ma'mūn in A.D. 813. His laboratory at Kiifa came to light some two centuries later, during building operations in a quarter of the town known as the Damascus Gate.

Jābir was a voluminous writer, and fortunately made a list of the titles of his books, which was reproduced in part by Ibn Al-Nadīm in his *Kitāb al-Fihrist,* a Muslim encyclopaedia of the 10th century A.D. Many of these books are still extant, nearly 100 having been reported as existing in manuscript or native lithographs in various European, Indian and North African libraries. They are, however, for the most part unedited (1928), and it is therefore impossible to express a final conclusion upon Jābir's scientific knowledge. In 1893, nine small works were edited and translated by O. Houdas and published by M. P. E. Berthelot in his *La Chimie au Moyen Age* (Paris), but they are by no means the most important. Among the Latin alchemical manuscripts in the *Bibliothèque Nationale* Berthelot found a mutilated treatise, entitled *Liber de Septuaginta (Johannis), Translatus a Magistro Renoldo Cremonensi* (Gerard of Cremona), which he considered was probably a translation from the Arabic Jābir. At that time (1893), the Arabic version was unknown; it was, however, discovered in 1926 by Prof. Max Meyerhof, who found two separate manuscripts of it in the private libraries of Nureddin Bey Mustafa and Ahmad Pasha Taimur, at Cairo. Berthelot's conjecture was therefore well founded. Of the remaining extant treatises, the most noteworthy are the *Great Book of Properties,* the three *Books of the Element* of *the Foundation,* and a *Book of Poisons,* the last having been discovered in 1928 by Prof. Julius Ruska of Berlin.

Jābir's thought is often confused and superstitious, yet he has a two-fold importance for the history of chemistry. In the first place he was a skilled and ingenious experimentalist, and describes for the first time the preparation of nitric acid, the method of conducting certain essential chemical operations, and many other things of the same kind. Secondly, he suggested the comprehensive theory that all metals are composed of two principles resembling sulphur and mercury. This theory, which was a development of the Aristotelian conception of two "exhalations," persisted for many centuries and was at last modified into the phlogiston theory of Beccher and Stahl (17th and 18th centuries A.D.) Jābir explained the existence of different varieties of metals by assuming that the sulphureous and mercurial principles are not always pure and that they do not always combine together in the same proportion. If they are perfectly pure and combine together in the most perfect natural equilibrium, then the product is the most perfect of metals, viz., gold. Defects in purity or proportion or both result in the formation of silver, lead, tin, iron or copper; but since these metals are all essentially composed of the same constituents as gold, the accidents of combination may be removed by suitable treatment. Such treatment, which Jābir believed could be effected by means of elixirs, was the object of *Alkimia* or alchemy.

Jābir's chemical theory was thus a development of Greek scientific and occult philosophy. Etymological and other evidence renders it likely that his contact with Hellenism was made through Persian channels rather than through Syria and Egypt. The reputation he acquired has never since been equalled in the whole development of chemistry; there is, indeed, scarcely a single later Arabic alchemical work in which he is not quoted, or at least mentioned. When, in the 12th and 13th centuries, Islamic science was transmitted to Latin Christianity, the fame of Jābir went with it; and, as we have seen, at least one of his books was translated into Latin. There are, however, several Latin treatises *(Summa perfectionis, magisterii, De investigatione perfectionis, De inventione veritatis, Liber fornacum, Testamentum Geberi)* which pass under his name, but of which no Arabic original has hitherto come to light. These works, while their content as a whole can be fairly closely paralleled in the presumably authentic Arabic works, show a very much greater regard for systematic treatment and exposition than the latter; hence several scholars, notably Kopp, Wiedemann, Berthelot and Darmstädter, have regarded them as European forgeries fathered upon the venerable name of Jābir. They are universally regarded as the most important of mediaeval chemical works, and the problem of their authorship is in urgent need of solution. It is perhaps significant that a 13th-century manuscript of the *Summa* and *De investigatione perfectionis,* discovered at Florence in 1925 by Darmstädter, contains also a Latin version of the genuine Arabic work, *The Book of Mercy.*

Darmstädter, *Die Alchemie des Geber* (Berlin, **1922**) and *Liber Misericordiae Geber* (Archiv, für Geschichte der Medizin, xvii., *4,* 181–197, 1925); **J.** Ruska, *Über des Schriftenverzeichnis des Giber ibn Ḥajjān* (Archiv. f. Gesch. d. Med. xv., **53–67,** 1923) and *Die siebzig Bücher des Gaber ibn Ḥajjan* (Lippmann Festschrift, Berlin, **1927,** pp. **38–47**); **E. J.** Holmyard, "Jābir ibn Hayyan" (*proc. Roy. Soc. Med.,* 1923, xvi., **46–57**); *An Essay on Jābir ibn Hayyan* (Lippmann Festschrift, **28–37**), and *The works of Geber* (London, **1928**). A complete edition of the Arabic works, with translation into English by E. J. Holmyard, is in course of publication (Paris, **1928**).

GEBHARD: TRUCHSESS VON WALDBURG (1547–1601), elector and archbishop of Cologne, second son of William, count of Waldburg, was born on Nov. 10. 1547, at Cologne, studied at Ingolstadt, Perugia and Louvain, and took orders. He held various positions at the cathedrals of Augsburg, Strasbourg, Cologne, and again at Augsburg, and in Dec. 1577 was elected elector archbishop of Cologne. He became a convert to the Reformed doctrines, but it was suspected that his conversion was due to his desire to marry Agnes, countess of Mansfeld. The marriage was celebrated in February 1583, and caused a great scandal.

Gebhard declined to give up his see, and collected an army. In April he was deposed and excommunicated by Pope Gregory XIII.; a Bavarian prince, Ernest, bishop of Liége, Freising and Hildesheim, was chosen elector, and war broke out between the rivals. The Lutheran princes of Germany gave no real support to Gebhard, who had Calvinistic leanings, and the only armed assistance he received was from John Casimir, administrator of the Rhenish Palatinate. Early in 1584 he was driven from Bonn. He found refuge in the Netherlands. In 1589 Gebhard went to live at Strasbourg, where he had held the office of dean of the cathedral since 1574. He died at Strasbourg on May 31, 1601. Gebhard was a drunken and licentious man, who owes his prominence rather to his surroundings than to his abilities.

See J. H. Hennes, *Der Kampf um das Erzstift Koln* (Cologne, *1878)*; L. Ennen, *Geschichte der Stadt Koln* (Cologne, 1863–80); and *Nuntiaturberzchte aus Deutschland. Der Kampf um Koln,* edited by J. Hansen (Berlin, 1892).

GEBHARDT, EDUARD VON (1830–1925), German painter, was born in Estonia, and studied at Diisseldorf, where he became a professor in the academy in 1873. He modelled his style on that of the old Nuremberg and Flemish schools, and depicted scriptural subjects, using the German costume of the 15th and 16th centuries for his figures. But his heads were drawn from nature, from the tough and hardy population of his native land. His art constituted a reaction towards realism after the staged and vapid productions of the Piloty school. Among his more important works are the "Last Supper," and the "Ascension," in the National Gallery at Berlin; the "Crucifixion" in the cathedral at Reval; there are examples of his work in the museums of Elberfeld, Diisseldorf, Dresden, Barmen, Breslau, and Magdeburg. Between 1884–91 he worked on mural decorations for a hall in the monastery of Loccum, Hanover. He also painted portraits. He died at Dusseldorf on Feb. 3, 1925.

GEBWEILER: *see* GUEBWILLER.

GECKO, a general term applied to any lizard of the family *Geckonidae.* For the most part geckoes are small creatures with a soft skin, a short, stout body, large head and weak limbs; the most salient constant characteristic of the group is the absence of connivent eyelids, the eyes, which are usually large and prominent, being protected by a transparent, watchglass-like covering which is probably a modified nictitating membrane.

The group is cosmopolitan in distribution, occurring everywhere in warmer climates, even on the remotest oceanic islands, and is adapted to very diverse habitats. All its members are insectivorous and the great majority have the digits modified for climbing; the fingers and toes are dilated either terminally or at their bases and the lower surface of the dilation is covered with transverse plates whose arrangement is exceedingly diverse in the different genera; each plate is beset with numerous tiny, hair-like processes which give the whole surface a velvety appearance. When the feet are placed on any surface the velvety pile accomodates itself to the slightest irrêgularities and pressure forces the air out from between the hairs; the resulting vacuum gives sufficient adhesion to enable many species to climb absolutely smooth and vertical surfaces and even to run across a whitewashed ceiling. Claws are well developed in most species and, in a few, are provided with a special sheath, into which they are retractile. The most remarkable modification of the feet is found in the genus *Palmatogecko* from the deserts of Damaraland; here there is no adhesive apparatus but the toes are webbed to their extremities to enable the animal to walk over and burrow into the loose sand.

The tail is extremely fragile and is quickly regenerated, the new one having a simpler scalation than the original. Often the tail is peculiar in shape; it may be long and tapering or short and blunt, or even globular; in one species *(Gymnodactylus platyurus)* it is leaf-shaped. It seems highly probable that in many instances, particularly where it is large and globular, the tail serves as a storehouse of reserve nutriment on which the animal can draw during unfavourable conditions. As a rule the skin is soft and delicate, and covered with minute granules, but frequently there are large tubercles intermixed with these. *Teratoscincus,* a western Asiatic desert dweller, has, however, developed large, overlapping smooth scales which enable it to slip through the sand with the minimum of friction. Colours as a rule are drab, greys, browns, and dirty whites predominating, and to the weird and forbidding aspect thus produced the general prejudice against those creatures in the countries where they occur, which has led to their being classed with toads and snakes, is no doubt to be attributed. Their bite was supposed to be venomous, and their saliva to produce painful cutaneous eruptions; even their touch was thought sufficient to convey a dangerous taint. It is needless to say that in this instance the popular mind was misled by appearances. The geckoes are exceedingly useful creatures, feeding on insects. Many species have a voice, the call differing with the species but being usually a feeble click or chirp. All species so far as known are oviparous, the eggs being white, hard-shelled and usually laid beneath the bark of trees or attached to the under side of leaves.

(H. W. P.)

GED, WILLIAM (1690–1749), the inventor of stereotyping, was born at Edinburgh. In 1725 he patented his invention, developed from the simple process of soldering together loose types of Van der Mey. Ged, although he succeeded in obtaining a cast in similar metal, of a type page, could not persuade Edinburgh printers to take up his invention, and finally entered into partnership with a London stationer named Jenner and Thomas James, a typefounder. The partnership, however, turned out very ill; and Ged, broken-hearted at his want of success due to trade jealousy and the compositors' dislike of the innovation, died in poverty on Oct. 19, 1749. Two prayer-books for the university of Cambridge and an edition of Sallust were printed from his stereotype plates. In his time the best type was imported from Holland, and Ged had repeated offers from the Dutch which, from patriotic motives, he refused. His sons tried to carry out his patent, and it was eventually perfected by Andrew Wilson.

GEDDES, SIR AUCKLAND CAMPBELL, K.C.B., 1917, and G.C.M.G., 1922 (1879–), British politician, was born on June 21, 1879, the son of Auckland Campbell Geddes of Edinburgh and the younger brother of Sir Eric Geddes, and was educated at George Watson's college, Edinburgh, and Edinburgh university. He studied medicine, qualified as a practitioner, was at the London hospital for a time and later studied at Freiburg. He was a demonstrator and professor of anatomy first at Edinburgh, then at the Royal college of surgeons, Dublin, and afterwards at McGill university, Montreal. He also had some military experience in the South African War and afterwards in the World War.

In 1916 Geddes became director of recruiting, and in Aug., 1917, minister of National Service, a seat in parliament being found for him at Basingstoke. After the Armistice Geddes became president of the Local Government Board and minister of Reconstruction, and in May, 1919, president of the Board of Trade. At the Board of Trade he began the removal of the barriers to British trade which the war had necessarily set up, and he had to deal with the difficulties which immediately arose in the coal industry. In this delicate task he was at least temporarily successful, and managed materially to reduce the price of domestic coal. In the same year an opportunity was afforded him to return to academic life by his election as principal of McGill university. He accepted the appointment, subject to its not being operative till the abatement of the coal crisis allowed of his leaving the Board of Trade. But during the delay the Government prevailed on him to accept instead the post of British ambassador in Washington. His tenure of the embassy (1920–3) was crowded with important negotiations in which he showed himself a successful diplomatist. On leaving Washington Geddes left the public service and became chairman of the Rio Tinto Company.

GEDDES, SIR ERIC CAMPBELL, G.C.B., 1919 (1875–1937), British man of business and administrator, born in India on Sept. 26, 1875, was the son of Auckland Campbell Geddes of Edinburgh, and the elder brother of Sir Auckland Geddes. He was educated at the Oxford Military college and Merchiston Castle school, Edinburgh. He gained some business experience at lumbering in the United States, and was afterwards connected

with railways—first, the Baltimore and Ohio system, and then the Rohilkhand and Kumaton in India. Returning to England he joined the North Eastern Railway Co. under Sir George Gibb, and, having succeeded him in 1906, was himself the general manager of this line when the World War broke out.

Geddes was one of the business men whom Lloyd George, on becoming Minister of Munitions, enlisted in Government employ. He became deputy director general of munitions supply, 1915–16, and was then appointed, though a civilian, director general of transportation, and succeeded in bringing the British lines of communication in France into a high state of efficiency. He was transferred to the Admiralty in May, 1917, as controller, in order to develop and utilize the whole of the shipbuilding resources of the country and concentrate them under one authority. A month or two later, in spite of having no parliamentary experience, he was appointed First Lord of the Admiralty, and was returned to the House of Commons as M.P. for the borough of Cambridge. After the Armistice Geddes was employed on questions connected with demobilization. When the Government was reconstructed in Jan., 1919, he left the Admiralty in order to organize and preside over a new Ministry of Transport. In 1921 a bill introduced by Geddes for the re-grouping of the railways was passed; he then resigned office in Oct., and the ministry was reduced in personnel and importance. Sir Eric himself was appointed in Aug., 1921, chairman of a small committee, later known as the "Geddes Axe," to recommend public economies to the Government. In various reports in the winter of 1921–22 the committee recommended savings amounting to £86,000,000; but Sir Eric complained that only £52,000,000 of this amount was actually saved. In 1922 he left Parliament and returned to a business career, becoming chairman of the Dunlop Rubber Co. and of Imperial Airways, Ltd. He died on June 22, 1937.

GEDDES, NORMAN BEL (1893–), American scenic artist, was born in Adrian, Mich., on April 27, 1893. After a short period at the Cleveland school of art, he went to the Chicago Art institute. From Chicago he moved to Detroit, where he was engaged as a commercial artist. Interested in the theatre, he soon secured a position as scenic director, his work attracting the attention of a California director. He removed to Los Angeles, where he presented his first dramatic production, *Nyu,* in 1916. His first scenic work in New York was for Chas. W. Cadman's *Shanewis,* presented in 1918 at the Metropolitan opera house, since which time he has designed many operas, musical comedies and plays, his most popular success being *The Miracle.* He designed and produced *Jeanne d'Arc* in Paris in 1925. He was co-designer of the Guild theatre in New York, and the author of *A Project for a Theatrical Presentation of the Divine Comedy of Dante Alighieri* (1924) and *Horizons* (1932).

GEDDES, SIR PATRICK (1854–1932), British biologist and sociologist, was born at Perth on Oct. 20. Trained in biology in the laboratory of T. H. Huxley, University College, London, and at several continental universities, he became successively demonstrator in physiology at University College, London, in zoology at Aberdeen and in botany at Edinburgh. In 1883 he was appointed professor of botany at University College, Dundee, and in 1919 became professor of sociology and civics at Bombay university. Geddes did pioneer research in the evolution of sex. His interest from the beginning was in the relation of biological science to society, and in particular to the problems of civics. His Outlook Tower in Edinburgh was for many years a stimulating laboratory of sociological enquiry, from which sprang a publishing house in Edinburgh and the regional survey movement, with its synthetic study of the organic relationship between city, country and industrial area—the theme of countless lectures and papers by Geddes, and of group meetings in many countries throughout a period of more than thirty years. Geddes, while retaining his professorship of botany at Dundee, was one of the founders of the Sociological Society in London (1903), giving attention mainly to the civic aspect of its work. Going in 1914 to London, he organised a civic exhibition. During his professorship in Bombay he made surveys and reports on many Indian cities and gardens, and in Jerusalem produced designs for enlarging the city and for the several university colleges. In collaboration with J. Arthur Thomson he wrote *The Evolution of Sex* (1889, rev. ed. 1901) and other works on kindred subjects.

His works include *Cities in Evolution* (1913) and *The Life and Works of Sir Jagadis Chandra Bose* (*q.v.*), the Bengali physicist (1920).

GEDYMIN (d. 1342), grand-duke of Lithuania, was supposed by some to have been the servant of Witen, prince of Lithuania, but more probably he was Witen's younger brother and the son of Lutuwer, another Lithuanian prince. Gedymin inherited a vast domain, comprising Lithuania proper, Samogitia, Red Russia, Polotsk and Minsk; but these lands were environed by powerful foes, the most dangerous being the Teutonic Knights and the Livonian Knights of the Sword. The systematic raiding of Lithuania by the knights under the pretext of converting it had long since united all the Lithuanian tribes against the common enemy; but Gedymin aimed at establishing a dynasty which should make Lithuania not merely secure but mighty, and for this purpose he began negotiations with the Holy See. At the end of 1322 he wrote to Pope John XXII. soliciting his protection against the persecution of the knights, informing him of the privileges already granted to the Dominicans and the Franciscans in Lithuania, and desiring that legates should be sent to receive him also into the church. Gedymin then issued circular letters, dated Jan. 25, 1325, to the principal Hanse towns, offering a free access into his domains to settlers. The immigrants were to choose their own settlements and be governed by their own laws. Similar letters were sent to the Wendish or Baltic cities, and to the bishops and landowners of Livonia and Esthonia. In short Gedymin anticipated Ivan the Terrible and Peter the Great by throwing open the semi-savage Russian lands to western culture.

In Oct. 1323 representatives of the archbishop of Riga, the bishop of Dorpat, the king of Denmark, the Dominican and Franciscan orders, and the Grand Master of the Teutonic Order assembled at Vilna, when Gedyrnin confirmed his promises and undertook to be baptized as soon as the papal legates arrived. A compact was then signed at Vilna confirming the promised privileges. But the christianizing of Lithuania was by no means to the liking of the Teutonic Knights, and they strove to nullify Gedymin's design. Gedymin's chief object was to save Lithuania from destruction at the hands of the Germans. But he was still a pagan reigning over semi-pagan lands; he was equally bound to his pagan kinsmen in Samogitia, to his orthodox subjects in Red Russia, and to his Catholic allies in Masovia. His policy, therefore, was necessarily tentative and ambiguous. Thus his raid upon Dobrzyn, the latest acquisition of the knights on Polish soil, gave them a weapon against him. The Prussian bishops, who were devoted to the knights, at a synod at Elbing questioned the authority of Gedymin's letters and denounced him as an enemy of the faith; his orthodox subjects reproached him with leaning towards the Latin heresy; while the pagan Lithuanians accused him of abandoning the ancient gods. Gedymin then repudiated his former promises; he refused to receive the papal legates who arrived at Riga in Sept. 1323, and dismissed the Franciscans. Gedymin saw that the pagan element was still the strongest force in Lithuania, and could not yet be dispensed with in the coming struggle for nationality. But, through his ambassadors, he privately informed the papal legates at Riga that his difficult position compelled him to postpone his own baptism, and the legates showed their confidence in him by forbidding the neighbouring states to war against Lithuania for the next four years, besides ratifying the treaty made between Gedymin and the archbishop of Riga. Nevertheless in 1325 the Order, disregarding the censures of the church, resumed the war with Gedymin, who by the marriage of his daughter to Casimir, son of Wladislaus Lokietek, king of Poland, had improved his position.

While on his guard against his northern foes, Gedyrnin from 1316 to 1340 was extending his rule over neighbouring Russian principalities. The principality of Halicz-Vladimir was obtained by the marriage of his son Lubart with the daughter of the Halician prince; Kiev seems to have been acquired by conquest. Gedymin also secured an alliance with the grand-duchy of Muscovy by marrying his daughter, Anastasia, to the grand-duke

Simeon. He was strong enough to counterpoise the influence of Muscovy in northern Russia, and assisted the republic of Pskov, which acknowledged his overlordship, to break away from Great Novgorod. His internal administration bears all the marks of a wise ruler. He protected the Catholic as well as the orthodox clergy, encouraging them both to civilize his subjects; he raised the Lithuanian army to the highest state of efficiency then attainable; defended his borders with a chain of strong fortresses; and built numerous towns including Vilna, the capital (*c.* 1321). Gedymin died in the winter of 1342 of a wound received at the siege of Wielowa. He was married three times, and left seven sons and six daughters.

See Teodor Narbutt, *History of the Lithuanian Nation* (Pol.) (Vilna, 1835); Antoni Prochaska, *On the Genuineness of the Letters of Gedymin* (Pol.) (Cracow, 1895); Vladimir Bonifatovich Antonovich, *Monograph concerning the History of Western and Southwestern Russia* (Rus.) (Kiev, 1885). (R. N. B.; X.)

GEELONG, a seaport of Grant county, Victoria, Australia, situated on a land-locked arm of Port Phillip known as Corio bay, 45 m i by rail S.W. of Melbourne. Pop. (1940) 40,730. Geelong was incorporated in 1849. As a manufacturing centre it is of considerable importance. The first woollen mill in the colony was established here, and the tweeds, cloths and other woollen fabrics of the town are noted throughout Australia. There are extensive tanneries, flour-mills and salt works, while at Fyansford, 3 mi. distant, there are important cement works and paper-mills. Corio bay, a safe and commodious harbour, has a depth of 25 ft. at low water and was deepened to 29 ft. There is extensive quayage, and the largest wool ships are able to load alongside the wharves, which are connected by rail with all parts of the colony. The facilities given for shipping wool direct to England from this port have caused a very extensive wool-broking trade to grow up in the town.

GEERTGEN VAN HAARLEM (c. 1465–1493), Dutch painter active in Haarlem. He was surnamed "tot Sint Jans," as he lived with the knights of St. John at Haarlem. He is one of the most interesting Dutch artists of the 15th century and he is important, as he represents a school of which very few works have survived destruction. According to Van Mander, who is the authority on what is known of his life, he was a pupil of Ouwater at Haarlem. Neither the year of his birth nor of his death is known, but only that he was 28 years old when he died. Dürer, on seeing his work, is said to have exclaimed: "Here is a born painter," but as Dürer is not known to have visited Haarlem the truth of this story has been doubted. Geertgen painted a large triptych for the high altar of the knights of St. John. The central panel with the "crucifixion" and one of the wings were destroyed in the religious troubles; but the other wing has been identified with the aid of Van Mander's description. This wing is now in the Vienna gallery, sliced into two separate panels, front and back. The front represents the dead Christ being mourned by His friends. The pathos of the scene is expressed with deep feeling. The influence of Rogier van der Weyden is seen in the Magdalen wringing her hands. In the background is a realistic burial scene on Mount Calvary. Here the artist broke away from the traditional symbolical assemblage of emblematic figures on the altarpieces of his time and felt his way towards the more vivid and dramatic style of the next generation of Dutch painters.

The same is true of the other panel (the back of the wing) on which the emperor Julian the Apostate is causing the bones of St. John the Baptist to be buried. In the mid-distance of this panel is an admirable group of portraits of the knights of St. John at Haarlem among whom the artist lived. They are lifelike studies of individual characters and seem to presage those great democratic portrait groups famous in Dutch paintings of the 17th century.

A number of pictures are ascribed to him on stylistic grounds. Among these is the "St. John the Baptist" of the Berlin museum, where the pensive saint is sitting in beautiful park-like scenery. In the same collection is "Virgin and Child." The Louvre contains the "Resurrection of Lazarus," the Amsterdam museum "The Virgin's Kindred" and the "Adoration of the Magi." The "Man of Sorrows" at Utrecht is a painful but wonderful picture; a triptych at Prague represents the "Adoration of the Magi" in the centre and "Donors and Saints" on the wings. It is distinguished for the original conception of some of its figures and for its animated background.

Another "Adoration of the Magi" is in the possession of Oscar Reinhart at Winterthur. The National Gallery, London, has acquired one of the most attractive pictures by the master. It represents "Nativity," a night scene, remarkable for its rendering of chiaroscuro.

GEEZ. The name given to the language of an ancient nomadic Semitic race of Ethiopia. *See* ETHIOPIA and SEMITIC LANGUAGES.

GEFLE (GÄVLE), a seaport of Sweden on an inlet of the Gulf of Bothnia, chief town of the district (*län*) of Gavleborg, 112 mi. N.N.W. of Stockholm by rail. Pop. (1943) 39,897. It is the chief port of the district of Kopparberg, with its iron and other mines and forests. The exports consist principally of timber and woodpulp, iron and steel, imports of coal, grain and machinery. The harbour, which has two entrances about 20 ft. deep, is usually icebound from January to April. Large vessels generally load in the roads at Gråberg, 6 m. distant. There are slips and shipbuilding yards, and a manufacture of sail-cloth. The town is an important industrial centre, having tobacco and textile mills, and breweries. At Skutsk'ar at the mouth of the Dal river are woodpulp- and sawmills, dealing with the timber floated down the river. The principal buildings are a castle, founded by King John III. (1568–1592), but rebuilt later, and a council-house erected by Gustavus III.

GEGENBAUR, CARL (1826–1903), German anatomist, was born on Aug. 21, 1826 at Wiirzburg and was educated at the university there. In 1855 he was appointed professor of anatomy at Jena, and in 1873 at Heidelberg, where he was also director of the Anatomical Institute until 1901. In his best known work, *Grundriss der vergleichenden Anatomie* (Leipzig, 1874; Eng. trans. 1878), Gegenbaur laid stress on the high value of comparative anatomy as the basis of the study of homologies. A distinctive piece of work was effected by him in 1871 in supplementing the evidence adduced by Huxley in refutation of the theory of the origin of the skull from expanded vertebrae. Huxley demonstrated that the skull is built up of cartilaginous pieces; Gegenbaur showed that "in the lowest (gristly) fishes, where hints of the original vertebrae might be most expected, the skull is an unsegmented gristly brain-box, and that in higher forms the vertebral nature of the skull cannot be maintained, since many of the bones, notably those along the top of the skull, arise in the skin." Other publications by Gegenbaur include a *Textbook of Human Anatomy* (Leipzig, 1883, new ed. 1903), the *Epiglottis* (1892) and *Comparative Anatomy* of *the Vertebrates in relation to the Invertebrates* (Leipzig, 2 vols., 1898, 1901). In 1875 he founded the *Morphologisches Jahrbuch,* which he edited for many years In 1901 he published a short autobiography under the title *Erlebtes und Erstrebtes.* Gegenbaur died at Heidelberg in 1903.

See Fiirbringer: *Heidetberger Professoren aus dem 19ten Jahrhundert* (Heidelberg, 1903).

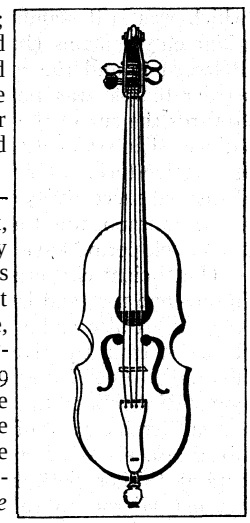
GEGENSCHEIN or counterglow, an extremely faint luminescence of the sky, seen opposite the direction of the sun. Its faintness is such that it can be seen only by a practised eye under favourable conditions. It is invisible during the greater part of June, July, December and January. owing to its being then blotted out by the superior light of the Milky Way. It is also invisible during moonlight and near the horizon, and the neighbourhood of a bright star or planet may interfere with its recognition. When none of these unfavourable conditions supervenes it may be seen at nearly any time when the air is clear and the depression of the sun below the horizon more than 20 degrees. (*See* ZODIACAL LIGHT.)

GEIBEL, EMANUEL (1815–1884), German poet, was born at Liibeck on Oct. 17, 1815, the son of a pastor in the city. He studied theology at Bonn and Berlin, but his real interests lay not in theology but in classical and romance philology. In 1838 he accepted a tutorship at Athens, where he remained until

1840. His first poems, *Zeitstimmen,* political poems directed against radicalism, appeared in 1841; a tragedy, *Konig Roderich,* in 1843. In the same year he received a pension from the king of Prussia, which he retained until his invitation to Munich by the king of Bavaria in 1851 as honorary professor at the university. Meanwhile he had produced *Konig Sigurds Brautfahrt* (1846), an epic, and *Juttiuslieder* (1848, 33rd ed., 1901), lyrics which both in content and in poetic form showed a great advance on his early work. A volume of *Neue Gedichte* (Munich 1857) mainly on classical subjects, was followed by the *Spätherbstblätter* (1877). His later years were spent in Liibeck, where he died on April 6, 1884. His works further include two tragedies, *Brunhild* (1858, 5th ed., 1890), and *Sophonisbe* (1869), and translations of French and Spanish popular poetry. Beginning as a member of the group of political poets who heralded the revolution of 1848, Geibel became gradually conservative. He was the chief poet to welcome the establishment of the empire in 1871 and was one of the early singers of German imperialism. His strength lay not, however, in his political songs but in his purely lyric poetry, such as the fine cycle *Ada* and his still popular love-songs.

Geibel's *Gesammelte Werke* were published in 8 vols. (1883, 4th ed. 1906); his *Gedichte* have gone through about 130 editions. An excellent selection in one volume appeared in 1904. *See* also K. Goedeke, E. *Geibel* (1869); C. C. T. Litzmann, E. *Geibel, aus Erinnerungen, Briefen und Tagebüchern* (1887), and biographies by C. Leimbach (2nd ed., 1894), K. T. Gaedertz (1897) and Kohut (1915). *See* further F. *E. A.* Geibel, *Der Briefwechsel von E. Geibel und P. Heyse* (1922).

GEIGE, in modern German the violin; in mediaeval German the name applied to the first stringed instruments played with a bow, in contradistinction to those whose strings were plucked by fingers or plectrum such as the cithara, rotta, and fidula.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

AN ITALIAN TENOR GEIGE OF THE 16TH CENTURY

GEIGER, ABRAHAM (1810–1874), Jewish theologian and orientalist, was born at Frankfort-on-Main on May 24, 1810, and educated at the universities of Heidelberg and Bonn. In 1832 he went to Wiesbaden as rabbi of the synagogue, and in 1835 helped to found the *Zeitschrift für jüdische Theologie* (1835–39 and 1842–47). From 1838 to 1863 he lived in Breslau, where he organized the reform movement in Judaism and wrote some of his most important works, including *Lehr- und Lesebuch zur Sprache der Mischna* (1845), *Studien* from Maimonides (1850), translation into German of the poems of Juda ha-Levi (1851), and *Urschrift und Übersetzungen der Bibel in ihrer Abhängigkeit von der innern Entwickelung des Judentums* (1857). In 1863 Geiger became head of the synagogue of Frankfort, and in 1870 he removed to Berlin, where, in addition to his duties as chief rabbi, he took the principal charge of the newly established seminary for Jewish science. His later works included a history of Judaism, *Das Judentum und seine Geschichte* (1865–71). He died on Oct. 23, 1874.

See J. Derenbourg in *Jud. Zeitschrift,* xi. 299–308; *E.* Schrieber, *Abraham Geiger als Reformator des Judentums* (1880), art. (with portrait) in *Jewish Encyclopaedia.*

GEIGER, WILHELM (1856–), German scholar, was born in Nuremberg on July 21, 1856. He became professor at Erlangen in 1891, and was professor of Indian and Iranian philology at Munich from 1920 to 1924. He edited the *Zeitschrift fur Buddhismus* and prepared, with E. Kuhn, *Grundriss der Iranischen Philologie* (4 vols., 1895–1904). Other works are: *Handbuch der Avestasprache* (1879); *Ostiranische Kultur im Alterturn* (1882) ; *Ceylon, Tagebuckblatter und Reiseerinnerungen* (1898); *Litteratur und Sprache der Singhalesen* (1900); *Dipavamsa und Mahavamsa und die Entwicklung der geschichtlichen Ueberlieferung in Ceylon* (edited 1905); *Pãli, Litteratur und Sprache* (1916); *Pãli Dhamma* (1921); *Elementarbuch des Sanskrit* (3rd ed., 1923); and a translation of *Samyutta Nikaya* (Eng. trans, 1924).

GEIJER, ERIK GUSTAF (1783–1847), Swedish historian and poet, was born at Ransater in Varmland, on Jan. 12, 1783. He was educated at the University of Uppsala, and, after a short period of teaching in the university, entered the public record office at Stockholm. There, with some friends, he founded the "Gothic Society," to whose organ *Iduna* he contributed a number of prose essays and of songs, which he set to music. About the same time he issued a volume of hymns, of which several are inserted in the Swedish Psalter.

Geijer became assistant to Erik M. Fant, professor of history at Uppsala, and succeeded him in 1817. In 1824 he was elected a member of the Swedish Academy. A single volume of a great projected work, *Svea Rikes Hafder,* a masterly critical examination of the sources of Sweden's legendary history, appeared in 1825. His *Svenska folkets historia* (3 vols., 1832–36; Eng. trans. by J. H. Turner, 1845), a clear view of the political and social development of Sweden down to 1654. The acute critical insight, just thought, and finished historical art of these incomplete works of Geijer entitle him to a high place among Swedish historians. His chief other historical and political writings are his *Teckning af Sveriges tillstånd 1718–1772* (1838), and *Feodalism och republikanism, ett bidrag till Samhällsförfattningens historia* (1844). Geijer also edited, with the aid of J. H. Schroder, a continuation of Fant's *Scriptores rerum svecicarum medii aevi* (1818–28), and, by himself, Thomas Thorild's *Samlade skrifter* (1819–25), and *Konung Gustaf III.'s efterlemnade Papper* (4 vols., 1843–46). Failing health forced Geijer to resign his chair in 1846, after which he removed to Stockholm for the purpose of completing his *Svenska folkets historia,* and died there on April 23, 1847. His *Samlade skrifter* (13 vols., 1849–55; new ed., 1873–77) include a large number of philosophical and political essays contributed to reviews. His poems were collected and published as *Skaldestycken* (Uppsala, 1835 and 1878).

For Geijer's biography, *see* his own *Minnen* (1834), which contains copious extracts from his letters and diaries; B. E. Malmstrom, *Minnestal öfver E. G. Geijer,* addressed to the Uppsala students (June 6, 1848), and printed among his *Tal och esthetiska afhandlingar* (1868), and *Grunddragen af Svenska vitterhetens hafder* (1866–68); and S *A.* Hollander, *Minne af* E. *G. Geijer* (Orebro, 1869). *See* also lives of Geijer by J. Hellstenius (1876), J. Niekson (Odense, 1902) and J. Landquist (1924).

GEIKIE, SIR ARCHIBALD (1835–1924), Scottish geologist, was born at Edinburgh on Dec. 28, 1835. He was educated at the high school and university of Edinburgh, and in 1855 was appointed an assistant on the Geological survey. His ability at once attracted the notice of his chief, Sir Roderick Murchison, with whom some of his earliest work was done on the complicated regions of the Highland schists; the small geological map of Scotland published in 1862 was their joint work, and a larger map was issued by Geikie in 1892. In 1863 he published his essay "On the Phenomena of the Glacial Drift of Scotland" *(Trans. Geol. Soc. Glasgow)* in which the effects of ice action in that country were for the first time clearly and connectedly delineated. His *Scenery of Scotland* (1865; 3rd ed., 1901), was, he claimed, "the first attempt to elucidate in some detail the history of the topography of a country." In the same year he was elected F.R.S. At this time the Edinburgh school of geologists — prominent among them Sir Andrew Ramsay, with his *Physical Geology and Geography of Great Britain — were* maintaining the supreme importance of denudation in the configuration of land-surfaces. and particularly the erosion of valleys by the action of running water. Geikie's book, based on extensive personal knowledge of the country, was an able contribution to the doctrines of the Edinburgh school, of which he himself soon began to rank as one of the leaders.

In 1867, when a separate branch of the Geological Survey was established for Scotland, he was appointed director. He was the first holder (1871) of the Murchison professorship of geology and mineralogy at Edinburgh. These two appointments he held till 1881, when he succeeded Andrew Ramsay in the joint offices

of director-general of the Geological Survey of the United Kingdom and director of the museum of practical geology, London, from which he retired in February 1901. A feature of his tenure of office was the impetus given to microscopic petrography, a branch of geology to which he had devoted special study, by a splendid collection of sections of British rocks. Later he wrote two important and interesting Survey Memoirs, *The Geology of Central and Western Fife and Kinross* (1900), and *The Geology of Eastern Fife* (1902).

In 1871 Geikie brought before the Geological Society of London an outline of the Tertiary volcanic history of Britain. He travelled not only throughout Europe, but in western America to examine volcanic formations. While the canyons of the Colorado confirmed his long-standing views on erosion, the eruptive regions of Wyoming, Montana and Utah supplied him with valuable data in explanation of volcanic phenomena. The results of his further researches were given in his paper on "The History of Volcanic Action during the Tertiary Period in the British Isles," *Trans. Roy. Soc. Edin.* (1888). His mature views on volcanic geology were stated in his presidential addresses to the Geological Society in 1891 and 1892, and afterwards in his book, *The Ancient Volcanoes of Great Britain* (1897). Other results of his travels are collected in his *Geological Sketches* at *Home and Abroad* (1882).

Geikie was president of the British Association in 1892 and of the Royal Society in 1909; he received the Order of Merit in 1914. He died near Haslemere, Surrey, on Nov. 10, 1924. His experience as a field geologist resulted in an admirable text-hook, *Outlines of Field Geology* (5th ed. 1900). His *Text-Book* (1882, 4th ed. 1903), and *Class-Book* of geology are standard works.

His other works include *Memoir of Edward Forbes* (with G. Wilson), and memoirs of his old chiefs Sir R. I. Murchison (1875) and Sir Andrew Crombie Ramsay (1895); *Founders of Geology* (lectures at Hopkins University 1897); *Geological Map of England and Wales, with Descriptive Notes* (1897); *Types of Scenery and their Influence on Literature* (Romanes lectures, 1898); *The Teaching of Geography* (1887); *Scottish Reminiscences* (1904); and *Landscape in History and other Essays* (1905).

GEIKIE, JAMES (1839–1915), Scottish geologist, younger brother of Sir Archibald Geikie, was born at Edinburgh on Aug. 23, 1839. He was educated at the high school and university of Edinburgh. He served on the Geological Survey from 1861 until 1882, when he succeeded his brother as Murchison professor of geology and mineralogy at the university of Edinburgh. He investigated the origin of surface-features, and the part played in their formation by glacial action. His views are embodied in his chief work, *The Great Ice Age and its Relation to the Antiquity of Man* (1874; 3rd ed., 1894). He was elected F.R.S. in 1875. He died in Edinburgh on March 1, 1915. James Geikie became the leader of the school that upholds the all-important action of land-ice, as against those geologists who assign chief importance to the work of pack-ice and icebergs. Continuing this line of investigation in his *Prehistoric Europe* (1881), he maintained the hypothesis of five inter-Glacial periods in Great Britain, and argued that the palaeolithic deposits of the Pleistocene period were not post- but inter- or pre-Glacial.

His works include: *Outlines of Geology* (1886; 3rd ed. 1896); and *Structural and Field Geology* (1905).

GEILER (or **GEYLER), VON KAISERSBERG, JOHANN** (1445–1510), "the German Savonarola," was born at Schaffhausen on March 16, 1445, but in 1448 went to liye at Kaisersberg in Upper Alsace. He studied at Freiburg university where he afterwards lectured until 1478 when he accepted a call to the cathedral of Strasbourg. There his sermons—bold, incisive, denunciatory, abounding in quaint illustrations and based on texts by no means confined to the Bible—won for him a well deserved fame. Geiler died at Strasbourg on March 10, 1510.

The genuineness of the numerous works ascribed to Geiler has been investigated by E. Martin in the *Allgemeine deutsche Biographie. See* also *F.* W. von Ammon, *Geyler's Leben, Lehren und Predigten* (1826); *L.* Dacheux, *Un Réformateur catholique à la fin du XV^e siècle,* J. G. *de* K. (1876); R. Cruel, *Gesch. der deutschen Predigt.* (1879); *P.* de Lorenzi, *Geiler's ausgewahlte Schriften* (4 vols., 1881); T. M. Lindsay, *History of the Reformation,* i. (1906); and Herzog-Hauck, *Real-encyklopädie,* vi.

GEISHA, the name of the professional dancing and singing girls of Japan (a Sino-Japanese word meaning "person of pleasing accomplishments"). The training of the true Geisha or singing girl, which includes lessons in dancing, begins often as early as her seventh year. Her apprenticeship over, she contracts with her employer for a number of years, and is seldom able to reach independence except by marriage. There is a capitation fee of two *yen* per month on the actual singing girls, and of one *yen* on the apprentices.

See Jukichi Inouye, *Sketches of Tokyo Life;* Sir Ian Hamilton, *Staff Officer's Scrapbook.*

GEISLINGEN, a town in the *Land* of Wiirttemberg, on the Thierbach, 38 mi. by rail E.S.E. of Stuttgart. Pop. (1939) 17,656. It has shops for the carving and turning of ivory and wood, besides iron-works, machinery factories, glass-works and brewing. The church of St. Mary contains fine wood-carving. Above the town lie the ruins of the castle of Helfenstein, which was destroyed in 1552. The town, which passed to Wiirttemberg in 1810, has chalybeate springs.

GEL, the name given by Graham (*q.v.*) to the coagulated precipitate from a *sol* or colloidal solution *(see* COLLOIDS).

GELA, a town of Sicily on the S. coast, province of Caltanisetta, 74 mi. by rail and 41 mi. direct E.S.E. of Girgenti. Pop. (1936) 31,918. The poorly built modern town stands on a sand-hill near the sea, with a fertile plain (the ancient *Campi Geloi)* to the north of it. It has only an open roadstead. Outside it on the east are scanty remains of a Doric temple (480–440 B.C.?) which was still standing in the 18th century, of which a single pillar only remains (height about 26½ ft., lower diameter 5⅔ ft.). Between it and the modern town the stylobate of a large and earlier temple was found. This seems to have been constructed towards the end of the 7th century B.C. on the site of a still earlier edifice. The stylobate measures 115 by 58 ft. A large number of decorative terracottas were found. Both buildings were probably dedicated successively to Athena. On the west of the town, on the Capo Soprano, was the ancient necropolis, where many tombs of the Greek period have been discovered.

The ancient city was founded by Cretan and Rhodian colonists in 691–690 B.C., and itself founded Acragas *(see* AGRIGENTUM) in 582 B.C. It also had a treasure-house at Olympia. The town took its name from the river to the east. The Rhodian settlers called it Lindioi *(see* LINDUS). Gela enjoyed its greatest prosperity under Hippocrates (492–485 B.C.), whose dominion extended over a considerable part of the island. Gelon seized the tyranny on his death, soon became master of Syracuse and transferred his capital thither with half the inhabitants of Gela, leaving his brother Hieron to rule over the rest. Its prosperity returned, however, after the expulsion of Thrasybulus in 466 B.C., but in 405 it was abandoned by Dionysius' order *(see* SYRACUSE). The inhabitants returned and rebuilt the town but it was only refortified in the time of Timoleon. In 311 B.C. Agathocles put to death over 4,000 of its inhabitants; and finally, after its destruction by the Mamertines about 281 B.C., Phintias of Agrigentum transferred the remainder to the new town of Phintias (now Licata, *q.v.*). In Roman times they still kept the name of Gelenses or Geloi in their new abode. The modern town was formerly known as Terranova di Sicilia. It was heavily bombed by the Allies in World War II.

Remains of a temple of Athena of the 6th cent. B.C. with five terracottas have been found; also scanty remains of another, a century later (perhaps that of Apollo). (T. A.)

See the monograph by Orsi, *Monumenti dei Lincei, xvii.* (1906); *Notizie degli Scavi,* 1907, Pareti in *Romische Mitteilungen,* 1910.

GELADA, a large species of baboon, *Theropithecus gelada,* differing from the members of the genus *Papio (see* BABOON) by the nostrils being situated some distance from the tip of the muzzle. In the heavy mantle of long brown hair covering the fore-quarters of the old males, with the exception of the bare chest, which is reddish flesh-colour, the gelada recalls the Arabian baboon *(Papio hamadryas).* The gelada inhabits the mountains of Abyssinia, where it descends in droves to pillage cultivated lands. A second species, *T. obscurus,* inhabits eastern Abyssinia.

GELASIUS, the name of two popes.

GELASIUS I., pope from 492 to 496, was the successor of Felix III. He confirmed the estrangement between the Eastern and Western churches by insisting on the removal of the name of Acacius, bishop of Constantinople, from the diptychs. He is the author of *De duabus in Christo naturis adversus Eutychen et Nestorium.* A great number of his letters has also come down to us. His name has been attached to a *Liber Sacramentorum* anterior to that of St. Gregory, but he can have composed only certain parts of it. As to the so-called *Decretum Gelasii de libris recipiendis et non recipiendis,* it also is a compilation of documents anterior to Gelasius, and it is difficult to determine Gelasius's contributions to it. At all events, as we know it, it is of Roman origin, and 6th-century or later. (L. D.)

GELASIUS II. (Giovanni Coniulo), pope from Jan. 24, 1118, to Jan. 29, 1119, was born at Gaeta of an illustrious family. He became a monk of Monte Cassino, was taken to Rome by Urban II., and made chancellor and cardinal-deacon of Sta. Maria in Cosmedin. Shortly after his unanimous election to succeed Paschal II. he was seized by Cencius Frangipane, a partisan of the emperor Henry V., but freed by a general uprising of the Romans in his behalf. The emperor drove Gelasius from Rome in March, pronounced his election null and void, and set up Burdinus, archbishop of Braga, as antipope under the name of Gregory VIII Gelasius fled to Gaeta, where he was ordained priest on March 9, and on the following day received episcopal consecration. He at once excommunicated Henry and the antipope and, under Norman protection, was able to return to Rome in July; but the disturbances of the imperialist party, especially of the Frangipani, who attacked the pope while celebrating mass in the church of St. Prassede, compelled Gelasius to go once more into exile. He set out for France, consecrating the cathedral of Pisa on the way, and arrived at Marseilles in October. He was received with great enthusiasm at Avignon, Montpellier and other cities, held a synod at Vienne in Jan., 1119, and was planning to hold a general council to settle the investiture contest when he died at Cluny. His successor was Calixtus II.

His letters are in J. P. Migne, *Patrol. Lat.* vol. 163. The original life by Pandulf is in J. M. Watterich, *Pontif. Roman. vitae* (Leipzig, 1862), and there is an important digest of his bulls and official acts in Jaffé-Wattenbach, *Regesta pontif. Roman.* (1885–88).

See J. Langen, *Geschichte der römischen Kirche von Gregor VII. bis Innocenz III.* (Bonn, 1893); F. Gregorovius, *Rome in the Middle Ages,* vol. 4, trans. by Mrs. G. W. Hamilton (1896); A. Wagner, *Die unteritalischen Normannen und das Papsttum, 1086–1150* (Breslau, 1885); W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit,* Bd. iii. (Brunswick, 1890); G. Richter, *Annalen der deutschen Geschichte im Mittelalter,* iii. (Halle, 1898); H. H. Milman, *Latin Christianity,* vol. 4 (1899). (C. H. H.)

GELATI, a village in the Georgian S.S.R., 11 m. east of the town of Kutais, on a rocky spur 705 ft. above sea level in the valley of the Rion, which is growing in importance because of coal mines. It was an ancient monastery and its principal church, a sandstone cathedral, dates from the end of the eleventh century, and contains the royal crown of the former Georgian kingdom of Imeretia, besides ancient mss., ecclesiological furniture, and fresco portraits of the kings of Imeretia.

GELATIN, a familiar protein (*q.v.*); it is derived from substances in the supporting structures of vertebrate animals by boiling with water or dilute acids. These precursors are known as "collagens," and belong to the class of proteins called "Scleroproteins" or "Albuminoids." They are characteristically deposited in long fibres in the tendons, cartilages, bones, skin and white connective tissue, for the purpose of supporting and padding the tissue. They are insoluble in water or salt solution, hot or cold, and swell in dilute acids and alkalis, but do not appear to dissolve. If hydrolysed gently by boiling in water, by means of high-pressure steam or by boiling with dilute acids, the collagen is converted to gelatin, some of which is further hydrolysed to products intermediate between gelatin and the amino-acids. It is probable that the conversion of collagen to gelatin is not merely an hydration, since ammonia is evolved on heating collagen with water, but not on boiling gelatin.

?reparation. — Gelatin occurs in commerce in varying degrees of purity; the purer form obtained from skins and bones (to which this article is restricted) is named gelatin; a preparation of great purity is "patent isinglass," while isinglass (*q.v.*) itself is a fish-gelatin; less pure forms constitute glue (*q.v.*), and an aqueous solution appears in commerce as size.

In the manufacture of gelatin the bones are degreased and steeped in dilute hydrochloric acid to remove the mineral matter, which together with the acid is removed by repeated washings with water. The product is known as osseine. Skin gelatin is limed to remove the albuminous and mucinous constituents. This process has to be carefully controlled to minimize bacterial decomposition. This is done by frequently turning the stock and also by replacing the liquor with fresh milk of lime. The stock is then thoroughly washed with water to remove the lime, and subsequently treated with dilute hydrochloric or sulphurous acid to cause the maximum swelling; the latter acid is often used for its bleaching properties though seldom for food or photographic gelatin. Sulphites are subsequently removed (in the preparation of edible gelatin) by oxidation to sulphates by means of hydrogen peroxide. The hydrochloric acid used must be free from iron, which has an effect on the colour of the final product, and from arsenic.

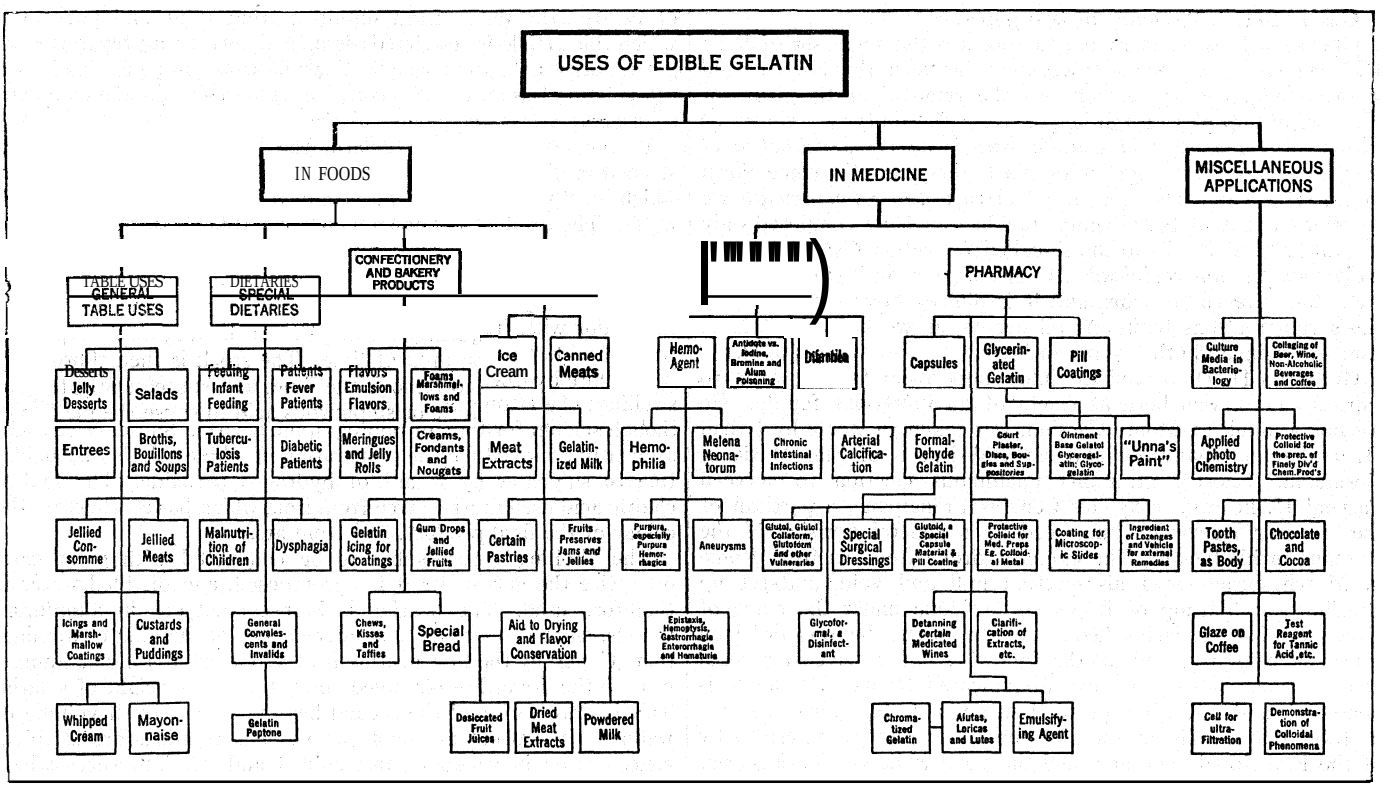
The "boiling' process has to be conducted with great care, otherwise the gelatin itself is decomposed, and distilled water is therefore used. The heating is best carried out in aluminium vessels, since copper and zinc offer danger of metallic contamination. Generally the first heating is at about 60° C for some hours, or until the liquor has dissolved about 5% of its weight of gelatin This is drawn off and the second heating with a fresh volume of water is carried out at about 70° C. The runnings are clarified, concentrated in vacuum pans, chilled and cut into slices which are dried by hot air. The dried sheets can be further purified by soaking in dilute hydrochloric acid, to convert insoluble calcium phosphate to soluble calcium chloride, and then dialysing against a stream of distilled water till free from chlorides. Methods designed to produce a specially pure product for scientific work are described by S. B. Schryver (1923–27).

The percentage composition of pure gelatin is very similar to that of the other proteins (*q.v.*). On the whole the nitrogen is rather higher (18%), and the sulphur very low (0·2% to 0·6%). The amino-acids obtained by complete hydrolysis are characterized by the high amounts of glycine, proline, oxyproline and the absence of tryptophane and tyrosine.

Properties. — Gelatin is a nearly colourless, transparent, amorphous substance, flexible and horny when in the normal dry condition, in which state, however, it retains about 17% of water. It swells to many times its normal volume when immersed in cold water, dilute alkalis and salt solutions. The amount of swelling depends on the acidity, being least at the isoelectric point which is about p_H 4.7. (*See* HYDROGEN-ION CONCENTRATION.) The swelling increases on either side of this reaction, reaching a maximum at about p_H 2.6 and then decreasing to p_H 1·1. In solutions more acid than this the gelatin passes into solution. On the alkaline side the swelling increases to about p_H 9.8 and then decreases slightly. In solutions more alkaline than p_H 11·6 the gelatin dissolves. The swelling at maximum acidity is about double that at maximum alkalinity. Inorganic salts generally depress the swelling, the percentage reduction being greater with increasing strength of salt.

A slight contraction of total volume accompanies swelling, and also a liberation of heat. From this it follows that low temperatures favour the absorption of water by gelatin, whilst high temperatures favour the drying-out process. When the swollen gelatin is heated to 35° C it goes into solution. If this solution contains more than 1% of gelatin it sets to a firm jelly when allowed to stand at 10° C. This is the most characteristic and important property of gelatin, and on this depends its great use as an adhesive, in the form of glue.

Gelatin is insoluble in the usual organic solvents, such as ether, chloroform, benzene, and absolute alcohol. The amount of alcohol required to precipitate gelatin from aqueous solution depends on the hydrogen ion concentration of the fluid and the temperature. It is most readily precipitated at the isoelectric point. Gelatin is completely precipitated from aqueous solution by the addition of



BY COURTESY OF THE MELLON INSTITUTE OF UNIVERSITY OF PITTSBURGH

GRAPH SHOWING THE USES OF EDIBLE GELATIN

an equal volume of an aqueous saturated solution of ammonium sulphate. Potassium dichromate reacts with gelatin in the presence of light to produce a jelly which, on drying out, is insoluble. This property is made use of in photography and photo-lithography. Formaldehyde produces an insoluble condensation product with gelatin.

Gelatin, like all other proteins and amino-acids, is an amphoteric substance, acting as a weak base in solutions more acid than the isoelectric point, and as a weak acid in solutions more alkaline. Thus it will form gelatine chloride when treated with dilute hydrochloric acid. This is more soluble and more ionized than gelatin itself. Also these acid salts carry a positive electric charge. In solutions made alkaline to the isoelectric point by the addition of caustic soda or milk of lime, sodium or calcium gelatinates are formed, which are more soluble than gelatin and carry a negative electric charge. It has been shown that at the isoelectric point, osmotic pressure, electrical conductivity and the lowering of the surface tension are at a minimum; whereas the viscosity, turbidity and precipitability by alcohol are at a maximum.

Observations on the specific rotatory power of gelatin solutions at various temperatures by C. R. Smith (1919) have led him to the view that there are at least two substances in gelatin or two forms of the same substance. One, "sol form A," is stable at 35° C and above; the other, the "gel form B," is stable at 15° and below. Apparently 0·55 to 1·0% of the gel form B must be present for gelation to occur; below 15°, the gelatin being all in this form, a 0·55% solution will set. At 30°, at least 10 grams of gelatin must be present in 100 c c. in order that there may be 0·55–1·0 gram of the gel form present. Above 35° all the gelatin is in the sol state and gelation does not occur at any concentration.

Schryver and his colleagues have described experiments on purified gelatin which also indicate that at least two substances are present; previous to this a great deal of work was done by Field, Sheppard and Smith. They find further that on heating gelatin with water intramolecular changes take place which result in a profound modification of the physical properties, but which are not accompanied by the degradation into lower products as with commercial gelatin It would seem, therefore, that gelatin behaves as a mixture of substances which may undergo reversible changes on heating and cooling, and also irreversible changes on prolonged heating in water.

Uses of Gelatin. — As a food, in jellies and soups, it has considerable value, being readily digested and absorbed; but owing to the lack of certain essential amino-acids it can only partially replace other proteins in the diet. As an emulsoid colloid, it has a protective action, inhibiting the precipitation of salts and the flocculation of other colloids. For this reason it is sometimes added to cow's milk when used for infant feeding, to inhibit the formation of large curds of casein in the stomach. It is also extensively used in the manufacture of ice-cream, to prevent the formation of large ice crystals, to maintain the permanency of the emulsion of milk and to give "body" to the material. As an emulsifying agent it is used in the confectionery trade, in the preparation of such sweets as "marsh mallows." For the same reason it is employed in making spraying emulsions of insecticides and fungicides. Pure gelatin is used extensively in the preparation of photographic plates, films and papers, for obtaining the precipitated silver salts in an extremely fine-grained suspension. In pharmaceutical preparations it is used for coating pills and making capsules. It is also used for making culture media for bacteriological work. A new use for gelatin that is rapidly assuming importance is the adding of one quarter of 1% in cultural buttermilk to prevent wheying off, *i.e.*, the separation of the casein from the liquid.

See R. H. Bogue, *The Chemistry and Technology of Gelatin and Glue* (1922). (S. W. C.)

GELDERLAND (*Guelders*), a province of Holland, bounded S. by Rhenish Prussia and North Brabant, W. by Utrecht and South Holland, N. by the Zuider Zee, N.E. by Overysel and S.E. by the Prussian province of Westphalia. It has an area of 1,940 sq.mi. and a pop. **(1938)** of 914,207, the density per sq.mi. being 411. The province was occupied by Germany in May 1940.

The main portion of Gelderland north of the Rhine and the Old Ysel forms an extension of the province of Overysel and is composed of diluvial sand and gravel, covered with heaths and patches of fen. South of this line, however, the soil consists of fertile river-clay. The northern portion is divided by the New (or Gelders) Ysel into two distinct regions, namely, the Veluwe

("bad land") on the west, and the former countship of Zutphen on the east. In this last division the ground slopes downward from southeast to northwest (131 to 26 ft.) and is intersected by several fertilizing streams which flow in the same direction to join the Ysel. The extreme eastern corner is occupied by older Tertiary loam, which is used for making bricks, and upon this and the river banks are the most fertile spots, woods, cultivated land, pastures, towns and villages. The highlands of the Veluwe lying west of the Ysel really extend as far as the Crooked Rhine and the Vecht in the province of Utrecht, but are slightly detached from the Utrecht hills by the Gelders depression, which forms the boundary between the two provinces. This extends from the Rhine along the Grift, the Luntersche Beek and the Eem to the Zuider Zee, and would still offer an outlet in this direction to the Rhine at high water if it were not for the river dikes. The two main ridges of the Veluwe hills (164 and 360 ft.) extend from the neighbourhood of Arnhem northwest to Harderwyk and north to Hattem. In the south they stretch along the banks of the Rhine, forming a strip made up of sandhills and trees, claylands and pastures. All over the Veluwe are heaths, scantily cultivated, with fields of rye and buckwheat, cattle of inferior quality and sheep, and a sparse population. There is also a considerable cultivation of wood, especially of fir and copse, while tobacco plantations are found at Nykerk.

The southern division of the province is watered by three large rivers, the Rhine, the Waal and the Maas, and has a level clay soil, varied only by isolated hills and a sandy, wooded stretch between Nijmegen and the southern border. The region enclosed between the Rhine and the Waal and watered by the Linge is called the Betuwe ("good land") and gave its name to the Germanic tribe of Batavians. There is here a denser population, occupied in the cultivation of wheat, beetroot and fruit, the breeding of excellent cattle, shipping and industrial pursuits. The principal centres of population, such as Zutphen, Arnhem (the chief town of the province), Nijmegen and Tiel, as well as smaller old towns, lie along the rivers. (X.)

History. — It was formerly a duchy of the empire, bounded by Friesland, Westphalia, Brabant, Holland and the Zuider Zee, part of which has become the province of Holland. The territory of the later duchy of Gelder formed part of the Frankish kingdom of Austrasia. In 843, by the treaty of Verdun, it became part of Lotharingia (Lorraine), and in 879 was annexed to the kingdom of East Francia by the treaty of Mersen. The nucleus of the later county and duchy was the district surrounding the town of Gelder or Gelre, lying between the Meuse and the Niers, and after 1715 included in Rhenish Prussia.

There were in the 11th century a number of counts ruling in various parts of what was afterward known as Gelderland. Toward the close of that century Gerard of Wassenburg acquired a dominant position and is generally reckoned as the first hereditary count of Gelder (d. 1117–18). His son, Gerard II (d. 1131), married Irmingardis, daughter and heiress of Otto, count of Zutphen, and their son, Henry I (d. 1182), inherited both countships. His successors, Otto I (1182–1207) and Gerard III (1207–29), were lovers of peace and strong supporters of the Hohenstaufen emperors, through whose favour they were able to increase their territories by acquisitions in the districts of Veluwe and Betuwe. Otto II (1229–71) became a person of so much importance that he was urged to be a candidate for the dignity of emperor, but he preferred to support the claims of his cousin, William II of Holland. In return for the loan of a considerable sum of money William gave to him the city of Nijmegen in pledge. His son Reinald I (d. 1326) married Irmingardis, heiress of Limburg, and in right of his wife laid claim to the duchy against Adolf of Berg, who had sold his rights to John I of Brabant. War followed, and on June 5, 1288, Reinald was defeated and taken prisoner at the battle of Woeringen and surrendered his claims to John of Brabant. In 1310, Reinald received from the emperor Henry VII the exemption of his subjects from the liability to be sued before any court outside his jurisdiction, and in 1317 he was made a prince of the empire.

Reinald II., his son (1326–43), was one of the foremost princes in the Netherlands of his day. He married (1) Sophia, heiress of Mechlin, and (2) in 1331 Eleanor, sister of Edward III of England. By purchase or conquest he added considerably to his territories. He did much to improve the condition of the country, to foster trade, to promote the prosperity of the towns and to maintain order and security in his lands by wise laws and firm administration. In 1338 the title of duke was bestowed upon him by the emperor Louis the Bavarian, who at the same time granted to him the fief of East Friesland. He died in 1343, leaving three daughters by his first marriage, and two sons, Reinald and Edward, by Eleanor of England. His elder son was ten years of age and succeeded to the duchy under the guardianship of his mother, Eleanor. Declared of age two years later, Reinald III found himself involved in a struggle between two rival factions which ended only after his death in 1374, with the recognition as duke of his nephew William of Julich, son of his younger sister, Maria.

Duke William was able, restless and adventurous. He took part in no less than five crusades with the Teutonic order against the heathen Lithuanians and Prussians. In 1393 he inherited the duchy of Jiilich and died in 1402. He was succeeded by his brother, Reinald IV (d. 1423), in the united sovereignty of Gelder, Zutphen and Jiilich. On his death Gelder passed to the young Arnold of Egmont, grandson of his sister Johanna. whose daughter Maria (d. 1415) was wife of John, count of Egmont (d. 1451). Arnold was recognized as duke in 1424 by the emperor Sigismund, but in the following year the emperor revoked his decision and bestowed the duchy upon Adolf of Berg. Arnold in retaliation laid claim to the duchy of Jiilich, which had likewise been granted to Adolf by Sigismund, and a war followed which ended in Arnold's retaining Gelder and Zutphen, and Gerard, the son of Adolf (d. 1437), being acknowledged as duke of Jiilich. To gain the support of the estates of Gelder in this war, Arnold had made many concessions limiting the ducal prerogatives and granting large powers to a council consisting of representatives of the nobles and the four chief cities; his extravagance and exactions led to continual conflicts, and in his later years a conspiracy was formed against him, headed by his wife and his son Adolf, which gave an opportunity of intervention to Charles the Bold of Burgundy. For 92,000 golden gulden, Arnold sold the reversion of the duchy to Charles (1471). On Feb. 23, 1473, Arnold died and Charles became duke of Gelder. His succession was not unopposed. Nijmegen offered an heroic resistance and only fell after a long siege. After Charles's death in 1477 Adolf was released from the captivity in which he had been held and placed himself at the head of a party in the powerful city of Ghent, which sought to settle the disputed succession by forcing a match between him and Mary, the heiress of Burgundy. On June 29, 1477, however, he was killed at the siege of Tournai; and Mary gave her hand to the archduke Maximilian. Catherine, Adolf's sister, made an attempt to assert the rights of his son, Charles, but by 1483 Maximilian had crushed all opposition and established himself as duke of Gelder.

Charles of Egmont, however, did not surrender his claims, but with the aid of the French collected an army, and in the course of 1492 and 1493 succeeded in reconquering his inheritance. In 1507 he invaded Holland and Brabant, captured Harderwijk and Bommel in 1511, threatened Amsterdam in 1512 and took Groningen. It was undoubtedly a great and heroic achievement for the ruler of a petty state like Gelder thus to assert and maintain his independence against the overwhelming power of the house of Austria. It was not till 1528 that the emperor Charles V could force him to accept the compromise of the treaty of Gorinchem, by which he received Gelder and Zutphen for life as fiefs of the empire. In 1534 the duke, who was childless, attempted to transfer the reversion of Gelder to France, but was compelled by the estates in 1538 to appoint as his successor William V of Cleves (d. 1592). Charles died the same year. William, with the aid of the French, succeeded in maintaining his position in Gelder for several years, but was forced to cede the duchy to Charles V by the treaty of Venlo (Sept. 7, 1543).

Gelder was now definitely amalgamated with the Habsburg dominions in the Netherlands, until the revolt of the Low Countries led to its partition. In 1579 the northern and greater part, comprising the three "quarters" of Nijmegen, Arnhem and Zutphen, joined the Union of Utrecht and became the province of Gelderland in the Dutch republic. Only the quarter of Roermond remained subject to the crown of Spain, and was called Spanish Gelderland. By the treaty of Utrecht (1715) this was ceded to Prussia with the exception of Venlo, which fell to the United Provinces, and Roermond, which with the remaining Spanish Netherlands passed to Austria. Of this, part was ceded to France at the peace of Basle in 1795, and the whole by the treaty of Lunéville in 1801, when it received the name of the department of the Roer. By the peace of Paris of 1814 the bulk of Gelderland was incorporated in the United Netherlands, the remainder falling to Prussia, where it forms the circle of Diisseldorf.

The rise of the towns in Gelderland began in the 13th century, river commerce and markets being the chief cause of their prosperity, but they never attained to the importance of the larger cities in Holland and Utrecht, much less to that of the great Flemish municipalities. They differed also from the Flemish cities in the nature of their privileges and immunities, since they did not possess the rights of communes but only those of "free cities" of the Rhenish type. The power of the feudal lord over them was much greater. The states of Gelder first became a considerable power in the land during the reign of Arnold of Egmont (1423–73). From this time the absolute authority of the sovereign in Gelder was broken. The states consisted of two members — the nobility and the towns. The towns were divided into four separate districts or "quarters" named after the chief town in each — Nijmegen, Arnhem, Zutphen and Roermond. Each quarter had peculiar rights and customs, and their representatives met together in a separate assembly before taking part in the diet of the states. The nobility possessed great influence in Gelder and retained it in the time of the republic. (G. E.; X.)

GELDERN, a town in Rhenish Prussia, on the Niers, 28 mi. N.W. of Diisseldorf, at the junction of railways to Wesel and Cologne. Pop. (1933) 7,006. The town dates from about 1100 and was an important fortified place; until 1371 it was the residence of the counts and dukes of Gelder. Its fortifications were strengthened by Philip II. of Spain but they were razed by Frederick the Great, the town having been in the possession of Prussia since 1703. Its industries include the manufacture of metal ware, shoes, cigars and silk.

GELIMER or **GEILAMIR** (*fl.* 530–534), last king of the Vandals in Africa, a great grandson of Gaiseric, succeeded when Hilderic was deposed in 530. Justinian invited him to allow the old king to remain sovereign in name and to content himself with the actual power; he was in reality desirous of an excuse for interference in Africa. In 533 he sent against him a great expedition under Belisarius (*q.v.*). Gelimer was completely defeated, and in 534 taken prisoner. He was then permitted to settle in Galatia.

GELLERT, CHRISTIAN FÜRCHTEGOTT (1715–1769), German poet, born at Hainichen, Saxony, on July 4, 1715, the son of a pastor, studied at Leipzig, became privatdocent there in 1745 and in 1751 extraordinary professor. He died at Leipzig on Dec. 13, 1769 Gellert's lovable personality endeared him to a wide circle of friends and readers His best work is to be found in the admirable *Fabeln und Erzählungen* (1746–48), for which he took La Fontaine as his model. His *Geistliche Oden und Lieder* (1757), though in force and dignity they cannot compare with the older church hymns, were among the great religious poems of their time. Some of them were set to music by Beethoven. Gellert wrote a few comedies: *Die Betschwester* (1745), *Dze kranke Frau* (1748), *Das Los in der Lotterie* (1748) and *Die zärtlichen Schwestern* (1748)

See Gellert's *Sämtliche Schriften* (first edition, 10 vols., 1769–74; last edition, 1867) *Sämtliche Fabeln und Erzählungen* have been repeatedly reprinted. A selection of Gellert's poetry (with an excellent introduction) will be found in F Muncker, *Die Bremer Beiträge* (Stuttgart, 1899). A translation by J. A. Murke, *Gellert's Fables and other Poems* (1851). For a further account of Gellert's life and work *see* lives by J. A. Cramer (Leipzig, 1744), H. Döring (Greiz, 1833), and H. O. Nietschmahn (2nd ed., Halle, 1901); also *Gellerts Tagebuch aus dem Jahre 1761* (2nd ed., Leipzig, 1863) and *Gellerts Briefwechsel mit Demoiselle Lucius* (Leipzig, 1823).

GELLERT or **KILLHART,** in Welsh traditional history, the dog of Llewellyn, prince of Wales. The dog, a greyhound, is left to guard the cradle in which the infant heir sleeps. A wolf enters and is about to attack the child, when Gellert flies at him. In the struggle the cradle is upset and the infant falls underneath. Gellert kills the wolf, but when Prince Llewellyn arrives and sees the empty cradle and blood all around, he thinks Gellert has killed the baby. He at once stabs him and then finds his son safe under the cradle and realizes the dog's bravery. Gellert is supposed to have been buried near the village of Beddgelert ("grave of Gellert"), Snowdon, where his tomb is pointed out to visitors. The date of the incident is traditionally given as 1205. The story is only the Welsh version of a common tale which is traced to the Indian Panchatantra and perhaps as far back as 200 B.C.

See W. A. Clouston, *Popular Tales and Fictions* (1887); *D. E.* Jenkins, *Beddgelert, Its Facts, Fairies and Folklore* (Portmadoc, 1899).

GELLIUS, AULUS (c. A.D. 130–180), Latin author and grammarian, probably born at Rome. He studied grammar and rhetoric at Rome and philosophy at Athens, after which he returned to Rome, where he held a judicial office. His teachers and friends included many distinguished men — Sulpicius Apollinaris, Herodes Atticus and Fronto. His only work, the *Noctes Atticae,* is compiled from a commonplace book, and comprises notes on grammar, geometry, philosophy, history and almost every other branch of knowledge. The work, of which all but one book is extant, is valuable for the insight it affords into the life of those times and for the numerous excerpts it contains from the works of lost ancient authors.

Editio princeps (Rome, 1469); the best editions are those of Gronovius (1706) and M. Hertz (1883–85; editio minor, 1886, revised by C. Hosius, 1903, with bibliography). There is a translation in English by W. Beloe (1795) and in French by various hands (1896). *See* Sandys, *Hist. Class. Schol.,* i. (1906), 210.

GELLIVARA [GÄLLIVARE], a mining town of Sweden in the district *(lan)* of Norrbotten, 815 mi. N. of Stockholm by rail. It lies in the well-nigh uninhabited region of Swedish Lapland, 43 mi. N. of the Arctic Circle. Population, 1,926. There are iron mines in the mountain Malmberget 4½ mi. to the north, rising to 2,024 ft. above sea-level (830 ft. above Gellivara town). During the dark winter months work proceeds by the aid of electric light. In 1864 the mines were opened but abandoned in 1867. They were reopened in 1884 and a provisional railway built from Malmberget to Luleå at the head of the Gulf of Bothnia (127 mi. S.S.E.). In 1891 the Swedish Government bought the railway. The output of ore was insignificant until 1892 but later increased considerably. *(See* KIRUNA.)

GELNHAUSEN, a town in the Prussian province of Hesse-Nassau, Germany, 27 mi. E.N.E. of Frankfort-on-Main, on the railway to Bebra. Pop. (1933) 4,838. Gelnhausen became an imperial town in 1169, and here diets of the Empire were frequently held. In 1803 the town became the property of Hesse-Cassel and in 1866 passed to Prussia. It is still surrounded by ancient walls and towers. On an island in the river are ruins of the palace built by Frederick I (Barbarossa) before 1170 and destroyed by the Swedes in the Thirty Years' War. The beautiful Marien Kirche, with four spires (of which that on the transept is curiously crooked), was built in the 13th century and restored in 1876–79; among other ancient buildings are the town hall, the Fiirstenhof (now administrative offices) and the Hexenthurm. India-rubber goods and brushes are manufactured.

GELON, son of Deinomenes, tyrant of Gela and Syracuse. On the death of Hippocrates, tyrant of Gela (491 B.C.), Gelon, who had been his commander of cavalry, succeeded him, and in 485, his aid having been invoked by the Gamori (the oligarchical landed proprietors) of Syracuse, who had been driven out by the populace, he seized the opportunity of making himself despot. From this time Gelon paid little attention to Gela and devoted himself to the aggrandizement of Syracuse, which attained extraordinary wealth and influence. When the Greeks solicited his aid

against Xerxes, he refused it, since they would not give him command of the allied forces (Herodotus vii. 171). In the same year the Carthaginians invaded Sicily, but were totally defeated at Himera, the result of the victory being that Gelon became lord of all Sicily. After he had thus established his power, he made a show of resigning it; but his proposal was rejected by the multitude, and he reigned without opposition till his death (478).

See Herodotus vii.; Diod. Sic. xi. 2—38; also SICILY: *History,* and SYRACUSE.

GELSEMIUM, a drug consisting of the root of *Gelsemium nitidum,* a clinging shrub of the natural order Loganiaceae, having a milky juice, opposite, lanceolate, shining leaves, and axillary clusters of from one to five large, funnel-shaped very fragrant yellow flowers. The fruit is composed of two separable jointed pods, containing numerous flat-winged seeds. The stem often runs underground for a considerable distance, and indiscriminately with the root it is used in medicine. The plant is a native of the United States, growing on rich clay soil by the side of streams near the coast, from Virginia to the south of Florida. In the United States it is commonly known as the wild, yellow, or Carolina jasmine, although in no way related to the true jasmine, which belong to the order Oleaceae. It was first described in 1640 by John Parkinson, who grew it in his garden from seed sent by Tradescant from Virginia; at the present time it is but rarely seen, even in botanical gardens, in Great Britain.

BY COURTESY OF THE ROYAL HORTICULTURAL SOCIETY
FLOWERING BRANCH OF THE CAROLINA JASMINE, A SHRUB WHOSE ROOT YIELDS A DRUG USED IN MEDICINE

The drug contains a volatile oil and two potent alkaloids, gelseminine and gelsemine. Gelseminine is a yellowish, bitter substance, readily soluble in ether and alcohol. It is not employed therapeutically. Gelsemine has the formula, $C_{11}H_{19}NO_2$, and is a colourless, odourless, intensely bitter solid, which is insoluble in water, but readily forms a soluble hydrochloride. The dose of this salt is from $\frac{1}{60}$th to $\frac{1}{20}$th of a grain. The British Pharmacopoeia contains a tincture of gelsemium, the dose of which is from five to 15 minims.

The drug is essentially a nerve poison. It has no action on the skin and no marked action on the alimentary or circulatory systems. Its action on the cerebrum is slight, consciousness being retained even after toxic doses, but there may be headache and giddiness. The drug rapidly causes failure of vision, diplopia, ptosis or falling of the upper eyelid, dilatation of the pupil, and a lowering of the intra-ocular tension. This last action is doubtful. The most marked action of the drug is upon the anterior cornua of grey matter in the spinal cord. It can be shown by a process of experimental exclusion that to an arrest of function of these cells is due the paralysis of all the voluntary muscles of the body that follows the administration of gelsemium or gelsemine. Just before death the sensory part of the spinal cord is also paralysed. general anaesthesia resulting. Shortly after the administration of even a moderate dose respiration is slowed and ultimately the drug kills by its action on the respiratory centre in the medulla oblongata. In cases of poisoning the essential treatment is artificial respiration, which may be aided by the subcutaneous exhibition of strychnine.

Though the drug is still widely used, the rational indications for its employment are singularly rare and uncertain. The conditions in which it is most frequently employed are convulsions, bronchitis, severe and purposeless coughing, myalgia or muscular pain, neuralgia, and various vague forms of pain.

GELSENKIRCHEN, a town of Germany in the Prussian province of Westphalia, 27 mi. W. of Dortmund on the railway Duisburg-Hamm. Pop. (1939) 313,003. It has coal mines, iron furnaces, tin, steel and boiler works, soap and chemical factories, oil plants and storage tanks, and was very heavily bombed by the British in World War II.

GEM, a word applied in a wide sense to certain minerals which, by reason of their brilliancy, hardness, and rarity, are valued for personal decoration; it is extended to include pearl (Lat. *gemma,* a bud—from the root gen, meaning "to produce"—or precious stone). In a restricted sense the term is applied only to precious stones after they have been cut and polished as jewels, whilst in their raw state the minerals are conveniently called "gem-stones." Sometimes, again, the term "gem" is used in a yet narrower sense, being restricted to engraved stones, like seals and cameos.

Confining attention here to the mineralogy and general properties of gems, it may be noted that the term "precious stone" is usually applied only to diamond, ruby, sapphire and emerald. Other stones, such as opal, topaz, spinel, aquamarine, chrysoberyl, peridot, zircon, tourmaline, amethysr and moonstone, are included in the group "semi-precious stones," but the particular species in it may vary from time to time with changes in fashions. In the trade, owing to the vastly superior hardness of diamond, dealers in diamonds are sharply distinguished from those in other stones, a firm practically never handling both sorts, and in consequence stones other than diamonds are grouped together and are known as "fancy stones."

Descriptions of the several gem-stones will be found under their respective headings, and the present article gives only a brief review of the general characters of the group.

Crystalline Form and Cleavage.—Most precious stones occur crystallized, but the characteristic form is destroyed in cutting. The crystal forms of the several stones are noticed under their respective headings, and the subject is discussed fully under CRYSTALLOGRAPHY. A few substances used as ornamental stones, like opal, are amorphous or without crystalline form; whilst others, like the various stones of the chalcedony group, display no obvious crystal characters, but are seen under the microscope to possess a crystalline structure. Gem-stones are frequently found in gravels or other detrital deposits, where they occur as rolled crystals or fragments of crystals, having survived owing to their superior density and hardness.

Many crystallized gem-stones possess the property of cleavage and tend to split parallel to planes intimately related to their atomic structure. This property must not be confused with the "parting" shown, for instance, by corundum which is the result of repeated twinning, the stones tending to split along the planes separating individuals. An easy cleavage, such as characterizes topaz, may render the fashioning of the stone difficult and produce incipient cracks in a cut stone; such flaws are called "feathers." The cutting of diamonds was very laborious until the discovery that the rough stone could easily be reduced by cleavage to an octahedron; owing to the use of high-speed cutting-discs in recent years, the practice of splitting diamonds has to some extent lessened. The method of cutting gem-stones is described under LAPIDARY.

Hardness.—A high degree of hardness is an essential property of a gem-stone, for however beautiful a mineral may be, it is useless to the jeweller unless it be hard enough to take a brilliant polish and to withstand the abrasion to which articles of personal adornment are necessarily subjected. Paste imitations may be brilliant when new, but they soon become dull through rubbing or even chemical change of the surface. Minerals are arranged on the following arbitrary scale of hardness, which is due to Mohs: diamond 10, corundum (ruby, sapphire) 9, topaz 8, quartz 7, felspar 6, apatite 5, fluor 4, calcite 3, gypsum 2, talc 1. It is merely an order and has no arithmetical significance; thus diamond differs much more from corundum than does the latter from talc. Chrysoberyl scratches topaz but is scratched by corundum, and is therefore said to have a degree of hardness $8\frac{1}{2}$. A steel file will scratch anything with hardness below 7. The test of hardness must be used

with caution in order to avoid injuring the stone; it should preferably be used to attempt to scratch a known mineral, for instance a piece of quartz, and care must be taken to avoid breaking or splitting the stone.

Specific Gravity. — Gem-stones differ markedly among themselves in density or specific weight; and, although this is a character which does not directly affect their value for ornamental purposes, it furnishes by its constancy an important means of distinguishing one stone from another. Moreover, it is a character very easily determined and can be applied to cut stones without injury. The relative weightiness of a stone is called its specific gravity, and is often abbreviated as S.G. The number given in the description of a mineral as S.G. shows how many times the stone is heavier than an equal bulk of the standard with which it is compared, the standard being distilled water at 4° C. If, for example, the S.G. of diamond is said to be 3·5, it means that a diamond weighs $3\frac{1}{2}$ times as much as a mass of water of the same bulk. The various methods of determining specific gravity are described under DENSITY. The readiest method of testing precious stones, especially when cut, is to use dense liquids. The most convenient of them is methyline iodide, with density 3·32, which may be mixed with benzol, with density 0·88. By pouring a little benzol on to methyline iodide in a tube and gently shaking it, a diffusion column is formed and stones of differing density will float at corresponding depths. Chips of known stones may be used as indicators. Methyline iodide readily separates the true from the false topaz (yellow quartz) as the latter floats in it. For denser stones Retgers's salt, silver-thallium nitrate, may be used. It melts above 75° C. to a clear yellow liquid, miscible with water, with a density of 4.6.

Absorption: **Colour,** Dichroism, **Etc.**—The beauty and consequent value of gems depend on the depth or the absence of colour. Diamonds are prized according to their freedom from any trace of colour, especially yellow, except that a slight bluish shade is greatly appreciated; colourless stones are said to be of pure "water." Corundum, topaz and quartz provide water-clear stones, but the absence of "fire" hinders their use. "Burnt" zircons have considerable fire and have been mistaken for diamonds. The value of coloured stones depends on their translucency and depth of tint. The colour of most gem-stones is not an essential property of the mineral, but is due to some pigmentary matter often too minute in quantity for certain determination. Thus corundum when pure is colourless, and the presence of various mineral substances is responsible for the red of ruby, the blue of sapphire, and the many other shades of corundum that occur. The tinctorial matter is not always distributed uniformly throughout the stone, but may be arranged in separate layers or zones or even in irregular patches. Sapphire, for instance, is often patchy, only one small piece of fhe stone being blue and the remainder yellow or white; the skilful lapidary arranges the blue patch on the culet so that, as all the emergent light traverses this portion, the effect is a uniformly blue stone. On the other hand, the remarkably variegated character of tourmaline is due to the complexity of its constitution which includes molecular groups exercising great tinctorial power. The character of the pigment in the case of a stone is often not definitely known. It by no means follows that the agent responsible for the colour of a piece of glass is capable of imparting the same tint to a natural stone: thus a glass of sapphire-blue may be obtained by the use of cobalt, but experience of synthetic stones has shown that cobalt will not diffuse without the addition of sufficient magnesia to produce a blue spinel and not a sapphire, and that a blue sapphire may be produced by the use of titanium. Probably ferric oxide causes a yellow, and ferrous oxide a bottle-green tint, and red is due to chromium, pink to lithium and manganese. Many colours fade on exposure of the stone to sunlight, pink being particularly fugitive.

Exposure to heat often alters the colour and, when it brings about an improvement in the appearance of the stone, the method is often employed; for instance, the beautiful pink topazes are the result of heating certain yellow stones, and again certain brownish zircons can be decolorized by heat. the stones then on account of their brilliance and "fire" closely resembling diamonds. Radium emanations have the power of imparting colour to certain species, such as diamond, kunzite and quartz; the change appears to result from the displacement of electrons within the atom, and the original colour may be restored by exposure to light or the ultra-violet rays, or by heating. The alteration in colour brought about by light or heat is due to the displacement of the constituent atoms without derangement of their relative positions; the example of topaz shows that the displacement may be relatively considerable, because of the relatively considerable increase in the refractivity and density.

Inasmuch as the eye has not the power of analysis, the tint of a stone depends on the balance of the parts of the spectrum transmitted by it, and consequently the appearance of a stone in daylight and in artificial light may be different; thus many sapphires darken in artificial light; in alexandrite the yellow part of the spectrum is absorbed, and in consequence the colour is green by daylight and cherry-red by artificial light. In certain zircons and in almandine-garnet, as was shown by Sir A. H. Church, the absorbed portions in the spectrum are narrow, and these stones show characteristic absorption spectra; in the former instance the cause of the peculiar absorption is a minute trace of uranium, so that all zircons do not show this absorption.

A doubly-refractive stone may exercise different absorption in the case of the two rays into which it splits up the light falling on it, and is then said to possess dichroism. Sometimes the difference is so marked, as in the instance of tourmaline and kunzite, as to be discernible by the unaided eye, but generally a dichroiscope (*see* CRYSTALLOGRAPHY) must be used. In the direction of single refraction (optic axis) no dichroism exists, and therefore a stone must be viewed in several directions. Dichroism is a useful property for distinguishing between ruby and garnet, as the latter, being singly refractive, shows no dichroism.

Lustre and Sheen. — The brilliancy of a cut stone depends upon the relative amount of light which is reflected from a surface and which itself depends on the refractivity and hardness of the stone. Diamond, being both very hard and highly refractive, has a lustre of its own, known as "adamantine"; zircon and demantoid approach it, but gem-stones generally have a "vitreous" lustre, like fractured glass.

The presence of twin lamellae, fibres, or cleavage-cracks affects the appearance of the stone. The asterism of star-ruby or star-sapphire is due to an arrangement of tubular cavities arranged at 60° in planes perpendicular to the crystallographical axis. A similar arrangement of fibres parallel to a single direction produces chatoyancy; cat's-eyes, as such stones are called, are provided by chrysoberyl and quartz, and tiger's-eye is a silicified crocidolite. Twin lamellae are responsible for the sheen of moonstone, and the peculiar iridescence of opal is caused by the interference of light within the stone.

Refraction. — As the optical properties of minerals are fully explained under CRYSTALLOGRAPHY little need be said here on this subject. In the "brilliant" form of cutting, the facets at the base of the stone are arranged so that the light refracted through a facet at the top returns in a nearly parallel direction but with lateral displacement so that it emerges through another facet. In the case of diamond with the highest refractive index of any gem-stone (2·42) all the light is reflected at the base of a well-cut stone, and the same is very nearly true of zircon (the optically denser type, 1·93–1·98) and sphene (1·90–1·98), but as the refractivity decreases a larger proportion of the light escapes at the base. Since most gem-stones contain in their constitution one or more of the molecular groups — silica, alumina, magnesia or their isomorphous equivalents — the refractivity and specific gravity are closely related as was shown by Sir H. A. Miers, but with the introduction of other elements as in the case of diamond, sphene and topaz, the relation no longer holds. The refractive indices and the double refraction are important characters for the discrimination of gem-stones, and may be determined, except in the case of stones of very high refraction, by means of a total-reflectometer, for a faceted stone without its removal from the setting. A convenient form of refractometer, which may be used for indices

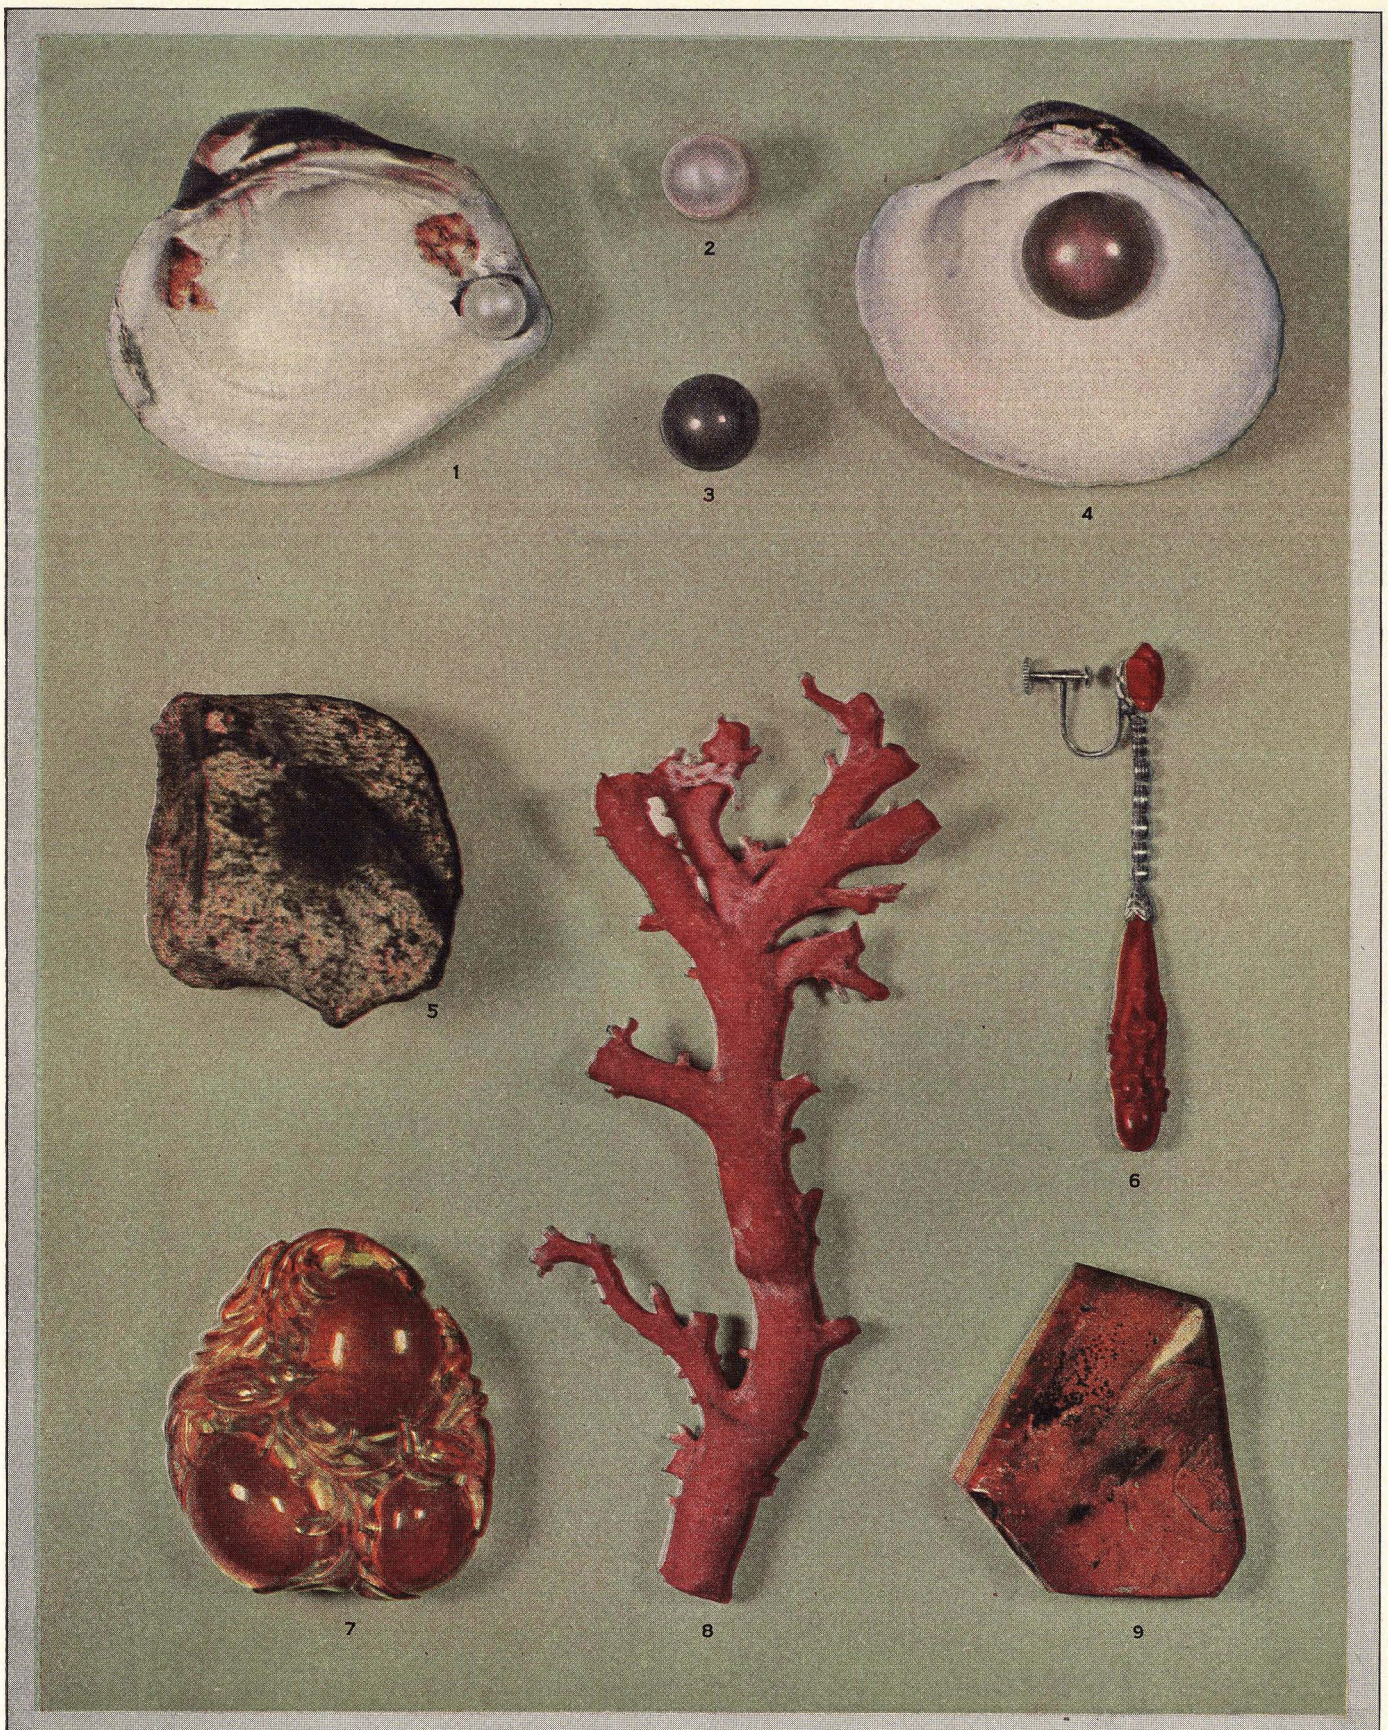
DIAMONDS AND OTHER HARD STONES

1, Sapphire, crystal, Ceylon; 2, sapphire, blue, Ceylon: 3, ohrysoberyl, Ceylon; 4, ruby, Burma; 5, star sapphire, Ceylon; 6, ruby; 7, diamonds, natural round bort (white, grey, black); 8, diamond, crystal in blue ground matrix, Kimberley, S. Africa; 9, diamond, Brazil; 10, emerald In limestone, Muzo Mine, Colombia; 11, emerald, East Indian carving, Muzo Mine, Colombia; 12, jade (Jadeite) Mogaung, Burma; 13, jade (Nephrite), New Zealand



PREPARED UNDER THE DIRECTION OF DR. GEORGE F. KUNZ, HON. CURATOR OF PRECIOUS STONES, AMERICAN MUSEUM OF NATURAL HISTORY; GEM EXPERT WITH TIFFANY AND COMPANY; BY COURTESY OF (1, 4, 8, 9) DR. GEORGE F. KUNZ, (2, 3) THE AMERICAN MUSEUM OF NATURAL HISTORY, (5) DUVAL COMPAGNIE, (6) MRS. W. E. COX, (7) YAMANAKA AND CO.

PRECIOUS MARINE SUBSTANCES

1, Pearl in Unio, common fresh water mussel; 2, Pearl from Unio, fresh water mussel; 3, Oriental pearl, black, Gulf of Mexico; 4, Pearl in shell of oommon clam (*Venus mercenaria*), Long Island Sound; 5, ambergris, concretion from whale; 6, coral, precious, Japan; 7, amber, Chinese carving, Burma; 8, *Corallum rubrum*, precious coral, Mediterranean; 9, amber, enclosing insect, Samland, Baltic coast

ranging from 1·300–1·800, has been devised by Dr. G. F. Herbert Smith. Another instrument on the same principle but with longer focal length has recently been devised by Mr. B. J. Tully.

Dispersion.—Whenever light is incident on one facet and emerges through another not parallel to the first it is split up into a spectrum, the angular width of which depends upon the dispersion of the stone, this being measured by the difference between the refractive indices for the extreme red and violet rays. This play of colour is known as "fire," and is especially characteristic of diamond, which combines large dispersion with high refraction. Colourless zircon is not much inferior to diamond in "fire". sphene and green garnet (demantoid) are even superior to it, but being coloured stones do not show it as conspicuously.

Chemical **Composition.**—With the exception of diamond, which is crystallized carbon, the gem-stones are composed of alumina or silica or a combination of them in varying proportions with or without other molecules. Corundum (ruby, sapphire) is alumina, and quartz (rock-crystal, amethyst, etc.) is silica; spinel and chrysoberyl are aluminates, beryllonite, apatite and turquoise are phosphates, and the remainder are silicates of varying complexity of constitution. In the examination of cut stones chemical tests are obviously impracticable. The artificial production of certain gems, chiefly rubies and sapphires, by processes which yield products identical in composition and physical properties with natural stones is described in the article GEMS, SYNTHETIC.

Gem-stones have been imitated not only by paste and other glassy substances but by composite stones called doublets and triplets. In a doublet the front is real but the back paste, and in a triplet the front and back are real but the central section is paste, the purpose of which is to impart colour to the stone or to improve it. By immersing such imitations in oil or water, the bounding surfaces may be detected, and if the stone be unmounted it may be immersed in boiling water, or in alcohol or chloroform, when it will fall to pieces owing to the dissolution of the binding cement.

Nomenclature.—Before the days of mineralogy as a science the classification of gem-stones was vague and based almost solely on colour, which is the least reliable of all the physical characters, and the names which were used by early writers and mostly survive to this day, though not always with the same significance, are related to this character with possibly only one exception—diamond *(adiamentem,* unconquerable, in reference to its supposed resistance to a blow with a hammer). Thus emerald (*smaragdus*) was used generally for green, sapphire for blue, ruby (*ruber*) for red, topaz for yellow stones. The earliest known lucid descriptions of stones are contained in the great work on natural history by the elder Pliny, a victim of the great eruption of Mt. Vesuvius in A.D. 79. A study of them shows that many of the names though still surviving have a different significance; thus his sapphire is known to us as lapis lazuli, and his topaz is our peridot.

Superstitions.—In early days gem-stones were believed to possess many magic virtues and charms; thus emeralds were supposed to benefit the eyes and amethysts to prevent drunkenness. The belief in lucky stones still lingers, and the prejudice against opals as a source of misfortune has not wholly disappeared.

BIBLIOGRAPHY.—The most comprehensive work on gem-stones is Prof. Max Bauer's *Edelsteinkunde* (1909), the first edition of which was translated, with additions, by L. J. Spencer under the title *Precious Stones* (1904). A full account of the properties of gem-stones is given in G. F. Herbert Smith's *Gem-Stones and their distinctive characters* (4th ed. 1923). Summaries of the subject are contained in Sir A. H. Church's *Precious Stones* (1913), which serves also as a guide to the collections in the Victoria and Albert museum, and W. F. P. McLintock's *Guide to the Collection of Gemstones in the Museum of Practical Geology, London* (1912). Certain aspects of gem-stones have been discussed by G. F. Kunz in *The curious lore of precious stones* (1913), *The magic of jewels and charms* (1915), *Shakespeare and precious stones* (1916). Information regarding finds and localities is included in *Mineral Resources,* published annually by the United States Geological Survey. Other recent books which may be consulted are J. Wodiska, *A book of Precious Stones* (1909); A. Wruck, *Die Geheimmisse der Edelsteine* (1911); A. Eppler, *Die Schmuck-und Edelstein* (1912); C. GEMBLOUX, a town in the province of Namur, Belgium, 25 m. S.E. of Brussels on the main line to Namur. Pop. (1930) was 5,198. Here on Jan. 31st, 1578, Don John of Austria defeated the army of the provinces under Antony de Goignies. In 1860 the State institute of agriculture was founded here. Gembloux is a busy railway centre with engine works.

GEM CUTTING: *see* LAPIDARY AND GEM CUTTING.

GEMINI (The Twins, *i.e.,* Castor and Pollux), in astronomy, the third sign in the zodiac, denoted by the symbol ♊. By the Egyptians this constellation was symbolized as a couple of young kids; the Greeks altered this symbol to two children, variously said to be Castor and Pollux, Hercules and Apollo, or Triptolemus and Iasion; the Arabians used the symbol of a pair of peacocks. Castor is a double star with a separation of nearly 6″ easily resolved with small telescopes; the period of revolution of the two components is 350 years. Each of these visual components is a spectroscopic binary, the periods being 9.2 days and 2.9 days respectively. Another interesting star is ζ Geminorum, which is variable in a period of 10·15 days; it belongs to the Cepheid class of variables.

GEMINIANI, FRANCESCO (*c.* 1667–1762), Italian violinist, was a native of Lucca, and studied the violin under Lunati (Gobbo) and afterwards under Corelli. He may also have had lessons in composition from Scarlatti. In 1714 he arrived in London, where he found a patron in the earl of Essex. In 1715 he played his violin concertos with Handel at the English court and later spent much time in Dublin, where he had a fine house in which he gave private concerts. After visiting Paris and residing there for some time, he returned to England in 1755. On a visit to Dublin in 1761 a servant robbed him of a manuscript, an incident which is said to have hastened his death (Sept. 17, 1762). Geminiani brought to England great improvements in the technique of violin-playing, and he handed down his method in the first book on the subject, his *Art of Playing the Violin.*

GEMISTUS PLETHO [or PLETHON], **GEORGIUS** (*c.* 1355–1450), Greek Platonic philosopher and pioneer of the revival of learning in Western Europe, was a Byzantine by birth, but settled at Mistra in the Peloponnese. He changed his name to the equivalent Pletho ("the full"), perhaps owing to its similarity to that of his master Plato, whom he introduced to the West during his visit to Florence in 1439, as one of the deputies from Constantinople on occasion of the general council. Cosimo de' Medici and Cardinal Bessarion were much impressed by him. He endeavoured to promote the union of the Greek and Latin Churches, and founded a sect on the speculative mysticism of Neoplatonism.

He probably died before the capture of Constantinople. His treatises on the distinction between Plato and Aristotle appeared at Venice (1540), on the religion of Zoroaster (Paris, 1538); on the condition of the Peloponnese (ed. A. Ellissen in *Analekten der mittel- und neugriechischen Literatur,* iv.); and the Νόμοι (ed. C. Alexandre, Paris, 1858). Many of his volumes of excerpts from ancient authors, and works on geography, music and other subjects exist in ms.

See especially F. Schultze, *Geschichte der Philosophie der Renaissance* (1874); J. A. Symonds, *The Renaissance in Italy* (1877), ii. H. F. Tozer, "A Byzantine Reformer," in *Journal of Hellenic Studies,* vii. (1886), chiefly on Pletho's scheme of political and social reform for the Peloponnese; W. Gass, *Gennadius und Pletho* (1844). Most of Pletho's works are in Migne, *Patrologia Graeca,* clx.; for a complete list *see* Fabricius, *Bibliotheca Graeca* (ed. Harles), xii.

GEMS, SYNTHETIC, denote precious stones artificially made and having the chemical, physical and optical properties of natural gems. Of the precious stones, the diamond, emerald, ruby and sapphire have all been successfully synthesized. Only the ruby sapphire, and spinel, however, have outgrown the laboratory stage of the production and represent the principal products of the synthetic precious stone or artificial gem industry. Artificial amethysts, garnets, tourmalines, etc., have not appealed to the industry because they are not valuable enough as natural products.

The pearl is almost altogether of animal origin. Only the diamond, emerald, ruby, sapphire and spinel will be treated here. The beauty of natural precious stones is due to their composition and cutting. Permanence of beauty is due to the hardness of the stones and to the fact that they are chemically inert. Extraneous conditions, such as custom and rareness may also affect their value.

The Diamond.—The transformation of the diamond to graphite or carbon has been accomplished frequently. The process has also been reversed and some few diamonds have been produced by various investigators. The work of Moissan is an interesting instance. He developed his experiments from the analytical work of Friedel. The Devil's canyon in Arizona was once littered with meteorites. Some of these were analyzed by Friedel. Tiny diamonds were found embedded in the mass of iron. Moissan tried to reproduce the conditions of the fiery meteor. In an electric furnace he placed a carbon crucible containing pure iron and carbon. The carbon dissolved in the molten iron until a saturated solution was formed, and while the material was at white heat he plunged it in a bath of molten lead. The sudden cooling caused tremendous internal pressure and the liquid carbon was crystallized into small diamonds. One of these, weighing about 6 mg. (about $\frac{1}{30}$ of a carat), when burned in oxygen produced about 23 mg. of carbon dioxide. Frequent efforts by scientists to repeat Moissan's experiment have been unsuccessful. Up to 1940 synthetic diamonds had not been commercially produced although numerous experiments were in progress. The high dispersion of light gives to the diamond its so-called "play of fire." It reflects almost all the rays of light that strike its surface and give it the characteristic lustre known as adamantine.

The Emerald.—Chemically, the emerald is a metasilicate of aluminium and glucinum. Hautefeuille and Perrey, 1890, dissolved the constituents of the gem in their relative proportions in a bath of dimolybdate of lithium and, keeping the bath at 800° C for 15 days, succeeded in crystallizing out tiny emerald crystals. A little chromic oxide was used to give the green colour. These crystals were perfect, but too small; the largest being only 2 mm. long by 1 mm. wide and 1 mm. thick. They were much more expensive than the natural product. Recent attempts to synthesize emeralds have resulted in crystals up to 20 mm. in length. The process is not as yet economically successful. Beryl, the natural metasilicate of glucinum and aluminium, is golden yellow in colour. The emerald is identical with it save its green colour. This difference is due to the presence of different impurities. Almost all rhe rays of light impinging upon the surface of an emerald enter it, and very few are reflected from its surface, very much as in the case of glass, and the emerald is not as optically dense as the diamond.

The Ruby.—The ruby was the first of the precious stones to be synthesized on a commercial scale. Chemically, it is the oxide of aluminium with a trace of chromic oxide, to which it owes its rich pigeon-blood colour. Corundum (Al_2O_3) is often free from the oxide of chromium and we have either a colourless stone or, if some other oxides are present, we may have a blue stone—the sapphire, or shades of green, smoky tinges, etc. The effect of radium emanations on natural and synthetic rubies is shown in an experiment by F. Bordas. Using radium bromide of 1,800,000 activity he turned natural rubies into a brick red colour. The synthetic stones were not affected. But the synthetic product is often ruined during manufacture by quantities of impurities that are so small they can scarcely be detected by analytical methods.

An interesting attempt to crystallize aluminium oxide out of a molten bath was that of Fremy and Hautefeuille. The oxides of lead, aluminium and chromium were fused in a large crucible for about seven to eight days in a furnace used for glass making. Masses of rubies from **30** to **40** kg. were sometimes obtained, but among these not a ruby was found that was thick enough to be of any value as a gem. One of the crystallographic axes developed more than another, and only thin, laminated crystals were produced. Attempts to condense alumina vapour produced similarly imperfect gems. Fremy and Verneuil carried on a series of experiments with ordinary sand crucibles for this purpose. It was found that in the presence of vapour of potassium carbonate amorphous alumina would be changed into corundum. Sand crucibles were filled with alumina, potassium carbonate and chromic oxide; mixed with fine charcoal, packed around a core composed of alumina and calcium fluoride and gently heated. The charcoal escaped as carbon dioxide and made the mass porous. After eight days the largest stone produced was **4** to 5 mm. long and about 1 mm. thick, weighing **60** mg. or about $\frac{1}{3}$ of a carat. These not only were too thin to be cut into gems, but lacked the beauty of the natural stone which appears to be made up of a series of layers The light coming through these layers gives to the ruby its wealth of colour. Reconstructed rubies were made by a priest near Geneva, by fusing chips of natural rubies into stones. Verneuil succeeded in fusing the oxide of aluminium and developed the process to a point where rubies were made that were large in size, of good colour and at a speed sufficient to make an industry possible. One workman can operate about ten furnaces producing 30 or more carats per hour per furnace.

Rubies are made commercially by fusing alumina in the oxy-hydrogen flame and permitting the molten mass to solidify in the cooler zones of the flame. A modified inverted oxy-hydrogen torch invented by Verneuil is used. It produces a flame of many zones varying in temperature from 1,900° to 2,400° **C.** The torch consists of two concentric tubes: the inner tube carries the oxygen, extends about a foot beyond the outer and has a cylindrical shaped top. In the lower portion of the torch, the outer or hydrogen-carrying tube extends an inch or two beyond the oxygen tube. The ruby-forming powder is placed in a sieve bottom box which, in turn, is screwed into the cylindrical top of the oxygen tube. When the torch is lit a hammer is caused to knock periodically on the top of this box, and particles of alumina are thus blown into the flame. In the beginning of the process, the flame is comparatively cold and just heats a rod that is placed to catch this powder. As the powder continues to fall on this rod it forms a pyramid of fritted alumina. The heat is gradually increased until the top of this pyramid becomes molten and a tiny stalk or "pin-head" begins to grow. At this stage the flame is made still hotter and the powder falls in molten drops upon this pin-head. Each succeeding drop falls upon a larger base until an unflawed pear-shaped, or so-called ruby boule, is produced.

This boule is one single crystal with the optical axes directly perpendicular to one another. When the stem of this boule is broken the stone breaks in two. Pure alumina is essential for this process. The presence of even 0.0005 of 1% of a certain impurity jeopardize the industry, as this amount is sufficient absolutely to discolour the ruby, and produce a brick-red instead of the pigeon-blood stone. This impurity was found by Levin to be magnesium oxide Mg.O. The stone cut from a boule is physically and chemically identical to the natural ruby. There is perhaps but one method of telling the synthetic from the natural stone. In the natural stones the imperfections have flat bounding sides and are so-called negative crystals; the imperfections in the synthetic stones have round surfaces and are simply air bubbles which in many cases can be detected only by a powerful magnifying glass Both the natural and the synthetic stones are made up of a series of successive layers; the synthetic stone having curved layers, the natural product flat, parallel layers.

The Sapphire.——Sapphire chips cannot be fused into reconstructed sapphires in a way similar to the making of reconstructed rubies because the colour disappears. In some experiments of Deville and Carron with the ruby, blue patches were obtained, and it was believed by them that the sapphire owed its blue colour to a lower oxide of chromium. Experimenters, however, failed to realize any blue colour by the use of some of the oxides of chromium. The cobalt oxides, which are used so extensively in ceramics to produce blue, cannot be retained in the corundum. By the addition of materials, such as calcium oxide, blue stones are obtained, but are not genuine, synthetic sapphires. Research was abandoned and then taken up again in 1909 by Verneuil and Levin. The sapphire owes its blue colour to the presence of the oxides of iron and titanium. Up to the time of the actual synthesizing of the sapphire, there existed no complete analysis showing

both of these oxides present in the natural gem. Titanium is widely distributed in the earth's crust. The titanium oxides grade away in colour from white to blue and purple.

The higher oxide of titanium, TiO_2, is the stable oxide in molten corundum and gives to the corundum a lavender colour. Pinkish stones and not blue stones were first obtained in the fusion of the iron oxide and titanium oxide with corundum. A greater quantity of iron oxide produced the necessary reduction of the titanium oxide and the true blue colour of the natural sapphire was finally obtained. The reaction is delicately balanced and prolonged heating will cause the blue colour to change back to pinkish. This explains why natural sapphire chips lose their colour when fused. The blue corundum boule is identical with the natural stone and they are distinguished only with great difficulty by experts. After fusion only part of the iron and titanium oxides are left. A. J. Moses found only traces of Fe_2O_3 and about 0·1 of 1% of TiO_2. The analysis of the natural products extant before the synthesis of the sapphire did not show the presence of titanium oxide.

The **Spinel.**—Although magnesium aluminate, the gem mineral spinel, has been often synthesized in the laboratory, it is only since 1926 that synthetic spine! gems have achieved commercia! importance. The Verneuil vertical oxyhydrogen blowpipe has succeeded in producing from a mixture of magnesium oxide arid alumina in fine powder synthetic spinel boules which are even more true to nature than those of the synthetic corundum gems. About 20,000,000 carats of rubies and 12,000,000 carats of sapphires are produced annually.

GEMS IN ART. The word gem is used as a general term for precious and semi-precious stones especially when engraved with designs for sealing (intaglio) or for decoration (cameo). Such gems exist in large numbers from the early Sumerian period to the decline of the Roman civilization and again from the Renaissance to modern times. They exercise a strong appeal in many ways. The inherent beauty of the material, with its rich and varied colours, its lustre and brilliance, gives pleasure at first sight. The hard and durable quality of the stones has made for unusually good preservation, so that we can appreciate in many cases the artist's work in its original state—a rare opportunity in ancient art. Moreover, the smallness and preciousness of the gems invited exquisite workmanship, and in certain periods, when art was at a high level, the achievements in this field were very notable. The best ancient gem engravers combined minuteness and accuracy of detail with a largeness of style that is indeed remarkable. A gem engraving of this class possesses the nobility and dignity of a marble or bronze sculptural work, though it is often confined to the space of less than half a square inch.

The Technique of Gem Engraving.--Only soft stones and metals can be worked free hand with cutting tools; the harder stones require the wheel technique. This technique was known in Mesopotamia as early as c. 4000–3000 B.C. (Plate II., 1), as well as to the Minoans from the middle Minoan III. period (c. 1800–1600 B.C., Plate II., 13). The method of work seems to have been similar to that in use to-day, to judge by the references we have in classical literature (see especially Pliny, N.H. xxxvii., 76; xxxvii., 15; Theophrastus, De *lapidibus* I., 5; VII., 41), and an examination of the stones themselves (fig. 2 *A,* B, C, D). By this method the stones were worked with variously shaped drills ending in balls, discs, cylinders, etc. (Plate VI., 1), which were made to rotate by the help of the wheel (fig. 1). Nowadays the stone to be engraved is fastened to a handle and held to the head of the

FIG. 1.—A GEM ENGRAVER OF THE 18TH CENTURY AT WORK IN HIS SHOP SURROUNDED BY THE VARIOUS TOOLS OF HIS TRADE

rotating drill and moved as the work requires (Plate VI., 2). It has been suggested that the ancients reversed the process and held the stone stationary while the rotating tools were guided by the hand, as in modern dentistry. The cutting is not actually done by the drills but by the powder which is rubbed on the stone with the drill. This is nowadays diamond powder, mixed with oil; it was known also to the Romans (*see* Pliny, *N.H.* xxxvii., 15, and Manilius, *Astronomica* IV., 926), but in the period before Alexander emery powder was probably used. The wheel used in our times is either worked by the foot (fig. 1) or by an electric motor lathe. The former, though more cumbrous, has the advantage of giving the artist more direct control over the speed. On the gravestone of a gem cutter of the Roman empire found at Philadelphia in Asia Minor (fig. 2, *N*) a tool is represented which looks like the bow used by modern jewellers and which, by being drawn back and forth, could impart a rotating movement similar to that of the wheel. But since we know that the rotating wheel was well known to the ancients in the making of pottery it is probable that they made use of it in gem engraving also. After the cutting of the gem was complete the surface was often polished. Such a polish was especially popular among the Etruscans and in the later Greek and Roman periods.

For this purpose Naxian stone (*naxium*) was used, as Pliny informs us (N.H. xxxvi., 10).

We do not know definitely whether the ancient gem cutters made use of the magnifying glass but it is probable that they did. The general principle of concentrating rays was known to Aristophanes (*Clouds,* 766 seq.). Pliny several times mentions the use of balls of glass or crystal brought in contact with the rays of the sun to generate heat (N.H. xxxvi., 67 and xxxvii., 10), and Seneca speaks more specifically of this principle applied for magnifying objects (*Nat.* Quaest. I., vi., 5).

For actual examples of what seem to be ancient lenses, found in Egypt, Crete, etc., some going back to the second millennium B.C., see Beck, Ant. J. viii., 3, pp. 328–330 (July 1928).

HISTORY

Mesopotamia.—The art of engraving stones probably originated in south Mesopotamia. There it attained a high degree of proficiency as early as the fourth millennium B.C.; *i.e.,* during the Elamite and Sumerian civilizations. The engravings were worked on stones mostly of cylindrical shape (Plate I., 19), suspended by a string and used as seals. The materials were petrified shell and marble, and the subjects are chiefly heroes fighting **animals,**

deities with worshippers and decorative motives (Plate II., 1, 2). After the Akkadian invasion (c. 2800 B.C.) the art of seal engraving reaches its greatest height, and semi-precious stones like rock crystal were cut in masterly fashion. The mythical King Gilgamesh performing his great exploits is the favourite representation (Plate II., 3). Cuneiform inscriptions begin to appear. After the decline of the Akkadian empire the representations become more and more conventionalized. Hematite gradually

becomes the prevailing material. The most frequent subjects are the "Introduction Scene"—a seated goddess towards whom a second deity leads a worshipper, the Gilgamesh legend, and other mythical representations (Plate II., 4). During the Amorite dynasty (c. 2100–1800), to which belonged the famous King Hamurabi, we are again in a highly artistic period, but probably of short duration. The representations are mostly the same as during the preceding epoch, and the use of cuneiform inscriptions becomes important (Plate II., 5), until in the Kassite period (*c.* 1800) it constitutes the most conspicuous feature (Plate II., 7).

After the downfall of the Amorites in Babylonia, southern Mesopotamia no longer played an important part politically, serving only as a cultural centre. The other oriental countries which now came into prominence naturally profited by the older civilization, and the Hittites (second millennium B.C.), the Assyrians (first half of first millennium B.C.) and other peoples of Asia Minor all became conversant with the art of gem engraving. They carried on the southern Mesopotamian tradition with some contributions of their own (Plate II., 6, g, 10). The favourite subjects are adoration scenes and heraldic groupings of deities and animals. Decorative motives are popular. The cylinder form remains in vogue, but conical and dome-shaped seals with a flat base for the intaglio are the most popular (fig. 2, J, M). The coloured quartzes are the favourite material. When the power of Assyria gave way to that of Persia, the Persian gem engravers followed in the footsteps of their predecessors both in technique and style; but the favourite theme now becomes the exploits of the great king of Persia (Plate II., 8).

Egypt.—The Egyptians early adopted the art of engraving, employing first the cylinder form, then, from about the 9th dynasty on, the scarab or beetle and kindred shapes. As subjects for their engravings they used chiefly symbols, script and ornaments (Plate II., 14), only occasionally pictorial scenes. Though historically, therefore, these scarabs are of great importance—especially as they have been found in great numbers and form a continuous series—the artistic value is frequently secondary. The great majority lack the interest of subject treatment, though the finish of their execution is remarkable. The commonest materials are glazed steatite and faience, but the coloured quartzes—carnelian, amethyst, jasper, etc.—are also employed.

Crete.—From the earliest times we find Greece treading an independent path influenced but not conditioned by her oriental neighbours. In Crete gem engraving occupied an important place. The stones of the early Minoan period (c. 3500–2200 B.C.) show a great variety of shapes—including cylindrical, pyramidal, conoid, quadrilateral and three-sided rounded beads—and are engraved with rude pictographs, consisting of primitive renderings of human beings, animals, ships and floral and linear patterns (Plate II., 11). It is clearly an experimental stage without traditional forms. The stone is invariably of a soft variety, *i.e.*, steatite of different colours worked by hand. As time went on—during the first and second middle Minoan periods (c. 2000–1800 B.C.)—the three-sided elongated bead became the standardized shape and the pictographs were transformed into less rude, more conventionalized forms (Plate II., 12). Several symbols now generally occur together, showing that from mere ideographic meaning they had acquired a phonographic value as syllables or letters. In other words, the primitive pictographs have evolved into hieroglyphs. The material still remains the soft steatite. During the middle Minoan third period (*c.* 1800–1600 B.C.) the hieroglyphic script reached its full development, the symbols appearing in highly systematized form, executed often with great nicety (Plate II., 16). The stones are no longer steatite but hard varieties, such as carnelian, chalcedony and green jasper. They are worked with the wheel, the use of which was apparently learned from the Orient.

In the next period (late Minoan, c. 1600–1100) we note a great change. The Minoan written language has finally evolved into a linear script and concurrently it disappears from the seal stones. In its stead we find naturalistic designs—animals (Plate II., 17), cult and sacrificial subjects (Plate II., 13), deities and demons, hunting and war scenes, *i.e.*, the stock subjects of Cretan art, executed with an amazing *élan* and vivacity. The stones are now regularly the hard quartzes, of lentoid and glandular forms (fig. 2, E, F). Similar engraved gems as well as gold rings with engraved bezels have been found at Mycenae and other places within the range of Cretan influence. Towards the end of the late Minoan period the art deteriorated. The soft steatite again took the place of the harder stones, and the subjects became merely conventionalized representations. Gradually there was established the geometric style in which linear designs were engraved by hand on soft stones of the prevalent oriental forms (Plate II., 19). In the 7th century B.C. a revival in artistic conceptions is noticeable. Highly decorative animals are carved with considerable feeling for life on steatites of glandular and lentoid forms (Plate II., 18). This was the prelude to several centuries of a flourishing output, lasting throughout the classical civilizations.

Greece.—The study of Greek and Roman gems is the study of classical art in miniature; for the gems reflect faithfully the styles of the various periods to which they belong, so that they represent an accurate picture of the development, the prime and the decadence of classical art. In the gems of the 6th and early 5th century B.C. the dainty charm of archaic Greek art finds a happy expression. The chief forms are the scarab and the scaraboid (fig. 2, H, I) regularly set in swivel rings (fig. 2, *K*, L, *O*). The subjects are the same as in other branches of archaic art. At the beginning of the period the human figure in kneeling posture is the most popular, but soon a greater variety was attempted. Gods and goddesses are comparatively rare, but Werakles is a favourite; and various demons, the Silenus, the Siren and the Sphinx are also common. Among the figures without mythological significance, the commonest are warriors, archers, athletes and horsemen; and among the animals the lion, bull, boar, deer, ram, cock and horse (Plate III., 1–8) are favoured. The coloured

quartzes, such as the carnelian, chalcedony and agate, are the chief materials used.

The second half of the 5th and the 4th centuries mark another climax in the history of Greek gem engraving. We find the same conception of serene beauty in the minute products of the gem-cutters as in the contemporary statues. The favourite shape employed is no longer the scarab but the scaraboid (fig. 2, *I*), generally large and thick, and perforated to be worn on a swivel (fig. 2, L, *O*) or as a pendant (fig. 2, G). With regard to the choice of subjects the chief theme is now the daily life of the people, especially of the women. A woman taking a bath, making music, playing with animals, etc., are all favourite representations; animals are likewise common; mythological subjects are less popular. The favourite deities are Aphrodite, Eros and Nike (Plates III., 9–13, IV., 1–9). By far the commonest stone of this period is the chalcedony. Less frequent are the carnelian, agate, rock crystal, jasper and lapis lazuli.

The inscriptions which occur on Greek gems form an interesting study. They generally give the name of the owner, often only the beginning of his name being recorded. Occasionally they refer to the people represented or they contain a greeting. Sometimes the name of the artist is given. Of the latter the most prominent are Epimenes (Plate III., 3) and Dexamenos (fig. 2, *O* and Plate III., 9, 10). Their works rank among the best which have been produced in Greek gem-cutting.

The Greek gems of the Hellenistic period, about 323–30 B.C., reflect the heterogeneous styles of contemporary sculpture; but there are now also some notable representations (Plate IV., 13). A change takes place in the shape of the stones. Instead of the perforated scarabs and scaraboids the unperforated ringstone, generally flat on one side and convex on the other, becomes the accepted form. The stones are often of considerable size and the large rings in which they are mounted are not uncommonly preserved. The favourite stones are the hyacinth, garnet, beryl, topaz, amethyst, rock crystal, carnelian, sard, agate and sardonyx, many of them introduced into the Greek world from the East after the conquests of Alexander the Great. Glass, as a substitute for more precious material, is often used. Among the subjects represented the most important is the portrait, which now acquires great popularity (Plate IV., 12–13). Scenes from daily life and mythology both occur (Plate IV., 14).

A great technical innovation introduced in this period is the cameo, in which the representation instead of being engraved in the surface of the gem is carved in relief (Plate V., 12). It is therefore the converse of the intaglio. These cameos naturally did not serve as seals, as did the intaglios, but were used purely for decorative purposes. In such work the colourcd quartzes were generally employed, their various layers being skilfully and effectively utilized; but imitations in glass paste also occur (Plate I., 30). The technique was popular in Roman times.

Graeco-Phoenician and Graeco-Persian Gems.—A class of gems in which the influence of Greek art is shown is that of the Graeco-Phoenician scarabs, chiefly found in the Carthaginian cemeteries of Sardinia, Carthage and Iviza (Plate II., 15). The stones there discovered show that at first Phoenician art was strongly subjected to Egyptian influence, but from the 6th century B.C. onward both the Greek style and Greek subjects were adopted. The archaic Greek style persevered in the Phoenician stones throughout the 5th century and into the 4th, long after a freer style had been introduced in Greece itself—a phenomenon with which we are familiar from Carthaginian coins. The shape of stone is regularly the scarab and the favourite material green jasper. The representations consist chiefly of the favourite Greek types of youths and men, and of mythological creatures. Fantastic combinations of heads and masks probably had an apotropaic significance.

The Graeco-Persian gems illustrate the influence of Greek art in the East. In Persia the gems of purely Persian style (Plate II., 8) are followed in the second half of the 5th and the first half of the 4th century by gems in which Persian and Greek elements commingled. They were evidently made by Greeks for Persians. The subjects are taken from the daily life of the Persian nobles, preferably contests of Persians and Greeks, or hunting scenes, or single figures of Persian nobles or ladies (Plate IV., 10). Animals are also favourite subjects (Plate IV., 11). These representations are executed in a broad, spirited style, chiefly on chalcedony stones of scaraboid form. A rectangular shape with one faceted side is also popular.

Etruria.—Etruscan gems make their appearance toward the end of the 6th century B.C. and remain in vogue until the 4th. They closely copy Greek styles, forms and subjects (Plate V., 1–3). At times their execution is excellent, but there is always a certain dryness and stiffness which serve to distinguish even their best products from pure Greek work. The shape is invariably that of the scarab, worked often with minute care, while to the Greek artist the backs of the engraved gems were of secondary interest. Moreover, the edge of the base on which the beetle stands, which in the Greek examples is left plain, is ornamented in the Etruscan gems, except in the earliest period and in the more careless specimens. By far the commonest material is the carnelian. The subjects chosen are chiefly taken from Greek mythology. Homeric and Theban heroes predominate (Peleus, Achilles, Odysseus, Ajax, Tydeus and Kapaneus) Inscriptions sometimes occur; they do not, as in the Greek gems, give the name of the owner or of the artist but of the figure represented.

At the end of the 5th century another class of scarab becomes prevalent, lasting until the beginning of the 3rd century B.C. It is not confined to Etruria but occurs also elsewhere in Italy. The distinguishing characteristic is that it is roughly worked with the round drill (Plate V., 4), evidently merely for decorative effect, which is heightened by the brilliant polish. Herakles, Silenus and animals are popular subjects.

Roman Gems.—The Etruscan scarabs are superseded in Italy in the 3rd and 2nd centuries B.C. by ringstones in which we can distinguish two styles, according as they imitate Etruscan (Plate V., 6) or Hellenistic art (Plate V., 5). There are no great artistic achievements among them but they are nevertheless of interest in that they form an important source of knowledge for the Roman art of the earlier republican period. In the 1st century B.C. the two styles became merged, with Greek elements predominating (Plate V., 7) and growing gradually into the classicist style of the Augustan age.

Engraved gems enjoyed a great popularity in Rome during the late republican and early imperial periods. We know this not only from the large number of examples which have survived, but also from literary sources. Gem-collecting became a passionate pursuit. Wealthy men vied with one another in procuring fine specimens and paid enormous prices for them. The keenness of this rivalry can be gauged by the story that the senator Nonius was exiled from Rome because he refused to give a certain gem (valued at 20,000 sesterces) to Mark Antony. Public-spirited men, then as nowadays, after having formed their collections would deposit them in the temples for all to enjoy. Scaurus, the son-in-law of Sulla, is said to have been the first Roman to have a collection of gems. Julius Caesar was an eager and discriminating collector and deposited as many as six separate collections in the temple of Venus Genetrix. The style of the representations is that of the classicist art of the early imperial period which we encounter in other contemporary products. Its dominant characteristic is a quiet, cold elegance. The subjects have a wide range comprising mythological and every-day themes, including portraits of distinguished men, copies and adaptations of famous statues, symbols and grylloi—fantastic combinations of heads and figures, probably with superstitious import (Plate V., 8–11). The prevalent form throughout is the ringstone. The variety of stones used is large, for at this time of Roman world dominion and increased commercial facilities a wide range of stones could be obtained from all parts of the empire. The commonest are the carnelian, sard, sardonyx, chalcedony and amethyst; especially fine engravings are often found on garnets, hyacinths, beryls, topazes and peridots, more rarely on emeralds and sapphires. The nicolo and red jasper, which occurred only occasionally in former periods, now enjoyed great popularity. The Roman enthusiasm for this wealth of beautifulstones can be gauged from the remarks of Pliny

(N.H. xxxvii., 1) who declared that some gems are considered "beyond any price and even beyond human estimation, so that to many men one gem suffices for the contemplation of all nature."

Cameos continued in use throughout this period, chiefly of sardonyx, onyx and glass paste (Plate V., 12). The favourite subjects are portraits and mythological scenes. Among the former are valuable representations of emperors and princes.

Signatures of artists are found not infrequently both on the intaglios and cameos. In fact, by far the majority of ancient gem-cutters known to us belong to early imperial times. The most distinguished artist was Dioskourides, of whom we know that he made the imperial seal-ring of Augustus (Pliny N.H. xxxvii., 50 and 73). Other well-known names are Gnaios (Plate V., 9), Aspasios, Eutyches, Aulos, Apollonios, Agathangelos. (See GREEK ART; ROMAN ART.)

Late Roman Period.—By the and century A.D. glyptic art was on the decline. Of the large number of gems of that period which have survived very few have any artistic value. The majority show hasty, careless workinanship and the representations are lifeless and monotonous (Plate V., 14). The shape of the gems is always the ringstone and the materials are very much the same as those in use during the preceding period. Nicolo and jasper now become specially common, probably on account of supposed magical properties.

The same deterioration is noticeable in the early Christian (Plate V., 18) and Gnostic gems (Plate V., 16). A gem now became a talisman with long, often unintelligible formulae. The symbolism is largely associated with Mithraic worship. The name Abraxas (or Abrasax) occurs with great frequency (Plate V., 16). The commonest materials are hematite and jasper.

More important artistically are the Sassanian gems (3rd to 7th century A.D.) which indeed represent the last important product of gem engraving in the ancient world. The representations are a mixture of oriental traditions and late Roman forms. Especially fine are some of the portraits (Plate V., 17).

In north India the Ephthalites (white Huns) established a civilization about A.D. 475 which lasted until about A.D. 550. That they too practised the art of gem engraving is shown by a recently discovered stone with the portrait of an Indian king (Plate I., 26).

Post-classical Times.—In post-classical times there are two epochs in which the art of gem engraving again flourished, the Renaissance and the 18th and early 19th centuries. The artists of both periods borrowed freely from the antique. Those of the Renaissance were tooindividual to keep very closely to the ancient spirit, and Renaissance works are therefore seldom difficult to distinguish from ancient gems (Plate V., 13). The gem engravers of the 18th and 19th centuries, on the other hand, consciously tried to copy ancient work as exactly as possible in style and in subject. And though at first this copying was done out of admiration for the antique, it soon developed with unscrupulous people into an extensive output of forgeries. At times it is extremely difficult to tell definitely whether a certain piece is ancient or a faithful copy. Mostly, however, the copyist betrayed himself by a slight innovation characteristic of the spirit of his own time rather than that of the antique (Plate V., 15); and in a large number of cases, notably in the famous Poniatowski gems (Plate V., 15), the spirit and composition are so far removed from ancient work that few people would nowadays be deceived by them.

An interesting feature of the gems of this period is presented by the inscriptions which often appear and give the signatures of the artist or would-be artist. For besides signing their own names, often in Greek or Roman letters, artists inscribed their works with names of famous ancient artists. Generally such forged inscriptions are easily detected, but sometimes they are cut with great care and present a difficult problem. Moreover, at times genuine ancient gems are supplied with forged signatures. The best-known gem-cutters of this period are the famous Natter, the three Pichlers, Marchant and Burch.

In modern times the art has a certain limited vogue, not comparable, however, with the great periods we have described.

GENE. The word gene (Gr. γένος, race) has come to be used, more particularly in the United States, as the equivalent of the word gen. The latter was first coined by Johannsen (1909) to signify the unit in inheritance. As a prefix, gen appears in such words as genetic and genealogical, but used by itself it stands for a purely hypothetical unit in inheritance. In England the word "factor" is more frequently used, but factor has also a wider significance; gene is equivalent to genetic factor. The word is used almost exclusively in Mendelian literature, and has come to have a more specific application to the elementary unit carried by chromosomes. The functional significance of the gene in development, in determining the character of the individual, is the subject at present of much speculation, and diverse views have been expressed as to how the genes are related to the characters for which they are, in a sense, the sponsors in the germinal material.

The assumption of fundamental units in heredity is a familiar procedure in biological literature. Herbert Spencer postulated physiological units out of which the body is built, somewhat as are crystals from molecules of a salt in solution. Darwin's theory of pangensis called for "gemmules," supposed to be specific particles set free from all parts of the body, which uniting with similar particles in the eggs and sperm-cells render the inheritance of acquired characters possible. Haeckel used the word "plastidule" for the ultimate particles of the protoplasm. De Vries postulated intracellular pangenes, which, being set free from the nucleus, determine the character of the cell but do not pass beyond the cell boundaries. Weismann invented an elaborate system of hierarchies of elements consisting of biophors (the simplest) determinants, ids and idants (chromosomes). The determinants were supposed to be sorted out during the earlier embryonic cell-divisions in an orderly fashion, each cell finally getting a particular kind that determined its functional behaviour. None of Weismann's units were supposed to pass beyond the limits of the cell. In all these earlier hypotheses the units were purely fictitious in the sense that they were devised to carry out certain imaginary processes. To the units were assigned arbitrarily such properties as the particular end in view required.

The idea of units in Mendelian work has a different derivation. The results of experimental breeding have shown that when certain contrasted characters are brought together in a hybrid (F_1),

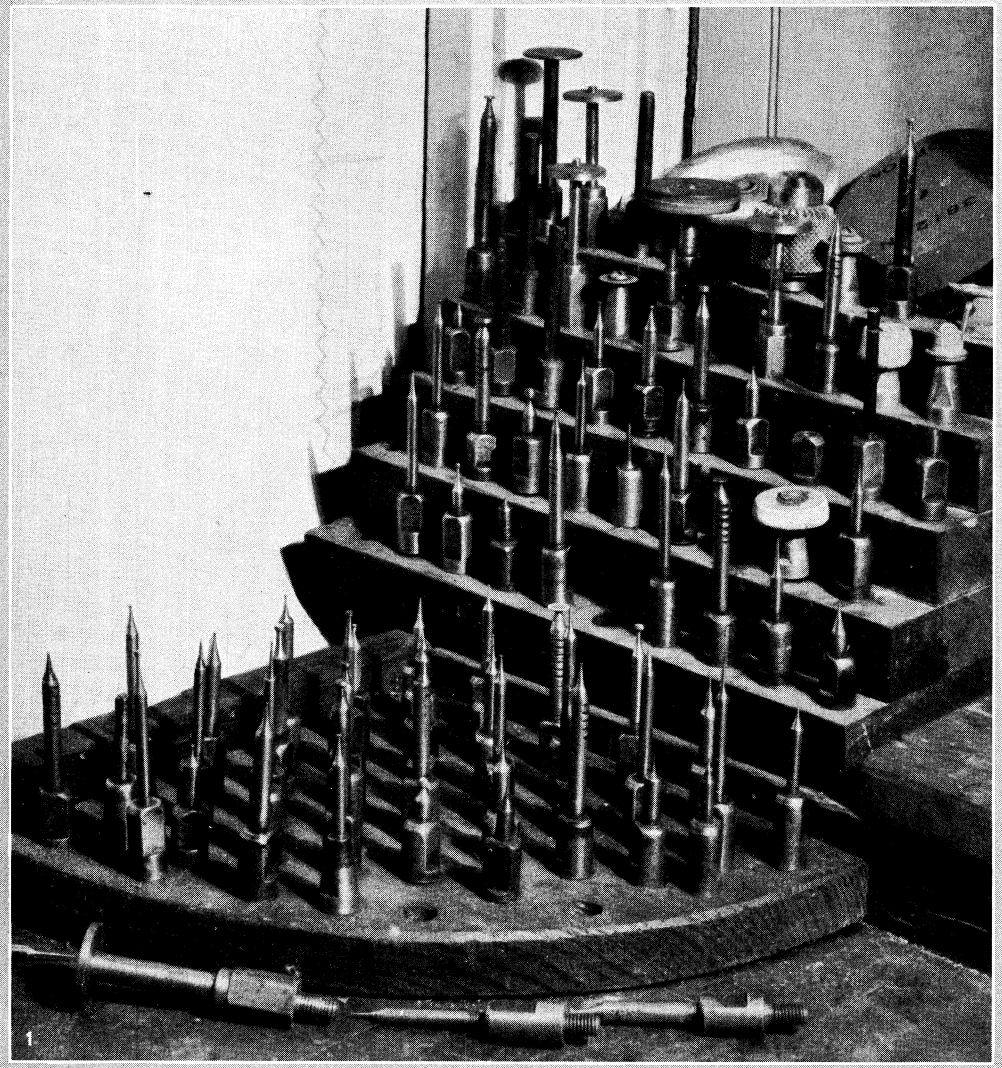
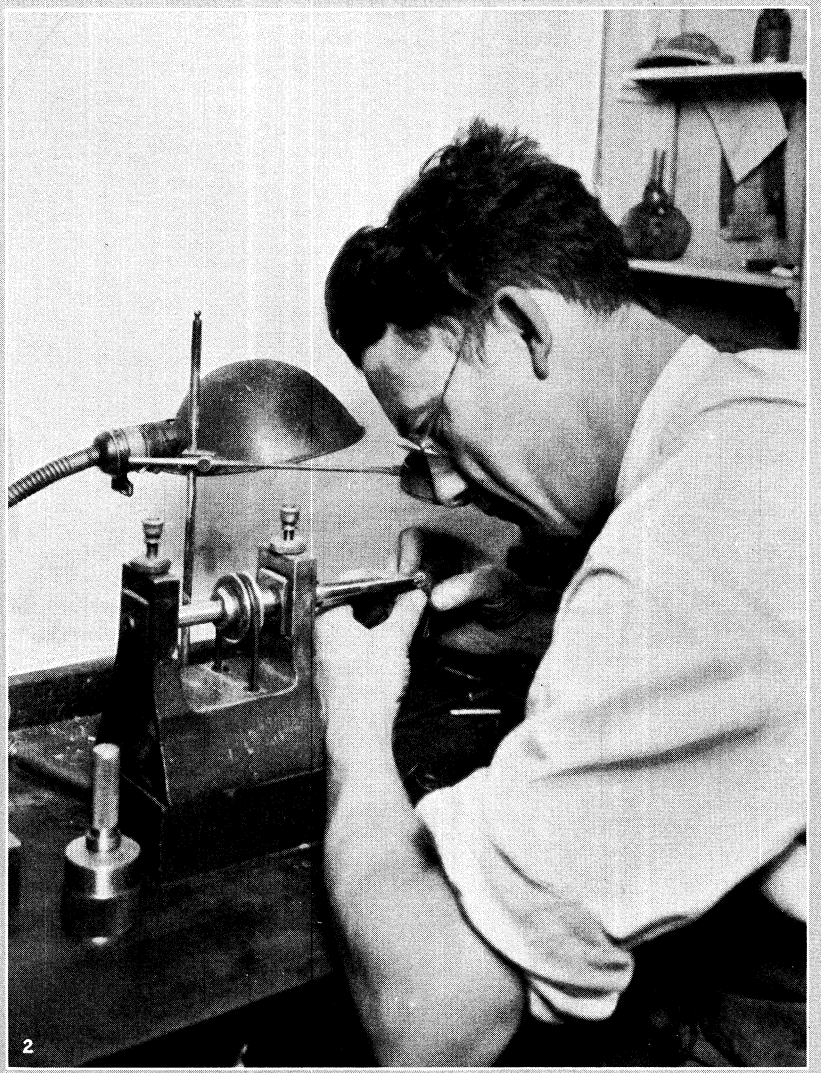
ETRUSCAN, ROMAN, EARLY CHRISTIAN, GNOSTIC, SASSANIAN, RENAISSANCE AND 19TH CENTURY GEMS

(ACTUAL SIZE. FROM PLASTER IMPRESSIONS, EXCEPT FIGS. 12–13)

1–4. ETRUSCAN: 1. Satyr. Banded agate, early 5th century. 2. Greeks emerging from the wooden horse of Troy. Carnelian scarab, early 5th century. 3. **Herakles and Nemean lion.** Banded agate, 5th century. 4. Horses. Carnelian, probably 4th century. 5–7. ROMAN, 3rd–1st CENTURY B.C.: 5. Eros. Brown glass paste. 6. Man working on prow of ship. Carnelian. 7. **Dioskouroi** at battle of Regillus. Carnelian. 8–11. ROMAN. 1st CENTURY B.C.–1st CENTURY A.D.: 8. **Portrait.** Carnelian. 9. Head of **Herakles,** signed by **Gnaios.** Blue beryl. 10. **Theseus.** Sard. 11. **Gryllos.** Carnelian. 12–13. CAMEOS: 12. **Bacchic** scene. Roman, Sardonyx. 13 Mars and Venus with cupid. Onyx, Renaissance middle of 16th century. LATE ROMAN, 2nd CENTURY A.D.: 14. Roma **holding** a victory.' Red jasper. 19th CENTURY: 15. Jason and Cheiron, inscribed **Kromos.** Carnelian. GNOSTIC: 16, Abraxas. Heliotrope. SASSANIAN: 17. Portrait. Carnelian. EARLY CHRISTIAN: 18. The Good Shepherd. Jasper





TECHNIQUE OF MODERN GEM ENGRAVING

1. Drills and chucks used with machines in modern gem-engraving. The cutting is done, not by the drills, but by the powder (diamond dust mixed with oil) which is rubbed on the stone with the drill

2. An engraver at work on a seal. The stone to be engraved is fastened to a handle. It is held to the head of the rotating drill and moved as the work requires

the two original characters appear in the next generation (F_2), in definite proportions. Mendel pointed out that these numerical relations could be understood if for any one pair it is assumed that the reproductive cells of the first two parents that were crossed each introduced into the hybrid an element representative of the character in question. He further assumed that these elements are sorted out in the germ-cells of the hybrid (without having contaminated each other) in such a way that each germ-cell (egg or sperm) carries one or the other of these elements. Chance fertilization of any egg by any sperm will give the numerical ratios found in the next (F_2) generation. No special functions or characteristics are assigned to these elements (genes) other than their power to divide, or at least to reproduce themselves and each to retain in the hybrid its specificity. All later work in genetics rests on these Mendelian postulates, but in the further development of the subject evidence has been found that makes it possible to locate the genes in the chromosomes and even to determine their relation there with respect to one another. For example, in the vinegar (or fruit) fly, Drosophila *melanogaster*, which has been more thoroughly examined than any other form, it has been found that the genes are inherited in great groups. They are said to be linked together. There are as many of these linkage groups as there are chromosome pairs. The members of one group usually remain united, but there may be occasional interchanges between the members of a group, always in an orderly fashion (crossing over). Such interchanges take place only between like linkage groups, *i.e.*, between each group derived from the father with that from the mother—never between different linkage groups. Crossing over has made it possible to determine the sequence of the genes within each group, and to get a rough measure of their distances apart, on the assumption that this distance apart determines the chance of crossing over between them. The mapping of the genes on this assumption has made it possible to predict accurately the behaviour of the genes in any known situation.

The localization of the genes in the chromosomes (which are material bodies easily visible under the microscope) has undoubtedly led to the conception of the genes as material particles lying in a single line in each chromosome. Whether they are so conceived or not does not affect the theory that the characters of the individual have representatives in the chromosomes that permit formulation of definite laws of heredity.

There is some further evidence concerning the relation of the genes of characters that is significant. While it is true that our knowledge concerning the gene has been determined by following the reappearance of single contrasted pairs of characters from one generation to the next, nevertheless there is abundant evidence that each gene may affect many characters at the same time; a study of any pair of which will lead to the same result. The genes then are thought of as fundamentally different from Weismann's determinants. In fact, there is reason to infer that every gene contributes to every part of the body, affecting some parts more than others, and the latter are only those that are picked out for convenience in studying heredity. As a corollary to this view there is the further inference, based on sufficient evidence, that the character of the individual is the result of a definite balance (or interaction) between the activities of the genes. If this balance is changed the end result is affected. This is most evident in the case of sex determination where the female is the result of one kind of balance and the male of another in animals and plants with separate sexes. Alterations in this balance, if not too extreme, may give rise to intersexes that stand in certain respects between the typical males and females. The balance also carries with it the tacit assumption of a normal environment. If the environment is altered the end result may be different. Thus in certain hermaphroditic plants, and perhaps also in animals, it is possible to suppress the development of one set of sexual organs by changing the outside influences (light, temperature, etc.). It is more questionable whether in the higher animals with separate sexes it is possible to change one sex into the other by alteration in the environment, although it has been demonstrated that by changing the internal environment (especially by altering the relation of the endocrine substances produced by the gonad or other glands having internal secretions), it is possible to change the secondary sexual organs of one sex into those of the other.

(T. H. M.)

GENEALOGY, a pedigree or list of ancestors. or the study of family history (from the Gr. γένος, family, and λόγος, theory).

Biblical Genealogies.—The aims and methods of ancient genealogists require to be carefully considered before the value of the numerous ancestral lists in the Bible can be properly estimated. Many of the old "genealogies," like those of Greece, have arisen from the desire to explain the origin of the various groups which they include. The subdivision of tribes, their relation to each other, the intermingling of populations and the like are thus frequently represented in the form of genealogies. The "sons" of a "father" often stand for the branches of a family as they existed at some one period, and since in course of time tribal relations would vary, lists will present discrepancies. Many of the Biblical names are nothing more than personifications of nations, tribes, towns, etc., grouped together to convey some idea of the bond by which they were believed to be connected. Thus we find among the "sons" of Japher: (the nations) Gomer, Javan, Tubai; Canaan "begat" Sidon and Heth; the "sons" of Ishmael include the well-known tribes Kedar and Jetur; Jacob, or the synonym Israel, personifies the "children of Israel." The recognition of this usage often furnishes an ethnological interpretation to those genealogical stories which obviously do not relate to persons, but to tribes or peoples personified. The Edomites and Israelites are regarded as "brothers" and since Esau (Edom) was born before Jacob (Israel) it would appear that the Edomites were held to be the older nation. The union of two clans is expressed as a marriage, or the wife is the territory which is dominated by the husband (tribe); see CALEB. If the woman is not of noble blood, but is a handmaiden or concubine, her children are naturally not upon the same footing as those of the wife; consequently the descendants of Ishmael, the son of Hagar (Sarah's maid), are inferior to Isaac and his descendants, whilst the children of Keturah, Abraham's concubine, are still lower—from the Israelite point of view. This application of the terms of relationship is characteristic of the Semites. The "father" of the Rechabites is their head or founder and a common bond, not necessarily physical, unites all "sons," whether they are "sons of the prophets" (members of prophetic guilds) or "sons of Belial" (worthless men).

Every case has to be judged upon its own merits, and allowance made both for the ambition of the weaker to claim or to strengthen an alliance with the stronger, and for the desire of clans or individuals to magnify the greatness of their ancestry. The first step must always be the careful comparison of related lists in order to test the consistency of the tradition. Next, these must be critically studied in the light of all available historical material, though indeed such evidence is not necessarily conclusive. Finally, (a) literary criticism must be employed to determine if possible the dates of such lists, since obviously a contemporary register is more trustworthy than one which is centuries later; (b) a critical estimate of the character of the names and of their use in various periods of Old Testament history is of importance in estimating the antiquity of the list—for example, many of the names in Chronicles attributed to the time of David are indubitably exilic or post-exilic; and (c) principles of ordinary historical probability are as necessary here as in dealing with the genealogies of other ancient peoples, and attention must be paid to such features as fluctuation in the number of links, representation of theories inconsistent with the growth of national life, schemes of relationship not in accordance with sociological conditions, etc. G. B. Gray's Hebrew Proper Names (1896), with his article in the Expositor (Sept. 1897), pp. 173–190, should be consulted for the application and range of Hebrew names in O.T. genealogies and lists.

The Biblical genealogies commence with "the generations of the heaven and earth," and by a process of elimination pass from Adam and Eve by successive steps to Jacob and to his sons (the tribes), and finally to the subdivisions of each tribe. According to this theory every Israelite could trace back his descent to Jacob, the common father of the whole nation. Such a scheme, however,

is full of manifest improbabilities. It demands that every tribe and every clan should have been a homogeneous group which had preserved its unity from the earliest times, that family records extending back for several centuries were in existence, and that such a tribe as Simeon was able to maintain its independence in spite of the tradition that it lost its autonomy in very early times (Gen. xlix. 7). The whole conception of the unity of the tribes cannot be referred to a date previous to the time of David, and in the older writings a David or a Jeroboam was sufficiently described as the son of Jesse or of Nebat. The genealogical zeal as represented in the Old Testament is chiefly of later growth, and the exceptions are due to interpolation (Josh. vii. 1 18, contrast v. 24), or to the desire to modify or qualify an older notice. This, in the case of Saul (1 Sam. ix. 1), has led to textual corruption; a list of such a length as his should have reached back to one of the "sons" of Benjamin (cf. *e.g.* Gen. xlvi. 21), else it were purposeless. The genealogies, too, are often inconsistent amongst themselves and in contradiction to their object. They show, for example, that the population of southern Judah, so far from being "Israelite" was half-Edomite (see JUDAH), and several of the clans in this district bear names which indicate their original affinity with Midian or Edom. Moreover, there was a free intermixture of races, and many cities had a Canaanite (*i.e.* pre-Israelite) population which must have been gradually absorbed by the Israelites (cf. Judg. i.). That spirit of religious exclusiveness which marked later Judaism did not become prominent before the Deuteronomic reformation and it is under its influence that the writings begin to emphasize the importance of maintaining the purity of Israelite blood, although by this time the fusion was complete (see Judg. iii. 6) and for practical purposes a distinction between Canaanites and Israelites within the borders of Palestine could scarcely be discerned.

Many of the genealogical data are intricate. Thus, the interpretation of Gen. xxxiv. is particularly obscure (see LEVITES ad fin.; SIMEON). As regards the sons of Jacob, it is difficult to explain their division among the four wives of Jacob; viz. (a) the sons of Leah are Reuben, Simeon, Levi and Judah (S. Palestine), Issachar and Zebulun (in the north), and Dinah (associated with Shechem); (b) of Leah's maid Zilpah, Gad and Asher (E. and N. Palestine); (c) of Rachel, Joseph (Manasseh and Ephraim, *i.e.*, central Palestine) and Benjamin; (d) of Rachel's maid Bilhah. Dan and Naphtali (N. Palestine). It has been urged that (b) and (d) stood upon a lower footing than the rest, or were of later origin; or that Bilhah points to an old clan associated with Reuben (Gen. xxxv. 22) or Edom (Bilhan, Gen. xxxvi. 27), whilst Zilpah represents an Aramaean strain. Tradition may have combined distinct schemes, and the belief that the wives were Aramaean at least coincides with the circumstance that Aramaean elements predominated in certain of the twelve tribes. The number "twelve" is artificial and can be obtained only by counting Manasseh and Ephraim as one or by omitting Levi, and a careful study of Old Testament history makes it extremely difficult to recover the tribes as historical units. See, on these points, the articles on the several tribes, B. Luther, *Zeit.* d. *alttest.* Wissens. (1901), pp. 1 sqq.; G. B. Gray, Expositor (March 1902), pp. 225–240, and in Ency. Bib., art. "Tribes"; and H. W. Hogg's thorough treatment of the tribes in the last-mentioned work.

The ideal of purity of descent shows itself conspicuously in portions of Deuteronomic law (Deut. vii. 1–3, xxiii. 2–8), and in the reforms of Nehemiah and Ezra. The desire to prove the continuity of the race, enforced by the experience of the exile, gave the impetus to genealogical zeal, and many of the extant lists proceed from this age when the true historical succession of names was a memory of the past. This applies with special force to the lists in Chronicles which present finished schemes of the Levitical divisions by the side of earlier attempts, with consequent confusion and contradiction. Thus the immediate ancestors of Ethan appear in the time of Hezekiah (2 Chron. xxix. 12), but he with Asaiah and Heman are contemporaries of David, and their genealogies from Levi downwards contain a very unequal number of links (1 Chron. vi.). By another application of genealogical method the account of the institution of priests and Levites by David (1 Chron. xxiv.) presents many names which belong solely to post-exilic days, thus suggesting that the scribes desired to show that the honourable families of their time were not unknown centuries previously. Everywhere we find the results of much skill and labour, often in accordance with definite theories, but a thorough investigation reveals their weakness and often quite incidentally furnishes valuable evidence of another nature.

The intricate Levitical genealogies betray the result of successive genealogists who sought to give effect to the development of the hierarchal system. The climax is reached when all Levites are traced back to Gershon, Kehath and Merari, to which are ascribed respectively Asaph, Heman and Ethan (or Jeduthun). The last two were not originally Levites in the later accepted sense of the term (see 1 Kings iv. 31). To Kehath is reckoned an important subdivision descended from Korah, but in 2 Chron. xx. 19 the two are distinct groups, and Korah's name is that of an Edomite clan (Gen. xxxvi. 5, 14, 18) related to Caleb, and thus included among the descendants of Judah (1 Chron. ii. 43). Cases of adjustment, redistribution and "Levitizing" of individuals are frequent. There are traces of varying divisions both of the singers (Neh. xi. 17) and of the Levites (Num. xxvi. 58; Ezr. ii. 40, iii. 9; 1 Chron. xv. 5–10, xxiii.), and it is noteworthy that in the case of the latter we have mention of such families as Hebroni (Hebronite), Libni (from Libnah)—ethnics of south Judaean towns. In fact, a significant number of Levitical names find their analogy in the lists of names belonging to Judah, Simeon and even Edom, or are closely connected with the family of Moses; *e.g.* Mushi (*i.e.*, Mosaïte), Gershon and Eleazar (cf. Gershom and Eliezer, sons of Moses). The Levites bear a class-name, and the genealogies show that many of them were connected with the minor clans and families of South Palestine which included among them Moses and his kin. Hence, it is not unnatural that Obed-edom, for example, obviously a southerner, should have been reckoned later as a Levite, and the work ascribed by the chronicler's history to the closing years of David's life may be influenced by the tradition that it was through him these mixed populations first attained importance.

In the time of Josephus every priest was supposed to be able to prove his descent, and perhaps from the time of Ezra downwards lists were carefully kept. But when Anna is called an Asherite (Luke ii. 36), or Paul a Benjamite (Rom. xi. 1), family tradition was probably the sole support to the claim, although the tribal feeling had not become entirely extinct. The genealogies of Jesus prefixed to two of the gospels are intended to prove that He was a son of David. But not that alone, for in Matt. i. He is traced back to Abraham the father of the Jews, whilst in Luke iii. He, as the second Adam, is traced back to the first man. The two lists are hopelessly inconsistent; not because one of them follows the line of Mary, but because they represent independent attempts. That in Matthew is characteristically arranged in three series of fourteen generations each through the kings of Judah, whilst Luke's passes through an almost unknown son of David; in spite of this, however, both converge in the person of Zerubbabel.

M'Lennan's *Studies* (2nd ser., ch. ix., "fabricated genealogies"); S. A. Cook, Ency. *Bib.* ii. col. 1657 sqq. (with references); W. R. Smith, *Kinship* and **Marriage** (2nd ed., especially ch. i.). (S. A. C.)

Modern.—Two forces have combined to give genealogy its importance during the period of modern history: the laws of inheritance, particularly those which govern the descent of real estate, and the desire to assert the privileges of a hereditary aristocracy. But it is long before genealogies are found in the possession of private families. The succession of kings and princes is in the chronicle book; the line of the founders and patrons of abbeys is recorded by the monks with curious embellishment of legend. But the famous suit of Scrope against Grosvenor will illustrate the late appearance of private genealogies in England. In 1385 Sir Richard Scrope, lord of Bolton, displaying his banner in the host that invaded Scotland, found that his arms of a golden bend in a blue field were borne by a knight of the Chester palatinate, one Sir Robert Grosvenor. He carried the dispute to a court of chivalry, whose decision in his favour was confirmed on appeal

to the king. Grosvenor asserted that he derived his right from an ancestor, Sir Gilbert Grosvenor, who had come over with the Conqueror, while an intervening claimant, a Cornish squire named Thomas Carminowe, boasted that his own ancestors had borne the like arms since the days of King Arthur's Round Table. It is remarkable that in support of the false statements made by the claimants no written genealogy is produced. The evidence of tombs and monuments and the reports of ancient men are advanced, but no pedigree is exhibited in a case which hangs upon genealogy. It is possible that the art of pedigree-making had its first impulse in England from the many genealogies constructed to make men familiar with the claims of Edward III. to the crown of France, a second crop of such royal pedigrees being raised in later generations during the contests of York and Lancaster. But it is not until after the close of the middle ages that genealogies multiply in men's houses and are collected into volumes. The mediaeval baron, knight or squire, although proud of the nobility of his race, was content to let it rest upon legend handed down the generations. The exact line of his descent was sought only when it was demanded for a plea in the king's courts to support his title to his lands.

From the first the work of the genealogist in England had that taint of inaccuracy tempered with forgery from which it has not yet been cleansed. The mediaeval kings, like the Welsh gentry of later ages, traced their lines to the household of Eden garden, while lesser men, even as early as the 14th century, eagerly asserted their descent from a companion of the Conqueror. Yet beside these false imaginations we find the law courts, whose business was often a clash of pedigrees, dealing with genealogies centuries long which, constructed as it would seem from worthy evidences, will often bear the test of modern criticism.

Genealogies in great plenty are found in manuscripts and printed volumes from the 16th century onward. Remarkable among these are the descents recorded in the Visitation Books of the heralds, who, armed with commissions from the crown, the first of which was issued in 20 Hen. VIII., perambulated the English counties, viewing arms and registering pedigrees. The notes in their register books range from the simple registration of a man's name and arms to entries of pedigrees many generations long. To the heralds these visitations were rare opportunities of obtaining fees from the visited, and the value of the pedigrees registered is notably unequal. Although it has always been the boast of the College of Arms that Visitation records may be produced as evidence in the law courts, few of these officially recorded genealogies are wholly trustworthy. Many of the officers of arms who recorded them were, even by the testimony of their comrades, of indifferent character, and even when the visiting herald was an honourable and industrious man he had little time to spare for the investigation of any single genealogy. Deeds and evidences in private hands may have been hastily examined in some instances—indeed, a herald's summons invites their production—and monuments were often viewed in the churches, but for the most part men's memories and the hearsay of the country-side made the backbone of the pedigree. The further the pedigree is carried beyond the memory of living men the less trustworthy does it become. The principal visitations took place in the reigns of Elizabeth, James I., Charles I. and Charles II. No commission has been issued since the accession of William and Mary, but from that time onwards large numbers of genealogies have been recorded in the registers of the College of Arms, the modern ones being compiled with a care which contrasts remarkably with the unsupported statements of the Tudor heralds.

Outside the doors of the College of Arms genealogy has now been for some centuries a favourite study of antiquaries, whose researches have been of the utmost value to the historian, the topographer and the biographer. County histories, following the example of Dugdale's Warwickshire folios, have given much space to the elucidation of genealogies and to the amassing of material from which they may be constructed. Dugdale's great work on the English baronage heads another host of works occupied with the genealogy of English noble families, and the second edition of "G.E.C.'s" *Complete Peerage* shows the mighty advance of the modern critical spirit. Nevertheless, the 20th century has not yet seen the abandoning of all the genealogical fables nourished by the Elizabethan pedigree-mongers, and the ancestry of many noble houses as recorded in popular works of reference is still derived from mythical forefathers. Thus the dukes of Norfolk, who, by their office of earl marshal are patrons of the heralds, are provided with a 10th century Hereward for an ancestor; the dukes of Bedford, descendants of a 15th century burgess of Weymouth, are traced to the knightly house of Russell of Kingston Russell, and the dukes of Westminster to the mythical Gilbert le Grosvenor who "came over in the train of the Conqueror."

Genealogical research has, however, made great advance during the last generation. The critical spirit shown in such works as Round's *Studies* in *Peerage and Family History* (1901) has assailed with effective ridicule the methods of dishonest pedigree-makers. Much raw material of genealogy has been made available for all by the publication of parish registers, marriage-licence allegations, monumental inscriptions and the like, and above all by the mass of evidences contained in the volumes issued by the Public Record Office.

Within a small space it is impossible to set forth in detail the methods by which an English genealogy may be traced. But those who are setting out upon the task may be warned at the outset to avoid guesswork based upon the possession of a surname which may be shared by a dozen families between whom is no tie of kinship. A man whose family name is Howard may be presumed to descend from an ancestor for whom Howard was a personal name: it may not be presumed that this ancestor was he in whom the dukes of Norfolk have their origin. A genealogy should not be allowed to stray from facts which can be supported by evidence. A man may know that his grandfather was John Stiles who died in 1850 at the age of fifty-five. It does not follow that this John is identical with the John Stiles who is found as baptized in 1795 at Blackacre, the son of William Stiles. But if John the grandfather names in his letters a sister named Isabel Nokes, while the will of William Stiles gives legacies to his son and daughter John Stiles and Isabel Nokes, we may agree that reasonable proof has been given of the added generation. A new pedigree should begin with the carefully tested statements of living members of a family. The next step should be to collate such family records as Bible entries, letters and diaries, and inscriptions on mourning rings, with monumental inscriptions of acknowledged members of the family. From such beginnings the genealogist will continue his search through the registers of parishes with which the family has been connected; wills and administrations registered in the various probate courts form, with parish registers, the backbone of most middle-class family histories. Court rolls of manors in which members of the family were tenants give, when existing and accessible, proofs which may carry back a line, however obscure, through many descents. When these have been exhausted the records of legal proceedings, and notably those of the court of chancery, may be searched. Few English households have been able in the past to avoid an appeal to the chancery court, and the bill and answer of a chancery plaintiff and defendant will often tell the story of a family quarrel in which a score of kinsfolk are involved; the pleadings may contain the material for a family tree of many branching generations. Coram Rege and De Banco rolls may even, in the course of a dispute over a knight's fee or a manor carry a pedigree to the Conquest of England, although such good fortune can hardly be expected by the searcher out of an undistinguished line. In proving a genealogy it must be remembered that in the descent of an estate in land must be sought the best evidence for a pedigree.

At the present time the study of genealogy grows rapidly in English estimation. It is no less popular in America, where societies and private persons have of late years published a vast number of genealogies, many of which combine the results of laborious research in American records with extravagant and unfounded claims concerning the European origin of the families dealt with. A family with the surname of Cuthbert has been known to hail St. Cuthbert of Lindisfarne as its progenitor, and one surnamed Eberhardt has incorporated in its pedigree such German princes of old

times as were found to have Eberhardt for a Christian name.

Genealogy in modern France has, with a few honourable exceptions, fallen into the hands of the popular pedigree-makers, whose concern is to gratify the vanity of their employers. Italy likewise has not yet shaken off the influence of those venal genealonists who, three hundred years ago, sold pedigrees cheaply to all comers. But much laborious genealogical inquiry had been made in Germany since the days of Hiibner, and even in Russia there was some attempt to apply modern standards of criticism to the chronicles of the swarming descendants of the blood of Rurik.

In no way is the gap made by the dark ages between ancient and modern history more marked than by the fact that no European family makes a serious claim to bridge it with its genealogy. The unsupported claim of the Roman house of Massimo to a descent from Fabius Maximus is respectable beside such legends as that which made Lévis-Mirepoix head of the priestly tribe of Levi, but even the boast of such remote ancestry has now become rare. The ancient sovereign houses of Europe are, for the most part, content to attach themselves to some ancestor who, when the mist that followed the fall of the Western empire begins to lift, is seen rallying with his sword some group of spearmen.

BIBLIOGRAPHY.—Genealogical works have been published in such abundance that the bibliographies of the subject are already substantial volumes. Amongst the earlier books from the press may be noted Benvenuto de San Georgio's *Montisferrati marchionum et principum regiae propagium successionumque series* (1515); Pingonius's *Arbor gentilitiae Sabaudiae Saxoniaeque domus* (1521); Gebweiler's *Epitome regii ac vetustissimi ortus Caroli V. et Ferdinandi I., omniumque archiducum Austriae et comitum Hübsburgiensium* (1527); Meyer's work on the counts of Flanders (1531), and Du Boulay's genealogies of the dukes of Lorraine (1547). Later in the same century Reineck of Helmstadt put forth many works having a wider genealogical scope, and we may cite Henninges's *Genealogiae Saxonicae* (1587) and *Theatrum genealogicum* (1598), and Reusner's *Opus genealogicum catholicum* (1589–1592). For the politically inconvenient falseness of François de Rosières's *Stemmata Lotharingiae ac Barri ducum* (1580), wherein the dukes of Lorraine were deduced from the line of Charlemagne, the author was sent to the Bastille by the *parlement* of Paris and his book suppressed.

The 17th century saw the production in England of Dugdale's great *Baronage* (1675–1676), a work which still holds a respectable place by reason of its citation of authorities, and of Sandford's history of the royal house. In the same century André Duchesne, the historian of the Montmorencys, Pierre d'Hozier, the chronicler of the house of La Rochefoucauld, Rittershusius, Imhoff, Spener, Lohmeier and many others contribute to the body of continental genealogies. Pierre de Guibours, known as Père Anselme de Ste Marie, published in 1674 the first edition of his magnificent *Histoire gtntalogique de la maison royale de France, des pairs, grands officiers de la couronne et de la maison du roy et des anciens barons du royaume*. Of this encyclopaedic work a third and complete edition appeared in 1726–1733. A modern edition under the editorship of M. Potier de Courcy began to be issued in 1873, but remains incomplete. Among 18th-century work Johann Hiibner's *Bibliotheca genealogica* (1729) and *Genealogische Tabellen* (1725–1733), with Lenzen's commentary on the latter work (*c.* 1756), may be signalized, with Gatterer's *Handbuch der Genealogie* (1761) and his *Abriss der Genealogie* (1788), the latter an early manual on the science of genealogy. Hergott's *Genealogia diplomatica augustae gentis Habsburgicae* (1737) is the imperial genealogy compiled by the emperor's own historiographer.

Modern peerages in England may be said to date from that of Arthur Collins, whose one-volume first edition was published in 1709. The fifth edition appeared in 1778, in eight volumes, to be republished in 1812 by Sir Egerton Brydges, the "Baptist Hatton" of Disraeli's novel, who corrected many legendary pedigrees, besides inserting his own forged descent from a common ancestor with the dukes of Chandos. From this work and from the Irish peerage of Lodge (as re-edited by Archdall) most of the later peerages have quarried their material. With these may be named the baronetages of Wotton and Betham. Of modern popular peerages and baronetages that of Burke has been published since 1822 in many editions and now appears yearly. Most important for the historian are the *Complete Peerage* of G. E. C[ockayne] (2nd ed., 1910), and the *Complete Baronetage* of the same author. The *Peerage of Scotland* (1769) of Sir Robert Douglas of Glenbervie came to a second edition in 1813, edited by J. P. Wood, and the whole work has been revised and re-edited by Sir James Balfour Paul (1904, etc.). Of the popular manuals of English untitled families, Burke's *Genealogical and Heraldic Dictionary of the Commoners* (1833–1838) is now brought up to date from time to time and reissued as the *Landed Gentry*.

Lists of pedigrees in English printed works are supplied by Marshall's *Genealogist's Guide* (1903), while pedigrees in the manuscript collections of the British Museum are indexed in the list of R. Sims (1849). Valuable genealogical material will be found in such periodicals as the *Genealogist*, the *Herald and Genealogist*, the *Topographer and Genealogist*, *Collectanea topographica et genealogica*, *Miscellanea genealogica et heraldica* and the *Ancestor*. In Germany the *Deutscher Herold* is the organ of the Berlin Heraldic and Genealogical Society. The *Nederlandsche Leeuw* is a similar publication.

Modern criticism of the older genealogical methods will be found in J. H. Round's *Peerage and Pedigree*, 2 vols. (London, 1910), and in other volumes by the same author. The Harleian Society has published many volumes of the Herald's Visitations; and the British Record Society's publications, supplying a key to a vast mass of wills, chancery suits and marriage licences, are of still greater importance. The *Victoria History of the Counties of England* includes genealogies of the ancient English county families still among the land-owning classes. English pedigrees before the Conquest are in W. G. Searle's *Anglo-Saxon Bishops, Kings and Nobles* (1899).

Genealogical dictionaries of noble French families include Victor de Saint Allais's *Nobiliaire universel* (21 vols., 1872–1877) and Aubert de la Chenaye-Desbois' *Dictionnaire de la noblesse* (15 vols., 1863–1876). A sumptuous work on the genealogy and heraldry of the ancient duchy of Savoy by Count Amédée de Foras began to appear in 1863. Spain has Lopez de Haro's *Nobiliario genealogico de los reyes y títulos de España*. Italy has the *Teatro araldico* of Tettoni and Saladini (1841–1848), Litti's *Famiglie celebri* and an *Annuario della nobilità*. Such annuals are now published more or less intermittently in many European countries. Finland has a *Ridderscap och Adels Kalender*, Belgium the *Annuaire de la noblesse*, the Dutch Netherlands an *Adelsboek*, Denmark the *Adels-Garbog* and Russia had the *Annuaire* of Ermerin. But chief of all such publications is the ancient *Almanach de Gotha*, containing the modern kinship of royal and princely houses, and now accompanied by volumes dealing with the houses of German and Austrian counts and barons, and with houses ennobled in modern times by patent. A useful modern reference book for students of history is Stokvis's *Manuel d'histoire et de généalogie de tous les états du globe* (1888–1893). The best manual for the English genealogist is Walter Rye's *Records and Record Searching* (1897). G. Gatfield'sbibliography (1892) is helpful. (O. B.)

Data for American genealogies may be found in the *New England Historical and Genealogical Register; New York Genealogical and Biographical Record; Genealogical Magazine of New Jersey; Publications of the Genealogical Society of Pennsylvania; Mayflower Descendant: New Haven Genealogical Magazine; William and Mary College Quarterly; Maryland Historical Magazine; Virginia Magazine of History and Biography; South Carolina Historical and Genealogical Magazine; Nebraska and Midwest Genealogical Record; Utah Genealogical and Historical Magazine; National Genealogical Society Quarterly; Americana; Vineland Historical Magazine; Magazine of American Genealogy; Lineage Books of the Daughters of the Am. Rev.*

GENÉE, ADELINE (1878–), Danish dancer, was born at Aarhus, Jutland, and began to study her steps when a child. After appearing in Berlin, Copenhagen and Paris, she came to London. The precision and technical perfection of her dancing made her a great favourite. For many seasons she was *première danseuse* at the Empire, London. She was in America in 1908–13.

GENERAL, a term which, from its pointing to all or most of the members of a class, the whole of an area, etc., as opposed to "particular" or to "local," is hence used in various shades of meaning for that which is prevalent, usual, widespread, or miscellaneous, indefinite, vague (Lat. *generalis*, of or relating to a *genus*, kind or class). It has been added to the titles of various officials, military officers and others; thus the head of a religious order is the "superior-general," more usually the "general," and we find the same combination in such offices as that of "accountant-general," "postmaster-general," "attorney-" or "(solicitor-general," and many others, the additional word implying that the official in question is of superior rank, as having a wider authority or sphere of activity. This is the use that accounts for the application of the term, as a substantive, to a military officer of superior rank, a "general officer," or "general," who commands or administers bodies of troops larger than a regiment, or consisting of more than one arm of the service (*see* also OFFICERS). It was towards the end of the 16th century that the word began to be used in its present sense as a noun, and in the armies of the time the "general" was commander-in-chief, the "lieutenant-general" commander of the horse and second in command of the army, and the "major-general" (strictly "sergeant-major-general") commander of the foot and chief of the staff. Field marshals, who have now the highest rank, were formerly subordinate to the general officers. These titles—general, lieutenant-general and major-general—are still applied in most armies to the first, second and third grades of general officer. It may be noted that during the 17th century "general" was not confined to a commanding

officer of an army, and was also equivalent to "admiral"; thus when under the Protectorate the office of lord high admiral was put into commission, the three first commissioners, Blake, Edward Popham and Richard Deane, were styled "generals at sea."

GENERAL AVERAGE: *see* AVERAGE.

GENERAL ELECTRIC COMPANY. The largest electrical manufacturing concern in the world, whose existence dates from 1878 with the founding of the Edison Electric Light Company by Thomas A. Edison. In 1892, that company's successor merged with the Thomson-Houston Electric Company to form the General Electric Company. The company is incorporated in New York and its principal office is at Schenectady, New York.

The company has no funded debt or notes payable outstanding. It has a continuous record of cash dividend payments since 1899.

In 1892, the total capital investment of the company was about $46,000,000 and at the beginning of 1939 it was $324,000,000. Sales increased from $12,000,000 in 1892 to $415,000,000 in 1929 and in 1939 were $305,000,000. Its manufacturing floor space increased from 400,000 to more than 25,000,000 sq.ft., while the average number of employees grew from 4,000 to a peak of 88,000 in 1929, and was 63,000 in 1939. These figures do not include those of its affiliated companies, the latter being included in investments valued at $141,000,000.

In the United States the company has over 20 main manufacturing plants, is represented by distributors in all important cities and has sales offices in all trade centres. The Canadian General Electric Co., Ltd., operates throughout Canada. The export and foreign business is conducted by the International General Electric Co., Inc., which is represented throughout the world.

The General Electric Company maintains fully a dozen laboratories, including the research laboratory (known as the "House of Magic") at Schenectady, N.Y. General Electric and its affiliated companies design, manufacture, and sell almost every form of apparatus and device for the generation, transmission, distribution, control, measurement, and consumption of electric energy.

(C. E. WI.)

GENERAL ELECTRIC COMPANY, LTD., a British joint stock company, covers in its operations the entire field of electrical engineering, from the equipment of the largest generating stations, power transmission systems, railway electrifications tnd the like down to lamps, bells and the small electrical accessories used in domestic service.

The foundations of the present company were laid in 1886 with a small London establishment for the supply of electrical apparatus. With electric lighting a commercial success, a new department was established, and the "G.E.C.," as it is familiarly known, has developed. In the early eighteen-nineties the lamp works, the source of Osram lamps, were incorporated, followed by glass works for the conversion of the raw material at Lemington.

In 1900 42 acres of land were purchased at Witton, Birmingham, for the erection of works for the making of dynamos, motors, conduit tubes, etc., followed soon after by the purchase of a further 63 acres, partly for works extensions and partly for a housing estate for the employees. The arc-lamp carbon works established at this time on this site, the only one of its kind in Great Britain, subsequently played an important part in the World War.

While the war was in progress the G.E.C. made further extensions in many directions, chiefly at the instance of the Government and in 1928 was a self-contained enterprise, covering every department of electrical manufacture. The nominal capital of the company is nearly £10,000,000, all of which is share capital. There are no debentures. The profits in 1939 exceeded £1,775,000.

GENERAL MOTORS CORPORATION, incorporated in Delaware Oct. 13, 1916 to succeed a New Jersey company with a similar name formed Sept. 16, 1908, for the purpose of manufacturing automotive equipment, is primarily an operating organization owning the assets of manufacturing divisions. It also owns a large part or all of the stock of a number of subsidiary and affiliated companies directly connected with its activities. Its products include Chevrolet, Pontiac. Oldsmobile, Buick, La Salle and Cadillac passenger cars, all with body by Fisher; Chevrolet trucks and commercial cars, General Motors trucks, General cabs and Yellow coaches; such parts and accessories as AC spark plugs, speedometers, air cleaners and oil filters, Delco hydraulic shock absorbers, Delco-Remy batteries, ignition and starting systems. Harrison heaters and radiators, Hyatt roller bearings, Inland steering wheels, and New Departure ball bearings; also Delco-Light electric plants and water systems, Delco-Heat oil-fired boilers, burners and furnaces; Frigidaire refrigeration and air conditioning equipment; Winton Diesel and gasoline engines and Electro-Motive Diesel-electric power plants for locomotives and streamlined trains. Outstanding capital stock on March 31, 1940 consisted of 1,875,366 shares of $5 series preferred stock, no par value, with a declared value of $187,536,600; and 43,500,000 shares of common stock, $10 par value. There were no bonds.

The corporation has plants in more than 60 cities in the United States and elsewhere. In 1939 it built and sold 1,727,086 cars and trucks. The total number of cars and trucks sold outside the United States and Canada in that year was 331,146. General Motors products are sold by approximately 25.000 dealers in more than 100 countries. In 1925 the corporation made one in every five cars produced in the U.S.A. and Canada; in 1926 one in every four; in 1927 and subsequent years, about one in three. Total sales in 1939 were $1,376,828,337; total wages were more than $386,000,000; average number of employees, 220,000.

(A. P. SL.)

GENERAL STRIKE. The strike weapon (or stoppage of work, in the sense of withdrawal of labour) is usually employed for the purpose of securing an improvement in working conditions; it is often used to resist reductions of wages or addition to working hours, though in such a dispute the stoppage is usually a "lock-out." Many strikes are confined to individual factories or workshops. Others extend to towns or areas; and some to industries on a national scale, like coal mining or cotton manufacture. If all industries combined in stoppage that would form a national or general strike; but in practice no country has ever had, in the strictly comprehensive sense, a general strike. At best, stoppages have varied greatly in range and effect. And the broad experience of two centuries in Great Britain is roughly similar to that of practically all the industrial countries of the world.

It indicates that there is no easily identified body of theory or practice bearing on the general strike. In their *History of* Trades *Unionism*, Mr. and Mrs. Sidney Webb noted three different methods which during that period the trade unions had adopted for enforcing the common rules they wished to have adopted in the conditions of employment: (1) mutual insurance; (2) legal enactment; and (3) after 1824, collective bargaining. In the last 20 or 30 years, up to 1914, both the great strikes and the gradual changes of the period have been regarded as of less importance than the series of legal decisions of the House of Lords as final court of appeal.

Towards the end of the first quarter of last century there was considerable industrial strife; it included an almost general lock-out in Glasgow, a strong combination of seamen on the north-east coast, and the enforcement of many by-laws by the Dublin trades, then better organized than others in Great Britain. Joseph Hume and Francis Place pleaded for moderation. They warned the unions of the danger of reaction. But ship-owning interests, among others, at that time generally hostile to unionism, pressed for parliamentary inquiry into the conduct of workmen and the effect of recent legislation. Many of the employers suggested the complete abolition of trade unionism; others would have made even friendly societies impossible.

A more definite form of strike action is traceable in the revolutionary period or that of the new unionism between 1829 and 1842. Appreciating the weakness of isolated action, or effort on a purely craft basis, many trade union leaders attempted to form national societies of all trades; they also urged that all manual workers should belong to one comprehensive organization. When a six months' strike at Hyde, near Manchester, failed, there mas immediate support for the view that no local union could succeed against a combination of employers. Succeeding conferences advocated central executives for different industries; and in the tase of the cotton spinners a grand general council of the United King-

dom was established, although the records of its representative character as covering the three kingdoms are incomplete. From such projects emerged the greater ambition of the trades union; that is, a national association representative of all classes of wage-earners whose large-scale organizations would be able to face considerable strain both in strike and lock-out. But such machinery was at this point impressive only on paper; the employers were generally victorious; and the admittedly prejudiced report of Nassau Senior supplied fresh material for the opponents of trade unionism, particularly in arguments regarding restraint of trade. Ultimately the Grand National Consolidated Trades Union (1833–34, see ROBERT OWEN) collapsed; and not even an increasing economic prosperity brought success to strikes promoted in the interests of better conditions of labour. In the summer of 1834 federal organizations were plainly in process of disintegration, later, the membership turned in part to consideration of Owenite social reform. Nor did the considerable industrial dislocation of 1842 merit the description of a general strike. Much of the activity of the period was bound up with Chartist agitation; at one point the trade union movement was almost submerged in political effort. But many trade union leaders came to disapprove of this economic-political association, and when, in that year, the Chartist executive at Manchester called for a general strike to obtain the charter, local trade union officials were active in persuading their members to avoid both the meetings and the resolutions.

Decline of the General Strike Idea.—In the next quarter of a century there was much gradual building up of large amalgamated societies of skilled artisans, with centralized administration, friendly society benefits, and substitution of industrial diplomacy for the cruder methods of class warfare. Between 1843 and 1860 trade unions were regarded as largely successful in achieving their more limited aims; in any event, of the aggressive policy of 1830–34 little remained. Strikes were deprecated; there was practically no trace of argument in favour of a general cessation of work. At a national conference in 1845 trade unionists declared their support of a new method of trade union activity in conciliation or arbitration. So quickly, however, did circumstances change in the trade depression of 1845 that the next two years were remarkable for reduction of wages, strikes and lock-outs (or turn-outs) in many branches of industry. Generally speaking, these stoppages proved disastrous for the workers; there was much complaint regarding the weakness of their central executives and committees. In the midst of this dislocation representative trade unionists were constantly urging the importance of timely words with the employers in the interest of pacific settlement. The weapon of the strike, in the sense of declaring war on the employers, was during these years of crisis taken away from many of the local branches; a local lodge had usually to submit its demand to a vote of the whole body of members throughout Great Britain, a procedure which involved delay and gave central committees an opportunity to work for peace. But Mr. and Mrs. Webb emphasize the fact that although most of the executive committees were from 1845 always setting their faces against strikes, that did not imply the abandonment of an energetic trade policy. This period, and succeeding periods, like their predecessors, included a bewildering variety of movements for organization on a national basis, usually ending in failure; minor or local stoppages; threats of general lock-out in the whole industry, as in the case of the engineering trade; and the growth and progress of large national trade societies like the Amalgamated Society of Engineers. From 1857 there was another period of strife. As before, the weakness of trade union organization was plain; in the 1859–60 strikes the masons alone of the building trades were regarded as effectively organized into a single society extending throughout England.

Most of the authorities regard the distinctive policy of the Junta, the committee which largely regulated union policy from 1860–70, as the combination of extreme caution in trade matters and energetic agitation for political reforms. About this period permanent trades councils appear in the leading industrial centres, an important step in the consolidation of the trade union movement. In early times every important strike had been supported by committees of sympathizers in other trade societies; they collected subscriptions and rendered other assistance. The London trades council began in a strike committee; the earlier and purely emergency committee gave way by 1860 to permanent councils in many of the large centres of population. In June 1866 delegates representing all the leading trade unions met at Sheffield to devise a method of defence against the constant use of the lock-out. The conference does not appear to have decided what constituted a lock-out as distinguished from a strike; there was certainly much friction among the individual organizations. The royal commission which investigated trade union problems at this period presented an inconclusive and inconsistent report. Succeeding years were full of similar sectional activity. The miners and cotton operatives achieved certain victories in legislation; trade unions had on occasion the support of several organs of the press; in some parts of the country stoppages for specific objects were successful; but throughout all this effort important organizations were regularly emphasizing the futility of the strike weapon. That attitude is particularly true of the central executive of the Amalgamated Society of Engineers. In tendering evidence to the royal commission in 1867 it remarked that all strikes were a complete waste of money, not only in relation to the workmen but also to the employers. The period 1873–74 is regarded as one of the high water marks in trade union history; but the immediately succeeding years include strikes on a large scale. The conflict in the cotton industry in 1878 ended in failure for the workmen. Almost immediately a general collapse of trade union forces began; it proved to be impossible to resist reductions in wages and increases in hours. Conflicting policy within the unions led to considerable weakness; their general machinery was clearly inadequate; and attempts at federation achieved only limited success.

The General Strike of 1926.—Such ebb and flow, characteristic of the remainder of the 19th century and of the first part of the present century until the outbreak of the World War, produced no definite theory or practice of the general strike. Certain stoppages were more comprehensive than others; the measure of support accorded by trade unions to their colleagues in the industries affected varied very considerably; and for the crisis of 1926 there was no effective preparation or precedent. That stoppage has been described by the general council of the trades union congress as a "national" rather than a "general" strike. Pending the report of a royal commission appointed to enquire into the condition of coal-mining the British Government in 1925 gave temporary subsidy, amounting to £23,000,000 in all, for the purpose of enabling the industry to tide over the intervening period. The detailed report of the general council of the congress summarizing events leading to the stoppage definitely suggests that the Miners' Federation of Great Britain, following the breakdown of negotiations, committed the future conduct of the dispute to the general council. Of great importance, this point is clearly stated in a letter of May 1, 1926 to the prime minister and signed by the acting secretary of the trades union congress. Early on May 3, 1926, the Government intimated that in their belief no solution of the difficulties in the coal industry which was both practicable and honourable to all concerned could be reached except by acceptance of the report of the royal commission. Prior to the continuance of the negotiations the Government called for the repudiation of a certain strike action (in the *Daily Mail* buildings), together with immediate and unconditional withdrawal of the instructions for a general strike. The T.U.C. general council pleaded that the action on the part of the members of the *Daily Mail* staff had been taken entirely without their authority. The trade unions had made no preparations for a stoppage on a large scale, and at once protested against Government's suggestions.

It was urged that the Government were in this case less mediators than a directly interested party, even before the negotiations broke down. In the opinion of the general council the position adopted by the Government in their ultimatum left only two alternatives, (1) the capitulation of the Government or (2) the termination of the strike by a process of attrition. By the general council the first was regarded as unlikely, in view of the national resources over which the Government had control. The second

was an alternative which the general council could not contemplate, on the ground that it would disorganize the trade union movement, completely establish reactionary elements in the country, and kill any possibility of getting fair consideration of the miners' case. By this time the national strike, as it afterwards was described by the T.U.C., or general strike as it was described by others, was in progreis, Informal meetings with Sir Herbert Samuel, who had acted as chairman of the royal commission, produced a formula which was recommended by the trades union congress for the acceptance of the Miners' Federation. Its proposals commended themselves to the council, but were rejected by the miners; and, finally appreciating that the deadlock was complete, the general council decided to issue notices terminating the strike. They pleaded that in view of all the facts known to them they felt it to be in accordance with the instructions they had received from the conference of trade union executives that the strike should be terminated with the maximum of advantage both to the miners and to the other trade unions; on that ground it was important that a decision should be reached while the unions remained strong and well disciplined. On the one hand, the miners rejected the Samuel memorandum, regarded by the general council of the trades union congress as an equitable basis for settlement; on the other. the general council pleaded its responsibility to trade unionism in general, contending that it could not follow the miners' executive in a policy of mere negation, that such a course would permit the splendid response of the sympathetic strike to disappear in process of attrition, bring the unions to bankruptcy, undermine the morale of their membership, destroy their capacity to resist attempts which might be made to impose adverse conditions, and to discriminate against the membership when the industries directly engaged in the strike resumed operations. This decision to end the strike was unanimous, and some months later the policy of the general council was approved by an overwhelming majority in a conference of trade union executives called to hold the "inquest" on the strike.

Why the **1926** Strike Failed.— Broadly speaking, the events of 1926 suggest that the difficulties of organizing a successful general strike are almost overwhelming. In Great Britain at least 15,000,000 people are definitely engaged in industrial and commercial pursuits. But trade union organization covered little more than 5,000,000 at the time of the strike; of that 5,000,000, 1,500,000 are estimated to have taken part, plus rather more than 1,000,000 in the coal-mining industry not at work. The aggregate response was small, even among people to be regarded as sympathetic, The direct cost to the State, placed in a supplementary estimate at £433,000, was far below what the maintenance of essential services was regarded as certain to involve; the volume of voluntary assistance was remarkable. The indirect cost is more difficult to measure; but £50,000,000 or £60,000,000 has been suggested. For industry as a whole the loss was undoubtedly much more substantial. But such loss does not involve immediate pressure on the community; the advantage to the strikers for purely strike purposes is therefore much reduced. On the other hand, the resources of the unions are speedily exhausted. The general strike cost the National Union of Railwaymen at least £1,000,000. In addition to assistance rendered directly by other unions the trades union congress was able to allocate from subscriptions more than £63,000 to the Miners' Federation. To a special fund promoted for the Miners' Federation, more than £93,000 was contributed. Impressive as these sums were, they were small in comparison with the need. At the end of 1925 the total membership of British trade unions was 4,447,818; the preliminary figures for 1926, the year of crisis, showed a loss of 300,000. Moreover, the general strike involved the heaviest expenditure in dispute pay ever experienced by registered trade unions in any one year. In consequence, their funds were reduced from £12,750,000 to a little more than £8,500,000. Only in 1921, when they disbursed £7,000,000 in unemployment pay, have trade unions suffered such inroads on their resources.

Although the printing and allied trades ceased work, the Government and private effort were able to organize a press service which speedily reached a considerable section of the people; compared with the publications in the interests of the strike it had an undeniable advantage Tens of thousands of volunteers facilitated food trains, lorries, and kindred provision; the milk pool in Hyde Park covered the metropolitan area and actually showed a profit of £73,000 at the end of the stoppage. Special constabulary were increased from 98,000 to 226,000; nearly half a million volunteers were enrolled; and increasing transport provision was further augmented by Admiralty resources in the carriage of mails and other urgent traffic. Naval ratings secured the operation of electricity works in important centres, including 28 power stations in London By May 10, more than 3,600 trains were running; considerable numbers of men had returned to work; a day later, Woolwich arsenal employees decided to return; and men engaged in the shipbuilding and engineering trades, who had been called out, made only partial response. British financial strength was fully maintained; and there was no suggestion of panic. All the facts indicate that a strike on a national scale is now exceedingly difficult to maintain, chiefly because (1) there is no guarantee of more than very limited response to the strike call by the workers themselves; (2) the remarkable growth of motor and other transport proves that alternative service, chiefly of voluntary character, can be readily mobilized; (3) essential services, such as gas, water and electricity, can be covered by Admiralty and War Office resources, at all events in the larger centres of population; and (4) there is nowhere that complete paralysis of effort which, in all theory of the general strike, has always been regarded as essential to its speedy success. Economic alternatives are now such that even a much larger stoppage than that of 1926 could be worn down in comparatively short time, especially as the strain on the resources of the unions would be immediately much greater than that of those of the State. And since leading transport unions on the conclusion of the strike signed agreements undertaking not to call a stoppage in future before negotiation with the railway companies and other employers, as well as the fact that the Trades Disputes Act of 1927 is now on the Statute Book, any large scale strike is apparently remote. *(See* DIRECT ACTION.) (W. GR.)

Arnot, *The General Strike, 2* separate vols. (1926–27).

The General Strike in the United States and **Canada.**— The trade union movement in the United States and Canada has neither used nor advocated the general strike. Only the Industrial Workers of the World, arisen in 1905 as a protest by socialists and syndicalists against the conservatism of the established unions, preached but was too weak to practice the general strike.

Nevertheless during the war and immediately after, general strike propaganda penetrated deeply into western American unions. The Seattle general strike of 60.000 workers called Feb. 6, 1919 by the city labour council, was ended Feb. 11 without obtaining its objective of helping shipyard workers on strike to gain wage increases. The Winnipeg strike called May 15, 1919 by the city central body in support of metal trades unionists striking for recognition and wage increases, lasted six weeks and involved 25,000 workers. Even civil servants joined the walkout and the police force nas discharged for strike sympathies.

Since 1919 there have been three general strikes, one in San Francisco in July 1934, another in Terre Haute, Indiana, in July 1935, and a third in Pekin, Illinois, in Feb. 1936.

The San Francisco strike developed from a longshoremen's strike, when employers began to operate the docks by force, and the California National Guard was called out. The general strike lasted for four days during which time the General Strike committee lessened the severity of the strike by allowing restrictions to be removed from street railways, food trucks, restaurants, and the food. gasoline and fuel oil industries. The A. F. of L. disclaimed any connection with the strike. The U.S. Bureau of Labor Statistics distinguishes the general strike from the "general industry

strike." The latter describes a strike called by a national or international union for an entire industry, whereas the general strike is one called in unison by all the local unions of a community. The general industry strike has occurred more frequently than has the general strike. A recent large scale general industry strike was the general bituminous coal strike of 1939 involving over 500,000 miners. (See STRIKES AND LOCK-OUTS: United States.) (S. PE.)

GENERATION, the act of procreation or begetting, hence any one of the various methods by which plants, animals or substances are produced (Lat. *generare*). The subject may be divided into the following branches, viz.: (1) the first origin of life and living beings, (2) non-sexual or agamic reproduction, and (3) gamic or sexual reproduction. For the first two of these branches see ABIOGENESIS, BIOGENESIS and PARTHENOGENESIS; for the third and more extensive division, including (1) the formation and fecundation of the ovum, and (2) the development of the embryo in different animals, see REPRODUCTION and EMBRYOLOGY.

GENERATIONS, ALTERNATION OF. The alternating phases—particularly the sexual and asexual changes—which take place in successive generations of animals and plants. In plants gamotophytes alternate with sporophytes, the latter being asexual, this phenomenon being found in all plants except certain lower forms in which sporophytes are absent. It is well exemplified in mosses and ferns. Among animals the alternation of generations takes several forms. The broods of butterflies and moths differ in colour at certain seasons. In flat worms or trematodes, and insects such as Phylloxera, heterogenesis—the succession of a parthenogetically produced generation by a dioecious—takes place. See REPRODUCTION, BRYOPHYTA, PTERIDOPHYTA, GYMNOSPERMS, PROTOZOA, COELENTERATA, PLATYHELMINTHES, ANNELIDA.

GENERATOR: see ELECTRIC GENERATOR.

GENESIS, the name of the first book in the Bible, derives its title from the Septuagint rendering of ch. ii. 4. It is the first of the five books (the Pentateuch), or, with the inclusion of Joshua, of the six (the Hexateuch), which cover the history of the Hebrews to their occupation of Canaan. The "genesis" or "becoming" (*i.e.*, coming into being) of history begins with records of antediluvian times: the creation of the world, of the first pair of human beings, and the origin of sin (i.–iii.), the civilization and moral degeneration of mankind, the history of man to the time of Noah (iv.–vi. 8), the flood (vi. 9–ix.), the confusion of languages and the divisions of the human race (x.–xi). Turning next to the descendants of Shem, the book deals with Abraham (xii.–xxv. 18), Isaac and Jacob (xxv. 19–xxxv.), the "fathers" of the tribes of Israel, and concludes with the personal history of Joseph, and the descent of his father Jacob (or Israel) and his brethren into the land of Egypt (xxxvii.–l.). The book of Genesis, as a whole, is closely connected with the subsequent oppression of the sons of Israel, the revelation of Yahweh the God of their fathers (Ex. iii. 6, 1; seq., vi. 2–8), the "exodus" of the Israelites to the land promised to their fathers (Ex. xiii. 5, Deut. i. 8, xxvi. 3 *sqq.*, xxxiv. 4) and its conquest (Josh. i. 6, xxiv.); cf. also the summaries Neh. ix. 7 sqq., Ps. cv. 6 sqq. For an analysis of the contents see the commentaries.

Its **Compositeness.**—Only on the assumption that the book of Genesis is a composite work is it possible to explain the duplication of events, the varying use of the divine names Yahweh and *Elōhīm*, the linguistic and stylistic differences, the ipternal intricacies of the subject matter, and the differing standpoints as regards tradition, chronology, morals and religion. The cumulative effect of the whole evidence is too strong to be withstood, and already in the 17th century it was recognized that the book was of composite origin. Immense labour has been spent upon the critical analysis of the contents, but it is only since the work of Graf (1866) and Wellhausen (1878) that a literary hypothesis has been found which explains the most obvious intricacies. The Graf-Wellhausen literary theory has gained the assent of almost all trained and unbiased biblical scholars; it has not been shaken by the more recent light from external evidence, and no alternative theory has as yet been produced. According to this, Genesis is a post-exilic work composed of a post-exilic priestly source (P) and non-priestly earlier sources which differ markedly from P in language, style and religious standpoint, but much less markedly from one and another. These sources can be traced elsewhere in the Pentateuch and Joshua, and P itself is related to the post-exilic works Chronicles, Ezra and Nehemiah. In its present form Genesis is an indispensable portion of the biblical history, and consequently its literary growth cannot be viewed apart from that of the books which follow. On internal grounds it appears that the Pentateuch and Joshua, as they now read, virtually come in between an older history by "Deuteronomic" compilers (easily recognizable in Judges and Kings), and the later treatment of the monarchy in Chronicles, where the influence of the circle which, produced P and the present Mosaic legislation is quite discernible. There have been stages where earlier extant sources have been cut down, adjusted or revised by compilers who have incorporated fresh material, and it is the later compilers of Genesis who have made the book a fairly knit whole. The technical investigation of the literary problems (especially the extent of the earlier sources) is a work of great complexity, and, for ordinary purposes, it is more important to obtain a preliminary appreciation of the general features of the contents of Genesis.

Value.—That the records of the pre-historic ages in Gen. i.–xi. are at complete variance with modern science and archaeological research is unquestionable. But although it is impossible to regard them any longer either as genuine history or as subjects for an allegorical interpretation (which would prove the accuracy of any record) they are of distinct value as human documents. They reflect the ideas and thoughts of the Hebrews, they illustrate their conceptions of God and the universe, and they furnish material for a comparison of the moral development of the Hebrews with that of other early races. Some of the traditions are closely akin to those current in ancient Babylonia, but a careful and impartial comparison at once illustrates in a striking manner the relative moral and spiritual superiority of our writers. On these subjects see COSMOGONY; DELUGE; PARADISE; and HEBREW RELIGION.

The records of the patriarchal age, xii.–l. are very variously estimated, although the great majority of scholars agree that they are not contemporary and that they cannot be used as they stand, for pre-Mosaic times. Apart from the ordinary arguments of historical criticism, it is to be noticed that external evidence does not support the assumption that the records preserve genuine pre-Mosaic history. There are no grounds for any arbitrary distinction between the "pre-historic" pre-Abrahamic age and the later age. External evidence, which recognizes no universal deluge and no dispersal of mankind in the third millennium B.C., throws its own light upon the opening centuries of the second. It has revealed conditions which are not reflected in Genesis, and important facts upon which the book is silent—unless, indeed, in Gen. xiv., there is a passing allusion to the great Babylonian monarch Khammurabi in the name Amraphel (see article ABRAHAM). A perusal of modem attempts to recover historical facts or historical outline from the book will show how very inadequate the material proves to be, and the reconstructions will be found to depend upon an interpretation of the narratives which is often liberal and not rarely precarious, and to imply such reshaping and rewriting of the presumed facts that the cautious reader can place little reliance on them. Whatever future research may bring, it cannot remove the internal peculiarities which combine to show that Genesis preserves, not literal history, but popular traditions of the past. External evidence has proved the antiquity of various elements, but not that of the form or context in which they now appear; and the difference is an important one. We have now a background upon which to view the book, and, on the one hand, it has become obvious that the records preserve (as is only to be expected) oriental customs, beliefs and modes of thought. But it has not been demonstrated that these are exclusively pre-Mosaic. On the other hand, a better acquaintance

with the ancient political, sociological and religious conditions has made it increasingly difficult to interpret the records as a whole literally, or even to find a place in pre-Mosaic Palestine for the lives of the patriarchs as they are depicted. Nevertheless though one cannot look to Genesis for the history of the early part of the second millennium B.C., the study of what was thought of the past, proves in this, as in many other cases, to be more instructive than the facts of the past, and it is distinctly more important for the biblical student and the theologian to understand the thought of the ages immediately preceding the foundation of Judaism in the 5th century B.C. than the actual history of many centuries earlier.

Characteristics.—A noteworthy feature is the frequent personification of peoples, tribes or clans. (See GENEALOGY.) Midian (*i.e.*, the Midianites) is a son of Abraham; Canaan is a son of Ham (ix. 22), and Cush the son of Ham is the father of Raamah and grandfather of the famous S. Arabian State Sheba and the traders of Dedan (x. 6 *sq.*, *cf.* Ezek. xxvii. 20–22). Bethuel the father of Rebekah is the brother of the tribal names Uz and Buz (xxii. 21 seq., cf. Jer. xxv. 20, 23). Jacob is otherwise known as Israel and becomes the father of the tribes of Israel; Joseph is the father of Ephraim and Manasseh, and incidents in the life of Judah lead to the birth of Perez and Zerah, Judaean clans. This personification is entirely natural to the oriental, and though "primitive" is not necessarily an ancient trait (cf. 1 Chron. iv. 10). It gives rise to what may be termed the "prophetical interpretation of history" (S. R. Driver Genesis, p. 111), where the character, fortunes or history of the apparent individual are practically descriptive of the people or tribe which, according to tradition, is named after or descended from him. The utterance of Noah over Canaan, Shem and Japheth (ix. 25 seq.), of Isaac over Esau and Jacob (xxvii.), of Jacob over his sons (xlix.) or grandsons (xlviii.), would have no meaning for Israelites unless they had some connection with and interest for contemporary life and thought. Herein lies the force of the description of the wild and independent Ishmael (xvi. 12), the "father" of certain well-known tribes (xxv. 13–15); or the contrast between the skilful hunter Esau and the quiet and respectable Jacob (xxv. 27), and between the tiller Cain who becomes the typical nomad and the pastoral Abel (iv. 1–15). The interest of the struggles between Jacob and Esau lay, not in the history of individuals of the distant past, but in the fact that the names actually represented Israel and its near rival Edom. These features are in entire accordance with oriental usage and give expression to current belief, existing relationships, or to a poetical foreshadowing of historical vicissitudes. But in the effort to understand them as they were originally understood, it is very obvious that this method of interpretation can be pressed too far. It would be precarious to insist that the entrances into Palestine of Abraham and Jacob (or Israel) typified two distinct immigrations. The separation of Abraham from Lot (cf. Lotan, an Edomite name), of Isaac from Hagar-Ishmael, or of Jacob from Esau-Edom scarcely points to the relative antiquity of the origin of these non-Israelite peoples who, to judge from the evidence, were closely related. Or, if the "sons" of Jacob had Aramaean mothers, to prove that those which are derived from the wives were upon a higher level than the "sons" of the concubines is more difficult than to allow that certain of the tribes must have contained some element of Aramaean blood (*cf.* 1 Chron, vii. 14, and see ASHER; GAD; MANASSEH, TRIBE OF). Some names are clearly not those of known clans or tribes (*e.g.*, Abraham, Isaac), and many of the details of the narratives obviously have no natural ethnological meaning. Stories of heroic ancestors and of tribal eponyms intermingle; personal, tribal and national traits are interwoven. The entrance of Jacob or Israel with his sons suggests that of the children of Israel. The story of Simeon and Levi at Shechem is clearly not that of two individuals, sons of the patriarch Israel; in fact the story actually uses the term "wrought folly in Israel" (cf. Jud. xx. 6, 10), and the individual Shechem, the son of Hamor, cannot be separated from the city, the scene of the incidents. Yet Jacob's life with Laban has many purely individual traits. And, further, there intervenes a remarkable passage with an account of his conflict with the divine being who fears the dawn and is unwilling to reveal his name. In a few verses the "wrestling" (*ʿ-b-k*) of Jacob (*yaʿăkōb*) is associated with the Jabbok (*yabbōk*); his "striving" explains his name Israel; at Peniel he sees "the face of God," and when touched on his vulnerable spot (the hollow of the thigh) he is lamed, hence "the children of Israel eat not the sinew of the hip which is upon the hollow of the thigh unto this day" (xxxii. 24–32). Other examples of the fusion of different features can be readily found. Three divine beings appear to Abraham at the sacred tree of Hebron, and when the birth of Isaac (from *ṣāḥaḳ*, "laugh") is foretold, the account of Sarah's behaviour is merely a popular and trivial story suggested by the child's name (xviii. 12–15; see also xvii. 17, xxi. 6, 9). An extremely fine passage then describes the patriarch's intercession for Sodom and Gomorrah, and the narrative passes on to the catastrophe which explains the Dead Sea and its desert region and has parallels elsewhere (*e.g.*, the Greek legend of Zeus and Hermes in Phrygia). Lot escapes to Zoar, the name gives rise to the pun on the "little" city (xix. 20), and his wife, on looking back, becomes one of those pillars of salt which still invite speculation. Finally the names of his children Moab and Ammon are explained by an incident when he is a cave-dweller on a mountain.

To primitive minds which speculated upon the "why and wherefore" of what they saw around them, the narratives of Genesis afforded an answer. They preserve, in fact, some of the popular philosophy and belief of the Hebrews. They furnish what must have been a satisfactory origin of the names Edom, Moab and Ammon, Mahanaim and Succoth, Bethel, Beersheba, etc. They explain why Shechem, Bethel and Beersheba were ancient sanctuaries (see further below); why the serpent writhes along the ground (iii. 14); and why the hip sinew might not be eaten (xxxii. 32). To these and a hundred other questions the national and tribal stories (of which no doubt only a few have survived, and of which other forms, earlier or later, more crude or more refined, were doubtless current) furnish an evidently adequate answer. Myth and legend, fact and fiction, the common stock of oral tradition, have been handed down, and thus constitute one of the most valuable sources for popular Hebrew thought.

The book is not to be judged from any one-sided estimate of its contents. By the side of much that seems trivial, and even nonmoral (for the patriarchs themselves are not saints) it is noteworthy how frequently the narratives are didactic. The characteristic sense of collective responsibility, which appears more incidentally in xx. 7, is treated with striking intensity in a passage (xviii. 23–33) which uses the legend of Sodom and Gomorrah as a vehicle for the statement of a familiar problem (cf. Ezek. xviii., Ps. lxxiii., Job). It will be observed that interviews with divine beings presented as little difficulty to the primitive minds of old as to the modern native; even the idea of intercourse of supernatural beings with mortals (vi. 1–4) is to-day equally intelligible. The modern untutored native has a not dissimilar undeveloped and childlike attitude towards the divine, a naïve theology and a simple cultus. The most circumstantial tales are told of imaginary figures, and the most incredible details clothe the lives of the historical heroes of the past. So abundant is the testimony of modern travellers to the extent of which Eastern custom and thought elucidate the interpretation of the Bible, that it is very important to notice those features which illustrate Genesis. "The oriental," writes S. I. Curtiss (Bibl. Sacra, Jan. 1901, pp. 103 *sqq.*), "is least of all a scientific historian. He is the prince of story-tellers; narratives, real and imaginative, spring from his lips, which are the truest portraiture of composite rather than individual oriental life, though narrated under forms of individual experience." There are, therefore, many fundamental facts which combine to show that the critical student cannot isolate the book from oriental life and thought; its uniqueness lies in the manner in which the material has been shaped and the use to which it has been put.

Questions of Date.—The Book of Jubilees (not later than *c.* 100 B.C.) presents the history in another form. It retains some of the canonical matter, often with considerable reshaping; it omits

many details (especially those to which exception could be taken), and adds much that is novel. The chronological system of the latest source in Genesis becomes an elaborate reckoning of heavenly origin. Written under the obvious influence of later religious aims, it is especially valuable because one can readily compare the two methods of presenting the old traditions. The Book of Jubilees (*q.v.*) also enables the student to test the arguments based upon any study restricted to Genesis alone. Thus it shows that the "primitive" features of Genesis afford a criterion which is sociological rather than chronological. This is often ignored. For example, the conveyance of the field of Machpelah (xxiii.) is conspicuous for the absence of any reference to a written contract in contrast to the "business" methods in Jer. xxxii. This does not prove that Gen. xxiii. is early, because writing was used in Palestine about 1400 B.C., and, on the other hand, the more simple forms of agreement are still familiar after the time of Jeremiah (*e.g.,* Ruth, Proverbs). Similarly, no safe argument can be based upon the institution of blood-revenge in Gen. iv., when one observes the undeveloped conditions among the Trachonites of the time of Herod the Great (Josephus, *Ant.* xvi. 9, 1), or the varying usages among modern tribes. In the Book of Jubilees there is the same kind of personification; there are fresh examples of the "prophetical interpretation of history," and by the side of the older "primitive" thought are ideas which can only belong to this later period. In each case we have merely a selection of current traditional lore. For example, Gen. vi. 1–4 mentions the marriage of divine beings with the daughters of men and the birth of Nephilim or giants (cf. Num. xiii. 33). Later allusions to this myth (*e.g.,* Baruch iii. 26–28, Book of Enoch vi. sqq., 2 Peter ii. 4, etc.) are not based upon this passage: the fragment itself is all that remains of a more complete written myth. Old myths underlie the account of the Creation and the garden of Eden, and traces of other versions or forms appear elsewhere in the Old Testament. Again, the Old Testament throws no light upon the redemption of Abraham (Is. xxix. 22), although the Targums and other sources profess to be well-informed. The isolated reference to Jacob's conquest of Shechem in Gen. xlviii. 22 must have belonged to another context, and later writings give in a later and thoroughly incredible form allied traditions. In Hosea xii. 4, Jacob's wrestling is mentioned before the scene at Bethel (Gen. xxxii. 24 sqq., xxviii. 11 sqq.). The overthrow of Sodom and Gomorrah is described in Genesis (xviii. seq.), but Hosea refers only to that of Admah and Zeboim (xi. 8, cf. Deut. xxix. 23, Gen. x. 19)—different versions of the great catastrophe were doubtless current. Consequently investigation must start with the particular details which happen to be preserved, and these not necessarily in their original or in their only form. Since the antiquity of elements of tradition is independent of the shape in which they appear before us, a careful distinction must be drawn between those details which do not admit of being dated or located and those which do. There is evidence for the existence of the *names* Abram, Jacob and Joseph in early times, but this does not prove the antiquity of the present narratives encircling them.

Historical Backgrounds. — Popular tradition often ignores events of historical importance, or, as repeated experience shows, will represent them in such a form that the true historical kernel could never have been recovered without some external clue. The absence of definite references to the events of the Israelite monarchy does not necessarily point to the priority of the traditions in Genesis or their later date. Nevertheless, some allusion to national fortunes is reflected in the exaltation of Jacob (Israel) over Esau (Edom), and in the promise that the latter should break the yoke from his neck; later writers (in the Targums) bring this up-to-date. Israelite kings are foreshadowed (xvii. 6, xxxv. 11 P), and Israel's kingdom has the ideal limits as ascribed to Solomon (xv. 18, see I. Kings iv. 21; but cf. art. SOLOMON). Judah is promised a world-wide king (xlix. 8–10), though elsewhere the supremacy of Joseph rouses the jealousy of his "brothers" (xxxvii. 8). Different dates and circles of interest are thus manifest. The cursing and dispersion of Simeon and Levi (xlix. 5–7) recall the fact that Simeon's cities were in the territory of Judah (Josh. xix. 1, 9), and that the Levitical priests are later scattered and commended to the benevolence of the Israelites. But the curse obviously represents an attitude quite opposed to the blessing pronounced upon Levi by Moses (Deut. xxxiii. 8–11). The Edomite genealogies (xxxvi.) represent a more extensive people than the references in the popular stories suggest, and the latter by no means indicate that Edom had so important a career as we actually gather from a few allusions to its kings (xxxvi. 31–39). The references to Philistines are anachronistic for the pre-Mosaic age, and it is clear that the tradition of a solemn covenant with a Philistine king and his general (xxi. 22 seq., xxvi. 26 seq.) does not belong to the age or the circle which remembered the heavy oppressions of the Philistines. Similarly, the treatment of the covenant by the author of Jubilees (xxiv. 28 sqq.) is only intelligible when one recalls the attitude of Judah to the Philistine cities in the 2nd century B.C. Finally, the thread of the tradition unmistakably represents a national unity of the 12 sons (tribes) of Israel; but this unity was not felt at certain periods of disorganization, and the idea of including Judah among the sons of Israel could not have arisen at a time when Israel and Judah were rival kingdoms. Thus in the original text of 2 Sam. xix. 43 the men of Israel claim to be the first-born rather than Judah; cf. also I. Chron. v. 1 sq. where Joseph obtains the birth-right. In so far as the traditions can be read in the light of biblical history it is evident that they belong to different ages and represent different national, tribal, or local standpoints.

Religious Interests. — Noteworthy is the interest taken in sacred sites. Certain places are distinguished by theophanies or by the erection of an altar (lit. place of sacrificial slaughter). *Mizpah* in Gilead is the scene of a covenant or treaty between Jacob and his Aramaean relative conimemorated by a pillar (*Maṣṣēbah*). It was otherwise known for an annual religious ceremony, the traditional origin of which is related in the story of Jephthah's vow and sacrifice (Judg. xi.), and its priests are denounced by Hosea (v. 1). *Shechem,* the famous city of the Samaritans ("the foolish nation," Ecclus I. 50, 26), where Joseph was buried (Josh. xxiv. 32), had a sanctuary and a sacred pillar and tree. It was the scene of the coronation (a religious ceremony) of Abimelech (Judg. ix.), and Rehoboam (I. Kings xii. 1). The pillar was ascribed to Joshua (Josh. xxiv. 26 seq.), and although Jacob set up at Shechem an "altar," the verb suggests that the original object was a pillar (Gen. xxxiii. 20). The first ancestor of Israel, on the other hand, is merely associated with a theophany at an oracular tree (xii. 6). The Benjamite *Bethel* was especially famous in Israelite religious history. The story tells how Jacob discovered its sanctity (it was the gate of heaven), made a covenant with its God, established the sacred pillar, and instituted its tithes (xxviii.). The prophetess Deborah dwelt under a palm-tree near Bethel (Judg. iv. 5), and her name is also that of the foster-mother of Rebekah who was buried near Eethel beneath the "oak of weeping" (xxxv. 8). *Bochim* ("weeping") elsewhere receives its name when an angel appeared to the Israelites (Judg. ii. 1, Septuagint adds Bethel). To the prophets Hosea and Amos the cultus of Bethel was heathen and immoral, even though it was Yahweh himself who was worshipped there (see BETHEL). South of Hebron lay Beersheba, an important centre and place of pilgrimage, with a special numen by whom oaths were taken (Amos viii. 14, sed Sept. and cf. the commentaries). Isaac built its altar, and Isaac's God guarded Jacob in his journeying (xxxi. 29, xlvi. 1). This patriarch and his "brother" Ishmael are closely associated with the district south of Judah; both are connected with *Beer-lahai-roi* (xxiv. 62, Sept. xxv. 11), whose fountain was the scene of a theophany (xvi.). Their traditions are thus localized in the district of Kadesh, famous in the events of the Exodus (cf. xvi. 14, xxi. 21, xxv. 18, Ex. xv. 22). Abraham planted a sacred tree at Beersheba and invoked "the everlasting God" (xxi. 33). But the patriarch is more closely identified with Hebron, which had a sanctuary (cf, 2 Sam. xv. 7 seq.), and an altar which he built "unto Yahweh" (xiii. 18). The sacred oak of Mamre was famous in the time of Josephus (B. J. iv. 9, 7), it was later a haunt of "angels" (Sozomen), and Constantine was obliged to put down the heathenish cultus. The place still has its holy tree. Beneath the oak there appeared the three di-

vine beings, and in the cave of Machpelah the illustrious ancestor and his wife were buried. There is a distinct tendency to emphasize the importance of Hebron. Taken from primitive giants by the non-Israelite clan Caleb (*q.v.*) it is predominant in the patriarchal traditions. Jacob leaves his dying father at Beersheba (xxviii. 10), but according to the latest source he returns to him at Hebron (xxxv. 27), and here, north of Beersheba, he continues to live (xxxvii. 14, xlvi. 1–5). The cave of Machpelah became the grave of Isaac, Rebekah and Leah (but not Rachel); and though Jacob appears to be buried beyond the Jordan, it is the latest source which places his grave at Hebron (l. 1–11 and 12 seq.). So in still later tradition, all the sons of Jacob with the exception of Joseph find their last resting-place at Hebron, and in Jewish prayers for the dead it is besought that their souls may be bound up with those of the patriarchs, or that they may go to the cave of Machpelah and thence to the Cherubim. The increasing prominence of the old Calebite locality is not the least interesting phase in the comparative study of the patriarchal traditions.

The association of the ancestors of Israel with certain sites is a feature which finds analogies even in modern Palestine. There are old centres of cult which have never lost the veneration of the people; the shrines are known as the tombs of saints or *welis* (patrons) with such orthodox names as St. George, Elijah, etc. Traditions justify the reputation for sanctity, and not only are similar stories told of distinct figures, but there are varying traditions of a single figure. Genesis preserves a selection of traditions relating to a few of the old Palestinian centres of cult. We cannot suppose that these first gained their sacred character in the pre-Mosaic "patriarchal" age; there is in any case the obvious difficulty of bridging the gap between the descent into Egypt and the Exodus; and it is clear that when the Israelites entered Palestine they came among a people whose religion, tradition and thought were fully established. It is only in accordance with analogy if stories were current in Israel of the institution of the sacred places, and closer study shows that we do not preserve the original version of these traditions.

A venerated tree in modern Palestine will owe its sanctity to some tradition, associating it, it may be, with some saint; the Israelites in their turn held the belief that the sacred tree at Hebron was one beneath which their first ancestor sat when three divine beings revealed themselves to him. But it is noteworthy that Yahweh alone is now prominent; the tradition has been revised, apparently in writing, and, later, the author of Jubilees (xvi.) ignores the triad. At Beer-lahai-roi an El ("god") appeared to Hagar, whence the name of her child Ishmael; but the writer prefers the unambiguous proper name Yahweh, and, what is more, the divine being is now Yahweh's angel—the Almighty's subordinate (xvi.). The older traits show themselves partly in the manifestation of various *Els*, and partly in the cruder anthropomorphism of the earlier sources. Later hands have by no means eliminated or modified them altogether, and in xxxi. 53 one can still perceive that the present text has endeavoured to obscure the older belief that the God of Abraham was not the God of his "brother" Nahor (see the commentaries). The sacred pillar erected by Jacob at Bethel was solemnly anointed with oil, and it (and not the place) was regarded as the abode of the Deity (xxviii. 18, 22). This agrees with all that is known of stone-cults, but it is quite obvious that this interesting example of popular belief is far below the religious ideas of the writer of the chapter in its present form. There were many places where it could be said that Yahweh had recorded his name and would bless his worshippers (Ex. xx. 24). They were abhorrent to the advanced ethical teaching of prophets and of those imbued with the spirit of Deuteronomy (cf. ii. Kings xviii. 4 with v. 22), and it is patent from Jeremiah, Ezekiel and Is. lvi.–lxvi. that even at a late date opinion varied as to how Yahweh was to be served. It is significant, therefore, that the narratives in Genesis (apart from P) reflect a certain tolerant attitude; there is much that is contrary to prophetical thought, but even the latest compilers have not obliterated all features that, from a strict standpoint, could appear distasteful. Although the priestly source shows how the lore could be reshaped, and Jubilees represents later efforts along similar lines, it is evident that for ordinary readers the patriarchal traditions could not be presented in an entirely new form, and that to achieve their aims the writers could not be at direct variance with current thought.

Southern Interests.—There is relatively little tradition from north Israel; Beersheba, Beer-lahai-roi and Hebron are more prominent than even Bethel or Shechem, and there are no stories of Gilgal, Shiloh or Dan. Yet in the nature of the case there must have been a great store of local tradition accessible to some writers and at some periods. Interest is taken not in Phoenicia, Damascus or the northern tribes, but in the east and south, in Gilead, Ammon, Moab and Ishmael. Particular attention is paid to Edom and Jacob, and there is good evidence for a close relationship between Edomite and allied names and those of south Palestine (including Simeon and Judah). Especially significant, too, is the interest in traditions which affected the south of Palestine, that district which is of importance for the history of Israel in the wilderness and of the Levites. It is noteworthy therefore, that while different peoples had their own theories of their earliest history, the first-born of the first human pair is Cain, the eponym of the Kenites, and the ancestor of the beginnings of civilization (iv. 17, 20–22). This "Kenite" version had its own view of the institution of the worship of Yahweh (iv. 26); it appears to have ignored the Deluge, and it implies the existence of a fuller corpus of written tradition. Elsewhere, in the records of the Exodus, there are traces of specific traditions associated with Kadesh, Kenites, Caleb and Jerahmeel, and with a movement into Judah, all originally independent of their present context. Like the prominence of the traditions of Hebron and its hero Abraham, these features are not fortuitous, though the problems they bring cannot be discussed here (see Camb. *Anc.* History, ii. 359 *sqq.*, iii. 472 sqq., vi. 185 seq.).

Bibliography.—S. R. Driver's commentary (Westminster Series) deals thoroughly with all preliminary problems of criticism, and is the best for the ordinary reader; Dillmann (6th ed., E. trans.) is technical, Ryle (Cambridge Bible) and Bennett (Century Bible) more popular. Spurrell, Notes on the Text of *Genesis*, and Ball (in Haupt's Sacred Books of the O. T.) appeal to Hebrew students. Addis, Documents of the Hexateuch, Carpenter and Harford-Battersby, *The Hexateuch*, and C. F. Kent, Beginnings of Hebrew History, are important for the literary analysis. J. Wellhausen's sketch in his *Proleg.* to *Hist.* of Israel (E. trans., pp. 259–342) is admirable, as also is the general intro. (trans. by W. H. Carruth, 1907) to Gunkel's valuable commentary. Fuller bibl. informaticn will be found in the works already mentioned, in the articles in the Ency. Bib. (G. F. Moore), and Hastings's *Dict.* (G. A. Smith), and in the fine volume by J. Skinner in the *International* Critical Series. (S. A. C.)

GENET, EDMOND CHARLES (1763–1834), French minister plenipotentiary to the United States in 1793, was born on Jan. 8, 1763, at Versailles. He was for a time attached to the embassy at Berlin and later to the embassy at Vienna; and at the age of 18, following his father's death, succeeded him as secretary interpreter at the ministry of foreign affairs. In 1787 he was sent to the embassy at St. Petersburg where he remained until July 1792, when his liberal views made him persona non grata. After a brief stay in Paris, where he came more fully under the influence of the Revolution, "citizen" Genet was sent as French minister to the Congress of the United States. He was assuming a position which would require much tact, but his impetuous nature combined with the ovations accorded him by the Democratic-Republicans, led him into misjudging public opinion regarding American neutrality. His activities in instigating military operations against the Spanish possessions of Florida and Louisiana and against Canada, the fitting out of privateers in American ports, his acrimonious debates with the Federal Government and his caustic attacks on the president, demonstrate conclusively his lack of diplomacy. Genet's threat to override the executive by appealing to the people caused Washington to ask the French republic to recall its representative. His successor, "citizen" Fauchet, brought orders to arrest him and send him back to France for trial, but Washington refused to permit the extradition. He subsequently became a naturalized American citizen. In 1794 he married Cornelia Tappen Clinton, daughter of the governor of New York and in 1814, four years after the death of his first wife, married Martha Brandon Osgood, daughter of the first postmaster general. He died on July 14, 1834.

Genet, *Washington, Jefferson and "Citizen" Genet 1793* (privately printed 1899); *Report 1896* (1897) and *Report 1897* (1898) of the American Historical Association; *The American Historical Review* vol. iii. (1898); and *Mississippi Valley Historical Review* vol. vi.

GENET, a south European carnivorous mammal referable to the Viverridae or family of civets, but also taken to include several allied species from Africa. The true genet (*Genetta genetta*) occurs throughout the south of Europe and in Palestine, as well as North Africa. The fur is of a dark-grey colour, thickly spotted with black, and having a dark streak along the back, while the tail, which is nearly as long as the body, is ringed with black and white. It frequents the banks of streams and feeds on small mammals and birds. It differs from the true civets in that the anal pouch is a mere depression and contains only a faint trace of the characteristic odour of the former.

COMMON GENET (GENETTA VULGARIS)

GENETICS, a term coined by Bateson to designate that portion of biology concerned with heredity, variation, development and evolution. It is the science which seeks to account for the resemblances and the differences which are exhibited among organisms related by descent. Its problems are those of the cause, the material basis, and the method of maintenance of the specificity of germinal substance; in other words, "how the characters of parents and offspring are related, how those of the adult lie latent in the egg, and how they become patent as development proceeds." Its methods are those of observation, experimental breeding, cytology and experimental morphology. Its prosecution demands a knowledge of general physiology and of mathematics. It has both scientific and practical application: its principles impinge upon all doctrines of evolution and upon agricultural, animal and plant breeding practices. Its possible applications to human affairs have created the need for and the development of the applied science of eugenics (*q.v.*).

Out of the accumulated facts of genetical experimentation, there has been developed the theory of the gene (*q.v.*) intended to accommodate these facts. It states (1) that the hereditary characters of the individual are referable to paired elements (the genes) in the germinal material (the chromosomes, *q.v.*) which are held together in a definite number of linkage groups; (2) that the members of each pair of genes separate when the germ-cells mature in accordance with Mendel's first law, and that in consequence each ripe germ-cell comes to contain one set only; (3) that the members of different linkage groups assort independently in accordance with Mendel's second law; (4) that an orderly interchange — crossing-over — also takes place, between the elements in corresponding linkage groups; and (5) that the frequency of crossing-over furnishes evidence of the linear order of the genes in each linkage group and of the relative position of the genes with respect to each other.

The gene, a conception as reasonable and as real as the atom, is to be looked upon as a particular state of organization of the chromatin at a particular point in the length of a particular chromosome. (See ANIMAL BREEDING, HEREDITY, CYTOLOGY, MENDELISM and PLANT BREEDING)

GENEVA, a city and canton of Switzerland, situated at the extreme south-west corner both of the country and of the Lake of Geneva or Lac Léman. The canton is, save Zug, the smallest in the Swiss Confederation, while the city, long the most populous in the land, is now surpassed by Zurich, Basle and Berne.

The Canton. — The canton has an area of 108·9 sq.m., of which 11½ are lake. It is entirely surrounded by French territory (the department of Haute Savoie to the south, and that of the Ain west and north), save for about 3½ m on the extreme north, where it borders on the Swiss canton of Vaud. The Rhone flows through it from east to west, and then along its south-west edge. The turbid Arve is its largest tributary and flows from the snows of the chain of Mont Blanc, the only other affluent of any size being the Allondon. Market gardens, orchards, and vineyards occupy a large proportion of the soil, the apparent fertility of which is largely due to the unremitting industry of the inhabitants. In 1941 there were 11,094 cattle, 1,979 horses, 3,802 swine, 1,157 goats and 5,642 sheep. Besides building materials, such as sandstone, slate, etc., the only mineral to be found within the canton is bituminous shale, the products of which can be used for petroleum and asphalt. The canton is served by broad gauge railways and electric tramways. It was admitted into the Swiss Confederation in 1815 and ranks as the junior of the 22 cantons. In 1815–1816 it was increased by adding to the old territory belonging to the city (just around it, with the outlying districts of Jussy, Genthod, Satigny and Cartigny) 16 communes (to the south and east, including Carouge and Chêne) ceded by Savoy, and 6 communes (to the north, including Versoix), cut off from the French district of Gex.

In 1941 the canton had 174,619, the city 124,442 inhabitants. This population was divided as follows in point of religion (1930 figures for the city are within brackets): Roman Catholic 72,073 (49,631), Protestants 88,979 (66,016) and Jews 2,345 (2,224).

In point of language 131,753 (93,058) were French-speaking, 24,213 (18,717) German-speaking, 10,099 (7,762) Italian-speaking, while there were also 215 (186) Romansch-speaking. Nationality was as follows: 57,604 (38,546) were Genevese citizens, and 72,874 (92,693) Swiss citizens of other cantons. In 1919 the canton contained 62,611 (51,740) foreigners, but by 1930 the number had fallen to 51,721 (42,599) in consequence of the emigration during and after World War I.

As a result of World War II the number of foreigners in Geneva fell to 40,888 (31,428), of whom 17,577 were French, 12,704 Italians, 3,938 subjects of Germany and 6,669 citizens of various other countries. The League of Nations had ceased to be a centre of attraction for visitors and delegates.

HISTORY

In prehistoric times a great lake city, built upon piles which may still be seen, existed where the waters from the Alpine lakes spread out over the plain before narrowing into the channel of the Rhône. This city was the prehistoric Geneva. After the end of the period of lake dwellings the inhabitants established themselves on the hill on the left bank of the lake and the river.

Caesar states that Geneva was a town (*oppidum*) situated in the extreme north of the country of the Allobroges; the Rhône separated it from the territory of the Helvetii, whose invasion Caesar repelled. The community (*vicus*) of Geneva was one of those dependent on the city of Vienne. It was of some size, and had temples, aqueducts, ports and ships. It was built on the usual plan of intersecting roads meeting in a central forum. One road ran from the south to the lake ports, and the other from the east to the bridge over the Rhône. When the district of Vienne was made into a province, Geneva became a Roman city (civitas) with part of what is now Savoy dependent on it. When the empire became Christian, a bishop was appointed at Geneva. After the Barbarian invasions the city shrank to half its former size. It was now concentrated on the high ground; at the foot of the hill the forum constituted a separate township, the *Bourg de* Four. The pagan temples were converted into Christian churches. At the top of the hill rose St. Peter's, while St. Victor's was built in the detached part of the town.

Order had been restored by the Burgundian kings in the 5th century, but Gundibald was defeated by Clovis and his sons were dethroned by the Franks (534). Geneva owed its importance to its bridge over the Rhône. In 563 the bridge was carried away by a flood caused by a landslide at the other end of the lake: it was, however, immediately rebuilt. Geneva lay on the path of the armies marching to the conquest of Italy. Charlemagne held an assembly there in 773. After the break-up of his empire, a new kingdom was set up in Burgundy, that of the Rudolphians. During the feudal period the Burgundian kings

had more to fear from the hereditary counts of Geneva than from the elected bishops. Rudolph III. conferred estates on the bishops and favoured them at the expense of the counts. On his death in 1032 the emperors of the Holy Roman empire inherited his lands. Frederick Barbarossa confirmed the temporal powers of the bishop of Geneva, who became a prince of the empire, and made the Church independent of the nobles of the district. The count of Geneva had a residence in the town, the old royal château, but had to do homage to the bishop for the château and for other fiefs.

The sole direct ruler of Geneva was the prince bishop. But the Genevese were always characterised by their passion for independence, and imitating the example of the Italian towns, with which they traded, they attempted towards the end of the 13th century to create a municipal organization for themselves. They were able to play off against one another the rival rulers of the district.

Savoy.—In Maurienne, a remote district of the country, there presently arose a count, who came to be known as the count of Savoy and was on bad terms with both the count of Geneva and the bishop. Peter of Savoy, who was well received in England by the queen, his niece, acquired the rights of the elder branch of the counts of Geneva, succeeded in depriving the younger branch of the county of Vaud, and entered into relations with the city of Geneva. His nephew Amadeus the Great declared himself the protector of the citizens, who had formed themselves into a municipality with syndics and other officers. The count of Geneva was reduced to a mere vassal of his cousin of Savoy, while the bishop was compelled to yield to the latter his palace, together with the *vidomnat,* the office empowering him to administer summary justice in the city. Finally the bishop recognized the municipality, after the citizens, posted on the towers of St. Peter's, had withstood bombardment by the count of Geneva from his castle. This castle was dismantled in 1320. In the meantime the citizens had defeated the count's army near the lake (June 6, 1307), a victory comparable with that of the Swiss over the duke of Austria at the other end of Switzerland (Morgarten, 1315). But by calling in the count of Savoy the Genevese had fallen out of the frying pan into the fire. They had been able to free themselves from the count of Geneva and to defy the bishop, but they discovered that their protector, not content with the office of *vidomne,* intended to make himself "prince" of the city. He still retained some partisans, however, although some of the bishops did more to deserve the support of the citizens—Guillaume de Marcossey, who rebuilt the walls, and Adhémar Fabry, who codified the privileges of the town (1387). The counts of Savoy, successors to the counts of Geneva and created dukes of Savoy, endeavoured to obtain election to the bishopric of Geneva either for themselves (Amadeus VIII., Pope Felix V.), or for a cadet of the family or for a prelate devoted to its interests. Involved in the struggle between France and Burgundy by the policy of the House of Savoy, the town was ransomed by the Swiss after their victory over Charles the Bold (1477). The measures taken by Louis XI. had destroyed the fairs at Geneva, and the prevalent distress of the 15th century became still worse in the 16th, when Duke Charles III., in 1525, went so far as to impose his will on the assembly of the citizens (*Conseil* des *Halle*bardes).

Better times came at last thanks to the commercial relations established between Geneva and the Swiss. Some of the citizens arranged an alliance with Fribourg. A few of the leaders were executed by the duke and the bishop, including Berthelier and Lévrier, but this did not prevent the two cities from being united, after several attempts, by a treaty of cornbourgeoisie (1526). The name of *Eiguenots* (*Eidgenossen,* confederates), was given to the patriotic party, and that of *Mamelus* to the remaining partisans of the duke, who were supported, outside the city, by the *gentilshommes* de la *Cuiller.*

The Reformation and Independence.— The situation was complicated by the Reformation. The canton of Berne had in the meantime joined the *combourgeoisie* of Geneva and Fribourg. The latter town remained attached to the old faith, while Berne embraced the Reformation. One party in Geneva showed a similar tendency, and this was encouraged by Berne. The French theologian Guillaume Farel was sent to convert the French-speaking districts. After a certain amount of conflict, the people of Geneva declared definitely in favour of the Reformed faith on May 21, 1536. The bishop. Pierre de la Baume, had already left the city, never to return (July 14, 1533). The syndics and the council took over the reins of authority, and claimed the sovereign powers of the bishop. The Fribourgeois, who, together with the Bernese, had again come to the help of Geneva in 1530, now seceded from the alliance. The Bernese had their hands full with their obligations to other cantons, and the Genevese had to defend their new republic unaided in the war which was waged without mercy from 1534 to 1536.

The bishop rallied his supporters at the château of Peney (they were therefore known as the *peneisans*) and joined forces with the duke to attack Geneva. The Genevese were on the point of succumbing in the unequal struggle when, in Jan. 1536, the Bernese at last came to their aid. They occupied the Vaud, which Charles III. had promised six years earlier to hand over to them as a pledge if he attacked Geneva. They also seized the Gex district, and, in combination with the Genevese, took the castle of Chillon, from which they delivered Bonivard, the prior of St. Victor. The Valaisans and even the Fribourgeois themselves joined in the struggle. The duke was on the point of losing his lands on the shores of Lake Leman and the bishop of Lausanne his city when King Francis I. undertook the conquest of the remainder of Savoy and Piedmont. The little war waged round Geneva was the match which set alight a larger conflagration. Francis I.'s rival, Charles V., took a hand in the quarrel. When peace was restored between the two potentates, Charles III. had lost his lands. Once the Genevese were rid of him they were able to organize their independent Protestant republic in peace.

Calvin.—It was at this stage that Calvin appeared on the scene. He was passing through the town and was induced by Farel to remain. The great reformer was not immediately successful, and was obliged to leave the town. He was, however, recalled by his partisans, and he undertook the task of imposing on the Genevese, who were intoxicated with their newly-won freedom, a severe moral discipline. He succeeded in subduing the libertins, though not without some executions, as was the manner of the day. One of his most lasting achievements was the foundation of the Academy of Geneva, which he set up with the assistance of Théodore de Bèze (1559). It became a sort of training school for Protestant missionaries. Geneva came to be to Protestantism what Rome was to Catholicism. It was a city of refuge for the persecuted from Italy, England and France, and it thus acquired a cosmopolitan character, and the love of learning was fostered. Calvin was the virtual ruler of the city, and from that fastness, through his emissaries and a voluminous correspondence, he directed his disciples in all parts of Europe. His influence was particularly great in France, and the Huguenots (*q.v.*) promised if necessary to send an army to the assistance of Geneva, "the holy city of Jerusalem," as Sully called it.

The gains of the war of 1536 were not lasting, Emmanuel-Philibert of Savoy recovered his lands; Berne only retained the Vaud; Geneva was once more encircled by enemies; and finally, Calvin died in 1564. On the other hand, Berne renewed the treaty of cornbourgeoisie, and Ziirich entered the alliance in 1584. Some time before this Henry III. of France had made an alliance with Berne and Solothurn for the "conservation" of Geneva (1579). Civil war broke out in France. Henry III.'s envoy Sancy brought a Swiss contingent to his aid, and Geneva entered the struggle. Sometimes in concert with Sancy's troops and the Bernese, sometimes alone, the Genevese fought and held their ground in the devastated districts like Gex. Henry of Navarre, the former Huguenot leader, presently succeeded Henry III. In spite of his former friendship with Geneva, he deprived the Genevese of the Gex district, which they had conquered, when he made peace with Savoy (1601).

With complete disregard of treaties, Duke Charles Emmanuel

attempted to take Geneva by surprise by scaling the walls with ladders (night of the *Escalade,* Dec. 12, 1602). He was checked, and after peace had been concluded the king of France and the Swiss came to realize that they must keep good guard over the town which served them as a door of communication. Henry IV. hoped to discharge the considerable debt which the crowns of France and Navarre owed Geneva by paying the garrison of the town.

Development. — Geneva now entered on a period of tranquillity. It enjoyed the friendship of the last of the Huguenot leaders, Agrippa d'Aubigné, who died in the city, and Henry de Rohan, who was buried there. Industry prospered, particularly the clock-making industry, with the assistance of the refugees who fled to Geneva at the time of the St. Bartholomew massacre and of the revocation of the Edict of Nantes (*qq.v.*). There grew up a patrician class, which constantly became more exclusive. The cultivated middle classes, however, claimed a share in the management of affairs.

The *Seigneurie* was governed by a *Petit Conseil* of 25 members, from among whom the four syndics were appointed annually. Although they were elected, or their elections were confirmed, by the other councils (which they appointed themselves), they were always chosen from a small group of families. The councils consisted of larger bodies including smaller ones; the "Sixty" included the "Twenty-five," and this again any smaller number of members considered suitable to deal with difficult cases; the "Two hundred" included the "Sixty," with a sufficient number of deputies to make up the total. The assembly of the citizens and burghers, which gradually became less and less influential, was called the *Conseil Général.*

The citizens were constantly restive under the rule of the *Petit Conseil;* during the 18th century there were sometimes such serious disturbances that the allies of Geneva were obliged to act as mediators or even to intervene and to guarantee the treaties of pacification which were concluded. The citizens had the right of protest (*représentation*) against the decisions of the *Petit Conseil,* but the latter did not consider itself obliged to take notice of the protests. Hence the terms *représentants* and *négatifs* which often occur in connection with the measures taken against Jean Jacques Rousseau.

The fame of Geneva had grown greatly. To Russia she had given Lefort, to France, Necker, to America, Gallatin, to the world, Rousseau. Among Rousseau's friends the physicist De Luc became reader to the queen of England, and the publicist D'Ivernois, who also lived in London, was, like Mallet du Pan, an opponent of the French Revolution. Voltaire, Rousseau's rival, made the chbteau of Ferney, not far from Geneva, a centre of European intellectual society, and Dr. Tronchin attracted many distinguished guests to his native country. Later, Horace Bénédict de Saussure undertook the scientific conquest of Mont Blanc; and a school of painters began to flourish. And on her exile, Madame de Staël, Necker's daughter, was to transfer to the château at Coppet, near Geneva, the salon she had formerly held at Paris.

The 19th Century. — Just as this Genevan school was developing, the French Revolution occurred. Revolutionary clubs were formed and under the influence of incitements from abroad, began to persecute the aristocrats. Geneva, imitating the example of Paris, had its "Terror." An attempt was made to remedy the situation by the egalitarian constitution of 1794, but an end was not put to disorder until the French occupation of 1798.

On the fall of Napoleon Geneva became the 22nd canton of Switzerland. Its territory was increased by the inclusion of certain Catholic communes, both Sardinian and French, and this linked it up directly with the rest of Switzerland. Geneva made an important contribution to the confederation in the person of General Dufour, who defeated the seceding league of Catholic cantons, the *Sonderbund.* The first Government of the Restoration period was regarded as reactionary. Democratic agitation in the 19th century resulted in the constitution of 1842, which set up the *Conseil d'Etat* as the executive authority and the *Grand Conseil* as the legislative body, and established municipal autonomy. In 1847 James Fazy instituted a pure radical régime; his failure to obtain re-election to the *Conseil d'Etat* led to the disturbances of Aug. 22, 1864.

The radical party returned to power under Antoine Carteret, and supported the church of Père Hyacinthe Loyson against the Catholics. The Catholic curé Gaspard Mermillod, who later became a cardinal, was exiled in 1873. A later radical leader, Henri Fazy, was more in sympathy with the Catholics. The separation of Church and State was voted in 1907. The conservative party, known as the Democrats, sometimes held office under Arthur Chenevière, Gustave Ador, and Théodore Turrettini. It introduced certain reforms such as the referendum, the popular initiative and proportional representation. The socialist party and other party formations later came into existence.

Culture. — Geneva is noted for its intellectual activities. One of the best-known periodicals was the old *Bibliothkque britannique,* or *Bibliothkque universelle,* now amalgamated with the *Revue de Genkve.* The Academy founded by Calvin has been transformed into a university with six faculties. An Institute of Higher International Studies was founded in 1927. The International Red Cross society was founded at Geneva in 1864.

Geneva, with its tradition of independence and Swiss neutrality and its fame as an intellectual and international centre, was quite naturally chosen as the seat of the League of Nations (*q.v.*). Housed after Nov. 1920 in the Hotel National for several years, the League was finally installed in 1937 in the magnificent new buildings provided by the generosity of John D. Rockefeller, Jr., and erected to the northeast of the city in Ariana park. Although a nucleus of League officials remained after the outbreak of World War II, no meetings of the council or the assembly were held, and the League's activities largely ceased. The International Labour Office was at first housed at Pregny, 1½ mi. outside Geneva, and in 1926 in a new building near the site of the new League edifice. After 1939 some of the Labour Office personnel were transferred to Toronto, Canada, Princeton, N.J., and Washington, D.C. The departure of tourists and officials interested in the League of Nations and the International Labour Office after 1939 dealt a blow to the prosperity of Geneva. In 1942, 6,400 houses and lodgings, or more than 11% of the total, were unoccupied. In spite of Swiss neutrality, foreign planes flew over Geneva, and in Jan. 1941 dropped bombs, presumably by mistake, which killed one and wounded three persons.

GENEVA, a city of Ontario county, New York, U.S.A., at the northern end of Lake Seneca (36m. long, with an average width of 2m. and a maximum depth of 624 feet). It is on federal highway 20 and the State Barge canal, and is served by the Lehigh Valley and the New York Central railways. The population was 14,648 in 1920 (83% native white) and was 15,555 in 1940 by the federal

census. Geneva is a well built city, with fine old residences and streets arched with century-old trees, and is surrounded by the beautiful and romantic scenery of the Finger Lake region. It is the seat of Hobart college for men (founded 1822) and William Smith college for women (a co-ordinate institution, founded 1908); the Smith observatory (1888); a State armory; and a State agricultural experiment station. The Lafayette tree, under which Gen. Lafayette held a reception in 1825, is said to be the largest tree in the State. A medicinal spring, struck at a depth of 64oft. in boring for natural gas in 1885, flows at the rate of 350,-ooogal. per day. There are large nurseries in and around the city, and it has manufactures of kitchen knives, optical frames, lenses, stoves and furnaces, preserved fruits and vegetables, canning machinery, enamelled ware and paste, with an aggregate output in 1940 valued at $16,420,372. Geneva was settled about 1787, near the site of a Seneca village (Kanadasega), which had been destroyed in 1779. The Indian burial mound, on the edge of the city, is still inviolate, in accordance with a pact made by the early settlers. A delegation from the Seneca Nation visits it annually to make sure that the agreement is kept. The city was chartered in 1898.

GENEVA, LAKE OF, the largest lake in central Europe. It is *Lacus Lemannus* of classical writers, but from the 16th century onwards *Lac de Genkve,* though from the end of the 18th century the name *Lac Le'man* was revived. Its area is 223 sq.m., of which about 140 sq.m. are Swiss and 83 sq.m. French. The French part takes in nearly the whole of the south shore, save its west and east ends, which belong respectively to Geneva and to Valais.

The lake is formed by the Rhone, which enters it at its east end, between Villeneuve and St. Gingolph and quits it at its west end, flowing through the city of Geneva. The only important tributaries are the Drance (S.), the Venoge (N.) and the Veveyse (N.). The direct length from Chillon to Geneva is 39½ m., the maximum depth is 1,015½ ft., mean depth 500 ft., greatest width (between Morges and Amphion) 8½ m., normal width 5 miles. The lake forms two well-marked divisions separated by the strait of Promenthoux, and as a bar, divides the Grand Lac from the Petit Lac. The "Grand Lac" is to the east and the "Petit Lac" (W.) is the special Genevese portion. The unusual blueness of the waters has long been remarked, and transparency increases away from the Rhone entry as the river-borne mud sinks to the bottom. The lake level is highest in summer. There are remarkable temporary disturbances of level known as *seiches* both longitudinal and transverse, in which the whole mass of water in the lake rhyfhmically swings from shore to shore. The currents are irregular. The principal winds that blow over the lake are the *bise* (north-east), the *vaudaire* or *Fohn* (south-east), the *sudois* or *vent de pluie* (south-west) and the *joran* (north-west). The storm winds are *molan* (from the Arve valley) and the *bornan* (from the Drance valley). The lake is not as rich in fish as the other Swiss lakes. Prof. Forel knows of but 20 indigenous species (of which the *Féra,* or *Coregonus fera,* is the principal) and six that have been introduced by man in the 19th century. Lake dwellings, of varying dates, have been found on the shores.

Despite steamers first placed on the lake in 1823, and railways along each shore, the red lateen sails of minor craft still brighten the landscape. The railway along the northern shore runs from Geneva past Nyon, Rolle, Morges, Ouchy (the port of Lausanne), Vevey and Montreux to Villeneuve (564 miles). That on the south shore gains the edge of the lake at Thonon only (22¼ m. from Geneva), and then runs past Evian and St. Gingolph to Le Bouveret (20 m. from Thonon). In the harbour of Geneva two erratic granite boulders project above the water, and are named *Pierres du Niton* (supposed to be altars of Neptune). The lower of the two has been taken as the basis of the triangulation of Switzerland.

See Prof. F. A. Forel's monumental work, *Le Léman* (3 vols., Lausanne, 1892–1904); also (with fine illustrations) G. Fatio and F. Boissonnas, *Autour du lac Léman* (Geneva, 1902); L. W. Collet, *Les Lacs* (1925).

GENEVA CONVENTION, an international agreement for the purpose of improving the condition of wounded soldiers of armies in the field, originally adopted at an international conference held at Geneva, Switzerland, in 1864, and afterwards replaced by the convention of July 6, 1906, also adopted at Geneva. This later agreement is the one now known as the Geneva Convention. The conference of 1864 was the result of a movement which sprang from the publication in 1862 of a book entitled *Un Souvenir de Solférino* by Henri Dunant, a Genevese philanthropist, in which he described the sufferings of the wounded at the battle of Solférino with such vivid effect that the subject became forthwith one of public interest. It was energetically taken up by M. Gustave Moynier, whose agitation led to an unofficial congress being held at Geneva in Oct. 1863. The convention afterwards received the adherence of every civilized power.

At a second conference on the same subject, held at Geneva in 1868, a supplementary convention was drawn up, consisting of 14 additional articles which never became operative. The Brussels International Conference (1874) for the codification of the law and customs of war occupied itself with the Geneva Convention, but in this relation led to no result.

At The Hague Peace Conference of 1899 Great Britain withdrew her objections to the application of the convention to maritime warfare, and agreed to the adoption of a special convention "adapting to Maritime warfare the principles of the Geneva Convention." After some unsuccessful efforts an invitation by the Swiss Government was accepted in March 1906 by 35 States, only Turkey, Salvador, Bolivia, Venezuela, Nicaragua and Colombia abstaining, and the conference was held at Geneva in July 1906, when a full revised convention was adopted, which replaced that of 1864. This was again revived at The Hague Peace Conference of 1907 and adopted as Convention X.

See *The Hague Conventions and Declarations of 1899 and 1907* (ed. by James Brown Scott, 1918), and the article, WAR, LAWS OF.

GENEVIÈVE, ST. (c. 422–512), patroness of Paris, was born, according to tradition, at Nanterre near Paris. At the age of seven she was induced by St. Germain, bishop of Auxerre, to dedicate herself to the religious life, and on the death of her parents she removed to Paris, where she distinguished herself by her benevolence, as well as by her austere life. She is said to have predicted the invasion of the Huns; and when Attila with his army was threatening the city, she persuaded the inhabitants to remain on the island and encouraged them by an assurance, justified by subsequent events, that the attack would come to nothing (451). She is also said to have had great influence over Childeric, father of Clovis, and in 460 to have caused a church to be built over the tomb of St. Denis. She was buried in the church of the Holy Apostles, popularly known as the church of St. Geneviève. In 1793 the body was taken from the new church, built in her honour by Louis XV. in 1764, when it became the Panthéon, and burnt on the Place de Grbve; but the relics were enshrined in the church of St. Étienne du Mont, where they still attract pilgrims. Her festival is celebrated on Jan. 3.

GENEVIÈVE (GENOVEVA OR GENOVEFA), **OF BRABANT,** heroine of mediaeval legend. Her story is a typical example of the widespread tale of the chaste wife falsely accused and repudiated, generally on the word of a rejected suitor. Genovefa of Rrabant, wife of the palatine Siegfried of Treves, was falsely accused by the majordomo Golo. Sentenced to death she was spared by the executioner, and lived for six years with her son in a cave in the Ardennes nourished by a roe. Siegfried, who had meanwhile found out Golo's treachery, was chasing the roe when he discovered her hiding-place, and reinstated her in her former honour. Her story is said to rest on the history of Marie of Brabant, wife of Louis II., duke of Bavaria, and count-palatine of the Rhine, who was beheaded on Jan. 18. 1256, for supposed infidelity, a crime for which Louis afterwards had to do penance. The change in name may have been due to the cult of St. Genevibve, patroness of Paris. The tale first obtained wide popularity in *L'Innocence reconnue, ou vie de Sainte Genevikve de Brabant* (pr. 1638) by the Jesuit René de Cérisier (1603–62),

and was a frequent subject for dramatic representation in Germany. Several other forms of the legend exist.

GENGA, GIROLAMO (*c.* 1476–1551), Italian architect and painter of the Umbrian school, was born in Urbino about 1476. He studied with Luca Signorelli and then with Pietro Perugino. According to Vasari, who knew him personally, he decorated the hall of Pandolfo Petrucci's palace at Siena with a series of frescoes. Six of these were carved out of the wall and sold; three are now in the National Gallery. *(See* J. P. Richter, *Mond Collection.)* In Rome he painted the "Resurrection" in the church of S. Caterina da Siena. One of his leading works is the "Disputation of the Four Fathers of the Church" in the Brera, Milan, painted for the church of S. Agostino at Cesena. As a painter he was an eclectic, making the different styles of Signorelli and Perugino his own. He also imitated Pintoricchio. His work is decorative in design and light in colour but does not rise to the excellence of his great masters. Genga was a sculptor, a musician, a theatrical designer and an architect as well as a painter. He was indeed in the first place an architect; when in Rome he studied and measured the antique buildings, and he was then appointed ducal architect by the duke of Urbino. His most important architectural wcrks are: San Giovanni Battista in Pesaro; the bishop's palace at Sinigaglia; the new palace for the duke of Urbino on the Monte Imperiale. He was also concerned in the fortifications of Pesaro. Genga died on July 11, 1551. His son Bartolommeo (1516–58) was an architect and painter.

GENISTA, in botany, a genus of over 100 species of shrubs of the family Leguminosae, and natives of Europe, western Asia and north Africa; three are British. G. *anglica* is the needle-furze or petty whin, found on heaths and moist moors, a spinous plant with slender spreading branches 1 to 2 ft. long, very small leaves and short racemes of small yellow flowers. G. *tinctoria*, the woad-waxen or dyer's greenweed, the flowers of which yield a yellow dye, has no spines. It is Eurasian and naturalized in the north-eastern United States.

Other species are grown in the rock garden or as greenhouse plants.

GENITIVE, in grammar the name given to one of the cases or declensions of nouns to indicate the relationship in which they stand to other words in the sentence. The Latin language contained six declensions of nouns the Nominative or subject, the Vocative or person addressed, the Accusative or the object towards which the action is directed, the Genitive indicating its origin or source, the Dative that to which an action is directed, and the Ablative from which something is taken. In Greek the ablative was excluded, and in French and Italian case is obviated by the use of prepositions. In English the genitive, also called the possessive case, is the only declension employed, though certain exceptions necessitate the use of the dative and accusative cases. *See* GRAMMAR and articles on the different languages.

GENIUS (Lat. the begetter). In its earliest meaning in private cult, the *genius* of the Roman house-father and the *iuno (see* JUNO) of the house-mother were worshipped. These certainly were not the souls of the married pair, as is clear both from their names and from the fact that we never hear in any early document of the *genius* or *iuno* of a dead person. As no cult was paid to the *genius* of any other member of the family, it seems reasonable to suppose that they were the male and female forms of the family's, or clan's, power of continuing itself by reproduction which were in the keeping of the heads of the family or clan for the time being, and passed at death to their successors. *(See* Rose, *Primitive Culture in Italy*, 149 *et seq.*) In this as in all forms of his cult, the *genius* was often conceived as appearing in the form of a snake, although he is also shown in art as a young man, generally engaged in sacrificing. At every wedding a bed, the *lectzis genialis*, was made for the *genius* and *iuno* of the husband and wife, and its presence in the house was a sign of matrimony (Horace, *Epp.* i. 1, 87; Paulus, *epit. Fest.* 83, 23 Lindsayj.

Individual **Genius.**—Owing to the rise of individualism and also to the prevalence of Greek ideas concerning a guardian spirit or *daimon*, the *genius* lost its original meaning, and came to be a sort of personification of the individual's natural desires and appetites. Hence the phrases *indulgere genio, genium defrudare*, signifying respectively to lead a pleasurable and a stingy life. However, the development did not stop here. The *genius* came to be thought of as a sort of guardian angel, a higher self; and, as the Greek *daimon* was sometimes rationalized into the individual's character or temper, so also Horace half-seriously (*Epp.* ii. 2, 187) says that only the *genius* knows what makes one person so different from another, adding that he is a god who is born and dies with each one of us. This individual *genius* was worshipped by each individual especially on his birthday. A few inscriptions even mention the *genius* of a dead person, as Christian epitaphs sometimes speak of his angel.

Genius of the Emperor.— To show reverence for the genius of another, or to swear by it, was a mark of deep respect; hence it is not unnatural that the *genius* of Augustus and of his successors formed objects of popular cult. Thus to worship the *genius Augusti* avoided the feeling against worshipping any living emperor, which remained fairly strong in Italy *(see* L. R. Taylor in *Trans. Amer. Philol. Assoc.*, vol. li., 116 et seq.); for of course all *genii* were divine and might properly be worshipped.

Further Developments.— As Greek *daimones* were by no means always the guardian spirits of individuals, so also we get a vast variety of *genii; i.e.*, guardian spirits, of places, *genius loci*, including buildings *(genius balneorzrm*, etc.) and corporations of all sorts, from the State *(genius populi Romani)* to small bodies of troops, guilds of tradesmen and so forth. A very curious development is that we sometimes hear of the *genius* of a god, even of Jupiter, or of the *iuno* of a goddess.

Use in English.— Apart from the Latin use of the term, the plural "genii" (with a singular "genie") is used in English, as equivalent to the Arabic *jinn*, for a class of spirits, good or bad, such as are described, for instance, in *The Arabian Nights*. But "genius" itself has become the regular English word for the highest conceivable form of original ability, something altogether extraordinary and beyond even supreme educational prowess, and differing, in kind apparently, from "talent," which is usually distinguished as marked intellectual capacity short only of the inexplicable and unique endowment to which the term "genius" is confined.

See further Wissowa, *Religion u. Kultus*, 2nd ed., p. 175 *et seq.*, and the classical dictionaries; also J. F. Nisbet, *Insanity of Genius* (1891); F. Galton, *Hereditary Genius* (new ed., 1892), and C. Lombroso, *Man of Genius* (Eng. trans., 1891).

GENLIS, STEPHANIE-FELICITE DU CREST DE SAINT-AUBIN, COMTESSE DE (1746–1830), French writer and educator, was born at Champcéry, Autun, France. At six years of age she was received as a canoness into the noble chapter of Alix, near Lyons, with the title of Madame la Comtesse de Lancy, taken from the town of Bourbon-Lancy. Her entire education, however, was conducted at home. In her 16th year she was married to Charles Brûlart de Genlis, a colonel of grenadiers, who afterwards became marquis de Sillery. Some years later, through the influence of her aunt, Madame de Montesson, who had been clandestinely married to the duke of Orleans, she entered the Palais Royal as lady-in-waiting to the duchess of Chartres (1770). She acted with great energy and zeal as governess to the daughters of the family, and was in 1781 appointed by the duke of Chartres to the responsible office of *gouverneur* of his sons, a step which led to the resignation of all the tutors as well as to much social scandal. She wrote several works for the use of her pupils, the best known of which are the *Théâtre d'éducation* (4 vols., 1779–80), a collection of short comedies for young people, *Les Annales de la vertu* (2 vols., 1781) and *Adèle et Théodore (3* vols., 1782). She anticipated many modern methods of teaching. His-

tory was taught with the help of magic lantern slides and her pupils learnt botany from a practical botanist during their walks. Madame de Genlis welcomed the Revolution, but the fall of the Girondins in 1793 compelled her to take refuge in Switzerland along with her pupil Mademoiselle d'Orléans. In this year her husband, from whom she had been separated since 1782, was guillotined.

In 1794 Madame de Genlis fixed her residence at Berlin, but was expelled by order of King Frederick William, and afterwards settled in Hamburg, where she supported herself for some years by writing and painting. After the 18th Brumaire (1799) she returned to France, and was well received by Napoleon, who gave her apartments at the arsenal, and assigned her a pension of 6,000 francs. Her government pension was discontinued by Louis XVIII. Her *Dîners du Baron d'Holbach* (1822) set forth with a good deal of sarcastic cleverness the intolerance and fanaticism of 18th century "philosophes." She died on Dec. 31, 1830.

The numerous works of Madame de Genlis (which exceed 80) owed much of their success to adventitious causes. They are useful, however (especially the voluminous *Mémoires inédits sur le XVIII^e siècle*, 10 vols., 1825), as furnishing material for history. Most of her writings were translated into English almost as soon as they were published. A list of her works with useful notes is given by Quérard in *La France littéraire*. Startling light was thrown on her relations with the duc de Chartres by the publication (1904) of her correspondence with him in *L'Idylle d'un "gouverneur"* by G. Maugras. *See* also Sainte-Beuve, *Causeries du lundi*, vol. iii.; H. Austin Dobson, *Four Frenchwomen* (1890); *W.* de Chabreul, *Gouverneur de princes, 1737–1830* (1900); *L.* Chabaud, *Les Précurseurs du féminisme* (1901); *Lettres inédites à . . . Casimir Baecker, 1802–1830* (1902), edited by H. Lapauze; and T. Harrnand, *Madame* de *Genlis* (1912).

GENLISEA: see PITCHER PLANTS.

GENNADIUS II. or **GEORGIOS SCHOLARIOS** (d. c. 1468), patriarch of Constantinople from 1454 to 1456, philosopher and theologian, was one of the last representatives of Byzantine learning. He appears to have been born at Constantinople and to have served the emperor John VII. Paleologus as counsellor. He was present at the great council held in 1438 at Ferrara and Florence with the object of uniting the Greek and Latin Churches, and there met the celebrated Platonist, Gemistus Pletho. In church matters, as in philosophy, the two were opposed,—Pletho maintaining strongly the principles of the Greek Church, Georgios being more willing to compromise. On his return to Greece, however, Georgios violently opposed the union. In 1448 he became a monk at Pantokrator, and in 1453 was elected patriarch of Constantinople by Mohammed II. A few years later he found his position under a Turkish sultan so irksome that he retired to the monastery of John the Baptist near Serrae in Macedonia, where he died about 1468.

His writings, which include philosophical translations and commentaries, defences of Aristotle, and expositions of Christianity for Mohammedans and Jews, are described in W. Gass, *Gennadius und Pletho* (1844), and in Fabricius, *Bibliotheca Graeca*, ed. Harles, vol. xi. Some are printed in Migne, *Patrol. Gr.* vol. clx. *See* also F. Schultze, *Gesch. der Phil. d. Renaissance* (1874), i.

GENOA (anc. *Genua*, Ital. *Genova*, Fr. *Gênes*), a port of Liguria, Italy, and capital of the province of Genoa, 119 mi. N.W. of Leghorn by rail. Pop. (1936) 512,313 (town); 634,646 (commune). The town is situated on the Gulf of Genoa, and is the chief port of Italy, the seat of an archbishop and a university and a strong fortress. The city, as seen from the sea, is "built nobly," and deserves the title of the Superb. Finding only a small space of level ground along rhe shore, it has been obliged to climb the lower hills of the Ligurian Alps, which afford many a coign of vantage for the effective display of its architectural magnificence. The original nucleus of the city is that portion which lies to the east of the port in the neighbourhood of the old pier (Molo Vecchio). In the middle of the 12th century, it was found necessary to extend the line of circumvallation: but it was not till 1320–30 that a third line took in the greater part of the modern site of the city proper This presented about 3 m. of rampart towards the land side, and can still be traced, though large portions, especially towards the east, have been dismantled. The present line of circumvallation dates from 1626–32, the period when the independence of Genoa was threatened by the dukes of Savoy. From the mouth of the Bisagno in the east, and from the lighthouse point in the west, it stretches inland over hill and dale to the great fort of Sperone (the Spur), on the summits of Monte Peraldo at a height of 1,650 ft.,—the circuit being little less than 12 m., and all the important points along the line being defended by forts or batteries. A portion of the enclosed area is open country, dotted only here and there with houses and gardens, There are eight gates, the more important being Porta Pila and Porta Romana towards the east, and the Porta Lanterna or Lighthouse gate to the west.

Architectural Features.—The main architectural features of Genoa are its mediaeval churches, with striped facades of black and white marble, and its magnificent 16th-century palaces. The earlier churches of Genoa show a mixture of French Romanesque and the Pisan style—they are mostly basilicas with transepts, and as a rule a small dome; the pillars are sometimes ancient columns, and sometimes formed of alternate layers of black and white marble. The facades are simple, without galleries, having only pilasters projecting from the wall, and are also alternately black and white. This style continued in Gothic times also. The oldest is S. Maria di Castello (11th century), the columns and capitals of which are almost all antique. S. Cosma, S. Donato (with remains of the 10th-century building) and others belong to the 12th century, and S. Giovanni di Prè, S. Agostino (with a fine campanile), S. Stefano, etc., to the 13th. S. Matteo, the church of the Doria family, was founded in 1126 by Martino Doria. The facade dates from 1278, and the interior from 1543. In the crypt is the tomb of Andrea Doria by Montorsoli, and above the high altar hangs the dagger presented to the doge by Pope Paul III. To the left of the church is an exquisite cloister of 1308 with double columns, in which a number of sepulchral inscriptions of the family and the statue of Andrea Doria by Montorsoli are preserved. The little square in front of the church is surrounded by Gothic palaces of the Doria family. The cathedral of S. Lorenzo was reconstructed about the end of the 11th century, and consecrated in 1118. The facade has three elaborate doorways (13th century). The interior was rebuilt in 1307. The campanile, which rises above the right-hand doorway, was completed in 1522, and the cupola was erected after the designs of the architect Galeazzo Alessi in 1567. The fine Early Renaissance (1448) sculptural decorations of the chapel of S. John the Baptist were due to Domenico Gagini of Bissone on the Lake of Lugano. In the treasury of the cathedral is an octagonal bowl, the Sacro Catino, brought from Caesarea in 1101, which corresponds to the descriptions given of the Holy Grail, and was long regarded as an emerald of matchless value, but is in reality only a remarkable piece of ancient glass

The church of S. Ambrose, rebuilt by the Jesuits (1587), has a richly decorated interior (16th century). The Annunziata del Guastato (1587), one of the largest churches in the city, is a cruciform structure, with a dome. The interior is covered with gilding and frescoes of the 17th century. San Siro was rebuilt by the Benedictines in the 11th century, and restored and enlarged by the Theatines in 1576, the facade being added in 1830. Santa Maria di Carignano, belongs mainly to the 16th century, and was designed by Galeazzo Alessi in imitation of S. Peter's at Rome. The interior is fine, while the colouring of the exterior is less pleasing. The highest gallery of the dome is 368 ft. above the sea-level, and 194 ft. above the ground.

The palaces of the Genoese patricians, famous for their sumptuous architecture, their general effectiveness, and their artistic collections, were many of them built in the latter part of the 16th century by Galeazzo Alessi, a pupil of Michelangelo, whose style is imposing and displays marvellous ingenuity in using a limited or unfavourable site to the greatest advantage. Several of the villas in the vicinity of the city are also his work. The Via Garibaldi is flanked by a succession of magnificent palaces, chief among which is the Palazzo Rosso. It was presented by the duchess of Galliera to the city (1874), along with its valuable contents, its library and picture gallery, which includes fine examples of Van Dyck and Paris Bordone. The Palazzo Municipale, built by Rocco Eurago at the end of the 16th century, once the

property of the dukes of Turin, has a beautiful entrance court and a hanging terraced garden fronting a noble staircase of marble which leads to the spacious council chamber. In an adjoining room are preserved two autograph letters of Columbus, and the violin of Paganini (*q.v.*). Opposite the Palazzo Rosso is the Palazzo Bianco, bequeathed to the city by the duchess of Galliera (1889) and subsequently converted into a museum. In the Via Balbi is the Durazzo Pallavicini palace with a noble façade and staircase and a rich picture-gallery; also the Palazzo Balbi-Senarega, which has Doric colonnades and a fine orangery. The Palazzo dell' Università has an extremely fine court and staircase of the early 17th century. The Palazzo Doria in the Piazza Principe, presented to Andrea Doria by the Genoese in 1522, was remodelled in 1529 by Montorsoli and decorated with fine frescoes by Perino del Vaga. Its garden was destroyed by the building of the railway. The old palace of the doges, originally a building of the 13th century, to which the tower alone belongs, stands near the cathedral. Another very fine building is the Gothic Palazzo di S. Giorgio, near the harbour, dating from about 1260, occupied from 1408 to 1797 by the Banca di S. Giorgio, now completely restored and occupied by the offices of the Port Authority. The Cimitero di Staglieno, about 1½ mi. from the city on the banks of the Bisagno, is one of the chief features of Genoa; its situation is of great natural beauty and it is remarkable for its modern sepulchral monuments. The university, founded in 1471, had some 3,000 students in 1939, with faculties in law, medicine, natural science, engineering and philosophy. There is also a naval engineering school and an institute of economics and commerce. Genoa is also well supplied with other institutions for higher education.

The hospitals and the asylum for the poor are among the finest institutions of their kind in Italy. Mention must also be made of the academy of fine arts, the municipal library, the Teatro Carlo Felice and the Verdi Institute of Music.

The irregular relief of its site and its long confinement within the fortifications have made Genoa a picturesque confusion of narrow streets, lanes and alleys, varied with stairways climbing the steeper slopes and bridges spanning the deeper valleys. Large portions of the town are inaccessible to cars, and many of the important streets have very little room for traffic. In modern times, however, a number of fine streets and squares with beautiful gardens have been laid out. The Piazza Deferrari, a large irregular space, is the chief focus of traffic and the centre of the Genoese tramway system; and imposing new buildings have been erected in and round it. The Via Venti Settembre leads southeast to the Ponte Pila, the central bridge over the Bisagno, and to a growing residential quarter beyond it, with a new sea front, the Corso d'Italia, connecting with the previously existing coast road. The Via Roma, which gives on to the Via Carlo Felice near the Piazza Deferrari, leads to the Piazza Corvetto, with the equestrian statue of Victor Emmanuel II. To the left is the Villetta Dinegro, a beautiful park belonging to the city. To the right is another park, the Acquasola, laid out in 1837 on the site of the old ramparts. In front of the principal station is the Piazza Acquaverde, with a statue of Columbus, at whose feet kneels the figure of America. The Via di Circonvallazione a Monte leads up to the hills at the back of the town, where new suburbs have been constructed.

San Pier d'Arena on the west has now become a part of Genoa. Genoa is well served with electric tramuays, which run into the suburbs on the east as far as Nervi and to Pegli on the west.

Three funicular railways from different points of the city give access to the highest parts of the hills behind the town.

Commerce **and** Industry.— Though its existence as a maritime power was originally due to its port, it was only after 1870 that Genoa provided the conveniences necessary for the modern development of its trade, the duke of Galliera's gift of £800,000 to the city in 1875 being devoted to this purpose. A further enlargement of the harbour was necessitated upon the opening of the St. Gotthard tunnel in 1882, which extended the commercial range of the port of Genoa through Switzerland into Germany.

The old harbour is semicircular in shape, 232 ac. in area, with numerous quays, and protected by moles from southern and southwesterly winds.

An outer harbour, 247 ac. in area, has been constructed in front of this by extending the Molo Nuovo by the Molo Duca di Galliera, and another basin, the Vittorio Emanuele III, for coal vessels, with an area of 96 ac., has been formed to the west of this, between it and the lofty lighthouse which rises on the promontory at the southwest extremity of the harbour, while a further extension in front of San Pier d'Arena as far as the mouth of the river Polcevera is in progress.

The largest ships can enter the harbour, which has a minimum depth of 30 ft.; it has two dry docks, a graving dock and a floating dry dock.

Very large warehouses have been constructed. The exports are olive oil, hemp, flax, rice, fruit, wine, hats, cheese, steel, velvets, gloves, flour, paper, soap and marble, while the main imports are coal, cotton, grain, machinery, etc.

Genoa in the years preceding World War II had a large emigrant traffic with South America, and a large general passenger steamer traffic both for America and for the east.

The development of industry has kept pace with that of the harbour. The Ansaldo shipbuilding yards construct armoured cruisers both for the Italian navy and for foreign governments. The Odero yards, for the construction of merchant and passenger steamers, have been similarly extended, and the Foce yard is also important.

A number of foundries and metallurgical works supply material for repairs and shipbuilding. Tanneries and cotton-spinning and weaving mills have considerably extended throughout the province.

Cement works have acquired considerable importance. The manufactures of motor cars, hats, crystallized fruits and of filigree silver-work may also be mentioned.

The four main lines which centre on Genoa — (I) the Novi, which is the junction for Alessandria, where lines diverge to Turin and France via the Mont Cenis, and to Novara and Switzerland and France via the Simplon, and for Milan; (2) to Acqui and Piedmont; (3) to Savona, Ventimiglia and the French Riviera, along the coast; (4) to Spezia and Pisa — all have been electrified, and the first has two alternative double lines for the passage over the Apennines, as far as Arquata Scrivia. There is a marshalling station, connected directly with the harbour by tunnels, at Campasso north of San Pier d'Arena.

Genoa is the most important harbour in the western Mediterranean, with the exception of Marseilles, with which it carries on a keen rivalry.

HISTORY

The discovery of a Greek cemetery of the 4th century B.C. is the only proof that Genoa was ever occupied by the Greeks. It was destroyed by the Carthaginians in 209 B.C. but restored by the Romans, nho made it and Placentia their headquarters against the Ligurians. An inscription of 117 B.C. (now preserved in the Palazzo Municipale at Genoa) gives the text of the decision given by the *patroni,* Q. and M. Minucius of Genua, in a controversy between the people of Genua and the Langenses or Langates, the inhabitants of a neighbouring hill-town. It is only from inscriptions of other places that we know that Genoa had municipal rights, and we do not know at what period it obtained them. Strabo (iv. 6. 2, p. 202) states that Genoa exported wood, skins and honey, and imported olive oil and wine, though Pliny speaks of the wine of the district as the best of Liguria (*Hist. Nat.* xiv. 67).

The history of Genoa during the dark ages, throughout the Lombard and Carolingian periods, is but the repetition of the general history of the Italian communes. The patriotic spirit and naval prowess of the Genoese, developed in their defensive wars against the Saracens, led to the foundation of a popular constitution and to the rapid growth of a powerful marine. From the necessity of leaguing together against the common Saracen foe,

Genoa united with Pisa early in the 11th century in expelling the Muslims from the island of Sardinia; but the Sardinian territory thus acquired soon furnished occasions of jealousy to the conquering allies, and there commenced between the two republics the long naval wars which terminated fatally for Pisa in the battle of Meloria (1284). Genoa secured great advantages from the trade stimulated by the crusades. The seaports wrested at the same period from the Saracens along the Spanish and Barbary coasts became important Genoese colonies, whilst in the Levant, on the shores of the Black Sea, and along the banks of the Euphrates were erected Genoese fortresses of great strength.

The commercial and naval successes of the Genoese during the middle ages were the more remarkable because, unlike their rivals, the Venetians, they were the unceasing prey to intestine discord—the Genoese commons and nobles fighting against each other, rival factions amongst the nobles themselves striving to grasp the supreme power in the state, nobles and commons alike invoking the arbitration and rule of some foreign captain as the sole means of obtaining a temporary truce. From these contests of rival nobles, in which the names of Spinola and Doria stand forth with greatest prominence, Genoa was soon drawn into the great vortex of the Guelph and Ghibelline factions; but its recognition of foreign authority—successively German, Neapolitan, and Milanese—gave way to greater independence in 1339, when the government assumed a more permanent form with the appointment of the first doge, an office held at Genoa for life, in the person of Simone Boccanera. Alternate victories and defeats of the Venetians and Genoese—the most terrible being the defeat sustained by the Venetians at Chioggia in 1380—ended by establishing the great relative inferiority of the Genoese rulers, who fell under the power now of France, now of the Visconti of Milan. The Banca di S. Giorgio, with its large possessions, mainly in Corsica, formed during this period the most stable element in the state, until in 1528 the national spirit appeared to regain its ancient vigour when Andrea Doria succeeded in throwing off the French domination and restoring the old form of government. The government as restored by him, with certain modifications tending to impart to it a more conservative character, remained unchanged until the outbreak of the French Revolution and the creation of the Ligurian republic.

The Ligurian republic was soon swallowed up in the French empire, but not before Genoa had experienced terrible privations in the siege when Masséna held the city against the Austrians (1800). In 1814 Genoa rose against the French, on the assurance given by Lord William Bentinck that the allies would restore to the republic its independence. It had, however, been determined by a secret clause of the treaty of Paris that Genoa should be incorporated with the dominions of the king of Sardinia. The discontent so created kept alive in Genoa the republican spirit which, through the influence of a young Genoese citizen, Joseph Mazzini, was a permanent menace not only to the Sardinian monarchy but to all the established governments of the peninsula. A republican outbreak occurred in 1848, but after a short and sharp struggle the city, momentarily seized by the republican party, was recovered by General Alfonzo La Marmora.

In World War II Genoa was heavily bombed by the Allies; its port and industrial areas were virtually demolished by the repeated aerial attacks.

BIBLIOGRAPHY.—Among the earlier Genoese historians the most important are Bartolommeo Fazio and Jacopo Bracelli, both of the 15th century, and Paolo Partenopeo, Jacopo Bonfadio, Oberto Foglietta, and Agostino Giustiniano of the 16th. Paganetti wrote the ecclesiastical history of the city; and Accinelli and Gaggero collected material for the ecclesiastical archaeology. The memoirs of local writers and artists were treated by Soprani and Ratti. *See* also Bréquigny, *Histoire des révolutions de Gênes jusqu'en 1748;* Serra, *La Storia dell' antica Liguria e di Genova* (1834); *Nuova istoria della repubblica di Genova* (1858), and *Storia della rep. di Genova dall' anno 1528 al 1550* (Genoa, 1874); Blumenthal, *Zur Verfassungs- und Verwaltungsgeschichte Genua's im 12ten Jahrhundert* (Kalbe an der Saale, 1872); Malleson, *Studies from Genoese History* (1875); L. Celesia, *Storia della Università di Genova* (Genoa, 1861–67); The *Liber jurium reipublicae Genuensis* was edited by Ricotti in the 7th, 8th, and 9th volumes of the *Monumenta historiae patriae* (1854–57). *See* further *Atti della Societd Ligure di storia patria* (1861 *seq.*); *Giornale Ligustico di archeologia, storia, e belle arti.*

GENOA, CONFERENCE OF (April 10–May 19, 1922), a meeting of representatives of the British self-governing Dominions and of 29 European states, including not only the Allies and ex-neutrals, but all the ex-enemy Powers except Turkey (who was excluded on the ground that she was an Asiatic country). Above all, the conference was attended by representatives of Soviet Russia, and the dominant issue was the renewal of relations between Russia and the countries of Europe. Before the conference met M. Briand had been succeeded as prime minister by M. Poincaré. Since the project of the Genoa conference had already been accepted by the supreme council, M. Poincaré could not reject it altogether, but he sought to interpret the agreed programme in the narrowest sense and to hedge the participation of Russia with the fullest possible restrictions. He gave detailed and stringent instructions in this sense to his representative, M. Barthou.

The general conference was preceded by a meeting between M. Poincaré and Mr. Lloyd George at Boulogne, on Feb. 25, a meeting of Allied economic experts in London from March 20 to 28, which drew up detailed agenda for Genoa, and two other preliminary meetings of a regional character, one between the members of the Little Entente at Belgrade, and another at Warsaw between Poland, Latvia, Estonia, and Finland. The parties represented at Warsaw subsequently conferred at Riga with representatives of Soviet Russia. The invitation to Genoa was accepted by the Soviet Government with alacrity, but was declined by the United States.

Adverse Influence **of** the **Rapallo** Treaty.—At its first plenary session the conference set up four commissions, the first to examine methods of putting into practice the principles of the Cannes resolution of Jan. 6, 1922 (see CANNES, CONFERENCE OF), while the other three were to deal respectively with financial subjects, economic and commercial subjects, and transport. These three latter commissions all reported before the conference came to an end; but their reports were bound to remain academic unless the first commission achieved positive results. The task of the first commission was mare difficult, because it was general and political in character, and its work was soon suspended in favour of informal discussions between the three principal Allied Powers and Belgium on the one side and the Russians on the other. Meanwhile the Germans signed, on April 16, a separate treaty with the Russians at Rapallo, in which the objects of the Genoa conference were achieved as between these two parties by a mutual renunciation of reparation claims and a resumption of normal consular and diplomatic relations.

This separate Russo-German treaty damaged the general prospects of the conference by the fear it instilled into the Allies. In these circumstances there was little prospect of success for a general pact of non-aggression, which Mr. Lloyd George suggested on April 25. But the conference actually broke down through the intransigence of Belgium, who insisted upon the integral restitution of foreign-owned private property in Russia. France supported the Belgian contention. Eventually a formula on the British lines was carried, even Belgium finally giving way; but it was so evident that, with Great Britain and France divided, no positive result could be achieved, that the Genoa conference was quietly wound up by remitting its agenda to a mixed commission of experts, who duly met at The Hague from June 26 to July 20, 1922, but also foundered on the rock of foreign-owned private property in Russia. The Genoa conference was interesting because economic and financial problems were approached from the point of view of reconstruction, and not of reparation. It was also the first attempt at a settlement between the European governments and Soviet Russia.

See Sir C. Gordon and E. Montpetit, *The Genoa Conference,* Joint Report of the Canadian Delegates (1922); J. S. Mills, The *Genoa Conference* (1922).

GENOVESI, ANTONIO (1712–1769), Italian writer on philosophy and political economy, was born at Castiglione, near Salerno, on the 1st of November 1712. He was educated for the church, and, after some hesitation, took orders in 1736 at Salerno, where he was appointed professor of eloquence at the theological seminary. During this period of his life he began the study of

philosophy, being especially attracted by Locke. Dissatisfied with ecclesiastical life, Genovesi resigned his post, and qualified as an advocate at Rome. Finding law as distasteful as theology, he devoted himself entirely to philosophy, of which he was appointed extraordinary professor in the university of Naples. His first works were *Elementa Metaphysicae* (1743 et seq.) and *Logica* (1745). The former is divided into four parts, Ontosophy, Cosmosophy, Theosophy, Psychosophy, supplemented by a treatise on ethics and a dissertation on first causes. The *Logic,* an eminently practical work, written from the point of view of Locke, is in five parts, dealing with (1) the nature of the human mind, its faculties and operations; (2) ideas and their kinds; (3) the true and the false, and the various degrees of knowledge; (4) reasoning and argumentation; (5) method and the ordering of our thoughts. If Genovesi does not take a high rank in philosophy, he deserves the credit of having introduced the new order of ideas into Italy, at the same time preserving a just mean between the two extremes of sensualism and idealism. Although bitterly opposed by the partisans of scholastic routine, Genovesi found influential patrons, amongst them Bartolomeo Intieri, a Florentine, who in 1754 founded the first Italian or European chair of political economy (commerce and mechanics), on condition that Genovesi should be the first professor, and that it should never be held by an ecclesiastic. The fruit of Genovesi's professorial labours was the *Lezioni di Commercio,* the first complete and systematic work in Italian on economics. On the whole he belongs to the "Mercantile" school, though he does not regard money as the only form of wealth. Specially noteworthy in the *Lezioni* are the sections on human wants as the foundation of economical theory, on labour as the source of wealth, on personal services as economic factors, and on the united working of the great industrial functions. He advocated freedom of the corn trade, reduction of the number of religious communities, and deprecated regulation of the interest on loans. In the spirit of his age he denounced the relics of mediaeval institutions, such as entails and tenures in mortmain. Gioja's more important treatise owes much to Genovesi's lectures. Genovesi died on the 22nd of September 1769.

GENRE, as applied to paintings, has primarily to do with a type of subject, but the proper application of the term is limited also by the painter's attitude toward the subject. In genre painting the artist deals with intimate scenes and subjects from ordinary daily life. The elimination of imaginative content serves to focus attention upon the shrewd observation of types, costumes and settings and upon the beauty and appropriateness of colour, form and texture. True genre painting should reduce to a minimum such subjective qualities as the dramatic, historical, ceremonial, satirical, didactic, romantic, sentimental and religious. Characteristic works by Steen, Daumier, Rowlandson and Hogarth would thus be too satirical or didactic to qualify perfectly as genre, while those of Wheatley, Morland and Fragonard would be too sentimental and those of J. F. Millet too romantic.

In Europe, genre painting scarcely deserves serious notice until the late middle ages when we often find in manuscript books illuminated calendars showing the occupations appropriate to the months or seasons. *(See* ILLUMINATED MANUSCRIPTS.) These little genre pictures give intimate glimpses of the life of the time. Soon the taste for genre becomes so keen that Petrus Cristus, Pieter Aertsen and Pieter Bruegel paint scenes in shops and kitchens thinly disguised as religious subjects. This practice was followed later by Rembrandt, supreme in his ability to express profound emotion without surrendering the objective attitude. The greatest home of genre painting was indeed Holland in Rembrandt's time when flourished Adriaen van Ostade, Gerard Dou, Gabriel Metsu, Jan Vermeer, Pieter de Hooch and Terborch. Among later exponents are Jean Siméon Chardin in France and Pietro Longhi in Italy.

GENSONNÉ, ARMAND (1758–1793), French revolutionary, son of a military surgeon, was born at Bordeaux on August 10, 1758. He studied law, and at the outbreak of the Revolution was an advocate of the parlement of Bordeaux. In 1790 he became *procureur* of the Commune, and in July 1791 was elected by the newly created department of the Gironde a member of the court of appeal. In the same year he was elected deputy for the department to the Legislative Assembly. As reporter of the diplomatic committee, in which he supported the policy of Brissot, he proposed two of the most revolutionary measures passed by the Assembly: the decree of accusation against the king's brothers (January 1, 1792), and the declaration of war against the king of Bohemia and Hungary (April 20, 1792). He was vigorous in his denunciations of the intrigues of the court and of the "Austrian committee"; but the violence of the extreme democrats, culminating in the events of Aug. 10, greatly alarmed him; and when he was returned to the National Convention, he attacked the Commune of Paris (October 24 and 25). At the trial of Louis XVI. he supported an appeal to the people, but voted for the death sentence. As a member of the Committee of General Defence, and as president of the Convention (March 7–21, 1793), he shared in the bitter attacks of the Girondists on the Mountain; and on the fatal day, June 2, 1793, his name appeared among the first of those inscribed on the prosecution list. He was tried by the Revolutionary Tribunal on Oct. 24, 1793, condemned to death and guillotined on the 31st of the month, displaying on the scaffold a stoic fortitude. Gensonné was accounted one of the most brilliant of the little band of brilliant orators from the Gironde, though his eloquence was somewhat cold and he always read his speeches.

See F. A. Aulard, *L'Eloquence Parlementaire pendant la Revolution française,* vol. 2 p. *462.*

GENTIAN, botanically *Gentiana,* a large genus of herbaceous plants belonging to the family Gentianaceae. The genus comprises about 400 species—most of them perennial plants with tufted growth, growing in hilly or mountainous districts, chiefly in the northern hemisphere; but they are absent from Africa. The leaves are opposite, entire, smooth, and often strongly ribbed. The flowers have a persistent 4- to 5-lobed calyx and a 4- to 5-lobed tubular corolla; the stamens are equal in number to the lobes of the corolla. The ovary is one-celled, with two stigmas, either separate and rolled back or contiguous and funnel-shaped. The fruit when ripe separates into two valves, and contains numerous small seeds. The majority of the genus are remarkable for the deep or brilliant blue colour of their blossoms, comparatively few having yellow, white, or more rarely red flowers; the last are almost exclusively found in the Andes.

Only six species occur in Great Britain. G. *Amarella* (felwort or autumn gentian) and G. *campestris* are small annuals growing on chalky or calcareous+hills, and bearing in autumn tubular pale purple flowers; the latter is most easily distinguished by having two of the lobes of the calyx larger than the other two, while the former has the parts of the calyx in fives, and equal in size. Some intermediate forms between these two species occur, although rarely, in England; one of these, G. *germanica,* has larger flowers of a bluer tint, spreading branches, and a stouter stem. Some of these forms flower in spring. G. *Pneumonanthe,* the Calathian violet, is a rather rare perennial species, growing in moist heathy places from Cumberland to Dorsetshire. Its average height is from 6 to 9 in. It has linear leaves, and a bright blue corolla $1\frac{1}{2}$ in. long, marked externally with five greenish bands. It is the handsomest of the British species; two varieties of it are known in cultivation, one with spotted and the other with white flowers. G. *verna* and *G. nivalis* are small species with brilliant blue flowers and small leaves. The former is a rare and local perennial, occurring, however, in Teesdale and the county of Clare in Ireland. It has a tufted habit of growth, and each stem bears only one flower. It is sometimes cultivated as an edging for flower borders. G. *nivalis* in Britain is very rare and occurs only on a few of the loftiest Scottish mountains. It differs from the last in being an annual, and having a more isolated habit of growth, and in the stem bearing several flowers. On the Swiss mountains these beautiful little plants are very abundant, and

are one of the striking floral features of the Alps. For ornamental purposes several species are cultivated.

About 50 species occur in North America, widely distributed throughout the continent, but most numerous in the Rocky Mountain region. Of some 15 species found from the Great Plains eastward, among the best known are the fringed gentian (*G. crinita*), one of the most beautiful American wild flowers; the closed or bottle gentian (G. *Andrewsii*), the most common species; the downy gentian (G. *puberula*), of the prairie region; and the stiff gentian or ague-weed (G. *quinqueflora*), which extends southward to Florida. Of the many Rocky Mountain species, those with fringed flowers, as G. elegans and G. barbellata, are among the most conspicuous. Representative of the 12 or more species found in California and northward in the coastal mountains are the single-flowered gentian (G. simplex), with slightly fringed flowers, and the western blue gentian (G. *calycosa*), which throughout the summer forms sheets of intense blue in alpine meadows from California to British Columbia and eastward to Montana.

By far the most important of the species used in medicine is G. *lutea*, a large handsome plant 3 or 4 ft. high, growing in open grassy places on the Alps, Apennines and Pyrenees, as weli as on some of the mountainous ranges of France and Germany, extending as far east as Bosnia and the Danubian principalities. It has large oval strongly-ribbed leaves and dense whorls of conspicuous yellow flowers. Its use in medicine is of very ancient date. Pliny and Dioscorides mention that the plant was noticed by Gentius, a king of the Illyrians, living 180–167 B.C., from whom the name Gentiana is supposed to be derived. During the middle ages it was much employed in the cure of disease, and as an ingredient in counter-poisons. In 1552 Hieronymus Bock (Tragus) (1498–1554), a German priest, physician and botanist, mentions the use of the root as a means of dilating wounds.

The root, which is the part used in medicine, is tough and flexible, scarcely branched, and of a brownish colour and spongy texture. It has a pure bitter taste and faint distinctive odour. The bitter principle, known as *gentianin*, is a glucoside, soluble in water and alcohol. It can be decomposed into glucose and gentiopicrin by the acticn of dilute mineral acids. It is not precipitated by tannin or subacetate of lead. A solution of caustic potash or soda forms with gentianin a yellow solution, and the tincture of the root to which either of these alkalis has been added loses its bitterness in a few days. Gentian root also contains *gentianic* acid ($C_{14}H_{10}O_5$), which is inert and tasteless. It forms pale yellow silky crystals, very slightly soluble in water or ether, but soluble in hot strong alcohol and in aqueous alkaline solutions. This substance is also called *gentianin, gentisin* and gentksic acid.

The root also contains 12 to 15% of an uncrystallizable sugar called gentianose, of which fact advantage has long been taken in Switzerland and Bavaria for the production of a bitter cordial spirit called *Enzianbranntwein*. The use of this spirit, especially in Switzerland, has sometimes been followed by poisonous symptoms, which have been doubtfully attributed to inherent narcotic properties possessed by some species of gentian, the roots of which may have been indiscriminately collected with it; but it is quite possible that it may be due to the contamination of the root with that of *Veratrum* album, a poisonous plant growing at the same altitude, and having leaves extremely similar in appearance and size to those of *G.* lutea.

Gentian is one of the most efficient of the class of substances which act upon the stomach so as to invigorate digestion and thereby increase the general nutrition, without exerting any direct influence upon any other portion of the body than the alimentary canal. Having a pleasant taste and being nonastringent (owing to the absence of tannic acid), it is the most widely used of all bitter tonics. The British Pharmacopoeia contains an aqueous extract (dose, 2–8 grains), a compound infusion with orange and lemon peel (dose, ½–1 ounce), and a compound tincture with orange peel and cardamoms (dose ½–1 drachm). It is used in dyspepsia, chlorosis, anaemia and various other diseases, in which the tone of the stomach and alimentary canal is deficient, and is sometimes added to purgative medicines to increase and improve their action. In veterinary medicine it is also used as a tonic, and enters into a well-known compound called *diapente* as a chief ingredient.

GENTIANACEAE (the gentian family), a family of Dicotyledons belonging to the sub-class Sympetalae, and containing about 800 species and 80 genera. It has a world-wide distribution, and representatives adapted to very various conditions, including alpine plants, like the true gentians (*Gentiana*), meadow plants such as the British Chlora *perfoliata* (yellow-wort) or Erythraea *Centaurium* (centaury), marsh plants such as *Menyanthes trifoliata* (bog-bean), floating water plants such as *Limnanthemum*, or steppe and seacoast plants such as Cicendia. They are annual or perennial herbs, rarely shrubs, and generally growing erect, with a characteristic forked manner of branching; the Asiatic genus Crawfurdia, very close to *Gentiana*, has a climbing stem; they are often low-growing and caespitose, as in the alpine gentians.

FROM REGEL, "GARTEN FLORA" (FERDINAND ENKE)
GENTIAN (GENTIANA ACAULIS), A STEMLESS ALPINE SPECIES

The leaves are in decussating pairs (that is, each pair is in a plane at right angles to the previous or succeeding pair), except in *Menyanthes* and a few allied aquatic or marsh genera, where they are alternate or radical. Several genera, chiefly American, are saprophytes, forming slender low-growing herbs, containing little or no chlorophyll and with leaves reduced to scales; such is *Voyria*, mainly tropical American. The inflorescence is generally cymose, often dichasial, recalling that of Caryophyllaceae, the lateral branches often becoming monochasial; it is sometimes reduced to a few flowers or one only. as in some gentians. The flowers are hermaphrodite and regular, with parts in fours and fives, with reduction to two in the pistil; in *Chlora* there are six to eight members in each whorl. The calyx generally forms a tube with teeth or segments which usually overlap in the bud. The corolla shows great variety in form; thus among the British genera it is rotate in Chlora, funnel-shaped in Erythraea, and cylindrical, bell-shaped, funnel-shaped or salver-shaped in *Gentiana*; the segments are generally twisted to the right in the bud; the throat is often fimbriate or bears scales. The stamens, as many as, and alternating with, the corolla-segments, are inserted at very different heights on the corolla-tube; the filaments are slender, the anthers are usually attached dorsally, are versatile, and dehisce by two longitudinal slits; after escape of the pollen they sometimes become spirally twisted as in Erythraea. Dimorphic flowers are frequent, as in the bog-bean (*Menyanthes*). There is considerable variation in the size, shape and external markings of the pollen grains. The form of the honey-secreting developments of the disk at the base of the ovary also shows considerable variety. The superior ovary is generally one-chambered, with two variously developed parietal placentas, which occasionally meet, forming two chambers; the ovules are generally numerous and anatropous or half-anatropous in form. The style, which varies much in length. is simple, with an undivided or bilobed or bipartite stigma. The fruit is generally a membranous or leathery capsule, splitting septicidally into two valves; the seeds are small and numerous, and contain a small embryo in a copious endosperm.

The brilliant colour of the flowers, which often occur in large numbers (as in the alpine gentians), the presence of honey-glands and the frequency of dimorphy and dichogamy, are adaptations for pollination by insect visitors. In the true gentians (Geiztiana) the flowers of different species are adapted for widely differing types of insect visitors. Thus *Gentiana* lutea, with a rotate yellow corolla and freely exposed honey, is adapted to short-tongued insect visitors; G. *Pneumonanthe*, with a long-tubed, bright blue corolla, is visited by humble bees; and G. *verna*, with a still longer

narrower tube, is visited by Lepidoptera. *Gentiana*, the largest genus, contains about 400 species, distributed over Europe (including arctic), five being British, the mountains of Asia, south-east Australia and New Zealand, the whole of North America (30 species) and along the Andes to Cape Horn; it does not occur in Africa but is very highly developed in Asia. Bitter principles are general in the vegetative parts, especially in the rhizomes and roots. and have given a medicinal value to many species. *e.g., Gentiana lutea* and others. The next largest genus in North America is *Sabbatia*, with representatives from the Atlantic coast west into the prairie region. (*See* GENTIAN.)

GENTILE, GIOVANNI (1875–), Italian philosopher and politician, was born at Castelvetrano (Trapani) on May 29, 1875. He studied literature and philosophy at the University of Palermo, and after a series of university appointments became in 1918 professor of the history of philosophy in the University of Rome. Two years later he founded the *Giornale critico della filosofia italiana*. Created a Senator in 1918, he supported the Fascist movement from its beginnings, and when Mussolini's Government came into power, Gentile. was appointed minister of education. He was then a Liberal, but subsequently joined the Fascist party, of which he became a prominent member. As minister of education, he carried out an organic reform of the Italian educational system, impressing upon teachers the importance of an understanding of the development of mind and reviving religious teaching in the schools". For Gentile, education is a process of self-formation which should culminate in philosophy, the supreme form of self-consciousness. At this point alone do we arrive at reality, which is something given in the pure actuality of mind. Reality is not identifiable with the ideas of individual minds, but with the pure thinking or perfect self-consciousness of the super-personal, transcendental principle in the universe which overcomes all oppositions and distinctions. In this obvious attempt to revive idealism, Gentile endeavours to reform Hegelian dialectics and often appeals to the system of Vico.

Among his numerous works, which include an edition of Bruno's writings (1907), one of Vico's works (1914) and a translation of Kant's *Critique of Pure Reason* (1910), are:—La *Filosofia di Marx* (1899); *Storia della filosofia italiana* (1902, etc.); *Il modernismo* (1909); *Bernardino Telesio* (1911); *I problemi della scolastica e il pensiero italiano* (1913); *Sommario di Pedagogia come scienza filosofica* (2 vols., 1913–14); *Teoria generale dello spirito come atto puro* (1916; 3rd ed., 1920; Eng. trans., 1922); *Sistema di Logica come teorie del conoscere* (1917; 2nd ed., 1918); *I fondamenti della filosofia del diritto* (1917); *Le origini della filosofia contemporanea in Italia* (4 vols., 1917–23); *Il Problemo scolastico del dopo guerra* (1919); *La Riforma dell' educazione* (1920; Eng. trans., 1923); *Studi sul Rinascimento* (1923); *Lo Spaventa* (1924); *Il Fascismo al governo della scuola* (1924); *Che cosa è il fascismo* (1925); *Scritti politici* (1925).

See E. Chiocchetti, *La filosofia di Gentile* (1922); V. La Via, *L'Idealismo Attuale di Gentile* (1925) and F. de Sarlo, *Gentile e Croce* (1925).

GENTILE, in the English Bible, the term generally applied to those who were not of the Jewish race. It is an adaptation of the Lat. *gentilis*, of or belonging to the same *gens*, the clan or family; as defined by the grammarian Sextus Pompeius Festus (*c.* A.D. 150, edit. K. O. Miiller, 1839, p. 94): "gentilis dicitur et ex eodem genere ortus et is qui simili nomine appellatur; ut ait Cincius [*c.* 210 B.C.], gentiles mihi sunt, qui meo nomine appellantur." In post-Augustan Latin *gentilis* meant "national," belonging to the same race. Later still it meant "foreign," *i.e.*, other than Roman, and was used in the Vulgate with *gentes*, to translate the Hebrew *goyyim*, nations, LXX. ἔθνη, the non-Israelitish peoples (*see* further JEWS). It is also used by Mormons of all who are not Mormons. (A. L. W.)

GENTILE DA FABRIANO (*c.* 1370–1427), Italian painter, born at Fabriano, was the first great Umbrian master. About 1411 he went to Venice, where by order of the doge and senate he was engaged to adorn the great hall of the palace with frescoes from the life of Barbarossa. He executed this work so entirely to the satisfaction of his employers that they granted him a pension for life, and accorded him the privilege of wearing the habit of a Venetian noble. These paintings influenced the development of Venetian art; they are unfortunately no longer extant. About 1420 he went to Florence, where in 1423 he painted an "Adoration of the Magi" for the church of Santa Trinita, which is preserved in the Uffizi, Florence, and is considered his best work now extant. To the same period belongs a "Madonna and Child," which is now in the Berlin museum. Another fine example of his work is the "Madonna with Angels" (1425) lent by H.M. the King to the National Gallery, London. The wings of this altarpiece are in the Uffizi. He attained a wide reputation, and was engaged to paint pictures for various churches, more particularly Brescia, Siena, Perugia and Orvieto. In 1427 he was called to Rome by Martin V. to adorn the church of St. John Lateran with frescoes. Michelangelo said of him that his works resembled his name, meaning noble or refined. They are full of a quiet joyousness, and show a naïve delight in splendour and in gold ornaments.

GENTILESCHI, ARTEMISIA and **ORAZIO DE',** Italian painters.

ORAZIO (*c.* 1562–*c.* 1647) is generally named Orazio Lomi de' Gentileschi. He was born in Pisa, and studied under his half-brother Aurelio Lomi. He afterwards went to Rome and painted frescoes in S. Maria Maggiore, in the Lateran and in San Niccolo in Carcere; he was associated with the landscape-painter Agostino Tassi, executing the figures for the landscapes of this artist. Among his best works are: "The Circumcision" in the church of Gesu at Ancona; "The Madonna and S. Clara" in the Casa Rosei at Fabriano; "The Annunciation" in San Siro, Genoa; "Mary Magdalene" in Pal. Negrotti at Genoa; "The Finding of Moses" in the Prado, Madrid; "Saints Cecilia and Valerian" in the Brera, Milan; a "Flight into Egypt" in the Louvre, Paris; another in the Belvedere, Vienna, and "Joseph and Potiphar's Wife" at Hampton Court. At an advanced age Gentileschi went to England at the invitation of Charles I., and he was employed in the palace at Greenwich. Van Dyck included him in his portraits of a hundred illustrious men. His works generally are strong in shadow and positive in colour. He died in England about 1647.

ARTEMISIA (1597– after 1651), Orazio's daughter, studied first under Guido Reni, acquired much renown for portrait-painting, and considerably excelled her father's fame. She was a beautiful and elegant woman; her likeness, painted by her own hand, is to be seen in Hampton Court. Her most celebrated composition is "Judith and Holofernes," in the Uffizi gallery, Florence, certainly a work of singular energy, but repulsive in its physical horror. She went to England about 1638 and painted many portraits there. Artemisia refused an offer of marriage from Agostino Tassi, and bestowed her hand on Pier Antonio Schiattesi, continuing, however, to use her own surname. She settled in Naples, whither she returned from England, and was commissioned to paint three pictures for the cathedral of Pozzuoli.

GENTILI, ALBERICO (1552–1608), Italian jurist, who has great claims to be considered the founder of the science of international law, second son of Matteo Gentili, a physician of noble family and scientific eminence, was born on the 14th of January 1552 at Sanginesio, a small town of the march of Ancona which looks down from the slopes of the Apennines upon the distant Adriatic. After taking the degree of doctor of civil law at the university of Perugia, and holding a judicial office at Ascoli, he returned to his native city, and was entrusted with the task of recasting its statutes. Sharing the Protestant opinions of his father, he and his brother, Scipio, afterwards a famous professor at Altdorf, fled with their father to Carniola, where in 1579 Matteo was appointed physician to the duchy. The Inquisition condemned the fugitives as contumacious, and they soon received orders to quit the dominions of Austria.

Alberico set out for England, travelling by way of Tiibingen and Heidelberg, and everywhere meeting with the reception to which his already high reputation entitled him. He arrived at Oxford in the autumn of 1580, with a commendatory letter from the earl of Leicester, at that time chancellor of the university, and was shortly afterwards qualified to teach by being admitted to the same degree which he had taken at Perugia. His lectures on Ro-

man law soon became famous, and the dialogues, disputations and commentaries, which he published henceforth in rapid succession, established his position as an accomplished civilian, of the older and severer type, and secured his appointment in 1587 to the regius professorship of civil law. It was, however, rather by an application of the old learning to the new questions suggested by the modern relations of states that his labours have produced their most lasting result. In 1584 he was consulted by government as to the proper course to be pursued with Mendoza, the Spanish ambassador, who had been detected in plotting against Elizabeth. He chose the topic to which his attention had thus been directed as a subject for a disputation when Leicester and Sir Philip Sidney visited the schools at Oxford in the same year; and this was six months later expanded into a book, the *De legationibus libri tres.* In 1588 Alberico selected the law of war as the subject of the law disputations at the annual "Act" which took place in July; and in the autumn published in London the *De Jure Belli commentatio prima.* A second and a third *Commentatio* followed, and the whole matter, with large additions and improvements, appeared at Hanau, in 1598, as the *De Jure Belli libri tres.* It was doubtless in consequence of the reputation gained by these works that Gentili became henceforth more and more engaged in forensic practice, and resided chiefly in London, leaving his Oxford work to be partly discharged by a deputy. In 1600 he was admitted to be a member of Gray's Inn, and in 1605 was appointed standing counsel to the king of Spain. He died on the 19th of June 1608, and was buried, by the side of Dr. Matteo Gentili, who had followed his son to England, in the churchyard of St. Helen's, Bishopsgate. By his wife, Hester de Peigni, he left two sons, Robert and Matthew, and a daughter, Anna, who married Sir John Colt. His notes of the cases in which he was engaged for the Spaniards were posthumously published in 1613 at Hanau, as *Hispanicae advocationis libri duo.* This was in accordance with his last wishes; but his direction that the remainder of his MSS. should be burnt was not complied with, since fifteen volumes of them found their way, at the beginning of the 19th century, from Amsterdam to their permanent home in the Bodleian library.

The true history of Gentili and of his principal writings has only been ascertained in recent years, in consequence of a revived appreciation of the services which he rendered to international law. The movement to do him honour originated in 1875 in England, as the result of the inaugural lecture of Prof. T. E. Holland, and was warmly taken up in Italy. In spreading through Europe it encountered two curious cross-currents of opinion—one the ultra-Catholic, which three centuries before had ordered his name to be erased from all public documents and placed his works in the *Index;* another the narrowly-Dutch, which is, it seems, needlessly careful of the supremacy of Grotius. These two currents resulted respectively in a bust of Garcia Moreno being placed in the Vatican, and in the unveiling in 1886, with much international oratory, of a fine statue of Grotius at Delft. The English committee, under the honorary presidency of Prince Leopold, in 18;; erected a monument to the memory of Gentili in St. Helen's church, and saw to the publication of a new edition of the *De Jure Belli.* The Italian committee, of which Prince (afterwards King) Humbert was honorary president, was less successful. It was only in 1908, the tercentenary of the death of Alberico, that the statue of the great heretic was at length unveiled in his native city by the minister of public instruction, in the presence of numerous deputations from Italian cities and universities. Preceding writers had dealt with various international questions, but they dealt with them singly, and with a servile submission to the decisions of the church. It was left to Gentili to grasp as a whole the relations of states one to another, to distinguish international questions from questions with which they are more or less intimately connected, and to attempt their solution by principles entirely independent of the authority of Rome. He uses the reasonings of the civil and even the canon law, but he proclaims as his real guide the *Jus Naturae,* the highest common sense of mankind, by which historical precedents are to be criticized and, when this appears to be necessary, set aside.

His faults are not few. His style is prolix, obscure, and to the modern reader pedantic enough; but a comparison of his greatest work with what had been written upon the same subject by, for instance, Belli, or Soto, or even Ayala, will show that he greatly improved upon his predecessors, not only by the fullness with which he has worked out points of detail, but also by clearly separating the law of war from martial law, and by placing the subject once for all upon a non-theological basis. If, on the other hand, the same work be compared with the *De Jure Belli et Pacis* of Grotius, it is at once evident that the later writer is indebted to the earlier, not only for a large portion of his illustrative erudition, but also for all that is commendable in the method and arrangement of the treatise.

The following is probably a complete list of the writings of Gentili, with the places and dates of their first publication: *De juris interpretibus dialogi sex* (London, 1582); *Lectionum et epist. quae ad jus civile pertinent libri tres* (London, 1583–1584); *De legationibus libri tres* (London, 1585); *Legal. comitiorum Oxon. actio* (London, 1585–1586); *De divers. temp. appellationibus* (Hanau, 1586); *De nascendi tempore disputatio* (Witteb., 1586); *Disputationum decas prima* (London, 1587); *Conditionum liber singularis* (London, 1587); *De jure belli comm. prima* (London, 1588); *secunda,* ib. (1588–1589); *tertia* (1589); *De injustitia bellica Romanorum* (Oxon. 1590); *Ad tit. de Malef. et Math. de Prof. et Med.* (Hanau, 1593); *De jure belli libri tres* (Hanau, 1598); *De armis Romanis, etc.* (Hanau, 1599); *De actoribus et de abusu mendacii* (Hanau, 1599); *De ludis scenicis epist. duae* (Middleburg, 1600); *Ad* I. *Maccabaeorum et de linguarum mistura disp.* (Frankfurt, 1600); *Lectiones Virgilianae* (Hanau, 1600); *De nuptiis libri septem* (1601); *In tit. si quis principi, et ad leg. Jul. maiest.* (Hanau, 1604); *De latin. vet. Bibl.* (Hanau, 1604); *De libro Pyano* (Oxon. 1604); *Laudes Acad. Perus. et Oxon.* (Hanau, 1605); *De unione Angliae et Scotiae* (London, 1605); *Disputationes tres, de libris jur. can., de libris jur. civ., de latinitate vet. vers.* (Hanau, 1605); *Regales disput. tres, de pot. regis absoluta, de unione regnorum, de vi civium* (London, 1605); *Hispanicae advocationis libri duo* (Hanau, 1613); *In tit, de verb. signif.* (Hanau, 1614); *De legatis in test.* (Amsterdam, 1661).

An edition of the *Opera omnia,* commenced at Naples in 1770, was cut short by the death of the publisher, Gravier, after the second volume. *See* several tracts by the Abate Benigni in Colucci, *Antichità Picene* (1790); a dissertation by W. Reiger annexed to the *Program of the Groningen Gymnasium* for 1867; an inaugural lecture delivered in 1874 by T. E. Holland. translated into Italian. with additions by the author, by A. Saffi (1884); the preface to a new edition of the *De jure belli* (1877) and *Studies in International Law* (1898) (which *see,* for details as to the family and mss. of Gentili), by the same; works by Valdarnini and Foglietti (1874), Speranza and De Giorgi (1876), Fiorini (a translation of the *De jure belli,* with essay, 1877), A. Saffi (1878), L. Marson (1885), M. Thamm (1896), B. Brugi (1898), T. A. Walker (an analysis of the principal works of Gentili) in his *History of the Law of Nations,* vol. i. (1899); H. Nézarel, in Pillet's *Fondateurs de droit international* (1904); E. Agabiti (1908). *See* also E. Comba, in the *Rivista Christiana* (1876–77); Sir T. Twiss, in the *Law Review* (1878); articles in the *Revue de droit international* (1875–78, 1883, 1886, 1908); O. Scalvanti, in the *Annali dell' Univ. di Perugia,* N.S., vol. viii. (1898); A. Gentili, *Hispanicae advocationis Eibri dvo.,* with an introduction and translation by F. F. Abbott (1921); *A.* Gentili, *De legationibus Libri Tres,* with an introduction by E. Nys and a translation of the text by G. J. Laing (1924).

GENTLEMAN, in its original and strict signification, a term denoting a man of good family (from Lat. *gentilis,* "belonging to a race or *gens,*" and "man"; the Lat. *generosus* [its invariable translation in English-Latin documents]). In this sense it is the equivalent of the Fr. *gentilhomme,* "nobleman," which latter term has in Great Britain been long confined to the peerage *(see* NOBILITY); and the term "gentry" ("gentrice" from O.Fr. *genterise* for *gentelise)* has much of the significance of the Fr. *noblesse* or the Ger. *Adel.* This was what was meant by the rebels under John Ball in the 14th century when they repeated:

> When Adam delved and Eve span,
> Who was then the gentleman?

Selden *(Titles of Honor,* 16; 2), discussing the title "gentleman," speaks of "our English use of it" as "convertible with *nobilis,*" and describes in connection with it the forms of ennobling in various European countries William Harrison, writing a century

earlier, says "gentlemen be those whom their race and blood, or at the least their virtues, do make noble and known." But for the complete gentleman the possession of a coat of arms was in his time considered necessary; and Harrison gives the following account of how gentlemen were made in Shakespeare's day:

"Who soever studieth the laws of the realm, who so abideth in the university, giving his mind to his book, or professeth physic and the liberal sciences, or beside his service in the room of a captain in the wars, or good counsel given at home, whereby his commonwealth is benefited, can live without manual labour, and thereto is able and will bear the port, charge and countenance of a gentleman, he shall for money have a coat and arms bestowed upon him by heralds (who in the charter of the same do of custom pretend antiquity and service, and many gay things) and thereunto being made so good cheap be called master, which is the title that men give to esquires and gentlemen, and reputed for a gentleman ever after. No man hath hurt by it but himself, who peradventure will go in wider buskins than his legs will bear, or as our proverb saith, now and then bear a bigger sail than his boat is able to sustain."

In this way Shakespeare himself was turned, by the grant of a coat of arms, from a "vagabond" into a gentleman.

The fundamental idea of "gentry," symbolized in this grant of coat-armour, had come to be that of the essential superiority of the fighting man; and, as Selden points out (p. 707), the fiction was usually maintained in the granting of arms "to an ennobled person though of the long Robe wherein he hath little use of them as they mean a shield." At the last the wearing of a sword on all occasions was the outward and visible sign of a "gentleman"; and the custom survives in the sword worn with "court dress." This idea that a gentleman must have a coat of arms, and that no one is a "gentleman" without one is, however, of comparatively late growth, the outcome of the natural desire of the heralds to magnify their office and collect fees for registering coats; and the same is true of the conception of "gentlemen" as a separate class. That a distinct order of "gentry" existed in England very early has, indeed, been often assumed, and is supported by weighty authorities. Thus, the late Professor Freeman (Ency. *Brit.* xvii. p. 540 b, 9th ed.) said: "Early in the 11th century the order of 'gentlemen' as a separate class seems to be forming as something new. By the time of the conquest of England the distinction seems to have been fully established." Stubbs (*Const. Hist.*, ed. 1878, iii. 544, 548) takes the same view. Sir George Sitwell, however, has conclusively proved that this opinion is based on a wrong conception of the conditions of mediaeval society, and that it is wholly opposed to the documentary evidence. Even so late as 1400 the word "gentleman" still only had the sense of *generosus,* and could not be used as a personal description denoting rank or quality, or as the title of a class. Yet after 1413 we find it increasingly so used; and the list of landowners in 1431, printed in Feudal Aids, contains, besides knights, esquires, yeomen and husbandmen, a fair number who are classed as "gentilman."

Sir George Sitwell gives a lucid explanation of this development. The immediate cause was the statute 1 Henry V. cap. v. of 1413, which laid down that in all original writs of action, personal appeals and indictments, in which process of outlawry lies, the "estate, degree or mystery" of the defendant must be stated, as well as his present or former domicile. Now the Black Death (1349) had put the traditional social organization out of gear. Before that the younger sons of the *nobiles* had received their share of the farm stock, bought or hired land, and settled down as agriculturists in their native villages. Under the new conditions this became increasingly impossible, and they were forced to seek their fortunes abroad in the French wars, or at home as hangers-on of the great nobles. These men, under the old system, had no definite status; but they were generosi, men of birth, and, being now forced to describe themselves, they disdained to be classed with franklins (now sinking in the social scale), still more with yeomen or husbandmen; they chose, therefore, to be described as "gentlemen." On the character of these earliest "gentlemen" the records throw a lurid light. According to Sir George Sitwell (p. 76), "the premier gentleman of England, as the matter now stands, is 'Robert Erdeswyke of Stafford, gentilman,'" who had served among the men-at-arms of Lord Talbot at Agincourt (ib. note). He is typical of his class. "Fortunately — for the gentle reader will no doubt be anxious to follow in his footsteps — some particulars of his life may be gleaned from the public records. He was charged at the Staffordshire Assizes with housebreaking, wounding with intent to kill, and procuring the murder of one Thomas Page, who was cut to pieces while on his knees begging for his life." If any earlier claimant to the title of "gentleman" be discovered, Sir George Sitwell predicts that it will be within the same year (1414) and in connection with some similar disreputable proceedings.

From these unpromising beginnings the separate order of "gentlemen" was very slowly evolved. The first "gentleman" commemorated on an existing monument was John Daundelyon of Margate (d. *c.* 1445); the first gentleman to enter the House of Commons, hitherto composed mainly of "valets," was "William Weston, gentylman"; but even in the latter half of the 15th century the order was not clearly established. As to the connection of "gentilesse" with the official grant or recognition of coat-armour, that is a profitable fiction invented and upheld by the heralds; for coat-armour was but the badge assumed by gentlemen to distinguish them in battle, and many gentlemen of long descent never had occasion to assume it, and never did. This fiction, however, had its effect; and by the 16th century, as has been already pointed out, the official view had become clearly established that "gentlemen" constituted a distinct order, and that the badge of this distinction was the heralds' recognition of the right to bear arms. It is unfortunate that this view, which is quite unhistorical, has of late years been given a wide currency in popular manuals of heraldry.

In this narrow sense, however, the word "gentleman" has long since become obsolete. The idea of "gentry" in the continental sense of *noblesse* is extinct in England, and is likely to remain so, in spite of the efforts of certain enthusiasts to revive it (see A. C. Fox-Davies, Armorial Families, Edinburgh, 1895). That it once existed has been sufficiently shown; but the whole spirit and tendency of English constitutional and social development tended to its early destruction. The comparative good order of England was not favourable to the continuance of a class, developed during the foreign and civil wars of the 14th and 15th centuries, for whom fighting was the sole honourable occupation. The younger sons of noble families became apprentices in the cities, and there grew up a new aristocracy of trade. Merchants are still "citizens" to William Harrison; but he adds "they often change estate with gentlemen, as gentlemen do with them, by mutual conversion of the one into the other." A frontier line between classes so indefinite could not be maintained, especially as in England there was never a "nobiliary prefix" to stamp a person as a gentleman by his surname, as in France or Germany. The process was hastened, moreover, by the corruption of the Heralds' College and by the ease with which coats of arms could be assumed without a shadow of claim; which tended to bring the "science of armory" into contempt. The word "gentleman" as an index of rank had already become of doubtful value before the great political and social changes of the 19th century gave to it a wider and essentially higher significance. The change is well illustrated in the definitions given in the successive editions of the *Encyclopædia Britannica.* In the 5th edition (1815) "a gentleman is one, who without any title, bears a coat of arms, or whose ancestors have been freemen." In the 7th edition (1845) it still implies a definite social status: "All above the rank of yeomen." In the 8th edition (1856) this is still its "most extended sense"; "in a more limited sense" it is defined in the same words as those quoted above from the 5th edition; but the writer adds, "By courtesy this title is generally accorded to all persons above the rank of common tradesmen when their manners are indicative of a certain amount of refinement and intelligence." The Reform Bill of 1832 has done its work; the "middle classes" have come into their own; and the word "gentleman" has come in common use to signify not a distinction of blood but a distinction of position, education and manners. The test is no longer good birth, or the right to bear arms, but the capacity to mingle on

equal terms in good society. In its best use, moreover, "gentleman" involves a certain superior standard of conduct, due, to quote the 8th edition once more, to "that self-respect and intellectual refinement which manifest themselves in unrestrained yet delicate manners." The word "gentle," originally implying a certain social status, had very early come to be associated with the standard of manners expected from that status. Thus by a sort of punning process the "gentleman" becomes a "gentle-man." Chaucer in the *Meliboeus (c.* 1386) says: "Certes he sholde not be called a gentil man, that . . . ne dooth his diligence and bisynesse, **to** kepen his good name"; and in the *Wife of Bath's Tale:*

> Loke who that is most vertuous alway
> Prive and apert, and most entendeth ay
> To do the gentil dedes that he can
> And take him for the gretest gentilman,

and in the *Romance of the Rose (c.* 1400) we find "he is gentil bycause he doth as longeth to a gentilman." This use develops through the centuries, until in 1714 we have Steele, in the *Tatler* (No. 207), laying down that "the appellation of Gentleman is never to be affixed to a man's circumstances, but to his Behaviour in them," a limitation over-narrow even for the present day. In this connection, too, may be quoted the old story, told by some—very improbably—of James II., of the monarch who replied to a lady petitioning him to make her son a gentleman, "I could make him a nobleman, but God Almighty could not make him a gentleman." Selden, however, in referring to similar stories "that no Charter can make a Gentleman, which is cited as out of the mouth of some great Princes that have said it," adds that "they without question understood Gentlemen for *Generosus* in the ancient sense, or as if it came from *Gentilis* in that sense, as *Gentilis* denotes one of a noble Family, or indeed for a Gentleman by birth." For "no creation could make a man of another blood than he is." The word "gentleman," used in the wide sense with which birth and circumstances have nothing to do, is necessarily incapable of strict definition. For "to behave like a gentleman" may mean little or much, according to the person by whom the phrase is used; "to spend money like a gentleman" may even be no great praise; but "to conduct a business like a gentleman" implies a standard at least as high as that involved in the phrase *"noblesse oblige."* In this sense of a person of culture, character and good manners the word "gentleman" has supplied a gap in more than one foreign language.

The evolution of this meaning of "gentleman" reflects very accurately that of English society; and there are not wanting signs that the process of evolution, in the one as in the other, is not complete. The indefinableness of the word mirrors the indefinite character of "society" in England; and the use by "the masses" of "gentleman" as a mere synonym for "man" has spread *pari passu* with the growth of democracy. It is a protest against implied inferiority, and is cherished as the modern French *bourgeois* cherishes his right of duelling with swords, under the *ancien régime* a prerogative of the *noblesse.* Nor is there much justification for the denunciation by purists of the "vulgarization" and "abuse" of the "grand old name of gentleman." Its strict meaning has now fallen completely obsolete. Its current meaning varies with every class of society that uses it. But it always implies some sort of excellency of manners or morals. It may by courtesy be over-loosely applied by one common man to another; but the common man would understand the reproach conveyed in "You're no gentleman."

A. P.)

GENTLEMEN'S AGREEMENTS. Where two or more rivals in business meet privately and agree as to what prices they shall charge or what areas they shall serve or what goods they will or will not handle, the arrangement is known as a Gentlemen's Agreement or honourable understanding. Such arrangements have always been a common feature of local trade. Coal dealers will meet and agree not to cut below a certain price, or arrange that one shall confine his canvassing to the north side of the town and the other to the south. The grocer and the greengrocer will agree, the one not to sell oranges if the other will not sell packet peas. At the other end of the economic scale steel or shipping magnates will meet and come to an understanding as to tonnage, prices, markets, freights or routes. Such arrangements are essentially informal and temporary; there are no documents, there is no association, there is no bond except that of good faith; but they are not on that account of negligible importance; they are, indeed, a particularly insidious and undetectable form of trade combination. They do not necessarily make for ill; they may serve a useful purpose in restraining vicious competition and in avoiding the overlapping of services; but because they are secret they lend themselves the more easily to the exploitation of the buying public.

In the United Kingdom such arrangements are not illegal unless they involve an illegal act, in which case they constitute a breach of the common law. In the United States they are forbidden under the Sherman Law, which declares illegal "every . . . conspiracy in restraint of trade or commerce," but the detection and penalising of "honourable understandings" has proved to be one of the most difficult of all the applications of that law. The most notable example of the Gentlemen's Agreement in industrial history is the "Gary Dinners" which the president of the United States Steel Corporation gave to presidents of other American steel companies from Nov. 1907 to Jan. 1911. At these dinners "honourable understandings" were reached between persons controlling some 90% of the entire steel output of the country.

At one stage of the development of the "Open Price Association" movement in the United States *(see* ASSOCIATION, INDUSTRIAL) the plan was tried of regular meetings of Association members at which the prices quoted by members were openly announced and discussed without any agreement being reached as to what prices ought to be and would be charged; but this was held in the courts to have the effect in practice of establishing a concerted price on the ground that members conformed, by an honourable understanding, to the conclusions reached in the course of the discussion. *(See* TRUSTS and COMBINATION for an account of other forms of trade combination.) (J. H.)

GENTZ, FRIEDRICN VON (1764–1832), German publicist and statesman, was born at Breslau on May 2, 1764. His father was an official, his mother an Ancillon, distantly related to the Prussian minister of that name. On his father's transference to Berlin, as director of the mint, the boy was sent to the Joachimsthal gymnasium there; his brilliant talents, however, did not develop until, at the university of Königsberg, he fell under the influence of Kant. But though his intellect was sharpened and his zeal for learning quickened by the greater thinker's influence, Kant's "categorical imperative" did not prevent him from yielding to the taste for wine, women and high play which pursued him through life. In 1785 he received the appointment of secret secretary to the royal *Generaldirectorium* in Berlin.

His interest in public affairs was first aroused by the outbreak of the French Revolution, which he greeted at first with enthusiasm; but its subsequent developments cooled his ardour and he was converted to more conservative counsels by Burke's *Essay on the French Revolution,* a translation of which into German (1794) was his first literary venture. This was followed, next year, by translations of works on the Revolution by Mallet du Pan and Mounier. He also founded and edited a monthly journal, the *Neue deutsche Monatsschrift,* in which for five years he wrote, mainly on historical and political questions, maintaining the principles of British constitutionalism against those of revolutionary France. The knowledge he displayed of the principles and practice of finance was especially remarkable. His literary output at this time, all inspired by a moderate Liberalism, included an essay

on the results of the discovery of America, and another, written in French, on the English financial system (*Essai sur l'état de l'administration des finances de la Grande-Bretagne,* London, 1800). Especially noteworthy, however, was the *Denkschrift* or *Missive* addressed by him to King Frederick William III. on his accession (1797), in which, *inter alia,* he urged upon the king the necessity for granting freedom to the press and to commerce. Opposition to France was the inspiring principle of the *Historisches Journal* founded by him in 1799–1800, which once more held up English institutions as the model, and became in Germany the mouthpiece of British policy towards the revolutionary aggressions of the French republic. In 1801 he ceased the publication of the *Journal,* and issued instead, under the title *Beitriige zur Geschichte,* etc., a series of essays on contemporary politics. The first of these was *Über den Ursprung und Charakter des Krieges gegen die französische Revolution* (1801), by many regarded as Gentz's masterpiece.

This activity brought him reputation and gifts of money from the British and Austrian governments; but it made his position as an official in Berlin impossible, for the Prussian government had no mind to abandon its attitude of cautious neutrality. A separation from his wife also made it desirable for Gentz to leave the Prussian service. In May 1802, accordingly, he took leave of his wife and left with his friend Adam Miiller for Vienna. In Berlin he had been intimate with the Austrian ambassador, Count Stadion, whose good offices procured him an introduction to the emperor Francis. The immediate result was the title of imperial councillor, with a yearly salary of 4,000 gulden (December 6th, 1802); but he was not actively employed until 1809. Before returning to Berlin to make arrangements for transferring himself finally to Vienna, Gentz paid a visit to London, where he made the acquaintance of Pitt and Granville, who guaranteed him an annual pension by the British government in recognition of the value of his writings against Bonaparte. From this time forward he was engaged in a ceaseless polemic against every fresh advance of the Napoleonic power and pretensions; he denounced the recognition of Napoleon's imperial title, and drew up a manifesto of Louis XVIII. against it. The formation of the coalition and the outbreak of war for a while raised his hopes, in spite of his lively distrust of the competence of Austrian ministers; but the hopes were speedily dashed by Austerlitz and its results. Gentz used his enforced leisure to write a brilliant essay on "The relations between England and Spain before the outbreak of war between the two powers" (Leipzig, 1806); and shortly afterwards appeared *Fragmente aus der neuesten Geschichte des politischen Gleichgewichts in Europa* (trans. *Fragments on the Balance of Power in Europe,* London, 1806). This latter, the last of Gentz's works as an independent publicist, was a masterly expos6 of the actual political situation, and at the same time prophetic in its suggestions as to how this should be retrieved: "Through Germany Europe has perished, through Germany it must rise again."

He realized that the dominance of France could only be broken by the union of Austria and Prussia, acting in concert with Great Britain. He watched with interest the Prussian military preparations, and, at the invitation of Count Haugwitz, he went at the outset of the campaign to the Prussian headquarters at Erfurt, where he drafted the king's proclamation and his letter to Napoleon. The writer was known, and it was in this connection that Napoleon referred to him as "a wretched scribe named Gentz, one of those men without honour who sell themselves for money." In this mission Gentz had no official mandate from the Austrian government, and whatever hopes he may have cherished of privately influencing the situation in the direction of an alliance between the two German powers were dashed by the campaign of Jena.

The downfall of Prussia left Austria the sole hope of Germany and of Europe. Gentz, who from the winter of 1806 onwards divided his time between Prague and the Bohemian watering-places, occupied himself with a series of essays on the future of Austria and the best means of liberating Germany and redressing the balance of Europe.

In 1809, on the outbreak of war between Austria and France, Gentz was for the first time actively employed by the Austrian government under Stadion; he drafted the proclamation announcing the declaration of war (April 15), and during the continuance of hostilities his pen was ceaselessly employed. But the peace of 1810 and the fall of Stadion once more dashed his hopes, and he once more retired to Prague. It was not till 1812 that there sprang up between him and Metternich the close relations that were to ripen into life-long friendship. But when Gentz returned to Vienna as Metternich's adviser and henchman, he was no longer the fiery patriot who had sympathized and corresponded with Stein in the darkest days of German depression and in fiery periods called upon all Europe to free itself from foreign rule. Disillusioned and cynical, though clear-sighted as ever, he was henceforth before all things an Austrian, more Austrian on occasion even than Metternich; as, *e.g.,* when, during the final stages of the campaign of 1814, he expressed the hope that Metternich would substitute "Austria" for "Europe" in his diplomacy and secure an Austro-French alliance by maintaining the husband of Marie Louise on the throne of France.

For ten years, from 1812 onward, Gentz was in closest touch with all the great affairs of European history, the assistant, confidant, and adviser of Metternich. He accompanied the chancellor on all his journeys; was present at all the conferences that preceded and followed the war; no political secrets were hidden from him; and his hand drafted all important diplomatic documents. He was secretary to the congress of Vienna (1814–1815) and to all the congresses and conferences that followed, up to that of Verona (1822), and in all his vast knowledge of men and affairs made him a power. He was under no illusion as to their achievements; his memoir on the work of the congress of Vienna is at once an incisive piece of criticism and a monument of his own disillusionment. But the liberalism of his early years was gone for ever, and he had become reconciled to Metternich's view that, in an age of decay, the sole function of a statesman was to "prop up mouldering institutions." It was the hand of the author of that offensive *Missive* to Frederick William III., on the liberty of the press, that drafted the Carlsbad decrees; it was he who inspired the policy of repressing the freedom of the universities; and he noted in his diary as "a day more important than that of Leipzig" the session of the Vienna conference of 1819, in which it was decided to make the convocation of representative assemblies in the German states impossible, by enforcing the letter of Article XIII. of the Act of Confederation.

As to Gentz's private life there is not much to be said. His love affairs are too numerous to record. Passion tormented him to the end, and his infatuation for Fanny Elssler, the celebrated *danseuse,* forms the subject of some remarkable letters to his friend Rahel, the wife of Varnhagen von Ense (1830–1831). He died on June 9, 1832.

Gentz has been described as a mercenary of the pen, but he was more than the "wretched scribe" sneered at by Napoleon. Though by birth belonging to the middle class in a country of hide-bound aristocracy, he lived to move on equal terms in the society of princes and statesmen; which would never have been the case had he been notoriously "bought and sold." Yet that he was in the habit of receiving gifts from all and sundry who hoped for his backing is beyond dispute. He notes that at the congress of Vienna he received 22,000 florins through Talleyrand from Louis XVIII., while Castlereagh gave him £600, accompanied by *les plus folles promesses;* and his diary is full of such entries. Yet he never made any secret of these gifts; Metternich was aware of them, and he never suspected Gentz of writing or acting in consequence against his convictions. No man was more free or outspoken in his criticism of the policy of his employers than this apparently venal writer.

Indeed, the very impartiality and objectivity of his attitude make the writings of Gentz such illuminating documents for the period. Allowance must of course be made for his point of view, but less so perhaps than in the case ot any other writer so intimately concerned with the policies which he criticizes. And, apart from their historical value, Gentz's writings are literary monuments, classical examples of nervous and luminous German prose.

or of French which is a model for diplomatic style.

A selection of Gentz's works (*Ausgewählte Schriften*) was published by Weick in 5 vols. (1836–38); his lesser works (Mannheim, 1838–40) in 3 vols. and *Mémoires et lettres inédites* (Stuttgart, *1841*) were edited by G. Schlesier. Subsequently there have appeared *Briefe an Ckr. Garve* (Breslau, 1857); correspondence (*Briefwechsel*) with Adam Miiller (Stuttgart, 1857); *Briefe an Pilat* (2 vols., Leipzig, *1868*); *Aus dent Nachlass Friedriclzs von Gentz* (2 vols.), ed. Count Anton Prokesch-Osten (Vienna, *1867*); *Aus der alten Registratur der Staats-Kanzlei: Briefe politischen Inhalts von und an Friedrich von Gentz,* edited by C. von Klinckowström (Vienna, 1870); *Dépêches intdites du chev. de Gentz aux Hospodars de Valachie 1813–1828* (a correspondence on current affairs commissioned by the Austrian government), ed. Count Anton von Prokesch-Osten the younger (3 vols., Paris, 1876), incomplete, but partly supplemented in *Oesterreichs Teilnahme* an *den Befreiungskriegen* (Vienna, 1887), a collection of documents of the greatest value; *Zur Geschichfe der orientalischen Frage: Briefe aus dem Nachlass Friedrichs von Gentz* (Vienna, 1877), ed. Count Prokesch-Osten the younger; *Briefe von und an Friedrichs von Gentz,* ed. *F.* C. Wittichen (*4* vols., 1909–13). Finally Gentz's diaries. from 1800 to 1828, an invaluable mine of authentic material. were edited by Varnhagen von Ense and published after his death under the title *Tagebücher,* etc. (Leipzig, 1861; new ed., 4 vols., *ib.* 1873). For the biography of Gentz *see* K. Mendelssohn-Bartholdy, *Friedrich von Gentz* (1867); *E.* Guglia. *Friedrich von Gentz* (1901); M. Pfliiger, *Friedrich von Gentz als Widersacher Napoleons* (1904). E. Guglia, *Friedrich von Gent:* (Vienna, 1901).

GEODESY, in modern English usage is the science of surveying tracts of country so large that the curvature of the earth must be allowed for; also the determination of the figure of the Earth, including the various geophysical problems most intimately connected therewith. Sometimes in modern languages other than English the word cognate to *geodesy* may mean hardly more than the original Greek (Gr. γεωδαισία, the art or science of mensuration, from γῆ, Earth, and δαίειν, to divide), that is, it may mean merely accurate land surveying, and some epithet, such as *higher,* must be added to make the phrase coextensive with the English word *geodesy.*

(I.) THE FIGURE OF THE EARTH—HISTORICAL

The earliest geodesy (in the English sense) was concerned almost exclusively with determining the figure of the Earth, a problem then chiefly of speculative interest, for the need of accurate maps, in which the figure of the Earth must be taken into account, was hardly felt until the time of Columbus.[1] The naïve view of primitive man, still held by the backward and uneducated, was that the Earth is a flat plane, or a circular disk, diversified by seas, rivers and mountains. It might seem as if some notion of the approximate sphericity, or at least of the curvature, of the Earth might have originated with those earlier peoples, such as the Babylonians, who cultivated the science of astronomy, and who must have noticed that when an observer travelled south the aspect of the heavens changed, as stars hitherto never seen came into view over the southern horizon and the number of northern circumpolar star always on view became smaller, the phenomena being reversed as the observer journeyed northward. But no record of any explanation of all this based on the curvature of the Earth has come down to us from any pre-Hellenic source. Or it might seem as if any seafaring people, observing a vessel go "hull down, down and under," as the observer's distance from it increased, might have conceived the idea of a spherical or at least of a rotund Earth. But again we have no record of any such doctrine emanating from any of the earlier maritime peoples.

The earliest enunciation of the doctrine of a spherical Earth comes from Pythagoras or from his school of philosophy, and even then the doctrine may have been based quite as much on metaphysical as on physical considerations. By the time of Aristotle, however, the doctrine of a spherical Earth had at least a respectable amount of support among the more learned of his contemporary Greeks. Aristotle devotes a part of his book *De Caelo* to a defence of the doctrine. He even gives an estimate of the size of the Earth, saying:

"Moreover those mathematicians who try to compute the circumference of the Earth say that it is 400.000 stadia, which indicates not only that the earth's mass is spherical in shape but also that it is of no great size as compared with the heavenly bodies." (*De Caelo,* Book II., Chap. 14.)

This passage follows a long argument in favour of the sphericity of the earth. Some of the arguments sound modern enough; others seem strange to our present wavs of thinking. This seems to represent the first scientific attempt now on record to determine the size of the Earth. Even the unit has been supplied by the commentators, the word *stadia* not occurring in the best texts. How this figure of 400,000 stadia was attained we do not know. It may have been by a process such as that used by Eratosthenes, who will next be mentioned, or it may have been by crude measures of the depression of objects at sea. If we take Aristotle's stadion to be the Attic stadion of 185 meters (607 ft.), then this figure represents a considerable overestimate, but is of the right order of magnitude, as a mathematician would say.

Eratosthenes of Alexandria (*c.* 276–*c.* 195 B.C.) is the first known writer to describe and apply a method for determining the size of the Earth. He assumed that Syene (the modern Assuan on the Nile) lay on the Tropic of Cancer so that the sun at the summer solstice was exactly overhead. Eratosthenes observing at Alexandria at the solstice found the sun to be 1/50 of a circumference away from the zenith, that is, the difference of latitude between the two places he took to be 1/50 of 360° =7° 12′. He assumed that Alexandria and Syene lie on the same meridian, which is not exactly true, and that the distance between them is 5,000 stadia.

On the principle of the exact correspondence between angular distances in the heavens and distances measured on the terrestrial globe it follows that 1/50 of the circumference represents 5,000 stadia, or that the whole circumference is 250,000 stadia. With any plausible modern equivalent of that stadion this is much nearer the truth than Aristotle's figure.

We have reports of two other Greek attempts to determine the circumference of the Earth, but there is no reason to suppose the results to be any better than that found by Eratosthenes. Ptolemy in his *Geography* gives the length of a degree as 500 stadia, which makes the circumference 180,000 stadia. These results are all clouded by the uncertainty as to the modern equivalent of the stadion, and it may well be that the stadion used by different writers was different. The same uncertainty affects a determination on principles similar to those of Eratosthenes made on the plains of Shinar in Mesopotamia under the orders of the Caliph Abdullah al Mamun (AD. 786–833), although the distances were actually measured instead of being estimated.

No refinement of theory over Eratosthenes was made until the oblateness of the Earth came into question during the late 17th and the first half of the 18th centuries. For determining distances on the Earth, Willebrord Snell (1591–1626) substituted a chain of triangles in Holland for direct measurement.

In 1669 Picard (*q.v.*) first used the telescope both in the determination of latitude and in the measurement of angles of triangulation, a device whereby the accuracy of both operations was increased. Picard's results for the length of a degree were used by Newton in his calculations to prove that the attraction of the Earth is the principal force governing the motion of the Moon in its orbit.

With Newton and his contemporary Huyghens a new era in geodesy begins. The physical proofs of the sphericity of the Earth had so far been proofs of its general rotundity. In the Ptolemaic astronomy it had seemed natural to assume—for reasons usually of a metaphysical sort—the earth to be an exact sphere; but with the growing conviction that the Copernican system is true and that the earth rotates about its axis, and with the advance in mechanical knowledge due chiefly to Newton and Huyghens, it seemed natural to conceive the earth as an oblate spheroid flattened at the poles. There was also the experimental evidence of the astronomer Jean Richer, who found that his clock, regulated

[1] This does not mean that until about this time there were no maps in which places were located by their latitude and longitude; there had been such at least as early as the time of the Greco-Egyptian astronomer, Claudius Ptolemy, although they were extremely inaccurate. Nor does it mean that fairly accurate charts did not exist before the time of Columbus, for the mediaeval seamen's charts, or portolani, had then long been known, but these made little or no use of latitude and longitude.

to keep time at Paris, lost two and a half minutes a day at Cayenne in South America, where he had been sent to make observations.

But the arguments from theory and the evidence of Richer's clock, confirmed by the experience of other observers, seemed to be contradicted by the work of the Cassinis in France. If the Earth is an oblate spheroid, the length of a degree of latitude must increase from the equator to the pole[1], but the Cassinis, continuing Picard's work, found a small difference in the opposite direction; the length of a degree seemed to decrease as the pole was approached, as if the Earth were a prolate ellipsoid instead of an oblate one.

The difference was small because the range of latitude available in France was comparatively small, and might conceivably be due to observational error; nevertheless many accepted it as real and there ensued a lively controversy between the Earth-flatteners and the Earth-elongators. To settle the matter the Paris Academy of Sciences sent two expeditions to places whose difference of latitude was as great as was reasonably possible, one to "Peru"[2] and the other to Lapland. The northern party measured an arc extending from Tornea at the upper end of the Gulf of Bothnia to Kittis, not quite a degree to the northward, and finished its work before the Peruvian expedition did. This latter expedition left France in 1735 and did not return till 1743.

The result of a comparison of the Peruvian with the Lapland arc was a vindication of the theory of an earth flattened at the poles, but it was realized that the inevitable errors made the exact amount of the flattening uncertain. By taking the two measurements as exact the flattening found was &; the modern value is $\frac{1}{297}$.

During the century that followed there were numerous measurements of arc that in this brief sketch cannot even be mentioned by name. The trigonometrical survey of England was begun in 1783, in the first place to establish a geodetic connection between Greenwich and Paris; and Méchain and Delambre undertook operations in France to determine the length of the meter.[3]

Gradually of course methods and instruments improved and standards of precision became more exacting. Gauss devised the method of least squares, a method that diminished the arbitrary element that had hitherto entered into the adjustment of conflicting observations. This method was used extensively by the German astronomer Bessel in the Prussian arc of 1830–35. In geodesy, as in astronomy, Bessel was a leader in the introduction of refined methods of observation and higher standards of accuracy.

(2.) GEODETIC SURVEYING INSTRUMENTS AND METHODS OF OBSERVATION

In a sketch of this sort it would not be desirable to enter into details about the design, construction and use of the instruments employed in geodesy. The instruments used in the astronomical part of the work for determining latitude and longitude are simply the ordinary astronomical instruments for those purposes. For longitudes the transit instrument is, and has been for a long time, in general use. Nowadays it is ordinarily provided with a self-recording micrometer and is used in connection with a chronograph. For latitude determinations the zenith telescope and the broken-telescope transit are in almost universal use. For the determination of azimuths and for the measurement of the angles of triangulation, theodolites are used, of a type more accurate than those needed in ordinary surveying but not differing from them in principle. As an additional means to secure greater accuracy a large number of measurements are taken, the pointings on any given object being evenly distributed around the horizontal circle of the instrument, in order to eliminate errors of graduation as far as possible.

The sides of the triangles are of any convenient length up to the maximum length of intervisibility between stations. Exceptionally this may be 200 miles or more in mountainous regions, and 100 miles is by no means unusual. At the other extreme, it is not desirable to make the sides of the principal triangles too short, for then errors in centering both the instrument and the object sighted on play too large a part. Moreover, too many triangles, each subject to error, are then required for a given amount of linear progress. The practical lower limit for the best work is now considered to be about 2 miles. Theoretically, one measured base connected with the triangulation and taken in conjunction with the measured angles would suffice to determine the lengths of all the sides of the triangles, but in practice directly measured bases are connected with the triangulation at frequent intervals. The accuracy of a base directly measured is much greater than that of the length of the same line computed by means of angular measurements from another measured base, though the two bases may be separated by only, a few intervening triangles. The direct measurement of frequent bases serves therefore as a check on the measurements of angle.

Formerly bases were measured with bars or rods. Great care was necessary in making contacts between the ends of the bars and in determining their temperature, which might not be the same as the temperature of the surrounding air, because the expansion of the bars by heat made a very appreciable difference in their lengths. Nowadays bases are measured with tapes or wires made of invar alloy. The coefficient of the thermal expansion of this alloy is so low that the temperatures need not be determined with any great accuracy. The wires or tapes are always used at a standard tension maintained with weights and pulleys, or with spring balances, and their lengths are accurately determined in a standardizing laboratory — under conditions similar to those in the field — both before and after a campaign in the field. In this way the accuracy of a base measured with invar tapes or wires is quite as great in practice as that obtainable with the more elaborate and cumbrous base-bar apparatus used during the 19th century. Roughly speaking, an accuracy of one part in 500,000 or even one part in 1,000,000 may be obtained in base measurements.

The instruments for precise leveling are in principle the same as the usual engineering instruments for spirit leveling, but various refinements have been introduced into the design, and special precautions to secure accuracy are adopted.

(3.) FUNDAMENTAL PRINCIPLES AND DEFINITIONS

The gradual increase in the accuracy of geodetic observations has been accompanied by an increasing precision in definition of the quantities sought and an increasing attention to details of theory. When we say that we are endeavouring to determine the figure of the Earth, we are not concerned with the exact contours of the hills, valleys and ocean basins. These are matters for the topographer and hydrographer. The forms of these superficial features are specified with reference to a surface that defines the figure of the Earth. Over the sea this surface is mean sea level, and beneath the land it is an imaginary sea-level surface defined by spirit leveling. If small sea-level canals were dug into the

[1] It may seem as if just the reverse would be true, but this is because the reader may be thinking of the length of a degree of geocentric latitude, that is the length of an elliptical arc subtending an angle of one degree at the center of the Earth. The latitude meant, however, is not the geocentric latitude, which is not susceptible of direct observation, but the astronomic latitude (see LATITUDE), which is the angle between the plumb-line and the plane of the equator. The plumb-line is assumed to be normal to the meridian section through the place of observation. The ratio of the change in latitude to the change in linear distance from the equator is obviously a measure of the curvature, and the curvature of an ellipse (which may be taken as typical of all symmetrical ovals) is obviously greatest at the vertex, which corresponds to the end of the major axis or to the equator, and least at the end of the minor axis, that is, at the poles.

[2] The then Spanish province of Peru included what is now Ecuador, where all the geodetic work was done. The word "Peru" has become inseparably attached to this expedition. The measuring bar used was called the "toise of Peru" and because it was made with special care it became the standard of length on which much later geodetic work was based. A toise consisted of six French feet, equivalent to a little less than 6 feet 5 inches English measure.

[3] It was intended that the meter should be one ten-millionth of the length of the quadrant of a meridian, as nearly as could be determined. With the meter established, however, as a length defined by a certain standard bar, this bar serves as the definition, and later determinations of the figure of the Earth have no effect on the length of the meter.

interior of the continents or open-ended pipes like inverted siphons were run from the land out into the ocean, the surface sought would be defined physically at various points by the level of the water in these canals or pipes. But even this physical definition lacks mathematical precision. Sea level is affected by winds, salinity, barometric pressure and temperature. What is really sought is the form of what is known mathematically as an equipotential surface or level surface, characterized by the fact that over its entire extent the so-called potential function is constant. This potential function is due to the effect of the gravitational attraction of the matter composing the Earth, as it is and where it is, combined with the effect due to the rotation of the earth about its axis. Any shifting of mass such as would be implied in the digging of the supposed sea-level canals would change slightly the form of these equipotential surfaces; and so, to be accurate, we must resort to the mathematical fiction that these canals are to be infinitesimal.

There is an indefinite number of equipotential surfaces all characterized by the property that they are everywhere perpendicular to the direction of the apparent gravity[1]. What is sought is the form of the psrticular equipotential surface that most nearly coincides with the mean level of the ocean. The figure of this surface is by definition the figure of the Earth, and the surface is termed the *Geoid,* a term invented to avoid any commitment in advance of exact knowledge as to the exact shape of the Earth, for the use of this non-committal term merely means that the Earth is Earth-shaped. We know of course that it is approximately an ellipsoid of revolution flattened at the poles. Spirit leveling gives the elevation of points with respect to the geoid[2], not with respect to the terrestrial ellipsoid.

For mapping purposes it is customary to use an ellipsoid of revolution as an adequate and convenient substitute for the geoid. The dimensions and orientation of the assumed ellipsoid may represent an attempt to find the ellipsoid that most nearly fits the geoid as a whole, or they may represent an attempt to fit only a particular part of the geoid without regard to the rest of it When we speak of the figure of the Earth we usually mean the dimensions of the ellipsoid most nearly representing the geoid as a whole. If the Earth is assumed to be a sphere, the length of a single meridional arc with the difference of latitude of its end points suffices to determine its size. If it is assumed to be an eliipsoid of revolution, at least two meridional arcs and the latitudes of all end points must be determined. If we have more than two such arcs, various combinations of them two and two will not give precisely the same result because the geoid is not exactly an ellipsoid. The accepted way down to the middle of the 19th century was to take as many meridional arcs as might be available, rejecting perhaps those whose end latitudes were judged abnormal because of marked topographical relief in the vicinity, and reconcile them as well as might be by some arbitrary procedure or later by a least-squares adjustment.

It is obvious that if differences of longitude could be obtained as accurately as differences of latitude, measured arcs of parallel would serve as well as measured meridional arcs to determine the figure of the Earth. There were methods of determining astronomical differences of longitude before the invention of the electric telegraph, and arcs of parallel were measured, but little weight was given to them because of the inaccuracy of the astronomic longitudes. With the invention of the electric telegraph[3] differences of longitude began to be used, at first in much the same way as differences of latitude, but later in connection with what may be called the area method or the deflection method of determining the figure of the geoid[4], in contradistinction to the arc method, or method involving only unconnected arcs of meridians and parallels.

The area or deflection method supposes a considerable extent of territory more or less covered by connected chains of triangulation. Somewhere in the midst of this triangulation a point is taken as the origin, a latitude and a longitude are assigned to this point, an azimuth is also assigned to a side of one of the triangles passing through this point. The latitude, longitude and azimuth are to a certain extent arbitrary, but it would not be usual or convenient to assign to them values differing greatly from the astronomic values of those quantities. Besides these, dimensions of the terrestrial ellipsoid are assumed. These five quantities, the latitude and longitude of the initial point, the azimuth of a line through the point, and the two parameters necessary to specify the dimensions of the terrestrial ellipsoid of revolution, constitute a *geodetic datum* for the area covered by the triangulation. For instance, for the triangulation of the United States the initial point is Meades Ranch in Kansas, latitude 39° 13' 26".686 longitude 98° 32' 30".506, azimuth to Waldo 7j° 28' 14".j2. The dimensions of the terrestrial spheroid used in computing the triangulation are those known as the Clarke Spheroid of 1866 expressed in meters, namely semi-major axis 6,378,206.4 meters and semi-minor axis 6,356,583.8 meters.

The triangles are assumed to lie on the assumed ellipsoid and from the assumed values for the origin and the known sides and angles of the triangulation the latitude and longitude of every vertex of every triangle and the azimuth of every side may be computed, all without reference to the astronomic values of those quantities The quantities so computed are termed the geodetic latitude, west longitude and azimuth. If we denote these quantities by ϕ, λ and a, affecting them with subscript A or G to denote respectively the astronomic or geodetic values, the deflections or differences between the astronomic and geodetic verticals are:

$$\text{In the meridian } \phi_A - \phi_G,$$
$$\text{in the prime vertical } (\lambda_A - \lambda_G)\cos\phi,$$
$$\text{or } -(\alpha_A - \alpha_G)\cot\phi.$$

Stations at which observations of both longitude and azimuth are available are called Laplace stations; at such stations there are two determinations of the deflection in the prime vertical. These should be made consistent; in doing this the geodetic azimuth generally receives most of the correction, as it is much more subject to an accumulation of error than the geodetic longitude.

The deflections obtained in this way obviously depend on the geodetic datum used. It is usual to assume, in accordance with the principle of least squares, that the best geodetic datum is that which makes the sum of the squares of the deflections (weighted, perhaps, according to some principle) a minimum. The dimensions of the ellipsoid constituting part of this geodetic datum then represent the *figure* of *the Earth* for this territory.

It should be noted that geodetic latitudes, longitudes and azimuths, as previously defined, are quantities dependent partly on convention, that is, on the assumed geodetic datum, and partly on a series of observed quantities, that is, the angles and sides of the triangles; a least-squares adjustment may also be involved. The geodetic latitude, longitude and azimuth at a station are then not capable of immediate verification by direct observation on the spot as the corresponding astronomic quantities are, except of course that the longitude must be referred to the prime meridian.

The difference between an astronomic latitude, longitude or azimuth and the corresponding geodetic quantity is usually small. The average value is only a few seconds of arc and differences of over 10" of arc are rare except in mountainous regions. There is, however, a classic instance of large deflections of contrary sign at stations no great distance apart in the midst of a plain near Moscow. Some mass of abnormally low density must lie beneath

[1]Gravity, as here used, means the combined effect of gravitational attraction and the centrifugal force of rotation.

[2]Except of course in so far as the relation of the geoid to the assumed mean sea level on which the leveling operations are based may be uncertain for reasons already given. Strictly speaking, a knowledge of gravity at points along the level line is also needed, but this is a refinement that need not be here considered.

[3]Recently radiotelegraph) has been used with great success in the deterinination of longitudes. Bv this method it is easier to determine the longitude of a large number of points than when the electric telegraph is used, and it is possible to select, if desired, points remote from towns. There is no difference in principle, geodetically speaking, between the two methods but only differences in technical detail.

[4]The word **geoid** is used advisedly rather than *Earth,* because it may be the purpose to determine by the deflection method the figure of a portion of the geoid in the given area rather than to determine the figure of the Earth as a whole.

the surrace. It might seem as if the astronomic values of the latitude and longitude would be the ones used for mapping purposes; but this is not the case. Where the geodetic values are available they are invariably used in preference to the astronomic values, in spite of the conventional and derivative character of the former. This is because astronomic latitude and longitude depend on the direction of the plumb line and are therefore so affected by local topographic conditions as to render inaccurate any determinations of distance and direction based on the astronomic values.

For instance, if we used the astronomic latitudes of two points one on the north coast of Porto Rico and one on the south coast, and computed the distance between them from these latitudes and from the known size of the Earth, the distance would come out about a mile in error, or about one part in 50, as against an accuracy of one part in 100,000, or better, obtainable from direct measurement by triangulation. Again, the western part of the boundary between the United States and Canada is the 49th parallel of latitude; for reasons of convenience this parallel was defined astronomically, and the result is that in one instance one bounding station is about 8″ north of where a geodetic determination would have put it, and another station less than 100 miles away is some 6" south. The greatest relative error between two adjacent stations is about 7" in a distance of 20 miles, which would mean an error in the direction from one station to the other, as inferred from the latitudes, of about 35 ft. to the mile.

(4.) ISOSTASY

These irregular deflections of the plumb line have plagued geodesists from the beginning; they far exceed the errors in either the astronomical or geodetic determinations, and even for a comparatively small region they cannot be greatly reduced by changing the geodetic datum. If the region covered is large or if the same dimensions of the terrestrial ellipsoid are used for several separate regions, the deflections are still larger.

At first the only feasible procedure for determining the figure of the Earth as a whole was to reject those arcs where the ruggedness of the topography seemed likely to introduce abnormally large deflections, treat the remaining deflections like accidental errors, and hope that their effects would more or less balance out in the final result. As better topographic maps became available and geodetic surveys became better organized, it began to seem feasible to calculate by some sort of mechanical integration the effects of the visible topography — mountains, plateaus, valleys, ocean basins, etc.—on the direction of the plumb line, that is, on the deflections. J. H. Pratt, archdeacon of Calcutta, was the first one to try calculations of this sort on a large scale with some attempt to make the calculations apply with fair approximation, even at the expense of considerable labour, to the actual topography instead of to highly conventionalized geometrical substitutes for it.

Pratt found, what had already been suspected, that although the plumb line was in general deflected toward a hill, a range of mountains, or the interior of a continent, and away from a hollow, a valley, or the ocean deeps, nevertheless the amount of such deflection was in general considerably less than the amount computed by taking these topographic features at what might be termed their full face value. The most satisfactory way of obtaining approximate agreement between the observed and the computed deflections was found to be the assumption that apparent excesses of matter protruding above the geoid, such as hills, mountain ranges and continents, and apparent deficiencies of matter where the Earth's surface is depressed below the level of the surrounding country, or indeed below the level of the geoid, such as valleys and ocean basins, are not real excesses or deficiencies of matter, but that these apparent excesses or deficiencies are *compensated.* That is, beneath each apparent excess as represented by the surface form there is somewhere a deficiency of density, so that there is little or no real excess of matter; similarly, below each apparent deficiency of matter as revealed by surface configuration there is a compensating excess of density. In short, under mountain ranges and plateaus the density of the crust is less and under the oceans greater.

It is convenient for mathematical reasons and is in fair agreement with the observed facts to assume that the excess or deficiency of mass, as shown by surface conformation, is exactly compensated by the subterranean deficiency or excess of density. This compensation is called *isostatic compensation* and the corresponding state of affairs *isostasy,* a name invented by C. E. Dutton. To state the matter differently: assume unit areas at some depth to be specified later and called the *depth of compensation* in different regions, and compare the total mass standing upon the various unit areas. The hypothesis of isostasy states that the amount of matter standing upon a unit area will be the same regardless of whether it is under highlands or lowlands, continents or ocean deeps. It is not to be supposed that the unit area may be taken indefinitely small, or that the state of isostasy is perfect. A circle with a radius of 100 miles is almost certainly large enough to serve as a unit area, and a much smaller circle might be large enough in most cases.

There are two competing hypotheses as to the way in which isostatic compensation is effected; to these the names of Pratt and of Sir George Biddell Airy, former Astronomer Royal, have been attached. According to the Pratt hypothesis there is a definite depth of compensation, the crustal material underneath the higher parts of the surface being less dense and under lower parts more dense, so that the total mass standing on any unit area is the same. The Airy theory is, roughly speaking, a flotation theory, the blocks of lighter crust floating in a denser plastic material, which Airy called the *lava,* but which modern geologists prefer to call *magma*[1]. The deficiency of density corresponding to a height of land is secured, not in the upper part of the crust, but in the "root" which projects down into the denser magma and displaces it. Just as a tall iceberg means one that extends far below the surface, so a high mountain or plateau has its roots dipping deep into the magma. On the Pratt hypothesis the depth of compensation is perhaps 60 miles (100 km.), according to investigations of Bowie and others, but this is merely an average figure. On the Airy hypothesis the lighter crust extends down to an average depth of perhaps half this, say 30 miles or less; less under the oceans, more under the continents and highlands. As a rule geologists prefer the Airy hypothesis, as more in accordance with their way of thinking, but most of the existing computations have been made according to the Pratt hypothesis. For geodetic purposes there is not much to choose between the two hypotheses.

When the deflections are applied to determine the ellipsoid that best fits a comparatively small region, the deflections that are to be minimized by the method of least squares should be the actual deflections for which formulas have previously been given. But if it is desired to make the region to which the deflections apply representative of the earth as a whole in order to determine the figure of the earth, then the deflections should be corrected for the visible surface topography and its presumed isostatic compensation.

This isostatic method was first applied by Hayford to observations extending over the United States. In spite of the limited extent of the territory covered — in comparison with the land surface of the globe — the figure of the Earth deduced by him was adopted in 1924 by the Section of Geodesy of the International Geodetic and Geophysical Union as the best available figure of the Earth as a whole. This terrestrial ellipsoid thus determined is known as the International Ellipsoid of Reference. Heiskanen applied the isostatic method to deflections of the vertical in Europe and found results agreeing substantially with Hayford's. The dimensions of the International Ellipsoid are given in a later section. The conclusions regarding isostasy derived from a study of the vertical are in general supported by a study of the observations of gravity discussed in the next section.

(5.) OBSERVATIONS WITH THE PENDULUM

If the Earth were composed of a series of homogeneous con-

[1] Or *sima* in the language of the Wegener hypothesis of continental drift. The crust corresponds to Wegener's *Sial* or Sal.

centric spherical shells, its attraction would be uniform all over its surface and would be directed towards the common centre. For the sake of simplicity, let us imagine that the Earth had this spherical form at the start and then acquired its present rotation about its axis. Even if the Earth were absolutely rigid and unyielding the "centrifugal" force of rotation, being zero at the poles and a maximum at the equator, would introduce a variation into the apparent gravity, a variation dependent on the latitude. The substance of which the Earth is composed is, however, not unyielding, but gives way under the "centrifugal force" so that the Earth has approximately the form that it would have if it were fluid and in equilibrium under the combined forces of its own attraction and the "centrifugal force" of rotation;[1] its form is nearly that of an ellipsoid of revolution flattened at the poles. This departure from the spherical form is a further cause of a change of apparent gravity between poles and equator.

The intensity of gravity can be measured very accurately by means of the oscillations of a pendulum[2] and from the variation in gravity between equator and pole the flattening or ellipticity of the earth may be determined.

The process is as follows: From theoretical considerations it is known that the gravity on the surface of an ellipsoid of revolution, this surface being at the same time an equipotential surface, may be written in the form

$$g_0 = g_E(1 + b\sin^2\phi - b_4\sin^2 2\phi).$$

Here g_0 is gravity at the surface in geographic latitude ϕ, g_E is gravity at the equator, b and b_4 are constant coefficients, depending on the flattening. The coefficient b_4 is small and the flattening is sufficiently well known so that its value may be set down in advance as 0·000006 for an exact ellipsoid. This leaves two coefficients, g and b, to be determined by observation. Theoretically, two values of g in different latitudes would suffice for this. In practice as many gravity stations as are available are used, the discordances being adjusted by the method of least squares. These discordances arise from the fact that the earth is not an exact ellipsoid of revolution, as is assumed in the formula, and furthermore that local topographic and geological conditions, that is, the existence of mountains, valleys, oceans, and abnormally high or low densities in the neighbourhood of a gravity station, cause deviations from any theoretical formula that can be devised. These deviations are called gravity anomalies.

When the best obtainable values of the coefficients g_E and b have been found the flattening f is found from the relation

$$b = \frac{5}{2}\frac{w^2a}{g_E} - f - \frac{17}{14}\frac{\omega^2a}{g_E}f.$$

Here a is the equatorial radius of the ellipsoid, which must be known in advance and w is the angular velocity of the Earth's rotation. This formula is due in substance to Clairaut (*q.v.*), who, however, did not push his approximations far enough to include the term $\frac{17}{14}\frac{\omega^2a}{g_E}f$. This term is correct only when, as stated, the Earth's surface is assumed to be exactly that of an ellipsoid of revolution.

The observations of gravity are generally taken at or near the surface of the Earth, though occasional observations have been made in mines. The formulas given refer to the ideal level surface of the spheroid or ellipsoid. The observed values of gravity could be reduced to this level surface by adding

$$\frac{2g_E}{a}\left[1 + \frac{\omega^2a}{g_E} + f - \left(3f - \frac{5}{2}\frac{\omega^2a}{g_E}\right)\sin^2\phi\right]H,$$

where H is the height of the point of observation above the level surface in question.[1] But we do not know our elevations with respect to the ellipsoid or spheroid of reference. The best available approximation is the elevation with respect to the geoid. Observations of gravity are then reduced to the geoid, which is treated as if it were a regular surface. The coefficients g_E and b are found by a least squares adjustment, b_4 being so small that a very approximate value of the flattening determines it with more than sufficient accuracy, and from these the value of the flattening f is obtained. Theoretically it is possible to determine a also, but the determination is so poor as to be valueless. Gravity observations thus determine the shape but not the size of the terrestrial ellipsoid.

The preceding formula for the correction for the elevation of the station is derived on the supposition that there is no matter intervening between the station and the level surface to which the observation is reduced, a method based on a supposition manifestly false and yet found to work better on the whole in practice than the method of computing the effect of all visible surface irregularities either in the neighbourhood of the station only or over the entire globe and taking this effect at its full face value. This fact is another manifestation of isostasy. The effect of the visible irregularities of the surface is largely counteracted by effects of contrary nature in the crust beneath them. This was noticed very early. In the expedition of the Paris Academy to Peru Bouguer swung his crude pendulums at sea-level and then at Quito in about the same latitude but over 9,000 feet above sea-level. He found to his surprise that the land masses below the level of Quito seemed to have much less effect than they apparently should. Later writers commented on this and speculated on the possibility of extensive cavities, but it was not until over a century later that Pratt undertook the extensive computations that established isostasy on a comparatively secure basis.

Gravity observations may be used not only, as has been stated, to determine the flattening of the terrestrial ellipsoid but also to determine the deviations of the geoid from this assumed ellipsoid. The practical possibility of this was shown by Sir George Gabriel Stokes (*q.v.*) in 1849, but the requisite observations seemed then unobtainable, for Stokes' theory required that gravity be observed at fairly close intervals over the entire globe, including the sea, and there seemed no way to do this with the requisite accuracy.' Various devices were tried for measuring gravity at sea, the most successful, until very recently, being a method due to Hecker based on the comparison of the atmospheric pressure obtained by a determination of the boiling point of water with that obtained by a direct reading of the mercury barometer. Hecker's method was accurate enough to prove that in a general way isostasy prevailed over the oceans as well as over the land, but the accuracy obtained by great labour and complication was far inferior to that easily obtainable on land with the pendulum.

Finally, a Dutch geodesist, Vening Meinesz, in seeking to overcome the difficulties of the unstable support of the pendulum apparatus in a country like Holland where the land itself is none too stable, hit on the idea of eliminating the *horizontal* acceleration of the pendulum, which was found to be the principal cause of the difficulty, by swinging two pendulums in the same vertical plane and therefore subject to the same horizontal acceleration. By using a certain hypothetical pendulum, the phase of which at any instant is the difference between the phases of the two pendulums at that instant, the effect of the horizontal acceleration was eliminated. The idea was found capable of adaptation to even more trying conditions than those presented by the unstable soil of Holland. By using an improved form of the apparatus in a submarine vessel submerged deep enough to escape most of the motion on the surface of the sea, and by supporting the apparatus

[1]Mountains, plateaus and ocean deeps are obvious exceptions; they are supported by the stiffness of the outer crust, but the general conformation of the Earth is as stated. On the subject of fluid equilibrium see in this article under the subhead *Isostasy*.

[2]If the *same* pendulum is swung at two different places and the periods of an oscillation there are found to be ti and tz, the values of gravity g_1 and g_2 at the two places are connected by the relation $g_2/g_1 = (t_1/t_2)^2$. The modern process of determining the figure of the earth from gravity observations depends on this formula for the *relative* gravity at two places. *Relative* gravity may be determined within one or two parts in a million. The *absolute* value of the acceleration of gravity at any given place is found from the formula $g = \pi^2(l/t^2)$, l being the length of the pendulum. The accurate determination of *absolute* gravity is much more difficult, on account of the complications arising in measuring l.

[1]The factor of H is nearly constant and corresponds to a variation in gravity of about one part in 1,000,000 for each three meters (or 10 ft.) of elevation.

on gimbals, it was found possible to get gravity observations on the open ocean. The accuracy obtainable is not quite as great as on solid land but the results are nevertheless very gratifying.

In this way Meinesz has observed gravity at 250 ocean stations, mostly in low or middle latitudes. It is to be hoped that, soon, enough ocean gravity stations will be observed over all oceanic areas so that when taken in conjunction with the numerous stations on land they will enable the bumps and hollows of the geoid to be determined by Stokes' method, that is, bumps and hollows when compared with the regular mathematical surface of the terrestrial ellipsoid.

Enough has already been learned to raise interesting questions. In regard to the perfectness of the isostatic condition over ocean areas there seem to be two opposite tendencies toward imperfection. On the one hand, stations over great ocean deeps show a tendency toward abnormally small gravity—from the point of view of perfect isostasy—as if the hollows in the sea bottom represented real uncompensated, or only partly compensated, deficits of matter. On the other hand, there seems to be a slight though definite tendency toward an excess of gravity—still from the point of view of perfect isostasy—over ocean areas in general. Some indication of this state of affairs had previously been given by gravity observations on land The theory of isostasy would predict slight hollows in the geoid over oceanic areas. The fact seems to be that there are slight bumps. It is well, however, to be cautious in drawing conclusions as the observational evidence is still rather meager and no consensus of opinion has been reached in regard to the interpretation of it.

(6.) THE VARIATION OF LATITUDE

The deflections of the vertical in the meridian depend on both the astronomical latitude and the geodetic latitude. The latter, as has been noted, involves a certain convention, that is, the assumed geodetic datum, and moreover depends upon surveying operations to connect the initial point of the datum with the point whose geodetic latitude is sought. The astronomic latitude, though depending on observation at the place in question, is not absolutely invariable. The variability is due to a displacement of the axis of rotation in the body of the Earth. There is in every body, however irregular in shape, an *axis* of *figure,* the axis about which the moment of inertia is a maximum. If for any reason the axis of figure and the axis of rotation do not coincide, the pole of the axis of rotation will describe in *the* body a closed curve about the pole of the axis figure. For a nearly spherical body like the Earth, the axis of rotation will retain in space a nearly invariable direction.

The laws of these phenomena were first stated for a rigid rotating body by Leonhard Euler (*q.v.*). With Euler's theorems in mind astronomers sought to detect by observation a possible variation in latitude, but succeeded only in reaching the conclusion that if any such existed, it must be small Finally S. C. Chandler undertook a careful study apart from any preconceived theory, basing it both on observations of his own and a study of old records, notably those of Greenwich Observatory. At about the same time, the reality of a change in latitude due to a motion of the pole was proved by simultaneous latitude observations in Berlin and Honolulu, places differing in longitude by nearly 180°. It was found that an increase in latitude in one occurred simultaneously with an approximately equal decrease at the other. This could not have been due to local conditions nor to defective star places, but it must have been dce to a motion of the pole of rotation which in approaching one place receded from the other.

Chandler found that the motion of the pole of rotation about the pole of figure required about 14 months where Euler's theory had led astronomers to expect a ten-month period. The longer period was soon explained by Newcomb as due to the fact that Euler's theory was based on an ideal body absolutely unyielding and unchangeable in shape, a thing unknown in nature. The elastic yielding of the earth and the mobility of the ocean water lengthen the period from 10 months to 14.

There is also a motion of the pole of rotation in the body of the Earth due to the fact that the pole of figure itself is not invariable but undergoes a displacement due to seasonal variations in barometric pressure, snow-load, etc. The period of these seasonal changes is obviously one year.

The amplitudes of both the annual and the fourteen-month variations are of the order of magnitude of 0″.1. The quantities sought are small and difficult to measure, but it appears that both components of the polar motion are subject to unpredictable changes. Since the maximum deviation of the pole from its mean position is about 0″.3, which is small in comparison with the usual deflections of the vertical, the reduction of the observed astronomical latitudes to some more or less conventional mean value is not a very vital matter in ordinary geodetic work. (It should be noted that the motion of the pole affects longitudes and azimuths also.) The interest of the subject is more on the astronomical and geophysical side. Many interesting problems into which we cannot here enter are raised by this phenomenon and still await complete solution.

The International Geodetic Association *(see* § 10 of this article) organized in 1899 an International Latitude Service with six special latitude observatories, all on the parallel of 39° 08′, three of which have remained in continuous operation The advantage of having them all in the same latitude is that the same stars may be used at all of them and uncertainties in the star places do not affect the conclusions. The observations may in fact be used to correct the star places.

(7.) ASTRONOMICAL METHODS OF DETERMINING THE FIGURE OF THE EARTH

There are several astronomical methods of determining the flattening of the Earth. For the most part they determine the flattening by means of the observed mechanical effects produced by the Earth's equatorial protuberance. These effects are most noticeable in connection with the Earth's nearest neighbour, the Moon. The equatorial bulge produces periodic perturbations in the Moon's celestial longitude and latitude, and secular changes in the motion of the Moon's perigee and of the node of its orbit on the ecliptic. The Moon in turn acting on the equatorial bulge of the Earth produces the greater part of the slow displacement of the equinoxes known as precession; the Sun contributes a fairly large part of the observed precession and the planets a small remainder. From any one of the effects mentioned above the flattening of the Earth may be deduced. There are theoretical difficulties in all of the methods. Perhaps the flattening deduced from the precession is as satisfactory as any; it agrees substantially with the flattening of the International Ellipsoid of Reference, namely 1/297. The tendency of the flattening deduced by the other lunar methods is to come out a trifle greater than this.

These methods all deal with the average flattening without reference to local irregularities. The flattening or the equatorial radius—one or the other—may also be deduced by a calculation essentially similar in principle to that used by Newton to show that terrestrial gravitation and the force controlling the Moon's orbital motion are one and the same. The result, however, is affected by the fact that the geoid is not a perfect ellipsoid of revolution.

(8.) THE EOTVOS TORSION BALANCE

If we think of the elevation of the geoid above the terrestrial ellipsoid, or depression below it, as the case may be, as a mathematical function of the geographical coordinates (latitude and longitude) of a point on the ellipsoid, then this mathematical function itself may in theory be found by the application of Stokes' formula to gravity observations. Observations of the deflections of the vertical obviously give us the first derivatives of this function and enable us to build up the function itself by a process of integration. The next stage in this line of thought is obviously a consideration of the second derivatives, quantities intimately connected with the curvature of the geoid. It is possible to determine certain quantities connected with the curvature by means of the Eötvös torsion balance devised by the late Baron Roland Eotvos of Budapest.

The Eotvos balance is simple in principle, being merely a rod

suspended at the middle by a very delicate fiber. In one form of the balance the principal masses are concentrated at the ends of the rod. In another form, rnore used in practice, the mass at one end is at a different level from the mass at the other.

If we consider only the general conformation of the geoid, it seems to differ in vertical elevation from an exact ellipsoid only by small and slowly changing amounts. If we look, however, at the directions of the tangents to this surface as disclosed by a study of the deflections of the vertical, we find considerable irregularity; if we look to the curvatures as disclosed by the Eotvos balance, we find apparently wild irregularity. This irregularity is due to the fact that the geoid (or any equipotential surface studied in practice by the balance) cuts into discontinuities of density, such as in the sides of hills, walls of buildings, irregularities in subsurface geologic structure, etc. We know that the second derivatives, about which the balance gives us information and on which the curvature of the equipotential surfaces depends, is discontinuous at such discontinuities in density. Near them the second derivative and the curvature, although not actually discontinuous, appear extremely irregular.

The surface of the geoid has been compared to that of a withered apple. This is something of an exaggeration, for actual concavities in the geoid, such as would be found in the apple, though possible are probably quite rare. Moreover, the wrinkles, or more properly irregular undulations, in the geoid are so fine and change character so quickly that in the aggregate they mean comparatively little in the way of actual rise or fall of the geoid as compared with the terrestrial ellipsoid; nevertheless the comparison is suggestive. The details of all the wrinkles in the geoid, as the torsion balance gives them, are really too fine for the purpose of the geodesist. They simply confuse him.

(9.) NUMERICAL DATA CONNECTED WITH THE FIGURE OF THE EARTH

The following table gives the principal determinations of the mean figure of the Earth, beginning with the work of Méchain and Delambre undertaken to establish a basis for the metric system. The table was taken chiefly from "La figure de la Terre" (*Revue de géographie annuelle*—Tome 11., 1908) by Capt. (now Gen.) Georges Perrier. Other, somewhat different, numerical values may sometimes be found if other sources of information are used. The discrepancies will usually be due to the use of relations between the foot, toise and meter different from those used in this table:

Elements of the Earth's Mean Figure.

Author	Date	Semi-major xis (a)	Reciprocal of the flattening (1/f)
		Kilometers	
Commission générale des poids et mesures (for the metric system)	1799	6,375·739	334·29

*Using deflections of the vertical corrected for topography and isostatic compensation.

†Using deflections of the vertical left uncorrected and the spheroid determined to fit as nearly as possible to the uncorrected deflections.

As has been remarked, the mean figure for the Earth as a whole is not necessarily the figure best adapted to a particular region. The following table gives some of the ellipsoids actually in use.

Spheroids Used for Geographic Purposes.

A spheroid with a flattening equal to that of the Bessel Spheroid, but with its major axis greater than the major axis of the Bessel Spheroid by 1 part in 10,000 has been extensively used by the Central Bureau of the International Geodetic Association for geodetic calculations relating to Europe. This choice was made because many tables to facilitate computation have been based on the Bessel Spheroid, and these can be adapted to the increased major axis with comparative ease, whereas a change in the flattening would require a recomputation of the whole set of tables.

The following table may be useful for reference:

Fundamental Elements of the International Ellipsoid of Reference.

a=semi-major axis (equatorial radius)=6,378,388 meters

f=ellipticity (flattening)=$\frac{a-b}{a}$=1/297=0.003, 367, 0034

Derived Quantities

b=semi-minor axis (polar radius)=6,356, 911.946 meters

e^2=square of eccentricity=$\frac{a^2-b^2}{a^2}$=0.006, 722, 6700

Length of quadrant of the equator=10,019,148.4 meters
Length of quadrant of the meridian=10,002,288.3 meters
Area of the ellipsoid=510,100,934 sq. km.
Volume of the ellipsoid=1,083,319,780,000 cu. km.
Radius of sphere having same area as ellipsoid=6,371,227.7 meters
Radius of sphere having same volume as ellipsoid=6,371,221.3 meters
Mass of the ellipsoid*=5.988×10^{21} metric tonnes

*Mean density taken as 5·527, the value found by both Boys, *Phil. Trans.* A. vol. 186 (1895) p. 1. and Braun, "*Denkschriften der Akademie der Wissenschaften zu Wien,*" *Mathematisch-naturwissenschaftliche Klasse,* 64, 1896, p. 187.

The range of uncertainty in these quantities is largely a matter of opinion. Probably the semi-major axis is correct within 50 meters and the reciprocal of the flattening within half a unit or less. But the question of how closely the adopted ellipsoid of reference represents the actual geoid is by no means exhausted even when we have stated to our own satisfaction the probable range of error of the parameters that determine the ellipsoid. It is also of interest to know how far the geoid and the ellipsoid may deviate from one another. To take an ideal case, let us suppose a perfectly ellipsoidal mass as large as the earth, its outer physical surface and the surfaces of equal density within being also equipotential surfaces. Then let us suppose that the outer crust down to a certain depth shrinks and swells here and there so as to form oceans, continents and mountains like the existing ones, but with perfect isostatic adjustment always maintained. The geoid, which formerly coincided with the outer surface, would go up with the continents and mountains and down with the ocean bottoms, but to a much less extent, the exact amount depending on the law of isostatic compensation. For existing areas of elevation and depression and a depth of compensation of 100 km., the distance between the geoid and the ideal ellipsoid of closest fit (which need not be exactly our international ellipsoid) would be 50 meters or less. If, however, isostatic compensation is imperfect to the extent of 10 or 15% of the total excess or deficiency of load, which is about the generally accepted estimate, and over wide

areas, the 50 meters might be more than doubled. We should expect, however, these extreme figures of 100 or 150 meters to occur only very exceptionally, say in the Himalayan region or near the great ocean deeps.

Geoid contours mere coristructed by Hayford in connection with his earlier investigation of his figures of the Earth. Within the United States he found a variation in the elevation of the geoid above the Clarke spheroid of 1866 amounting to 38 meters. Similar investigations by others give results of the same order of magnitude. This is somewhat greater than would be inferred from known differences of elevation and perfect isostasy with a depth of compensation of 100 km. but is by no means more than might be expected in view of ignorance of the real depth of compensation and the known imperfectness of isostatic adjustment.

The following are recent formulas for theoretical gravity at the surface of the earth, and the flattening derived from them. In these formulas ϕ is the geographic latitude and λ the East longitude reckoned from Greenwich. The unit is dynes per gram, or cm/sec^2. The date of publication of the formula is given in parentheses.

Helmert (1915)

$$g_0 = 978{\cdot}052\,[1 + 0{\cdot}005285 \sin^2\phi - 0{\cdot}000007 \sin^2 2\phi + 0{\cdot}000018 \cos^2\phi \cos 2(\lambda + 17^\circ)],\ 1/296{\cdot}7$$

Bowie (1917)

$$g_0 = 978{\cdot}039\,[1 + 0{\cdot}005294 \sin^2\phi - 0{\cdot}000007 \sin^2 2\phi],\ 1/297{\cdot}4$$

Heiskanen (1928)

$$g_0 = 978{\cdot}049\,[1 + 0{\cdot}005293 - 0{\cdot}000007 \sin^2\phi + 0{\cdot}000019 \cos^2\phi \cos 2(\lambda - 0^\circ)],\ 1/297{\cdot}3$$

The fact that the coefficient of $\sin^2 2\phi$ is 0~000007rather than 0.000006 means that the spheroid on which these formulas are based is depressed a very little in middle latitudes below an exact ellipsoid having the same axes. The longitude term has the effect of turning this spheroid of revolution into a spheroid (approximately an ellipsoid) of three unequal axes. The longest semi-axis of the equator, according to Heiskanen, lies in the meridian plane of Greenwich and is 121 meters longer than the mean. The least equatorial semi-axis is in longitude $\pm 90^\circ$ and is 121 meters shorter than the mean. The validity of these longitude terms is closely connected with the apparent tendency of gravity at sea to be greater than that on land. Geodesists are not yet agreed as to their validity or their geophysical interpretation, if real. If they are accepted, the conception of isostasy must be modified and the geoid instead of being in general below the mean ellipsoid over the ocean would be above it.

If we take the International Ellipsoid as the basis of a gravity formula and in addition adopt 978·050 cm/sec^2 for gravity at the equator, we get

$$g_0 = 978{\cdot}050\,[1 + 0{\cdot}005288 \sin^2\phi - 0{\cdot}000006 \sin^2 2\phi].$$

(10.) INTERNATIONAL GEODETIC ORGANIZATIONS

Geodesy is essentially an international science. This was realized when in 1862 a Central European Geodetic Association (Mitteleuropaische Gradmessung) was organized on the initiative of Lieutenant-General Baeyer of Prussia. The first general conference of the organization was held in 1864 with representatives of 13 States or countries, many of them being German States later united into the German Empire. General conferences at intervals of three years were arranged for with a permanent committee directing the affairs of the organization between conferences. At the next conference, in 1867, in recognition of widening scope the name was changed to European Geodetic Association (Europaische Gradmessung).

At the general conference in 1883 representatives of England and the United States were present. This conference discussed matters of world-wide interest, such as a common prime meridian and an international time system. At the next conference in 1886 the name International Geodetic Association (Internationale Erdmessung) was adopted to indicate a still wider scope, and a definite ipternational convention was adopted providing for contributions from the member nations. At the beginning of the same year F. R. Helmert became director of the Prussian Geodetic Institute. He reorganized it in the years that followed, and exerted a powerful and beneficent influence on the nork of the International Association, the headquarters of which remained associated with the Prussian Geodetic Institute The general conference of 1912 at Hamburg was the last held under this organiaation. The outbreak of the World War prevented the holding of the general conference planned for 1915.

After the World War the International Geodetic and Geophysical Union was organized in connection with the newly created International Research Council The International Geodetic and Geophysical Union consists of various semi-independent sections, one of which, the section of Geodesy, took over the work of the former International Geodetic Association. The new type of organization emphasizes the fact that geodesy is really a branch of geophysics. The work of the International Latitude Service was taken over jointly by the Section of Geodesy and the newly formed International Astronomical Union, since the subject was of interest to both organizations. Germany and Austria have so far remained outside the new organization, but there has been organized a Baltic Geodetic Commission, which includes representatives of Germany and of other nations bordering on the Baltic and deals with geodetic problems of common interest to them. Some of the Baltic nations are members both of the Baltic Commission and of the International Geodetic and Geophysical Union.

(W. D. LA)

GEOFFREY (c. 1152–1212), archbishop of York, was a bastard son of Henry II., king of England. He was distinguished from his legitimate half-brothers by his consistent attachment and fidelity to his father. He was made bishop of Lincoln at the age of twenty-one (1173); but though he enjoyed the temporalities he was never consecrated and resigned the see, under papal pressure, in 1182. He then became his father's chancellor, holding a large number of lucrative benefices in plurality. Richard nominated him archbishop of York in 1189, but he was not consecrated till 1191, or enthroned till 1194. Geoffrey's history is chiefly one of quarrels, with the see of Canterbury, with the chancellor William Longchamp, with his half-brothers Richard and John, and especially with his canons at York. This last dispute kept him in litigation before Richard and the pope for many years. He led the clergy in their refusal to be taxed by John, and was forced to fly the kingdom in 1207. He died in Normandy on Dec. 12, 1212.

See Giraldus Cambrensis, *Vita Galfridi;* Stubbs's prefaces to *Roger de Hoveden,* vols. iii. and iv. (Rolls Series.)

GEOFFREY (1158–1186), duke of Brittany, fourth son of the English king Henry II. and his wife Eleanor of Aquitaine, was born on Sept. 23, 1158. In 1167 Henry suggested a marriage between Geoffrey and Constance (d. 1201), daughter and heiress of Conan IV., duke of Brittany (d. 1171). Conan assented, perhaps under compulsion, to this proposal but surrendered the greater part of his unruly duchy to the English king. Having received the homage of the Breton nobles, Geoffrey joined his brothers, Henry and Richard, who, in alliance with Louis VII. of France, were in revolt against their father; but he made his peace in 1174, afterwards helping to restore order in Brittany and Normandy, and aiding the new French king, Philip Augustus, to crush some rebellious vassals. In July 1181 his marriage with Constance was celebrated, and practically the whole of his subsequent life was spent in warfare with his brother Richard. In 1183 he made peace with his father, who had come to Richard's assistance; but a fresh struggle soon broke out for the possession of Anjou, and Geoffrey was in Paris treating for aid with Philip Augustus, when he died on Aug. 19, 1186. He left a daughter, Eleanor, and his wife bore a posthumous son, the unfortunate Arthur (*q.v.*).

GEOFFREY, surnamed MARTEL (1006–1060), count of Anjou, son of the count Fulk Nerra (*q.v.*) and of the countess Hildegarde or Audegarde, was born on Oct. 14, 1006. During his father's lifetime he was recognized as suzerain by Fulk l'Oison ("the Gosling"), count of Vendôme, the son of his half-sister Adela. Fulk having revolted, he confiscated the countship, which he did not restore till 1050. On Jan. 1, 1032, he married Agnes, widow of William the Great, duke of Aquitaine, and taking arms against William the Fat, eldest son and successor of William the Great, defeated him and took him prisoner at Mont-Couer (Sept. 20, 1033). He then tried to win recognition as dukes of Aquitaine for the sons of his wife Agnes by William the Great, who were still minors, but Fulk Kerra promptly took up arms to defend his suzerain William the Fat, from whom he held the Loudunois and Saintonge in fief against his son. In 1036 Geoffrey Martel had to liberate William the Fat, on payment of a heavy ransom, but the latter having died in 1038, and the second son of William the Great, Odo, duke of Gascony, having fallen in his turn at the siege of Mauzé (March 10, 1039) Geoffrey made peace with his father, and had his wife's two sons recognized as dukes. He had interfered in the affairs of Maine, though without much result; for having sided against Gervais, bishop of Le Mans, who was trying to make himself guardian of the young count of Maine, Hugh, he had been beaten and forced to make terms with Gervais in 1038. In 1040 he succeeded his father in Anjou and was able to conquer Touraine (1044) and assert his authority over Maine (see ANJOU). He was four times married, but left no children, and was succeeded in the countship of Anjou by Geoffrey the Bearded, the eldest of his nephews. He died at Angers on Nov. 14, 1060.

See Louis Halphen, *Le Comté d'Anjou au XIe siècle* (1906). A summary biography is given by Célestin Port, *Dictionnaire historique, géographique et biographique de Maine-et-Loire* (3 vols., Paris-Angers, 1874–78), vol. ii., pp. 252–253, and a sketch of the wars by Kate Norgate, *England under the Angevin Kings* (2 vols., 1887), vol. i. chs. iii. iv.

GEOFFREY, surnamed PLANTAGENET (or PLANTEGENET) (1113–1151), count of Anjou, was the son of Count Fulk the Young and of Eremburge (or Arembourg) of La Flèche; he was born on Aug. 24, 1113. He is also called "le bel" or "the handsome," and received the surname of Plantagenet from the habit which he is said to have had of wearing in his cap a sprig of broom (*genêt*). He married (June 2, 1129) Matilda, daughter of Henry I. of England, and widow of the emperor Henry V. He died on Sept. 7, 1151, and was buried in the cathedral of Le Mans. By his wife Matilda he had three sons: Henry Plantagenet (see HENRY II.), Geoffrey, and William. (See also ANJOU.)

See Kate Norgate, *England under the Angevin Kings* (2 vols., 1887), vol. i. chs. v.–viii.; Célestin Port, *Dictionnaire historique, géographique et biographique de Maine-et-Loire* (3 vols., Paris-Angers, 1874–78), vol. ii. pp. 254–256. Thert is a biography of Geoffrey written in the 12th century by Jean, a monk of Marmoutier, *Historia Gaufredi, ducis Normannorum et comitis Andegavorum,* published by Marchegay et Salmon; "Chroniques des comtes d'Anjou" (*Société de l'histoire de France,* 1856), pp. 229–310.

GEOFFREY DE MONTBRAY (d. 1093), bishop of Coutances (*Constantiensis*), a right-hand man of William the Conqueror, was a type of the great feudal prelate, warrior and administrator at need. He knew, says Orderic, more about marshalling mailed knights than edifying psalm-singing clerks. Obtaining, as a young man, in 1048, the see of Coutances, by his brother's influence (see MOW-BRAY), he raised from his fellow nobles and from their Sicilian spoils funds for completing his cathedral, which was consecrated in 1056. With bishop Odo, a warrior like himself, he was on the battle-field of Hastings, exhorting the Normans to victory; and at William's coronation it was he who called on them to acclaim their duke as king. His reward in England was a mighty fief scattered over twelve counties. He accompanied William on his visit to Normandy (1067), but, returning, led a royal force to the relief of Montacute in September 1069. In 1075 he again took the field, leading with bishop Odo a vast host against the rebel earl of Norfolk, whose stronghold at Norwich they besieged and captured.

Meanwhile the Conqueror had invested him with important judicial functions. In 1072 he had presided over the great Kentish suit between the primate and bishop Odo, and about the same time over those between the abbot of Ely and his despoilers, and between the bishop of Worcester and the abbot of Ely, and there is some reason to think that he acted as a Domesday commissioner (1086), and was placed about the same time in charge of Northumberland. The bishop, who attended the Conqueror's funeral, joined in the great rising against William Rufus next year (1088), making Bristol, with which (as Domesday shows) he was closely connected and where he had built a strong castle, his base of operations. He burned Bath and ravaged Somerset, but had submitted to the king before the end of the year. He appears to have been at Dover with William in January 1090, but, withdrawing to Normandy, died at Coutances three years later. In his fidelity to Duke Robert he seems to have there held out for him against his brother Henry, when the latter obtained the Cotentin.

See E. A. Freeman, *Norman Conquest* and *William Rufus;* J. H. Round, *Feudal England;* and, for original authorities, the works of Orderic Vitalis and William of Poitiers, and of Florence of Worcester; the Anglo-Saxon Chronicle; William of Malmesbury's *Gesta pontificum.* and Lanfranc's works, ed. Giles; Domesday Book. (J. H. R.)

GEOFFREY OF MONMOUTH (d. 1154), bishop of St. Asaph and creator of the Arthurian legend, was born about the year 1100. He received a liberal education under his paternal uncle, Uchtryd, at that time archdeacon, and subsequently bishop, of Llandaff. In 1129 Geoffrey appears at Oxford among the witnesses of an Oseney charter. He subscribes himself "Geoffrey Arturus." A first edition of his *Historia Britonum* was in circulation by the year 1139, although the text which we possess appears to date from 1147. This famous work professes to be a translation from a Celtic source; "a very old book in the British tongue" which Walter, archdeacon of Oxford, had brought from Brittany. Walter the archdeacon is a historical personage; whether his book has any real existence may be fairly questioned. There is nothing in the matter or the style of the *Historia* to preclude us from supposing that Geoffrey drew partly upon confused traditions, partly on his own powers of invention, and to a very slight degree upon the accepted authorities for early British history. The romancer achieved an immediate success. He was patronized by Robert, earl of Gloucester, and by two bishops of Lincoln; he obtained, about 1140, the archdeaconry of Llandaff "on account of his learning"; and in 1151 was promoted to the see of St. Asaph.

Before his death the *Historia Britonum* had already become a model and a quarry for poets and chroniclers. The list of imitators begins with Geoffrey Gaimar, the author of the Estorie *des Engles* (*c.* 1147), and Wace, whose *Roman* de *Brut* (1155) is partly a translation and partly a free paraphrase of the *Historia.* In the next century the influence of Geoffrey appears in the *Brut* of Layamon, and in the rhyming English chronicle of Robert of

Gloucester. Among later historians who were deceived by the *Historia Britonum* it is only needful to mention Higden, Hardyng, Fabyan (1512), Holinshed (1580) and John Milton. Still greater was the influence of Geoffrey upon Warner in *Albion's England* (1586), and Drayton in *Polyolbion* (1613). The *Historia Britonum* provided the material for the earliest English tragedy, *Gorboduc* (1565), the *Mirror for Magistrates* (1587), and Shakespeare's *Lear*.

But in the work of expanding and elaborating this theme the successors of Geoffrey went as far beyond him as he had gone beyond Nennius; but he retains the credit due to the founder of a great school. For the development of the tradition *see* ARTHURIAN LEGEND. Of the twelve books into which it is divided oniy three (Bks. IX., X., XI.) are concerned with Arthur. Earlier in the work, however, we have the adventures of Brutus; of his follower Corineus, the vanquisher of the Cornish giant Goemagol (Gogmagog); of Locrinus and his daughter Sabre (immortalized in Milton's *Comus*); of Bladud the builder of Bath; of Lear and his daughters; of the three pairs of brothers, Ferrex and Porrex, Brennius and Belinus, Elidure and Peridure. The story of Vortigern and Rowena takes its final form in the *Historia Britonum;* and Merlin makes his first appearance in the prelude to the Arthur legend. Besides the *Historia Britonum* Geoffrey is also credited with a *Life of Merlin* composed in Latin verse. The authorship of this work has, however, been disputed, on the ground that the style is distinctly superior to that of the *Historia.* A minor composition, the *Prophecies of Merlin,* was written before 1136, and afterwards incorporated with the *Historia,* of which it forms the seventh book.

For a discussion of the manuscripts of Geoffrey's work, *see* T. D. Hardy, *Descriptive Catalogue* (Rolls Series, No. 26. vol. i., **1862**); for those in the British Museum, H. L. D. Ward, *Catalogue of Romances* (vol. i, 1883), and those in Leyden, L. V. Delisle, *Bibliothèque de l'École de Cbartes* (LXXI., 1910); A. Griscom *(Speculum* vol. i., Mediaeval Academy of America, **1926**) has studied some of the mss. The Latin text of the *Historia* (ed. San Marte [A. Schulzl Halle, 1854) follows J. A. Giles, *Galfredi Monumentensis Historia Britonum* (Caxton Society, *1844)* which is based on **16th** century editions. Eng. trans., *History of the Kings of Britain,* ed. L. Paton (Everyman Series, 1912). For biography, *see* W. L. Jones, "Geoffrey of Monmouth" in the *Transactions of the Cymmrodorion Society* **(1899).** *See* also **A.** de la Borderie, *Études historiques bretonnes* **(1883)**; *W.* E. Mead, *Outlines of the History of the Legend of Merlin* (1899); *G.* Heeger, *Trojanersaga der Britten* **(1886)**; *F.* Lot, *Études sur Merlin* (Rennes, **1900);** R. **H.** Fletcher, "Two Notes on the *Historia,"* in the *Publications of the Modern Languages Association of America* (Baltimore, 1901); and *The Arthurian Material in the Chronicles* (Harvard Studies and Notes, 1906); *Vita Merlini* (ed. *J.* J. Parry, Illinois Studies, 1925). The subject has been dealt with exhaustively by E. K. Chambers, *Arthur of Britain,* with bibliography (1927). (H. W. C. D.; X.)

GEOFFREY OF PARIS (d. *c.* 1320), French chronicler, was probably the author of the *Chronique métrique de Philippe le Bel,* or *Chronique rimée de Geoffroi de Paris.* This work, which deals with the history of France from 1300 to 1316, contains 7,918 verses. Various short historical poems have also been attributed to Geoffrey, but there is no certain information about either his life or his writings.

The *Chronique* was published *by* J. **A.** Buchon in his *Collection des chroniques,* tome ix. (Paris, 1827), and it has also been printed in tome xxii. of the *Recueil des historiens des Gaules et de la France* (1865). *See* G. Paris, *Histoire de la littérature française au moyen âge* (Paris, 1890); and A. Molinier, *Les Sources de l'histoire de France,* tome iii. (Paris, 1903).

GEOFFREY THE BAKER (d. *c.* 1360), English chronicler, is also called Walter of Swinbroke. and was probably a secular clerk at Swinbrook in Oxfordshire. He wrote a *Chronicon Angliae temporibus Edwardi II. et Edwardi III.,* which deals with the history of England from 1303 to 1356. From the beginning until about 1324 this work is based upon Adam Murimuth's *Continuatio chronicarum,* but after this date it contains information not found elsewhere, and closes with a good account of the battle of Poitiers. The author obtained his knowledge about the last days of Edward II. from William Bisschop, a companion of the king's murderers, Thomas Gurney and John Maltravers. Geoffrey also wrote a *Chroniculum* from the creation of the world until 1336. His writings have been edited with notes by Sir E. M. Thompson as the *Chronicon Galfridi le Baker de Swynebroke* (Oxford, 1889).

GEOFFRIN, MARIE THÉRÈSE, *née* **RODET** (1699–1777), French hostess, was born in Paris on June 2, 1699. She married, on July 19, 1713, Pierre François Geoffrin, a rich manufacturer and lieutenant-colonel of the National Guard, who died in 1750. It was not till 1748, when Mme. Geoffrin was nearly 50, that she became a power in Parisian society and started her two dinners a week, one on Monday for artists, and one on Wednesday for her friends the encyclopaedists and other men of letters. She received many foreigners of distinction, Hume and Horace Walpole among others. Walpole spent much time in her society before he was finally attached to Mme. du Deffand, and speaks of her in his letters as a model of common sense. She was indeed somewhat of a small tyrant in her circle, She had adopted the pose of an old woman earlier than necessary, and her coquetry, if such it can be called, took the form of being mother and mentor to her guests, many of whom were indebted to her generosity for substantial help. Although her aim appears to have been to have the *Encyclopédie* in conversation and action around her, her advanced views did not prevent her from observing the forms of religion, and she was extremely displeased with any of her friends who were so rash as to incur open disgrace. Marmontel, for instance, losing her favour after the official censure of *Bélisaire.* A devoted Parisian, Mme. Geoffrin rarely left the city, so that her journey to Poland in 1766 to visit the king, Stanislas Poniatowski, whom she had known in his early days in Paris, was a great event in her life. Her experiences induced a sensible gratitude that she had been born *"Française"* and *"particulière."* She died in Paris on Oct. 6, 1777.

See *Correspondance inédite du roi Stanislas Auguste Poniatowski et de Madame Geoffrin,* edited by the comte de Mouy (1875); P. de Ségur, *Le Royaume de la rue Saint-Honoré, Madame Geoffrin et sa fille* **(1897)**; **A.** Tornezy, *Un Bureau d'esprit au XVIIIe siècle: le salon de Madame Geoffrin* **(1895)**; and Janet Aldis, *Madame Geoffrin, her Salon and her Times, 1750–1777* (1905).

GEOFFROY, ÉTIENNE FRANÇOIS (1672–1731), French chemist, born in Paris on Feb 13, 1672, was first an apothecary and afterwards practised medicine After studying at Montpellier he accompanied Marshal Tallard on his embassy to London in 1698 and thence travelled to Holland and Italy Returning to Paris he became professor of chemistry at the Jardin du Roi and of pharmacy and medicine at the Collège de France, and dean of the faculty of medicine. He died in Paris on Jan. 6, 1731. His name is best known in connection with his tables of affinities *(tables des rapports),* which he presented to the French Academy in 1718 and 1720. These were lists, prepared by collating observations on the actions of substances one upon another, showing the varying degrees of affinity exhibited by analogous bodies for different reagents, and they retained their vogue for the rest of the century, until displaced by the profounder conceptions introduced by C. L. Berthollet. Another of his papers dealt with the delusions of the philosopher's stone, but nevertheless he believed that iron could be artificially formed in the combustion of vegetable matter. His *Tractatus de materia medica,* published posthumously in 1741, was long celebrated.

His brother CLAUDE JOSEPH, known as Geoffroy the younger (1685–1752), was also an apothecary and chemist who, having a considerable knowledge of botany, devoted himself especially to the study of the essential oils in plants.

GEOFFROY, JULIEN LOUIS (1743–1814), French critic, a native of Rennes, Brittany, was editor of *L'Année littéraire* from 1776 to 1792 and was a bitter critic of Voltaire. During the Terror he went into hiding, only returning to Paris in 1799, when he became dramatic critic of the *Journal des Débats.* He died in Paris on Feb. 27, 1814.

GEOFFROY SAINT-HILAIRE, ETIENNE (1772–1844), French naturalist, was the son of Jean Gèrard Geoffroy, procurator and magistrate of Étampes, Seine-et-Oise, where he was born on April 15, 1772. Destined for the church he entered the college of Navarre, in Paris, where he studied natural philosophy under M. J. Brisson; and in 1788 he obtained one of

the canonicates of the chapter of Sainte Croix at Étampes, and also a benefice. Science, however, offered him a more congenial career, and he gained from his father permission to remain in Paris, and to attend the lectures at the Collège de France and the Jardin des Plantes, on the condition that he should also read law. He accordingly took up his residence at Cardinal Lemoine's college, and there became the pupil and soon the esteemed associate of Brisson's friend, the abbé Hauy, the mineralogist. Having, before the close of the year 1790, taken the degree of bachelor in law, he became a student of medicine, and attended the lectures of A. F. de Fourcroy at the Jardin des Plantes, and of L. J. M. Daubenton at the Collège de France. His studies at Paris were at length suddenly interrupted, for, in August 1792, Haiiy and the other professors of Lemoine's college, as also those of the college of Navarre, were arrested by the revolutionists as priests, and confined in the prison of St. Firmin. Through the influence of Daubenton and some others Geoffroy on August 14 obtained an order for the release of Hauy in the name of the Academy; still the other professors of the two colleges, save C. F. Lhomond, who had been rescued by his pupil J. L. Tallien, remained in confinement. Geoffroy, foreseeing their certain destruction if they remained in the hands of the revolutionists, determined if possible to secure their liberty by stratagem. By bribing one of the officials at St. Firmin, and disguising himself as a commissioner of prisons, he gained admission to his friends, and entreated them to effect their escape by following him. All, however, dreading lest their deliverance should render the doom of their fellow-captives the more certain, refused the offer, and one priest only, who was unknown to Geoffroy, left the prison. Already on the night of September 2 the massacre of the proscribed had begun, when Geoffroy, yet intent on saving the lives of his friends and teachers, repaired to St. Firmin. At 4 o'clock on the morning of September 3, after eight hours' waiting, he by means of a ladder assisted the escape of twelve ecclesiastics, not of the number of his acquaintance, and then the approach of dawn and the discharge of a gun directed at him warned him, his chief purpose unaccomplished, to return to his lodgings. Leaving Paris he retired to Étampes, where, in consequence of the anxieties of which he had lately been the prey, and the horrors which he had witnessed, he was for some time seriously ill. At the beginning of the winter of 1792 he returned to his studies in Paris, and in March of the following year Daubenton, through the interest of Bernardin de Saint Pierre, procured him the office of sub-keeper and assistant demonstrator of the cabinet of natural history, vacant by the resignation of B. G. E. Lacépède. By a law passed in June 1793, Geoffroy was appointed one of the twelve professors of the newly constituted museum of natural history, being assigned the chair of zoology. In the same year he busied himself with the formation of a menagerie at that institution.

In 1794 through the introduction of A. H. Tessier he entered into correspondence with Georges Cuvier, to whom, after the perusal of some of his manuscripts, he wrote: "Venez jouer parmi nous le rôle de Linné, d'un autre législateur de l'histoire naturelle." Shortly after the appointment of Cuvier as assistant at the Muséum d'Histoire Naturelle, Geoffroy received him into his house. The two friends wrote together five memoirs on natural history, one of which, on the classification of mammals, puts fonvard the idea of the subordination of characters upon which Cuvier based his zoclogical system. It was in a paper entitled "Histoire des Makis, ou singes de Madagascar," written in 1795, that Geoffroy first gave expression to his views on "the unity of organic composition," the influence of which is perceptible in all his subsequent writings; nature, he observes, presents us with only one plan of construction, the same in principle, but varied in its accessory parts.

In 1798 Geoffroy was chosen a member of the great scientific expedition to Egypt, and on the capitulation of Alexandria in August 1801, he took part in resisting the claim made by the British general to the collections of the expedition, declaring that, were that demand persisted in, history would have to record that he also had burnt a library in Alexandria. Early in January 1802 Geoffroy returned to his accustomed labours in Paris. He was elected a member of the academy of sciences of that city in September 1807. In March of the following year the emperor, who had already recognized his national services by the award of the Cross of the Legion of Honour, selected him to visit the museums of Portugal, for the purpose of procuring collections from them, and in the face of considerable opposition from the British he eventually was successful in retaining them as a permanent possession for his country. In 1809, the year after his return to France, he was made professor of zoology at the faculty of sciences at Paris, and from that period he devoted himself more exclusively than before to anatomical study. In 1818 he gave to the world the first part of his celebrated *Philosophie anatomique,* the second volume of which, published in 1822, and subsequent memoirs account for the formation of monstrosities on the principle of arrest of development, and of the attraction of similar parts. When, in 1830, Geoffroy proceeded to apply to the invertebrata his views as to the unity of animal composition, he found a vigorous opponent in Ceorges Cuvier, and the discussion between them, continued up to the time of the death of the latter, soon attracted the atrencion of the scientific throughout Europe. Geoffroy, a synthesist, contended, in accordance with his theory of unity of plan in organic composition, that all animals are formed of the same elements, in the same number, and with the same connections: homologous parts, however they differ in form and size, must remain associated in the same invariable order. With Goethe he held that there is in nature a law of compensation or balancing of growth, so that if one organ take on an excess of development, it is at the expense of some other part; and he maintained that, since nature takes no sudden leaps, even organs which are superfluous in any given species, if they have played an important part in other species of the same family, are retained as rudiments, which testify to the permanence of the general plan of creation. It was his conviction that, owing to the conditions of life, the same forms had not been perpetuated since the origin of all things, although it was not his belief that existing species are becoming modified. Cuvier, who was an analytical observer of facts, admitted only the prevalence of "laws of co-existence" or "harmony" in animal organs, and maintained the absolute invariability of species, which he declared had been created with a regard to the circumstances in which they were placed, each organ contrived with a view to the function it had to fulfil, thus putting, in Geoffroy's considerations, the effect for the cause.

In July 1840 Geoffroy became blind, and some months later he had a paralytic attack. From that time his strength gradually failed him. He resigned his chair at the museum in 1841, and died at Paris on June 19, 1844.

Geoffroy urote: *Catalogue des mammifères du Muséum National d'Histoire Naturelle* (1813), not quite completed; *Philosophie anatomique—t.* i., *Des organes respiratoires* (1818), and *t.* ii., *Des monstruosite's humaines* (1822); *Système dentaire des mammifères et des oiseaux* (1st pt., 1824); *Sur le principe de l'unité de composition organique* (1828); *Cours de l'histoire naturelle des mammifères* (1829); *Principes de philosophie zoologique* (1830); *Etudes progressives d'un naturabste* (1835); *Fragments biographiques* (1832); *Notions synthétiques, historiques et physiologiques de philosophie naturelle* (1838), and other works; also part of the *Description de l'Égypte par la commission des sciences* (1821–1830); and, with Frédéric Cuvier (1773–1838), a younger brother of G. Cuvier, *Histoire naturelle des mammifères (4* vols., 1820–1842); besides numerous papers on such subjects as the anatomy of marsupials, ruminants and electrical fishes, the vertebrate theory of the skull, the opercula of fishes, teratoloey, palaeontology and the influence of surrounding conditions in modifying animal forms.

See *Vie, travaux, et doctrine scientifique d'Étienne Geoffroy Saint-Hilaire, par son fils M. Isidore Geoffroy Saint-Hilaire* (Paris and Strasburg, 1847), to uhich is appended a list of Geoffroy's works; and Joly, in *Biog. universelle, t.* xvi. (1856).

GEBFFROY SAINT-WILAIRE, **ISIDORE** (1805–1861), French zoologist, son of the preceding, was born in Paris on Dec. 16, 1805. He received his M.D. in 1824, and from 1830–33 taught zoology at the Athénée. In 1832 was published his great teratological work, *Histoire générale et particulière des anomalies de l'organisation chez l'homme et les animaux* (3 vols.). He was elected a member of the Academy of Sciences in Paris

in *1833,* was in *1837* appointed to act as deputy for his father at the Faculty of Sciences in Paris, and in the following year was sent to Bordeaux to organize a similar faculty there. He became successively inspector of the Academy of Paris (1840), professor of the museum on the retirement of his father (1841), inspector-general of the university (1844), a member of the royal council for public instruction (1845) and professor of zoology at the Faculty of Sciences (1850). He died in Paris on Nov. 10, *1861.*

Besides the above works, he wrote: *Essais de zoologie générale* **(1841);** *Vie . . . d'Étienne Geoffroy Saint-Hilaire* (1847); *Acclimatation et donzestication des animaux utiles* (1849); *Lettres sur les substances alimentaires* (1856) and *Histoire naturelle générale des règnes organiques (3* vols., 1854–62), and various papers on zoology, comparative anatomy and palaeontology.

GEOGRAPHICAL ARTICLES. The articles on the various territories in this *Encyclopædia* are prefaced by a geographical sketch giving the chief characteristics of the area in question. This, in the case of the continents, is general, and for particular details the reader is referred to some article of more restricted scope. In the case of countries the geography is given first and references made to later sections where *Geology* and *Archaeology* and *Antiquities* may add something of importance to the understanding of the territory. In the British Isles each county has its own heading and the important cities and towns have likewise separate entries. In the United States the main article is concerned with the general geography, etc.; and each State is treated separately. The chief towns also have entries as in the case of other countries.

Where divisions or special districts of continents had, before the World War, a well-established name which has since been officially changed, the old name is given a place with a cross-reference to the new designation. Changes of government and administration, mandates and changes of territorial allocation have been dealt with in the same way.

In addition to the articles to be found under well-known geographical names attention may be drawn to such comprehensive articles as ARCTIC REGIONS, METEOROLOGY, STEREOGRAPHY, and TIDES. Articles on natural phenomena such as MONSOON, EARTHQUAKE, HURRICANE, etc., carry cross-references to articles on the territories and waters where they are commonly found. Mountain ranges have, in some instances, their own articles (ALPS, HIMALAYA, etc.), as is also the case with the world's chief rivers.

Every subdivision of geographical study has been treated, either under its own head or that of a related subject. In every case where confusion might possibly arise cross-references have been inserted. The many archipelagos of the Pacific, have, for example, been treated comprehensively in the article PACIFIC ISLANDS but each group (and the main islands separately) has its own heading where the geography and physical features are given, with a cross-reference to the regional article.

GEOGRAPHICAL SOCIETIES. The *Congrks International pour les Progrks des Sciences Géographiques* first met in *1871.* The *Royal Geographical Society of London,* founded in *1830,* had joined to it in the following year the *African Association* (1788), the successor of the *Saturday Club;* the *Palestine Association* (1805) became merged with it in *1834.* It publishes *Journal* (1832–*80), Proceedings (18j7–92)* and *Geogr. Journal (1893 seq.).* The *Hakluyt Society (1846)* has printed more than *136* volumes of rare voyages and travels. *The Alpine Club* (1858), whose publications are *Peaks, Passes and Glaciers (1859–62)* and *Journal (1863 seq.),* meets in London. The *Royal Scottish Geographical Society (1884)* has its centre at Edinburgh and issues the *Scottish Geographical Magazine.* Newcastle has the *Tyneside Geographical Society* and Manchester also has a *Geographical Society (1884).* Aberystwyth, Wales, has a Geographical Society (1900), and publishes *Geography.* AUSTRALIA: Adelaide, *Roy. Geogr. Soc. of Australasia, S. Austral. Br.* (1885), *Proc.* Brisbane, *Roy. Geogr. Soc. of Australasia,* Queensland (1885), *Queensland Geogr. Journal.* Melbourne, *Roy. Geogr. Soc. of Australasia, Victoria Br.* (1883), incorporated with *The Hist. Soc. of Victoria (1921), Victorian Geogr. Journ.* Sydney, *Geogr. Soc. of New S. Wales, Austral. Geographer* (1928). SOUTH AFRICA: Johannesburg, *Geogr. Soc. of S. Africa* (1917), *S. Afr. Geogr. Journ.* CANADA: Quebec, *Soc. de Ge'ogr. de Quebec* (1877), *Bull.* INDIA: Bombay, *Roy. Asiatic Soc., Bombay Br. (1871).* EGYPT: Cairo, *Soc. Khédiviale de Ge'ogr.* (1875), *Bull. (1876 seq.),* changed to *Soc. Roy. de Ge'ogr. de'Égypte* (1917), *Bull., Mem.* UNITED STATES: Chicago, *Geogr. Soc.* (1898), *Bull. (1898 seq.), Assoc. of Anter. Geographers* (1904), *Annals.* New York, *Amer. Geogr. Soc. of New York (1851), Bull.* (1852–57); *Journ. (1859 seq.),* later *Bzcll.* (1901–15), continued as *The Geogr. Rev.* (1916–20); *Proc.* (1862–65) and 137 separate publications. Philadelphia, *Gcogr. Soc.* (1893), *Bull.* Washington, *Nat. Geogr. Soc.* (1888), *Nat. Geogr. Magazine (1888 seq.); Soc. of Women Geographers (192j), Bull.* AUSTRIA: Vienna, *Geogr. Ges.* (1856), *dfitteil.* (1857 *seq.*), *Abhandl. GEOGRAPHY, the exact and organised knowledge of the distribution of phenomena on the surface of the Earth (γῆ, the Earth, and γράφειν, to write). It deals with the form and motion of the planet so far as a knowledge of these is necessary for fixing positions on the surface and explaining the incidence of solar radiation, more fully with the forms of the lithosphere or stony crust of the Earth, the extent of the water envelope or hydrosphere, the movements of the water and of the all-surrounding atmosphere, the distribution of plants and animals and very fully with that of the human race, and with all the interactions and relationships between these distributions.

Geography is a synthetic science, largely dependent for its data on the results of specialized sciences such as astronomy, physics, geology, oceanography, meteorology, biology and anthropology and always having respect to the natural regions of the world. The characteristic task of geography is to investigate the control exercised by the forms and vertical relief of the surface of the lithosphere directly or indirectly on the various mobile distributions. Viewed in this light geography is a unified and definite science of wide outlook and comprehensive grasp. It is essential to classify its subject matter so as to give prominence to facts in their relationships and to the natural order in which they occur.

This article first sketches the progress of geographical discovery, then deals with the growth of geographical theory and finally indicates the general principles of geography as they are understood at the present time.

I. PROGRESS OF GEOGRAPHICAL DISCOVERY

Although geographical discovery must have started from every isolated centre of ancient civilization it is only possible to deal here with the stream of exploration which, starting 3,000 years ago in the eastern Mediterranean where a wedge of Asia unites Africa with Europe, has spread down the ages until to-day it has reached almost to every part of the Earth's surface on land and sea. This sketch touches only the main outlines of the progress of discovery, its object being to indicate the changes which have occurred through the centuries in the motives and the methods as well as in the objectives of exploration.

Widening the Mediterranean Horizon. — The Egyptians had explored and conquered large tracts of land before the 14th century B.C., both southward up the Nile and northeastward to the borders of Assyria, but the first sea-going explorers seem to have been the Phoenicians who made Sidon a commercial port as early as 1400 B.C. and later raised Tyre to equal fame. The merchant adventurers of Tyre and Sidon explored the whole coast of the Mediterranean, founding the colony of Carthage before 800 B.C. They and other colonizers on the shores of the Iberian peninsula sailed northward along the Atlantic coast, probably trading direct with Cornwall for tin, and to the south going far along the west coast of Africa. They certainly reached the Azores as Carthaginian coins of the 4th century B.C. have been found on the island of Corvo. With the support of Egypt they traded also on the Red Sea reaching lands yielding gold and ivory probably on the coast of Africa or Arabia. It is probable that they also reached India from the Red Sea. Herodotus heard in Egypt that in the days of King Nicho (600 B.C.) a Phoenician fleet sent from the Red Sea southward along the African coast had returned to Egypt by the Pillars of Hercules Herodotus was the earliest of the Greek travellers to give a full and trustworthy narrative of his peregrinations in Asia as far as Persia, in Egypt and north Africa, on the Black Sea coasts as far as the Caucasus and in Italy (480–440 B.C.).

The maritime trade of the Greek City States and their colonies became more important than that of the Phoenicians soon after the fifth century B.C. Greek ships sailed beyond the Mediterranean, opening up the Black Sea on the east and the borders of the Atlantic on the west. Massilia (on the site of the modern Marseille) was a colony of Greeks from Phocaea and thence a voyage of great importance was made by Pytheas about 330 B.C. His own narrative is lost and the facts have to be gathered from references by Strabo 300 years later to criticisms of the voyage in lost books of the Greek geographers. Pytheas was probably the first navigator to fix the position of the lands he reached by crude astronomical observations and he seems to have been a keen observer of places and people. He coasted the Bay of Biscay, and the east of Britain as far as Orkney where he heard a report of Thule, a more northern land, and a confused hint of the Arctic regions. On a later voyage he coasted the east side of the North Sea and probably entered the Baltic. During the same years the conquests of Alexander the Great opened to the Greek world a knowledge of the continent of Asia as far as the northern plain of India, and his general Nearchus conducted a fleet from the mouth of the Indus to the Persian Gulf, the first voyage in the Indian Ocean to be described in a manner comparable with the record of the land journey of Xenophon a century earlier when after the death of Cyrus he led the 10,000 from Mesopotamia across the plateau of Armenia to the Black sea. In the following centuries the Ptolemies, Greek kings of Egypt, encouraged exploration and about 115 B.C. Eudoxus under their auspices explored the Arabian sea, and planned to circumnavigate Africa, but could not get support for so daring a project.

The rise and extension of the Roman Empire involved scouting expeditions before and surveys after the conquest of each province of the lands bordering on the Mediterranean in Europe, Asia and Africa. Conquering generals described the tribes they subdued and the regions they occupied and Julius Caesar won renown as a writer no less than as a fighter. Each province of the empire was bound to Rome by the imperishable causeways which still form the skeleton of the road map of Europe. Pliny and Seneca say that Nero (about A.D. 60) sent two centurions to follow up the Nile from Egypt, and they were stopped by great marshes, probably those of the Sudan about 19° N. The practical advantages of discovery appealed to the Roman mentality more powerfully than the abstract theories which fascinated the Greeks and Hippalus who about A.D. 79, learning from the Arabs of the regular seasonal changes of the monsoons, made these winds serve him as the means of establishing a trade route between the Red Sea and India across the open ocean instead of hugging the coast as of yore. This trade continued to deveiop and a century

later Pausanias makes it appear that direct communication had even been opened up with China. In the time of Justinian (483–56j) two Nestorian monks made the journey from Constantirlople overland to China and succeeded in introducing the first silkworms into the Mediterranean lands.

After the fall of the Roman Empire and the incursion of barbarians from the north a wave of Arab domination surged over the Asiatic and African provinces and swept far into the southern peninsulas of Europe. The geographical learning of the Greeks and Romans enshrined in the writings of Ptolemy of Alexandria (A.D. 150) passed to the Arabs and was forgotten in Christian Europe where the conception of the globe degenerated to that of a flat disc with Jerusalem at the centre. The Arabs trading with India, China and the east coast of Africa acquired a sound knowledge of the Indian Ocean and a fair idea of the interior of Africa before the year 1000. Among the well-known geographical writers of this period were Abu Zaid, Masudi, Istakhri and Idrisi.

Meanwhile the Northmen from the fjords of Scandinavia were harrying the coasts of northern Europe and even making their way into the Mediterranean. Most of the vikings pushed southwards for plunder and conquest, but some turned northward to hunt the fur and ivory yielding animals of the northern seas. Othar of Helgeland discovered the North Cape and rounding it proceeded as far as the White Sea in the middle of the 9th century. Later he visited the court of Alfred the Great and it was the English king who first reduced to writing the discoveries of the earliest Polar explorer and introduced to literature the midnight sun of the Arctic summer. The commerce of the Arabs and of the less warlike of the Northmen interlaced at several points and their trade routes ran overland between the Black Sea and the Baltic. Late in the 9th century Iceiand was colonized from Norway and in 985 Eric the Red, sailing westward, discovered Greenland and soon afterwards his son Leif Ericsson sailing thence to the southwest came on a new land which he named Vinland, and was thus the first European to reach America. If news of this event percolated southwards the distracted Europe of the Middle Ages had other things to think of and only vague legends or the scribbling of fanciful islands on the vacant Atlantic margins of the mediaeval maps justify the suggestion that it did. A horror of the unknown territories, still more of unknown oceans, settled on the mind of mediaeval Europe. The church, not yet roused to missionary effort, was keen in the encouragement of the Crusaders who were recruited from every country of Europe to drive the Infidels from the Holy City. In this way the culture and graceful luxury of the caliphs became known to the rough courts of the western kings, and the attention of the merchants of the growing Italian city-states, Genoa and Venice in particular, was concentrated on the Far East as the source of all wealth.

The domination of Central Asia from the Caspian to the Pacific by the Mongol emperors made very long overland journeys practicable at the close of the middle ages and Venetian merchants had thus established contact with China before Marco Polo set out in 1265 for Peking, the capital of Kubla Khan. The story of his seventeen years' sojourn in the Far East and of his journeyings by land and sea in central Asia, China, the Malay Archipelago, and India was the greatest work of travel of the middle ages and for the first time it made the venerable civilization and the rich products of the Orient familiar to the people of Europe. Many of his statements were derided by contemporaries but his substantial veracity and remarkable powers of observation have been vindicated by modern travellers and students. Missionaries. whose activity increased as that of the crusaders diminished, pushed far afield in Asia and their records contain some grains of geographical value amongst a vast quantity of superstitious and ignorant chaff. One only need be mentioned here; Friar Odoric of Pordonone who, early in the 14th century, visited India, the Malay Archipelago, China and Tibet where he was the first European to enter Lhasa, not yet a forbidden city. A Moslem contemporary Ibn Batuta was the greatest of the Arabian travellers who left accounts of their journeys. Between 132j and 1353 he explored Arabia and Persia and spent eight years in the service of the Mogul ruler of Delhl, going on to China and the Malay Archipelago, He also visited the east African coast as far south as Mombasa and Kilwa and crossed the desert from the Red sea to Syene on the Nile; finally he explored west Africa by land reaching Timbuktu and the Niger.

COMMERCE AND EXPLORATION

Many travellers in the early part of the 15th century made notable journeys throughout the mainland of Asia and the Eastern archipelago impelled by the growing demand for the silks, spices and other valuable products of the tropics. From Spain Ruy Gonzalez de Clavijo journeyed to the court of Timur at Samarkand; from Italy Nicolo Conti later in the century spent 25 years in the Far East reaching China, Java and Sumatra.

The Opening **of** the Oceans.—In the 1jth century the use of the magnetic compass became general amongst the Mediterranean mariners giving them for the first time confidence in navigation out of sight of land or when the stars were hidden, and leading to the introduction of the *portulani* or compass charts of the coasts. Latitude at sea began to be measured by the astrolabe or other cumbrous instrument for observing the altitude of the sun. but longitude was long destined to remain a matter of guesswork. The Italian merchants continued to foster trade with the east through the land routes controlled by the Muslim nations though the rise of the Turks made this increasingly difficult. In the west the Portuguese took the lead in developing maritime enterprise in the hope of perhaps finding a route to the Indies by the south of Africa and with the more immediate object of founding a great Portuguese overseas empire. Prince Henry of Portugal with the spirit of a crusader determined to overcome the Muslim power in North Africa and explore the coast southward in order to find a way by which to get in touch with Abyssinia the half mythical Christian kingdom of Prester John, behind the country of the Moors. The Portuguese missionary Covilham (q *v.*) succeeded in reaching Abyssinia in 1487 from Egypt but was not allowed to return. Effective contact with that country had to wait for some years. Meanwhile the Order of Christ, of which Prince Henry was the head, received a papal grant of lands to be discovered, and funds were raised for the good work by trading in slaves captured on the coast.

The Azores, 800 miles out in the open Atlantic, had been vaguely known before, but were rediscovered and settled in 1432, while successive expeditions stimulated by the Prince crept by degrees along the Sahara coast to the fertile lands beyond; in 1462, after his death, they reached Sierra Leone and a few years later explored the whole Guinea coast. Then discovery became rapid In 1481 the equator was crossed, in 1484 Diago Cam passed the mouth of the Congo and in 1486 Bartholomem Diaz by a splendid effort fetched a wide sweep far out of sight of land and reached Mossel Bay. In returning he saw the southern point of Africa and named the Cape of Storms. This was the greatest landmark in the history of exploration. The King of Portugal seeing the wealth of the Indies within his grasp changed the name to Cape of Good Hope and Vasco da Gama (*q.v.*) realized the hope in 1498 by sailing round the Cape to the Arab port of Mombasa whence with the aid of local pilots he reached India and fulfilled the dream of ages. Camoens, who himself made the voyage 70 years later, celebrated the achievement in his great poem the Lusiad.

Toscanelli as early as 1474 had pointed out from Ptolemy's maps that the east coast of Asia might be reached more easily by sailing due west than by going south and then east and north. Christopher Columbus (*q.v.*), a native of Genoa who had much experience of navigating the Atlantic and had sailed to Iceland, became possessed with the idea of making this voyage. He spent many years in the endeavour to find a patron, and in 1492 had almost persuaded the King of England and the King of Spain to embark on the enterprise; the Ring of England hesitated the longer and Columbus with Spanish ships made an easy passage from the Azores to the islands which he named the West Indies. Following a suggestion of the Pope a meridian line running down the middle of the Atlantic was fixed by treaty between Spain and Portugal, the former country agreeing to restrict exploration to

the western hemisphere so marked out and the latter country to the eastern hemisphere. Columbus after other voyages to the West Indies died in 1506 in the belief that he had reached the islands off the coast of Asia. The merchants of Bristol had often sent out their ships some week's sail to the westward into the Atlantic in search of legendary islands and in 1497 John Cabot. no doubt inspired by the success of Columbus, persevered until he found the coast of Labrador and Newfoundland, thus repeating the old Norse discovery of North America and, though the quest was not then pursued, pegging out a claim to England's oldest colony. The companions of Columbus continued to cruise among the West Indies and quickly traced out the shores of the Spanish Main to the south, and the limits of the Caribbean Sea to west and north. In 1513 Balboa caught the first glimpse of an inaccessible ocean to the west from "a peak in Darien" and recognized that Asia was still far off. In 1500 Vicente Pinzon (*q.v.*) sent from Spain to explore the coast southward from the Orinoco, first sighted land near Pernambuco and following it northward round Cape San Roque discovered the mouth of the Amazon. His shipmate, Amerigo Vespucci (*q.v.*), a clever man who took part in several voyages of discovery, described this voyage and by a curious chance his Christian name in its latinized form was attached for ever to the continents of America. By making a westward sweep in a voyage to the Cape of Good Hope, Cabral lit on the coast of Brazil in the same year and this accounts for the presence of the Portuguese-speaking Brazilians in the midst of the Spanish-speaking republics of South America. The Spaniards realizing that America was a solid obstacle between Europe and Asia pushed forward to discover a passage by the south. In 1515 de Solis reached the River Plate which seemed to offer a way through. Ferdinand Magellan (*q.v.*) five years later showed that it was only an estuary and, proceeding southward he found and passed through the tortuous strait which bears his name, so piercing the barrier of America. Persevering in face of every difficulty which could befall an explorer he pushed on across the awful and incredible breadth of the Pacific. Although he met his death in the Philippine Islands in 1521, his ship the "Victoria" under Sebastian del Cano with a handful of survivors returned to Spain in 1522 by the Cape of Good Hope after the greatest voyage that ever was, for it accomplished the first circumnavigation. Amongst his rewards Del Cano received the world as his crest with the proud motto *Primus circumdedisti me*. The Spanish and Portuguese between them soon completed the rough outlines of Africa and the two Americas; but the sixteenth century saw their maritime power challenged by the enterprise of France and the Protestant Powers of England and Holland whose sailors disregarded alike Papal Bulls and the private agreements between Spain and Portugal.

The northern peoples claimed their share in the new world and in the sea routes to the east. French fishermen following in the track of Cabot early began to frequent the Grand Banks of Newfoundland and the king of France in 1524 sent out Verazzano, a Florentine, who explored the coast of North America between the lands discovered by Cabot in the north and by the Spaniards in the South. He found no way through, and ten years later a French expedition under Jacques Cartier set out to search the Gulf of St. Lawrence for a way to the Far East. In a second voyage in 1535 he ascended the St. Lawrence to the present site of Montreal and, although only the name of Lachine Rapids remains of this attempt to reach China that way, he spent two years in the effort to start the French colony of Canada.

Queen Elizabeth saw a wave of enthusiasm for discovery sweep over England, rousing sailors, soldiers, merchants, parsons, philosophers, poets and politicians to vie with each other in promoting expeditions overseas for the glory of their country and their own fame and profit. The gallants of the court were ever ready to command the expeditions for which the shrewd city merchants found the means; while quiet scholars like Richard Hakluyt promoted the work by recording the great deeds of earlier as well as contemporary adventurers. His *Principall Navigations* first published in 1589 are to this day delightful reading and, supplemented by *Hakluytus Posthumus or Purchase his Pilgrimes* published in 1625, form the only record of many great expeditions. On the continent similar compilations such as those of the Italian Ramusio (1583–1613) and the splendidly illustrated Dutch volumes of De Bry (1590–1634) played a similar stimulating part. In England as elsewhere at first the object was to find a westward route to the Far East. Richard Chancellor tried for a North East Passage and though he got no farther than the White Sea he went on by land to Moscow and opened up direct trade with Russia, leading to the formation of the Muscovy Company, the first of many chartered companies for exploration and trade. In 1576 Martin Frobisher (*q.v.*) made a spirited attempt to find a North West Passage to China and reached the coast of Labrador at its northern extremity. John Davis (*q.v.*) one of the greatest Arctic explorers who ever lived, took up the quest in 1585, and in successive years he navigated the broad strait which bears his name to 72° N. finding open sea to the northward and hope of an ultimate passage westward. Francis Drake, setting out to trace a route from the other side, made the second circumnavigation of the world in 1577–80. He went by Magellan's Strait, after passing which he was blown southward to 56° S., and satisfied himself that the Atlantic and Pacific Oceans met south of Tierra del Fuego. Diake proceeded northward and explored the Pacific coast of North America to 48° in vain search of a passage to the east. Eventually he returned by the Philippines and the Cape of Good Hope. Cavendish repeated this voyage in 1586–88, adding to the confidence with which long voyages were undertaken and John Hawkins, though less fortunate, again showed the flag in the Pacific before the end of the century.

Walter Raleigh, Humphrey Gilbert and many more took part in exploring the North American Atlantic coast and in 1599 Queen Elizabeth granted a charter to the East India Company which initiated direct trade with India and prepared the way for the British Empire in the east. Spanish exploration from the Pacific ports of their American possessions was renewed, partly no doubt in order to anticipate English discoveries. In 1577 Alvarez de Mendana sailing from Callao crossed the Pacific and discovered the Solomon islands. Pedro Sarmiento in 1579 went south from Callao and surveyed the Strait of Magellan with a view to fortifying it and so holding for the Spaniards what they then supposed to be the only entry to the Pacific. The Dutch made many attempts to find a northern passage to China in the last decade of the sixteenth century. Willem Barents, after discovering Spitsbergen, was wrecked on the north coast of Novaya Zemlya and after wintering there made a heroic journey by boat along the coast, on which he died, but his crew returned safely in 1596.

In the 17th century the search for a northern passage to the Far East still went on. The work of Davis was followed by that of Henry Hudson who in 1607 reached a latitude of 81" N. in the Spitzbergen region and in 1610 he discovered the inland sea now known as Hudson Bay. Baffin came later reaching 78° N. in 1616, and naming Smith Sound to the north of the great bay called after him at the end of Davis Strait. A charter for the Hudson's Bay company was granted in 1670.

THE SEARCH FOR THE SOUTH LAND

A belief in a southern continent surrounding the pole and extending into temperate and tropical latitudes had found expression in the maps of European cartographers since the time of Magellan whose Tierra del Fuego was held to be part of it. Many explorers were drawn by the magnet of this illusion into the unknown parts of the great oceans. Pedro Fernandez de Quiños and Luiz Vares de Torres were sent out in 1605 by the Viceroy of Peru to take possession of the supposed Southern continent and on reaching the New Hebrides Quiiios believed he had gained his goal and took possession with great ceremony of "Australia del Espiritu Santo," the first appearance of the name Australia on the map. In returning Torres passed through the Strait which bears his name discovering the northern end of Australia and exploring part of the coast of New Guinea. The great period of Dutch voyages began with the formation of the Dutch East India Company in 1602 though Dutch merchant adventurers, sailing by the Cape of Good Hope, were active on the coast of Japan by 1600 and soon after were successful rivals to the Portuguese already established in India and the Malay Archi-

pelago. The Company in 1614 determined to find a way into the Pacific south of Magellan Strait and sent out Jacob Lemaire in the "Eendracht" and Willem Schouten in the "Hoorn." These ships passed south of Tierra del Fuego proving that it was no part of a southern continent, named Staten Land (not recognising it as an island), and navigating Strait Lemaire saw and named Cape Horn on January 31, 1615. Lemaire and Schouten crossed the Pacific, sailed along the north coast of New Guinea and reached the Moluccas. Other Dutch mariners working from the north discovered the west coast of Australia, still supposed to be a projection of a vast southern continent, Dirk Hartog reaching 26° S. on that coast in 1616.. Anthony Van Diemen, governor of the Dutch East Indies, resolved in 1642 to explore the coast of the Southern Continent and sent out Abel Janszoon Tasman to carry out the task. The voyage was the greatest contribution to maritime exploration since Magellan. He sailed westward across the Indian Ocean to Mauritius, then in a great sweep southward and eastward he came on high land which he named after Van Diemen though it is now known as Tasmania. Sailing farther east he came on the west coast of another lofty land which he named Staten Land, believing it t~ be part of the Southern Continent continuous with Schouten's Staten Land off South America. It was really New Zealand. He sailed on to the Fiji Islands and returned along the north coast of New Britain and New Guinea to Batavia. In 1643 he went out again with three ships when he explored in some detail the south coast of New Guinea and the north and west coasts of Australia which he called New Holland. In 1699 William Dampier, a noted buccaneer in his early days, made an important voyage on H.M.S. "Roebuck" along the west and north of Australia and the north of New Guinea, rediscovering and naming New Britain. His voyages were remarkable for his extraordinarily keen observations of natural phenomena: in some respects he was the pioneer of scientific exploration. The Dutchman Roggeveen in 1721 and the Frenchman Bouvet in 1738 set out expressly to discover and annex the South Land and the latter took an ice-clad islet of the South Atlantic to be part of it.

By the middle of the eighteenth century the methods of navigation had greatly improved and the introduction of the quadrant gave new precision to determinations of latitude. The great bugbear of long voyages was scurvy, supposed to be an inevitable result of life on board the small craft of those days and often fatal to the larger part of the crew. In the second half of the eighteenth century scientific geographers in Europe secured a more systematic system of exploration in which adventure, though still encountered, was subordinated to research. Already in the first year of the century the astronomer Halley had been sent in command of a British war-ship to the South Atlantic in order to study the variation of the compass. In 1764 John Byron was sent on a circumnavigation for discovery and on his return a larger expedition was despatched under Samuel Wallis and Philip Carteret and was absent from 1766 to 1769 discovering Tahiti and many other islands in the Pacific. A French expedition under Bougainville followed and for half a century there was keen rivalry between France and Great Britain in the Pacific. Meanwhile the Royal Society had planned an expedition to observe the transit of Venus of 1769 from some point in the Pacific and approached the Admiralty to obtain a ship to be placed under the command of Alexander Dalrymple a civilian and a fervent believer in the existence of a vast temperate southern continent. The expedition was sanctioned in time to instruct Wallis to look out for a suitable position in the Pacific; but the Admiralty by a stroke of unconscious genius gave the command to James Cook and thereby created a new era in exploration and raised the fame of British maritime enterprise to a unique place in the esteem of the world. Cook was accompanied by the great naturalist Joseph Banks, D. C. Solander (a student of Linnaeus) and two astronomers. The expedition, which was absent from 1767 to 1770, did all that was required of it and much more. It discovered many island groups in the Pacific, sailed round New Zealand proving it to be no part of the Southern Continent and surveyed much of the east coast of Australia so accurately that the charts are still serviceable. A second voyage was determined on, to settle the question of the Southern Continent and Cook set out again in the "Resolution" and "Adventure" in 1772. The voyage lasted until 1775; Cook penetrated far to the south of the Antarctic Circle at several points proving beyond question that there was no habitable land, save a few sterile islands south of the known continents, but his most important discovery was that scurvy was preventible by proper diet and care. Immediately on his return a third great voyage was planned to endeavour to find a passage by sea from the North Pacific to the Atlantic; the old ghost of a North West Passage still walked. Cook sailed in 1776, visited Kerguelen Island in the South Indian Ocean which had been discovered three years before and proceeded to survey the northern extremity of the west coast of North America passing through Bering Strait until stopped by the ice in 70° N. Thus Cook had spanned the earth through more than 140 degrees of latitude as well as through all longitudes. On retiring to Hawaii for the winter Cook was killed by the natives in 1779, but Edward Clarke his second in command spent another season in the effortto penetrate the Arctic Sea from Bering Strait and returned to England in 1780. Cook's voyage round the Antarctic continent was supplemented by a great Russian expedition under Bellingshausen in 1819–1821; and by a group of hardy American and British sealers in the first third of the nineteenth century, chief among them Weddell who in 1823 reached 73° S. in the sea named after him, and Biscoe in 1831–32 who made a complete circumnavigation discovering the most southerly land so far known.

Port Jackson, the present Sydney, was founded as the first settlement in Australia in 1788 and the coasts were explored by such daring boat-travellers as Flinders and Bass, the latter proving that Tasmania was an island in 1795. Cook was followed on the west coast of North America in 1792–1794 by Vancouver who extended northward from Cape Mendocino the work of Spanish explorers and made exact surveys along the coast. The French expedition of La Pérouse in two ships spent the years 1785 to 1788 in crossing and recrossing the widest part of the Pacific but never returned and many efforts were made to discover its fate, the most extensive being that made by Entrecasteaux in 1791–1793.

The 18th century saw the completion of the great task of outlining the continental shores; even those of the Arctic Sea had been traced out by Russian travellers like Bering (by birth a Dane), Dezhneff and Chelyuskin, whose name remains on the most northerly cape of the old world. The Spaniards had made known the broad lines of the geography of South America, Central America and the southern part of North America, the central and northern portions of which had been penetrated in all directions by French and British pioneers. The interior of Australia remained totally unknown as were the Arctic regions north of 80° N. and the Antarctic south of the Polar Circle. In the Old World Asia had been traversed in all directions although large areas remained unvisited between the trade routes and the tracks of explorers. China was mapped by Jesuit missionaries in the early years of the century, and the accurate mapping of India was in full swing before its close. Africa was the least known of the continents and the French geographer D'Anville despairing of reconciling the conflicting accounts of the interior drawn from tradition and the stories of Arab traders, who had undoubtedly penetrated far into the interior, swept the map clear of all features which had not been seen by European travellers and left a blank of "Unexplored Territory" within the coast line from Morocco and Abyssinia on the north to Cape Colony and Natal on the south. James Bruce explored the Blue Nile from its source in Abyssinia to its junction with the White Nile and before his death a strong effort was made in England by the founding of the African Association which enabled John Ledyard to make a great journey across the Sudan from east to west and Mungo Park to trace much of the course of the Niger. Scientific geography was powerfully advanced by the determination of the size and figure of the earth by the measurement of arcs of the meridian near Quito on the equator by a French commission under C. M de la Condamine in 1735–43 and another in the far north under P. L M. de Maupertuis in Lapland in 1738

THE NINETEENTH CENTURY

Exploration. — The progress of geographical discovery by exploration and by research entered on a new phase with the nineteenth century. Instruments for fixing position had been perfected, the sextant was handier and more accurate than the old quadrant, the chronometer, first used on Cook's second voyage, made good determinations of longitude possible at last, the institution of the "Nautical Almanac" with resultant improvements in the art of navigation and the amelioration of life on shipboard had banished the fear of scurvy. Most of all, the introduction of steam power speeded up and gave certainty to ocean travel, and tropical hygiene made life safe on land. Submarine cables facilitated the exact fixing of the position of important bases and photography replaced the labour of the artists carried on the earlier expeditions.

The first society devoted exclusively to geographical discovery was the African Association which was founded in London in 1788, and passed on its functions to the Royal Geographical Society, which was established in 1830, with a world-wide outlook and had a roll of 6,000 fellows in 1928. There are nearly one hundred geographical societies scattered over the countries of the world, their function being to advance geography by encouraging and rewarding explorers and investigators, publishing the results of their work, and maintaining the public interest in all that concerns geography. (See GEOGRAPHICAL SOCIETIES.)

Exploration in the 19th century can only be sketched in the most general way by referring to a few outstanding explorers amongst the hundreds who did sound and distinguished work. Sir John Ross in 1818 reached the mouth of Smith Sound beyond Baffin bay and seeking a north-west passage, his nephew James Clark Ross reached the North Magnetic Pole in Boothia peninsula in 1831.

Sir John Franklin set out in 1845, lured by the fatal fascination of the Passage, and when he failed to return there set in the rush of Arctic exploration known as the Franklin search. Out of much that was weak, foolish and incompetent in direction there arose in execution heroes and geniuses like Sir Leopold McClintock who developed the method of man-hauled sledging and shone amongst those who explored the coasts and channels of the Arctic archipelago. Americans vied with British in the search and a high place must be given to Elisha Kent Kane who in 1853 pushed through Smith Sound and some of his parties reached 80° N. In 1872 Weyprecht and Payer on an Austrian expedition discovered Franz Josef Land. In 1875–77 the last of the old fashioned British naval polar expeditions in two ships with hundreds of men was sent out under Sir George Nares to reach the North Pole. It failed to get through Smith Sound but Albert H. Markham in a sledge journey pushed on to 83° 20′ N. In 1878 Baron A. E. Nordenskjold in the Swedish ship "Vega" made the long sought North-East Passage along the coast of Siberia and circumnavigated Europe and Asia. In 1882 a series of circumpolar stations for scientific observations was set up by international agreement; the honour of occupying the most northerly point fell to the American expedition under A. W. Greely and from his base Lockwood got to 83° 24′ N. Fridtjof Nansen in 1888 crossed the interior of Greenland for the first time and by travelling on ski and inventing new devices for camping and cooking revolutionised polar travel. Five years later by a still more daring and original plan he drifted in the "Fram" across the Arctic Sea and got to 86° 28′ N. In 1903–1905 Roald Amundsen, another Norwegian, in the "Gjoa" was the first to carry a ship through the half-forgotten North West Passage. Invaluable work has been done by American, Italian, British and especially by Danish explorers including Mylius Erichsen, Knud Rasmussen and Lange Koch in northern Greenland, and the labours of the American Robert E. Peary in a series of approximations carried on with infinite skill and patience from 1886 onwards at last brought him in 1909 the honour of attaining the North Pole.

The Antarctic regions were explored for the last time with sailing ships in 1838–43 when a French expedition under Dumont D'Urville discovered Adélie Land south of Australia, an American expedition under Charles Wilkes coasted the pack-ice surrounding the Antarctic continent for 2,000 miles, and a British expedition under James Clark Ross, elaborately equipped for magnetic observations, broke through the girdle of pack-ice for the first time and discovered the south running coast of Victoria Land, Mounts Erebus and Terror in 78° S. and the Great Ice Barrier. The Antarctic seas remained unvisited, except for a southward dash by the "Challenger" in 1874, until Scottish and Norwegian whalers went in search of new whaling grounds in 1892–95. Scientific expeditions equipped mainly by private enterprise under the inspiration of the International Geographical Congress of 1895 went out from Belgium under Gerlache in 1897, spending the Antarctic night for the first time drifting in the pack-ice south of South America, and from London under Borchgrevink in the "Southern Cross" spending the winter upon the Antarctic continent for the first time in 1898–99. These were succeeded by four simultaneous purely scientific expeditions in 1901–04, the British national expedition in the "Discovery" under Robert F. Scott of the British Royal navy initiating Antarctic sledging, taking advantage of Nansen's methods, and penetrating far into the frozen continent. The German expedition under Erich v. Drygalski in the "Gauss," the Swedish expedition under Otto Nordenskjöld in the Antarctic and the private Scottish National Expedition under William Bruce in the "Scotia" were all commanded by men of science, and did much valuable scientific work.

In 1907–08 Ernest H. Shackleton in a private expedition in the "Nimrod" succeeded by the innovation of using ponies for transport in getting to within 97 geographical miles of the South Pole and turned only because his provisions were exhausted, while other parties climbed Mount Erebus and reached the Magnetic Pole. In 1912 Scott in the great "Terra Nova" expedition succeeded in reaching the Pole by Shackleton's route only to find that he had been anticipated by a month by Roald Amundsen who had made a dash on ski with dog-sledges from a more easterly base. Meanwhile an Australian expedition under Douglas Mawson, with J. K. Davis in command of the "Aurora" explored a great stretch of coast from King George Land to Queen Mary Land and penetrated far into the icy interior.

In Asia three great regions remained practically unexplored well into the nineteenth century, viz., Arabia, the mountains and tablelands north and east of India and the deserts of Central Asia beyond them. The northern half of Arabia was traversed in many directions by European travellers prominent amongst them Palgrave in the middle of the century followed by C. Doughty. W. Blunt, C. Huber and others, by T. E. Lawrence during the World War and later by Gertrude Bell. To the north of India the great effort was to penetrate the Himalayas and explore Tibet. Most of the work was done by officers of the survey of India like Everest, the two Stracheys and Godwin Austen. Private explorers also had their part, foremost among them the French missionaries Huc and Gabet in 1844–46, who reached Lhasa from China, the great botanist Joseph D. Hooker who explored Sikkim in 1848–49; mountaineers including the three brothers Schlagentweit in 1854–57, W. M. Conway, Douglas Freshfield, the Duke of the Abruzzi, F. de Filippi, Dr. and Mrs. Workman, and finally the Mt. Everest expedition of 1926, members of which possibly reached the summit of the loftiest mountain of the earth. Officers of the Indian army and civilians of the Indian service have spent much spare time in expeditions into and across the mountains and so have big game hunters like St. George Littledale in 1894–95, and scholars like W. W. Rockhill in 1889–91. In earlier years native surveyors made some important journeys in Tibet, at that time practically inaccessible to Europeans. The last of the great problems of Asiatic geography to be solved was the complex of mountain ranges and river-valleys between India and China involving the middle course of the Brahmaputra which was finally settled by Rawlings and Bailey in 1914.

In Central Asia north of the great plateau Russian travellers visited the Khanates of Bokhara and Samarkand and many scientific expeditions ranged the vast spaces. Chief among them were those of Prjevalsky between 1871 and 1885 traversing nearly the whole breadth of the continent and defining the great system of internal drainage and its mountain rampart His work was supplemented and extended by many of his countrymen and in a high

degree by the Swedish scholar Sven Hedin from 1894 onwards. Francis Younghusband and other British officers made great journeys in the deserts of Gobi and Takla Makan and the remains of ancient cities attracted the Archaeological Survey of India for which Aurel Stein made important journeys.

Africa had been left at the end of the 18th century with the map of its interior a blank, leaving the lower course of the Nile, the middle of the Niger and the mouths of the Congo and Zambezi as openings to the mysteries of the interior. The Niger was traced to its mouth at an early date and between 1822 and 1827 Denham and Clapperton made difficult journeys in the Sahara and Sudan and discovered Lake Chad for the African Association. In 1849 David Livingstone, the greatest of all African travellers, began his missionary journeys from Cape Colony and explored the Kalahari desert discovering the salt lake Ngami. Convinced that mission work was of little use until the continent was opened up, he spent the rest of his life in settling the puzzling hydrography of Central Africa. He traced the course of the Zambezi by 1855. Later he pushed his way northward, discovering Lake Nyassa, exploring Lake Tanganyika and at the time of his death in 1873 he was intently following the north-flowing Lualaba in the hope that it would prove to be the ultimate source of the Nile. The Nile problem, under the encouragement of the Royal Geographical Society attracted many scientific and adventurous explorers. Richard F. Burton and John H. Speke in 1858 discovered the vast Victoria Nyanza on the high plateau under the equator collecting the head waters which issued from it as the White Nile, and pushing southwards reached Lake Tanganyika in the great rift which cleaves Africa from north to south. In 1864 Baker exploring the Sudan discovered the Albert Nyanza another feeder of the Nile and details of the geography of the Sudan were worked out by the patient labours of scientific men like Gerhard Rohlfs, Georg Scheinfurth and Junker between 1869 and 1871. H. M. Stanley, who as a newspaper correspondent, had been sent out by the *New* York Herald to "find Livingstone" in 1871 found also that he himself was a born explorer, and in a magnificent journey lasting from 1873 to 1879 he crossed Africa from east to west, proving that Livingstone's Lualaba ran not to the Nile but to the Congo and following that huge equatorial river to the sea. The formation of the Congo State under the King of the Belgians led to the rapid exploration of the Congo basin largely by Belgian officers, and the launching of a German colonial policy in 1884 brought many German explorers and men of science into eastern and western Africa. The race for the extension of spheres of influence solved the geographical problems of the once dark continent before the end of the century, French officers (General Lyautey prominent among them), completing our knowledge of the western Sahara and Sudan.

Australia was practically completely explored by the white settlers under their own governments within the 19th century. Flinders was the first to sail round Australia the coast of which he laid down in 1801–03. The eastern mountain chain shut off the first settlers in New South Wales from the west but when the range was crossed rivers were found flowing inland and a vague theory of a great inland sea attracted explorers. Oxley traced part of the Lachlan river in 1816, the fine pastures of the Darling Downs were discovered in 1827 and the Murray river was followed to the sea in 1828. The search for new pastures was the main motive for discovery until after 1850 when prospective new gold fields became a rival lure. The formation of the Swan River Settlement in 1834 and of Adelaide in 1836 gave new points of attack on the interior and in 1840 E. J. Eyre travelled on foot round the shore of the Great Australian Bight which separated them. In 1844 Ludwig Leichhardt made a splendid journey of 3,000 miles across tropical Australia from east to west including the southern shore of the Gulf of Carpentaria and in the following year Charles Sturt, leaving the east coast farther south, penetrated to the very centre of the continent. J. M. Stuart succeeded in crossing the continent from S. to N. in 1862 after two abortive attempts and his route was afterwards followed by an overland telegraph line In 1861 Robert O'Hara Burke and Wills crossed the continent with the aid of camels but perished on the return, a calamity which drew many expeditions into the wilderness to learn their fate. From 1874 for more than 30 years Western Australia was the scene of exploration in search of pasture and of gold, beginning with the journeys of John Forrest, A. C. and F. J. Gregory, P. E. Warburton and Ernest Giles and culminating in the great 5,000 mile march of David Carnegie in 1895–97. Journeys of pure scientific research were also made, foremost amongst them those of Baldwin Spencer. Except in the polar region little remains for the twentieth century to do in the way of geographical discovery.

THE TWENTIETH CENTURY

Up to 1914 travel as developed in the nineteenth century had enabled explorers to reach the poles and cross every great blank in the map of the continents. Tentative experiments had been made with newer methods of transport and investigation but it was only when the war ended and geographers could look about again that the new processes, matured by the intensity of life-or-death experience, became available for the new period which is now with us. Motor engines took the place of steam in the later Norwegian polar expeditions. Shackleton, Scott and Mawson had made attempts to use motor cars and modified aeroplanes in the Antarctic but with no real success and experiments with radio-telegraphy had tantalized rather than helped some of them.' Explorers since 1918 have found to their hand a full equipment for the new era of geographical research. The crossing of the Sahara by a French expedition under G. M. Haardt and L. Audouin-Dubreuil in 1923 proved the power of special types of motor cars to traverse roadless deserts, and the establishment of a trans-desert motor service between Damascus and Baghdad shows that the eastern deserts also can be traversed in this way. Valuable scientific results bearing on the early history of life on the globe were obtained in Mongolia by the expeditions of the Natural History Museum of New York in 1923 and 1924 under R. C. Andrews who resumed the work in the Gobi desert with the help of motor caravans in 1928.

Frequent flights have shown that no ocean or mountain range interposes a bar to aeroplanes. Alan Cobham in flying from Cairo to Cape Town in 1926 and in encircling Africa in 1928 showed that valuable geographical information could be gleaned from the air in the tropics and Roald Amundsen with Lincoln Ellsworth, an American of means, reached 88° N. in a flying boat in 1925 and returned safely after spending 25 days upon the Arctic ice-floes. In 1926 the American aviator Byrd reached go° N. in an aeroplane, circled the North Pole and returned without alighting to his base in Spitsbergen. A few days later Amundsen and Ellsworth with the Italian air-pilot Nobile flew in the air-ship "Norge" (which had just flown from Rome to Spitsbergen) to and across the North Pole, landing in Alaska. Nobile's further expedition to the North Pole, which started from Rome with Spitsbergen again as base in May 1928, proved that such attempts are still hazardous. The "Italia" became a wreck in the Arctic and several members of Nobile's party perished.

By means of a number of overlapping photographs taken from a great height a British Air Service company has mapped a large area in Rhodesia and it has been found by the British Ordnance Survey that many features, such as ancient camps and roads, imperceptible on the ground, are clearly visible when viewed from a great height. Photography has also been introduced successfully in surveying from the ground, results of extreme accuracy both for horizontal and vertical angles having been obtained by K. Mason with the photo-theodolite in the Shaksgam valley of the Himalayas in 1926. Other methods have been used with success in the official survey of Canada and in other countries. Radio-telegraphy affords a means of fixing longitudes in any part of the world on land or sea.

Little remains to be done by explorers on land, they must give place there to highly trained surveyors; but even the broad features of the configuration of two-thirds of the surface of the lithosphere are still vaguely guessed at under the veil of the hydrosphere. A British expedition in the "Challenger" broke ground in all the oceans in 1872–76 when about 500 deep soundings were made laboriously with hemp lines several miles in length, each

sounding taking a whole working day. In the succeeding decades sounding machines using fine stranded wire enabled the telegraph ships to run many sections across the deepest oceans where submarine cables were required at the rate of half a dozen soundings per day. During the great war a method of sounding by the echo from the bottom of a noise made at the surface was perfected and in 1926–27 the German research ship "Meteor" under Captain Spiess made an expedition planned by Alfred Mertz in the South Atlantic during which 67,000 separate and almost instantaneous soundings were taken while the ship was under way at intervals of 20 minutes day and night.

II. HISTORY OF GEOGRAPHICAL THEORY

Early Greek Ideas.—The earliest conceptions of the earth, like those held by primitive peoples of to-day, are difficult to discover and almost impossible to grasp. The first definite geographical theories to affect the western world were those evolved, or at least first expressed, by the Greeks. The earliest theoretical problem of geography was the form of the earth. The natural supposition that the earth is a flat disc, circular in outline, had in the time of Homer (before 900 B.C.) acquired a special definiteness by the introduction of the idea of the river Oceanus bounding the whole.

Thales of Miletus is claimed as the first exponent of the idea of a spherical earth; but, although this does not appear to be warranted, his disciple Anaximander (c. 580 B.C.) put forward the theory that the earth had the figure of a solid body hanging freely in the centre of the hollow sphere of the starry heavens. The Pythagorean school of philosophers adopted the theory of a spherical earth, arguing that a sphere being the most perfect solid figure was the only one worthy to circumscribe the dwelling place of man. The division of the sphere into parallel zones of climate was suggested by Parmenides (c. 450 B.C.). These ideas did not influence the Ionian school of philosophers, who preferred to deal with facts demonstrable by travel rather than with speculations. Thus Hecataeus (c. 500 B.C.), claimed by H. F. Tozer as the father of geography on account of his general treatise on the earth, did not advance beyond the primitive conception of a circular disc. He systematized the form of the land within the ring of ocean—the *οἰκουμένη* or habitable world—by recognising two continents: Europe to the north, and Asia to the south of the midland sea. Herodotus (c. 450 B.C.) equally oblivious of the sphere, criticized and ridiculed the circular outline of the *οἰκουμένη* which he held to be longer from east to west than it was broad from north to south (hence the modern designation of longitude and latitude), and he divided the land into three continents—Europe, Asia and Africa. Beyond the limits of his personal travels Herodotus applied the characteristically Greek theory of symmetry to complete, in the unknown, outlines of lands and rivers analogous to those which had been explored. Symmetry was in fact the first geographical theory, and the effect of Herodotus's hypothesis that the Nile must flow from west to east before turning north in order to balance the Danube running from west to east before turning south, lingered in the maps of Africa down to the time of Mungo Park.

Aristotle (384–322 B.C.) must be given the distinction of founding scientific geography. He demonstrated the sphericity of the earth by three arguments: (1) that the earth must be spherical, because of the tendency of matter to fall together towards a common centre: (2) that only a sphere could always throw a circular shadow on the moon during an eclipse: and (3) that the shifting of the horizon and the appearance of new constellations, or the disappearance of familiar stars, as one travelled from north to south, could only be explained on the hypothesis that the earth was a sphere. Parmenides had pictured a torrid zone uninhabitable by reason of heat, two frigid zones uninhabitable by reason of cold, and two intermediate temperate zones fit for human occupation, but Aristotle was the first of the philosophers who defined the temperate zone as extending from the tropic to the Arctic circle.

The fitting of the *οἰκουμένη* to the sphere was the second theoretical problem of geography. Aristotle was inclined to view the habitable world as a very long and relatively narrow band almost encircling the globe in the north temperate zone, but his argument as to the narrowness of the sea between West Africa and East Asia from the occurrence of elephants at both extremities, is difficult to understand.

The word *geography* did not appear before Aristotle and he may have used it, but H. Berger considers that the expression was introduced by Eratosthenes. Aristotle was certainly conversant with many facts, such as the formation of deltas, coast-erosion, and to a certain extent the dependence of plants and animals on their physical surroundings. He formed a comprehensive theory of the variations of climate with latitude and season, and was convinced of the necessity of a circulation of water between the sea and rivers, though, like Plato, he held that this took place by water rising from the sea through crevices in the rocks, losing its dissolved salts in the process. He speculated on the differences in the character of races of mankind living in different climates and correlated the political forms of communities with their-situation on a seashore, or in the neighbourhood of natural strongholds.

Problem of the Antipodes.—Pythagoras (*c.* 530 B.C.) had speculated as to the existence of antipodes, and when the first approximately accurate measurement of the globe and estimates of the length and breadth of the *οἰκουμένη* were made by Eratosthenes (c. 250 B.C.) the fact that, as then known, the habitable world occupied less than a quarter of the surface of the sphere was clearly recognised. It was natural, if not strictly logical, that the river Oceanus should be extended from a narrow stream to a world-embracing sea, and here again Greek theory, or rather fancy, gave its modern name to the greatest feature of the globe. The old instinctive idea of symmetry probably led the Stoic philosophers represented by Crates of Mallus (*c.* 150 B.C.) to place an *οἰκουμένη* in each quarter of the sphere in order to satisfy the love of nature for life; the three unknown world-islands being those of *Antoeci, Perioeci* and *Antipodes*. This was a theory not only attractive to the philosophical mind, but eminently adapted to promote exploration. It had its opponents, however, for Herodotus had shown that sea-basins like the Caspian existed cut off from the ocean, and it is still a matter of controversy how far the pre-Ptolemaic geographers believed in a water-connection between the Atlantic and the Indian oceans.

Roman Geographers.—Strabo (50 B.C.–A.D. 24) followed Eratosthenes rather than Aristotle, but with sympathies which went out more to the human interests than to the mathematical basis of geography. He compiled a very remarkable work dealing, in large measure from personal travel, with the countries surrounding the Mediterranean. He may be said to have set the pattern which was followed in succeeding ages by the compilers of "political geographies." Pomponius Mela (c. A.D. 40), following Strabo, held that the southern temperate zone contained a habitable land, which he designated by the name *Antichthones*. Claudius Ptolemaeus (c. A.D. 150), concentrated in his writings the final outcome of all Greek geographical learning and passed it across the gulf of the middle ages by the hands of the Arabs, to form the starting point of the science in modern times. His geography was based broadly on the work of his predecessor, Marinus of Tyre, and on that of Hipparchus, the follower and critic of Eratosthenes. It was the ambition of Ptolemy to describe and represent accurately the surface of the *οἰκουμένη*, for which purpose he took immense trouble to collect all existing astronomical determinations of the latitude of places, all estimates of longitude, and to make every possible rectification of distances by land or sea. His work was mainly cartographical in its aim, and theory was as far as possible excluded. The symmetrically placed hypothetical islands in the great continuous ocean disappeared and the *οἰκουμένη* acquired a new form by the representation of the Indian ocean as a larger Mediterranean completely cut off by land from the Atlantic. The terra *incognita* uniting Africa and Farther Asia was an unfortunate hypothesis which discouraged exploration. Ptolemy used the word geography to signify the description of the whole *οἰκουμένη* on mathematical principles, while chorography signified the fuller: descrip-

tion of a particular region, and topography the very detailed description of a smaller locality. The Caliph al-Mamun (*c.* A.D. 815), the son and successor of Harun al-Rashid, caused an Arabic version of Ptolemy's great astronomical work to be made, which is known as the *Almagest*. The geography of Ptolemy was also known and is constantly referred to by Arab writers. The Arab astronomers measured a degree on the plains of Mesopotamia, thereby deducing a fair approximation to the size of the earth, and the caliph's librarian, Abu Jafar Muhammad ben Musa, wrote a geographical work, now unfortunately lost, composed on the model of that of Ptolemy.

The Middle Ages.—The Middle Ages saw geographical knowledge die out in Christendom, although it retained a certain vitality in Islam. The verbal interpretation of scripture led Lactantius (*c.* A.D. 320) and other ecclesiastics to denounce the spherical theory of the earth as heretical, and as all learning was confined to the church, Greek science gave place to primitive ignorance as shown in the monkish wheel-maps. The journey of Marco Polo, the increasing trade with the east and the voyages of the Arabs in the Indian Ocean prepared the way for the reacceptance of Ptolemy's ideas even amongst churchmen when the sealed books of the Greek original were translated into Latin by Angelus in 1410.

Revival of Geography.—The old arguments of Aristotle and the old measurements of Ptolemy were used by Toscanelli and Columbus in urging a westward voyage to India and mainly on this account did the crossing of the Atlantic rank higher in the history of scientific geography than the laborious feeling out of the coast line of Africa. But not until the voyage of Magellan shook the scales from the eyes of Europe did modern geography begin to advance. Discovery had outrun theory; the rush of new facts made Ptolemy practically obsolete in a generation.

The earliest evidence of the reincarnation of a sound theoretical geography is to be found in the text-books by Peter Apian and Sebastian Miinster. Apian in his *Cosmographicus liber*, published in 1524 and subsequently edited and added to by Gemma Frisius under the title of *Cosmographia*, based the whole science on mathematics and measurement. He followed Ptolemy closely, enlarging on his distinction between geography and chorography. This slender distinction was made much of by most subsequent writers until Nathanael Carpenter in 1625 pointed out that the difference was simply one of degree, not of kind. Sebastian Münster, on the other hand, in his *Cosmographia universalis* of 1544, paid no regard to the mathematical basis of geography, but following the model of Strabo, described the world according to its different political divisions, and entered with great zest into the question of the productions of countries, and into the manners and costumes of the various peoples. Thus early began the separation between mathematical and political geography.

The Seventeenth Century.—Throughout the 16th and 17th centuries the rapidly accumulating store of facts as to the extent, outline and mountain and river systems of the lands of the earth were put in order by the generation of cartographers of whom Mercator was the chief; but the writings of Apian and Münster held the field for a hundred years without a serious rival. Meanwhile the new facts were the subject of original study by philosophers and by practical men without reference to classical traditions. Bacon argued keenly on geographical matters and was a lover of maps.

Philip Cluver's *Introductio in geographiam universam tam veterem quam novam* was published in 1624. Geography he defined as "the description of the whole earth, so far as it is known to us." It is distinguished from cosmography by dealing with the earth alone, not with the universe, and from chorography and topography by dealing with the whole earth, not with a country or a place. The first book, of fourteen short chapters, is concerned with the general properties of the globe; the remaining six books treat in considerable detail of the countries of Europe and of the other continents. Each country is described with particular regard to its people as well as to its surface.

In 1625 Nathanael Carpenter, Fellow of Exeter College, Oxford, published a little book, *Geographie delineated forth in Two Bookes, containing the Spherical1 and Topicall parts thereof.* It is discursive in its style and verbose; but it is remarkable for the strong common sense displayed by the author, his comparative freedom from prejudice, and his firm application of the methods of scientific reasoning to the interpretation of phenomena. Basing his work on the principles of Ptolemy, he brings together illustrations from the most recent travellers, and does not hesitate to take as illustrative examples, the familiar city of Oxford and his native county of Devon. He divides geography into *The Spherical Part*, or that for the study of which mathematics alone is required, and *The Topical Part*, or the description of the physical relations of parts of the earth's surface, preferring this division to that favoured by the ancient geographers into general and special.

Varenius.—A much more important work in the history of geographical method is the *Geographia generalis* of Bernhard Varenius, a German medical doctor of Leyden, who died at the age of twenty-eight in 1650, the year of the publication of his book. Although for a time it was lost sight of on the continent, Sir Isaac Newton thought so highly of this book that he prepared an annotated Latin edition which was published in Cambridge in 1672, with the addition of the plates which had been planned by Varenius, but not produced by the original publishers. Dugdale in his English translation (1733) says "The reason why this great man took so much care in correcting and publishing our author, was because he thought him necessary to be read by his audience, the young gentlemen of Cambridge, while he was delivering lectures on the same subject from the Lucasian Chair." The treatise of Varenius is a mode; of logical arrangement and terse expression; it is a work of science and of genius; one of the few of that age which can still be studied with profit. The English translation renders the definition thus: "Geography is that part of *mixed mathematics* which explains the state of the earth and of its parts, depending on quantity, viz., its figure, place, magnitude and motion, with the celestial appearances, etc. By some it is taken in too limited a sense, for a bare description of the several countries; and by others too extensively who along with such a description would have their political constitution." But Varenius, though he was reluctant to include the human side of geography in his system, allowed it as a concession to custom. His division of geography was into (1) General or universal, dealing with the earth in general, and explaining its properties without regard to particular countries; and (2) Special or particular, dealing with each country in turn from the chorographical or topographical point of view. General geography was divided into—(1) the absolute part, dealing with the form, dimensions, position and substance of the earth, the distribution of land and water, mountains, woods and deserts, hydrography (including all the waters of the earth) and the atmosphere; (2) the relative part, including the celestial properties, *i.e.*, latitude, climate, zones, longitude, etc.; and (3) the comparative part, which "considers the particulars arising from comparing one part with another"; but under this head the questions discussed were longitude, the situation and distances of places, and navigation. Varenius does not treat of special geography, but gives a scheme for it under three heads—terrestrial, celestial, human. This system of geography founded a new era, and the book was the unchallenged standard for more than a century.

The Eighteenth Century.—The next marked advance in the theory of geography was made nearly simultaneously by the studies of the Swedish chemist, Torbern Bergman, acting under the impulse of Linnaeus, and by those of the German philosopher, Immanuel Kant. Bergman's *Physical Description of the Earth* was published in Swedish in 1766, and translated into English in 1772 and into German in 1774. It is a plain, straightforward description of the globe, and of the various phenomena of the surface, dealing only with definitely ascertained facts in the natural order of their relationships, but avoiding any systematic classification or even definitions of terms.

The problems of geography had been lightened by the destructive criticism of the French cartographer D'Anville, who had purged the map of the world of the last remnants of unverified tradition, and rendered it richer by the dawn of the new era of scientific travel, when Kant brought his logical powers to bear

upon them. Kant's lectures on physical geography were delivered in the university of Konigsberg from 1765 onwards. Geography appealed to him as a valuable educational discipline, the joint foundation with anthropology of that "knowledge of the m-orld" which was the result of reason and experience. In this connection he divided the communication of experience from one person to another into two categories — the narrative or historical and the descriptive or geographical; both history and geography being viewed as descriptions, the former in order of time, the latter in order of space. Physical geography he viewed as a summary of nature, the basis not only of history but also of "all the other possible geographies," of which he enumerates five, viz., (1) *Mathematical* geography, which deals with the form, size and movements of the earth and its place in the solar system; (2) Moral geography, or an account of the different customs and characters of mankind according to the region they inhabit; (3) Political geography, the divisions according to their organized governments; (4) *Mercantile geography,* dealing with the trade in the surplus products of countries; (5) Theological geography, or the distribution of religions. Here there is a clear and formal statement of the interaction and causal relation of all the phenomena of distribution on the earth's surface, including the influence of physical geography upon the various activities of mankind from the lowest to the highest. Notwithstanding the form of this classification Kant himself treats mathematical geography as preliminary to, and therefore not dependent on, physical geography. Physical geography itself is divided into two parts: general, which has to do with the earth and all that belongs to it —water, air and land; and particular, which deals with special products of the earth — mankind, animals, plants and minerals.

The Nineteenth Century. — Alexander von Humboldt (1769–1859) was the first modern geographer to become a great traveller. The impulse given to the study of natural history by the example of Linnaeus, the results brought back by Banks, Solander and the two Forsters, who accompanied Cook in his voyages of discovery, the studies of De Saussure in the Alps, and the lists of desiderata in physical geography drawn up by that investigator, combined to prepare the way for Humboldt who advanced the theory of geography mainly by his insistence on the great principle of the unity of nature. In his *Cosmos* and other works he brought all the "observable things" which the eager collectors of the previous century had been heaping together regardless of order or system, into relation with the vertical relief and the horizontal forms of the earth's surface. Thus he demonstrated that the forms of the land exercise a directive and determining influence on climate, plant life, animal life and on man himself. The idea was not new for Kant himself had given it full expression, but Humboldt's concrete illustrations and the remarkable power of his personality enabled him to enforce these principles with immediate and lasting effect. The treatises on physical geography by Mary Somerville and John Herschel fully showed the effect produced in Great Britain by the stimulus of Humboldt's work. Humboldt's contemporary, Karl Ritter (1779–1859) extended and disseminated the same views, and in his interpretation of "Comparative Geography" he laid stress on the importance of forming conclusions, not from the study of one region by itself, but from the comparison of the phenomena of many places. Impressed by the influence of terrestrial relief and climate on human movements, Ritter was led deeper and deeper into the study of history and archaeology. His monumental *Vergleichende Geographie,* which was to have made the world its theme, died out in a wilderness of detail in twenty-one volumes before it had covered more of the earth's surface than Asia and a portion of Africa.

During the rapid development of physical geography many branches of the study of nature, which had been included in the cosmography of the early writers, the physiography of Linnaeus and even the *Erdkunde* of Ritter, had been so much advanced by the labours of specialists that their connection was apt to be forgotten. The science of geography, passed on from antiquity by Ptolemy, re-established by Varenius and Newton, and systematized by Kant, included within itself definite aspects of all those terrestrial phenomena which are now treated exhaustively under the heads of 'geology, meteorology, oceanography and anthropology; and the inclusion of the requisite portions of perfected results of these sciences in geography is simply the gathering in of fruit matured from the seed scattered by geography itself. The study of geography was advanced by improvements in cartography, not only in the methods of survey and projection, but in the representation of the third dimension by means of contour lines introduced by Philippe Buache in 1737, and the more remarkable because less obvious invention of isotherms introduced by Humboldt in 1817.

Theories of Nature. — Teleology or the argument from design had been a favourite form of reasoning among Christian theologians and, as worked out by Paley in his *Natural* Theology, it served the useful purpose of emphasizing the fitness which exists between all the inhabitants of the earth and their physical environment. It was held that the earth had been created so as to fit the wants of man in every particular. This argument was tacitly accepted or explicitly avowed by almost every writer on the theory of geography, and Karl Ritter distinctly recognized and adopted it as the unifying principle of his system. As a student of nature, however, he did not fail to see, and as a professor of geography he always taught, that man was in very large measure conditioned by his physical environment.

The evolutionary theory, more than hinted at in Kant's "Physical Geography" and worked out by the researches of Charles Darwin, Alfred Russel Wallace and Joseph Dalton Hooker, from their observations as travelling naturalists, has become the unifying principle in geography. The conception of the development of the plan of the earth from the first cooling of the surface of the planet throughout the long geological periods, the guiding power of environment on the circulation of water and of air, on the distribution of plants and animals, and finally on the movements of man, give to geography a philosophical dignity and a scientific completeness which it never previously possessed. The influence of environment on the organism may not be quite so potent as it was believed to be, in the writings of Henry Thomas Buckle for instance, and certainly man, the ultimate term in the series, reacts upon and greatly modifies his environment; yet the fact that environment does influence all distributions is established so that it cannot be moved. In this way also the position of geography, at the point where physical science meets and mingles with mental science is explained and justified. The change which took place during the 19th century in the substance and style of geography may be well seen by comparing the eight volumes of Malte-Brun's *Géographie universelle* (Paris, 1812–1829) with the twenty-one volumes of Elisée Reclus's *Géographie Universelle* (Paris, 1876–1895) and the new and larger edition planned by Vidal de la Blache as the work of many authors including A. Demangeon and Pierre Denis, shows that development is still going on. It has been usual to assign to Oscar Peschel (1826–1875) the credit of having corrected the preponderance which Ritter gave to the historical element, and of restoring physical geography to its old pre-eminence. As a matter of fact, each of the leading modern exponents of geography — such as Ferdinand von Richthofen, Hermann Wagner, Friedrich Ratzel, William M. Davis, Albrecht Penck, A. de Lapparent, Elisée Reclus, E. de Martonne, G. G. Chisholm, Halford Mackinder and Ellsworth Huntington, has his individual point of view.

The Twentieth Century. — The theory of geography developed by a series of efforts to cope with accumulations of new facts of discovery. In the earlier centuries a traveller required little more than sound health and adventurous spirit to enable him to make discoveries which have crowned his name for all time; but in the twentieth century this is no longer the case. In order to discover facts of importance the traveller must now be himself a geographer grounded in the principles of the science which have crystallized out of the labours of the past. Extensive wanderings have given place to intensive studies and wisely-directed researches. The elementary teacher of geography can no longer be content to repeat lists of features and haphazard remarks as to notable things; but must have a foundation of systematic

knowledge. This was not generally realized until the nineteenth century was near its end. Professors of geography had indeed existed for many years in Germany, France and some other continental countries, but they lectured to few students, and it was only in the last decade after great advances had been made in continental universities that the universities of Great Britain and the United States admitted geography into their curricula. In 1892 the efforts of Douglas Freshfield through the Royal Geographical Society secured the appointment of lecturers on geography in Oxford and Cambridge. Progress in the development of a school of geography in these universities has been steady and in each there are now several instructors on the subject under a Reader preparing students for a Geographical Tripos awarding Honours degrees. The four universities of Scotland, most of the constituent colleges of the University of London, the newer provincial English universities and the University of Wales have appointed Professors or Readers of geography who, despite (1928) the financial difficulties, endeavour to develop interest of a high order. The United States had three professors of geography in 1897: W. M. Davis at Harvard, R. F. Tarr at Cornell and W. Libbey at Princeton; by their efforts, and especially by the brilliant work of Davis, a demand was created for trained geography teachers which led to immense development. In 1924 there were fully equipped departments of geography, several of them with 15 or more instructors, in the universities of California, Chicago, Clark (at Worcester, Mass.), Michigan (Ann Arbor), Ohio, State and Ohio (Athens), while fifty other universities had less complete equipment, and, in all, university instruction in geography was being given to 14,000 students annually.

III. THE *PRINCIPLES OF GEOGRAPHY*

Any part of geography may serve as a starting point from which by a series of approximations the whole field of the science may be surveyed. The best line of approach for an advanced student leads from simple fundamental facts step by step to the most complex interactions, and the following scheme may be taken as expressing the views of modern geographers.

The Earth as a Functioning Organism.— To begin with, the earth may be viewed hypothetically as a smooth, homogeneous, solid ball, spinning as it wheels round the sun. Mathematical physics assigns polarity as an inevitable result of rotation. The ends of the axis differ from every other point on the surface by being relatively at rest. One of these points, from which the stars would appear to turn in the direction of the hands of a watch is called the North Pole, the other, from which the stars appear to rotate counter clockwise, the South Pole. These are points of reference by which positions in latitude can be fixed by angular measurements of the elevation above the horizon of the points in the sky vertically over them. Rotation regulates the succession of day and night affording a measure of time and so of position in longitude. The angle which the axis of rotation makes with the plane in which the earth revolves round the sun determines the position of the tropics and polar circles, the seasons, the varying duration of daylight and darkness in different latitudes and the distribution of solar energy on the surface of the earth. On such a hypothetical sphere the temperature of the solid surface follows the astronomical zones of climate, solar radiation predominating in the Torrid zone, terrestrial radiation in the Frigid zones, and in any latitude the temperature would be the same at every point.

These simple conditions do not occur in fact The lithosphere is composed of diverse rocks, each kind of which has its own specific heat and conductivity so that the rate of heating and cooling varies and different temperatures result under the same radiation. The surface of the lithosphere is not smooth but ridged into heights and hollows of every size and shape and the process of elevation and depression is always at work. Alternate heating and cooling by radiation from the sun and to space splinter the outer surface of the rocks and the pull of gravity causes the detritus to slip down the steep slopes and accumulate below. The earth is not all solid lithosphere but is partially enveloped in a hydrosphere which gathers in the great hollows and leaves the crests of the great ridges projecting thus producing the division of the surface into sea and land. Solar radiation falling on the mobile water alters its density and so sets up a circulation between the heated tropics and the chilled polar areas. while the rotation of the earth causes a deviation of the slow moving currents towards the right in the Northern hemisphere and towards the left in the Southern hemisphere; the coast lines and the inequalities of the sea-bed also clirect the movement of the currents so that they carry warmth from the tropics far towards the polar regions, along certain coasts, and coolness from the polar regions far towards the tropics along others, destroying the uniformity of the mathematical zones of temperature in the sea.

The differential attraction of the sun and moon sets up tidal waves in the hydrosphere which like the currents impinge upon and rub against the shores, and a similar though less noticeable strain is also produced in the lithosphere. The terraqueous globe is completely enveloped by the atmosphere of air which rests in uneasy equilibrium on land and sea alike. The air, interpenetrated in its lower layers by water-vapour from the hydrosphere, is set into lively circulation by solar radiation which is greatest in the tropics and by terrestrial radiation which preponderates in the polar regions, the general flow to north and south being deviated by tlie earth's rotation so as to have a westerly component in the pole-seeking winds and an easterly component in the equator-seeking winds. Since heat is more readily added to and removed from air by contact with heated and cooled surfaces than by direct radiation, the atmosphere is subject to a more powerful stimulus over land than over the sea as land heats and cools the more rapidly and to a greater degree. On the other hand the varied surface of the land opposes more friction than the smooth water surfaces, and the theoretical circulation of the air is more characteristically developed on the oceans than on land. Thus land or continental climates are extreme, while sea or oceanic climates are equable. Wind, in virtue of the very high velocity it may attain, is a powerful agency for wearing the rocks and for carrying fine particles to great distances, and it exercises still greater power as the vehicle of water-vapour the precipitation of which as rain is closely conditioned by the configuration of the land over which it is carried. Water, falling as rain on the higher slopes descends by gravity, collecting into runnels which eventually converge to rivers. Running water, aided by the detritus it carries, cuts for itself ravines or valleys and finally it spreads the material (well ground in the journey) as alluvium on the plains and silt on the shore of the sea. River action is the chief agent in carving the scenery of the land from the uplifted masses of rock and next to it comes the action of glacial ice. Wind also drives before it the surface water of the sea, checking, diverting or reinforcing the slow creep of the waters of the hydrosphere with the well marked currents which largely affect the temperature of the air and modify the crude extremes of astronomical climate zones on land as well as on sea. Waves raised by the wind sharpen the sea's edge to gnaw and wear away the margins of the land. The lower lands are sheathed in soil ground from the rocks of the mountains and the surface of most of the land is moistened by graduated rainfall and warmed or cooled by the prevailing wind according to the way in which the land-forms guide its flow.

To this point the earth can be treated as the product of chemical and physical processes which leave it as a finished house built, furnished, warmed and lighted in readiness for its occupation by life. The distribution of plant life on land and in the sea depends primarily on climate, especially on temperature and sunlight. On land the presence of moisture is at least an equal factor, vegetation being stunted to herbs and shrubs in the cold moist lands bordering the polar and Alpine zones, strengthened into deciduous forests and grasslands in the temperate zones, reduced almost to nothing in the rainless parts of the tropical zones, and brought to the height of luxuriant profusion in the rainy forests of the equator. The species of plants associated in the various regions are separated into special groups by barriers of mountain, desert or sea. The distribution of animals is conditioned in turn by their entire dependence for food on plants, directly in the herbivora, indirectly in the carnivora. Their species are equally conditioned by environment and natural barriers. Both plants and

animals have the power in some degree of modifying the environment which controls them as exemplified by the change of lagoons into swamps and ultimately into meadows by plants and the formation of coral reefs by animals.

A far more complicated set of conditions governs the distribution of mankind over the land and the association of races and communities with particular regions. Primitive races are conditioned by their environment almost as much as animals. They are dependent on climate, plucking wild fruits or hunting game for food and completely isolated one from another by natural barriers. The rising degrees of civilization exhibit a growing superiority to the thraldom of such conditions until the white race of the present day may be looked upon as escaping from geographical control which no longer raises barriers to movement or settlement.

Races of mankind grow to be associated with particular regions and aggregate into nations occupying separate countries. Each nation, retentive of differing languages and conflicting religious ideals, creates and maintains boundaries natural or artificial, the protection or the alteration of which throughout the ages makes it necessary to call in history to explain the geography of to-day. Still more complex are the conditions governing the discovery, production, transport and exchange of useful and desirable things between people of different nationality.

THE SUBJECT MATTER OF GEOGRAPHY

Classification and Content of Geography.— SO complex a science demands the labour of many specialists in order to advance it by the separate study of its interdependent parts. There is a geographical aspect of all the sciences which are concerned with the earth and its phenomena and it follows that some knowledge of each of these sciences is required of the geographer in dealing with his proper subject. Though one aspect of geography merges into and is interwoven with another, lines must be drawn to allow of a classification for practical purposes. Each division of geography draws its data from some source which is no longer viewed as essentially geographical but is known as one of the abstract or natural or human sciences, and on the other hand each division of geography is capable of practical applications in the arts or interests of civilized life. The degree of subdivision of the subject-matter of geography varies according to the share of attention which each has received, but the main divisions, now recognized, are four: mathematical, physical, biological and human.

Mathematical Geography.— This deals with dimensions, figure and movements of the earth. Astronomical geography is a name sometimes given to the determination of position on the earth's surface by reference to the heavenly bodies and navigation is a practical application, the data of which are compiled in the British *Nautical Almanac* and similar publications of other governments. The earth's surface can be truly represented on a small scale only on a sphere and the terrestrial globe showing the degree net or lines of latitude and longitude is an essential geographical instrument. To represent the degree net, on a flat surface or map, mathematical projections are necessary and these must be of various kinds to suit different purposes as every projection necessarily distorts the form or the area of any portion of the surface of the globe. The part of mathematical geography dealing with the size and figure of the earth is Geodesy which depends on astronomical positions and the exact determination of distances on the surface by triangulation from bases which are directly measured. Geodetic operations do not necessarily do more than fix the degree net on the sphere, the process of topographical surveying serving to fill in details for maps on various scales, the production of which is the art of Cartography. Maps are adapted for the representation of any uniformly-varying distribution by the use of isopleths, of which the most familiar forms are contour-lines and isotherms, and by the use of conventional signs and distinctive colouring. Mathematical geography has also to do with the phenomena of the tides and of terrestrial magnetism while mathematical methods are essential in many departments of physical geography and in the treatment of all statistics distributionally. The figure of the earth is very nearly a spheroid of revolution, the equatorial radius of which measures 20,926,200 feet and the polar radius 20,854,900 feet, while a degree of latitude crossing the equator measures 362,745 feet and one crossing the pole 366,480 feet. The whole superficial area of the earth is approximately 196,940,000 square British statute miles.

Physical Geography.—The words "physical geography" have often been loosely used as equivalent to Physiography or the description of all nature. Here they are taken to mean the description of the forms of the lithosphere at their present stage of development and of the functions which these forms exercise in controlling the action of solar energy in the hydrosphere and atmosphere. The origin of the forms themselves and their relations to living creatures are excluded except incidentally for purposes of classification. It is evident that a physical geography is possible at any point of time in the life-history of the world during the unceasing process of development by the powers tending simultaneously to increase the diiferences of level in the lithosphere, by stresses set up in it as it cools, and to decrease these differences by solar energy acting through air and water so as to cut down the heights and fill up the hollows. Physical geography falls into three divisions all depending on the laws of geophysics, viz.— Geomorphology or treating of the forms of ihe lithosphere dependent in a special degree on geology; Oceanography or the conditions of the hydrosphere depending in a special manner on chemistry and physics; and Climatology or the condition of the atmosphere with respect to the earth's surface, depending largely on meteorology. Attention is concentrated here on geomorphology as climatology and oceanography are dealt with in special articles.

PLAN OF THE EARTH

Although the vertical distance between the highest point on the surface of the lithosphere and the lowest point on this surface amounts to about 12 miles the surface is moulded into such low relief, having respect to the terrestrial circumference of about 25,000 miles, that a correct model eight inches in diameter would appear almost smooth. The surface is nevertheless impressed with a distinct system of depressions and elevations showing a rough symmetry in its plan. Round the north pole there is a region of depression within the parallel of 80° N. and round the south pole an area of elevation within the Antarctic circle. All the rest of the surface is occupied by two great areas interlocking with each other, one of elevation, the other of depression. The depressed area encircles the globe about 65° S. and stretches northward in three great bays or world-hollows corresponding to the Pacific, the Indian and the Atlantic basins. The floors of the world-hollows are gently undulated in their configuration for the most part but they exhibit considerable diversities of level, the deepest depressions occurring as a rule near the margins while gentle rises form a central low ridge along the narrow Atlantic hollow, and more or less parallel bands across the wide Indian and Pacific hollows. The elevated area surrounds the north polar depression as a continuous ring and stretches southward with an easterly twist in three tapering world-ridges culminating respectively in the continents of North and South America, Europe and Africa and Asia and Australia. From the depressed area the lower portion of the elevated area slopes upward with a gradient so steep compared with any prevailing on the floor of the depressed area as to form a sharp transition between the two; but near the top of the world-ridges there is a notable flattening into a broad gently shelving plain which leads to a culminating region of abrupt elevations and high plateaux.

The two world areas are separated by the line of mean-sphere level which lies in such a position that if all the elevations projecting above it were shaved off parallel with the surface of the spheroid the material so cut off would suffice to fill all the hollows lying below it. The average level of the depressed area is, so far as can be guessed in our present ignorance of its detailed coniiguration, rather more than two miles below the average level of the elevated area.

The effort to visualize the plan of the lithosphere with reference to the line of mean sphere level is rendered difficult because it ignores the familiar divison of the earth's surface into land and sea. The areal ratio between land and sea of course depends on the volume of the hydrosphere. If that were just enough to fill

the world-hollows up to mean sphere level, the outlines of the restricted oceans would be similar to what they are at present; the outlines of the continents, although enlarged and smoothed, would be easily recognizable, and the areas of land and sea would be practically equal. The volume of the hydrosphere is, however, such that the water covers the steep slopes of the world-ridges and reaches half way over the shelving plain so that the present coast line is in a position where a given rise or fall in level would make the greatest possible difference in the area of sea and land. Only 28 per cent of the surface of the lithosphere projects as land through the hydrosphere into the atmosphere. The volume of the hydrosphere is not fixed; a considerable portion of it exists as water flowing over or resting in hollows in the land, a considerable portion is withdrawn in the form of permanent ice in the polar regions and on high mountains, and a portion is diffused through the atmosphere in the form of vapour. Thus, apart from movements of upheaval or subsidence in the solid crust the level at which the water stands against the land may vary from time to time under the action of climatic changes.

The surface of the sea furnishes a convenient datum level from which to reckon heights and depths. Speaking precisely, the surface of the sea, even when calm and at its mean tidal range, is not that of a spheroid concentric with the earth from which absolute measures of distance from that centre can be made; it is a surface of equilibrium, distorted from that of the spheroid by the gravitational attraction of the lithosphere which varies with the form of the crust and density of the rocks. Except in geodetic measurements no allowance is made for distortion of surface.

As new and much more exact measurements of the depths of the oceans are in progress it seems undesirable to repeat the approximations to the volumes of the heights and hollows of the lithosphere and the boundaries between its various areas based upon them by John Murray, H. R. Mill and Hermann Wagner. It may suffice to say that the mean level of the lithosphere lies somewhere between 1,000 and 2,000 fathoms below sea-level. Murray's term *abysmal area* or Wagner's *oceanic plateau* may be applied to the whole of the depression below mean sphere level.

Wagner's *continental slope* to the steep rise from mean sphere level to the outer margin of his *continental plateau* that includes the shelving plain of which the seaward portion retains Mill's name of *continental shelf* and the landward portion the *lowland plains,* while all above the level of 600 or 700 feet above sea-level may be termed the *culminating continental area.* The four contours known as mean sphere level, the edge of the continental shelf, the coast line and the line of 650 feet above the sea (which is the approximate mean level of the surface of the terraqueous globe) have a definite physical meaning and are not a mere arbitrary choice. While physically the outer edge of the continental shelf is situated at the abrupt change of gradient between the continental slope and the shelving plain, which is not always at the same depth, it is usually found so near 600 feet that generally speaking it is well defined by the contour line of 100 fathoms or of 200 metres, now shown on all bathymetrical maps. Wider or narrower, this shelf surrounds all the continents and in its wider parts often bears groups of islands which are to be classed as parts of the continents although separated from the nearest mainland by shallow seas.

Homology of the Continents. — The three great world-ridges which radiate southward and eastward from the north polar region bear each a pair of continents, either separate or united, all of which exhibit a certain homology or approximation to a common type. Each pair consists of a north-western and a south-eastern partner separated by a group of islands and south-pointing peninsulas. The outline of a typical continent approaches a triangle, widest in the north. The central portion is a low plain dipping southward and eastward in the southern part and northward and eastward in the northern part. On the east there is a broad highland area of ancient rocks the eroded remnant of a folded mountain system, and beyond that on the east is a broad coastal plain. On the west of the central plain there is a high continuous chain of mountains folded up out of geologically recent rocks and enclosing an elevated plateau, while beyond on the west there is a very narrow coastal plain. On the western world-ridge this type is well exemplified by South America, and North America diverges but little from it except by being broader in the south where it merges into the West Indian archipelago. On the eastern world-ridge Asia and Australia diverge considerably from the type both in outline and orientation, but there is the contrast of mountain and plateau with a low central plain and, to some extent, lower heights may be traced on the other side, while the Malay Archipelago uniting the two partners is on a far larger scale than the West Indies. The continents of the central world-ridge, Europe and Africa, are much farther from the type. Like the other northern partners of the pairs, Europe is the more diversified into peninsulas and gulfs while Africa like the other southern partners has a smoother outline practically without minor sinuosities; but here plateaux take the place of folded mountains except for the Atlas system in the north. The exact configuration of Antarctica crowning the isolated southern elevation has still to be discovered, but high mountains bordering the coast of Victoria Land certainly buttress a great plateau to the west. Greenland though united to the American World Ridge may from some of its aspects be also claimed as a continent in itself. New Guinea, Borneo and Sumatra as the largest members of the Malay Archipelago belong to the continental system of Asia and Australia.

Islands. — Two classes of islands are recognised: the first, termed continental, and usually found on the continental shelf, are incidents of sea-level and a comparatively slight rise of the shelving plain or a fall of the ocean would unite them with the neighbouring mainland. A few other islands, of which Madagascar is the largest, are classed as continental on account of their rocks being geologically characteristic of the large land masses. In contrast with these are oceanic islands which never formed part of a continent but rise more or less abruptly from the floor of the oceans. They are classified by their origin into volcanic islands consisting of erupted lava or ashes and coral islands composed of limestone derived from the calcareous supports of polyps produced by their physiological action on sea water.

Coasts. — The line along which the sea meets the land is from every point of view the most important which is shown on a map. Coast lines have been classified in many ways with reference both to their form and their origin. One distinction is between the coasts of regions where the land has long been stationary as regards sea level, and those of regions where depression or upheaval is taking place. On stationary coasts the effect of wave-erosion is to form broad shelving beaches of sand or gravel where the land is low or the rocks soft and to produce narrow beaches where the land is high or the rocks hard, the beach in each case being cut out of the land by wave action and erosion in its upper part and built up from the sea bed by the deposit of detritus or sediment in its lower part. On sinking coasts the sea has invaded the lower valleys of the land forming wide funnel-shaped estuaries for the rivers where the land is low and narrow winding fjords or rias where the land is high. On rising coasts the shore-line, being newer, is less indented than in other types, and shelf-like raised beaches may be found backed by the old wave eroded cliffs. The minuter classification of coast-lines on this basis is complicated by alternations of elevation and depression or tilting of the land masses.

Land Forms. — Richthofen and Penck, the founders of geomorphology, have elaborated the classification of land-forms with reference both to origin and configuration and many volumes have been written on the subject. Fundamentally the typical form of the land is a slope or inclined plane which may stand at any angle from the horizontal to the vertical. Such slopes may be grouped together in many ways, giving rise to a great variety of form-elements amongst which Penck recognizes six as primary. These are (1) the Plain or gently inclined uniform surface, (2) the Scarp or steeply inclined slope, (3) the Valley consisting of two lateral parallel or slightly diverging slopes inclined towards a narrow strip or plain at a lower level which itself dips downwards in the direction of its length. (4) the Mount or slope falling away on every side from a particular place which may be a small area as in the case of a volcanic cone, or a line as in the case of a ridge or a mountain chain. (5) the Hollow or converse of a mount,

being a slope digging inwards on all sides to a point or a relatively small plain, and (6) the Cavern or space entirely surrounded by a land surface. The character of a region depends on the size and grouping of these form elements and any particular landscape may be a complex of several of them. Only a plain can extend as a single unit for hundreds of miles in every direction and at any elevation above sea-level. All the other form elements are restricted to comparatively small areas or extend in length only as relatively narrow strips. The varieties of mountains and valleys necessitate a very complex classification if full account is to be taken of them.

Mountains. — From the morphological point of view it is most important to distinguish the association of forms as the mountain-mass or group of mountains radiating from a centre, with valleys furrowing their flanks and spreading towards every direction; the mountain-chain or line of heights forming a long narrow ridge or series of ridges separated by parallel valleys, the dissected plateau or highland, divided into mountains of circumdenudation by a system of wide and deeply-cut valleys, and the isolated peak usually a volcanic cone or a hard rock mass left projecting after the softer strata which embedded it have been worn away. The distribution of mountains is closeiy related to the great structural lines of the continents of which they form the culminating region. Lofty mountains folded up from comparatively recent geological strata form the backbones of North America (the Rocky Mountains and the western Coast Ranges), South America (the Andes), Europe (the Pyrenees, Alps, Carpathians and Caucasus), and of Asia in the mountains of Asia Minor converging on the Pamirs and diverging thence in the Himalayas and the vast ranges of central and eastern Asia north of the Tibetan plateau.

Functions of Land Forms. — The simplest function of land-forms in the economy of the earth as a machine worked by solar energy is the guiding of loose material descending from a higher to a lower level under the pull of gravity. The slope and state of the surface of the land determine the path by which rock fragments, broken off by alternate expansion and contraction due to heating and cooling by radiation, will slip or roll and the distance to which they can be carried. On a uniform scarp detritus falling from above comes to rest near the bottom thus gradually reducing the slope by forming a talus or scree at the base. Where the surface is broken by valleys and plains the heaping up of rolling stones and sand add greatly to the variety of the scenery. So far the sun, gravity and the land forms could work if there were no atmosphere but the process of erosion is enormously accelerated when solar energy acts through the agency of air and water.

OROGRAPHICAL ASPECTS ,

Orographic Control of Rainfall. — The sun's heat raises water-vapour from the hydrosphere and sets up a system of winds which carry it over the land. When vapour-laden air is raised in the atmosphere by any cause it cools and the vapour condenses to fall as rain, snow or hail. When the uprising is due to storms of the cyclonic, squall or thunder type the place where the rain falls depends on the intensity of the meteorological disturbance and the path it takes, conditions which have no clear relation to the form of the land surface. The dominance of orographic control asserts itself, however, in the much more common case of a steady sea wind blowing in horizontally towards the land. Vapour carried by such a wind does not condense over the sea and to a very slight extent on low islands or level plains, but when it encounters rising ground the wedge-like action of the land compels the air to rise and as the slope increases in steepness the rate cf rising is accelerated, cooling becomes rapid and rain falls more and more heavily as the height increases until if the range is high enough all available moisture is deposited as rain on the slopes, or as snow on the summits and the air descends on the other side as a drying wind. In these circumstances the windward slope is abundantly watered; the leeward lands are arid. On lower hills the maximum rainfall occurs just over the summit as the air continues to rise by inertia for a little may after the summit is passed. So close and intimate is the relation between rainfall and land forms that a map of the rainfall of western Europe, to take a typical example, is a close repetition of the orographical map.

Orographic Control of Glaciers and Rivers. — When snow is the material dragged down by gravity from the mountain tops, its plastic nature, even when compressed by its own weight into ice, causes it to flow along the valley lines extremely slowly until the glacier meets the sea or melts in a valley giving rise to a stream or river. Glaciers effect a certain amount of erosion and polishing on their beds and leave very characteristic marks. The clay formed in this process with the boulders which fell on the ice from above heap great moraines on the lower ground which often produce an entirely new configuration of the surface.

When rain falls on a hillside it runs over the surface in trickles which follow the steepest and shortest path downwards, gradually wearing a deeper bed for themselves, meeting where the slopes converge and forming definite streams. In their steep torrential course the streams foam along carrying boulders and rock-rubbish with them which continually deepen the channel in which they flow. Where an abrupt change of level takes place the stream plunges over as a waterfall, where a hollow in the ground is encountered the stream fills it up forming a lake whence the water overflows at the lowest point and proceeds along the steepest path to the sea, or in an arid region to a salt lake with no outlet. As the slope of the land diminishes its control of the flow becomes feebler, the current slackens, the material carried along by the water is dropped by degrees until only fine mud is moved by the slow current which meanders on its plain, shifting its course with every flood, and if the tides at its mouth are not too strong, gradually building a delta out to sea. The course of a river and of the ramified tributaries coming into it is absolutely dictated by the primitive land forms; but by degrees the river system entrenches itself in the land, always deepening its valleys, until rivers become the strongest and most permanent lines in nature. The deepest drainage line is termed the *thalweg*, literally "dale-way" of a river. The area sending the rain which falls upon it to one river is termed the basin, the drainage area or the gathering ground of that river, and the line which divides it from neighbouring drainage areas is termed a watershed, water-parting or divide. Taking all the continents into account it has been calculated that rather more than half the land area drains into the Atlantic and Arctic Sea the greater part of America sloping eastward and northward and most of Europe, Asia and Africa sloping westward and northward, leaving little more than one-quarter of the land surface to send its rivers in equal measure to the Indian Ocean and the vast Pacific. The rainfall of the remainder of the land-surface, amounting almost to one-quarter of its area, does not reach the sea at all but is intercepted by lakes in arid regions where the evaporation so far exceeds the rainfall of the drainage areas in question that the rivers cannot fill up the lake basins to overflowing. Regions of internal drainage occur in each of the continents in accordance with climatic conditions the origin of which is still obscure. In the case of Lake Titicaca in South America and of the great Salt Lake of Utah, Lakes Van and Urumia in Armenia, and the many salt lakes of Tibet the position is on a high plateau shut in by mountain ranges which shut off the rain-bearing winds. In the case of the Aral Sea, Lake Balkhash and Lob Nor in Asia and of Lakes Eyre and Torrens in Australia the elevation is moderate, and in the case of the Caspian Sea, the Dead Sea in Asia and the shotts of the Sahara in Africa, is considerably below the level of the sea.

Fluvial Reaction on **Orography.**—While the *thalwegs* of a river system tend to become permanently established on the primitive drainage lines the watersheds are liable to slow change. If the downward slopes on either side of a watershed are of unequal gradient the stream flowing down the steeper slope is stronger and, if the rocks are of equal hardness, it erodes its bed more rapidly and eventually cuts a way backward on to the gentler slope capturing the upper tributaries which formerly flowed down the other side and so enlarging its own drainage-area at the expense of that of its neighbour As a river valley deepens, the sides are cut back by the smaller tributaries and their slope reduced. This is most marked when the climate is rainy as the rain wash helps to bring down the smaller detritus and gradually works out a U-shaped cross-section. In an arid

climate the valley is usually narrow and its sides are steep, the cross-section approaching that of a V in the canyons of Arizona.

The Geographical Cycle.—There is nothing more remarkable in geography than the adjustment of a great river system to a land that has remained stable for a long period. Before full adjustment has been attained the river bed may be broken in places by waterfalls or interrupted by lakes. After adjustment the slope of the river-bed diminishes gradually without a break in its symmetrical descent from source to sea; a gorge takes the place of a waterfall, a meadow that of a lake. The action of rivers on the land has been made the basis of a system of physical geography by W. M. Davis who classifies land surfaces in terms of the three factors—structure, process and time. Of these the most important is time during which the process is acting on the structure. A land may thus be characterized by its position in the geographical cycle or cycle of erosion, as young, mature or old, the last term being reached when the base level of erosion is attained. By a re-elevation of a peneplain the rivers of the old land surface are restored to activity and start the geographical cycle anew.

GEOGRAPHICAL TERMS

Biogeography takes account of the distribution of living organisms on the surface of the globe. As a matter of practical convenience the term is usually limited to the land surface, leaving the life in the sea to be treated as a subdivision of oceanography. The biogeography of the land is divided into Phytogeography which deals with the distribution of plants and Zoogeography which is concerned with the distribution of animals. The distribution of plants is controlled mainly by soil, climate and barriers to the natural spread of seed. The older students of biogeography devoted most attention to the distribution of species and divided the surface of the earth into regions in which similar species preponderated. The difficulty of deciding the boundaries of such areas lies in the fact that each small group of allied species requires a geographical classification of its own. By making various compromises different phytogeographers have put forward schemes of subdivision of which that of Oscar Drude is typical. Drude adopted the climate zones as his chief units dividing them according to the continents, (1) the Arctic-Alpine Zone including all regions bordering perpetual snow, (2) the Boreal Zone including the temperate parts of the three northern continents, (3) the Tropical Zone divided into that of America and that of Africa and Asia, (4) the Austral Zone including the very dissimilar subregions of South America, South Africa and Australia, and (6) Oceanic including all oceanic islands. Zoogeographers have, in like manner, endeavoured to divide the earth's surface into faunal regions according to the occurrence of similar species. P. L. Sclater's divisions take account of a large number of facts; they are (1) Palaearctic including Europe with Africa north of the Atlas range and Asia north of the Himalayas, (2) Ethiopian including Africa south of the Atlas and Madagascar, (3) Oriental including southern Asia and the northern half of the Malay Archipelago, (4) Australian including the southern islands of the Malay Archipelago, Australia, New Zealand and Polynesia,. (5) Nearctic or North America and (6) Neotropical or South America.

Ecology.—In the last thirty years biogeographers have devoted increasing attention to ecology which means the relation of organisms or groups of organisms to their environment, and as the factors of environment are very largely geographical the ecological as distinct from the floristic or faunistic distribution of plants and animals is now an object of active geographical research. The associations of plants which thrive in the same environment give a distinctive character to a district, and the variable factors are so numerous that any complete classification of the districts must be complicated. The subject is dealt with in great detail from the botanical point of view in PLANTS: *Ecology*. Here it is enough to indicate the broad outlines of successive ecological zones (each susceptible of minute sub-division) from the pole to the equator based on the habit and luxuriance of growth of the several associations. They are (1) Polar Ice Desert where there is practically no Life (2) Frozen Tundra, the surface of which thaws in summer and bears mosses and dwarf herbage, the growing period being short, moisture being abundant and temperature low, this merges through temperate bogs and moorlands to (3) Temperate Forests of evergreen or deciduous trees where the growing season is longer, rainfall and temperature are moderate, (4) Temperate Steppe or prairie where rainfall is scanty and temperature extreme while grasses and bulbous plants predominate. (5) Arid Desert with rainfall at a minimum and range of temperature at a maximum allowing only the sparsest growth of plants specially modified to conserve moisture. (6) Tropical Bush where the growing period is restricted by drought; high temperature and light rainfall favour grass and shrubs and (7) Equatorial Forest where great heat and abundant moisture encourages the most exuberant vegetation as the growing season is continuous throughout the year. Each plant association and the animals which accompany it tends to get into adjustment with the geographical environment and to extend its district as far as natural barriers permit. Any change brought about from without, such as the incursion of new species or the destruction of some of those established disturbs the balance of life and may lead to very remarkable changes. The study of the flora and fauna of primitive lands separated by barriers opposing various degrees of resistance to the migration of species led Darwin, Wallace and Hooker to develop the theory of the evolution of species by natural selection. The same phenomena seen in the light of ecology enable geologists to sketch the distribution of land and sea in the various geological periods; this study is known as palaeogeography.

Human Geography.—This takes cognizance of the distribution of mankind and of human societies in relation to all the conditions of geographical environment, bearing the same relation to anthropology that biogeography does to biology. In the view of some writers this is the whole theme of geography which they define as the study of the earth in its relation to man; other writers look on it only as a division of biogeography and they would define it as the ecology of the human species. The view taken in this article is that just as the phenomena of life require biogeography to be considered not as part of physical geography but as superimposed upon it, so the phenomena of mind require that human geography be regarded, not as a part of biogeography, but as superimposed upon it as a higher storey of the great structure of geography the foundations of which are physical and mathematical. Friedrich Ratzel developed the subject in his *Anthropogeographie* which has long been the standard presentation. His students have applied the principles he laid down to elucidate many detailed problems. Those who have made original contributions of this kind in English include Ellen Churchill Semple, Mark Jefferson, Ellsworth Huntington and J. Russell Smith in America and Marion I. Newbigin, Halford Mackinder and H. J. Fleure in Great Britain. In France the subject has been handled in a slightly different orientation by Vidal de la Blache and with great fullness, charm and clarity by Jean Brunhes whose *Géographie Humaine* has been translated into English by Isaiah Bowman and R. E. Dodge. All authorities agree in dealing with human geography on the basis of the control exercised upon man in his settlements and in his movements by geographical conditions especially the relief of the land, climate and the distribution of plants and animals; but all also recognize the reaction of man on his environment which increases towards completeness with the civilization of the higher races. The study of human geography involves the use of statistics, such as census reports and registration returns of births, marriages and deaths in order to take account of the ever-changing relation of populations to inhabited areas. This specialized study acquired the name of Demography in the middle of the nineteenth century.

Ethnography considers the different races of mankind and their subdivisions with reference to the areas they inhabit, their languages, cultural development and religions.

Political Geography takes account of the relation of organized groups of people to the region they inhabit. In the case of nomadic tribes with no permanent tie to any particular portion of land, political geography hardly exists, but it becomes important as soon as people settle on some position favourable to their needs under the control of chiefs or committees. The smaller units may

confederate or coalesce to form larger organizations under more powerful leadership each controlling a larger area recognized as a country. As time proceeds countries, once small and possibly separated by vast stretches of empty territory, grow in size until their boundaries meet and they fill the whole continent on which they are situated. Political geography has mainly to do with the boundaries and mode of government of countries.

Historical geography may thus be taken as an introduction to political geography. A typical country is a natural region with fixed boundaries occupied by a homogeneous nation of one race, speaking one language and content to live under one code of laws. In such a country patriotism, which is a product of geographical conditions, and loyalty, which is a racial instinct, are one, and this harmony produces a stable, independent and powerful nation. In many cases contiguous countries differ from each other in race, language and religion; thus conditions favourable to the growth of rivalry and misunderstanding already exist. The efforts of a homogeneous state to extend its boundaries or to protect them from the aggression of a neighbouring state have led to the development of military geography.

Often differences of race and language occur within a country, alien elements being grouped together voluntarily or otherwise under one government; then diverse loyalties tend to weaken the spirit of patriotism without developing that of international brotherhood. The boundaries are not always natural, coastlines, mountain ranges, watersheds or rivers forming only a part of them, and sometimes these are hard to delimit. Boundaries in undeveloped countries are often most satisfactory when defined by the meridians and parallels of pure mathematical geography which traverse all physical features with indifference. Most often boundaries are fixed by treaties so as to attempt to take account of historical facts or ethnographical conditions, or it may be to secure a share of certain favourable territories at the cost of dividing people of one race and language between two countries to one of which they are alien. The question of national boundaries is the most difficult part of political geography.

Commercial Geography.— This deals with production, transport and exchange of useful commodities. J. S. Keltie proposed the name applied geography for this aspect but that name is too wide and should equally include political geography. It rests as largely on economics as political geography does on history. Primitive tribes living in a tropical forest afford the simplest example of what might truly be called economic geography or even human ecology, for depending only on wild fruits and the hunting of animals the savage is in harmony with the rest of nature and the power of environment is complete. As civilization advances man begins to react on his environment, introducing flocks of domestic animals to the grass-lands, cultivating the soil in order to replace the native flora by roots and fruit and grain and fibre-plants, digging for minerals, smelting metals, devising tools and machinery. As division of labour extends trade becomes essential, means of transport have to be found, commerce established. The control of physical geography, at first dominant in dictating sites of settlement and lines of communication, gives way with the improvement of processes until cost of production, manufacture and distribution is the final arbiter as to whether raw material shall be brought to the site of power or power to the source of raw material or both to convenient centres for distribution. G. G. Chisholm's *Commercial Geography* is the standard English text bock.

Regional Geography.— The attempt made in the foregoing sections to unravel the various threads interwoven in the fabric of geography is apt to spoil the pattern in the reader's mind unless they are put together again in a concrete synthesis. For this reason the early teaching of geography should begin not with general principles but with the example of a familiar locality from which the world beyond may be opened out as it was opened to the early explorers, and gradually explained as it mas explained by the early theorists who fitted facts together in logical order. The scope and hearing of geography can only be fully grasped by the systematic study of a definite region, a river-basin as taken by T. H. Huxley in the introduction to his *Physiography* or an island, a mountain group, a country or even a continent. A. J. Herbertson, when professor of geography at Oxford, laid great stress on regional geography and made a successful attempt to divide the world into natural regions of large extent. The degree of detail must be adjusted inversely to the size of the area under review, but the order of treatment and the inter-relation of the different aspects are the same whatever the magnitude of the work. The material for regional studies is enormous but it is doubtful whether it is anywhere complete. The scheme for a regional survey of the British Isles on the basis of the Ordnance Survey map of 1 inch to the mile (H. R. Mill in *Geographical Journal* 7 [1896], 345 and 15 [1900] 205, 353) proposed the map-sheet as the unit for the preliminary description which should take account also of the Geological Survey maps on the same scale, the hydrographic charts of the coast, the unmapped data of the Meteorological Office, the Census Reports, the Statistics of the Ministry of Agriculture, the Ministry of Health and the Board of Trade. When these official sources were dealt with new surveys would be required to take account of plant associations in uncultivated districts, of native fauna, of local industries and customs and much besides. It was proposed to generalise the sheet-descriptions in groups of natural regions and finally to digest the whole into a treatise on the geography of the British Isles. The project remains a fragment. On a grander scale the American Geographical Society under the guidance of Isaiah Bowman has undertaken a regional study of Latin America of which a stimulating instalment on the Central Andes by A. G. Ogilvie appeared in 1922. The regional idea has been fruitful in developing the most recent geographical research in all parts of the world, especially in France and in Germany where the work of Gustav Braun on the Baltic lands and that of Fritz Machatschek on the Sudetic region are models of their kind, while A. Hettner's treatment of the continents in his *Länderkunde* is a perfect application of the regional idea to the largest areas.

GEOID: *see* GEODESY.

GEOK-TEPÉ, a former fortress of the Turkomans, in the Turkmenistan S.S.R., lat. 38° 12′ N., long. 57° 58′ E., in the oasis of Akhal-tekke, on the Transcaspian railway, 28 m. N.W. of Askabad. It consisted of a walled enclosure $1\frac{3}{4}$ m. in circuit, the wall being 18 ft. high and 20 to 30 ft. thick. In December 1880

the place was attacked by 6,000 Russians under General Skobelev, and after a siege of twenty-three days was carried by storm, although the defenders numbered 25,000. A monument and a small museum commemorate the event.

GEOLOGICAL ARTICLES. In addition to the general article GEOLOGY, which treats of the history of the science and gives a sketch of its physical and stratigraphical divisions, there are in this *Encyclopædia* long articles treating of special branches, especially PETROLOGY, PALAEONTOLOGY, MINERALOGY, CRYSTALLOGRAPHY, ORE-DEPOSITS, METAMORPHISM, VOLCANOES, the GLACIAL PERIOD. Each of the more important varieties of rocks and mineral species is described in separate articles; since, however, geologists and mineralogists have introduced an enormous number of unnecessary names for minor varieties of rocks and minerals, as well as for the smaller subdivisions of the stratified rocks, it has not been found possible to have separate articles for all of them but in the index references are given to the places where they are described or referred to. The longer articles contain selected bibliographies of the classics of the subject and modern works in which full details will be found. For each of the major subdivisions of the stratified rocks (geological systems), a separate article is provided: e.g., CAMBRIAN, TRIAS, EOCENE, while accounts of the geology of the principal countries of the world will be found in the articles on those countries.

GEOLOGICAL SOCIETIES. This account also includes mineralogical and palaeontological societies and institutions. The first International Congress of Geology took place at Bologna in 1878. The Geological Society of London, founded in 1807 and incorporated in 1826, is the largest and most important in Great Britain; it has published Proceedings (1834–1846), Transactions (1811, etc.), and a Quarterly Journal (1845, etc.). The Geologists Association was instituted in 1858, and issues Proceedings (1859, etc.). The Mineralogical Society (1876) has united with it the Crystallogical Society; it issues the Mineralogical Magazine (1876, etc.). The Palaeontographical Society was founded in 1847 for the delineation and description of British fossils; it issues Publications (4to, 1847, etc.). The Royal Geological Society of Cornwall (1814) devotes special attention to the mining interests of the county, and publishes Transactions (1818, etc.). It holds its meetings at Penzance. The Geological Society of Edinburgh (1834) issues Transactions (1870, etc.). The Royal Geological Society of Ireland (1832) principally studied the geology of the country. It published a Journal (1837, etc.). There are also the Geological Associations of Leeds (1874) and Liverpool (1880), Trans., and the Societies of Liverpool (1859), Proc., and Manchester (1838), Trans.

SOUTH AFRICA: Johannesburg, Geol. Soc. of S. A. (1895); Trans. (1895, etc.). UNITED STATES: Louisville, Ky., Ohio Falls Geolog. Soc. San Francisco, California State Geolog. Soc. (1876). ARGENTINE REPUBLIC: Buenos Aires, Soc. Paleontol. MEXICO: Mexico, Soc. Geol. Mexicana (1904), Bol.

GEOLOGY, in the broadest sense, has for its object the elucidation of the history of the earth and its living inhabitants. For practical purposes, however, it is necessary to adopt somewhat arbitrary limitations. The earliest stages in the development of the earth belong to astronomy and cosmogony, whereas, at the other end of the scale, geology in some of its aspects merges into history and geography, as well as into the biological sciences, including anthropology and ethnology. It may perhaps be said that the province of geology begins at the period when the earth acquired a permanent solid crust; from that time onward it studies the development of the physical features of the earth, the composition and structures of the rocks composing it, and the evolution of animals and plants from their unknown beginnings. It will thus be seen that geology is a very comprehensive subject, closely linked to numerous other sciences, and capable of being regarded from many different points of view, but for most purposes it can be divided more or less clearly into four distinct branches, or five if, as is usual, the cosmogonic aspect is included.

1. *Cosmogony* deals with the relation of the earth to the solar system and to the universe, its origin and early stages.

2. *Physical Geology* is the study of the forms of the earth's surface, their structure, their manner of origin, and the nature of the processes that have moulded and are still modifying it.

3. *Petrology* describes the composition of the rocks that now form the accessible portion of the crust, and their mode of origin.

4. *Palaeontology* may be defined as the biology of fossils, the remains of former animals and plants now buried in the rocks.

5. *Stratigraphical Geology* works out the history of the earth and its geography in past ages through the study of the rocks and the fossils that they contain.

The present article includes sections dealing with the second and fifth of these categories; Cosmogony, Petrology and Palaeontology are relegated to separate articles.

I. HISTORY OF THE SCIENCE

The earliest beginnings of geological thought, like those of many other sciences, are so mixed up with myth and legend and vague cosmical speculations, and so little founded on observation and induction, that a lengthy consideration of them would not be very illuminating from the scientific point of view, though of much interest in the development of philosophy and psychology. However, even these myths and legends must have had their basis in the observation and interpretation of natural phenomena, so that they are in some sense geological.

It so happens that the Mediterranean basin, the home of many of the early civilizations whose written records have come down to us, is an area in which geological phenomena are peculiarly well displayed and striking, and it may well be a matter of wonder that the acute thinkers of antiquity did not manage to arrive at a more reasonable and more correct interpretation of the facts than they did: it is perhaps worth remembering that geology even in its modern forms depends far less on complicated instruments and appliances than almost any other science. It is nearly all naked-eye observation of things on a large scale, and therefore might have been thought peculiarly well adapted to development at an early stage of civilization.

Many of the earlier philosophers of Greece and Rome were naturally dissatisfied with the vague and often obviously impossible theories of the meaning of natural phenomena embodied in the popular myths and, traditions, and sought to find more reasonable explanations of them. The opinions entertained in antiquity on these subjects may be conveniently grouped under two heads: (1) geological processes in operation at the time, and (2) geological changes in the past.

1. *Contemporary Processes.*—Earthquakes, owing to their often disastrous character, received much attention from the Greeks and Romans. Aristotle, in his Meteorics, quotes the views of older writers and rejects them in favour of his own idea that

earthquakes are due to wind within the earth, produced by the warmth of the sun and internal heat. He looked upon earthquakes and volcanic phenomena as closely connected, the eruption being due to the final escape of the wind that caused earthquakes. Very similar and equally crude ideas were put forward by Lucretius, who also followed Anaximenes in attributing earthquakes in part to falls of rock within the earth. Strabo recognized that Vesuvius was a dormant volcano, though there was then no record of an eruption; he continued to believe in wind as the active agent in underground disturbances. He cites in his *Geograplzy* a number of cases of sinking and rising of land and he recognized that some islands are volcanic, while others were originally part of the mainland. The most detailed account of earthquakes that has come down to us from antiquity is in the *Quaestiones Naturales* of Seneca. He was much interested in an earthquake at Naples in A.D. 63 and distinguished several different motions of the ground, up and down, oscillatory and vibrational. He held firmly to the old idea that the most important factor was wind, while admitting the possibility of some shocks being due to collapse of caverns. Volcanoes he supposed to be due to this wind meeting stores of sulphur and other combustibles, which were set on fire by friction.

The action of rivers also, being of much importance to mankind, was observed with more or less care. Herodotus noted the great amount of silt brought down annually by the Nile, and pertinently remarked "Egypt is the gift of the river," which is perfectly true. Aristotle displays considerable knowledge of the drainage system on the north side of the Mediterranean basin. He refers to the mountains as condensers of rain and snow and shows that the largest rivers rise in the highest ground. He also points out how river deposits are encroaching on the sea, and mentions specially in this connection some parts of the Black Sea, where after sixty years it became necessary to use ships of much lighter draught, as the water had become much shallower and would soon be converted into dry land. Strabo also discussed the formation of plains and deltas by rivers.

2. *Processes of the Past.*—*It* so happens that at many places around the Mediterranean there are found deposits at high levels containing abunddnce of shells very like the present inhabitants of that sea. These naturally attracted attention at an early date, and are often referred to in classical writings as proofs of elevation of the land or a former much wider extension of the sea. Xenophanes of Colophon (614 B.C.) noticed the occurrence of sea-shells among the mountains; Xanthus the Lydian (464 B.C.) found scallops and cockles far from the sea in Armenia and Phrygia. Herodotus, Eratosthenes, Strato and Strabo noted vast quantities of fossil shells in Egypt, along with beds of salt, as proofs of a former extension of the sea. Aristotle recognized clearly that areas once covered by the sea are now dry land, and that land may one day reappear where there is now sea. He regarded these changes as periodic, but requiring a long lapse of time and therefore likely to escape our notice. In a famous passage in his *Metamorphoses* Ovid affirms the interchange of land and sea, the wearing away of mountains, the disappearance of rivers, the submergence of land owing to earthquakes, the formation and disappearance of islands, the uprise and extinction of volcanoes.

From these selected examples it might appear that the classical writers had accumulated a good deal of observational material, but in point of fact most of the conclusions that they drew as to ultimate causes were mere speculation and guesswork It can hardly be said that scientific geology made any real progress throughout these ages.

Mediaeval and Early Geologists.—During the dark ages that followed the collapse of the Latin culture of the Roman Empire before the invasion of the Germanic barbarians geology naturally made no progress, and even the great scholastic philosophers of the 13th century were apparently not much interested in natural phenomena. What science they knew was mainly derived from Greece and Rome. The Arabs however collected and translated the literature, and a treatise ascribed to Avicenna contains some very modern ideas on the origin of mountains.

After the general revival of classical studies, the problems of geology, as dealt with in the ancient writings, once more began to attract attention, especially in Italy. In that country fossil shells are very abundant, and several different theories of their origin were put forward. Some writers regarded them as mere freaks of nature *"lapides sui generis,"* which had never been alive; others considered them to be relics of the universal deluge More practicable theories soon began to prevail. Leonardo da Vinci (1452–1519) maintained that they had once been normal living organisms, and that what is now land had formerly been covered by the sea. Girolamo Frascatorio (1483–1553) claimed that a single temporary deluge was inadequate to produce the observed effects, but that the mountains in which the shells are found must have been uplifted from the sea

But it was the Catholic ecclesiastic, Nicholas Steno (Stensen) (1631–87) at one time Bishop of Hamburg and Vicar-Apostolic of Denmark, afterwards resident in Florence, who must be regarded as the founder of modern geology and mineralogy. After making a world-wide reputation as an anatomist, he turned to the study of fossils. and in 1669 published a small tract with the not very lucid title *De solido inter solidum naturaliter contento* in which he developed his ideas as to the past history of the earth as derived from his study of the rocks, dealing with many of the fundamental problems of physical geology and stratigraphy on quite modern lines.

The Italian geological school of this period also included Antonio Vallisneri (1661–1730) who had a wide knowledge of fossils, and Lazzaro Moro (1687–1740) who made an extensive study of stratigraphy but attached too much weight to volcanic accumulation as the source of sedimentary deposits.

The Cosmogonists and Their Successors. In other countries however, and especially in England, the study of geology ran on rather different lines. Instead of a patient accumulation of facts and inferences from those facts alone many writers indulged in fanciful speculation and wildly extravagant theories of cosmogony, mostly founded on sheer imagination. During the last twenty years of the 17th century there appeared a number of writings which attracted attention mainly by their sensationalism, both in England and abroad. As examples may be mentioned the works of Thomas Burnet and William Whiston. Hardly less fanciful in his theories, although a much better observer, was John Woodward whose *Essay towards a Natural History of the Earth* appeared in 1695. His large and valuable collection of fossils is still religiously preserved intact in the Sedgwick Museum at Cambridge, in accordance with the terms of his will. Woodward published a catalogue of this collection in 1728–29 under the title *An attempt towards a Natural History of tlze Fossils of England.* It is to be noted that at this time the term *fossil* included minerals as well as organic remains and the Woodwardian Collection contains some very fine mineral specimens.

A striking contrast is afforded by another group of geologists in France and Germany, who gave to the world the first really practical ideas as to the evolution of the earth. The first of them was René Descartes (1596–1650) who ascribed the origin of the earth and the other planets to the cooling of an originally incandescent mass like the sun, leading to the formation of a solid crust over a still hot nucleus.

The ideas of Descartes were enlarged and systematized by Wilhelm Gottfried Leibnitz (1646–1716) whose work has had a permanent value. In his great tract, the *Protogaca,* published only *in* 1749, he traced the passage of the earth from an incandescent mass of vapour to a molten globe, which by further cooling acquired a solid crust, perhaps now surviving in part as some of the most ancient rocks. He thought that as cooling went on great cavities might be left, filled with air and water; these cavities by collapse might give rise to valleys, while the more solid parts formed the mountains. Water escaping from the cevities might form the sedimentary deposits. Leibnitz also attached much importance to fossils as indices of past changes and alternations of land and sea.

Of much greater importance however in the development of geology was the work of G. L. L. de Buffon (1707–88) who had a much wider acquaintance with rocks and fossils. He accepted the ideas of Descartes and Leibnitz as to planetary evolution. but

in his first geological work (1749) he supposed that fossils had all been deposited in a universal ocean; which was later swallowed by the cavities within the earth. Thirty years later, in his famous *Epoques de la Nature*, he endeavoured to draw up a chronology of the earth, dividing it into six periods of unequal length, based on the supposed rate of cooling from the incandescent stage.

Modern **Geologists.**—With the work of James Hutton (1726–97), which is rather difficult reading, and its lucid exposition by John Playfair (1748–1819), we at last come to the beginnings of modern geology. James Hutton was originally a medical man who studied at Edinburgh and Paris and took his doctor's degree at Leiden. Later he took to farming in Berwickshire and eventually went to live in Edinburgh, where he published his *Theory of the Earth, with Proofs and Illustrations* (2 vols., 1795), an expansion of a paper read to the Royal Society of Edinburgh. Owing to the obscurity of the style however the book did not receive full recognition till the appearance of a kind of commentary on it by Playfair, entitled *Illustrations of the Huttonian Theory*, published in 1802. This was so clear and striking as to gain a general acceptance for Hutton's ideas, which may perhaps be fairly summed up in the general formula that the processes that have been at work on the earth in the past are the same as those now in operation, and that it is not allowable to invoke any agents which cannot now be seen and proved to be effective. This affords a strong contrast to the wild speculations of the cosmogonists and is in fact the foundation of the so-called Uniformitarian school of geology, which has prevailed almost without opposition ever since, although there is now a growing feeling that it has been pushed too far, though true in its main features. Since the ideas of Hutton and Playfair have to a large extent become the commonplaces of physical geology, this subject is discussed more fully below *(see* II., PHYSICAL GEOLOGY). The work of Sir Charles Lyell *(see* below) was the direct consequence of Hutton's writings.

To return for a while to the French school, it may perhaps be said that the founder of invertebrate palaeontology was Lamarck (1744–1829), who is universally regarded as one of the originators of the doctrine of evolution and continuous progress of living beings, as opposed to the theory of catastrophic destruction and repeated creations, which largely prevailed everywhere during his time. This eminent naturalist turned his attention somewhat late in life to the study of fossils, which led him to formulate some geological ideas very similar to those of Hutton and Playfair, though arrived at quite independently. However, he did not pay sufficient attention to the possibilities of earth-movement, and attributed even the highest non-volcanic mountains to the wearing away of elevated plateaux, and he attached an exaggerated value to the tides as geological agents. As a biologist he brought fossils into the forefront of his theories as a means of working out the history of the earth and the succession of events.

In a somewhat similar way the great comparative anatomist, Cuvier (1769–1832) is to be regarded as the founder of vertebrate palaeontology. Cuvier's knowledge of comparative anatomy was so marvellous that he was literally almost able to reconstruct a whole animal from a single bone or tooth. In a preliminary section of his great work, *Récherches sur les ossemens fossiles* (1821), he gave an outline of what he believed to have been the history of the globe. This was frankly catastrophic, in the most extreme form of the doctrine; he believed that there was evidence for the occurrence in the past of cataclysms of world-wide extent, far surpassing even the conventional destructiveness of the Biblical deluge; he rejected entirely all ideas of organic continuity and postulated fresh creations of new forms of animals and plants. It is interesting, to digress for a moment, to find that after a century of the quietistic Uniformitarianism of Hutton and Lyell, there are now signs of a return to a form of catastrophism, though without a complete destruction of life.

During the latter half of the eighteenth century and the beginning of the nineteenth there was a violent and rather absurd controversy as to the origin of the igneous rocks; some writers continued to maintain, up to the middle of the eighteenth century, that volcanic phenomena are due to combustion and they attributed lava flows to the melting of ordinary rocks, such as clay and sandstone, by the heat of such combustion. The true nature of vulcanicity will be discussed in detail later: it must suffice to say here that eruptions are due to the escape, under gas pressure, of portions of the heated interior of the earth in a molten state, giving rise to flows of lava and showers of ashes, with steam and other vapours. But in earlier days trouble arose over the nature of certain rocks found among the earlier formations while resembling the products of modern volcanoes, and also as to the origin of such rocks as granite which appear to have invaded newer formations while in a molten condition.

The last and most famous of the geologists of this older school was Abraham Gottlob Werner (1749–1815) of Freiberg, Saxony. Werner apparently was a magnificent teacher, although the doctrines he taught were erroneous, and he certainly deserves the utmost credit as the real founder of economic geology. The Mining Academy at Freiberg has been in the forefront of the study of the metalliferous deposits ever since his day, but Werner's obstinate adherence to the worn-out doctrine of the aqueous origin of basalt had a disastrous effect on petrographical geology for many years.

As early as 1752 J. E. Guettard (1715–86) had studied the extinct volcanoes of Auvergne and had shown that the basaltic lava, there so abundant, far from being a chemical precipitate, as supposed by Werner, was in reality poured out in a molten state at many different times and places. Desmarest (1725–1815) followed this up a few years later by mapping the area in detail and working out the whole complicated history. In Scotland Hutton proved the intrusive nature of granite and various "trap" rocks. J. F. d'Aubuisson, who had written a memoir on the aqueous origin of the basalts of Saxony, was converted by a visit to Auvergne, and even the great Leopold von Buch, at one time the most shining light of the Neptunist school, abandoned his Wernerian faith for the same reason. From that time the igneous origin of both deep-seated intrusions and surface lava-flows was established.

The Nineteenth Century.— In the early years of the nineteenth century geology began to receive in England an amount of attention not hitherto accorded to it. A number of eminent men, keenly interested in the subject, but rather bored by the futile speculations of the cosmogonists and by the bitter personal Wernerian controversies, combined in **1807** to found the Geological Society of London. The avowed object of the founders was to steer clear of all preconceived notions and ready-made theories, and to collect the facts for future discussion.

From about this same date, the beginning of the nineteenth century, the history of the development of geology becomes so complicated that it is impossible to follow up all the threads simultaneously, or within any reasonable compass to give a general account of the whole. The various branches, such as physical geology, petrology, palaeontology and stratigraphy, began to have a more or less clearly defined separate existence, each with its own line of evolution and development, under the impulse of varying forces, such as the advance of physics and chemistry, the coming of evolution, the advance of geographical exploration and so forth, and all these various lines of progress ceased to be confined to one small corner of north-western Europe, but spread over the world. Hence from this point onward the only possible course is to exercise some kind of selection. The development of petrology and palaeontology will be sufficiently apparent from the articles on those subjects, while the closely allied subject of mineralogy has a history of its own—troubled by far fewer controversies. What follows, therefore, is a brief sketch of the progress of general geology, especially on its physical and stratigraphical sides, in the British Isles during the nineteenth century, with occasional excursions into other parts of the world where needed by the context.

One of the most remarkable figures in the whole history of geology is William Smith (1789–1839) a man of quite humble origin, who spent most of his life as a canal engineer in Somerset and as a land-agent near Scarborough. During a busy professional life he managed to find time to construct a geological map of England and Wales, and at the same time to work out the succession of the stratified formations of the country by means of

their contained fossils. The majority of the rather rough-and-ready names that he coined for the different formations have remained to this day as the classical designations, and it is to be hoped that they may so continue to remain, a reminder to the stratigraphers of all countries of the birthplace of their science. William Smith has aptly been called the "Father of British Geology," and his large coloured wall-map, dated 1815, compares to some extent with the latest productions of the Geological Survey and was a monumental achievement for one self-taught man.

The work of the pioneers of physical and stratigraphical geology was admirably generalized and amplified by Sir Charles Lyell (1797–1875). He was able to travel extensively throughout his life, and to add by his own acute observations great masses of facts to the stores accumulated by his predecessors. His *Principles of Geology* (3 vols.. 1830–33), which rapidly passed into numerous editions, is one of the great books of the world. On the physical side the line of thought is strictly Huttonian, an exposition of the doctrine of uniform causes, while on the biological side for many years Lyell maintained the permanence of species; but in later life he frankly became a convert to the doctrine of evolution, especially the form of it expounded by Darwin. It is a question which of these great men was the more influenced by the other; the whole tendency of Lyell's work was in the direction of converting geology from a physical into a biological science, and he took little interest in mineralogy, apart from volcanic phenomena. Lyell's *Principles* remains a classic of geology, and may still be profitably read. About the same time the work of G. P. Scrope in Auvergne, following on the lines laid down by Guettard and Desmarest, established the modern science of vulcanology.

Up to the first quarter of the nineteenth century very little was known about the older rocks constituting the western and the northern parts of Great Britain, though by 1830 the succession of the newer formations in the south and east had been fairly thoroughly worked out. About this time Adam Sedgwick (1785–1873), Professor of Geology at Cambridge, and Sir Roderick Impey Murchison (1792–1871) began to investigate the rocks of Wales and the western Midlands. Sedgwick started in the north-west in Caernarvonshire and succeeded in working out the succession of the slaty rocks far to the south-east of his starting point, calling them the Cambrian system. Murchison on the other hand began in Shropshire and worked north-westwards, naming his rocks the Silurian system. In general terms Sedgwick was working upwards in the succession of the stratified rocks and Murchison downwards; but the sequence was not quite simple. The rocks there are thrown into wavy folds, by crumpling of the crust, so that there is some repetition of strata at the surface. The natural result was that the respective systems of Sedgwick and Murchison overlapped. Murchison claimed for his Silurian system nearly the whole of Sedgwick's Cambrian, leaving him only a remnant of unfossiliferous slates at the bottom, while Sedgwick on the other hand perhaps claimed too much for his Cambrian. Lapworth proposed as a practical compromise that the beds mostly in dispute (Murchison's Lower Silurian', should be constituted into a separate system, called the Ordovician. This is now universally accepted, though for many years Sir Archibald Geikie (1835–1924) valiantly upheld the Lower Silurian.

The brilliant and original work of Charles Lapworth (1842–1920) exercised a profound influence on geology in the third quarter of the nineteenth century. He established the order of succession of the different forms of the great group of fossils known as the graptolites, which were found to follow one another in a definite evolutionary order, each in a layer of rock (of very variable thickness in different places, be it understood), which Lapworth called the *zone* of that particular fossil. By means of these zones he was able to unravel the intensely complicated structure of the southern uplands of Scotland and of other areas, thus throwing a flood of light on mountain-building and the folding of the earth's crust. By thus revealing the "Secret of the Highlands" he paved the way for the proper understanding of the geology of many other areas. Lapworth's great work has been and still is being ably carried on by his pupils, his followers and their disciples. Another problem of first-class importance and somewhat cognate nature that arose during this same period was the question of the time order of succession of the rocks of the north-west Highlands of Scotland and the age of the crystalline racks composing the central and the southern Highlands. The intensely complicated structures of the far north-west were worked out by Lapworth and the officers of the Geological Survey, and proved to be the relics of an ancient mountain chain of Alpine type. In the central and southern Highlands work is still in progress.

From this point it becomes impossible to refer in any detail to the progress of geology without mentioning the names of living workers. Immense progress has been made in British stratigraphy, mostly in matters of detail, without any very fundamental new discoveries. In structural geology one of the most important advances is the recognition of the principle of "posthumous movement," which means in simple language that when once the earth's crust has been crumpled into a fold running in a particular direction, further crumpling is likely to take place along the same line at later dates. This principle has proved of immense importance in working out the structure and limits of coalfields buried under newer strata. Further, the zonary method of stratigraphy has been extended to nearly all the fossiliferous formations.

Physical Geology. — During the last fifty years physical geology has continued to develop, and as is only natural, the geological exploration of the great lands beyond the seas has tended to broaden the originally mainly European outlook. In the other continents things are on a bigger scale, and probably geological processes are more rapid, owing to differences of climate, the greater prevalence of volcanoes and earthquakes and so on. It has also come to be recognized that in past ages processes probably were, at certain times at any rate, more active and intense than they now are. Hence the present conception of physical geology may fairly be described as evolutionary rather than uniformitarian in the strict sense, though there is no proof that processes ever differed notably in kind from those now in operation. The differences were mainly in degree. Very great attention has been paid of late to the formation of continents and oceans and of mountain ranges, as well as to crust movements in general, but this phase of the subject belongs rather to cosmogony and geodesy than to geology proper. Special mention should be made of the great progress of the study of glaciation in the past half century.

Petrology. — Turning now to the history of petrology, reference has already been made to the Wernerian controversy. By the beginning of the nineteenth century it was generally accepted that both lavas and certain deep seated rocks such as granite were of direct igneous origin, their outpouring or intrusion being brought about by true volcanic action and depending on the internal heat of the earth. But for many years scientific petrology made little progress, owing to certain difficulties inherent in the subject. Many igneous rocks are mixtures of different minerals while others are of very fine texture. A chemical analysis of an obvious mixture is not in itself very illuminating, without other data, and for long these were lacking. It was not till in the fifties of last century Henry Clifton Sorby (1826–1908) of Sheffield discovered a method of making thin sections of rocks suitable for the microscope, that any real advance was made. Such microscopic examination, largely by the aid of polarized light, is the foundation of scientific petrology. It enables us to determine accurately the mineral composition of the rock, its structure and the order of crystallization of the different minerals, also revealing the nature of the finer-grained rocks. From the time of this discovery petrology soon began to make great strides in the hands of Haughton, Allport, Bonney, Zirkel and Rosenbusch, to name only a few of the pioneers. Similar methods are also applicable to the sedimentary and other rocks. The latest developments of petrology, largely due to American and Norwegian workers, are rather in the direction of extremely accurate chemical and physical investigation, coupled with experimental work in the synthesis of rocks and minerals.

Prehistoric Man. — It was stated at the beginning of this article that geology tends to merge into various sciences dealing with the living inhabitants of the earth. Palaeontology must necessarily do so, and another not very well-defined branch of

geology concerns itself with the origin and earliest history of the human race, thus joining up with prehistoric archaeology. The geological history of the human race has of late years been carried back much further than at one time seemed possible.

II. *PHYSICAL GEOLOGY*

Physical Geology is that part of the science which deals with the form and constitution of the accessible portion of the earth, and studies the nature of the processes that have been at work in the past and are still moulding and modifying the earth's surface. The term has to be interpreted very widely, in order to avoid unnecessary and confusing subdivisions of the subject, and physical geology has of necessity to take cognizance of all other parts of geology, as well as of mineralogy and of physics, chemistry, biology, etc.—which have a direct bearing on it. The relationship between physical geology and physical geography is very close.

Physical geology also entails some acquaintance with the general principles of meteorology, since climate is a factor of great importance.

THE GEOLOGICAL CYCLE

The fundamental principle of modern physical geology is that processes on the broad scale work in cycles. The simplest observations show that the land surface as a whole is gradually being worn away by the action of rain, snow, wind, etc. The material loosened by these agents eventually finds its way to the sea, where it is finally deposited to form new rock-masses. Hence the land is being worn away and the sea filled up. But geology shows that in many areas there has been an alternation of land and sea, often many times repeated; hence, part of the sea must have been uplifted to form land to be worn away in its turn. It can also be shown that the periods of uplift are also periods of folding of the earth's crust to form mountain ranges, and are usually accompanied by great outbursts of volcanic activity. In the history of the British Isles and of North America there is evidence of four or five such cycles, the phases of quiet or disturbance being nearly or quite contemporaneous in the two areas. In the southern hemisphere there were also similar revolutions, tending to alternate with those of the north.

In the study of such a continuous series of events it is obviously immaterial where we begin. For most purposes it is convenient to start with a consideration of the stage that is most clearly displayed before our eyes, namely the degradation of the land, and then to follow the material in its course to the sea, with an investigation of the nature of the accumulations that it there forms. These two stages are known to the geologist as denudation and deposition. After these come in natural sequence earth-movements and vulcanicity, leading to the establishment of new earth structures and land-building, whence we arrive at the starting point of another cycle.

The Zonary Structure of the Earth.—Regarding the earth as a whole it is easy to recognize four broad sub-divisions of its structure, namely the air, the water, the rocks of the surface and the unknown core below. These are arranged as three concentric shells and a nucleus.

The Atmosphere.—The general character of the atmosphere is described in separate articles (see *especially* ATMOSPHERE and METEOROLOGY), and only a few of its properties have here to be considered. Air consists, roughly, of four-fifths nitrogen, one-fifth oxygen, a small percentage of carbon dioxide and a varying amount of water vapour, with small traces of other gases, and a little fine dust in suspension, the last being more abundant in towns and in very dry regions. The oxygen, the water vapour and the carbon dioxide are the geologically active agents, bringing about numerous chemical and physical changes in rocks. The water vapour also is of primary importance as the source of rain, snow and dew.

The Hydrosphere.—This includes all the water on the surface of the globe: not only the sea, but also the rivers and the lakes of the land areas, both salt and fresh. It is the custom to speak of salt and fresh water as if they were essentially different, but in reality the difference is one of degree only. All natural waters contain dissolved salts, but when there is not enough salt to taste the water is called fresh. The water of the open sea is very salt, containing about 3.5 per cent of salts, mainly sodium chloride, but also including chlorides and sulphates of potassium and magnesium, a little calcium carbonate and traces of bromine and iodine. Many salt lakes contain far more salt than this and some are saturated so that they actually deposit solid salts in crystals. The calcium carbonate in sea-water, though small in amount, is of great importance, both in forming the basis of the shells of molluscs, crustacea, etc., and as providing the material with which certain rock-building animals—the corals, for instance—and plants do their work. Vast quantities of carbonate are poured into the sea by rivers running through limestone countries, but it is quickly annexed by these shell- and rock-making organisms.

The Lithosphere.—Under this name is comprised the solid earth, of which the outer part at any rate is composed of rocks (Gk. λιθος, a stone). The outer part is obviously solid, but we do not know what is the condition of the interior (see EARTH). Strictly the geologist is only concerned with the part he can see or whose condition he can infer by analogy, as will be explained later. Here it need only be said that the core of the earth is certainly made of heavier material than the outside rocky part, which is usually spoken of rather vaguely as the crust. This term may well be adopted for convenience, although it must not be understood as necessarily implying a sudden change of material or state at any particular depth. There is reason to believe that concentric depth-zones do exist in the earth, but we do not yet know for certain what they are made of. At any rate the earth as a whole is a very rigid body, as strong as solid steel at least; it is impossible to believe in a liquid interior of any considerable size, although the phenomena of vulcanicity do seem to indicate the existence of local fluid patches, and it is also certain from similar reasoning that the interior is intensely hot. The actual composition of the accessible part of the lithosphere and the mode of origin of its component rocks come within the province of petrology (*q.v.*). Another point of first-rate significance in modern theories of earth-physics and earth-movements is the undoubted fact that the distribution of density in even the outer crust is not uniform: it is clear that on the whole the continents and mountain ranges consist of light rocks, while those underlying the great oceans are heavier. This discovery has far-reaching consequences, for a discussion of which see ISOSTASY.

The internal heat of the earth, together with the circulation of water from the hydrosphere to the atmosphere and back again to the lithosphere, which is mainly due to the energy of the sun, constitute the main motive power of the geological engine.

Denudation.—In an earlier section it was suggested that the best starting point for a discussion of the geological cycle is the wearing away of the earth's surface, or denudation.

Weathering.—This consists of three stages, weathering, transport and corrasion. The first consists of the loosening of the material of the rocks by various chemical and physical agents, mostly of a meteorological character, rain, snow, ice, the action of atmospheric gases and so on. The meaning of the second term is almost self-evident: to see examples it is only necessary to look at a muddy river during a flood, to examine the material piled up at the foot of a glacier, or to watch the clouds of dust on a windy day. The term corrasion needs a little more explanation: it means the work done by the weathered material during transport; the wearing away of the bed of a stream by the sand held in suspension, the scooping out of its bed by a glacier, or the fretting of a rock surface in the desert by wind-blown sand. The solution of limestone by water, which often leads to the formation of caverns, and the wearing away of cliffs by the sea are also further examples. Corrasion at some particular point is often followed by collapse of adjoining rock masses, as when a river undermines its banks. The formation of the screes so well known in mountain regions is due to the breaking up of the rocks by frost.

Purely chemical processes also have an important effect in weathering of rocks. Compounds of iron are very abundant in nature and these readily undergo a process exactly like the rusting of steel under the influence of water and oxygen. Nearly all rocks show a rusty crust very unlike the appearance of a freshly broken

surface. In the tropics this chemical action is so powerful that normally hard rocks like granite become so soft to a depth of scores or even hundreds of feet that they can be dug with a spade or washed away by hydraulic power in the mining of the valuable minerals that they contain, such as ores of tin. The natural denudation of such rocks has also set free great quantities of tin ore, gold and platinum and valuable gems, which are carried down to lower levels and form rich alluvial deposits.

Certain sulphides of iron and other metals, which are very abundant in nature, easily undergo oxidation, giving rise among other products to sulphuric acid, which is a most powerful corrosive, and brings about a pronounced decomposition of many minerals and rocks.

By the action of these and similar processes the rocks are either removed altogether or reduced to a crumbly condition, so that they may easily be removed.

Transport. — The next stage of denudation consists of the removal of the material thus prepared by weathering. Some constituents may simply be carried away dissolved in water, but more commonly it is transported in a solid form, the chief agents concerned being water. ice. wind and gravity.

The transporting power of streams is a commonplace hardly needing elaboration: it is certainly a fact that most streams do nearly all their work in flood-time. The amount of mud and silt brought down by great rivers like the Nile and the Mississippi is proverbial, while steeper streams and mountain torrents bring down vast quantities of gravel and great boulders of rock, often to the plains below. There are instances in some of the drier regions of the world, as in parts of Central Asia, where rivers flow into great depressions among mountain ranges and there dry up, owing to great evaporation. In such cases there may evidently be terrestrial deposits of very long duration and of very great thickness, but this must be regarded as an exceptional type, although it is believed to have occurred fairly often in the past.

The second great agent of transport is moving ice, but of course this is only effective in cold regions, either in the Arctic and Antarctic, or in high mountains in more temperate latitudes, where glaciers are formed. They carry down vast quantities of rock-waste derived from the sides and floor of the valleys, and deposit it at lower levels. The glaciers of high latitudes, which reach the sea, deposit their material there direct.

It is only in desert regions that wind is the chief agent of transport, where it forms sand-dunes, but even in temperate climates a lot of fine dust is blown from place to place in dry weather. In East Anglia a lot of material is shifted by wind, and the sandhills of the coasts of western England and Wales and the east of Scotland may also be instanced. Such sandhills are common where an on-shore wind prevails and blows the beach sand inland. This is really a process of deposition rather than denudation, but is mentioned here as an instance of the geological power of the wind.

In a similar way the transporting power of waves, tides and currents, belongs largely to deposition. The wearing away of coasts by the sea will be considered later, as it is so inextricably mixed up with the formation of marine deposits.

Rivers and the Development of Drainage Systems. — It is apparent from what has already been said that rivers form one of the most important, if not the most important, of geological agents under normal conditions of climate, in temperate and also in tropical regions: it is really only in the arctic areas that they are non-existent. The drainage basin of a river-system is the whole area from which the drainage is carried off by one river and its tributaries; and it has been found by study of drainage systems in areas of simple and uniform geological structure, such as some of the Western States of America, that there is a considerable amount of regularity in the plan and development; and the history of some British river systems has been worked out, though most of these are more complicated

The Ideal River-system. — The classical description of the development of an ideal river-system was worked out by G. K. Gilbert in his Geology of *the* Henry *Mountains* (1877). Gilbert begins with the conception of the rise of a new continent from the sea, in the form of a simple arch, known technically to geologists as an *anticline*, or *anticlinal* uplift. Rain soaks into the ground to some extent, to issue eventually as springs a little below the summit line on either side, thus giving two rows, which are usually supposed to alternate, and not to lie opposite to one another in pairs. From these springs streams run down the continental slopes in either direction, naturally choosing the steepest slope, which is also the shortest line to the sea. Such rivers are called consequent streams, because they are the direct result of the uplift. These rivers naturally increase in volume downwards, by collecting the rainfall from the lower slopes, which gives rise to tributaries. In Gilbert's original theoretical exposition it is argued that these tributaries should run into the main stream at right angles, for the reason that most stratified rocks consist of layers of varying hardness, of which the harder naturally resist denudation more than the softer; hence when the surface of the continent has been lowered somewhat by general denudation there will be strips of hard and soft rock, or of high and low ground, running parallel to the original main line of uplift, and therefore at right angles to the consequent streams. In the slight hollows formed by the softer strata the principal tributaries settle down and are called *subsequent* streams. In reality they always incline a bit do nhill and enter the main stream at oblique angles. These subsequent streams themselves develop tributaries which may in practice run at all sorts of angles into the subsequents.

Some of the rivers of north-eastern England, such as the Tyne, Wear and Tees, conform more or less to this ideal arrangement, though there are complications which cannot be described here in detail. The rivers of the west and south of England are even more complicated, since in the course of their history some of them have interfered with others and spoiled their symmetry.

Diversions of Drainage. — The next thing to be considered is the manner in which some of the more simple of these departures from the ideal development have been brought about. One of the easiest of them depends again on the principle just mentioned that soft rocks wear away more quickly than hard ones. The general lowering of a valley, by steepening the slopes, makes denudation more rapid.

Now let us suppose that for some reason, for example a higher rainfall, denudation is more rapid in the valleys of one subsequent than in another running in exactly the opposite direction along the same line of soft rocks. It may then happen that the first named, by working backwards at its head more rapidly, may capture some of the minor streams that originally fed the other. Or it might even cut back so far as to intercept the next consequent stream and divert all its water.

Any one who has looked intelligently at the scenery of a mountain region will have no difficulty in grasping what is meant by the idea of a stream working back at its head. The steep slopes and piles of detritus at the top of any mountain valley are eloquent witnesses of the process. The pass always found between two peaks shows the cutting-down in operation, and indeed the forms of most mountains are the direct result of the encroachment of valleys on their mass in this way. The eastward-flowing rivers of Yorkshire and the northern Midlands which combine to form the Ouse and Trent, and eventually the Humber, afford a magnificent example of this process of capture and diversion.

Sometimes the original uplift, instead of being an elongated ridge, was a rounded dome. Then the drainage system will be radial like the spokes of a wheel, as is seen in the English Lake District. Along the courses of most of these radial rivers lakes have been formed, for reasons to be discussed in a later section.

Sometimes, again, instead of being a simple arch, it takes the form of two or more parallel ridges. Then it is evident that the consequent streams just described must run as tributaries into a river flowing along the trough between the ridges, which is called a syncline. This trough will probably be tilted one way or the other, so as to determine the direction of this stream, which is also a kind of consequent, since its course is directly determined by the earth-movement. The lower part of the Thames below Reading is a river of this kind, flowing in the trough between the

North Downs and the Chiltern Hills.

Meanders.—Rivers do not as a rule keep a straight course throughout the whole of their history, but eventually develop curves, called meanders, from the name of a singularly winding river in Asia Minor. This depends largely on the fact that there is a limit to the deepening of a valley, which cannot be cut below sea-level, and eventually assumes a very gradual slope from its source to its mouth. This limiting level of deepening is called the base-line of erosion. When this is reached, the river has to use up its energy somehow, and does so by cutting sideways. Any original slight variation from a straight course tends to get accentuated, and this is a cumulative process. Cases are known where the curves have become so sharp that the river in a flood cuts across the narrow neck between two bends and shortens its course, leaving part of its bed as a sort of crescent-shaped lake, known as ox-bows in parts of the United States.

Rejuvenation.—If at some time during the existence of a river a further uplift of the land takes place, the river will again begin to deepen its valley backwards from the mouth, thus producing a step somewhere in its course; this is one way in which "hanging valleys" (see Ice and Snow as *Geological* Agents below) can be formed. If the river was meandering on a wide plain when the second uplift occurred the result may be a deep meandering gorge, like the course of the Wear at and below Durham. The second uplift causes the river to deepen its bed, but it cannot lower the whole plain.

Inconsequent Drainage.—The types of drainage system hitherto discussed are those in which the arrangement of the rivers is the direct consequence of the structure of the underlying rocks, but some examples are known in which it appears to be quite independent of such structures. In certain instances it is observed that rivers, rising at one side of a great mountain chain, cut right through the range and continue their course on the opposite side. Some of the best instances are the Indus and the Brahmaputra, both of which rise on the northern side of the Himalayas. Again, the Danube twice cuts through the great mountain chain of southern Europe, once at Vienna and again at the Iron Gates (see Earth Movements, below). In such cases the only possible explanation seems to be that the river is actually older than the mountains, and kept its course open through them as they rose. Such a relation is called *Inconsequent* Drainage.

ICE AND SNOW AS GEOLOGICAL AGENTS

It has already been stated that ice is an important agent of transport. It is now necessary to consider its efficacy from a more general point of view in moulding the surface of the earth into the existing forms. For there is no doubt that in the colder regions of the earth land-ice has a great power of erosion.

The existence of permanent snow in any given region is a matter of climate. When the temperature is below freezing-point, precipitation falls as snow. If the average temperature of any region is below this point it is obvious that the snow will remain, and will continue to accumulate. In the arctic and antarctic zones this condition prevails down to sea-level: even on the equator the snow-line is reached at about 16,000 feet. Consequently in many temperate regions we find permanently snow-clad mountains, as in the Alps, the Caucasus, the Himalayas, the Rockies and the Andes. The snow-line is the level at which the snowfall of winter and the melting of summer exactly balance. But in many valleys glaciers extend far below this level.

Glaciers.—When snow accumulates to a great thickness the weight of the upper part squeezes the lower layers together to form ice, exactly as a handful of loose snow can be squeezed into a snowball. Now when ice occurs in very large masses, it acquires, in a manner not yet quite explained, the power of flowing downhill, like a very viscous liquid The rate of flow of a large glacier is very slow, being measurable by inches, or at most a few feet per day; nevertheless they move sufficiently fast to extend below the snow-line, and to do much geological work in transport and corrasion.

In addition to the mountain glaciers of the type just sketched, it is necessary to take into account the ice-caps and ice-sheets such as are now found only in the highest latitudes of both hemispheres, but formerly existed in many other parts of the globe (see GLACIAL PERIOD). These have often covered enormous areas, and have transported vast masses of material. Thus the great Scandinavian ice-sheet of the latest northern glaciation brought innumerable boulders of Norwegian rocks to the east of England, and effected great modifications of the topography of Yorkshire and East Anglia by deposition and erosion.

The material transported by mountain glaciers of the Alpine type is derived from two sources. Part of it falls on to the surface of the ice from the steep slopes above, where it is mainly loosened by frost action, and part of it is torn from the bed of the glacier by the movement of the ice. Much of the surface material eventually falls down cracks (crevasses), and reaches the floor where it becomes mixed up with the material torn from the bed, the two forming the ground-moraine. The rock waste that remains on the surface also forms moraines, ridges of gravel and sand, whose form and distribution depend on the number of valleys that join to form the glacier. Where two valleys join, the trains of moraine from the right bank of one and the left bank of the other combine to form a medial moraine down the middle of the compound glacier. When a glacier ends in a wide open valley the moraine material is dumped as transverse ridges, often crescent-shaped, called ternzinal *moraine*. Many of the large Alpine glaciers however end in deep gorges, like the Aletsch, the biggest glacier in Europe. In such a case the moraine material is usually carried away by the stream that always issues from the end of a glacier, and forms torrential river deposits below.

In a good many cases where glaciers have retreated owing to a change in climate, they have left moraine barriers across valleys; these barriers often hold up lakes, as described in a later section.

Ice-Erosion and Hanging Valleys.—For many years there has been discussion and difference of opinion as to the power of glaciers to scoop out the valleys in which they lie. Some authorities maintain that they have little effect, being able only to bring about slight modifications in the form of pre-existing valleys due to rivers. Glacier ice is a powerful agent of erosion and has been the main factor in the formation of many great mountain valleys. At present probably the balance of opinion inclines to the latter view. One of the strongest arguments in favour of extensive ice-erosion is the existence of "hanging valleys," a term denoting (a) a sudden steepening of slope in the floor of a main valley for a short distance—a kind of step, and (*b*) the sudden fall of a tributary valley of fairly flat grade in its upper parts down a steep slope into the main valley, sometimes forming a waterfall. The last-named is probably the more significant for the present purpose. The argument is that the valley system was once occupied by ice, which was thickest in the main valley and therefore more powerful in erosion. Hence the main valley was deepened more rapidly than the tributaries, whose mouths were left hanging in the air, as it were. Or it might have so happened that there was no ice at all in the tributaries. Further it is noticed in many cases that the main valley shows a U-shaped section, with a flat floor, steep sides, and no projecting spurs, whereas the tributaries have the V-shaped section and alternating spurs characteristic of valleys in regions that have never been glaciated. Borrowdale in the Lake District shows some good examples of hanging tributaries, *e.g.*, the Falls of Lodore, and Sour Milk Ghyll, above Seatoller.

Glaciers also produce certain characteristic features in the rocks over which they travel, features often only properly observable when the ice has disappeared. The surface of the rocks forming the sides and floor of the valley is often remarkably smoothed and polished, with sometimes scratches and grooves produced by stones embedded in the ice, showing clearly the direction of motion. In the same way stones embedded in the sole of the ice are scratched by the rock below, and are often found in terminal moraines thus marked. The presence of such scratched stones is one of the best criteria for the glacial origin of a deposit.

Roches *Moutonnées.*—Again, the rocks over which a glacier has passed often show a peculiarly hummocky outline, known as roches *moutonnées,* a term derived from a supposed resemblance to the curly fleece-like wigs of the 18th century. These rocks often

show a smooth gentle slope up-stream, due to the grinding action of the ice, and a rough abrupt scarp down-stream, where blocks of stone have been torn off bodily along joints. Below a large *roche moutonnée* or any other projecting boss, there is often a long line of debris, this formation being known as crag *and* tuil. Another notable feature of glaciated valleys is that the smooth and polished lock-surfaces often end abruptly upwards, at the original line of the top of the ice, the slopes above showing the sharp pinnacles of frost-riven rocks, which have not been ground down by the ice. All these phenomena are clearly apparent, along with moraines, in regions where there are now no glaciers, giving clear evidence of their former presence.

Erratic blocks.—Further evidence of the same fact is afforded by what are called "erratic blocks," great boulders which have often been transported far from their original home and left stranded when the ice melted (see GLACIAL PERIOD). Such are abundant in all formerly glaciated areas, and are often of the utmost value in tracing the courses of former ice-streams.

Wind **Erosion.**—A brief reference has already been made to transport by wind, the geological effect of which in many desert regions is important, since rocks are to a large degree worn away by the erosive power of the wind-borne sand. Opinions have differed as to how much of the denudation of arid regions is actually due to the wind: some authorities attribute most of the erosion to the chemical action of dew and salt solutions rising from the ground owing to evaporation, and hold that wind merely puts a superficial polish or etching on forms produced in other ways; other geologists consider that quite large rock-masses can be removed in time by the gradual effect of the sand-blast. One very noticeable effect of wind action in many areas is the under-cutting at the base of cliffs, and in dry regions many strange rock-pillars, mushroom rocks and other forms are to be found. Such indeed are not unknown in the drier parts of England.

As a matter of fact wind is much more important in geology as an agent of transport and deposition than of erosion. More will have to be said about this when we come to consider the characteristic deposits of arid regions (see also DUNES).

Limestone Regions.—There is another and very distinctive type of denudation which may well be considered here in somewhat more detail. It is well known that calcium carbonate, the essential constituent of limestone, is much more soluble in water than most common minerals, and it is specially so in acid water (all freely-circulating water is slightly acid; only the stagnant water at great depths is neutral or feebly alkaline). Hence the denudation of limestone rocks is mostly due to solution, and is of a special character. Another important factor is that limestone rocks are usually well jointed (see JOINTS), with a strong tendency to form more or less cubical blocks.

Many limestones are very pure, such as the Chalk and a good deal of the Carboniferous limestone of England and North America. Hence the whole rock can be dissolved away, leaving very little residue, which is mostly a fine sand or more commonly a reddish clay. Soils on such rocks are therefore often very thin, or even non-existent. A large bare expanse of limestone rock is by no msans rare; rain falling on such a bare surface with open joints will of course flow down into the joints and will widen them by solution, thus giving rise to the peculiar forms known as "grikes" in the north-west of England (Ingleborough, etc.) where there is in some places nearly as much open joint as rock; the joints usually run parallel for long distances and the surface consists of knife-edges of rock with fissures many feet deep between them. If there are two equally well developed sets of joints more or less at right angles the surface will consist of isolated four-sided blocks.

Caves.—It is easy to understand that if solution is so active at the surface it will also go on underground. Rain and small streams falling down joints and running underground often widen the joints very greatly far below the surface. to such a degree as to form great caverns, which are very numerous in many limestone regions, as in west Yorkshire, Derbyshire and the Mendips in England; south-eastern Belgium, the country east of the Adriatic; and Kentucky among many others (see CAVE). Besides actual caves in many places, indeed in most limestone areas, the main part of the river system is underground; surface streams are rare, and often disappear at some part of their course. Dry valleys sometimes occupied by streams in very wet weather are numerous in the Chalk Downs of southern England.

Another remarkable phenomenon is afforded by the *swallow*-holes or pot-holes often seen in such regions, where a stream suddenly disappears down a vertical shaft, often running into a cave below. One of the most remarkable is Gaping Ghyll on Ingleborough, Yorks., which is 365 ft. in vertical depth; the stream runs for a long way underground and eventually comes out in Clapham Cave. Most of its course has been explored.

The above-ground topography of limestone regions is often very remarkable. Rock-pillars, cliffs and gorges are common in many places, such as Dovedale and Matlock in Derbyshire. The Cheddar Gorge in Somerset is supposed to be due to the collapse of a cave. Some of the most remarkable limestone hills are found in Kedah and Perak, in the Malay peninsula; some show vertical or nearly vertical faces from 1,500 to 2,000 ft. high and many of these cliffs overhang considerably for a height of hundreds of feet.

Limestone pinnacles.—Another remarkable feature seen in the same area, especially in the Kinta Valley, is the formation of pinnacles of limestone, below a covering of newer deposits. These pinnacles, where uncovered in the alluvial tin-mines of the Kinta Valley, show very extraordinary forms. From the disposition of the overlying deposits it is quite clear that the upper surface of the limestone was once smooth and that the solution went on underground and is even now in progress.

All the features of limestone denudation, which may be equally well developed in dolomite rock, are specially well seen in the Karst plateau east of Trieste; hence, geologically, this kind of scenery and formation is known as the Karst type.

In order to save space and avoid repetition a general account will here be given of the geology of coast-lines; this involves a consideration of the joint effects of causes belonging to several different categories, namely denudation, deposition and earth-movements.

The geology of coast-lines is a complicated subject, because it is only rarely that one simple process or set of related processes is in operation. Still it is possible to state that on broad lines some coasts are being destroyed while others are being built up. Thus in England it has been shown by a Royal Commission on Coast Erosion that in a given period the gain of land in England, mainly on the west, was five times as great as the loss, mainly on the east. Thus the country is not being washed away, but is actually getting larger, though the destruction of existing land is more striking and spectacular than the building up of new areas and so receives more notice.

Loss of land may be due to two causes, marine denudation, or actual sinking of the land. Gain of land may be due to deposition of new material along a fixed coast line, or to an uplift of the whole area. In either case it is usually easy to decide which causes have been at work.

Marine Denudation.—The destructive power of the sea hardly needs extended demonstration. Its chief agents are waves, tides and currents. The power of the waves is enormous, as is easily seen by the destruction of sea-walls, breakwaters, etc., during a storm: and there is no doubt that the sea does most of its work of coast-erosion during storms just as rivers do most of their destructive work during floods. The waves batter at the cliffs and tear off blocks of rock, usually along joints; they thus undermine the base, and the upper parts of the cliff slide or fall down. The compression of air in cavities and open joints by the force of waves is important, and sometimes blows holes in the land some distance back from the end of the cliff, as is seen, *e.g.*, in S. Wales and Cornwall. There is a very fine specimen close to the Lizard lighthouse. Naturally the sea wears away soft rocks faster than hard ones, long narrow inlets formed along a band of soft rock running at right angles to the general coast-line being not uncommon. Another feature of coasts of hard rock undergoing destruction is the formation of stacks. pinnacles, skerries

and islands; abundant examples are found on the west of the British Isles, and some on the east. Common also on such a coast is a belt of shallow sea studded with sharp rocks, with a wave-cut platform extending far out to sea below low-water-mark, constituting a danger to navigation. In other cases there is a rock platform between tide-marks, and here there is little or no loose beach-material on the open coast, though it may accumulate in sheltered spots.

On coasts composed of soft material undergoing destruction, conditions are rather different. There is generally not much cliff but a gradual slope, the outline of the land is smoother and the wave-cut platform is not conspicuous, being replaced by a uniform slope seaward. Beach material is also more uniformly distributed and consists of smaller fragments; also, under the influence of the tidal currents, it tends to travel more along the coast, owing to the absence of sharp promontories to check it.

The two foregoing paragraphs describe simple, ideal cases, but in reality there are usually complications, and every shore-line has to be studied on its own merits. In a general way, if the effects of uplift or depression are excluded, a deeply indented coast-line indicates a country composed of rocks of very varying hardness, exposed to the fury of a prevailing on-shore wind and powerful tides. A smooth outline indicates a country of uniformly soft rock, sheltered from violent winds and with tides running parallel to the shore. Such in its broadest outlines is the reason of the contrast between the coasts of the west and east of the British Isles.

Drowned Valleys and Raised Beaches.—But a smooth coast-line can be broken up, or a rugged coast-line made simple in plan, by relative changes in level of land and sea. When the land sinks relatively to the sea the lower parts become submerged; the sea runs up the valleys and forms those long narrow winding estuaries which are so common in Cornwall and Brittany, and in north-west Spain, where they are called Rim. Within them submerged forests are often found. When, on the contrary, the land rises, its outline is frequently smoothed off and simplified in plan. The shallow sea floor is raised to form a low plain, often bounded by a row of inland cliffs, and if the rise is spasmodic, raised beaches may be formed at various levels. Thus, in many places round Scotland can be traced raised beaches at 25, 50 and 100 ft. respectively, above present sea-level; they are not uncommon in S. Wales, Devon and Cornwall; and in Norway they are well developed at great heights.

Fiords.—Striking effects are produced when an area of highly developed glacial topography is submerged. The sea runs far up the long, straight and steep-sided (U-shaped) valleys already described as characteristic of ice-erosion; waterfalls drop straight from the mouths of the hanging valleys to the sea and there is little or no beach at the foot of the cliffs. In some of the fiords of Norway, British Columbia and New Zealand great walls of rock ascend for 4,000 or 5,000 ft. almost sheer from the water's edge, giving rise to some of the finest scenery of the world, similar to that of the western Highlands of Scotland, which also originated in this way.

Marine Deposition.—It has already been pointed out that material removed from the land by denudation is ultimately carried down to the sea, there to be deposited and built up into the new rocks that take part in the next phase of uplift and land-formation. It is therefore obvious that marine deposition is one of the most important processes in geology.

The Materials of Marine Deposits.—These are in part brought down by rivers, in part derived from the waste of the coast, and in part provided by the activity of animals and plants. When the material forming any ordinary beach is examined it is usually found that there is a distinct gradation in the size of the fragments composing it. Near the base of the cliff, or about high-water-mark if there is no cliff, are found large blocks of rock, more or less angular or rounded. Below this comes shingle or gravel, usually well rounded, which gradually passes downwards into sand, extending commonly below low-water-mark. The material usually gets finer and finer out to sea, and soundings show that sand eventually passes into mud. Very often too, in the estuaries of large rivers and along certain low coast-lines, mud banks can be seen between tide-marks. Besides all this there are often shells and other organic matter, either living or dead, and in many of the warmer parts of the world, solid organic deposits, coral reefs, etc., are found. We thus arrive at a natural classification of modern marine deposits—boulders, gravel, sand, mud and organic material. The peculiar deposits found in the very deepest parts of the oceans will be disregarded for the present.

Distribution of Deposits.--One of the fundamental principles of geology is that the stratified rocks of past ages have been built up of exactly similar material, and that the modern deposits of the sea-beach will some day form rocks just like the older ones (see SEDIMENTARY ROCKS for mechanism of process). Of course the distribution of beach material is never uniform, for it is controlled by many agencies such as waves, tides and currents, and is sometimes transported for long distances; it is well known that along the south coast of England, for example, the shingle mostly travels from west to east, movement easily accounted for by the prevailing winds and tides. At one point, near Portland, there is a local eddy due to the shape of the land, and the shingle turns back west, thus forming the well-known Chesil Beach on the Dorset coast. In the east of England the set of the tides is mainly from north to south, and long gravel spits are formed, such as Spurn Head and the great beach at Aldeburgh, where the river is turned south and runs for 9 or 10 m. parallel to the shore before it can get through the shingle banks.

ARID REGIONS

An arid region may be defined as one in which the average annual rainfall is less than 10 inches. The limit thus fixed is of course quite arbitrary, but it represents approximately a boundary between moist and dry regions possessing different geological and biological characters. Within this category, however, there is room for a considerable amount of variation, and a great deal depends on the seasonal distribution of such rain as there is. Some areas with a quite appreciable amount of rain may be absolute deserts, if the rain all falls at once, or within a very limited range of time, whereas on the other hand a surprisingly small total, well distributed, may give comparative fertility. Obviously, also, temperature is an important factor. It is well to remember that in reality the arctic regions are rather dry, if the snow that falls is calculated as rain, but the effect of the low temperature is to create here a special type of geology, which is dealt with elsewhere.

Deserts.—What we are here concerned with is the hot, dry regions of the world (see CLIMATE and CLIMATOLOGY); the idea conveyed to most people by the mention of a desert is sand, and this is for the most part a true conception, but there are also rock-deserts, as in parts of Egypt and the Sahara.

The true arid regions of the world are defined also as those from which there is no drainage to the sea, and it is stated by Walther that no less than one-fifth of the whole land surface of the globe belongs to this type. Such arid regions naturally include all types of topography, mountains as well as plains or basins, and some parts of them are below sea-level (*e.g.*, the Dead Sea region, the lowest part of the earth's surface and one of the hottest).

Salt Lakes.—Now when a low plain or basin is surrounded by high mountains or plateaux there may be considerable rainfall or snow on the high ground, giving rise to rivers; these often dry up or become very small when they reach the low ground, owing to evaporation, or they may reach a lake, which is generally salt, because the dissolved matter carried down by the streams is concentrated as the water evaporates from the surface of the lake. The nature and origin of these salt deposits is described under PETROLOGY (*q.v.*) and will not be pursued further here, but it should be emphasized that salt deposits and salt lakes form some of the most characteristic features of deserts. If a dry region lies fairly near the sea a prevailing wind may carry a lot of salt inland for a long distance; the saltness of part of the desert region of N. W. India is attributed to this cause.

Desquamation.—In a dry region the chief weathering agent is sudden changes of temperature, aided by the chemical action of dew and strong salt solutions. The changes of temperature shatter

the rocks and often cause thin slabs to scale off and accumulate in piles at the foot of slopes (the desquamation of Richthofen): chemical action and wind carve the rocks into fantastic shapes, and the rocks are often covered by a peculiar dark enamel, due to evaporation of solutions containing iron or manganese.

Wind Transport.—The chief and practically the only transporting agent is ***wind.*** This differs from other geological agents in that it can, and often does, carry material uphill, against gravity. It can also carry fine particles across rivers and lakes and across even quite broad stretches of sea. During gales sand derived from the Sahara is often noticed in southern Spain and Sicily. The deposits of salt formed in lakes are often discoloured by fine dust blown in by the wind.

But it is the behaviour of sand under wind action (see DUNES) that is the most notable characteristic of deserts. The grains of wind-borne sand-deposits show special features (see SAND) which enable a specimen to be distinguished readily from sands of other origins, for such sand grains are usually very well rounded ("millet seed sands"), and are thus readily distinguished when occurring among the older formations, cemented to solid rocks. Such deposits are sometimes of a red colour, since the iron present exists in the anhydrous ferric condition, but they are more commonly yellowish grey.

In deserts the direction of the wind is often very constant (trade wind or monsoon type) hence the sand drift often makes very well-marked grooves in definite directions on rock surfaces, and pebbles fixed in the ground show a peculiar triangular cross-section of the exposed part (Dreikanter), often with an exceedingly sharp ridge at the top. One of the most remarkable types of deposit found in a dry region is the Loess (*q.v.*) of central Asia and eastern Europe.

Oases.—As a rule the barrenness of an arid region is simply due to want of water; the soil contains plant-food in abundance if only water can be got into it. Hence arises the great fertility of the oases, places where natural springs occur, and the success of artificial irrigation schemes in the western United States, South Africa and Australia among other places. The soil is sometimes poisoned by soluble salts, but when irrigation is carried far enough to wash these out it may become very fertile, as in the case of the alkali soils of the western U.S.A.

Islands.—A short general account of the origin of islands seems to come in conveniently immediately after the section on coast-lines, though in reality it is a complicated subject belonging to several different branches of geology, as will appear shortly. An island is an area of land part of which is permanently above high-water-mark: a similar area submerged at every tide would be called a reef, shoal or sandbank. It is not possible definitely to limit the area to which the name may be applied; any rock part of which is permanently above water may be called an island, and so may the 2,950,000 sq.m. of the continent of Australia; and an island may have almost any kind of geological structure, and may be formed in an immense variety of ways. Some are clearly bits of a continent which have been cut off geologically by erosion or earth-movement, or both. Of this type the British Isles form a typical example, and most of the large islands of the world belong to it. Again a chain of islands or a long continuous island are often the highest parts of a mountain ridge that rose from the sea, but did not unite itself to a continent, *e.g.*, Japan. Many islands, especially those far out in the oceans, are obviously in the main submarine volcanoes, and another very important class, aiso often found far away from other land, is afforded by the coral islands. Naturally there are many transitional and doubtful forms: volcanic and coral islands are often much mixed up, and in the history of the larger islands of the world several processes have often played a part.

The British Isles.—Light is often thrown on the geological history of an island by a study of its living fauna and flora, as well as by its fossils. Thus Great Britain has fewer species of mammals and reptiles than the continent of Europe, and Ireland has fewer species than Great Britain. The natural inference is that Ireland was cut off from Europe first, before many species had arrived there in their westward migration, and that Great Britain was cut off at a later date, when more animals had arrived. Further, the study of island faunas and floras has been of enormous importance in the development of the doctrine of organic evolution, as set forth by Darwin, Wallace and many later biologists.

Continental Islands.—Taking first the group of continental islands, it is obvious that a tract of land may be isolated in two ways, or by a combination of them. The connection with the Continent may be severed either by denudation, terrestrial or marine, or by submergence, and in most cases, probably, the finishing touch is given by submergence. This is what seems to have happened in the opening up of the English Channel, which was once a great river valley with its watershed between Dover and Calais. A river cannot well completely erode its own watershed to sea-level, but either submergence or the waves of the North Sea might finish the work and break down the land bridge by which the animals migrated from the Continent.

Complex Formations.—In other cases it is clear that earth movements played the most important part. Thus, Madagascar is separated from Africa by a very deep strait undoubtedly due to the sinking of a long narrow strip of land. It is in fact a *rift-valley*, a term to be explained later. The formation of the islands of the Malayan region was evidently very complex, due partly to crumpling of the earth's crust into folds and partly to changes in the relative levels of land and sea due to some more general cause. The Malay peninsula only just escaped being another island very like Sumatra, as there is quite a low isthmus in Siamese territory to the north, where it was once proposed by Germany to cut a canal and intercept the trade of Singapore.

Coral Islands.—Apart from volcanic islands like St. Helena and Ascension (see VOLCANO), one of the most interesting types comprises those islands partly or entirely composed of coral and other calcareous organisms. These are only formed in the warmer parts of the world, like the Pacific and Indian oceans, and the West Indies, because corals cannot live where the temperature of the water falls more than a degree or two below 70° F; there are none on the west coast of America, owing to the cold currents. Coral structures (see CORAL REEFS; JURASSIC, TRIASSIC), are not always islands: they may also be reefs along the coasts of large land-masses either close to, or at some distance from the shore. Both forms existed in many parts of the world, even in high northern latitudes, in earlier geological periods: their fossilized remains are found in several geological formations in Europe, indicating very different climatic conditions from those now prevailing.

Lakes.—A lake may be defined as "a hole full of water," and the study of lakes is a somewhat complicated matter, since holes on the earth's surface can be formed in many ways, involving many different geological processes. The simplest classification is based on the three elementary ideas of (1) a hollow formed by earth-movement, (2) a hollow formed by erosion, and (3) a basin formed by the accumulation of some sort of a dam or barrier. The last two categories evidently resemble artificial ponds and reservoirs, but the first class rather stands by itself. It is evident, however, that the level of a lake belonging to either of the first two classes may be raised by formation of a dam, natural or artificial, as has indeed happened in certain cases, to be mentioned later.

Lakes definitely formed by earth-movement are usually large, and some of them are salt. Thus it appears that the Caspian and the Sea of Aral were once connected with the open ocean, but were separated by uprise of the land. They have now no outlet, and are salt. The great lakes of North America were probably formed by the cutting off of an extension of Hudson Bay; at one time they drained to the Mississippi, but the drainage was much interfered with by land-ice, and the St. Lawrence became the outlet. Recent movements in the area are indicated by the bending or warping of old beaches. All the great lakes of East Africa, except the Victoria Nyanza, are in "rift-valleys," which were formed by the letting down of long narrow strips of ground between two fractures. Hence their shape, and hence, too, they are very deep and have extremely steep sides, both above and below water. Tanganyika is the most typical example. Many of the

lakes of mountain regions like the Alps, etc., are determined by the uprise of chains (see EARTH MOVEMENTS, below), but they are often modified by glaciation or other causes.

Solution Lakes.—Lakes due to erosion of various kinds are numerous. One of the simplest types is where a hollow has been formed by solution of the rock below, such as limestone, or beds of gypsum and rock salt. The soluble rock need not lie at the surface: the solution may take place underground, below an impervious cover, which sinks down in the form of a basin and thus holds water. Lakes of this kind are not uncommon in various salt-producing districts, *e.g.*, some of the meres of Cheshire. Artificial ones are often formed by subsidence after salt-mining or brine-pumping. Very similar are the large flooded areas often seen in coal-mining regions, also of artificial origin, but good illustrations of the natural process. Some of the Swiss lakes in the St. Gothard region are believed to be due to solution of beds of dolomite-rock, etc.

Rock-basins.—Of more importance are the lakes due to glacial erosion. There has been in the past much controversy as to whether a glacier can scoop out a rock-basin, but the question is now considered to be settled in the affirmative. Such lakes are commonly associated with U-shaped valleys and all the other signs of glacial action previously described. Many of these rock-basins extend far below sea-level and yet have a continuous rocky margin all round, even at the outlet. A precisely similar state of affairs exists in many of the fiords and sea-lochs of Norway, Scotland, British Columbia and New Zealand, except that the barrier is below sea-level. Only a glacier could scoop out a basin of this kind, deep inside and shallow at the mouth. Some of the world's finest scenery is around such lakes and fiords—and it is of importance to notice that there is no real difference between a freshwater lake of this kind and a fiord; one happens to have its lip above sea-level, the other below.

Barrier Lakes.—This category includes a good many varieties. Thus the barriers and therefore the lakes may be of a very temporary nature. Examples of these are afforded by the lakes sometimes held up by landslips or avalanches, such as are not uncommon in Switzerland. Behind such a dam water may accumulate to a great depth, and sometimes the dam bursts suddenly. Several disastrous floods produced in this way are on record in the Rhone valley and also in the Himalayas. It makes very little difference whether the barrier is ice and snow or rock. Sometimes it happens that a glacier in its advance creeps slowly down and holds up a lake, as is seen in several places in the Alps. A famous example is the Marjelen See in the Bernese Oberland, where the great Aletsch glacier holds up a lake in a tributary valley, which overflows over a low watershed into the next main valley; the lake shows a distinct beach line at the level of this outlet, and such appears to have been also the origin of the famous Parallel Roads of Glenroy, in Scotland. On the other hand a glacier coming down from a side valley may build a dam across the main valley, as at the Mattmark See, above Stalden in the Saas valley, near Visp, Switzerland.

Moraine Lakes.--One of the most important groups of lakes comprises those held up behind the heaps of moraine left by retreating and melting glaciers. As described in an earlier section the terminal moraines of glaciers take the form of ridges lying across the valleys, which obviously form admirable dams for lakes, which may be of any size, from the small tarns and lochans, so common in the higher parts of the Lake District mountains and of the Highlands of Scotland, to big sheets of water like Windermere and Loch Lomond. As a matter of fact both the lakes just named appear to be rock-basins as well as moraine lakes; that is, the deepest parts lie in a rock basin, but the level of the water has been raised by a moraine dam. This state of affairs appears to be exceedingly common, and naturally, because the glacier at its maximum scoops the rock-basin and on its retreat deposits moraines.

EARTH MOVEMENTS

The study of earth movements in general forms one of the most important and interesting branches of geology; but for its proper comprehension it needs some acquaintance with certain features of geological structure—the results of disturbances of the rocks—so that here it is necessary to begin by arguing in a circle. We can to some extent get over this difficulty by starting with large-scale earth-movements that do not involve small differential movements. Certain necessary definitions can then be introduced as required.

Relative Nature of Movements.—Many of the facts of geology show that the relative levels of land and sea have changed. Strata of marine origin are now found forming part of very high mountains (*e.g.*, at 16,000 ft. in the Himalayas), and historical geology shows that alternations of submergence and emergence have been frequent in many areas. In the British Isles at least three marine periods and four continental ones can be traced (see STRATIGRAPHY, below). It is a moot point whether the middles of continents and the abysmal depths of the oceans have ever changed places, but it is clear that the margins of continents and certain epicontinental areas have been drowned and have emerged many times. In studies of this kind there is always the difficulty that we have no fixed datum line; we cannot measure the distance of any given point from the centre of the earth, and so we cannot tell in any case whether the land rose or the sea sank. All such movements have to be treated as relative; hence we speak of emergence and submergence, not of rising and sinking. These relative movements are exemplified on a smaller scale by raised beaches and drowned valleys (see above); and in such cases there need not necessarily have been any horizontal component in the movement; mere rising or sinking of the land would produce all the effects, and a possible cause is contained in the doctrine of isostasy (*q.v.*).

It has been suggested by American geologists that an actual lowering of the sea-level, simulating a rise of the land, might be brought about during a glacial period, by the locking up on a continent of a vast mass of water as snow and ice, since all precipitation is ultimately derived from the sea. This seems very probable and has been applied to explain some actual examples of old sea-beaches and wave-cut platforms. It is evident that during upward or downward movements of the land, the earth's crust might be fractured along the edges of the moving blocks, thus giving rise to faults (*q.v.*) but much more complicated and, therefore, more difficult to explain are those movements that are wholly or in part horizontal, for these may give rise either to compression or stretching of the crust, usually with local fracture and relative displacement of the fractured blocks. Under the influence of such forces the earth's crust often behaves as if it were plastic, so that originally flat and horizontal strata are occasionally crumpled into the most fantastic forms, some instances worked out in detail in great mountain chains, such as the Alps, or even occurring in hand-specimens of rocks only a few inches square, almost passing the bounds of belief. It is probable that extreme crumpling of this kind (for detailed consideration of which see **FOLD**), mainly occurs in depth under a heavy load of rock, whereas near and at the surface fracture is the dominant feature.

Movements Mainly Vertical.—It has already been briefly stated that movements due wholly or almost wholly to forces acting vertically are believed to have occurred in the past, and probably to be in progress at the present time. Such may be conveniently designated continent-building movements, though it would be more strictly correct to call them movements of continental blocks. For full details of the mechanism of such movements reference should be made to the articles EARTH and ISOSTASY.

Floating Continents.—According to the most recent ideas the continents form more or less permanent units, blocks consisting of rocks of low average density which behave as if they were floating in a substratum of some plastic and considerably heavier material. This heavy material, which is supposed to have the composition of basalt, is found at or very near the floors of the great ocean basins, and extends under both oceans and continents to a very great depth. Further, in order that the equilibrium of floating may be maintained any extra high elevation on the top of a continent, *e.g.*, a mountain range or plateau, must be balanced or compensated by a corresponding bulge downwards of the lighter

rock of the continental block. According to this theory the continents are regarded as behaving like ice-floes and icebergs floating in the sea. If we know the densities of water and ice and the amount that the floe projects above the water, we can calculate the thickness of the part submerged. Similarly, in the case of a continental block; if we know its average density and that of the substratum, as well as the average height of the continent above the sea-floor the thickness of the continental block can be calculated, theoretically at any rate, for—since both are so uneven—the difficulty of determining the average height of the continent above the average sea-floor complicates matters.

Rise and *Fall* of Land Masses.—Now suppose such a floating continent is undergoing denudation; it is necessarily becoming lighter and will therefore rise, and the same effect will be produced if a great ice-sheet melts. On the other hand a continent may be made heavier by the formation of an ice-cap, or by the outpouring of great floods of lava, as has indeed happened in earlier geological times; while another cause that has been invoked to account for continental sinking depends on the melting of part of the substratum by heat generated by radioactive disintegration, the substratum thus losing part of its density and the equilibrium being deranged. This explanation is, however, at present regarded as highly speculative.

Many of the facts of geological observation, such as raised beaches, drowned valleys and what are called transgressions of the sea over the land on a large scale, as well as the corresponding general emergences, certainly seem to indicate that extremely widespread and uniform movements do take place, of just the kind that would be expected in accordance with the theory or group of theories here outlined. It is also clear that the greater movements of this kind may also be accompanied by subsidiary effects on a smaller scale, such as fractures of the crust and similar phenomena. These must, however, of necessity be very similar to the types to be presently described as resulting from a special kind of tangential force and the two may conveniently be discussed together.

Movements with a Horizontal Component.—The full discussion of these phenomena involves some of the most difficult problems of modern geology. However, we can discriminate between the causes and the effects. For the first-named, reference may be made to the article, **EARTH.** The main geological importance of the effectsis the part played by them in the structure of the visible crust, the effect on topography and scenery, and—what is of vastly greater importance—the economic bearing of such structures in mining and allied industries. And it is well worth while to emphasize the fact that the highly complex structure of many mining areas, especially coalfields, has been elucidated, and their economic working made possible, as a result of what were in their inception purely theoretical studies of earth-structures in some of the more complicated regions.

Tension and Compression.—Movements possessing a horizontal component result sometimes in tension (stretching) of the earth's crust, sometimes in compression, and the effects in the two cases naturally show differences. It may be remarked in passing that tension in one place is usually accompanied by compression elsewhere, since the total volume of the crust, regarded as a skin, does not change. In the early days of the earth's history, the crust probably did shrink in volume, owing to contraction on cooling, but for long ages its temperature has obviously been pretty constant, whatever may have happened to the interior. Hence mere shrinking of the crust will not account for its movements, nor, above all, for the forces of tension that have affected it.

In discussions of the general aspects of this subject, stress has been laid on the idea that after the crust cooled to a constant volume the interior may have gone on shrinking so that the crust became too large for it and tried to adjust itself to the new conditions by wrinkling like the skin of a dried apple. A few years ago most geologists poured scorn on this simple conception, but it has lately been revived, especially in Germany, and it certainly deserves grave consideration.

As a result of these processes, whatever their origin, two fairly clearly defined types of structure are produced—faults (*q.v.*) and folds (*q.v.*). It must be understood, however, that there are types of structure intermediate between them, or combining the two, in that folds, when pushed too far, often pass over into faults, just as excessive crumpling of a sheet of metal may cause it to crack. Furthermore, an extreme degree of compression often results in cleavage (see **SLATE** and **SCHIST**).

It has already been mentioned that lateral movements of the earth's crust may occasion either tension or compression, and that the resulting structures in each case are characteristic. It is not difficult to see that the chief result of tension will be cracks, *i.e.*, faults, while in compression folds will be dominant. Now the formations produced in regions of tension will in many ways resemble, though on a smaller scale, the results of the purely vertical movements already described. Naturally, one of the principal consequences of such movements will be the tilting and sinking of blocks between faults; it is difficult to see how they could ever result in elevation, for it seems inevitable that the only real movement possible under gravity is sinking; but in geology, movement always appears relative.

Plateau-building Movements.—Now if the crust, in a region of more or less horizontal strata, is cut up into blocks in this way, as a result of relative movement some may be left higher than others, forming plateaux. This result is so common and characteristic that the whole group of phenomena are often summed up as plateau-building movements.

The subject has been studied systematically in the Great Basin region, the area lying between the Rocky Mountains on the east and the Coast Ranges on the west, where conditions are specially simple and favourabie for generalization. The Rockies are the result of a thrust towards the east, while in the Coast Ranges, the thrust was towards the west; hence the area between was stretched and cracked, and collapsed in blocks with tilting of the individual blocks. As is so often the case, the collapse was accompanied by great floods of basaltic lava, which helped to weigh down the blocks. In some cases the strata were not cut clean through by faults, but bent sharply at the edges of the blocks. It appears that similar structures can also be produced by the forcing in below the surface of a mass of molten material, as explained in the section on igneous intrusion. In this case the surface may have been uplifted in the absolute sense, but this phenomenon belongs to a rather different category.

Block Structure in Britain.—Some of the types of structures just described as characteristic of plateau-building movements are also to be seen in the British Isles, though there the conditions are not quite so simple. Some of the best-known examples are found on the western side of the Pennines, on the borders of Yorkshire, Durham and Westmorland. Here the rocks are on the whole uplifted to form a very flat arch, steeper on the west than on the east. Especially on the western side, cracks and flexures developed in this arch, and the general result is very like the block-structure of the Great Basin, on a smaller scale. The blocks are separated by great faults, some of which show a very large displacement. Similar structures are also developed among the younger and less-disturbed rocks of many parts of the world where the conditions, on the whole, have involved tension rather than compression.

Effects of Compression.—When we come to consider the types of structure produced as a result of compression, the matter is much more complicated. The general effect is in most cases a combination of folding and faulting, sometimes one being dominant, sometimes the other, and it is with the general effects on topography and surface forms of certain types of these that we now have to deal.

One of the fundamental general principles is that violent movements of compression tend to occur periodically throughout geological history and that their occurrence is usually confined to certain fairly well-defined regions of the earth, often taking the form of long narrow zones. Furthermore, when a given region has once been compressed and folded there is always a tendency for similar effects to occur along the same or nearly the same lines. Without entering into a discussion of causes, a brief out-

line may be given of the usual order of events in an area affected by movements of this kind.

Mountain-building.—The first phase is that a long narrow area of the earth's crust, usually part of the sea floor, begins to sag, forming what is known as a geosynclinal: at the same time deposition of sediment goes on *pari passu* with the depression, so that eventually an enormous thickness of shallow-water marine sediment of very uniform character is accumulated, sometimes amounting to 50,000 feet. After a long time, probably owing to rise of temperature due to the blanketing effect of the sediment, the direction of movement is reversed and the geosynclinal begins to swell up and eventually as it were, boils over. At the same time the two stable margins of the trough approach each other, like the jaws of a vice, which accentuates the outward movement of the top layers. The rising strata are naturally thrown into violent folds, which tend to topple over outwards, and are often cracked and torn in the process. Broadly speaking, the effect is the production of mountain chains consisting of strata that have been strongly folded, fractured and over-thrust in one or more dominating directions.

It may happen that the thrust is mainly from one side, when the chain may consist of a series of nearly flat folds; on the other hand if the pressure from the two sides is nearly equal, the structure will be fan-shaped. The outer, complex margins of the fan may be separated by a considerable width of less complicated structure; sometimes, apparently when the main pressures have slacked off, this central portion may collapse and fall back to some extent. Such appears to be the origin of the Great Basin of western America, as before described, and it has been suggested that the Mediterranean region is actually a collapsed area between two mountain chains, the Alpine and Atlas systems—a complicated and much disputed question in which, however, it is generally admitted that the Mediterranean basin is a sunken area whatever may be the relations of the mountain chains around it. The plain of Hungary is another, on a smaller scale.

It must be clearly understood that a mountain chain in process of formation in the way just outlined may at the same time undergo denudation, so that the strata need not necessarily form such an enormous pile above the earth's surface as would be indicated by a theoretical restoration of all the missing bits of the folds. And we have also to consider the fact, which may be regarded as established, that rocks are only plastic when under a heavy load; near the surface they tend to fracture rather than to fold, forming thrust-planes and faults. Some thrust-planes, which are really only very flat faults, have a displacement to be reckoned by tens of miles—*e.g.*, the great Moine thrust in N.W. Scotland (see SCOTLAND, Geology) and the still greater Scandinavian overthrust in Norway and Sweden.

In this discussion we have hitherto dealt with phenomena on the very largest scales, measurable by miles in extent and thousands of feet in thickness. But in point of fact similar effects are found in every possible degree of magnitude. Precisely similar structures can be seen in slabs of rock only a few inches across, and even thin sections of rocks prepared for the microscope sometimes show them in the space of a few millimetres. Examples of complicated folding on a comparatively small scale, with its accompanying shattering and cleavage, are abundant in nearly all areas where the older rocks are exposed.

Vulcanicity.—This term will be used in a somewhat broad sense, to include not only the phenomena belonging to volcanic eruptions proper, but also those of an analogous character which occur in the depths of the earth's crust; the underlying cause is the same, the difference in the effects depending only on conditions.

The basis of the subject is the fact that the interior of the earth is very hot. At a depth of only a few miles the temperature is high enough to melt metals and all rocks such as we know at the surface. Whether the material is actually liquid is a moot point: at any rate it is potentially so. It is possible that it is really kept solid by the tremendous pressures that prevail in depth, but is liquefied if such pressure is in any way relieved, for example, by earth-movements. It is obvious that it is sometimes liquid, as shown by the streams of lava (*q.v.*) poured out by volcanoes. Geological observations also show that at times molten material has been injected underground into already existing rocks or into spaces between them. It is this aspect of the subject that will be chiefly described here. The superficial effects in general are dealt with under VOLCANO.

Magma.—The molten rock-material is, before its consolidation, usually spoken of as magma whatever its chemical composition; the types of rock that result from its consolidation are dealt with under PETROLOGY, and in numerous other articles under the appropriate headings. It is mainly the forms assumed by such masses that will here be considered, without much reference to their composition or nomenclature. These forms depend on several factors. In a superficial lava-flow one very obvious determinant is the form of the surface over which it has to run, and particularly the steepness of the slope; but another very important matter is its viscosity, which depends on two totally independent factors—its temperature and its chemical composition. Naturally, very hot lava flows more freely and, therefore, as a rule further than a cooler mass; and lavas which are rich in silica and alumina are much more viscous at any given temperature than those in which iron and magnesia are the characteristic constituents (see PETROLOGY). Consequently, dark-coloured lavas of the kind called basalt (*q.v.*) are the most liquid and tend to spread out into the thinnest sheets under any given conditions, whereas rhyolite and trachyte (*qq.v.*) often form thick lumpy masses close to the orifice of the volcano, or even fail to escape into the open at all.

Extrusive and Intrusive Rocks.—The mention of this fact leads to the other part of the subject, viz., the behaviour of intrusive magma, that is, magma that never reaches the surface, as even the most liquid lavas may fail to do. There is often an actual physical connection between a mass of rock poured out on the surface (extrusive magma) and the underground reservoir from whence it came; this gives us the simple classification of solidified masses of magma—extrusive and *intrusive*.

We must now consider the factors controlling the forms and positions of intrusive masses, as thus defined. All the considerations already detailed as to temperature and viscosity are equally applicable here, but instead of the forms of a surface we have to take into account the position of lines and planes of weakness in the rocks invaded by the magma, as well as the thickness and weight of the overlying crust. Another important thing is that when molten magma is confined underground, the steam and other vapours cannot readily escape from it, as they do at the surface, and their pressure helps to raise and fracture the rocks, and to drive a way for the passage of the magma; in fact the motive power behind it is very largely this vapour pressure, whether it escapes at the surface or is intruded below.

Planes of Weakness.—The planes of weakness in rocks may be classified as bedding-planes, joints, faults (see these headings), cleavage-planes and certain parts of folds. The forms assumed by intrusive masses are largely controlled by the different possible arrangements and combinations of any or all of these: the varieties are therefore endless; but it is not very difficult to select a few common types having some distinctive character about them.

First may be considered the kinds of intrusion possible in horizontal, or nearly horizontal, strata with well-defined bedding. It is evident that in order to reach such strata, if fairly near the surface, the magma must come up some more or less vertical fissure. It appears that often, on reaching a certain level in such a fissure it is easier for the magma to spread out sideways along bedding-planes, lifting the roof, rather than to go on cutting a vertical fissure. The point at which this spreading begins is controlled by the rate of the weight of the overlying rock to the driving power of the magma.

Sills, Laccoliths and *Bysmaliths.*—Now, other things being equal, a very liquid magma will be able to spread further along a bedding plane than a viscous one. In the first case, the result will be a flat sheet of rock of any thickness, with its top and bottom nearly parallel for a long distance, of course eventually

12. Undercliff formed by a landslip, near High Cliff, Boscastle, Cornwall

closing up at the ends. Such flat sheets, thin in comparison with their lateral extension, are called sills (*q.v.*). If on the other hand the magma is viscous, it will take a form something like a gigantic bun — thick in proportion to its extension — called a *laccolith* (*q.v.*). All such masses necessarily have a feeder in the form of a crack or pipe filled with magma, and must be more or less in the form of a mushroom, although the "stalk" is rarely seen and often ignored. Geometrically the feeder may be either a point or a line, and the resulting form of the whole will naturally vary somewhat in accordance. Certain related forms called *bysmaliths* or plutonic *plugs,* have been described by American authors.

Dykes. — Cracks similar to these magma-filled feeders often fail to spread out into mushrooms, or to allow their contents to overflow as lava-sheets at the surface; and, in other cases, the mushrooms or sheets have been removed by denudation leaving only the feeders. These more or less vertical sheets of rock formed by consolidation of magma and traversing all other rocks, form a well-defined geological unit, to which the term dyke (*q.v.*) is applied. The name is the Scotch word for a stone wall which, on denudation, they resemble as they sometimes project above the general surface owing to superior hardness. In many parts dykes are enormously abundant, and they vary from a fraction of an inch to hundreds of yards in width. It may perhaps be mentioned here that many mineral veins, as described under ORE-DEPOSITS, are of essentially similar form and nature, and the study of dykes and other masses of unmineralized igneous rock has thrown much light on problems connected with the mining of metalliferous deposits of similar form and sometimes of analogous origin.

It appears then that when the strata, or what a miner would call the "country rock," are horizontal or nearly so, the forms assumed by intrusions are very simple, and their classification is easy; but in areas where there has been much disturbance, a great variety is possible.

It may be noted that when the rocks are faulted intrusions of magma naturally tend to follow the fault-planes, which of necessity are, as a rule, more or less open fissures. Since faults may be inclined at any angle to the vertical it is sometimes difficult to decide whether a particular intrusion should be called a dyke or a sill, though there is usually more analogy to the dyke form, since faults very often cut across bedding-planes.

Phacoliths.—An important and common occurrence is an intrusion in folded rocks; and here the position of planes of weakness is the deciding factor. Taking the common case where the rocks are thrown into a series of fairly gentle anticlines and synclines(see FOLDS), it is clear that there will be a tendency to gape at the tops of the anticlines, as there the rocks are stretched, while at the bottoms of the synclines they are compressed. Hence magma will tend to spread along the tops of the anticline in a long narrow strip, convex upwards and concave downwards, with an indefinite extension along the top of the fold. Such structures are called by geologists *phacoliths* and by miners saddle-reefs. The gold-bearing saddle-reefs of Bendigo, Victoria, though perhaps not of direct igneous origin, are a well-known example of the form. Occasionally similar shaped bodies, but of course, inverted, are found in the bottoms of synclines.

When dealing with regions of really complex folding, it becomes quite impossible to lay down any rules as to the shapes assumed by intrusions. Owing to accidental variations in the position of planes of weakness, due to special causes, the intrusion may assume most complicated forms, each of which has to be dealt with on its own merits. Again in certain cases the magma, instead of occupying a definite, clearly bounded space, may permeate a whole region in thin sheets and veins, sometimes of microscopic dimensions, following planes of bedding or cleavage or cracks produced by fracturing of the crust. When the magma mainly follows planes of bedding or foliation in thin sheets the whole effect is described as lit-par-lit injection.

Inspection of a geological map of almost any highly disturbed region will show masses in a great variety of forms coloured as igneous rock. Some are clearly sill-like, while others may he interpreted as dykes. Often however large masses will be observed with a more or less circular outline, many being necks (*q.v.*), viz., the pipes or conduits of volcanoes that have long been worn away.

Bosses and Stocks. — It is also evident that many masses of igneous rock, similar in plan on the present surface, never did reach the open air. The mechanics of their formation are difficult to explain, more especially since it is usually impossible to determine the true form of their underground extension. Many of them however seem to have very steep margins and to be more or less plug-like in general shape; such are usually described as stocks or bosses. The meaning of neither of these terms is very clear, and the whole subject of the origin of the masses is in an unsatisfactory state. The nature of the downward extension is a matter of practical importance, since ore-bodies are often found at the margins of intrusions of this type, which have usually been formed under rather deep-seated conditions. Some remarkable circular occurrences of igneous rock, such as the granites of western Cornwall, are now regarded as domes or cupolas formed as subsidiary features on the top of a great batholith underlying the whole region. The ores of tin and other valuable metals show a tendency to accumulate in and around such cupolas, as has also been observed in many parts of western America. For further particulars see LACCOLITH and BATHOLITH.

III. STRATIGRAPHICAL GEOLOGY

The end and aim of stratigraphical geology is the elucidation of the history of the earth by a study of the rocks composing it. It is therefore sometimes called historical geology. For its proper comprehension it requires a knowledge of all the other branches, physical geology, petrology (including mineralogy) and palaeontology. Stratigraphy may therefore be well regarded as the highest category of geology, to which all the other divisions are subsidiary, though extremely interesting in themselves. Now stratigraphy is not a mere academic science, concerned only with abstract history and dry bones. It is of enormous practical value, for on it depend many problems in mining and quarrying, engineering, water supply, oil-finding, and a number of other subjects essential to the well-being of the world. The technicalities of stratigraphy, though apparently of the nature of jargon and often extremely arbitrary in their application, are in reality a convenient *lingua franca* universally understood in the geological world and thereby a means of saving time and space in verbose explanations.

Let us now consider briefly some of the principles and methods of stratigraphical geology, in a systematic way. Two of the fundamental laws may be defined and explained as follows.

The Law of **Similar** Conditions.--First of all, there is the principle that certain types of deposit are correlated with certain physical and geographical conditions, and that this held in the past as in the present. This is a re-statement of part of the Law of Uniformity, as described in the opening of this article. In modern times this has been qualified to some extent by the reservation that processes may have been more active in the past, differing in degree and not in kind from those now in operation. From this it follows that when we find among the older rocks certain well-defined types of deposit like those now being formed under known conditions, we are justified in drawing deductions as to the climatic and geographical conditions of the time when the rocks in question were formed.

Almost to be regarded as a corollary of the foregoing is the principle that certain types of organisms, both animals and plants, are characteristic of particular climatic and geographical conditions. From this it follows that deposits formed at the same time, under different conditions, may contain the remains of different assemblages of plants and animals, which can be used as indicators of the nature of such conditions. This is the principle of facies, which will be discussed in detail later.

The **Law** of Organic Evolution. — The second great law is that organisms, regarded from the broadest biological standpoint, have developed throughout the history of the world in a certain definite order of progression from the less organized to the more organized types, from lower to higher forms of life. This of

course is a mere bald statement of the general principle of evolution. From it follows the great generalization first stated by William Smith, that the ages of strata can be determined by means of their included fossils.

It cannot be denied that from a strictly philosophical standpoint geologists are here arguing in a circle. The succession of organisms has been determined by a study of their remains embedded in the rocks, and the relative ages of the rocks are determined by the remains of organisms that they contain. Nevertheless the arguments are perfectly conclusive. This apparent paradox will disappear in the light of a little further consideration, when the necessary limitations have been introduced. The true solution of the problem lies in the combination of the two laws above stated, taking into account the actual spatial distribution of the fossil remains, which is not haphazard, but controlled by definite laws. It is possible to a very large extent to determine the order of superposition and succession of the strata without any reference at all to their fossils. When the fossils in their turn are correlated with this succession they are found to occur in a certain definite order, and no other. Consequently, when the purely physical evidence of superposition cannot be applied, as for example to the strata of two widely separated regions, it is safe to take the fossils as a guide; this follows from the fact that when both kinds of evidence are available there is never any contradiction between them; consequently, in the limited number of cases where only one line of evidence is available, it alone may be taken as proof.

Taking all these facts into consideration, then, it has been found possible to construct a history of the earth, at any rate from the times when conditions became comparable with what they are now. Naturally, the further back we go in time the more difficult does the construction of such a history become, for the simple reason that the events of a later date have often masked or destroyed the evidence of earlier ones. Unfortunately also it happens that certain widespread and common types of deposit are often unfossiliferous, for reasons to be discussed later.

In many writings on evolution, especially in the earlier half of the nineteenth century, much stress was laid on the "imperfection of the geological record." The chapters with this heading in Lyell's *Principles* and in Darwin's *Origin* of *Species* are classics in scientific literature. This argument was brought forward, and quite justifiably in the then state of knowledge, to account for gaps in the apparent order of biological evolution At that time the geological succession of only very limited areas of the world was known, and that imperfectly. It is true that the geological succession in north-west Europe is unusually complete, as compared with many other parts of the world, but even there gaps are found, and certain formations are rather poorly represented by special and peculiar types of deposit. But as stratigraphical geology was extended to other parts of the world many of the gaps were filled up, and the geological record as at present known is not so incomplete as is still rather commonly believed, largely on the strength of certain of the older classical writings on evolution.

Importance of Marine Organisms.—There is also another point of great importance: in the earlier portions of geological time life seems to have been confined to the sea; or to put it perhaps more accurately and certainly in a safer form, in the earlier geological periods organisms whose remains are capable of preservation as fossils were apparently found only in the sea. Throughout the whole of geological history, in point of fact, the succession of marine animals is better known than that of terrestrial animals, because in the sea conditions for their preservation as fossils are more favourable than on land. Hence stratigraphy depends to a very large extent on marine biology, and in particular the evolutionary and palaeontological side of it has mostly been worked out on this line. Hence it follows that when any large area has been land for a considerable time we know less about the history of the area during that time than about the history of other parts of the earth during the same period. Consequently also, gaps in the evolutionary history of land animals during the earlier ages are specially prominent. It is only after the vertebrates appeared that we get anything like a complete succession, and even this shows many lacunae: thus the origin of the mammals is still very obscure, as is likewise the early history of the human race.

The Geological Datum-line.—From the evolutionary character of the development of organisms and the poor preservation of the earlier forms, another very important consequence follows, namely, the absence of any definite base-line as a starting point in the study of the stratified formations. This difficulty is accentuated by the high degree of alteration that most of the earlier rocks have undergone, so that the fossils, if there ever were any, have been wiped out. It is a very significant fact that the oldest known fossils are organisms of a comparatively high grade of development, highly specialized, and even in some cases-showing signs of biological degeneration. It is a fair inference therefore that they must have had forerunners capable of preservation; only by an unfortunate series of accidents all trace of these forerunners so far as yet known, has been destroyed. There is still a chance that some day they may yet be discovered in some of the less-known parts of the world, but this hope is becoming rather slender. It is quite impossible to believe that the highly organized and abundant fauna of the oldest known fossiliferous marine strata represents the absolute beginning. Such an assumption postulates a sudden special creation, and is entirely anti-evolutionary and inconsistent with all known evidence.

Another very important consideration is that the absence of fossils in the oldest known rocks makes it very difficult to work out their relations, and especially to establish the relative ages of formations not actually seen in contact. It is always dangerous to correlate rocks in two distant areas by lithological resemblances alone, since precisely similar physical conditions may and do recur over and over again. whereas precisely similar fossil assemblages do not. Hence thk stratigraphy of the oldest nonfossiliferous rocks is in a much less satisfactorv state than that of the later formations. In any one continuous area it is always possible to work out the succession of such rocks by means of the law of superposition, but it is not possible to be sure that the enormous development of these oldest rocks in Canada, for example, is the time-equivalent of the very similar series in South Africa. It is only by means of fossils that it is safe to extend geological time-divisions across the sea.

Taking all these points into account, the only allowable procedure for the stratigrapher is to take the oldest known fossiliferous formation as a datum-line from which to work both upwards and downwards, just as the heights of the land and the depths of the sea are both measured from mean tide level. Above this artificial datum-line the sequence of events is clear and well-known; below it is partly guess-work.

It may be well at this point to refer to a question of nomenclature. It is universally agreed that the oldest known fossiliferous rocks shall be called the *Cambrian System*. The exact meaning of the term "system" as here used is of no importance at the moment and will be duly explained later, as likewise will the reason for the name "Cambrian." It is only with the base-line of the system, the datum-line spoken of in the last paragraph, that we are here concerned, for a practical reason: all the rocks below this base-line are obviously older than any Cambrian rocks, hence it is convenient to speak of all of them, collectively, as the *Pre-Cambrian* rocks. Many other names have been applied to them, some suitable, some otherwise, but this one possesses the advantage that it is impossible to mistake its meaning.

The geological datum-line, then, is the base of the Cambrian System; but too much importance should not be attached to it. The average school-boy usually gets the idea that before the arrival of William the Conqueror in A.D. 1066 English history was a sort of chaos: just in the same way the geologist is in danger of regarding Pre-Cambrian times as a chaotic era, whereas in both cases conditions before and after the arbitrary dates chosen were very much the same; for though after 1066 there were Norman rulers in England and after the date represented by the base of the Cambrian there were animals in the sea, the presence of neither made very much real difference. The stratified rocks of the latest Pre-Cambrian times were very like those of earliest Cam-

brian times, and in some places there was little physical break between. In point of fact obscure traces of organisms have been detected in Pre-Cambrian rocks, but no well-defined fauna.

Structural Relations. — In working out the geological history of any given region or of the earth as a whole we have three main lines of evidence: (a) the structural and tectonic relations of the different rock series; (b) their petrological character; (c) their fossil contents. It is by the combination of all of these that the final results are reached. Each of these categories however requires a little further elucidation, especially with regard to the relations of one line of evidence to another and the principles to be employed in combining them to form a coherent whole.

The first principle here is that a continuous and uninterrupted series of stratified rocks represents either stable conditions or a gradual sinking of the sea floor. Any discordance, that is, failure of parallelism in the strata, must indicate an interruption of some kind, usually the occurrence of earth-movement. Such a discordance is known as an *unconformity*. The presence of an unconformity as a rule implies also a certain amount of denudation in an interval between the deposition of the two sets of discordant strata. For example. to take a very simple case: if the floor of the sea is buckled up into ridges and furrows, the tops of the ridges may be planed off by tides and currents till the floor is again flat. If now deposit is resumed there must obviously be some discordance on the site of the former ridges, while the material planed off their tops may have been deposited in the hollows between them, so that there the discordance will be less apparent. There will thus be a gap in the strata at certain points.

An even simpler case is where a large region has been merely tilted and then planed off by denudation, newer strata being afterwards laid down in flat horizontal beds on the top: this gives rise to what is called an angular unconformity. It is obvious that in all such cases the lower series of strata must have a steeper inclination than the upper ones, unless of course a further movement at a later date has tilted the whole back again, which often happens.

These are the conditions which must prevail if disturbance takes place in the open sea, far from a shore line. But if marine strata are raised above sea-level to form a land-surface, the effects are rather different. Let us suppose that new deposits are being formed along a coast-line with a moderate slope below sea-level. Then it is quite evident that each successive stratum of sediment laid down on the floor of the basin must extend farther towards the shore than the one below it. This relation is called overlap. The effect will obviously be more marked if the land is sinking, when marine strata may extend over what was once a land-surface: when this occurs on a large scale and for a considerable distance it is called transgression.

It is impossible here to enter into detail concerning all the varieties of structure that may result from these processes under varying conditions: the point here to be made is that these phenomena, which represent breaks or interruptions in the peaceful deposition of sediment, form convenient dividing lines in the stratigraphical succession, just as in history the end of the reign of a ruler forms a convenient end for one chapter and beginning of the next. The geological time-scale is divided arbitrarily into periods by means of these interruptions in the succession of strata; or, in other words, the major subdivisions of the stratified rocks are separated by well-marked unconformities.

Here two very important considerations arise: they may be put into simple language as follows:

(a) After a disturbance caused by earth-movements, deposition need not necessarily begin again immediately in that particular area, although it may be going on elsewhere. Thus there may be a long gap in the succession in any one place.

(b) Any given formation may be disturbed in any one place but not necessarily in other places. Thus a hiatus found in one locality may be bridged over by a complete series elsewhere.

These two statements really amount to the same thing, but the matter becomes clearer if they are stated separately. They have an important bearing on the subject of the imperfection of the geological record, already alluded to, and are, in fact, a re-statement of the arguments used in dealing with that matter. The repetition is excusable, since the question is of first-rate importance in stratigraphical geology.

Petrological Character. — The title of this section must be taken to indicate not only the study of the actual characters and composition, both chemical and mineralogical, of the rocks, but also the evidence given by these studies as to the conditions of their formation: it is genetic rather than descriptive.

It has already been emphasized in earlier portions of this article that particular types of deposit are characteristic of particular sets of physical and geographical conditions. This was then specially applied to modern instances, but it is equally applicable to the older rocks, since when in course of time the incoherent superficial deposits become consolidated to form rocks, their characteristics still persist and are just as easily recognizable. (For detailed treatment of this subject see PETROLOGY; SEDIMENTARY **ROCKS.**)

Facies of Deposition. — Thus by a petrological study of the older rocks we are able to determine how they were formed, whether their origin was marine or terrestrial, freshwater or aeolian, and so on. Volcanic and other igneous rocks and their relations to the sediments have also to be taken into account: thus we arrive at the general conception of facies of deposition.

On broad lines it may be said that there are three chief facies of deposition, having regard to purely geographical considerations, namely, marine, freshwater and terrestrial, the term terrestrial being used of deposit under arid conditions. The glacial type of deposition is well-marked and is usually to be associated with freshwater conditions, although glaciers and icebergs do also deposit material in the sea. Each of these primary categories, however, requires further subdivision; the types of sediment formed along the sea-shore, for instance, are distinctly different from those laid down in deep water; the deposits of lakes and rivers also show variations; and so on. Here also, it must be mentioned, the purely physical types of sedimentation come into relationship with the variations of organic remains proper to the particular conditions, so that it is hardly possible to treat the subject without bringing in also its palaeontological aspect. Just as at the present time the different regions of the world each have their own fauna and flora, so in the past, owing doubtless to climatic conditions, contemporaneous life-provinces can be recognized in the strata of one and the same age. Nevertheless certain groups of organisms, such as shore-dwellers and inhabitants of deep water, are characteristic of certain particular physical conditions; and though the particular species found in, say, the shallow-water shore deposits of a particular period will not be the same all over the world, there will be a general and characteristic similarity in the groups of animals represented. Hence it appears that the question of facies of deposit cannot be properly studied without including also the fossil remains found in the rocks.

Still, as a first approximation we may consider what subdivisions are to be made, on a physical basis, in each of the three major divisions above defined. It has already been stated that the chief types of modern marine sediment are gravel, sand, mud and calcareous material. When these are consolidated they form conglomerate, sandstone, clay, mudstone, shale and limestone. Of these, conglomerates clearly indicate the close proximity of a shore line; sandstones mean shallow water deposition; clay, mudstone and shale, being formed from mud, must have been formed in deeper water; while limestones can apparently be formed in water ranging from very shallow to moderately deep, causes other than depth, such as a clear sea and warm water being favourable to their formation.

Thus we obtain the following as a useful classification: —

Calcareous deposits may be found associated with any of the three. Thus some coral reefs belong to the littoral facies, shell banks are formed between tide-marks, and shells may also drift out to very considerable depths, while some molluscs live in quite deep water. The modern abyssal deposits (see OCEANOGRAPHY) are not known with certainty to be represented among the older rocks and therefore need not be considered here.

Estuarine and Delta Deposits.—A category intermediate between marine and freshwater deposits includes those formed in the estuaries and deltas of large rivers. The former class show most affinity to the littoral and shallow-water marine formations, since they usually contain marine fossils, but mixed up with organisms derived from the land, notably plant-remains. The types of sediment are much the same as described above, except that calcareous deposits are generally not well developed, probably owing to the muddiness of most large rivers. In deltaic deposits terrestrial fossils usually preponderate, but marine animals sometimes penetrate up the rivers and become entombed. Vegetable remains are generally very abundant, owing to the growth of swamps in deltas, and sometimes form coal. Any temporary sinking of the land, or rise of the sea may cause the intercalation of a definite marine band, as has happened in the Coal-measures at various horizons.

River Deposits.—Freshwater deposits (see ALLUVIUM) can be divided pretty clearly into those formed by rivers and in lakes. Evidently there must be a gradual transition from estuaries and delta deposits to those laid down in and along the upper parts of the course of the river; the sediment may be of any kind, except calcareous, and the fossils may obviously be a mixture of freshwater and land animals and plants. There will naturally be much variation in the kind of material deposited according to whether the river (or the particular part of it) in question flows placidly through lowlands or is a steep and rapid upland torrent. The former type lays down chiefly fine sand and silt, while the latter rolls along great boulders, stones and gravel. River deposits are therefore most like the littoral and estuarine facies from the petrographical point of view; but the fossils are different.

Lake Deposits.--Owing to the general stillness of the water, the material laid down in lakes is finer in grain than that in river beds. There may of course be gravels and stream deltas along the shores, but in the deeper waters we usually find fine silt and mud, often calcareous, from the abundance of freshwater shells. These sometimes eventually form regular bands of rather muddy limestone. Very large lakes differ from the sea mainly in the absence of tides. and the types of sediment are much the same. The smaller lakes, ana all lakes so far as we know (except salt lakes, see below), eventually become filled up; there is usually a delta at the head, which grows steadily, and at last fills the whole basin, leading first to an alluvial flat. On top of all the other deposits there is often a bed of peat, which later forms lignite or even coal.

Desert Deposits.—The deposits belonging to the arid facies, which in point of fact is of great importance in geology, possess several distinctive features. They are generally rather coarse in texture, forming eventually breccias, conglomerates and special types of sandstone with very well-rounded grains ("millet-seed sands"). Cross-bedding and dune-structure are common, and there are no fossils; further such deposits are nearly always associated with beds of rock-salt and gypsum laid down in salt-lakes, as described above, § Physical Geology. Furthermore, the strata are nearly always red, orange or yellow in colour, sometimes white, but never grey or bluish, like so many aqueous deposits. Red sandstones are by far the most characteristic feature.

Glacial Deposits.—In recent years it has been discovered that undoubted glacial deposits exist among the older rock-systems of many parts of the world. They consist of material similar to the deposits of modern glaciers, boulder clays like that of the Pleistocene ice-sheet, scratched stones, etc. Likewise they often overlie glaciated pavements with grooves and striae showing the direction of ice-movement in those ancient times. Magnificent examples have been found in South Africa and in other southern lands at several horizons, as well as in Canada, among the most ancient rocks of the mining regions of Ontario and Quebec. The glacial facies of deposit is therefore of increasing importance in stratigraphy.

In working out the geological history of any region it is of course necessary to take into account the volcanic intrusive igneous rocks that are found there. The age of these can usually be determined by considering their relations to the stratified rocks and to the disturbances that have taken place in them. It may perhaps be mentioned that igneous rocks are very often closely associated with such disturbances and frequently contemporaneous with them. Earth movements and igneous activity are closely related phenomena. Thus it is logical to recognize a volcanic facies of deposit, when lavas and ashes are found interstratified with sedimentary rocks.

PALAEONTOLOGY

The general principles of palaeontology are discussed in a separate article (*q.v.*), but for the sake of continuity and at the risk of slight repetition it will be well here to consider certain points having an important bearing on stratigraphical investigation.

Fossils as Time-indices.—In the first place, fossils are regarded as time-indices, on the general ground that any particular species comes into existence, lasts for a certain length of time and then dies out completely, never to recur. Therefore it would appear that if the same fossil is found in rocks in different places, these rocks must be of the same age. This of course is true in the broad sense, though some slight qualification is necessary. It may be safely assumed that any given species arises at a point, or within a very small area, and spreads outwards by migration. Hence it must take a considerable time, measured in years, to reach a distant region, and the concurrence of date in the deposits of the two areas can only be approximate, the discrepancy depending on the rate of migration; consequently, to a large extent on the character and mode of life of the organism. The two deposits are to be regarded as equivalent, not strictly contemporaneous. This is called the principle of homotaxy, and was first clearly enunciated by Huxley.

Life-provinces.—It is notorious that at the present time the animals and plants of different parts of the world differ widely, the variations being largely a matter of climate and environment. Many distinct life-provinces have been demarcated, both zoological and botanical. Now there is every reason to believe that the same state of things held in the past, and likewise many palaeozoological provinces have been recognized, though naturally in less detail than the modern ones. Consequently, it follows that contemporaneous deposits in different parts of the world need not contain the same fossils; but, just as at present a few species are almost world-wide, so they were in the past. Two contemporaneous faunas can usually be linked up by some forms common to both, especially among marine animals.

Biological *Facies*.—We now come to the important consideration of the value of fossils as indicators of geographical conditions. It is hardly necessary to point out that marine animals are found in marine deposits, land animals and plants in freshwater and terrestrial deposits, and so on; the real matter at issue is: to what extent slightly different assemblages of contemporaneous fossils can be taken as indicators of geographical conditions. This problem is exactly the same as that discussed in connection with lithological variations in rocks, and denotes the existence of biological facies.

For the sake of simplicity attention may be confined to marine conditions. Everybody knows that marine animals vary much in their habits; some remain fixed to rocks or buried in the mud and sand of the sea-floor, some swim freely, while others float passively as carried by tides and currents, some live between tide-marks and are above water for a considerable part of each day, others must be always submerged, some in shallow, some in deep water and so on. It is clear that among primeval creatures a similar state of things prevailed, as shown by analogy, and among extinct forms conclusions as to mode of life can be drawn from structure. Hence by a study of fossils it is possible to draw up a scheme of facier, just as in the case of rocks. In actual practice the two

are always combined, yielding precise information as to geographical and often as to climatic conditions.

Palaeontological Classification. — A few words must now be said as to the methods adopted in a purely palaeontological classification of rocks. In modern geological work biological evolution is assumed, either explicitly or implicitly, though no postulates are necessarily made as to how it is brought about. It is clear that groups of animals have appeared and have undergone variation, usually at first in the direction of multiplication of forms and progressive adaptation to their environment; equally obviously, some have retrogressed and finally died out; but the important matter here is that certain forms are characteristic of certain groups of strata, and of no others, and that by taking sufficiently large or sufficiently small groups the major and minor subdivisions of the stratified rocks can be demarcated. This principle can be extended even to the very smallest subdivision now recognized, which is called a zone, and is characterized by the presence of one particular species, arbitrarily selected from the general assemblage of fossils as being specially suitable for the end in view. Numerous examples of the methods of palaeontological classification of strata will be found in the articles dealing with the various stages and groups into which the succession of stratified rocks is now divided, and the subject need not here be pursued further.

In the foregoing sections a brief sketch has been given of the materials with which stratigraphical geology has to work; the "tools of the trade." Another point which scarcely needs elaboration is the importance of maps. Maps and sections are the only possible means of representing the results in a convenient form, capable of easy multiplication and distribution. A solid model is of course the best, but such are necessarily cumbrous, and suited only to a limited number of cases.

It may be said then that in the simplest terms the task of the stratigraphical geologist is first to work out the present structure of the earth, and from the facts thus ascertained to draw deductions as to events in the past. According to personal idiosyncrasies these deductions may take somewhat different forms; palaeontological, petrological, palaeogeographical and so on, but on the whole the aim is historical, the elucidation of the history of the earth. Over large areas this history has been worked out in very considerable detail, and the remainder of this article will be chiefly occupied by a very brief and generalized summary of the results so far attained. Much still remains to be done in the remoter and less developed regions, but it may probably be said with safety that the broad lines are now firmly established.

In treating a historical subject it is usually advisable to begin at the beginning, but, as before explained, this is just what geology cannot do. We are constrained therefore to adopt the large and unsatisfactory category of Pre-Cambrian rocks for our lowest division, fully aware that this group extends indefinitely downward and probably covers a vastly greater period than all the later formations put together; for while it is generally agreed by astronomers and cosmogonists that whatever may have been the origin of the earth it must have passed through a molten stage, and therefore must have had a "first crust," geologists hold that it is very improbable that any of this first crust has survived and that it was probably broken up and re-melted over and over again before a permanent solid covering for the molten interior was developed. It is true that the oldest known rocks are highly crystalline, but they always show signs of having been derived from older rocks rather than formed by direct crystallization from a fused state. In the later part of Pre-Cambrian time at any rate, conditions seem to have been very similar to what they are now, except for the absence or apparent absence of living beings; there is reason to believe that the earlier developments of life on any considerable scale were confined to the sea, for there is little or no evidence for the existence of land-dwellers till a later date than some highly organized marine faunas; but, though their remains have not been found, there is no proof that there were not lowly animals and plants on land as early as in the sea.

Methods of Subdivision. — The next point to be considered is the general principle to be adopted in the choice of subdivisions and nomenclature for the stratified rock-series. It will no doubt already be apparent that geological history is not a smooth and continuous sequence of uniform conditions; there are breaks in the continuity and these are naturally adopted to mark the periods. Now the most obvious kind of break is an unconformity, and most of the major time-divisions are determined by these. In the unfossiliferous rocks this is the only kind of subdivision that is possible; but when fossils are present the rocks may also be subdivided according to the palaeontological succession, and this method is now very extensively adopted, as being more scientific than the purely physical method. The ideal classification would be a combination of both, but unfortunately the well marked lines do not always coincide in the two scales. A change of fauna does often coincide with a physical break, but these physical breaks are not always contemporaneous in different places. Upheavals due to earth-movements crawl slowly over the world, as it were, and there is often time for a considerable change of fauna during their progress, so that the break may come at one life-zone in one place and at another life-zone in another place. This is a crude illustration of the kind of difficulty that stratigraphy has to contend with, but, when treated on the right lines, is very illuminating as to the history and geography of the past.

Space does not permit us to give here an account of the stratigraphy of the whole world; general summaries of the particular formations will be found in special articles and a sketch of the general geology is given in the articles dealing with each country; so all that will be attempted here is a brief outline, by way of example, of the principles adopted in subdividing the strata of the British Isles; the general geological history of North America is very similar, while that of Africa, India and Australia for example, are very different, and in some sense antithetical, especially in the later periods. There is evidence that in the earliest times climatic and other conditions were more uniform over the whole earth than they are now, and some of the earliest marine faunas were very widely spread.

Taking the British Isles as a whole, the oldest rocks are found in the north and west, the newest in the south and east: this means that in general the country is tilted towards the south-east, like a pile of books that has fallen over. In the extreme north-west of Scotland and in the Outer Hebrides are the oldest rocks of all, the Lewisian gneiss, a highly crystalline series mainly composed of igneous rocks; this is succeeded, with a very strongly marked unconformity, by the Torridon Sandstone, a quite normal series of sedimentary rocks, evidently formed under arid conditions. This again is followed unconformably by the lowest Cambrian fossiliferous rocks. Here then we have a very simple but typical succession: Pre-Cambrian rocks in two well-marked and strongly contrasted types, the later being clearly of continental origin, succeeded by a marine transgression. Here in this particular region the succession is cut off short, owing to later disturbances which need not now be discussed; but Cambrian rocks are found again in Wales and the Western Midlands, so that the succession can be picked up and continued. The marine transgression soon became very extensive and an immensely thick series of marine strata were laid down, with minor breaks locally: this state of affairs lasted a long time and the rocks are now divided into three systems, Cambrian, Ordovician and Silurian. These constitute the First Marine period. Towards the end of Silurian times uplift and disturbance occurred, culminating in the Caledonian mountain-building movements, which formed a great northern land-erea, leaving sea where Devonshire now is. On this great continent, named by Walther the "Old Red Northland," the desert deposits and lakes of the Old Red Sandstone were formed, while in the south were laid down the marine strata appropriately named Devonian, which extend underground to Belgium and Germany. In the north this constituted the Second Continental Period, and was accompanied by an immense development of igneous rocks (the Highland and Lake District granites, and the lavas of the Ochils, Sidlaws and Cheviots). After this the sea again crept north, spreading limestones far over England, with shales and sandstones and even coal in the north, indicating a shore line in Scotland. This constitutes the Second Marine Period of the Lower Carboniferous. This did not last very long: north-western Europe

was soon converted into a low-lying, swampy land area on which the Coal-measures were formed in the Upper Carboniferous. Then the continent rose and extended, so that desert conditions again set in and continued during the Permian and Trias. About the end of the Carboniferous there was another phase of mountain-building and igneous activity, when the Pennine Hills and the Mendips were formed and granites rich in metals were intruded in Devon and Cornwall. Salt lakes were also numerous. This was the Third Continental Period. After a long while the sea again broke into the desert basins of the Trias and rapidly extended, ushering in the Third Marine Period, which comprises the rocks of the Jurassic and Cretaceous, culminating in the great Chalk sea, which spread far into France and Germany, but was cut off from the Mediterranean region by a barrier. Soon after mountain-building became acute in central and southern Europe, leading to the uprise of the Alps, and slight earth-waves were propagated far to the north-west, again bringing in land conditions over most of the area, and this state of affairs continued for the rest of geological time, constituting the Tertiary and Recent, the Fourth Continental Period: accompanying these movements were violent volcanic eruptions in N.E. Ireland and Western Scotland.

Such in the baldest outline is the geological history of the British Isles, which may now be re-stated in the form of a table, from which certain generalizations will be drawn:

	Name of system	Character of period	Earth movements
Kainozoic	Neogene	Fourth Continental Period	Alpine
	Palaeogene		
Mesozoic	Cretaceous Jurassic Trias	Third Marine Period	
Palaeozoic	Permian	Third Continental Period	Armorican
	Upper Carboniferous Lower Carboniferous	Second Marine Period	
	Upper Old Red Sandstone	Second Continental Period	Caledonian
	Lower Old Red Sandstone Silurian Ordovician Cambrian	First Marine Period	
Pre-Cambrian	Torridonian	First Continental Period	Huronian
	Lewisian	Mainly igneous	

In connection with this table several points arise for comment. In the first place it brings out with great clearness the close relationship between unconformities, earth-movements and igneous activity. The major unconformities are due to the mountain-building movements, and minor unconformities, not here mentioned, are of course due to similar causes on a smaller scale: for example there are minor unconformities between Cambrian and Ordovician and Ordovician and Silurian: also in many places between Jurassic and Cretaceous. Locally again there are smaller unconformities and breaks within the systems, leading to minor subdivisions. In other cases the systems are subdivided by lithological variations, or by changes of fauna (zones). Both methods are now usually followed and often lead to inconsistent results, as explained in the section of this article on the biological side of stratigraphy.

Another important principle arising from a study of this table is that the beginning and end of a continental period differ in character. The beginning of a period of disturbance is indicated by an interruption in the regular deposition of marine strata, usually local at first, then becoming general, culminating in folding, denudation and a marked unconformity, so that the strata of the continental type rest on the eroded edges of the older rocks; but at the end of the period either the land gradually sinks or the sea-level rises, resulting in a quiet marine transgression, with well-marked overlap, and a continental period gradually slides into a marine period without any marked convulsion of nature. A good instance is afforded by the gradual transition from the Old Red Sandstone to the marine Carboniferous limestone. In many places the passage from one to the other is perfectly conformable, and the boundary can only be drawn on lithological or palaeontological grounds. This is a general principle of wide application. The lowest division, the Pre-Cambrian formations, happen to be rather poorly represented in the British Isles; in a similar table for Canada or India they would show up much more conspicuously, and in a South African table it would be necessary to show five or six systems of almost certainly Pre-Cambrian age, though unfortunately there the systems from Cambrian to Silurian, if present at all, contain no fossils. In Canada likewise a large number of undoubted Pre-Cambrian systems would have to be shown, though opinion is as yet by no means settled as to how they should be classified. But the British Isles happen to contain an unusually complete series of fossiliferous formations and therefore afford an excellent general example.

Nomenclature.—An inspection of any list of geological formations will at once show that the names adopted are purely arbitrary. Many of them are geographical, derived from localities where the rocks are well represented (Torridonian, from Loch Torridon, in N.W. Scotland; Devonian; Jurassic, from the Jura Mts., etc.); sometimes they are derived from ancient names for the country or for its inhabitants (Cambrian, the Roman name for Wales, Ordovician and Silurian from ancient tribes inhabiting the Welsh borderland), while another group comes from lithological characters (Old Red Sandstone; Carboniferous=coal-bearing; Cretaceous from creta, Lat. for chalk). "Trias" is derived from a three-fold division of the system on the continent of Europe, which is not seen in England. The Tertiary again is subdivided into Eocene, Oligocene, Miocene, Pliocene (see these headings), names of Greek origin founded on the numerical proportions of living species in each.

Most of these names are in world-wide use though they are not always very applicable in distant countries; it is when we come to those of the smaller subdivisions that chaos sets in, many of them being of purely chance origin, especially among the older ones. The British rocks were first roughly classified, as before mentioned, by William Smith, about the beginning of the last century; and many of his rough-and-ready names have stuck and have obtained world-wide currency, sometimes in their original form, sometimes slightly altered. They are usually descriptive of the character of the rocks and many have a geographical name tacked on, such as Oxford Clay, Stonesfield Slate, Lincolnshire Limestone. A few are derived from English dialect words, as are probably, Lias and Gault. Such names as Coal-measures, Lower Greensand and Magnesian Limestone explain themselves; in certain cases old names have been more or less classicized or modernized, taking such forms as Corallian, Callovian (from Kellaways Rock) and so on, and a large number of new names have been constructed on similar lines.

Attempts have been made, especially by palaeontologists, to sweep away these old historic names and to substitute an entirely new and "scientific" classification. On logical and utilitarian grounds such a procedure would perhaps be justified, but very many geologists, especially field geologists, would deeply regret their disappearance, since they do at any rate indicate where and how stratigraphical geology took its rise, and they serve as *a*

lasting memorial to William Smith, Adam Sedgwick, Sir Roderick Murchison and the other founders of stratigraphical geology.

In connection with nomenclature one more point remains in need of explanation; namely, the meaning of the names Palaeozoic, Mesozoic and Cainozoic, used in this table to indicate three out of the four major subdivisions adopted. Etymologically the words mean ancient, middle and recent life, and thus of course refer to the character of the fossils found in the rocks: each is the subject of a special article (*q.v.*) and the subject need not be elahorated here. Sometimes these names are replaced by Primary, Secondary and Tertiary respectively; the first is little used, Secondary and Mesozoic are employed almost indiscriminately, while Tertiary is perhaps even commoner than Cainozoic. It is all a matter of taste, a5 the connotations of the two sets of names are identical.

GEOMETRIC CONTINUITY: *see* PROJECTIVE GEOMEIRY.

GEOMETRIC PERIOD, in architecture, the earlier of the two sections into which the Decorated period (q v) of English Gothic (see GOTHIC ARCHITECTURE) is usually divided, comprising roughly, the last half of the 13th century.

GEOMETRIC SOLIDS: see SOLIDS, GEOMETRIC.

GEOMETRIES, FINITE, a class of geometries in each of which there is a finite number of (undefined) elements called points. falling into (undefined) subsets called lines. such that the mutual relations of lines and points (as well as various derived figures, such as planes, 3-spaces. etc.) are closely analogous to those of like objects in ordinary projective geometry. Following Professors Veblen and Bussey, we define them in this manner:

A finite geometry consists of a set S of elements, called points for suggestiveness, which are subject to the following five conditions or postulates:

I. The set S consists of a finite number of points. It contains one or more subsets called lines, each of which contains at least three points.

II. If A and B are distinct points, there is one and only one line that contains both A and B. (We denote this line by AB.)

III. If A, B, C are non-collinear points and if a line 1 contains a point D of the line AB and a point E of the line BC but does not contain A or B or C, then the line 1 contains a point F of the line CA.

IV_k. If m is an integer less than k, not all the points considered are in the same m-space.

V_k. When IV_k is satisfied, there exists in the set of points considered no (k+1)-space.

The geometry so defined is one of k dimensions.

In this system of postulates the terms point and line are left undefined. They are to be any objects of thought for which the postulates are true An m-space, or a space of m dimensions, is then defined inductively as follows: A point is a o-space and a line is a 1-space. If $P_1, P_2, ., P_m, P_{m+1}$ are points not all in the same (m—1)-space, then the set of all points each of which is collinear with P_{m+1} and some point of the (m—1)-space ($P_1, P_2, ..., P_m$) is the m-space ($P_1, P_2, ..., P_{m+1}$). A a-space is called a plane.

It may be observed that the foregoing definitions and postulates are all identical with corresponding definitions and propositions of the usual projective geometry, except for the one requirement here made that the number of points considered shall be finite. This is the justification for using the name geometry for the configurations here defined. Many of the propositions of projective geometry can be developed from postulates similar to the foregoing without saying whether the number of points is finite or infinite; and this is done in Veblen and Young's Projective Geometry. In fact this procedure is illuminating, so that the finite geometries justify themselves in the light which they throw on ordinary projective geometry. But they also have other uses, particularly in the development of the theory of permutation groups. Moreover, the theory in itself possesses such artistic elegance as to commend it strongly to one who takes pleasure in such aspects of thought.

As an example of a finite geometry of two dimensions we have one in which the set S consists of the 13 letters A, B, C, ..., M, while the lines consist of the 13 subsets of four elements each indicated by the columns of the following array:

A	B	C	D	E	F	G	H	I	J	K	L	M
B	C	D	E	F	G	H	I	J	K	L	M	A
D	E	F	G	H	I	J	K	L	M	A	B	C
J	K	L	M	A	B	C	D	E	F	G	H	I

That this set of points, with the indicated subsets forming lines, satisfy the given postulates the reader may readily verify.

There are special finite geometries of two dimensions which cannot be extended to, or imbedded in, geometries of higher dimensions. These exceptional geometries we shall not consider. All our further statements will refer only to those geometries remaining after these exceptional cases are excluded.

Some **Principal** Theorems. — In any given finite geometry ths number of points on one line is the same as the number on any other; and this number is always of the form $1+p^n$ where p is a prime and n is a positive integer. For every such p and n a unique k-dimensional finite (projective) geometry exists having $1+p^n$ points on a line; it is denoted by the symbol $PG(k,p^n)$. Many of its properties are common to it and the ordinary projective geometry of k-dimensional space. The number of points in a $PG(k, p^n)$ is

$$1+p^n+p^{2n}+. . .+p^{kn}$$

If one omits from a PG (k, p^n) any subspace of k—I dimensions, then there remains a set of p^{kn} points forming a Euclidean geometry $EG(k, p^n)$ of k dimensions. It has many properties in common with the usual geometry of k dimensions and of Euclidean type. The finite geometries $PG(k, p^n)$ exhibit a property of duality in all respects analogous to the property of duality in ordinary projective geometry. Thus, in a space of three dimensions the planes may be interpreted as points if one at the same time reinterprets the points as planes, while lines continue to be lines.

It is possible to introduce homogeneous co-ordinates into the geometry $PG(k, p^n)$ and thus to represent its points by means of k+1 homogeneous co-ordinates. This is simplest in the case when n=1. For the PG(k, p) we employ for the number system the integers taken modulo p. Thus we have in this case the distinct numbers o, 1, 2, . ., p—I. In the general case of $PG(k,p^n)$ we use for the number system the marks of the Galois field $GF(p^n)$. In each case a point is denoted by the symbol $(\mu_0, \mu_1, ..., \mu_k)$ interpreted as a set of homogeneous co-ordinates, that is, interpreted so that $(\mu_0, \mu_1, ..., \mu_k)$ and $(\nu\mu_0, \nu\mu_1, ..., \nu\mu_k)$ represent the same point if v is any mark different from zero; it is understood that one at least of the marks $\mu_0, \mu_1, ..., \mu_k$ is different from zero. Then the points $(x_0, x_1, ..., x_k,)$ whose co-ordinates satisfy one linear homogeneous equation

$$c_0x_0+c_1x_1+...+c_kx_k=0$$

constitute a space of k—1 dimensions; those satisfying two such equations (when these are independent) constitute a space of k—2 dimensions; and so on.

The geometry already exhibited as an example is the $PG(2, 3)$; and its number system consists of integers taken modulo 3. It affords a convenient illustration of the results stated in the two foregoing paragraphs.

The totality of transformations of points by each of which a $PG(k, p^n)$ is left invariant, that is, transformations of points by which lines go into lines, are of particular importance. They are called collineations. This totality contains all the linear homogeneous transformations on $k+1$ variables $(x_0, x_1, ..., x_k)$ into $k+1$ variables $(y_0, y_1, ..., y_k)$, the set of variables in each case representing a point of the geometry. When $n=1$ this totality contains all the collineations. When $n>1$ it is necessary to adjoin the transformation

$$y_i = x_i^p, \quad i = 0, 1, ..., k,$$

in order to generate all the collineations in $PG(k, p^n)$. Those transformations in this set, each of which leaves fixed a given $(k-1)$-space in $PG(k, p^n)$ transform among themselves the points of the corresponding $EB(k, p^n)$ according to the group of collineations of this Euclidean geometry.

Relations with Permutation Groups.—The collineation groups give rise to some of the most interesting permutation groups, particularly those known as primitive groups. But the finite geometries have a more intimate relation than this to the general theory of abstract finite groups. Thus an Abelian group H of order p^{k+1} and type $(1, 1, ..., 1)$ affords a representation of the $PG(k, p)$ by interpreting as points the subgroups of order p in H and as lines the subgroups of order p^2. This theorem, which is easily demonstrated, may be extended to the case of the geometries $PG(k, p^n)$. Here we consider an Abelian group G of order $p^{(k+1)n}$ and type $(1, 1, ..., 1)$ and select from G a certain special set of subgroups of order p^n, interpreting each subgroup as a point, while a group of order p^{2n} generated by two of them is called a line. Then the collineation groups are interpretable by means of the holomorph and the group of isomorphisms of G. Thus the finite geometries may be treated as a chapter in group theory; and conversely all propositions in the finite geometries may be translated into propositions about Abelian groups.

GEOMETRY, one of the three principal branches of mathematics (the other two being algebra and analysis), may be described as the branch which deals with the properties of space. Its most elementary part is known to every schoolboy under the name of plane and solid geometry, the former dealing with the properties of figures in a plane, the latter with the properties of figures in space (of three dimensions). These two subjects form, however, only a small part of geometry as the term is now understood. The present article attempts, first, to describe briefly these two elementary topics in geometry, and secondly, to give the reader some conception of the content of geometry as a whole with references to other articles where more detailed information on the various topics may be found. The article is then intended, in part, to orient the reader in a very large subject, sending him to other articles for more elaborate discussion of the special fields.

GENERAL SURVEY

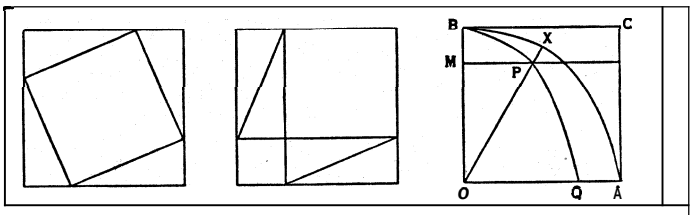
Like most other branches of knowledge, geometry arose originally in response to man's practical needs. The word "geometry" (Gr. $\gamma\eta$, earth and $\mu\epsilon\tau\rho o\nu$, measure) means "earth measurement." Indeed, the subject seems to have had its birth in ancient Egypt, where the periodic inundations of the Nile made the surveying of the land for the re-establishment of boundary lines a necessity. This early empirical geometry consisted merely of a number of crude rules for the mensuration of various simple geometric figures; for the laying out of angles, especially right angles, etc. (*See* below for details as to history.)

The ancient Greeks developed this crude beginning into the science which is now studied in the schools under the name of demonstrative geometry, the plane and solid geometry already mentioned. This form of geometry depends on the observation that the propositions of geometry are logically inter-related; *i.e.*, that, if certain propositions are granted, certain others can be proved as logical consequences of those assumed. This suggests the possibility of arranging all the propositions in a sequence such that every proposition in the list, after a certain *one*, is a logical consequence of some or all the propositions that precede it. The first comprehensive and systematic attempt to exhibit the propositions of geometry in such a sequence, which has come down to us, is one of the most famous works in all literature, the *Elements* pf Euclid (*q.v.*) of Alexandria (c. 300 B.C.). This work consists of 13 books, the first six and the last three of which are devoted to plane and solid geometry respectively. More or less literal translations of this ancient work were used to within a generation ago as textbooks in the public schools of England. The textbooks of the present time in all countries are adaptations of Euclid's Elements designed to meet the pedagogical needs of young pupils; they may claim pedagogical advantages, but at the sacrifice of some logical rigour and comprehensiveness.

The *Foundations* of Geometry.—If the propositions of geometry have been arranged in a strictly logical sequence, as above indicated, it is evident that a certain number at the beginning of the list are not logical consequences of the preceding ones. The first proposition is, of course, not a logical consequence of a preceding one; nor is it likely that the second is a logical consequence of the first. The question then, naturally, arises as to the logical status of these unproved propositions on which all the others depend. Moreover, these propositions involve certain terms, such as point, straight line, circle, etc. What meaning attaches to such terms? A definition defines a term in terms of certain others, the meaning of which is supposed known. In order to avoid defining in a circle some terms must remain undefined. The foundations of geometry must then consist, from the purely logical point of view, of a set of undefined terms and a set of unproved propositions concerning them, such that every new term can be defined in terms of the undefined, and such that every new proposition can be proved a consequence of the unproved. The unproved propositions are usually called axioms (*q.v.*) or postulates. Are these to be regarded as self-evident truths? Are they imposed on our minds a *priori*, as Kant (*q.v.*) taught, and is it impossible to think logically without granting them? Or are they, in accordance with the teaching of John Stuart Mill (*q.v.*) of experimental origin? Do the undefined terms denote primitive notions, the meaning of which is clear without definition to everybody? Prevailing opinion regards a geometric theorem as true beyond possibility of doubt by a reasonable being. Will a critical inspection bear out this opinicn? The answer is in the negative. Indeed, Bertrand Russell has said: "Mathematics may be defined as the science in which we never know what we are talking about nor whether what we say is true." ("Recent work on the Principles of Mathematics," The International *Monthly*, 1901.) Many a reader, in looking back on his school days, may heartily agree with this definition. Modern work on the foundations has shown that Kant was wrong and that Mill was only partly right. Logically considered, the axioms and postulates are mere assumptions. A certain writer has considered the dethroning of the "self-evident" as analogous to the change from an absolute monarchy to a democracy. The "self-evident truth," which ruled by the Divine right of the alleged inconceivability of the opposite, has been replaced by the "assumption," which is elected for its qualifications to serve (the reference is obviously to an ideal democracy).

Greek Geometry.—The more elementary part of Greek geometry is too well known to warrant a detailed exposition here. The reader will recall with pleasure or pain, but without difficulty, the theorems on the equality or congruence (to use the more modern term) of triangles, on parallel lines, on the circle, on the measurement of angles by various circular arcs, on the similarity of triangles and other figures, on regular polygons, on proportion, on perimeters and areas, etc , in plane geometry; and the various properties of planes and lines, dihedral, trihedral. and polyhedral angles, the mensuration of pyramids, prisms, cones, cylinders, and the sphere, etc., in solid geometry.

Among the high spots of this material we may mention the famous so called Pythagorean proposition (the square on the hypotenuse of a right triangle is equal to the sum of the squares on the other two sides) of which many proofs have been published. Among them the visual proofs are of special interest, one of which is reproduced herewith. A mere comparison of the adjoined figures establishes the theorem. The theorem is of interest



also for the problems to which it gave rise. Even in ancient times the problem of finding right triangles with integral sides, *i.e.*, to find three whole numbers $x, y,$ and z, such that $x^2+y^2=z^2$, engaged the attention of mathematicians and was completely solved by them. The generalization to the solution in whole numbers of the equation $x^n+y^n=z^n$ is still one of the unsolved problems in the theory of numbers (see THEORY OF NUMBERS), no solutions existing for any value of n greater than two and less than 100. Certain other famous problems deserve mention on account of their influence on the development of geometry and of mathematics in general.

The *Duplication of the Cube.*—The Athenians, so the story goes, appealed to the oracle at Delos to know how to stay the plague which visited their city in 430 B.C. The oracle replied that they must double in size the altar of Apollo without changing its shape. The altar being in the form of a cube, the problem was to find the size of a cube whose volume was twice that of a given cube. In modern notation, if a is the side of the given cube, the problem is to construct x such that $x^3=2a^3$. It must be remembered that, to the Greeks, "construct" meant construct *with ruler and* compasses only. With this limitation on the means to be employed the problem is now known to be impossible. But the attempts to solve it led to the invention of numerous new curves (see CURVE; CURVES, SPECIAL) and was a powerful stimulus to mathematicians through many centuries.

The Trisection of *an* Angle.—TO construct the bisector of any angle is one of the easiest problems in plane geometry. It was inevitable that a construction for dividing any angle into three (or more) equal parts should be sought. Again, if the construction is to apply to any angle (certain special angles such as a right angle are, of course, readily trisected) and if ruler and compasses only may be used, the problem is impossible; *i.e.*, there is no such construction. Many new curves, however, have been invented for the purpose of solution. Among these we may mention the curve that was later known as the *quadratrix,* because it furnished a solution also for the problem of squaring the circle (see below). In the figure shown above OX rotates at a uniform rate through one right angle from the position OB to the position OA, in the same time that the line MN, always parallel to OA, moves at a uniform rate from the position BC to the position OA. The intersection P of the line OX and M N then traces the curve in question. The use of this curve in trisecting an angle is almost trivially simple. Let XOB be the angle to be trisected. Divide BM into three equal parts and draw lines through the points of division parallel to OA. These lines meet the quadratrix in points which if joined to O yield the required trisectors.

The *Squaring of the Circle.*—This problem, perhaps the most famous one of all, consists in constructing a square equal in area to the area of a given circle. It, too, is impossible if ruler and compasses are the only instruments permitted. The use of the quadratrix in the solution of this problem depends on the following relation. In the preceding figure it may be proved that the length of the quadrant BXA satisfies the following proportion:

$$\frac{BXA}{OA}=\frac{OA}{OQ},$$

This makes it possible to construct a line equal in length to the circumference of the circle, from which a square equal in area to that of the circle is easily constructed. In spite of the fact that the solution of these problems by means of ruler and compasses alone has been known to be impossible for over 100 years, angle-trisecters and circle-squarers continue to appear. The best that can be said of these deluded individuals is that their enthusiasm has outstripped their scholarship. A later section of this article is devoted to the modern aspect of construction problems, and another section to developments arising from Euclid's parallel postulate.

The Conic *Sections.*—Partly under the stimulation of the problems just mentioned, the ancient Greeks investigated a class of curves known as the conic sections (*q.v.*), or more briefly the conics, and developed a large number of their properties. These curves arise as the plane sections of a right circular cone and have three distinct forms, the ellipse, the parabola, and the hyperbola. They have played a fundamentally important rôle in the development, not only of pure mathematics, but also in the applications. The reader may find further information in the article referred to (*see* also PROJECTIVE GEOMETRY). Suffice it to say that, had the conic sections not been previously studied, Kepler could not have discovered his famous laws concerning the motion of the planets, nor would we to-day have the benefit of searchlights with their parabolic reflectors. With the work of Apollonius on conics and the work of Archimedes on certain spirals and his remarkable determination of certain areas—he succeeded in finding the areas of an ellipse and of a parabolic segment—we reach the limits of ancient Greek geometry. No essential progress was made in this subject for over 1,000 years. We may, however, at this point say a few words about a more modern development, which is largely in the spirit of ancient geometry.

The Geometry of the Triangle *and* Circle.—This development relates to a detailed study of the triangle (*q.v.*) and circle (*q.v.*). It consists largely of the discovery of numerous points and lines connected with a triangle or circle and the discussion of their properties. Some of the latter are very remarkable. As an example, we may mention the nine-point circle related to a triangle, so-called because it passes through (a) the three mid-points of the sides, (b) the feet of the perpendiculars drawn from the vertices to the opposite sides, and (c) the mid-points of the lines joining the intersection of the three altitudes to the three vertices. This circle is tangent to the inscribed circle of the triangle, and also to the three circles which are each tangent to one side and the other two sides produced.

Descartes and the Invention of Analytic Geometry.—A new stimulus came to the development of geometry by the introduction through Descartes (1637, *q.v.*) of the so-called analytic methods. By representing a point in a plane by means of two numbers (co-ordinates, *q.v.*), giving the distance and direction of the point from two intersecting lines (axes) of the plane, it was found possible to translate any geometric situation into an algebraic situation, whereby the powerful methods of algebra became available as a means of geometric investigation. The resulting analytic geometry (*q.v.*) is distinguished from the older or synthetic geometry by its method rather than by its content. Analytic and synthetic geometry do not then constitute two different branches of geometry; they denote, rather, two distinct methods of studying geometry. There seems to be no need, therefore, to give further details as to this method at this point; the reader should consult the article just mentioned. We may, however, try to characterize briefly the effect on the development of geometry of the introduction of these new methods.

In the first place, it provided a systematic plan for further progress. A curve in the plane is represented by an equation in the variable co-ordinates (x, y) of a point on the curve. The straight lines are represented by equations of the first degree. Equations of the second degree turn out to represent the conic sections (*see* above). It was therefore natural to study next the curves represented by equations of the third degree (cubic curves); then those of the fourth degree (quartic curves); and so on It was possible even to develop a general theory of curves of

degree n. Some curves, such as the quadratrix previously mentioned, lead to equations that are not algebraic but transcendental (see EQUATION). Similar remarks apply to the geometry of space (of three dimensions). A point in space is represented by three co-ordinates (x, y, z); an equation in these three variables represents a surface; and surfaces may then be classified according to their degree (those of the first degree being the planes), and then systematically studied.

Construction Problems. — In the second place, and closely related to the preceding, the new method gave a means of classifying the construction problems inherited from the ancients, as well as new ones. A construction problem, when formulated analytically, is found to be equivalent to the solution of an equation or to that of a system of simultaneous equations. A construction with ruler and compasses is possible only when the corresponding equations can be solved by means of the rational operations (addition, subtraction, multiplication, division) and the extraction of square roots. The equations underlying the problem of duplicating the cube and that of trisecting an angle cannot be solved without introducing irrational operations of higher order than square roots (in both these cases cube roots suffice). These problems are, therefore, impossible with ruler and compasses, as previously stated. Another problem that had a great influence on the development of algebra was that of constructing a regular polygon of a given number of sides. The ancient Greeks were able, with ruler and compasses, to construct regular polygons of three, four, five, six, eight, ten, . . . sides; but failed in their attempts to construct one of seven sides. The determination of those values of n for which a regular polygon of n sides can be constructed with ruler and compasses led to a detailed study of the so-called cyclotomic equations, $x^n - 1 = 0$. As a result it was shown that the problem is possible only when n has the form $n = 2^k p_1 p_2 p_3 \ldots$, where each p represents a prime number of the form $2^{2^i}+1$. Since seven is not of this form, the problem is impossible when $n=7$. It will be noted that the first prime of the required form greater than 5 is 17; the next 257. The general result given is due to K. F. Gauss (1796) (*q.v.*).

Spaces of More Than Three Dimensions. — In the third place the analytic formulation of geometry led naturally, almost inevitably, to a vast extension of the domain of geometry. Since the points of a plane could be represented by pairs of co-ordinates (x, y), the points of a space of three dimensions by triples (x, y, z) of co-ordinates, the question arises as to the geometric interpretation of a set of four independent co-ordinates (x, y, z, u) of a set of five, . . .; in general, of a set of n such co-ordinates. This led to the conception of a space of four, five, . . . , or in general of n dimensions. The precise formulation of the idea of dimension (q v.), as here used, need not concern us at this place. We may note, however, that the notion of a space of four or more dimensions is not, as is generally supposed, necessarily beyond our powers of concrete representation. True, a space of points of more than three dimensions is an abstract generalization to visualize which is beyond the present powers of our imagination. But, if we use other elements than points with which to build our space, no such difficulty arises. Thus the totality of straight lines in ordinary space (of three dimensions) is four-dimensional; *i.e.*, constitutes a four-dimensional space (of lines). The totality of all spheres in ordinary space is a four-dimensional space of spheres. The corresponding geometries (line geometry and sphere geometry, see below) are just as concrete as the ordinary point geometries in the plane or in ordinary space. Nevertheless, point spaces of more than three dimensions are the ones usually thought of when n-dimensional spaces are being considered. Strangely enough, they find a large part of their interest in the field of applied mathematics. The four dimensional space-time manifold of Einstein-Minkowski is one that has recently aroused considerable popular interest in connection with' the theory of relativity (*q.v.*). In the field of applied mathematics the conception of a space of more than three dimensions is generally of value in that it makes possible the application of geometric language to a problem that is essentially analytic. This language is of great convenience and is often suggestive of the relations sought. As an example we may cite the dynamical theory of gases. Suppose a gas consists of a (very large) number, N, of molecules. The dynamical condition of each of these molecules is represented by six co-ordinates, three to specify its position in space and three more to give the three components of its velocity. To describe completely the state of the gas at any instant 6N co-ordinates would be necessary. Jeans, in his *Dynamical* Theory of Gases, says: "We can suppose this dynamical system represented in a generalized space of 6N dimensions." A space of 6N dimensions, where N is the number of molecules in a certain volume of a gas! After this, it will cause no surprise to learn that spaces of an infinite number of dimensions have also been defined and their properties investigated. Indeed, there are several different kinds of such spaces. Before leaving this topic, it should perhaps be noted that, while we have chosen to introduce the concept of an n-dimensional space on an analytic basis, the same can be done equally well on a purely synthetic basis.

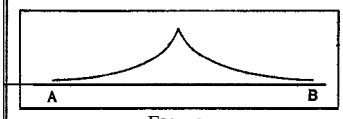


FIG. 3

Imaginary Elements — In the fourth place, the introduction of analytic methods led to the conception of imaginary points, lines, etc., a conception which proved very fruitful. Not only did it make possible a greater generality in the statement of theorems and give a deeper insight into geometric relations, as, for example, the characterization of a circle as any conic which passes through certain two imaginary points at infinity, but it also opened up a new field of enquiry. A complex variable $x = x' + ix''$ ($i^2 = -1$) depends on two real variables x', x''. A complex line has then two real dimensions; a complex plane of points (x, y), where x and y each depend on two real variables, is a space of four real dimensions. The discussions of the one-dimensional loci on the complex line, and the one-, two-, and three-dimensional spreads in the complex plane constitutes a new world for the geometer to explore.

Finally, we should mention the fact that the introduction of the analytic method contributed largely to the idea of the unity of mathematics. There have been several instances in the preceding paragraphs not merely illustrating the possibility of regarding every geometric situation from an analytic point of view, which is, of course, the very essence of analytic geometry, but also exemplifying the fact that analytic situations may be given a geometric interpretation. It becomes increasingly difficult to distinguish analysis from geometry; these two branches of mathematics appear rather as different aspects of the same thing.

Differential Geometry. — The introduction of the differential and integral calculus (Newton and Leibniz, qq v.) only a half century after the introduction of analytic geometry, greatly increased the power of the latter. The application of the fundamental ideas of the calculus to geometry introduced many new and valuable concepts. The resulting discipline is known as differential geometry (*q.v.*). Among the more elementary concepts referred to we may cite, by way of example, the curvature of a plane curve. The curvature at a point on a curve is a number which measures the sharpness of bending at that point. More precisely, if the curve is thought of as traced by a point moving with uniform speed along the curve, and this speed is taken as unity, the curvature at a point is proportional to the rate at which the tangent to the curve is turning at the instant when the moving point is at the given point. The curvature of a straight line is zero, the curvature of a circle is the same at every point and is equal to the reciprocal of the radius of the circle. This conception leads to a very beautiful theorem in the general theory of surfaces. The line drawn through a point on a surface perpendicular to the tangent plane at that point is called the *normal* to the surface. Let us consider the plane curves obtained as sections of our surface by planes passing through this normal — the so-called normal sections. Each of these plane curves has a curvature at the point. Among all these normal sections there will, in general, be one for which the curvature is a maximum, and one for which the curvature is a minimum. (The exception is when all the curvatures are the same, in which case the surface is a plane or a

sphere, or the point is some sort of exceptional point. We shall consider only "general" points, *i.e.*, points that are not exceptional.) The theorem referred to states that these two *normal* sections are *always* at *right* angles to each *other*. (The theorem is true, as stated, for all respectable surfaces other than planes or spheres; the exceptions may be disregarded in a survey of this kind.) Further, this theorem makes possible the definition of the so-called *total curvature of* a surface at a point as the product of the maximum and minimum curvatures of the normal sections just referred to. The investigation of surfaces of constant total curvature leads to the result that the only such surfaces are the plane whose total curvature at every point is zero; the sphere whose total curvature at every point is a positive constant (equal to the reciprocal of the radius squared); and the so-called pseudo-sphere whose total curvature at every point is a negative constant. (A negative total curvature indicates a saddle-shaped surface.) The pseudo-sphere is obtained by revolving about the line AB the curve (known as the tractrix) in the adjoined figure. These surfaces of constant curvature are of interest in connection with non-Euclidean geometry. (See below.)

Projective Geometry.—Early in the 17th century Desargues (1593–1662) proved the theorem that, if the vertices of two triangles lie on three lines meeting in a point, then their sides meet in three points lying on a line (see fig. 4). This theorem, it will be observed, has nothing to do with measurement, while the theorems of the older geometry are metric. Such theorems occur singly in the 17th century; they were not recognized as forming part of a new kind of geometry until about the beginning of the 19th century, when the so-called projective geometry (*q.v.*) was developed as a self-contained body of doctrine. If we take a photograph of a straight railroad track, with equally spaced ties, the parallel lines of the track appear in the photograph as converging, the equal distances between the ties appear unequal in the photograph, getting shorter and shorter as they recede in the picture. The right angles between the ties and the track appear as acute angles. If the landscape contains a circular pond it appears in the photograph as an ellipse. And yet the picture represents the scene; something of the actual relationships of the scene must be preserved, even though distances and angles are distorted, and parallel lines are no longer parallel. The properties of the scene that are preserved in the photograph, *i.e.*, the properties that are unchanged ("invariant" is the technical term), under the transformation produced by taking the photograph, are the properties studied by projective geometry. If the mechanism of this transformation is analysed, it is readily seen to consist of the following: Given any plane geometric figure (we confine ourselves to plane figures for the sake of simplicity), let O be any point not in the plane of the figure and think of straight lines drawn from O to every point of the figure. Let this set of lines be cut by any other plane not passing through O. This plane section of the lines through O gives a new figure in the cutting plane which is said to have been obtained from the original figure by the process of projection and section. It will be noted that in the case of our photograph the original scene is our first figure, the photographic plate is the cutting plane, while the point O is the point in the camera in which the light rays from the scene converge. Corresponding to every point of the original figure there is by this process determined a definite point in the new figure; corresponding to every straight line in the original there is a straight line in the new; if a point P in the original lies on a line l, the corresponding point P' in the new figure will lie on the line l' corresponding to l. A projective transformation consists of such a transformation by projection and section or of the result of a sequence of any number of such projections and sections. A projective transformation then transforms points into points, and straight lines into straight lines, and preserves the property of the incidence of points and lines. It does not preserve distances or angles; the latter, therefore, have no place in projective geometry as such. Its nature is to some extent characterized by calling it the geometry of position (Geometrie der *Lage*). It is, as to structure, a very simple geometry and an extraordinarily symmetric one. Further details must be sought in the article referred to above. Projective geometry, moreover, furnishes a scientific basis for descriptive geometry (*q.v.*) which is a branch of applied rather than of pure geometry.

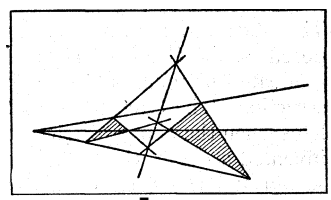

FIG. 4

The set of all projective transformations (in a plane or in space) form what is known as a group oj *transformations* by virtue of the fact that the result of performing any two of the operations of the set in succession is equivalent to a third transformation of the set. Projective geometry is characterized completely by the fact that it studies those properties of figures which are invariant under the group of all projective transformations. Similarly, the set of all rigid motions in space form a group (see **GROUPS**). Ordinary elementary metric Euclidean geometry is then the geometry which studies those properties of figures that remain invariant under the group of all such motions. These are special cases of a fundamental principle, first enunciated by Felix Klein in 1872, to the effect that corresponding to every grcup of transformations in space there is a geometry consisting of those properties of space which are invariant under the given group This principle provides at once a general classification of geometries; it also provides a systematic method of procedure in studying geometry as a whole, by the systematic investigation of all possible groups of transformations. In this project Sophus Lie (*q.v.*) laid the foundations in his theory of continuous groups. The group of motions just referred to is a sub-group of the general projective groups; other sub-groups are equivalent to the non-Euclidean (hyperbolic or elliptic) displacements; so that ordinary Euclidean and the two forms of non-Euclidean geometry are all implicitly contained in projective geometry, from which they are obtained by specialization. Furthermore, non-projective transformations may be defined by means of the projective, so that Arthur Cayley (*q.v.*) was led to exclaim: "Projective geometry is all geometry."

Inversion Geometry.—Among other geometries that have received extensive study, and in which the point is still the primary element of space, we may mention the inversion geometry in which the fundamental transformations are the so-called inversions with respect to a circle (plane inversion geometry), or with respect to a sphere (inversion geometry in space), or with respect to a hyper-sphere (in spaces of more than three dimensions).

Analysis Situs.—The set of all possible continuous transformations, *i.e.*, roughly speaking, the set of all twistings, bendings, stretchings or contractions without tearing anything apart, also form a group. The corresponding geometry is known as analysis situs (*q.v.*). It must consider, by what has been said. those properties of figures that remain invariant under any continuous transformation whatever. Are there such properties? A simple closed curve in a plane divides the plane into two regions, an inside and an outside. This is a theorem of analysis situs. A surface may be either one-sided or two-sided (a simple one-sided surface may be obtained by taking a strip of paper and fastening together the two ends, having previously turned one of the ends over through an angle of 180°; see fig. 5) and this property is invariant under any continuous transformation. If a map is drawn on any simple closed surface, say a sphere, by any set of intersecting lines on the surface dividing the surface into a set of regions (countries), and if the number of regions is denoted by r, the number of sides (the portions of the lines between two points of intersection) by s and the number of vertices (the points of intersection of the lines) by v, then the relation $v+r=s+2$ always holds. This, too, is a theorem of analysis situs (due to L. Euler, *q.v.*). It has been stated that, given any such map, four different colours are sufficient to colour the countries in such a way that no two countries with a boundary line in common shall have

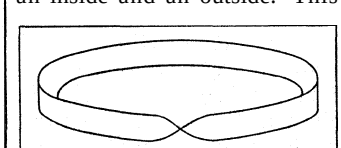

FIG. 5

the same colour. The proof of this apparently simple theorem, however, presents serious difficulties; it is still one of the unsolved problems of analysis situs.

Primitive Elements of Space.—We have hitherto assumed the point as the primitive element of space, except that once or twice we have hinted at the fact that this is not essential. In fact, the idea that some other geometric entity might be used as the primitive element, immediately opens up a new and vast field of geometric investigation. If, for example, we think of ordinary space as made up of all the straight lines in it, and study the properties of these lines and of systems of these lines, we enter the field of line geometry (*q.v.*), which, as has been said, is four-dimensional. If the sphere is taken as the primitive element of space, we obtain the so-called sphere geometry, and so on.

There are other aspects of geometry which it might be thought desirable to include in this general survey. For example, some may seek here a reference to such matters as curves without tangents, or to the so-called "crinkly" or surface-filling curves. But these are essentially problems of higher analysis in geometric garb. Others may look in vain for a discussion of the very important concept of elements at infinity in the various geometries; such a discussion will be found in the articles devoted to the geometries in question. Enough has been said, it is hoped, to give the reader some notion of the scope of geometry as a whole, and some idea of its fundamental conceptions and of the type of problem with which it deals.

BIBLIOGRAPHY.—Any one of the numerous school texts on plane or solid geometry will serve to refresh the reader's memory on these subjects. The standard edition of Euclid's *Elements* in English, is that by T. L. Heath in 3 vols. (Cambridge, 1908). For bibliographies of the various branches of geometry the reader should consult the articles referred to in this article. On certain special topics the following may be helpful: J. W. Young, *The Fundamental Concepts of Algebra and Geometry* (New York, 1911), for brief discussions of non-Euclidean geometry, construction problems, foundations of geometry, n-dimensional space, etc. This book presupposes no mathematical preparation beyond elementary algebra and geometry. Somewhat more mathematics is presupposed in *Monographs on Topics of Modern Mathematics*, edit. by J. W. A. Young (New York, 1911). It contains chapters on *The Foundations of Geometry* by O. Veblen; *Modern Pure Geometry* by T. F. Holgate; *Non-euclidean Geometry*, by *F. S.* Woods; *Constructions With Ruler and Compasses, by L.* E. Dickson. For imaginary elements in geometry *see* J. L. Coolidge, *Geometry in the Complex Domain* (Oxford, 1924). (J. W. Y.)

HISTORY OF GEOMETRY

The history of geometry may be considered under separate heads as follows: Ancient empirical geometry, ancient demonstrative geometry, sporadic developments during mediaeval times and the Renaissance, analytical geometry, modern synthetic geometry and, finally, the foundations of geometry.

Ancient Empirical Geometry.—Early Babylonian records disclose the use in auguries of triangles, quadrangles and parallel lines; drawings of Babylonian carriages indicate the division of a circumference into four and six equal parts. For angular measurement the circumference was divided into 360 equal parts or degrees, each degree into 60 minutes, and each minute into 60 seconds. Like the Hebrews (I. Kings vii. 23), the Babylonians took $\pi = 3$. One tablet reveals the approximate computation of the diagonal of a rectangle, expressed in the sexagesimal notation. More attention to geometry was given in Egypt. Greek writers state that land surveying was practised in Egypt because frequent overflows of the Nile obliterated landmarks. More reliable information is obtained from papyri and from inscriptions on the walls of temples. The Ahmes papyrus written about 1550 B.C. or, according to others, about 1700 B.C., is the most important ancient mathematical manuscript known. In this more stress is laid upon arithmetic and algebra than upon geometry. Ahmes calculates the areas of squares and rectangles; he approximates the area of an isosceles triangle by multiplying the slanting side by half the base, and of an isosceles trapezoid by multiplying half the sum of the two bases by the slant height. Remarkable is the rule for finding the area of a circle: From the diameter subtract one-ninth of it, and square the remainder. This rule implies that π nearly equals 3.16. Examples on the measurement of pyramids in Ahmes are of doubtful interpretation, but in another nearly contemporaneous papyrus (see *Ancient Egypt*, 1917), a calculation is given yielding the exact volume of the frustum of a rectangular pyramid—an astounding achievement in early Egyptian times.

The Greek geometry of Thales and his school, about the 7th century B.C., was only just emerging from the empirical stage; it dealt with such cases as the equality of vertical angles, the equality of the base angles of an isosceles triangle and the bisection of a circle by a diameter. This was a geometry of lines; Egyptian geometry was mainly one of areas and volumes. Thales's measurements of the heights of the pyramids by their shadows and of the distance of ships at sea presupposes the use of similar triangles.

Ancient Demonstrative Geometry.—The transition from empirical to rigorous demonstrative geometry was necessarily very slow. The discovery by the Pythagoreans in Italy of the existence of incommensurable magnitudes (such as the side and diagonal of a square) marks a long step toward reasoned conclusions. The story of the slaughter of a hecatomb of oxen in celebration of the discovery of a proof of the "Pythagorean theorem" of the right triangle is probably a myth, but it indicates a high appreciation of an intellectual achievement in pure geometry. Another indication of progress was the proposing, by the Sophists of Athens, of the three famous problems of construction—the squaring of the circle, the trisection of any given angle, and the duplication of a cube. These are now known to be impossible under the restrictions imposed by the Greeks—the use of a pair of compasses and an ungraduated or unmarked ruler in a finite number of steps of construction. The Greeks themselves found solutions of these problems when the above restrictions were abandoned. Hippias of Elis invented a curve, the "quadratrix," by which angles could be trisected and the circle could be squared. But the drawing of the quadratrix involved theoretically an infinite number of steps. Hippocrates of Chios, evidently hoping eventually to achieve the quadrature of the circle, successfully "squared" certain lunes and thus furnished the earliest example of a curvilinear area for which under the Greek restrictions an exactly equal area could be constructed in a plane which was bounded by straight lines. The duplication of the cube which, algebraically expressed, means constructing $X = \sqrt[3]{2}S$, where S is the side of a given cube, was solved "mechanically" by the aid of the conchoid of Nicomedes and by other means. Progress in giving definitions of fundamental concepts like "point," "line," "surface" and in giving explicit expression to axioms, was made by Plato and his pupils. The theory of proportion as related to magnitudes was developed by Eudoxus and Theaetetus. Eudoxus is credited also with the "method of exhaustion" which is not the same as the modern theory of limits, even though it involves the concept of a variable and a constant. The procedure as found in Euclid's *Elements*, bk. xii., Prop. 2, involves a part of our modern process of showing that a constant is the limit of a variable, but the Greeks did not actually pass, as we do, from the variable to its limit, but resorted, instead, to a process of *reductio ad absurdum*.

A most interesting phase in the development of the Greek philosophy of mathematics is seen in Zeno of Elea's arguments on motion. As explained in Aristotle's *Physics*, Zeno tried to prove that motion is impossible. Swift-footed Achilles could not catch a tortoise, the arrow in its flight is at any moment at rest, etc. For centuries Zeno was branded as a paralogist, but such recent writers as Paul Tannery and Bertrand Russell (*Principles* of *Mathematics*, 1903) advance the view that Zeno was misunderstood and that his arguments were sound and involved profound questions which have been successfully resolved only by the theory of the continuum as developed in recent mathematics. The paradoxes of Zeno, as well as Antiphon's attempt to square the circle by inscribing a series of regular polygons of an increasingly greater number of sides, the ultimate polygon coinciding with the circle, convinced Greek mathematicians that a clear and logical science of geometry could not be attained, except by eliminating the seemingly mystic concepts of infinity and of fixed infinitesimals. And thus we find Euclid excluding the infinitely little from his *Elements* by a definition (bk. v., def. 4): "Magnitudes are said to have a ratio to one another, when the less can be multiplied so as to exceed the other"; if the less were infinitely small, any finite

multiple of it would still be infinitely small and could not satisfy this definition. Likewise, Archimedes, in the preface to his Quadrature of *the* Parabola, gives a postulate which he attributes to Eudoxus: If a and *b* are magnitudes, such that $a<b$, it shall be possible to find a finite number *n*, such that nu> b. Thus in the classical writings of Euclid, Archimedes, and Apollonius of Perga, the infinitely small is carefully avoided.

Euclid was the author of several works, the most important of which is his Elements, written between 330 and 320 B.C. It contained 13 books, of which the first six and the last three were devoted to geometry (plane and solid), the seventh, eighth and ninth to arithmetic, and the tenth to irrationals. The proof of the theorem of Pythagoras on the right triangle is the only part of the geometry which Greek commentators definitely ascribe to Euclid. The geometrical theorems and the methods of proof (the method of exhaustion and the definition of proportion of magnitudes) appear to be due to earlier investigators. The great achievement of Euclid was the arrangement of the material handed down to him into a coherent, logical system. He ranks as a great systematizer. It is one of the marvels in the history of mathematics that the *Elements,* written in the 4th century B.C., should have established and maintained itself as a text-book in geometry for over 2,000 years. In England it was the authorized text down to the opening of the present century.

Euclid eschewed all practical applications of geometry. This attitude was abandoned by Archimedes who found the relation, $3\frac{1}{7}>\pi>3\frac{10}{71}$, needed in computing the area of a circle, and who discovered theorems on the areas of the surface of a sphere and of a cylinder, as well as on the volumes of a sphere and cylinder.

Besides the development of ordinary elementary geometry, the Greeks must be credited with the study of the conic sections (the ellipse, parabola, and hyperbola). The beginnings were made in the time of Plato; the culmination was reached in the work called the Conic Sections, written by Apollonius of Perga.

With Euclid, Archimedes and Apollonius, geometry reached the highest development during ancient times. Later Greek writers discovered certain curves (the conchoid of Nicomedes and the cissoid of Diocles); Pappus reached certain theorems and view points which were more fully developed in modern times. But these were the afterglow following the sunset of Greek geometry.

Mediaeval Times and the Renaissance.—The Hindus of this period did not excel in geometry. Their creative work is limited to theorems on the area and diagonals of a quadrilateral inscribed in a circle, theorems developed mainly by Brahmagupta (c. 628). The outstanding Arabic achievement was the geometric solution of cubic equations, by the method of intersecting conics, a process which had been foreshadowed by Archimedes. The fullest Arabic exposition of this topic was given by the poet Omar Khayyam. In Europe creative work began with Johann Kepler, who made use of the concepts of infinitely small and infinitely great quantities, which Euclid and Archimedes had carefully avoided in their classical writings. Kepler looked upon a circle as a polygon having an infinite number of sides, and upon a sphere as consisting of an infinite number of pyramids. He arrived at the areas and volumes of figures generated by curves revolving about a line as axis. The Italian, Bonaventura Cavalieri, a pupil of Galileo, developed the Geometry of *Indivisibles,* and succeeded in solving many of the problems on volumes which had been proposed by Kepler for solution. Researches which foreshadowed the great achievements of a more modern period are found in the work of Evangelista Torricelli, Vincenzo Viviani, Gilles P. de Roberval, and especially of Gérard Desargues and Blaise Pascal on modern synthetic geometry.

The Invention of Analytic Geometry.—Analytic geometry was created by two Frenchmen, René Descartes and Pierre de Fermat. The chief credit is rightly awarded to Descartes, who promptly published his results in his La ge'ome'trie, 1637; Fermat's treatise Ad locos *planos* et *solidos isagoge* appeared posthumously in 1679. The two main ideas involved in analytical geometry are the location of points in a figure by the use of co-ordinates and the algebraic representation of a curve or surface by an equation involving two or three variables. Of these, only the latter was new in the 17th century; co-ordinate representation was practised in ancient times by Apollonius and others. Descartes's La *géométrie* does not contain a systematic development of analytical geometry in the manner found in modern texts. The method must be constructed from isolated statements occurring in different parts of the treatise. Nevertheless, it is a work of genius occupying a conspicuous place in the history of geometry. The words "abscissa" and "ordinate" were not due to Descartes. In the technical sense of analytical geometry they were first used by Leibniz in 1692, in the *Acta* Eruditorum. An important example solved by Descartes in his La ge'ome'trie was the "Problem of Pappus": Given several straight lines in a plane find the locus of a point such that the perpendicular drawn from the point to the given lines, shall satisfy the condition that the product of certain of them shall be in a given ratio to the product of the others. This problem afforded an excellent example of the power of the analytical method, a power which Boltzmann more recently described by saying that the formula appears at times cleverer than the man who invented it.

The cultivators of analytical geometry in the 18th century were Jean Paul de Gua de Malves, Gabriel Cramer, Leonhard Euler and, in general, the mathematicians who developed the differential and integral calculus. Thus Newton in 1704 published a classification of cubic curves. The calculus offered a general and expeditious method of finding tangents at any point of a continuous curve having derivatives.

During the 19th century, new principles were introduced into analytic geometry which afforded greater power and generality to the science. Thus the principle of duality was applied by Julius Plucker to equations of lines and curves. The duality consisted in a double interpretation of one and the same equation so that $ux+vy+1=0$, for example, could be interpreted as having two variables *x*, y representing co-ordinates of points, u and *v* being constants, or the equation could be interpreted as having two variables u, v representing lines, *x* and y being constants. In the first case the equation represents a straight line, in the second case, a point. By this duality, one and the same process would yield two theorems. But for the full analytic application of duality, Augustus F. Mobius and Plucker found it necessary to abandon the ordinary Cartesian co-ordinates and to introduce the more general homogeneous co-ordinates. Pliicker studied the singularities of plane curves and developed four equations (the "Plucker equations") expressing the relations between the number of double points, double tangents, stationary points, and stationary tangents of a curve of a given degree and class. The discovery of these relations Arthur Cayley considered "the most important one beyond all comparison in the entire subject of modern geometry."

Etienne Bobillier and Pliicker introduced an "abridged notation." J. J. Sylvester and Otto Hesse showed how processes of elimination could be simplified by the use of determinants. Particularly prominent in elaborating the higher fields of the science were Alfred Clebsch, Henri Halphen, and Jean Gaston Darboux. Curves and surfaces of higher order afford fields of never-ending research. (See CURVES; CURVES, SPECIAL.)

Modern Synthetic Geometry.—This was cultivated in the 19th century simultaneously with analytic geometry. The two movements occupied the same field of study, but differed in method of exposition. Rivalry existed between the followers of the two methods, which was usually but not always friendly. The continual direct viewing of figures as existing in space adds exceptional charm to the study of synthetic geometry, but the equation of the analytic method may outrun thought itself and constitutes a powerful tool in research. Jean Victor Poncelet and others used both the synthetic and the analytic methods; Jakob Steiner used only the former, Pliicker only the latter. Modern synthetic geometry was first cultivated by Gaspard Monge, L. N. M. Carnot, and J. V. Poncelet in France, and by Mobius and Steiner in Germany and Switzerland, and was developed to still higher perfection by Michel Chasles in France and von Staudt in Germany. Monge in 1795 was the first to stress the "descriptive geometry" used in engineering. The principle of duality was advanced by J. D. Gergonne and Poncelet for **the**

study of descriptive properties without reference to the analytic processes elaborated by Pliicker. The use of the anharmonic or cross ratio was stressed by Steiner and Chasles.

The Foundations of Geometry. — The parallel postulate of Euclid (according to which two lines in a plane meet if the sum of the two interior angles on the same side of a transversal is less than two right angles) seemed unsatisfactory even to some of the ancient mathematicians. Proofs of it were attempted on the assumption of the other Euclidean axioms, but were always found invalid. After many failures, certain investigators tried to build up a geometry in which the postulate does not hold, in which, in other words, the angle sum in question may be less than two right angles and yet the lines may not meet, no matter how far they are produced. The result was a non-Euclidean geometry, perfectly consistent with its assumptions, developed independently by the Russian, Nicolai I. Lobachevski (1829) and the Hungarian mathematician, János Bolyai (1834). So novel were these creations that they failed to secure general attention for many years. With reference to the assumptions about parallel lines, there are now recognized three principal geometries — the "parabolic" or Euclidean based on Euclid's parallel postulate, the "hyperbolic" or Lobachevskian based on the denial of that postulate, and the "elliptic" or Riemannian geometry in which parallel lines do not exist at all. Felix Klein considered two forms of "elliptic" geometry. Two-dimensional geometric figures in the first of these geometries are visualized when drawn in a plane; those in the second geometry are partly visualized on a saddle-shaped surface like the pseudosphere; those in the third geometry are visualized on a sphere. Recently, these geometries have assumed importance in cosmological speculations. According to Albert Einstein, the universe is finite and its geometry is "elliptic."

The question of the number of dimensions has agitated mathematicians and philosophers since the time of the Greeks. The first to assume definitely the existence of a fourth dimension of space was the Platonist. Henry More, of Cambridge, England, a contemporary of Isaac Newton. But not till the 19th century did mathematicians enter upon an extensive study of geometries of higher dimensions. As a rule it was not claimed that these higher dimensions had real existence in our physical space; they were ideal creations of the human mind. However, as early as the 18th century, D'Alembert and Lagrange looked upon time, which appeared as a fourth variable in mechanics, as a fourth dimension. This idea was developed in more recent time by Hermann Minkowski and Einstein in a manner leading to a fourth dimensional world, a "fusion of geometry and physics." Said Minkowski (1908): "Nobody has ever noticed a place except at a time, or a time except at a place."

The foundations of geometry are the last part of the geometric structure to be firmly established. Italian and German mathematicians (Giuseppe Peano, 1880; Moritz Pasch, 1882; Mario Pieri, 1899) were the first to enter upon a minute study of independent, consistent and complete sets of axioms enabling the different geometries to be built up without borrowing anything from intuition. It was recognized that Euclid, who for centuries had been admired for the rigour of his demonstrations, does depend here and there upon facts not deduced from the axioms but obtained from visual inspection of the figures. Thus, in Euclid's *Elements*, in the very first proposition, it is assumed without proof that two circles drawn in the figure intersect each other. The study of the foundations of different geometries was continued in Germany, by David Hilbert, in France by Henri Poincaré and in the United States mainly by Oswald Veblen.

NON-EUCLIDEAN GEOMETRY

The various metrical geometries are concerned with the properties of the various types of congruence-groups, which are defined in the study of the *axioms of geometry* and of their immediate consequences. But this point of view of the subject is the outcome of recent research, and historically the subject has a different origin. Non-Euclidean geometry arose from the discussion, extending from the Greek period to the present day, of the various assumptions which are implicit in the traditional Euclidean system of geometry. In the course of these investigations it became evident that metrical geometries, each internally consistent but inconsistent in many respects with each other and with the Euclidean system, could be developed. A short historical sketch will explain this origin of the subject, and describe the famous and interesting progress of thought on the subject.

History. — In 1621 Sir Henry Savile called attention to the existence of two blemishes *(duo naevi)* in geometry, namely, the theory of parallels and the theory of proportion. In both respects the work of later scholars has given rise to important branches of mathematics, while at the same time showing that Euclid is in these respects more free from blemish than had been previously credible. It was from endeavours to improve the theory of parallels that non–Euclidean geometry arose; and though it has now acquired a far wider scope, its historical origin remains instructive and interesting. Euclid's "axiom of parallels" appears as Postulate V. to the first book of his *Elements*, and is stated thus, "And that, if a straight line falling on two straight lines make the angles, internal and on the same side, less than two right angles, the two straight lines, being produced indefinitely, meet on the side on which are the angles less than two right angles."

To Euclid's successors this axiom had signally failed to appear self-evident, and had failed equally to appear indemonstrable. Without the use of the postulate its converse is proved in Euclid's 18th proposition, and it was hoped that by further efforts the postulate itself could be also proved. The first step consisted in the discovery of equivalent axioms. Christopher Clavius in 1574 deduced the axiom from the assumption that a line whose points are all equidistant from a straight line is itself straight. John Wallis in 1663 showed that the postulate follows from the possibility of similar triangles on different scales. Girolamo Saccheri (1733) showed that it is sufficient to have a single triangle, the sum of whose angles is two right angles. Other equivalent forms may be obtained, but none shows any essential superiority to Euclid's. Indeed plausibility, which is chiefly aimed at, becomes a positive demerit where it conceals a real assumption.

Saccheri.—A new method, which, though it failed to lead to the desired goal, proved in the end immensely fruitful, was invented by Saccheri, in a work entitled *Euclides ab omni naevo vindicatus* (Milan, 1733). If the postulate of parallels is involved in Euclid's other assumptions, contradictions must emerge when it is denied while the others are maintained. This led Saccheri to attempt a *reductio ad absurdum,* in which he mistakenly believed himself to have succeeded. What is interesting, however, is not his fallacious conclusion, but the non-Euclidean results which he obtains in the process. Saccheri distinguishes three hypotheses (corresponding to what are now known as Euclidean or parabolic, elliptic and hyperbolic geometry), and proves that some one of the three must be universally true. His three hypotheses are thus obtained: equal perpendiculars AC, *BD* are drawn from a straight line *AB*, and *CD* are joined. It is shown that the angles *ACD, BDC* are equal. The first hypothesis is that these are both right angles; the second, that they are both obtuse; and the third, that they are both acute. Many of the results afterwards obtained by Lobachevski and Bolyai are here developed. Saccheri fails to be the founder of non-Euclidean geometry only because he does not perceive the possible truth of his non-Euclidean hypotheses.

Lambert.—Some advance is made by Johann Heinrich Lambert in his *Theorie der Parallellinien* (written 1766; posthumously published 1786). Though he still believed in the necessary truth of Euclidean geometry, he confessed that, in all his attempted proofs, something remained undemonstrated. He deals with the same three hypotheses as Saccheri, showing that the second holds on a sphere, while the third would hold on a sphere of purely imaginary radius. The second hypothesis he succeeds in condemning, since, like all who preceded Bernhard Riemann, he is

unable to conceive of the straight line as finite and closed. But the third hypothesis, which is the same as Lobachevski's, is not even professedly refuted

Three Periods **of** non-Euclidean Geometry.—Non-Euclidean geometry proper begins with Karl Friedrich Gauss. The advance which he made was rather philosophical than mathematical. It was he (probably) who first recognized that the postulate of parallels is possibly false, and should be empirically tested by measuring the angles of large triangles. The history of non-Euclidean geometry has been aptly divided by Felix Klein into three very distinct periods. The first—which contains only Gauss, Lobachevski and Bolyai—is characterized by its synthetic method and by its close relation to Euclid. The attempt at indirect proof of the disputed postulate would seem to have been the source of these three men's discoveries; but when the postulate had been denied, they found that the results, so far from showing contradictions, were just as self-consistent as Euclid. They inferred that the postulate, if true at all, can only be proved by observations and measurements. Only one kind of non-Euclidean space is known to them, namely, that which is now called hyperbolic. The second period is analytical, and is characterized by a close relation to the theory of surfaces. It begins with Riemann's inaugural dissertation, which regards space as a particular case of a manifold (see MANIFOLDS) ; but the characteristic standpoint of the period is chiefly emphasized by Eugenio Beltrami. The conception of measure of curvature is extended by Riemann from surfaces to spaces, and a new kind of space, finite but unbounded (corresponding to the second hypothesis of Saccheri and Lambert). is shown to be possible. As opposed to the second period, which is purely metrical, the third period is essentially projective in its method. It begins with Arthur Cayley, who showed that metrical properties are projective properties relative to a certain fundamental quadric, and that different geometries arise according as this quadric is real, imaginary or degenerate. Klein, to whom the development of Cayley's work is due, showed further that there are two forms of Riemann's space, called by him the elliptic and the spherical. Finally, it has been shown by Sophus Lie, that if figures are to be freely movable throughout all space in ∞^6 ways, no other three-dimensional spaces than the above four are possible.

Gauss.—Gauss published nothing on the theory of parallels, and it was not generally known until after his death that he had interested himself in that theory from a very early date. In 1799 he announces that Euclidean geometry would follow from the assumption that a triangle can be drawn greater than any given triangle. Though unwilling to assume this, we find him in 1804 still hoping to prove the postulate of parallels. In 1830 he announces his conviction that geometry is not an *a priori* science; in the following year he explains that non-Euclidean geometry is free from contradictions, and that, in this system, the angles of a triangle diminish without limit when all the sides are increased. He also gives for the circumference of a circle of radius r the formula $\pi k(e^{r/k}-e^{-r/k})$, where k is a constant depending upon the nature of the space. In 1832, in reply to the receipt of Bolyai's *Appendix*, he gives an elegant proof that the amount by which the sum of the angles of a triangle falls short of two right angles is proportional to the area of the triangle. From these and a few other remarks it appears that Gauss possessed the foundations of hyperbolic geometry, which he was probably the first to regard as perhaps true. It is not known with certainty whether he influenced Lobachevski and Bolyai, but the evidence we possess is against such a view.

Lobachevski.—The first to publish a non-Euclidean geometry was Nicholas Lobachevski, professor of mathematics in the new university of Kazan. In the place of the disputed postulate he puts the following: "All straight lines which, in a plane, radiate from a given point, can, with respect to any other straight line in the same plane, be divided into two classes, the *intersecting* and the *non-intersecting*. The *boundary* line of the one and the other class is called parallel to the given line" It follows that there are two parallels to the given line through any point, each meeting the line at infinity, like a Euclidean parallel. Hence a line has two distinct points at infinity, and not one only as in ordinary geometry. The two parallels to a line through a point make equal acute angles with the perpendicular to the line through the point. If p be the length of the perpendicular, either of these angles is denoted by $\Pi(p)$. The determination of $\Pi(p)$ is the chief problem; it appears finally that, with a suitable choice of the unit of length,

$$\text{tang } \Pi(p)=e^{-p}.$$

Before obtaining this result it is shown that spherical trigonometry is unchanged, and that the normals to a circle or a sphere still pass through its centre. When the radius of the circle or sphere becomes infinite all these normals become parallel, but the circle or sphere does not become a straight line or plane. It becomes what Lobachevski calls a limit-line or limit-surface. The geometry on such a surface is shown to be Euclidean. limit-lines replacing Euclidean straight lines. It is, in fact, a surface of zero measure of curvature. By the help of these propositions Lobachevski obtains the above value of $\Pi(p)$, and thence the solution of triangles. He points out that his formulae result from those of spherical trigonometry by substituting ia, ib, ic, for the sides a, b, c.

Bolyai.—John Bolyai, a Hungarian, obtained results closely corresponding to those of Lobachevski. These he published in an appendix to a work by his father, entitled Appendix *Scientiam spatii absolute veram exhibens:* a veritate aut falsitate Axiomatis XI. Euclidei (a priori haud *unquam* deeidenda) independentem: *adjecta* ad casum *falsitatis, quadratura circuli geometrica.* This work was published in 1831, but its conception dates from 1823. It reveals a profounder appreciation of the importance of the new ideas, but otherwise differs little from Lobnchevski's. Both men point out that Euclidean geometry is a limiting case of their own more general system, that the geometry of very small spaces is always approximately Euclidean, that no a priori grounds exist for a decision, and that observation can only give an approximate answer. Bolyai gives also, as his title indicates, a geometrical construction, in hyperbolic space, for the quadrature of the circle, and shows that the area of the greatest possible triangle, which has all its sides parallel and all its angles zero, is πi^2, where i is what we should now call the space-constant.

Riemann.—The works of Lobachevski and Bolyai, though known and valued by Gauss, remained obscure and ineffective until, in 1866, they were translated into French by J. Hoiiel. But at this time Riemann's dissertation, *Über* die Hypothesen, welche der Geometrie *zu Grunde* liegen, was already about to be published. In this work Riemann, without any knowledge of his predecessors in the same field, inaugurated a far more profound discussion, based on a far more general standpoint; and by its (posthumous) publication in 1867 the attention of mathematicians and philosophers was at last secured.

Riemann's work contains two fundamental conceptions, that of a manifold and that of the *measure* of *curvature* of a continuous manifold possessed of what he calls flatness in the smallest parts.

There are four points in which this profound and epoch-making work is open to criticism or development—(I) the idea of a manifold requires more precise determination; (2) the introduction of coordinates is entirely unexplained and the requisite presuppositions are unanalysed; (3) the assumption that ds is the square root of a quadratic function of $dx_1, dx_2, \ldots$ is arbitrary; (4) the idea of superposition, or congruence. is not adequately analysed. The modern solution of these difficulties is properly considered in connection with the general subject of the axioms of geometry.

Helmholtz.—The publication of Riemann's dissertation was closely followed by two works of Hermann von Helmholtz, again undertaken in ignorance of the work of predecessors. In these a proof is attempted that ds must be a rational integral quadratic function of the increments of the coordinates. This proof has since been shown by Lie to stand in need of correction. Helmholtz's remaining works on the subject are of almost exclusively philosophical interest.

Beltrami.—The only other writer of importance in the second period is Eugenio Beltrami, by whom Riemann's work was brought

into connection with that of Lobachevski and Bolyai. As he gave a convenient Euclidean interpretation of hyperbolic plane geometry, his results will be stated at some length. The *Saggio* shows that Lobachevski's plane geometry holds in Euclidean geometry on surfaces of constant negative curvature, straight lines being replaced by geodesics. Such surfaces are capable of a conformal representation (*q.v.*) on a plane, by which geodesics are represented by straight lines. Hence if we take, as coordinates on the surface, the Cartesian coordinates of corresponding points on the plane, the geodesics must have linear equations.

Transition to the Projective Method.—The *Saggio* gives a Euclidean interpretation confined to two dimensions. But a consideration of the auxiliary plane suggests a different interpretation, which may be extended to any number of dimensions. If, instead of referring to the pseudosphere, we merely *define* distance and angle, in the Euclidean plane, as those functions of the coordinates which gave us distance and angle on the pseudosphere, we find that the geometry of our plane has become Lobachevski's. All the points of the limiting circle are now at infinity, and points beyond it are imaginary. If we give our circle an imaginary radius the geometry on the plane become elliptic. Replacing the circle by a sphere, we obtain an analogous representation for three dimensions. Instead of a circle or sphere we may take any conic or quadric. With this definition, if the fundamental quadric be $\Sigma xx=0$, and if $\Sigma xx'$ be the polar form of Σxx, the distance p between x and x' is given by the projective formula

$$\cos(p/k)=\Sigma xx'/\{\Sigma xx\cdot\Sigma x'x'\}^{\frac{1}{2}}.$$

That this formula is projective is rendered evident by observing that $e^{-2ip/k}$ is the anharmonic ratio of the range consisting of the two points and the intersections of the line joining them with the fundamental quadric. With this we are brought to the third or projective period. The method of this period is due to Cayley; its application to previous non-Euclidean geometry is due to Klein. The projective method contains a generalization of discoveries already made by Laguerre in 1853 as regards Euclidean geometry. The arbitrariness of this procedure of deriving metrical geometry from the properties of conics is removed by Lie's theory of congruence. We then arrive at the stage of thought which finds its expression in the modern treatment of the axioms of geometry.

The Two Kinds of Elliptic Space.—The projective method leads to a discrimination, first made by Klein, of two varieties of Riemann's space; Klein calls these eliiptic and spherical. They are also called the polar and antipodal forms of elliptic space. The latter names will here be used. The difference is strictly analogous to that between the diameters and the points of a sphere. In the polar form two straight lines in a plane always intersect in one and only one point; in the antipodal form they intersect always in two points, which are antipodes. The antipodal form may be called a "quasi-geometry." Similarly in the antipodal form two diameters always determine a plane, but two points on a sphere do not determine a great circle when they are antipodes, and two great circles always intersect in two points. Again, a plane does not form a boundary among lines through a point: we can pass from any one such line to any other without passing through the plane. But a great circle does divide the surface of a sphere. So, in the polar form, a complete straight line does not divide a plane, and a plane does not divide space, and does not, like a Euclidean plane, have two sides. But, in the antipodal form, a plane is, in these respects, like a Euclidean plane.

Finally, it is of interest to note that, though it is theoretically possible to prove, by scientific methods, that our geometry is non-Euclidean, it is wholly impossible to prove by such methods that it is accurately Euclidean. For the unavoidable errors of observation must always leave a slight margin in our measurements. A triangle might be found whose angles were certainly greater, or certainly less, than two right angles; but to prove them *exactly* equal to right angles must always be beyond our powers. If, therefore, any man cherishes a hope of proving the exact truth of Euclid, such a hope must be based, not upon scientific, but upon philosophical considerations.

GEONIM: *see* TALMUD.

GEOPHYSICAL PROSPECTING (GEOPHYSICAL EXPLORATION, APPLIED GEOPHYSICS) is the application of the principles of geophysics (*q.v.*) to the location of mineral deposits.

In various branches of geophysical science (geodesy, seismology, terrestrial magnetism, etc.) a relation between the surface distribution of physical forces and the physical properties and disposition of major geologic features in the earth's crust had been observed at an early date. In geophysical prospecting, similar observation methods as in geophysical science, are employed; apparatus and methods are more sensitive and adapted to the determination of local geologic structure. Hence, geophysical prospecting may also be defined as the *location of subsurface structure and mineral deposits by surface measurements of physical quantities.* It is not to be confused with the divining-rod (*q.v.*) for which a sound scientific foundation has yet to be established. Geophysical prospecting is applicable only if *differences in physical properties* exist between the sought geologic bodies and their surroundings, such as: Magnetic susceptibility, density, elasticity, electric conductivity, thermal conductivity, and radioactivity. If a specific commercial mineral does not possess these properties itself, it may often occur in mineralogic, stratigraphic, or structural association with other media which have such properties and can be located. This is known as indirect geophysical prospecting. An outstanding example is the indirect location of oil. With present technique, oil cannot be found directly; geophysical oil exploration utilizes methods to locate geologic structures (anticlines, salt domes, faults) which are expected to be oil bearing.

(a) Review of Methods.—In accordance with the physical properties responsible for the effects of geologic bodies, the following methods may be distinguished in the order of properties enumerated above: Magnetic, gravitational, seismic, electrical, geothermal, and radioactive methods. In all these methods, certain physical effects are observed which must be interpreted in terms of geology. From the point of view of interpretation, geophysical methods fall into two major groups: (1) Methods without, and (2) methods with depth control. In the former, spontaneous effects are observed which represent the sum of the effects of all bodies within range; it is possible that a small body at shallow depth exerts the same influence as a large body at greater depth. The gravitational, magnetic, and the self-potential methods (*see* Table I) of electrical prospecting exhibit this lack of depth control. Interpretation of results obtained by these methods is of an indirect nature: Geologically justifiable assumptions are made about the subsurface section, its effects are calculated, compared with the field findings, and modified until a reasonable agreement between theoretical and field data is obtained. In the second group, effects of geologic bodies do not appear spontaneously but must be produced by transmitting (seismic or electric) energy through the ground; they thus appear as anomalies in seismic wave speed and electrical conductivity. As

it is possible to regulate the depth of penetration by a suitable spacing of transmission and reception points, effects of shallow bodies can be separated from those of deep bodies; as a matter of fact, depths can usually be determined directly. Another advantage of methods with depth control is that the physical properties of the formations traversed by the energy may be deduced.

It is customary to distinguish a number of subdivisions within the major geophysical methods, depending on type of instruments used, quantities measured, or on method of energy supply and reception. Table I illustrates the major groups of geophysical methods together with their subdivisions and geologic applications. Details on each method with special reference to rock properties, instruments, and interpretation procedure are given in the following sections.

(b) Gravity Methods. — These methods are based upon the measurement of physical quantities related to the gravitational field which in turn are affected by differences in densities and disposition of geologic bodies beneath.

The densities of a few minerals for which gravity prospecting has been done may be enumerated: Pyrite, 4·9–5·2; pyrrhotite, 4·5–4·7; galena, 7·5–7·8; barite, 4·3–4·7; magnetite, 4·9–5·2; lignite, 1·1–1·2. In oil exploration, the following densities are significant: Salt, 2·1–2·2; igneous rocks, 2·5–3·0; sedimentary rocks, 1·6 to 2.8. The latter increases with consolidation and geologic age and is the reason why faults and anticlines, in which older formations have been placed in the same elevation as younger formations, may be detected by gravity methods.

Three methods of gravity prospecting may be distinguished: (1) The (Eoetvoes) torsion balance, (2) the pendulum, and (3) the gravimeter. In the first method (see fig. 1), the horizontal variations of the horizontal and vertical gravity components are measured; in the second and third, relative gravity is observed. The torsion balance as used in geophysical exploration consists of two independently suspended beams reversed 180° with respect to one another and capable of rotation about a vertical axis represented by a fine platinum-iridium or tungsten wire. The beam is loaded with two weights; one is attached directly to one end while the other is suspended by a wire from the other end. In recent models this suspension is replaced by a beam tilted 45 degrees. The quantities measured by the torsion balance may be expressed as derivatives of the gravity potential; its action may be explained by considering the geometric disposition of the surfaces of equal potential which are at any point perpendicular to the direction of gravity. If an equipotential surface placed through the beam deviates from the spherical shape, differences in the horizontal gravity components acting on the beam weights are produced; the beam deflection is proportional to two quantities related to the curvature of the equipotential surface, known as "curvature values." Furthermore, if two converging equipotential surfaces, above one another, are placed through the upper and lower weight, the resulting difference in the direction of gravity forces acting on the upper and lower weights will deflect the beam. The convergence of the equipotential surfaces is proportional to the horizontal variation of gravity which may be resolved into two components commonly referred to as north and east "gradient" of gravity. To determine all four quantities the beam deflections must be observed in different positions of the entire instrument; for a double beam instrument, three positions are required. Usually the instrument is rotated automatically into these positions, left in each of them until the beams have come to rest and a record taken photographically of the beam position with reference to the case. From the records, gradients and curvature values are calculated; the former are represented as arrows whose length and direction indicate the amount and direction of horizontal gravity variation. Curvature values are represented by straight lines, their direction and length indicating the direction of minimum curvature and deviation from the spherical shape of the equipotential surfaces of gravity.

The pendulum (see fig. 5) measures changes in gravity by variations in its period of oscillation which is determined with an accuracy of one ten-millionth of a second. One pendulum is set up on a base station; its oscillations are transmitted by radio, through photoelectric pickup, to the field stations where they are recorded photographically together with the oscillations of the field pendulum. Generally two or three pendulums are swung simultaneously on the same support to eliminate the effect of its flexure. Results are obtained in form of gravity differences against a base station.

TABLE I—Summary of the Four Major Geophysical Methods

	Method			Picld	Geologic Application	
Spontaneous Action	I. Gravitational	A. Torsion-balance		Oil	Anticlinal structures, buried ridges; salt domes; faults; intrusions.	No Depth Control
		B. Pendulum C. Gravimeter		Oil	Salt domes; buried ridges; major structural trends.	
	II. Magnetic			Oil; Mining	Anticlinal structures; buried ridges; intrusions; faults; iron pyrrhotite, and assoc. sulphide ores; gold placers.	
	A. Self-potential			Mining	Sulphide ore bodies	
React' to Energin gFi e	III. Elec al	B. Gal-cation of primary energy	Potential distribu-tion of secondary field measured	a. Equi-pot. Poten. prof. b. Resis-tivity c. Pot. drop ratio	hlining; Civil ;	General stratigraphic and structural conditions; bed-rock depth on dam sites; ground-water; oil structures; sulphide ore bodies; highway problems; elec. coring.
			2. Electromagnetic field meas.		Mining	Sulphide ore bodies.
		C. Inductive applic. of prim. energy			Oil; Mining	Faults. anticlinal, etc., structure;; sulphide ore bodies.
	IV. Seismic		A. Refraction		Oil; Civil eng.	Salt domes; anticlinal, etc., structures; faults; foundation and highway problems.
			B. Reflection		Oil	Low-dip structures; buried ridges; faults.

Gravity variations may also be measured statically by observing variations in gravity pull on the weight of a balance beam in comparison with the restituting force of a spring (see fig. 2). Such an instrument is called a "gravimeter."

Interpretation of gravity anomalies obtained by pendulum or gravimeter is both qualitative and quantitative. A gravity high may indicate a change to a heavier formation in the same level or the rise of a given formation and vice versa. For quantitative interpretation, effects of geologic bodies of assumed densities, dimensions and depths are calculated and varied until reasonable agreement with the field findings is obtained. These calculations are based on the Newtonian potential of such bodies and its derivatives when they are limited in all directions and on their logarithmic potential and its derivatives if they are extended in the strike. Calculations are facilitated by diagrams consisting of sections of mass elements so calculated in respect to dimensions and distance that their effect at the station is identical. Interpretation procedure in torsion balance work is similar in principle; while for calculations of gravity anomalies only the first derivative of the potential with respect to the vertical is required, derivatives of higher order are calculated for torsion balance interpretation. For bodies extended in the strike, the required quantities are the second derivatives of the (logarithmic) potential with respect to the horizontal for curvature values and with respect to both horizontal and vertical for the gradients.

Gravity values obtained with pendulum or gravimeter must be corrected for terrain, normal gravity, elevation, and regional gravity variation. Torsion balance data require a more elaborate terrain correction and an allowance for variations due to the shape of the earth and to regional geologic structure.

(c) Magnetic Methods. — Most magnetic anomalies are due to the presence of magnetite in igneous and sedimentary rocks and in iron ore deposits. Magnetite has the greatest "magnetic susceptibility" (see MAGNETISM). In 10^{-6} units, susceptibilities of magnetite range from 10^5 to 10^6; next is pyrrhotite with 10^3 to 10^5; other iron minerals are but weakly magnetic, hematite being of the order of 10^3. Igneous rocks have susceptibilities ranging from 10^2 to 10^4 and sedimentary rocks from 10 to 10^2.

TABLE II—*Summary of* Minor Geophysical Methods

Methods		Field	Application
Utilizing elastic properties	Acoustic	Mining; Civil	Mine-safety; pipe leak detection.
		Military eng.	Sapper, submarine, aeroplane detection; sound ranging.
		Navigation	Echo depth sounding; iceberg location.
	Dynamic vibration tests	Structural; Civil eng.	Earthquake & vibration-damage tests of building, ground, and roadbeds
	Strain gauging	Mining; Civil eng.	Mine safety; tests of structures.
Utilizing thermal effects	Geothermal	Oil expl.	Structural correlation of wells; cementation problems.
	Thermal detection	Military; Navigation	Aeroplane location; iceberg location.
Gas detection		Oil; Mining; Military; Civil eng.	Location of oil (?); mine safety; poisonous gases; gas leaks.
Radioactive meas.		Mining; Oil(?)	Radioactive ores; shallow oil(?).

There exists a great variety of instruments for magnetic prospecting, from the simple mining compass used in the 17th century to the sensitive magnetic field balances permitting of intensity measurements with an accuracy greater than 1/10,000 part of the earth's field. It is possible to measure any angular or intensity component, but experience has shown that vertical intensity anomalies are the most interpretable; in some instances, supplementary horizontal intensity measurements are useful. The instrument most widely used is the Schmidt Vertical Magnetometer (see fig. 4). It consists of a magnetic system suspended by a knife edge and oriented at right angles to the magnetic meridian. Thus, magnetic vertical intensity is compared with gravity (assumed to be constant); the deflections of the system are read on an autocollimation telescope. Schmidt has also designed a balance for horizontal intensity measurements consisting of a magnetic system suspended to oscillate in the magnetic meridian. Instrument readings are referred to a base, corrected for temperature and diurnal variation (see TERRESTRIAL MAGNETISM), multiplied by the scale value and corrected for the normal geographic variation of the earth's magnetic field. Magnetic anomalies are expressed in "Gammas" (10^{-5} Gauss units) and magnetic contour maps prepared.

Interpretation of magnetic anomalies in terms of geologic structure is largely qualitative and empirical; the magnetic method is primarily a reconnaissance method to be followed, at least in oil exploration, with other more quantitative geophysical methods. In certain cases (mining problems) it is possible to make quantitative depth interpretations. These are largely of an indirect nature; magnetic anomalies of poles and magnets can be calculated from their potential; if the bodies are extended in the strike, the logarithmic potential takes the place of the Newtonian potential. In the former, the magnetic anomaly is inversely proportional to the square of distance; in the latter, inversely to the first power of distance. To bodies magnetized homogeneously by induction in the earth's field, a theorem formulated by Poisson applies; their magnetic potential is equal to their intensity of magnetization, multiplied by the gravity component in the direction of magnetization As magnetic intensities are gradients of magnetic potential, it follows that they are related to the gravity gradients measured with the Eoetvoes torsion balance (see above). Hence, magnetic effects of given bodies can be calculated by the same analytical and graphical methods as used in torsion balance work.

(d) Seismic Methods.—Most seismic methods are based on determinations of the time interval which elapses between the detonation of a dynamite charge and the arrival of the vibration impulses at one or more seismic detectors, set up at the surface. Seismic waves travel through the subsurface section by various paths, the most important being the refraction and the reflection paths. In the former, elastic waves are refracted (see REFRACTION) into high-speed media, propagate in them, leave them in the same manner and reach the surface. (See EARTH, fig. 2). The depths and media reached depend on the distance between shot point and receiving points; the first impulses or "breaks" in a seismogram (see fig. **3)** are caused by waves having travelled through the deepest high-speed layer within range. Reflection impulses are due to the reflection of seismic waves on media of greater elasticity and arrive later than the first refraction impulses. Their time of arrival depends on the average velocity between surface and reflecting bed and the distance between shot point and receiving points. (See Echoes and Echo Depth Sounding, in SOUND.) In refraction methods, depth reached is a fraction of distance between shot and receiving points; in reflection methods, a multiple thereof.

The most extensive application of refraction methods has been made in the location of Gulf Coast salt domes. In salt, the velocity of (longitudinal) elastic waves is of the order of 4·7 to 5·2 kilometres per second; in the adjacent media, from 2 to 3·5 km. $sec.^{-1}$; salt domes thus bring about an appreciable reduction in travel time compared with normal ground. Refraction methods are also used for depth determinations of shallow layers which generally possess great velocity contrasts. In mining and civil engineering applications, overburden velocities may range from several hundred to one thousand metres per second, while bedrock, if composed of igneous or metamorphic formations, may be 5–6000 m. $sec.^{-1}$. Velocities in sedimentary rocks range from about 1000 for the least consolidated to 4000 metres $sec.^{-1}$ for the more consolidated formations; limestone is of the order of 4–5000 m. $sec.^{-1}$. If consolidated beds exist in sedimentary columns, reflections are obtained from them. Velocities of less than that of sound in air are observed in unconsolidated near-surface formations (weathered layer). Uniform increase of compaction and velocity with depth produces curved rays (see fig. 3).

Seismic exploration equipment is elaborate (see fig. 3). For maximum utilization of energy, shot-holes are drilled (in deep refraction and reflection work) with truck-mounted rotaries. From 6 to 12 (and more, in series and series-multiple connection) receivers are employed which convert the mechanical ground vibrations into electrical energy in much the same manner as microphones or phonograph pickups. The electrical impulses are amplified and recorded by oscillograph-galvanometers on rapidly moving paper on which time lines are projected at intervals of hundredths of seconds. The instant of the shot is transferred electrically to the record so that the time elapsed between the arrival of impulses and firing of the shot may be read with an accuracy of 1/1000 of a second and be used in the construction of the time distance ("travel-time") curve. Amplifiers and camera are mounted in a recording truck. For shallow refraction applications, the equipment is less elaborate but follows the same general arrangement. Reflection methods are applicable to depths between 500 and 20,000ft.; refraction methods to depths of several feet to 6,000 feet.

Interpretation of refraction records is based on the "travel-time curve." Contrarily to the travel-time curves shown in fig. 3 of the article EARTHQUAKE for great crustal depths with uniform velocity increase, travel-time curves in seismic prospecting consist mostly of straight portions with well defined breaks. For horizontal stratification, the slopes of these portions indicate true wave velocities in the layers traversed. Considering two layers, one with low velocity above, the other with greater velocity below, the waves will travel through the upper layer but will also be refracted into the lower; the latter will follow the principle of Fermat which states that the waves follow such path as will permit them to arrive at their destination in the shortest possible time. This means that they enter the lower medium by the "critical" refraction angle whose sine is equal to the velocity ratio. **A** break (or intercept) will occur in the travel-time curve when the direct waves through the upper medium arrive simultaneously with those through the lower medium. Setting up the conditions for equality of their two travel-times it is possible to express the "intercept" distance as function of depth and velocities in the two layers. This applies to any number of

horizontal layers. For inclined beds, not the true but apparent velocities are indicated by the slopes of the travel-time curve and are functions of true velocity ratio and dip. By shooting profiles in opposite directions, two travel-time curves are obtained which by combination yield depth under the shot point, dip and true velocities. For great velocity contrasts it is permissible to substitute vertical paths for the classical refraction paths; for uniform velocity increase, straight path interpretation is replaced by "curved ray" interpretation. Depth calculation in reflection shooting is much simpler than in refraction shooting. For horizontal stratification or low dip it is sufficient to time reflection impulses at a mean distance, to apply a correction for the delay of the echo in the weathered layer (determined from separate refraction or "weathering" shots), to reduce the time thus obtained to a regional datum and to calculate the depth of a reflecting bed below it by assuming a straight wave path and an average velocity. The latter are obtained by shooting near a well in the area and measuring travel-times to a detector lowered to the depths corresponding to the reflecting beds. To determine dip, receivers may be set up in two opposite directions from the shot point whereby up-and-down-dip travel-times and up-and-down-dip time-gradients are obtained; to obtain dip and strike two such profiles are laid out at right angles (or another given angle) to one another. Reflection shooting is at present the most accurate method of geophysical oil exploration; depth determinations can be made with an accuracy of better than $\frac{1}{2}$ per cent.

(e) Electrical Methods.—With the possible exception of the self-potential method, electrical prospecting makes use of differences in electrical conductivity between the ores or formations sought and the surrounding media. Minerals of a metallic lustre range in resistivity from 1/100 to several ohm-cm; consolidated sediments of low water-content average about 10^4 ohm-cm., igneous rocks range from 10^4 to 10^6 ohm-cm., and unconsolidated sediments from 10^2 to 10^4. The resistivity of the latter depends largely on the amount and electrolytic nature of their pore-water.

The self-potential method makes use of the fact that many (sulphide) ore bodies when in contact with solutions of a different chemical nature at their upper and lower ends, act as a battery and are therefore surrounded by an electrical field. Its distribution may be measured by surveying lines of equal potential with non-polarizable electrodes and a milliammeter, or by measuring potential differences between successive profile stations with a potentiometer (see INSTRUMENTS, ELECTRICAL). The upper end of an ore body is indicated by a negative potential centre, usually of the order of several hundred millivolts. In all other electrical methods, electrical energy is supplied to the ground, either galvanically or inductively. Galvanic supply has the advantage that lower frequencies of greater depth penetration can be used, and that the potential distribution between the power electrodes can be investigated by search probes making direct contact with the ground. Potential methods have the further advantage of being sensitive to small differences in conductivity. Direct current is usable but the general tendency in potential studies is now toward A.C. of low frequency or to impulses. In the equipotential-line method, power is supplied to two point- or line-electrodes; the equipotential lines are traced by two search electrodes connected through an audio-amplifier with head-phones in the output; one of the probes is held stationary and the other is moved until the sound disappears. Good conductors beneath force the equipotential lines apart, poor conductors attract them. Interpretation is largely qualitative and empirical. More quantitative results are obtained by measuring potential differences between successive stations on profiles, in reference to voltage and phase in the supply circuit. For this purpose an A.C. compensator is used (see fig. 8). A third procedure is to connect three ground stakes to a bridge network (raliometer, fig. 7), giving the ratio of voltage differences between the adjacent ground intervals as well as their phase difference. This is known as the "potential-drop-ratio" method; it is applicable to the detection of horizontal variations in conductivity (location of faults, ore bodies); for horizontally stratified ground it gives depths to formation boundaries; ratio peaks occur at centre-stake distances from the power electrode equal to about $1\frac{1}{2}$ times their depth.

A variety of the potential method now in wide-spread application is known as the "resistivity" method. Four electrodes are driven into the ground; the external pair is supplied with current from dry batteries which is read on a milliammeter while the internal pair is connected to a potentiometer to determine the voltage difference between them (fig. 6). To avoid polarization effects, a commutator is inserted in the circuit so that the current through the ground changes in direction every half cycle but retains the same direction through the instrument. This is known as the Wenner-Gish-Rooney arrangement. The ratio of voltage and current, multiplied by a factor depending on electrode spacing, gives the true resistivity for homogeneous ground, or the so-called "apparent resistivity" for non-homogeneous ground. If the electrode arrangement is moved over the ground with constant spacing, the variation of resistivity in horizontal direction is obtained; this is known as "resistivity mapping." A variant of resistivity mapping is the "electrical coring" method applied in wells (*see* below). By leaving the centre of the arrangement constant and expanding the spacing, the change of resistivity with spacing is equivalent to its change with depth; this is called "resistivity sounding." Interpretation of results obtained in both cases is mostly qualitative; if not too many media are involved, depths may be calculated from the apparent resistivity by applying the theory of images. The potential distribution at the surface is then obtained by reflecting both current source and sink on whatever vertical or horizontal formation boundaries are assumed to exist. In the potential-drop-ratio method, there is a more direct relation between distance at which indications are obtained and depth, than in the resistivity method (see above); theoretical calculations follow the same procedure as in the resistivity methods.

For audio-frequency fields between the primary electrodes, their distribution and distortion by subsurface conductors may also be determined by electromagnetic measurements. The reception equipment in this case consists of a coil connected to a bridge network known as compensator, an amplifier, and a pair of head-phones (see fig. 8). This gives the field in terms of amplitude and phase of the primary current. Generally the horizontal components parallel and at right angles to the supposed strike as well as the vertical component are determined. Above a linear current concentration in a subsurface conductor the horizontal component at right angles to the strike is a maximum and the vertical component is zero; the distance of the minimum and maximum in the latter away from the conductor is equal to twice its depth. Instead of determining fields in terms of generator current, relative measurements may be made by "ratiometers," comparing the fields induced in two identical coils in respect to intensity and phase (see fig. 7). Reception devices in inductive methods are virtually the same as in electromagnetic methods, the primary field being supplied to the ground by insulated loops. This will induce eddy currents to flow along the edges of subsurface ore bodies; the depths of these current concentrations may be determined approximately from horizontal and vertical intensity measurements as mentioned above. Inductive methods have also been used in structural oil exploration; depths of conductive subsurface beds may be determined from measurements of the horizontal intensity; anomalies in the latter may be assumed to be due to the images of the primary cable produced by reflection on conductive layers at twice their depth.

Radio or high-frequency measurements are not in extensive use in geophysical prospecting owing to their lack of depth penetration and tendency to emphasize non-commercial conductors. An exception are devices based on the principle of the induction balance, also known as "treasure finders," intended for the location of pipes and other buried metallic objects at shallow depths.

(f) Miscellaneous Other Methods.—These are indicated in Table II and include applications of sound-ranging and echo-sounding for various military purposes, measurements of vibrations due to quarry blasts, traffic, etc., and dynamic response

measurements of structures with vibrators operated at varying frequencies to anticipate and avoid resonance in case of earthquakes and artificial vibrations. In addition to acoustic effects, thermal effects may be utilized for detection of aeroplanes and icebergs. In oil exploration, measurements of temperatures in wells are important for regional correlation of formations and in gas and water-flow and cementation problems. Gas detection methods are applied to the location of gas-pipe leaks and in mine safety work; attempts have been made recently to increase the sensitivity of these methods in order to locate subsurface gas and oil accumulations. Measurements of radioactivity may be utilized in prospecting for radioactive ores and shallow faults; observations on shallow oil deposits appear to indicate that there is a slight increase of radioactivity above them.

(g) Applications. — There are three principal commercial fields of application of geophysical prospecting: (1) oil exploration; (2) mining exploration; and (3) engineering and engineering geology. The first is by far of the greatest commercial significance. It is estimated that in the Unifed States alone the oil industry spends from fifteen to twenty million dollars each year on geophysical field work and laboratory research. There are vast potential oil territories in all parts of the world yet waiting to be explored by geophysics; the most extensive work has been done in the United States. In mining, geophysical exploration has been applied to a much lesser extent than in oil. This is due to various factors: (1) the small size of the average ore body, compared with the area to be covered; (2) geologic evidence obtained from outcrops, making structural geophysical work often superfluous; (3) greater complexity and variety of geologic occurrence of ore bodies; (4) interference from topographic effects; (5) absence of distinct differences in elasticity due to dynamo-metamorphism which renders the most promising methods such as seismic frequently inapplicable; (6) transportation difficulties. The countries in which the most extensive geophysical mining exploration has been done are Canada, South Africa, Russia, Australia, and the United States. In engineering fields, the technical difficulties mentioned above for the mining applications are not as pronounced; however, large projects and hence commercial stimulus have been lacking.

For each major geophysical method or its subdivisions, the tabulation of Table I indicates the principal field (oil, mining, or engineering) and the more important geologic problems to which a method is adapted. Applications in oil are (with the exception of electrical coring) of an indirect nature; the object is to locate structural traps likely to contain oil. Such traps are the tops of anticlines and domes which may be mapped by seismic reflection, gravimeter, torsion-balance, electrical potential and inductive methods and also by magnetic surveying if magnetic formations are interbedded, or if their cores contain igneous or metamorphic rocks. Other important traps are the flanks of salt domes; the latter have been located chiefly by seismic refraction, torsion balances and gravimeters (Gulf Coast); for mapping formations on the flanks or above a dome, electrical inductive and seismic reflection methods are applied. Faults, constituting another structural oil trap, may be mapped by seismic reflection, torsion-balance, electrical potential and inductive, and magnetic methods. Oil occurrences associated with igneous intrusions may likewise be located (indirectly) with magnetic methods. An important application of geophysical methods in oil exploration is electrical coring. This is a modification of the resistivity method (see above); electrodes are lowered into a (uncased) well and a record is obtained showing variations in resistivity of formations traversed; it not only is less expensive than mechanical coring but reveals occurrence and depth of oil and water-bearing strata.

Applications in mining are of both an indirect and direct nature. In the former, geologic structure giving a clue to the occurrence of ore is located; examples are: Magnetic surveys to determine the suboutcrop of magnetic formations bearing a known stratigraphic relation to deposits of gold (Witwatersrand), copper (Lake Superior), or other non-magnetic minerals; seismic refraction and gravity surveys of gold-placer channels (Australia); magnetic surveys tracing magnetic black sands associated with placer gold (Alaska, British Columbia); seismic and gravity surveys for locating salt domes whose cap rock may contain sulphur (Gulf Coast). The second group of mining applications involves a direct location of the sought minerals. This is true particularly for all types of sulphides (chiefly copper, nickel, and lead, with the exception of sphalerite) which can be located with the self-potential, the potential, electromagnetic, inductive and sometimes (pyrrhotite) the magnetic method, and the iron ores (chiefly magnetite) which are most readily located with magnetic methods. In non-metallic mining, applications are both direct and indirect (determination of structure); they are very diversified, each mineral or type of deposit presenting virtually its own problem. Suffice it to say that the methods most universally applicable in non-metallics are electrical potential for the direct, and electrical potential, seismic, and gravitational methods for the indirect applications.

In the field of engineering and engineering geology, geophysical prospecting has many diversified applications. The most important is probably the investigation of foundation conditions. Sites for proposed dams and tunnels, railroads, highways and bridges may be examined most conveniently with the electrical potential and the seismic refraction methods. If the latter are supplemented by vibrator tests it is frequently possible to derive from both surveys such elastic properties as are required in engineering design. Vibrator measurements likewise, furnish data determining the destructiveness of artificial vibrations and earthquakes for foundation and proposed structure. Conliderable expense for haulage may often be saved by applying geophysical methods to the location of construction materials for dams, railroads, and highways, the preferred methods being electrical potential and seismic refraction. Water for irrigation and domestic use may be located geophysically; the most reliable methods are, at present, the potential electric methods. The problem is not a simple one as water is not located directly but stratigraphically and may impart either a greater or a reduced conductivity to the impregnated layers. Other applications of geophysics in engineering include corrosion surveys (by self-potential and resistivity methods) and the detection of leaks from water and gas pipes (acoustic and gas detection methods). Uses of geophysics in military engineering are closely related to those in civil engineering (location of water; assistance in drainage problems; location of construction materials; foundation tests for roads, fortifications, and shelters) and are supplemented by various acoustic, thermal, and electrical detection methods of enemy activities.

(h) Geophysical Education; Societies; Literature. — Geophysical exploration may be considered as a highly specialized field of engineering which requires not only a thorough knowledge of physics, mathematics, and geology, but extensive field experience. Owing to this combination of requirements of a somewhat conflicting character, the tendency of many engaged in this field has been to specialize either in the physical or geologic phase of geophysical exploration. Special courses in all or several phases of this subject are given at the Colorado School of Mines, the Massachusetts Institute of Technology, the California Institute of Technology, the Imperial College of Science and Technology, The Technische Hochschule in Charlottenburg, and the University of Strasbourg, the latter giving a degree of *Ingenieur Géophysicien*. The above list is not complete; several universities and technical schools offer, in addition, general courses in geophysical prospecting in their geological departments.

Interest in research pertaining to geophysical exploration has been largely divided up among physical and geological societies; as yet there are but few societies organized specially for this particular profession. The most important are: The Society of Exploration Geophysicists and the Deutsche Geophysikalische Gesellschaft; the Geophysical Committee of the American Institute of Mining and Metallurgical Engineers also belongs in this group. Articles on geophysical exploration are found in a great variety of scientific, technical and trade journals in many languages, notably English, German, Russian, and French. Journals devoted to geophysical exploration alone are few: the journal *Geophysics* issued by the Society of Exploration Geophysicists,

GEOPHYSICS, the science of earth physics, derived from the Greek ἡ γῆ (earth) and ἡ φύσις (nature). In the broadest sense geophysics deals not only with the physical properties and forces of the solid earth (lithosphere) but also with those of its liquid (hydrosphere) and gaseous envelopes (atmosphere). It includes, therefore, the following sciences: Higher geodesy, in particular its phases dealing with the shape of the earth, isostasy, and gravity; seismology; terrestrial magnetism and electricity; volcanism; oceanography and hydrology; meteorology, climatology, and atmospheric electricity. The study of the following phenomena is also generally included: Movements of the earth in space; bodily tides; precession, nutation, and pole migrations; composition of the earth's interior; cosmogony; orogenic and epeirogenic movements; acoustic, optical, and electrical phenomena (aurora borealis, cosmic rays, etc.) in the atmosphere.

For details on the above branches of geophysics, *cf.* the articles on: ATMOSPHERE; AURORA POLARIS; CLIMATE AND CLIMATOLOGY; COSMOGONY; EARTH; EARTH CURRENTS; EARTHQUAKE; ELECTRICITY, ATMOSPHERIC; GEODESY; HYDROGRAPHY; METEOROLOGY; OCEAN AND OCEANOGRAPHY; PLANET; RADIOACTIVITY; SEISMOMETER; SOUND; TERRESTRIAL MAGNETISM; TIDES: *Earth-Tides;* VOLCANO.

Most major nations of the world have provided institutions and observatories to conduct geophysical researches of great variety. In many instances, such institutions are affiliated with Government divisions and appear under various names, such as Geodetic, Geographic, Hydrographic, Oceanographic, Meteorologic, etc. institutes or as Magnetic. Seismological, Geophysical, Meteorological or Oceanographic, etc. observatories. Some geophysical institutions have been established by private research foundations. In the United States, geophysical research and routine observations are carried out largely by the Coast and Geodetic Survey (gravity, magnetic, and seismological surveys; magnetic and seismic observatories), by the Carnegie Institution of Washington, D.C. (Department of Research in Terrestrial Magnetism, with several affiliated magnetic observatories in various parts of the world), and the Geophysical Laboratory in Washington, D.C.

In order to promote co-ordination of the efforts of the world's nations in the field of geophysical research. the International Geodetic and Geophysical Union was organized after the World War. In the United States, the American Geophysical Union was established in 1919 as the American Committee of the International Union of Geodesy and Geophysics; its executive committee is the Committee on Geophysics of the National Research Council. It is divided into 7 sections, namely geodesy, seismology, meteorology, terrestrial magnetism and electricity, oceanography, volcanology, and hydrology. Geophysical papers are published in a variety of media. Many geophysical institutions issue their own publications, research papers, activity reports, and compilations of observations. The International Geodetic and Geophysical Union publishes the reports and papers of its sections in various volumes; the *Transactions* of the American Geophysical Union are issued annually. Articles on geophysical subjects are found in a variety of periodicals such as *Terrestrial Magnetism and Atmospheric Electricity, Quarterly Journal* of the Royal Meteorological Society, *Meteorologische Zeitschrift, Gerland's Beitraege zur Geophysik, Zeitschrift der Deutschen Geophysikalischen Gesellschaft, Philosophical Transactions* of the Royal Society, etc References to books dealing with various fields of geophysics, etc. will be found in the articles previously referred to. Books covering the entire field of geophysics in English language are scarce. Under the auspices of the National Research Council (U.S.), a series of treatises entitled "Physics of the Earth" is now being published. In Germany, a comprehensive treatment of the subject has been published by Gutenberg and others under the title *Handbuch der Geophysik* and another has appeared in the *Handbuch der Experimentalphysik,* Part 25, in three volumes. (C. A. H.)

GEOPONICI, or *Scriptores rei rusticae,* the Greek and Roman writers on husbandry and agriculture. On the whole the Greeks paid less attention than the Romans to the scientific study of these subjects, which in classical times they regarded as a branch of economics. Thus Xenophon's *Oeconomicus (see* also *Memorabilia,* ii. 4) contains a eulogy of agriculture and its beneficial ethical effects, and much information is to be found in the writings of Aristotle and his pupil Theophrastus. About the same time as Xenophon, the philosopher Democritus of Abdera wrote a treatise Περὶ Γεωργίας, frequently quoted and much used by the later compilers of *Geoponica* (agricultural treatises). Greater attention was given to the subject in the Alexandrian period; a long list of names is given by Varro and Columella, amongst them Hieron II. and Attalus III. Philometor. Later, Cassius Dionysius of Utica translated and abridged the great work of the Carthaginian Mago, which was still further condensed by Diophanes of Nicaea in Bithynia for the use of King Deïotarus. From these and similar works Cassianus Bassus (*q.v.*) compiled his *Geoponica.* Mention may also be made of a little work Περὶ Γεωργικῶν by Michael Psellus (printed in Boissonade, *Anecdota Graeca,* i.).

The Romans, aware of the necessity of maintaining a numerous and thriving order of agriculturists, from very early times endeavoured to instil into their countrymen both a theoretical and a practical knowledge of the subject. The occupation of the farmer was regarded as next in importance to that of the soldier, and distinguished Romans did not disdain to practise it. In furtherance of this object, the great work of Mago was translated into Latin by order of the senate, and the elder Cato wrote his *De agri cultura* (extant in a very corrupt state), a simple record in homely language of the rules observed by the old Roman landed proprietors rather than a theoretical treatise. He was followed by the two Sasernae (father and son) and Gnaeus Tremellius Scrofa, whose works are lost. The learned Marcus Terentius Varro of Reate, when eighty years of age, composed his *Rerum rusticarum libri tres,* dealing with agriculture, the rearing of cattle, and the breeding of fishes. He was the first to systematize what had been written on the subject, and supplemented the labours of others by practical experience gained during his travels. In the Augustan age (to make no mention of Virgil's *Georgics)* Iulius Hyginus wrote on farming and bee-keeping, Sabinus Tiro on horticulture, and during the early empire Iulius Graecinus and Iulius Atticus on the culture of vines, and Cornelius Celsus (best known for his De *medicina*) on farming. The chief work of the kind, however, is that of Lucius Iunius Moderatus Columella (*q.v.*). About the middle of the second century the two Quintilii, natives of Troia, wrote on the subject in Greek. It is remarkable that Columella's work exercised less influence in Rome and Italy than in southern Gaul and Spain, where agriculture became one of the principal subjects of instruction in the superior educational establishments that were springing up in those countries. One result of this was the prepa-

ration of manuals of a popular kind for use in the schools. In the third century Gargilius Martialis of Mauretania compiled a *Geoponica* in which medical botany and the veterinary art were included. The De *re rustica* of Palladius (fourth century), in fourteen books, which is almost entirely borrowed from Columella, is greatly inferior in style and knowledge of the subject. It is a kind of farmer's calendar, in which the different rural occupations are arranged in order of the months. The 14th book (on forestry) is written in elegiacs (85 distichs). The whole of Palladius and considerable fragments of Martialis are extant.

The best edition of the *Scriptores rei rusticae* is by *T.* G. Schneider (1794–97), and the subject is treated by *A.* Magerstedt, *Bilder aus der romischer Landwirtschaft* (1858–63). *See* also H. Gummerus, *Der romische Gutsbetrieb (Klio,* 1st suppl. vol., Leipzig, 1906); Ll. Storr-Best, *Varro on Farming* (1912); *Roman Farm Management,* by a Virginia Farmer (1913); T. F. Heitland, *Agricola; a study of agriculture and rustic life in the Graeco-Roman world from the point of view of labour* (1921).

GEORGE, SAINT (d. *c.* 300), the patron saint of England, Aragon and Portugal. The only historical element in the intricate tradition that has grown up around his name seems to be his martyrdom at Lydda in Palestine. The dubious elements include his rapid advance to high military rank, his organization of the Christian community at Urmi (Urumiah), his visit to Britain on an imperial expedition and his protest against the persecutions by Diocletian. Calvin impugned the saint's existence, but two Syrian church inscriptions testify to the early date of his veneration and early pilgrims mention Lydda as the centre of an ancient cultus. Again in the canon of Pope Gelasius (494) George is mentioned in a list of those "whose names are justly reverenced among men, but whose acts are known only to God." Modern criticism hesitates to identify St. George with the nameless martyr described in Eusebius, *Hist. eccl.* viii. 5, or to accept Gibbon's theory that he was a legendary double of George of Cappadocia, an opponent of Athanasius.

The connection of St. George with a dragon, familiar since the *Golden Legend* of Jacobus de Voragine, can be traced to the close of the 6th century. At Arsuf or Joppa—neither of them far from Lydda—Perseus had slain the sea-monster that threatened the virgin Andromeda, and George, like many another Christian saint, entered into the inheritance of veneration previously enjoyed by a pagan hero. His popularity in England has never reached the height attained by St. Andrew in Scotland, St. David in Wales or St. Patrick in Ireland. The council of Oxford in 1222 ordered that his feast should be kept as a national festival; but it was not until the time of Edward III. that he was made patron of the kingdom. His feast is celebrated on April 23.

Budge, *The Martyrdom and Miracles of St. George of Cappadocia:* the Coptic texts edited with an English translation (1888); Delehaye, *Les saintes militaires* (1909); E. O. Gordon, *Saint Georga* (1907); *M.* H. Bulley, *St. George for Merrie England* (1908).

GEORGE I. (George Louis) (1660–1727), king of Great Britain and Ireland, born in 1660, was heir through his father Ernest Augustus to the hereditary lay bishopric of Osnabriick, and to the duchy of Calenberg, which formed one portion of the Hanoverian possessions of the house of Brunswick, whilst he secured the reversion of the other portion, the duchy of Celle or Zell, by his marriage (1682) with the heiress, his cousin Sophia Dorothea. The marriage was not a happy one. George Louis was a bad husband. Count Konigsmark—a handsome adventurer—seized the opportunity of paying court to the deserted wife. Conjugal infidelity was held at Hanover to be a privilege of the male sex. Count Königsmark was assassinated. Sophia Dorothea was divorced in 1694, and remained in seclusion till her death in 1726.

The prince's mother was Sophia, the youngest daughter of Elizabeth (*q.v.*) the daughter of James I. of England. Sophia found herself, upon the death of the duke of Gloucester, the next Protestant heir after Anne. The Act of Settlement in 1701 secured the inheritance to herself and her descendants. Being old and unambitious she rather permitted herself to be burthened with the honour than thrust herself forward to meet it. Her son George took a deeper interest in the matter. In his youth he had fought with determined courage in the wars of William III. Succeeding to the electorate on his father's death in 1698, he had sent a welcome reinforcement of Hanoverians to fight under Marlborough at Blenheim. With prudent persistence he attached himself closely to the Whigs and to Marlborough, refusing Tory offers of an independent command, and receiving in return for his fidelity a guarantee by the Dutch of his succession to England in the Barrier treaty of 1709.

In 1714 when Anne was growing old, and Bolingbroke and the more reckless Tories were coquetting with the son of James II., the Whigs invited George's only son, who was duke of Cambridge, to visit England in order to be on the spot in case of need. Neither the elector nor his mother approved of a step which was likely to alienate the queen, and which was specially distasteful to himself, as he was on very bad terms with his son. Yet they did not set themselves against the strong wish of the party to which they looked for support, and it is possible that troubles would have arisen from any attempt to carry out the plan, if the deaths, first of the electress (June 8) and then of the queen (Aug. 1, 1714), had not laid open George's way to the succession without further effort of his own.

George I. arrived in England when a great military struggle had come to an end. He had therefore no reason to call upon the nation to make great sacrifices. All that he wanted was to secure for himself and his family a high position which he hardly knew how to occupy, to fill the pockets of his German attendants and his German mistresses, to get away as often as possible from the uncongenial islanders whose language he could not speak; and to use the strength of England to obtain petty advantages for his German principality. He attached himself entirely to the Whig party, though he refused to place himself at the disposal of its leaders. He gave his confidence, not to Somers and Wharton and Marlborough, but to Stanhope and Townshend, the statesmen of the second rank. At first he seemed to be playing a dangerous game. The Tories, whom he rejected, were numerically superior to their adversaries, and were strong in the support of the country gentlemen and the country clergy. The strength of the Whigs lay in the towns and in the higher aristocracy. In 1715 a Jacobite insurrection in the north, supported by the appearance of the Pretender, the son of James II., in Scotland, was suppressed, and its suppression not only gave to the Government a character of stability, but displayed its adversaries in an unfavourable light as the disturbers of the peace.

The policy of George I.'s reign is the policy of his ministers. Stanhope and Townshend from 1714 to 1717 were mainly occupied with the defence of the Hanoverian settlement. After the dismissal of the latter in 1717, Stanhope in conjunction with Sunderland took up a more decided Whig policy. The Occasional Conformity Act and the Schism Act were repealed in 1719. But the wish of the liberal Whigs to modify if not to repeal the Test Act remained unsatisfied. In the following year the bursting of the South Sea bubble, and the subsequent deaths of Stanhope in 1721 and of Sunderland in 1722, cleared the way for the accession to power of Sir Robert Walpole, to whom and not to the king was due the conciliatory policy which quieted Tory opposition by abstaining from pushing Whig principles to their legitimate consequences.

Nevertheless something of the honour due to Walpole must be reckoned to the king's credit. It is evident that at his accession his decisions were by no means unimportant. The royal authority was still able within certain limits to make its own terms. This support was so necessary to the Whigs that they made no resistance when he threw aside their leaders on his arrival in England. When by his personal intervention he dismissed Townshend and appointed Sunderland, he had no such social and parliamentary combination to fear as that which almost mastered his great-grandson in his struggle for power. If such a combination

arose before the end of his reign it was owing more to his omitting to fulfil the duties of his station than from the necessity of the case. As he could talk no English, and his ministers could talk no German, he absented himself from the meetings of the cabinet, and his frequent absences from England and his want of interest in English politics strengthened the cabinet in its tendency to assert an independent position.

Walpole at last by his skill in the management of parliament rose as a subject into the almost royal position denoted by the name of prime minister. In connexion with Walpole the force of wealth and station established the Whig aristocracy in a point of vantage from which it was afterwards difficult to dislodge them. Yet, though George had allowed the power which had been exercised by William and Anne to slip through his hands, it was understood to the last that if he chose to exert himself he might cease to be a mere cipher in the conduct of affairs. As late as 1727 Bolingbroke gained over one of the king's mistresses, the duchess of Kendal; apd though her support of the fallen Jacobite took no effect, Walpole was not without fear that her reiterated entreaties would lead to his dismissal. The king's death in a carriage on his way to Hanover, in the night of June 10–11 in the same year, put an end to these apprehensions.

His only children were his successor George II. and Sophia Dorothea (1687–1757), who married in 1706 Frederick William, crown prince (afterwards king) of Prussia. She was the mother of Frederick the Great. (S. R. G.; X.)

Terry, *A Constitutional King—George the First* (1927).

GEORGE II. (George Augustus) (1683–1760), king of Great Britain and Ireland, the only son of George I., was born in 1683. In 1705 he married Wilhelmina Caroline of Anspach. In 1706 he was created earl of Cambridge. In 1708 he fought at Oudenarde. It was most unwillingly that, on his first journey to Hanover in 1716, George I., who was on bad terms with his son, appointed the prince of Wales guardian of the realm during his absence. In 1717 the existing ill-feeling ripened into an open breach. At the baptism of one of his children, the prince selected one godfather whilst the king persisted in selecting another. The young man spoke angrily, was ordered into arrest, and was subsequently commanded to leave St. James's and to be excluded from all court ceremonies. The prince took up his residence at Leicester House, and did everything in his power to support the opposition against his father's ministers.

When therefore George I. died in 1727, it was generally supposed that Walpole would be at once dismissed. The first direction of the new king was that Sir Spencer Compton would draw up the speech in which he was to announce to the privy council his accession. Compton, not knowing how to set about his task, applied to Walpole for aid. Queen Caroline took advantage of this evidence of incapacity, advocated Walpole's cause with her husband and procured his continuance in office. This curious scene was indicative of the course likely to be taken by the new sovereign. His own mind was incapable of rising above the merest details of business. He made war in the spirit of a drill-sergeant, and he economized his income with the minute regularity of a clerk. A blunder of a master of the ceremonies in marshalling the attendants on a levee put him out of temper. He took the greatest pleasure in counting his money piece by piece, and he never forgot a date. He was above all things methodical and regular. "He seems," said one who knew him well, "to think his having done a thing to-day an unanswerable reason for his doing it to-morrow."

Most men so utterly immersed in details would be very impracticable to deal with. George II. was exempt from this failing. He seemed to have an instinctive understanding that such and such persons were either wiser or even stronger than himself. and when he had once discovered that, he gave way with scarcely a struggle. Though in his domestic relations he was as loose a liver as his father, he was guided by the wise, unobtrusive counsels of his wife until her death in 1737, and when once he had recognized Walpole's superiority he was guided by the political sagacity of the great minister. It is difficult to exaggerate the importance of such a temper upon the development of the constitution. The apathy of the nation in all but the most exciting political questions, fostered by the calculated conservatism of Walpole, had thrown power into the hands of the great landowners. They maintained their authority by supporting a minister who was ready to make use of corruption, wherever corruption was likely to be useful, and who could veil over the baseness of the means which he employed by his talents in debate and in finance. To shake off a combination so strong would not have been easy. George II. submitted to it without a struggle.

So strong indeed had the Whig aristocracy grown that it began to lose its cohesion. Walpole dismissed all who opposed him. An opposition formidable in talents was gradually formed. In its composite ranks were Tories and discontented Whigs, discarded official hacks hungry for the emoluments of office, and youthful purists who fancied that if Walpole were removed corruption would cease. Behind them was Bolingbroke, excluded from parliament but suggesting every party move. In 1737 the opposition acquired the support of Frederick, prince of Wales. His marriage in 1736 to Augusta of Saxony brought on a quarrel with his father. In 1737, just as the princess of Wales was about to give birth to her first child, she was hurried away by her husband from Hampton court to St. James's palace at the imminent risk of her life, simply in order that the prince might show his spite to his father who had provided all necessary attendance at the former place. George ordered his son to quit St. James's, and to absent himself from court. Frederick in disgrace gave the support of his name, and he had nothing else to give, to the opposition. Later in the year 1737, on Nov. 20, Queen Caroline died. In 1742 Walpole, weighed down by the unpopularity both of his reluctance to engage in a war with Spain and of his supposed remissness in conducting the operations of that war, was driven from office. His successors formed a composite ministry in which Walpole's old colleagues and opponents were alike to be found.

War of the Austrian Succession.—The years which followed settled conclusively, at least for this reign, the constitutional question of the power of appointing ministers. The war between Spain and England had broken out in 1739. In 1741 the death of the emperor Charles VI. brought on the War of the Austrian Succession. The position of George II. as a Hanoverian prince drew him to the side of Maria Theresa through jealousy of the rising Prussian monarchy. Jealousy of France led England in the same direction, and in 1741 a subsidy of £300,000 was voted to Maria Theresa. The king himself went to Germany, and attempted to carry on the war according to his own notions. Those notions led him to regard the safety of Hanover as of far more importance than the wishes of England. Finding that a French army was about to march upon his German States, he concluded with France a treaty of neutrality for a year without consulting a single English minister. In England the news was received with feelings of disgust. The expenditure of English money and troops was to be thrown uselessly away as soon as it appeared that Hanover was in the slightest danger. In 1742 Walpole was no longer in office. Lord Wilmington, the nominal head of the ministry, was a mere cipher. The ablest and most energetic of his colleagues. Lord Carteret (afterwards Granville), attached himself specially to the king, and sought to maintain himself in power by his special favour and by brilliant achievements in diplomacy.

In part at least by Carteret's mediation the peace of Breslau

was signed, by which Maria Theresa ceded Silesia to Frederick (July 28, 1742). Thus relieved on her northern frontier, she struck out towards the west. Bavaria was overrun by her troops. In the beginning of 1743 one French army was driven across the Rhine. On June 27th another French army was defeated by George II. at Dettingen. Victory brought elation to Maria Theresa. Her war of defence was turned into a war of vengeance. Bavaria was to be annexed. The French frontier was to be driven back. George II. and Carteret after some hesitation placed themselves on her side. Of the public opinion of the political classes in England they took no thought. Hanoverian troops were indeed to be employed in the war, but they were to be taken into British pay. Collisions between British and Hanoverian officers were frequent. A storm arose against the preference shown to Hanoverian interests. After a brief struggle Carteret, now Lord Granville, was driven from office in 1744.

Henry Pelham, who had become prime minister the year before, thus saw himself established in power. By the acceptance of this ministry, the king acknowledged that the function of choosing a ministry and directing a policy had passed from his hands. In 1745 indeed he recalled Granville, but a few days were sufficient to convince him of the futility of his attempt, and the effort to exclude Pitt at a later time proved equally fruitless.

Opposition to **Pitt.**—Important as were the events of the remainder of the reign, therefore, they can hardly be grouped round the name of George II. The resistance to the invasion of the Young Pretender in 1745, the peace of Aix-la-Chapelle in 1748, the great war ministry of Pitt at the close of the reign, did not receive their impulse from him. He had indeed done his best to exclude Pitt from office. He disliked him on account of his opposition in former years to the sacrifices demanded by the Hanoverian connection. When in 1756 Pitt became secretary of State in the Devonshire administration, the king bore the yoke with difficulty. Early in the next year he complained of Pitt's long speeches as being above his comprehension, and on April 5, 1757, he dismissed him, only to take him back shortly after, when Pitt, coalescing with Newcastle, became master of the situation.

Before Pitt's dismissal George II. had for once an opportunity of placing himself on the popular side, though, as was the case of his grandson during the American war, it was when the popular side happened to be in the wrong. In the true spirit of a martinet, he wished to see Admiral Byng executed. Pitt urged the wish of the House of Commons to have him pardoned. "Sir," replied the king, "you have taught me to look for the sense of my subjects in another place than in the House of Commons." When George II. died in 1760, he left behind him a settled understanding that the monarchy was one of the least of the forces by which the policy of the country was directed. To this end he had contributed much by his disregard of English opinion in 1743; but it may fairly be added that, but for his readiness to give way to irresistible adversaries, the struggle might have been far more bitter and severe than it was.

Of the connection between Hanover and England in this reign two memorials remain more pleasant to contemplate than the records of parliamentary and ministerial intrigues. With the support of George II., amidst the derision of the English fashionable world, the Hanoverian Handel produced in England those masterpieces which have given delight to millions, whilst the foundation of the University of Göttingen by the same king opened a door through which English political ideas afterwards penetrated into Germany.

George II. had three sons, Frederick Louis (1707–51); George William (1717–18); and William Augustus, duke of Cumberland (1721–65); and five daughters, Anne (1709–59), married to William, prince of Orange, 1734; Amelia Sophia Eleonora (1711–1786); Elizabeth Caroline (1713–1757); Mary (1723–72), married to Frederick, landgrave of Hesse-Cassel, 1740; Louisa (1724–1751), married to Frederick V., king of Denmark, 1743.

GEORGE III. (George William Frederick), king of Great Britain and Ireland, was born June 4 (New Style), 1738, the son of George II.'s eldest son Frederick, Prince of Wales, and of Augusta, a princess of Saxe-Gotha. Almost from birth he was introduced to the ungainly squabbles that divided his father and grandfather; and Dr. Ayscough, the tutor assigned to him at the age of six, was chiefly remarkable as an adherent of the opposition. When George was thirteen his absurd father died; Ayscough was dismissed, and the unfortunate boy's education became a matter of acute political controversy, with the result that he had barely time to become accustomed to one set of instructors before they were changed for another. In later life the old king's recollection of his two successive governors was that Harcourt, though well-intentioned, was wholly unfit for his job, while Waldegrave was a "depraved, worthless man"; and though he had a kindly remembrance of his second episcopal preceptor, Thomas of Peterborough, and of his sub-preceptor, Scott, he called Thomas's predecessor, Hayter of Norwich, an "intriguing, unworthy man, more fitted to be a Jesuit than an English bishop." Though his mother was devoted to him, she was a foolish, ignorant woman, who once remarked that logic was "an odd study" for children of her son's condition. Unfortunately, too, she kept him almost isolated from the world except for the remnants of the little Leicester House clique, such as Egmont and Bubb Dodington and the Earl of Bute, who used to encourage Frederick in his futile intrigues against George II. and his ministers. George is described in his youth as lethargic, an epithet which certainly cannot be applied to him when he became king; but a certain "vanity and obstinacy" and a tendency to let "his anger be turned into sulkiness" and to "behave like a child," which Lady Sarah Lennox noted as traits in his character, remained and are confirmed by his own admission to George Rose in 1804 that "his memory being a good one . . . what he did not *forget* he could not *forgive*," a point he illustrated by his grim declaration that he would not admit Fox to his councils, "even at the hazard of civil war." This reserved and authoritative disposition was much encouraged by the training he received at his mother's court, where Bolingbroke's "Patriot King" was laid down as the guide for his conception of royal duties; while the constantly whispered injunction of his mother, "George, be a king," in contrast to his grandfather's dependence on a Whig oligarchy, was allowed to sink into his mind.

His first actions on being called to the throne on the death of George II. (Oct. 25, 1760) showed his determination to "be a king." Dismissing Pitt, who had come to announce his accession, to await his pleasure, he consulted none of his ministers on the speech he addressed to the Council, but only Bute. Pitt had then been gloriously conducting the Seven Years' War since 1756, but there was as yet no prospect of peace. George III., however, had realized that, as long as Pitt, supported by the Whig oligarchy, was directing a successful war, it would be impossible for the king to obtain control over the machinery of government; accordingly from the outset he proclaimed his intention to bring to an end what he termed a "bloody and expensive war." On Pitt's vehement expostulations this phrase was toned down in the printed version to "expensive, but just and necessary war," and a promise made to consider the interests of the allies, notably Frederick the Great; but the king's resolution was not thereby shaken. Bute was very soon substituted for Holderness, Pitt's docile fellow-secretary, and encouraged those members of the cabinet who were outraged by Pitt's supercilious method of treating them as nonentities but who till then had been too timid to combine against him. Thus the great minister's resignation was brought about when he failed to persuade his colleagues to declare war on Spain in 1761.

But the king's greatest stroke was in forcing Newcastle to resign a few months later; for Newcastle was the arch-schemer of Whig majorities, powerful from his control over elections and over all the patronage necessary to keep electors and members of

parliament contented. With the fall of Newcastle the king took into his own hands all the Treasury patronage, and showed that he meant to be master by turning out some of the greatest Whig lords from their offices in the household or from their lord-lieutenancies in the counties. Negotiations for peace were energetically pushed on by Bute, who succeeded Newcastle at the Treasury, and when the Preliminaries of Paris were ready for submission to parliament, a favourable majority was ensured by the ruthless determination of the king's agent, Henry Fox, who not only bribed existing members profusely, but secured future majorities in the constituencies by a further holocaust of great Whig office holders and by turning out the humblest official voters, such as tide-waiters and other Treasury satellites. At the end of December 1762 the king's victory was made patent to all by a majority of 319 for the Preliminaries, and the Princess of Wales was able to exclaim, "Now my son is king of England!" For the next twenty years of his reign he could summon or dismiss his ministries almost at pleasure.

But though George III. had thus early in his reign obtained control over the government, he had by no means succeeded in obtaining the affection of his people. In his first speech to parliament he had made a bid for this affection by his boast, "Born and bred in this country, I glory in the name of Briton," in pointed allusion to the German upbringing of his two predecessors; but unfortunately the appeal fell flat, largely owing to the use of the word *Briton* instead of *English*, at the presumed suggestion of Bute, whose unpopularity was enhanced by his Scottish nationality. Nor was his marriage in 1761 of a nature to awaken any romantic enthusiasm. In the early days of his reign he had been much attracted by the beauty and unconventional charm of Fox's niece, Lady Sarah Lennox, and had even made a clumsy attempt at a proposal of marriage to her; but the influence of his surroundings, aghast at the prospect of his marriage with a subject, allied too to a powerful Whig clique, overcame his incipient passion, and he chose as his wife Charlotte of Mecklenburg, consoling Lady Sarah by assigning to her the post of bridesmaid. Queen Charlotte, though a lady of no special beauty or charm, made an excellent wife for the king, for both shared a taste for homely domesticity, which, though a subject of derision in court circles, eventually proved one of the chief sources of their people's affections. But for the time being any natural inclination to rejoice at the marriage was overshadowed by the king's partiality to the unpopular Scotsman, Bute, and by the dismissal of the national hero, Pitt, who, it was noted, was shortly afterwards greeted with frenzied enthusiasm in the City, while the king was received with marked coldness. This unpopularity was expressed with cold, almost malignant insolence by Wilkes in his famous No. 45 of the ***North Briton*** (April 23, 1763). The king felt himself insulted by comments on his speech to parliament, which, Wilkes maintained as we should now, were constitutionally applicable only to ministers; and for the next seven years devoted himself with remarkable pertinacity to securing Wilkes's exclusion from parliament, browbeating ministers and influencing private members to carry out the vendetta against him.

By 1763 King George III. had recovered for the throne a good deal of the power and influence which had nominally been left to it by the Revolution, but which had largely lapsed during the reigns of the first two Georges. Constitutionally the king could choose and direct his own ministers, subject of course to the power left to parliament to force their dismissal if they failed to obtain the support of the majority to the king's policy. But now that the king had wrested from the Whigs the means of influencing electors and members of the unrepresentative House of Commons, he was comparatively untrammelled by parliament. It is true that the old parliamentary groups, from which he had to make his choice of ministers, remained: but by his power of patronage he was able in every group to secure a section of personal adherents, always ready to vote for the king's measures even against their own party and hence soon known collectively as "king's friends." But even so there was always a danger that a minister of determination and pronounced views might run counter to the king's wishes; so George III. took the additional precaution of having always a familiar, changed from time to time, either in the cabinet or on its outer fringes, who should report confidentially on the attitude of his colleagues and generally act as the king's spy. Egmont is perhaps the first who emerged in this character; and for short periods Hertford and Rochford seem to have played a similar part. But Northington was the most efficient of these adjuncts, especially in breaking up the first Rockingham administration; until finally the king found the ideal man in North, the prime minister himself. Such, in short, was the system by which the king tried to establish his personal rule as the Patriot King, on whom, as Bolingbroke lyrically exclaimed, "the eyes of a whole people are fixed, filled with admiration and glowing with affection." He was to decide on all measures, his ministers were to be chosen, not from one party, but each according to his fitness for the post he occupied, in the duties of which he was to be responsible to the king alone: in fact, when the system was at its zenith during North's ministry, the cabinet met as a body only when the king summoned it to consider some report of one of his ministers on which he desired further advice.

But the system was not perfected in a day. In spite of all precautions the right ministers to carry it out were not easy to find. Bute, whom the king afterwards described as "deficient in political firmness," resigned immediately after the Treaty of Paris (1763), and George Grenville was tried. But he and his allies, the Bedfords, had not learned the lesson and still attempted to lecture and browbeat the king, as if they were the masters, as in the old days of the Whig supremacy. So Grenville had to go (1765)—not, however, before he had passed the Stamp Act with the king's full approbation—and was succeeded by Rockingham and his party of remnants from the glorious days of Newcastle. Such a ministry was obviously not what the king wanted, was only tolerable for the moment as a means of escape from Grenville, and was intrigued against by the king almost from the start.

When the Rockingham ministry had been sufficiently sapped by Northington, George was able to turn to the one man whom he expected to share his views about a non-party ministry. Pitt indeed had always declared for "measures, not men," and was supremely indifferent to the claims of party when it was a question of national policy, so that superficially there appeared to be the elements of agreement between the two, especially when Pitt formed his ministry (1766) from men of all parties without distinction. No doubt had Chatham, as he had become, retained his faculties and been able to guide the ministry, he, not the king, would have settled its policy, for he was not apt to take his orders from anyone. But, after his virtual retirement within a few months, the ministry he had formed to carry out his own policy proved to be exactly the one best suited to carry out the king's system of government. When by 1770 Chatham, Shelburne, Grafton and Camden had all resigned and Lord North was promoted to the Treasury, the king at last had a ministry in which all the members, and above all their chief North, took their orders directly from him. Not only the general policy but the minutest details of administration were conveyed in the king's daily letters to North and other ministers. For the succeeding twelve years, therefore, the policy of the country was essentially that of the king.

Not only was the king the director of the national policy during the war with America (1776–83), but there is little doubt that he had the country on his side in that policy. George III. stood for the principle that Parliament, under his guidance, had the right to legislate for the colonies, and though Chatham might quite fairly insist on the distinction between general legislation applicable to the whole empire as within the purview of the imperial parliament and legislation affecting only the colonies, on which they had a clear right to decide through their own representatives, and Burke point to the calamitous consequences of alienating America, such distinctions or appeals left cold the bulk of the population of England, who felt that the colonies were ungrateful children, ready to profit from the security our arms had gained for them, but unwilling to pay the price. It was not indeed the merits of the war in which the king was the prime mover that finally disgusted the country, but the series of calamities which marked its

progress. For these the king's system of government was chiefly responsible. He himself did all that such a man could do. He supervised the general policy and even more meticulously the details of administration. As is made abundantly clear in his published correspondence[1], the king delighted in taking responsibility upon his own shoulders. He practically assumes the duty of leader of the House by his constant and detailed directions to North as to the conduct of business, he thinks no labour too great in inspecting troops or dockyards, in settling how regiments are to be raised, foreign mercenaries to be hired or naval expeditions to be equipped and, incidentally, devotes quite as much care to deciding how, on a journey to Portsmouth, his equerries and other attendants are to travel and what horses and carriages are to be taken from the royal stables. He certainly did not want courage, either physical or moral, as he showed throughout his life. "Let not this check dismay You," he wrote to Grafton, "in this World these things will happen, therefore rest assured that it will if possible stimulate me to act with greater vigour": as is well known, during the Gordon riots he and his old enemy Wilkes seem to have been the only people who did not lose their heads: when poor North moaned to him about the expense of the war he rebukes him for "weighing such events in the Scale of a Tradesman behind his Counter": he tells Sandwich that "the English Lion when roused has not only his wonted resolution but has added the swiftness of the Race Horse": and when there is some difficulty about Howe accepting the American command he writes to poor North, "Before I get to dinner I just take up my pen to acquaint You that things are very far from desperate, that if no one will interfere I do not despair of bringing things to rights . . . therefore rest satisfied till You hear more from Me."

But the trouble was that, though in some respects a shrewd judge of men when he was not crossed, George III. had not the eagle eye of a Chatham in planning and supervising a campaign, and still less the ability to make lesser men carry out his bidding. And owing to his calculated aversion to really able men who would undertake responsibility, he had to rely on ministers like Lord George Germain, incompetent and quarrelsome, odious too for his behaviour at Minden, North, a timorous soul, Sandwich, an evil liver. as the king himself admitted. Scandals in his own family, which led to the Royal Marriages Act of 1770, and his patent inability to control the excesses of his graceless heir did not add to the king's popularity, and cast doubts on his competence. Above all, his extravagant methods of securing a complacent parliament by the distribution of sinecures and even direct money bribes were at last beginning to awaken alarm. Debts amounting to over £1,000,000 on his ample civil List, which had to be paid by the nation while engaged in this "bloody and expensive" war, and the wasteful extravagance of the royal household under a king notoriously parsimonious were rightly attributed to the unavowed exercise of "influence," and tended to unite opposition in the country and even in the House, in a way that Wilkes, the American war and Junius's gross attack on the king had all failed to do. Finally in 1780 the hitherto docile House of Commons accepted Dunning's motion that "the power of the Crown has increased, is increasing and ought to be diminished": a resolution that George III. attributed merely to a few "factious Leaders and ruined men," who wished to overturn "this excellent Constitution . . . the most beautiful Combination that ever was framed."

But two years later, when England, with almost all Europe against her, was forced, after Yorktown, to give up the struggle in America, George at last realized that his attempt to govern on the lines of the "Patriot King" had finally failed. So fully was he aware of this that on two separate occasions he seriously contemplated abdication; and on both occasions drew up messages to announce his decision to Parliament. The first occasion was in 1782, when he was forced to take a Rockingham ministry after North's fall, the second when, on the defeat of Shelburne (1783), he saw no alternative to the hated Fox-North coalition. These draft messages are drawn up with a dignity of language all the more striking as they are a complete admission of failure. He emphasizes his scrupulous respect for the "Rights of Parliament," a perfectly true claim, since in normal times its composition gave him complete control over it. His more detailed reasons set forth in the drafts of 1783 give the best exposition of his principles of government and incidentally suggest the reasons for their ultimate failure. His "pleasing hope," he declares to have been that, "He might have proved the happy Instrument of conciliating all Parties, and thus collecting to the Service of the State, the most able Persons this Nation produced. . . . This Patriotic Endeavour has proved unsuccessful, by the Obstinacy of a Powerful Combination that has long manifested a resolution of not entering into Public Service, unless the whole Executive management of affairs is thrown entirely into their hands." In other words George III. was beaten by the demand for full responsibility of the people's representatives for the executive as well as the legislative functions of government.

The year 1783, therefore, marks a clear epoch, not only in the reign of George III., but also in our constitutional history. It is perfectly true that the king did not in a day give up his ingrained ambition "to be a king," and that there are many instances after the date of his draft abdication in 1783 of successful attempts by him to influence the government. He took an active part in securing the rejection of Fox's India Bill in 1783 and in dismissing the Coalition; and the *Parliamentary Papers of John Robinson* (Camden Series, 1922) afford conclusive evidence that Pitt's victory at the polls in 1784 was largely due to the active interference of the king in the elections. Pitt's resignation in March 1801 was entirely due to the king's refusal to agree to his minister's policy of conciliation to the Catholics; his refusal to admit Fox into Pitt's reconstituted ministry of 1804 was decisive. Although he admitted Fox into the ministry of All the Talents in 1806 and even went so far as to tell him that "I have no desire to look back upon old grievances, and you may rest assured that I never shall remind you of them," yet when, after Fox's death, the ministry wished to allow Roman Catholics to join the army, he not only flatly refused, but forced their resignation by demanding a written assurance that they would never again bring up the Catholic question in any form. All this is true, just as it is true that George IV. and William IV. and even Victoria and Edward VII. still could exercise a certain amount of personal influence in the composition of a ministry or on the execution of its measures. But largely owing to the long ministry of Pitt, who, no more than his father, was one to take directions from a king or anyone else as to the policy he thought good, the growth of the cabinet's and still more of a strong prime minister's independence became an established understanding of the constitution. It is to be remembered too that the unwillingness of Pitt and other ministers to oppose a strong prejudice of the king, such as that against the Catholic claims or against Fox, was almost entirely due to the fear of inducing another bout of insanity in their master and not to any concession to the king's view of his own powers.

As early as 1765 there appeared symptoms of insanity in the king during a comparatively trivial illness, but they soon passed off. In October 1788, however, his madness was unmistakable. He became violent and a danger even to those who loved him best, and had to be put under restraint. Unfortunately he was at first put under the care of ignorant doctors, whose only idea of treating madness was by means of a strait waistcoat and even more brutal measures. At last he came under the charge of Dr. Willis, who had introduced a new method of soothing and persuasive treatment. Even more pathetic were the political squabbles that ensued over the Regency Bill. The obvious regent was the Prince of Wales, but, as he was a bitter opponent of the king and consequently an ally of Fox and all the disappointed Whigs, Pitt naturally thought that his powers during the king's temporary illness should be limited. Feeling grew very bitter on the subject, the doctors were dragged into the dispute, and the Prince's ribaldry about his unfortunate father became a public scandal. Fortunately under Willis's treatment the king recovered by March 1789, and the contentious Regency Bill was dropped. Again in the first half of 1801 he had bouts of madness under the excitement of the Catholic question and again in 1804 and 1810; in 1811 after the

[1] *Correspondence of George III. from 1760 to 1783* edited by Hon. Sir John Fortescue, 6 vols., 1927–28.

death of his favourite daughter, Amelia, his insanity became permanent, a Regency Bill was passed, and the old king remained in seclusion, blind as well as mad, till his death on Jan. 29, 1820.

During the first twenty-three years of his reign, when he was attempting to revive personal government, George III. enjoyed little of his people's affection. The dynasty had never yet achieved popularity, and George III., in spite of the bright hopes with which he ascended the throne, had done very little to win it for himself. At first he was overshadowed by the popular hero, Pitt, and his predilection for the Scotsman Bute did not help him. Few stories likely to endear him with the people radiated from the court, for he hardly saw any even of his ministers except on business or at formal levees, and for choice lived frugally in the dull seclusion of his domestic circle. His devotion to public business took no romantic turn, for he rarely captivated his people by such appeals as Pitt's in the Seven Years' War, and his industry was rather that of a clerk than of a great statesman. So immersed was he in the routine duties of his office that until 1788, when he went to drink the waters at Cheltenham, he had never, according to Wraxall, stirred further from London than the Nore, Coxe Heath, Oxford and Portsmouth. But, paradoxically, when he was no longer the real master in the state his popularity increased enormously. The first strong demonstration of this new popularity was on his recovery from his illness in 1789, partly no doubt from sympathy with his affliction, partly in indignation at his son's and his friends' hardly concealed hope that he would not recover. After that his popularity never waned. His sturdy conservatism—"I will have no innovations in my time," as he said to Eldon—and even his narrow obstinacy in the American War and in resisting Catholic claims; still more his determination to fight on against the French regardless of defeats and desertions by allies, struck a sympathetic chord in the hearts of his subjects. And as he became better known, with his little trick of repetition and his "What? What?" at the end of every sentence, especially during his visits to Weymouth, where he talked unceasingly and shrewdly, if not always cleverly, with all and sundry about their homely concerns, their apple-dumplings and so on, he won the love of his countrymen as "farmer George," one of themselves, with the same tastes, though a king, as the country folk with whom he loved to gossip; in fact, as Wraxall observed, by the end of his reign "his virtues had obtained for him a higher place in our esteem than any prince has occupied since the conquest."

Viewing him from a greater distance of time, we can say of him that few kings have shown greater courage, both moral and physical, in accepting responsibility or affronting actual danger—"he could not bear," he once said, "that any of his family should want courage." With little appreciation of beauty he preferred West to Reynolds, thought little of Shakespeare's "sad stuff," and had "no taste for what was called the fine, wild, beauties of nature; he did not like mountains and other romantic scenes, of which he sometimes heard much"; still he had a good taste in music and was a generous and interested patron of science and learning—for is it not to him that we owe the nucleus of the British Museum Library? Though almost malignant in his vendettas against greater men such as Chatham who had crossed his purposes, yet when he had accepted defeat he could be a generous loser, as in his remark to Fox already quoted and in his speech to Adams, the first envoy to St. James's from the United States:—"I will be very frank with you. I was the last to consent to the separation: but the separation having been made and having become inevitable, I have always said, as I say now, that I would be the first to meet the friendship of the United States as an independent power." Lastly, not the least service he rendered the country was the homely domesticity, even the dullness of his life. Thereby he set a standard of faithful troth in the relations of private life, which was new at any rate in the court circles of England and which has survived even the Regency to become almost a commonplace of modern English life. (See genealogical table in article ENGLISH HISTORY.)

BIBLIOGRAPHY.—Correspondence of George III. from 1760 to 1783 (ed. Fortescue) 6 vols., 1927–28; this contains, *inter alia*, the king's letters in *Corr. of Geo. III. with Lord North* (ed. Donne) 2 vols. 1867, but the latter book has useful notes. Geo. Rose, *Diaries & Corr.* 2 vols. 1860, has some illuminating talks with the king. Most of the Memoirs and Correspondence of the latter half of the 18th century have information about Geo. III. The *Histories* of England by J. Adolphus (1803, etc.) & W. N. Massey (4 vols., 1855–63) have first hand stories. J. H. Jesse, *Memoirs of Life & Reign of Geo. III.*, 3 vols., 1867, may also be consulted. L. Melville, *Farmer George*, 2 vols., 1907, and B. Willson, *Geo. III. as man, monarch and statesman*, 1907, are more recent compilations about him. (B. WI.)

GEORGE IV. [George Augustus Frederick] (1762–1830), king of Great Britain and Ireland, eldest son of George III., was born at St. James's Palace, London, on Aug. 12, 1762. He was naturally gifted, was well taught in the classics, learnt to speak French, Italian and German fluently, and had considerable taste for music and the arts; and in person he was remarkably handsome. His tutor, Bishop Richard Hurd, said of him when 15 years old that he would be "either the most polished gentleman or the most accomplished blackguard in Europe—possibly both." Reaction from the strict and parsimonious style of his parents' domestic life had its natural effect in plunging the young prince of Wales, flattered and courted as he was, into a whirl of pleasure-seeking. At the outset his disposition was brilliant and generous, but it was essentially unstable, and he started even before he came of age on a career of dissipation which in later years became wholly profligate. He had an early amour with the actress Mary ("Perdita") Robinson, and in the selection of his friends he opposed and annoyed the king, with whom he soon became (and always remained) on the worst of terms, by associating himself with Fox and Sheridan and the Whig party. When in 1783 he came of age, a compromise between the coalition ministry and the king secured him an income of £50,000 from the Civil List, and £60,000 was voted by parliament to pay his debts and start his separate establishment at Carlton House. There, under the auspices of Fox and Georgiana, duchess of Devonshire, he posed as a patron of Whig politics and a leader in all the licence and luxury of gay society—the "First gentleman of Europe," as his flatterers described him as years went on. And at this early age he fell seriously in love with Mrs. Fitzherbert.

His connection with this lady was for some time the one redeeming and restraining factor in his life. Mary Anne (or as she always called herself, Maria) Fitzherbert (1756–1837) was the granddaughter of Sir John Smythe, Bart., of Acton Burnell Park, Shropshire, and came of an old Roman Catholic family. Her second husband, Thomas Fitzherbert, died in 1781, leaving his widow with a comfortable fortune. She became a prominent figure in London society, and the young prince wooed her with all the ardour of a violent passion. The Act of Settlement (1689) entailed his forfeiture of the succession if he married a Roman Catholic, apart from the fact that the Royal Marriage Act of 1772 made any marriage illegal without the king's consent, which was out of the question. They were secretly married by the Rev. R. Burt, a clergyman of the Church of England, on Dec. 15, 1785. There is no doubt as to Mrs. Fitzherbert's belief, supported by ecclesiastical considerations, in her correct and binding, though admittedly illegal, relationship to the prince as his canonical wife; and their relationship was treated by their intimates on the footing of a morganatic marriage. The position nevertheless was inevitably a false one; Mrs. Fitzherbert had promised not to publish the evidence of the marriage (which, according to a strict interpretation of the Act of Settlement might have barred succession to the crown), and the rumours which soon got about led the prince to allow it to be disavowed by his political friends. He became heavily involved in debt, and as the king would not assist him, shut up Carlton House, and went to live with Mrs. Fitzherbert at Brighton. In 1787 a proposal was brought before the House of Commons by Alderman Newnham for a grant in relief of his embarrassments. It was on this occasion that Fox publicly declared in the House of Commons, as on the prince's own authority, in answer to allusions to the marriage, that the story was a malicious falsehood. A little later Sheridan, in deference to Mrs. Fitzherbert's pressure and to the prince's own compunction, made a speech guardedly modifying Fox's statement; but though in private the denial was understood, it effected its object, the House voting a grant of £221,000 to the prince and the king adding £10,000 to his income; and Mrs. Fitzherbert, who at first thought

of severing her connection with the prince, forgave him. Their union—there was no child of the marriage—was brutally broken off in June 1794 by the prince, when further pressure of debts (and the influence of a new Egeria in Lady Jersey) made him contemplate his official marriage with princess Caroline; in 1800, however, it was renewed, after urgent pleading on the prince's part, and after Mrs. Fitzherbert had obtained a formal decision from the pope pronouncing her to be his wife, and sanctioning her taking him back; her influence over him continued till shortly before the prince became regent, when his relations with Lady Hertford brought about a final separation. For the best years of his life he had at least had in Mrs. Fitzherbert the nearest approach to a real wife, and this was fully recognized by the royal family[1]. But his dissolute nature was entirely selfish, and his various liaisons ended in the dominance of Lady Conyngham, the "Lady Steward" of his household, from 1821 till his death.

In 1788 his father's first attack of insanity made the prince's position in the State one of peculiar importance. Fox maintained and Pitt denied that the prince of Wales, as the heir-apparent, had a right to assume the regency independently of any parliamentary vote. Pitt, with the support of both Houses, proposed to confer upon him the regency with certain restrictions. The recovery of the king in Feb. 1789 put an end, however, to the prince's hopes. In 1794 the prince consented to a marriage with a German Protestant princess, because his father would not pay his debts on any other terms, and his cousin, Princess Caroline of Brunswick, was brought over from Germany and married to him in 1795. Her behaviour was light and flippant, and he was brutal and unloving. The ill-assorted pair soon parted, and soon after the birth of their only child, the princess Charlotte, they were formally separated. With great unwillingness the House of Commons voted fresh sums of money to pay the prince's debts.

In 1811 he at last became prince regent in consequence of his father's definite insanity. He had always lived in close connection with the Whig opposition, and he now empowered Lord Grenville to form a ministry. There soon arose differences of opinion between them on the answer to be returned to the address of the Houses, and the prince regent then informed the prime minister, Mr. Perceval, that he should continue the existing ministry in office. The ground alleged by him for this desertion of his friends was the fear lest his father's recovery might be rendered impossible if he should come to hear of the advent of the opposition to power. Lord Wellesley's resignation in Feb. 1812 made the reconstruction of the ministry inevitable. As there was no longer any hope of the king's recovery, the former objection to a Whig administration no longer existed. Instead of taking the course of inviting the Whigs to take office, he asked them to join the existing administration. The Whig leaders, however, refused to join, on the ground that the question of the Catholic disabilities was too important to be shelved, and that their difference of opinion with Mr. Perceval was too glaring to be ignored. The prince regent was excessively angry, and continued Perceval in office till that minister's assassination on May 11, when he was succeeded by Lord Liverpool, after a negotiation in which the proposition of entering the cabinet was again made to the Whigs and rejected by them. In the military glories of the following years the prince regent had no share. When the allied sovereigns visited England in 1814, he played the part of host to perfection. So great was his unpopularity at home that hisses were heard in the streets as he accompanied his guests into the city. In 1817 the windows of the prince regent's carriage were broken as he was on his way to open parliament.

The death of George III. on Jan. 29, 1820, gave to his son the title of king without altering the position which he had now held for nine years. The relations between the new king and his wife unavoidably became the subject of public discussion. In 1806 a charge against the princess of having given birth to an illegitimate child had been conclusively disproved, and the old king had consequently refused to withdraw her daughter, the princess Charlotte, from her custody. In the regency the prince was able to interfere, and prohibited his wife from seeing her daughter more than once a fortnight. On this, in 1813, the princess addressed to her husband a letter setting forth her complaints, and receiving no answer published it in the *Morning* Clzronicle. The prince regent then referred the letter, together with all papers relating to the inquiry of 1806, to a body of 23 privy councillors for an opinion whether it was fit that the restrictions on the intercourse between the princess Charlotte and her mother should continue in force. All except two answered as the regent wished them to answer. But the general public leaned towards the wife of a notorious profligate. Addresses of sympathy were sent up to the princess from the city of London and other public bodies.

The discord again broke out in 1814 in consequence of the exclusion of the princess from court during the visit of the allied sovereigns. In August in that year she left England, and after a little time took up her abode in Italy. The accession of George IV. brought matters to a crisis. He ordered that no prayer ior his wife as queen should be admitted into the Prayer Book. On June 7 she arrived in London. Before she left the continent she had been informed that proceedings would be taken against her for adultery if she landed in England. Two years before, in 1818, commissioners had been sent to Milan to investigate charges against her, and their report, laid before the cabinet in 1819, was made the basis of the prosecution. On the day on which she arrived in London a message was laid before both Houses recommending the criminating evidence to parliament. A secret committee in the House of Lords after considering this evidence brought in a report on which the prime minister founded a Bill of Pains and Penalties to divorce the queen and to deprive her of her royal title. The bill passed the three readings with diminished majorities, and when on the third reading it obtained only a majority of nine, it was abandoned by the Government. The king's unpopularity, great as it had been before, was now greater than ever. In the following year (1821) Caroline attempted to force her way into Westminster Abbey to take her place at the coronation. On this occasion popular support failed her; and her death in August relieved the king from further annoyance.

Immediately after the death of the queen, the king set out for Ireland. His good reception in Dublin encouraged him to attempt a visit to Edinburgh in the following year (Aug. 1822). Since Charles II. had come to play the sorry part of a covenanting king in 1650 no sovereign of the country had set foot on Scottish soil. Sir Walter Scott took the leading part in organizing his reception, which was enthusiastic. He returned from Edinburgh to face the question of the appointment of a secretary of state which had been raised by the death of Lord Londonderry (Castlercagh). It was upon the question of the appointment of ministers that the battle between the Whigs and the king had been fought in the reign of George III. George IV. had neither the firmness nor the moral weight to hold the reins which his father had grasped. He disliked Canning for having taken his wife's side very much as his father had disliked Fox for taking his own. Cut. Lord Liverpool insisted on Canning's admission to office, and the king gave way. Tacitly and without a struggle the constitutional victory of the last reign was surrendered. But it was not surrendered to the same foe as that from which it had been won. The coalition ministry in 1784 rested on the great landowners and the proprietors of rotten boroughs. Lord Liverpool's ministry had hitherto not been very enlightened, and it supported itself to a great extent upon a narrow constituency. But it did appeal to public

[1] Mrs. Fitzherbert herself, after her final separation from the prince, with an annuity of £6,000 a year, lived an honoured and more or less retired life mainly at Brighton. There she died in 1837. William IV. on his accession offered to create her a duchess, but she declined; she accepted, however, his permission to put her servants in royal livery. The actual existence of a marriage tie and the documentary evidence of her rights were not definitely established for many years; but in 1905 a sealed packet, deposited at Coutts's bank in 1833, was at length opened by royal permission and the marriage certificate and other conclusive proofs therein contained were published in W. H. Wilkins's Mrs. *Fitzherbert* and *George IV*. In 1796 the prince had made a remarkable will in Mrs. Fitzherbert's favour, which he gave her in 1799, and it is included among these documents (now in the private archives at Windsor). In this he speaks of her emphatically throughout as "my wife." It also contained directions that at his death a locket with her miniature, which he always wore, should be interred with him; and Mrs. Fitzherbert was privately assured, on the duke of Wellington's authority, that when the king was buried at Windsor the miniature was on hi4 breast.

opinion in a way that the coalition did not, and what it wanted itself in popular support would be supplied by its successors. What one king had gained from a clique another gave up to the nation.

Once more, on Lord Liverpool's death in 1827, the same question was tried with the same result. The king not only disliked Canning personally, but he was opposed to Canning's policy. Yet after some hesitation he accepted Canning as prime minister; and when, after Canning's death and the short ministry of Lord Goderich, the king in 1828 authorized the duke of Wellington to form a ministry, he was content to lay down the principle that the members of it were not expected to be unanimous on the Catholic question. When in 1829 the Wellington ministry unexpectedly proposed to introduce a Bill to remove the disabilities of the Catholics, he feebly strove against the proposal and quickly withdrew his opposition. The worn-out debauchee had neither the merit of acquiescing in the change nor the courage to resist it.

George IV. died on June 26, 1830, and was succeeded by his brother, the duke of Clarence, as William IV. His only child by Queen Caroline, the princess Charlotte Augusta, was married in 1816 to Leopold of Saxe-Coburg, afterwards king of the Belgians, and died in childbirth on Nov. 6, 1817.

George IV. was a bad king, and his reign did much to disgust the country with the Georgian type of monarchy; but libertine and profligate as he became, the abuse which has been lavished on his personal character has hardly taken into sufficient consideration the loose morals of contemporary society, the political position of the Whig party, and his own ebullient temperament. Thackeray, in his Four *Georges,* is frequently unfair in this respect. The just condemnation of the moralist and satirist requires some qualification in the light of the picture of the period handed down in the memoirs and diaries of the time, such as Greville's, Croker's, Creevey's, Lord Holland's, Lord Malmesbury's, etc.

GEORGE V. (1865–1936) King of Great Britain and Emperor of India was born at Marlborough House, London on June 3, 1865. He was a grandson of Queen Victoria and the second son of Albert Edward, the Prince of Wales, afterwards Edward VII. and of Alexandra, a Princess of Denmark and sister of the Empress Marie of Russia. King George was thus first cousin of the illfated Czar Nicholas II. whom he resembled in face and form especially in early life. Also he was first cousin of the Emperor William II. of Germany, Queen Victoria of Spain, Queen Marie of Rumania, King Constantine and Queen Sophie of Greece.

When 6½ years old, he and his elder brother, Prince Albert Victor, two years his senior, were placed under the tutorship of John Neale Dalton, then curate of Sandringham. In 1877 the two princes became naval cadets on the "Britannia" at Spithead, where they passed through the ordinary curriculum, and in 1879 they joined H.M.S. "Bacchante" under the command of Captain Lord Charles Scott, making a voyage to the West Indies, in the course of which they were rated midshipmen. After a month at home in 1880 they visited South America, South Africa, Australia, the Fiji Islands, Japan, Ceylon, Egypt, Palestine and Greece. A narrative of this voyage, The *Cruise* of H.M.S. "Bacchante," compiled from the letters, diaries and notebooks of the princes, was published in 1886. At the close of this tour in 1882 the brothers separated. Prince George, who remained in the naval service, was appointed to H.M.S. "Canada," on the North American and West Indian station, and was promoted sub-lieutenant. He passed through the Royal Naval college at Greenwich and the gunnery and torpedo schools, being promoted lieutenant in 1885. He served successively in H.M.S. "Thunderer," "Dreadnought" and "Alexandra" of the Mediterranean squadron and H.M.S. "Northumberland" of the Channel Squadron. In 1890 he commanded the gunboat "Thrush" on the North American and West Indian Station, and in 1891, promoted commander, he commissioned the "Melampus." He was promoted captain in 1893, rear-admiral in 1901 and vice-admiral in 1903 nor was there any doubt as to his aptitude for seamanship. Throughout his life, he was a familiar figure at Cowes where his yacht, the "Britannia"—a winner, it is stated, of 360 prizes in all—was frequently sailed by him in Person. Among his friends was John Masefield, the seaman who became poet laureate. George's punctuality, sense of order, vigorous vocabulary—even his famous parrot—suggested the sailor. His collection of stamps is the most complete in existence and, in later years, he was devoted to the radio and motion picture.

In January 1892, his elder brother the duke of Clarence died and as heir to the throne, George had to relinquish his active career in the navy. He was created duke of York, earl of Inverness and Baron Killarney in 1892, and on July 6, 1893 he married Princess Victoria Mary (born May 26, 1867), daughter of Francis, duke of Teck, and Princess Mary Adelaide, duchess of Teck, daughter of Adolphus Frederick, duke of Cambridge. Popularly she was beloved as the Princess Mary. Their eldest son, Prince Edward Albert, was born at White Lodge, Richmond, on June 23, 1894; Prince Albert Frederick George, duke of York, was born at Sandringham on December 14, 1895; Princess Victoria Alexandra Alice Mary on April 25, 1897; Prince Henry William Frederick Albert, duke of Gloucester, on March 31, 1900; Prince George Edward Alexander Edmund, duke of Kent, on December 20, 1902; and Prince John Charles Francis on July 12, 1905 (died January 18, 1919). For eighteen years, George and Mary, spending much of their time at York Cottage, near Sandringham, were overshadowed by the prestige of Queen Victoria and by the magnificent urbanity of King Edward VII. They visited Ireland in 1899 and it had been arranged before the death of Queen Victoria that they should make a tour in the colonies. On the accession of King Edward VII. (1901) this plan was confirmed. They sailed in the "Ophir" on March 16, 1901 travelling by the ordinary route, and landed at Melbourne in May, when they opened the first parliament of the Commonwealth. They then proceeded to New Zealand, returning by way of South Africa and Canada. In November 1901 the duke was created prince of Wales.

On May 6, 1910, King Edward VII. died. Since the new Prince of Wales was under 16, Queen Mary was nominated regent in the event of the demise of the Crown while the heir to the throne was under age. Parliament granted a civil list of £470,000 a year.

The domestic tastes of the King were a contrast to the social brilliance of his father and from the first, he appealed to the quiet solidities of the nation. The bitter quarrel between Edward and the Kaiser had no place in George's conception of duty. His only policy was conciliation and he began with the accession declaration which had contained words that were needlessly offensive to Roman Catholics. Acting under George's insistence, Parliament substituted the formula:

I do solemnly and sincerely in the presence of God, profess, testify and declare, that I am a faithful Protestant, and that I will according to the true intent of the enactments which secure the Protestant succession to the Throne of my Realm, uphold and maintain the said enactments to the best of my power according to law.

A constitutional crisis was raging. The House of Lords rejected a budget passed by the House of Commons and the Commons replied by carrying a Parliament Bill that limited the powers of the Lords. After two elections had been won by the Liberal government in power, George—following the precedent of the Reform Bill of 1832—agreed to create peers in order to secure

the passage of the measure which indication of the prerogative was sufficient for the purpose. Over Home Rule for Ireland, the crisis continued and the arming of Ulster, with a mutiny of British troops at the Curragh near Dublin, led the King to invite leaders of all parties—in 1914—to a conference at Buckingham Palace where, ho ever, no settlement was reached.

It was soon apparent that King George—however simple his private life—intended to continue and even to outshine the ceremonial splendors of the Edwardian era. The coronation at Westminster Abbey, on June 22, 1911, was attended by representatives from all parts of the Empire and other countries and, in order to complete the public assumption of royal authority throughout the United Kingdom, the King and Queen, with the prince of Wales and Princess Mary, made State visits to Ireland, Wales and Scotland during July. At the opening of Parliament, the King wore his crown and, amid some misgivings on the part of his advisers, he proceeded with Queen Mary to India, where a coronation durbar was held at Delhi (December 12, 1911). The constitutional functions of the King in Great Britain were entrusted to a Council of State.

King George exerted little influence over events in Europe that led up to the World War. During that prolonged ordeal. he appeared in uniform when opening Parliament and on other public occasions. The Court, like the nation, was mobilized for active service. Royal visits were paid to important factories and workshops at the munition centres throughout Great Britain, as well as to shipbuilding yards, hospitals and other institutions engaged in war-work. Periodical visits were made by him to the Grand Fleet. In 1917 Queen Mary accompanied the King to France. The King made frequent visits to the French and Belgian fronts. Finally, after the Armistice, the Ring made another visit to Paris and to the battle-fields, Nov. 27–Dec. 10, 1918, and had an enthusiastic reception in the French capital (Nov. 28-30).

The long record of royal attendances at notable ceremonies included the funeral services at St. Paul's for Lord Roberts (Nov. 19, 1914) and Lord Kitchener (June 13, 1916); the commemoration service there on the entry of the United States into the war (April 20, 1917); the Albert Hall commemoration of the first Seven Divisions (Dec. 15, 1917); the thanksgiving at St. Paul's on Their Majesties' silver wedding (July 6, 1918); the presentation to the King at Buckingham Palace by the special Japanese mission of the sword and badge of a Japanese field-marshal (Oct. 29, 1918); and other events. On the occasion of Their Majesties' silver wedding, the King and Queen were received at the Guildhall (July 6, 1918) and were presented with a cheque for £53,000, subscribed by the citizens of London, to be devoted to charities according to Their Majesties' wish, together with a silver tankard once owned by Charles II.

On July 17, 1917 it was announced that King George had abandoned all German titles for himself and his family. At the same time a proclamation was issued to the effect that henceforth the royal house of Great Britain and Ireland would be known, not as the house of Saxe-Coburg-Gotha, or popularly as the house of Hanover or Brunswick, but as the house of Windsor. It had previously been announced (June 20, 1917) that the King had decided that those princes of his family who were British subjects but bore German titles should relinquish those titles in favour of British names.

After the war, the world was faced by a dramatic paradox. The great autocracies of Russia, Germany and Austria-Hungary had collapsed in revolution. The British throne was unshaken. Immediately after the Armistice in 1918, the King and Queen on successive days made popular progresses through London and received general ovations. There were carriage drives through the city (Nov. 11) to a special thanksgiving at St. Paul's (Nov. 12), through the East End (Nov. 13), the south (Nov. 14), the north (Nov. 1j), the north-west (Nov. 18) and the south-west (Nov. 22). On Dec. 27 a banquet was given in honour of President Wilson at Buckingham Palace, where he and Mrs. Wilson were staying with the King and Queen.

On June 21–22, 1921, the King and Queen visited Belfast, where His Majesty inaugurated the new parliament of Northern Ireland. The King made an appeal to all Irishmen to pause and stretch out the hand of forbearance, to forgive and forget and to make for the land they loved a new era of peace, contentment and good-will. When, in the following December, an agreement was at last reached with the Irish Free State, the King in his telegram of congratulation to Mr. Lloyd George, ventured to hope that his own speech at Belfast might have contributed to bring it about.

The policy of cultivating pageantry was developed further when, on February 28, 1922, the King's only daughter, Princess Mary, was married to Viscount Lascelles (*q.v.*) not in the comparative seclusion of a royal chapel but in Westminster Abbey. An astonishing response by the people encouraged the King to arrange that the Abbey should be the scene of other weddings in his family—the duke of York to Lady Elizabeth Bowes-Lyon on April 26, 1923 and the duke of Kent to Princess Marina of Greece and Denmark on November 29, 1934 which was broadcast throughout the world. Owing to the death of the bride's father, the duke of Buccleuch, the duke of Gloucester was married quietly on Nov. 6, 1935 to Lady Alice Montagu Douglas Scott.

In 1922, the King and Queen paid a state visit to Belgium and in 1923 they visited Italy. They were guests of King Vittoria Emanuele III. but it was arranged that, on May 9, they should be received by the Pope. The appearance of the King and Queen at great functions—the British Empire Exhibition at Wembley in 1924, the dedication of Liverpool Cathedral and the opening of the Mersey Tunnel are typical of these occasions—demonstrated the evergrowing affection which surrounded them on every side. Occasionally, a Socialist would raise his voice in not very convincing dissent. But the failure of the General Strike of 1926 proved that Great Britain, however hard hit, wanted no Communism. In 1928, the grave illness of the King aroused sympathy throughaut the world and during the concluding years of an amazing reign, his prestige could hardly have been greater. His Christmas broadcasts, relayed from continent to continent, were irresistible in their dignified and intimate goodwill.

In May 1935, 25 years after accession. King George celebrated a Silver Jubilee which was marked by unforgettably enthusiastic expressions of affectionate loyalty of his subjects. Despite medical advice, King George insisted on wintering in England and on January 20, 1936 he succumbed at Sandringham to a chill. He was buried, with his parents in St. George's Chapel, Windsor and six kings attended the obsequies—Great Britain, Rumania, Denmark, Norway, Bulgaria and Belgium. His coffin was made by the village carpenter at Sandringham. At his funeral, the crowds were greater than any that ever gathered in the streets of London.

GEORGE VI. (1895–), king of Great Britain, Ireland and the British Dominions beyond the Seas, emperor of India, second son of King George V. and Queen Mary, was born at York Cottage, Sandringham, Dec. 14, 1895. After passing through Osborne and the Royal Naval college, Dartmouth, he was gazetted midshipman in Sept. 1913. His health had broken down during a tour, earlier in that year, of the West Indies, Canada and Newfoundland, and for this reason he was debarred from active service during the early years of the World War; but he served in the battle of Jutland as a sub-lieutenant, being mentioned in despatches. At the end of 1917 he was attached to the naval branch of the Royal Air Force and, in Oct. 1918, was on the Western Front, qualified as a pilot and eventually became wing-commander in 1920. After the war (Oct. 1919) he entered Trinity college, Cambridge, taking an abridged course in history, economics and civics.

Afterwards he continued to show a special interest in industrial questions, becoming president of the Society for Industrial Welfare; while his annual camp by the sea for 200 young workers and 200 public schoolboys became a regular institution. Prince Albert (as he was then known) was created K.G. on Dec. 14, 1916, duke of York in June 1920, and K.T. on April 26, 1923, on the occasion of his marriage to Lady Elizabeth Bowes-Lyon,

youngest daughter of the earl and countess of Strathmore and Kinghorne.

In 1922 and 1923 the duke represented the King at court ceremonies in Rumania, Yugoslavia and Czechoslovakia. In 1925 he was made president of the British Empire Exhibition, Wembley, and in June was appointed to the Privy Council. The duke and duchess visited Ulster in July 1924, and in 1924–25 toured Kenya Colony, Uganda and the Sudan.

In 1927 they visited Australia and New Zealand, the duke opening the new parliament buildings at Canberra on May 9. In July 1935 they visited the International Exhibition at Brussels, and in September the duke represented King George V. at the funeral of Queen Astrid of the Belgians. On the accession of his brother, Edward VIII. (*q.v.*), the duke became heir presumptive, and on Edward VIII.'s abdication on Dec. 11, 1936, he succeeded as George VI. Their majesties mere crowned on May 12, 1937. In May and June, 1939, they toured Canada, also paying a visit to the United States. In both countries they were enthusiastically welcomed. (See also ELIZABETH.)

GEORGE V. (1819–1878), king of Hanover, was the only son of Ernest Augustus, king of Hanover, and consequently a grandson of George III. of England. Born on May 27, 1819, he became totally blind in 1833. He succeeded his father in 1851. After the Prussian annexation of Hanover (*q.v.*) in 1866, he lived in Austria and France, and died on June 12, 1878.

GEORGE I. (1845–1913), king of the Hellenes, was the second son of Christian IX. of Denmark, and brother of Queen Alexandra of England. He was nominated for the Greek throne by the British Government, at the request of the Greek national assembly, on the expulsion of King Otto I. in 1862, his election being recognized by the Powers on June 6, 1863.

He was assassinated at Salonica on March 18, 1913, by a Greek named Schinas. For the events of his reign, see GREECE: History.

GEORGE II. (1890–), King of the Hellenes, eldest son of Ring Constantine, was born on July 20, 1890 at Tatoi, the royal villa near Athens. On account of his supposed Germanophile tendencies during the World War, he was excluded from the succession by the Allies in favour of his younger brother, Alexander, upon the deposition of his father by the ultimatum of June 11, 1917. After his father's restoration to the throne in 1920, he married on Feb. 27, 1921, Princess Elizabeth, elder daughter of King Ferdinand and Queen Marie of Rumania. Upon the second deposition of his father by the revolution of General Plasteras, his younger brother Alexander I. having died in 1920 he succeeded to the throne on Sept. 27, 1922. After the unsuccessful counter-revolution of Oct. 1923, his position became more difficult, although there was no proof that he had been a party to that rising. Republican feeling grew under the leadership of Papanastasiou and others, and, despite Venizelos' advice to await the decision of the National Assembly, a number of military and naval officers demanded the deposition of the Glucksburg dynasty. On Dec. 19, 1923 the King and Queen left Greece. Next day, Admiral Condouriotes, for the second time, became regent. On March 25, 1924 the Assembly deposed the dynasty and forbade its members to reside in Greece; and the plebiscite of April 13 confirmed the vote of the Assembly. On Oct. 10, 1935, the Assembly, summoned by General Kondyles, declared for the restoration of the monarchy; but the ex-King delayed his return until a plebiscite, in November, had shown convincingly that this was the popular desire, after which George II. returned as King. (See GREECE.)

GEORGE, king of Saxony (1832–1904), younger son of King John of Saxony (d. 1873) and Queen Amelia, was born at Dresden on Aug. 8, 1832. In the Austro-Prussian War of 1866 he commanded a Saxon cavalry brigade, and in the early part of the war of 1870–71 a division, but later succeeded to the supreme command of the XII. (Saxon) army corps in the room of his brother, the crown prince Albert (afterwards king) of Saxony. His name is inseparably associated with this campaign, during which he showed undoubted military ability and intrepidity, notably at the battles of St. Privat and Beaumont. He succeeded on Albert's death to the throne of Saxony. He died on Oct. 15, 1904, at Pilnitz.

GEORGE, HENRY (1839–1897), American author and political economist, was born in Philadelphia (Pa.), on Sept. 2, 1839. He settled in California in 1858; removed to New York, 1880; was first a printer, then an editor, but finally devoted his life to economic and social questions. In 1871 he published *Our* Land Policy, which, as further developed in 1879 under the title of Progress and Poverty, speedily attracted the widest attention both in America and in Europe. In 1886 he published Protection or Free Trade. Henry George had no political ambition, but in 1886 he received an independent nomination as mayor of New York city, and became so popular that only a coalition of the two strongest political parties prevented his election. He received 68,000 votes, against 90,000 for the coalition candidate. His death on Oct. 29, 1897, was followed by one of the greatest demonstrations of popular feeling and respect that ever attended the funeral of any private citizen in American history. The fundamental doctrine of Henry George, the equal right of all men to the use of the earth, did not originate with him; but his clear statement of a method by which it could be enforced, without increasing State machinery, and indeed with a great simplification of government, gave it a new form. This he named the Single *Tax.*

His doctrine may be condensed as follows: The land of every country belongs of right to all the people of that country. This right cannot be alienated by one generation, so as to affect the title of the next, any more than men can sell their yet unborn children for slaves. Private ownership of land has no more foundation in morality or reason than private ownership of air or sunlight. But the private occupancy and use of land are right and indispensable. Any attempt to divide land into equal shares is impossible and undesirable. Land should be, and practically is now, divided for private use in parcels among those who will pay the highest price for the use of each parcel. This price is now paid to some persons annually, and it is called rent. By applying the rent of land, exclusive of all improvements, to the equal benefit of the whole community, absolute justice would be done to all. As rent is always more than sufficient to defray all necessary expenses of government, those expenses should be met by a tax upon rent alone, to be brought about by the gradual abolition of all other taxes. Landlords should be left in undisturbed possession and nominal ownership of the land, with a sufficient margin over the tax to induce them to collect their rents and pay the tax. They would thus be transformed into mere land agents. Obviously this would involve absolute free trade, since all taxes on imports, manufactures, successions, documents, personal property, buildings or improvements would disappear. Nothing made by man would be taxed at all. The right of private property in all things made by man would thus be absolute, for the owner of such things could not be divested of his property, without full compensation, even under the pretence of taxation.

The idea of concentrating all taxes upon ground-rent has found followers in Great Britain, North America, Australia and New Zealand. In practical politics this doctrine is confined to the "Single Tax, Limited," which proposes to defray only the needful public expenses from ground-rent, leaving the surplus, whatever it may be, in the undisturbed possession of land-owners.

The principal books by Henry George are: *Progress and Poverty* (1879), *The Irish Land Question* (1881), *Social Problems* (1884), *Protection or Free Trade* (1886), *The Condition* of *Labor* (1891), *A Perplexed Philosopher* (1892), *Political Economy* (1898). His son, Henry George (b. 1862), has written a *Life* (1900). For the Single Tax theory *see* Shearman's *Natural Taxation* (1899). (T. G. S.)

GEORGE, STEFAN (1868–1933), German poet, was born at Büdesheim, Hesse, on July 12, 1868. After attending the grammar school at Darmstadt, he studied philosophy and the history of art in Paris, Munich and Berlin. He travelled extensively in Italy, France, England, Spain, Holland and Belgium and became associated with the Baudelaire and Mallarmé School in Paris and the disciples of the Pre-Raphaelites in London. His early poems were first published privately for a select circle of friends, for whom in 1892 he founded the *Blätter* fur die *Kunst.* George is the leader of the school of "art for art's sake" in Germany. He writes consciously as the high priest of an esoteric poetic cult in revolt against modern naturalism and achieves great beauty of

form and an austere power. Among his works are *Hymen* (1890); *Algabal* (1892); *Die Bücher der Hirten* (1895); *Jahr der Seele* (1897); *Der Teppich des Lebens* (1899); *Tage und Taten* (1900); *Die Fibel* (1901); *Der siebente Ring* (1907); *Stern des Bundes* (1914); *Der Krieg* (1917); *Drei Gesänge* (1921). He also translated Baudelaire, Dante and the sonnets of Shakespeare.

See L. Klage, *Stefan. George* (1902); **F.** Diiberg, *Stefan George* (1908).

GEORGE, LAKE, a long and narrow lake in the eastern part of New York State in the foothills of the Adirondack mountains, which rise more than 2,000ft. above it. Prospect mountain, rising some 1,700ft. above sea-level, and Black mountain, about 2,600ft. in height, are the most prominent. It has a maximum depth of about 400ft., is 325ft. above sea-level and 224ft. above Lake Champlain, into which it has an outlet to the north through a narrow channel containing many rapids and falls. The lake is about 33m. long and varies in width from $\frac{3}{4}$ of a mile to 3 miles. Its clear water, coming from mountain brooks and submerged springs, its clean, sandy bottom and its beautiful tints of green and blue make it a gem of beauty. It is also noted for its beautiful mountain scenery and islands and is a favourite summer resort. Lake steamers ply between the village of Lake George (formerly Caldwell), at the southern end of the lake, and other points along its shore to the northern end at Baldwin, whence there is rail connection with steamers on Lake Champlain. Geologists are of the opinion that Lake George is of glacial origin.

Before the advent of the white man the lake was a part of the natural trail over which the Iroquois Indians frequently made their way northward to attack the Algonquins and Hurons. During the struggle between the English and the French for supremacy in America, and during the American Revolution, this natural pathway was still the best route of communication between New York and Canada and was of great strategic importance. Samuel de Champlain explored Lake Champlain in 1609, and at that time heard from the Indians of the beautiful lake, called by them "Andiatarocte" (place where the lake contracts); but there are no records to show that Champlain ever visited Lake George. The first white man to see the lake (Aug. 18, 1642) appears to have been Father Jogues, a Jesuit missionary, who in company with René Goupil and Guillaume Conture was being taken by his Mohawk Indian captors from the St. Lawrence to the town of the Mohawks. In 1646 Father Jogues, while on a half-religious, half-political mission to the Mohawks, again visited the lake on the eve of Corpus Christi. He gave it the name "Lac Saint Sacrement," in allusion to the day of his visit. This name it bore until 1755, when Gen. William Johnson renamed it Lake George in honour of the British king. James Fenimore Cooper refers to it in his novels as Lake Horicon.

In the French and Indian War the plan of the British for operations against the French in North America included an expedition by Gen. William Johnson against the French at Crown Point on Lake Champlain. When this expedition was in camp at the head of Lake George, Gen. Johnson learned that Baron Ludwig August Dieskau, with a force of French and Indians, was marching from Crown Point to Ft. Lyman (later Ft. Edward), some 14m. to the south of his camp. On the morning of Sept. 8 Johnson sent a detachment of about 1,000 colonials, under Col. Ephraim Williams, and 200 Indians under Hendrick, a chief of the Mohawks, to the aid of Ft. Lyman. Dieskau prepared an ambuscade for this detachment, and in the engagement that followed both Williams and Hendrick were killed. The survivors of the fight retreated to their camp, pursued by the French forces. A severe engagement followed on this same day (Sept. 8) in which the British colonial forces, at first fighting behind hastily prepared defences, afterwards counter-attacked their opponents and gained a signal victory. Both Johnson and Dieskau were wounded, and the latter was captured. Gen. Johnson now proceeded to build on the shores of Lake George, near the battlefield, a fort of logs and earth, which he called Ft. William Henry. In the meantime the French entrenched themselves at Ticonderoga on Lake Champlain at the foot of the falls of the stream draining Lake George into Lake Champlain. Two years later, in March, 1757, the governor of Canada sent an expedition of about 1,600 men to capture the fort, but the expedition failed to accomplish its mission. In August of this same year the garrison, in desperate straits because of loss of ammunition and supplies, surrendered to the Marquis de Montcalm. The terms of the surrender provided that the garrison would be permitted to proceed under escort to Ft. Edward, but the strength of the escort was not sufficient to prevent the Indian allies of Gen. Montcalm from massacring or taking prisoner a large part of the force. Ft. William Henry was destroyed. Lake George was the scene of many other engagements during the French and Indian wars and during the Revolution. Gen. Abercrombie's large army marched from the lake to its defeat at Ticonderoga in July, 1758. Lord Amherst advanced along the lake *en route* to Ft. Ticonderoga, which he captured in July, 1759. Near the site of Ft. William Henry, Gen. Amherst later built a new fort known as Ft. George. Its ruins still remain.

GEORGE JUNIOR REPUBLIC, THE, an American colony of boys and girls located at Freeville, N.Y. It was founded in 1895 by W. R. George who conceived the idea that youth in their teens have sufficient brain power and physical strength to assume responsibilities of self-government and self-support, and contended that lack of such responsibility developed indifference to law and order and the dignity of labour. His little colony, composed of 144 boys and girls from New York city, was established on the basis of any other village, except that its citizens were between the ages of 16 and 21. The laws of New York State are followed, and in addition the citizens make special laws in their own town meetings for their particular needs. The same social, civic and economic conditions prevail in the Junior Republic as in other communities.

The Junior Republic has served to launch the self-government movement for youth in schools, institutions, prisons and communities in various parts of the world, and has demonstrated the applicability of its principles to youth of all classes and conditions of society. Other republics, modelled on the George Junior Republic, have been established in several other states.

(W. R. G.)

GEORGE OF LAODICEA in Syria, often called "the Cappadocian," from 356 to 361 Arian archbishop of Alexandria, was born probably at Epiphania, in Cilicia. After many wanderings, in which he amassed a fortune, first as an army-contractor and then as a receiver of taxes, he reached Alexandria. where in 356 he was promoted by the prevalent Arian faction to the vacant see. A semi-Arian or Homsiousian, George instigated the second Sirmian formula (promulgated by the third council of Sirmium 357), which was conciliatory towards strict Arianism, was opposed at the council of Ancyra in 358. His persecutions of the orthodox raised a rebellion which compelled him to flee for his life; but his authority was restored by a military demonstration. On the accession of Julian, he was killed by the people on Dec. 24, 361. Though brutal in character, George possessed a cultivated literary taste, and collected a splendid library, which Julian ordered to be conveyed to Antioch for his own use. An anonymous work against the Manicheans discovered by Lagarde in 1859 in a ms. of Titus of Bostra has been attributed to him.

The sources for the life of George of Laodicea are Ammianus, Gregory Nazianzen, Epiphanius and Athanasius. Gibbon's theory of his identification with the patron saint of England is now rejected (*see* GEORGE, SAINT). *See* J. H. Newman, *The Arians of the 4th Century* (1871); *C. S.* Hulst, *St. George of Cappadocia in Legend and History* (1910).

GEORGE OF TREBXZOND (1395–1484), Greek philosopher and pioneer of the revival of letters in the West, was horn in the island of Crete. In Italy, he learned Latin from Vittorino

da Feltre. His reputation as a teacher and a translator of Aristotle was very great, and he was selected as secretary by Pope Nicholas V., an ardent Aristotelian. His attacks upon Plato (in the *Comparatio Aristotelis et Platonis* [1464]), drew forth a powerful response from Bessarion (*q.v.*), and his inaccurate translations of Plato, Aristotle and other classical authors, combined to ruin his fame. He retired to the court of Alphonso V. at Naples, but returned to Rome where he died unheeded on Aug. 12, 1484.

See G. Voigt, *Die Wiederbelebung des klassischen Altertums* (1893). For a complete list of his translations from Greek into Latin (Plato, Aristotle and the Fathers) and original essays in Greek (chiefly theological) and Latin (grammatical and rhetorical), *see* Fabricius, *Bibliotheca Graeca* (ed. Harles), xii.

GEORGE PISIDA (GEORGIOS PISIDES), Byzantine poet, born in Pisidia, flourished during the 7th century A.D. He was a deacon and keeper of the records of the church of St. Sophia. His works include a poem in three cantos on the campaign of the emperor Heraclius against the Persians, apparently the work of an eye-witness; the *Avarica*, an account of a futile attack on Constantinople by the Avars (626); the *Heraclias*, a survey of the exploits of Heraclius down to the overthrow of Chosroes (627); a didactic poem, *Hexaëmeron* or *Cosmourgia*, on the creation of the world; a treatise on the vanity of life, after the manner of *Ecclesiastes;* a controversial composition against Severus, bishop of Antioch, and a poem on the resurrection of Christ. The metre chiefly used is the iambic. As a versifier Pisida is correct and even elegant; as a chronicler of contemporary events he is exceedingly useful; but though later Byzantines admired his work, modern criticism pronounces it dull.

Complete works in J. P. Migne, *Patrologia Graeca*, xcii.; *see* also *De Georgii Pisidae apud Theophanem aliosque historicos reliquiis* (1900), by S. L. Sternbach, who has edited several new poems for the first time from a Paris ms. in *Wiener Studien*, xiii., xiv. (1891–92); C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897); *C.* F. Bahr in Ersch and Gruber's *Allgemeine Encyklopadie.*

GEORGE THE MONK (Georgios Monachos), called Hamartolos (Greek for "sinner"), Byzantine chronicler, lived during the reign of Michael III. (842–867). He wrote a *Chronicle* of events, in four books, from the creation of the world to the death of the emperor Theophilus (842), whose widow Theodora restored the worship of images in the same year. It is the only original contemporary authority for the years 813–842, and therefore so far indispensable; the early parts of the work are merely a compilation. In the introduction the author declares that his only object was to relate with strict truth such things as were "useful and necessary." Far too much attention, however, is devoted to religious matters; the iconoclasts are fiercely attacked, and the work is full of theological discussions. The mss. give a continuation down to 948, the author of which is indicated simply as "the logothete," by whom probably Symeon Metaphrastes (second half of the 10th century) is meant. In this more attention is devoted to political history. Still further continuations of little value go down to 1143. The large circulation of the work and its subsequent reissues, with alterations and interpolations, make it very difficult to arrive at the original text.

EDITIONS: E. de Muralt (1859); J. P. Migne, *Patrologia Graeca*, cx.; C. de Boor (in Teubner series, 1904).

See F. Hirsch, *Byzantinische Studien* (1876); *C.* de Boor in *Historische Untersuchungen* (in honour of Arnold Schäfer, Bonn, 1882); C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

GEORGE THE SYNCELLUS (GEORGIOS SYNKELLOS), of Constantinople, Byzantine chronicler and ecclesiastic, lived at the end of the 8th and the beginning of the 9th century A.D. He was the *syncellzu* (cell-mate, the confidential companion assigned to the patriarchs, in reality sometimes little more than a spy) of Tara(u)sius, patriarch of Constantinople (784–806), after whose death he retired to a convent, and wrote his *Chronicle* of events from Adam to Diocletian (285). At his request, the work was continued after his death by his friend Theophanes Confessor. The *Chronicle*, which is rather a chronological table (with notes) than a history, is valuable, in spite of its religious bias and dry and uninteresting character, for the fragments of ancient writers and apocryphal books preserved in it (*e.g.*, considerable portions of the *Chronicle* of Eusebius).

Editio princeps, by J. Goar (1652); in Bonn *Corpus scriptorum hist. Byz.*, by *W.* Dindorf (1829). *See* also H. Gelzer, *Sextus Julius Africanus*, ii. 1 (1885); C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

GEORGETOWN, capital of British Guiana (*see* GUIANA), population (1939) 68,818, and seat of the colonial government, situated on the right bank of the Demerara river at its mouth, in 6° 29′ 24″ N. and 58° 11′ 30″ W. Known during the Dutch occupation as Stabroek, it was established as the seat of government of the combined colonies of Essequibo and Demerara (now with Berbice forming the three counties of British Guiana) in 1784, its name being changed to Georgetown in 1812. The streets are wide and straight, intersecting each other at right angles, several having double roadways with lily-covered canals between the grass banks carrying rows of handsome shade trees. In Main Street, the finest street in Georgetown, the canal has been filled in to form a broad walk. The principal residences, standing in their own gardens, are scattered over the town. Water Street, the business centre, runs parallel to the river for about 2½ m. and contains the stores of the wholesale and retail merchants, their wharves running out into the river to allow steamers to come alongside. Most of the houses and public buildings are constructed of wood. the former generally raised on brick pillars some 4–10 ft. from the ground, the bright colouring of the wooden walls, jalousies and roofs adding to the beauty of the best streets. The Public Buildings in the centre of the city, containing the offices of the government and the hall of the Court of Policy, were erected between 1829 and 1834. They form a handsome, E-shaped, brick-plastered block with deep porticos and marble-paved galleries carried on cast-iron columns. The law courts, built in the '80s, have a ground floor of concrete and iron, the upper storey being of hardwood. Among other public buildings are the town hall, the Anglican and Roman Catholic cathedrals, several handsome churches, the local banks and insurance offices, and the almshouse. The public hospital consists of several large blocks. The Royal Agricultural and Commercial Society has a large reading-room and lending library. The museum of the Royal Agricultural and Commercial Society is chiefly devoted to the fauna of British Guiana, but also contains collections of local economic, mineral and botanical exhibits, foreign birds and mammals, and views of the colony. The extensive botanical gardens to the east of the city are admirably laid out. The nurseries are devoted chiefly to the raising of plants of economic importance which can be purchased at nominal rates. The collections of ferns and orchids are very fine. In the gardens are located the fields of the board of agriculture, where experimental work in the growth of sugar-cane, rice, cotton, etc., is carried on. Other popular resorts are the sea wall and the promenade gardens in the centre of the city.

The local government of Georgetown is vested in a mayor and town council elected under a very restricted franchise. The city is divided into nine wards, each with one representative. Three councillors are nominated by the governor. The city has excellent sanitary conditions, a modern system of sewage disposal (completed in 1929 at a cost of $5,000,000) and electricity. The colonial government gives a grant-in-aid towards the upkeep of the streets. Water for public and domestic purposes is taken from the conservancy of the east coast and is delivered by pumping throughout the city, but drinking-water is collected in tanks from rain. There is an excellent service of telephones and a trolley service and a halfpenny postage within the city boundaries. Georgetown has two well-equipped foundries, a dry dock, and factories for the manufacture of rice, cigars, soap, boots, chocolate, candles, aerated waters and ice. It is connected by rail and ferry with New Amsterdam, by ferry and rail with the west coast of Demerara, and by steamer with all coastal districts and up the principal rivers.

GEORGETOWN, formerly a city of the District of Columbia, U.S.A., and now part of the city of Washington, U.S.A., at the confluence of the Potomac river and Rock Creek, about 2½m. W.N.W. of the National Capitol. The streets are old-fashioned, narrow and well shaded. On the "Heights" are many fine residences with beautiful gardens: the Monastery and Academy of Visitation for Girls, foundeil in 1799 by Leonard Neale, second

archbishop of Baltimore; and the college and the astronomical observatory (1842) of Georgetown university, founded in 1789. Rising in terraces from Rock Creek is Oak Hill cemetery, a beautiful burying-ground containing the graves of John Howard Payne, the author of "Home, Sweet Home," Edwin McMasters Stanton and Joseph Henry. On the bank of the Potomac is a brick house which was for several years the home of Francis Scott Key, author of "The-Star-Spangled Banner"; on Analostan island in the river was a home of James Murray Mason; Georgetown Heights was the home of the popular novelist, Mrs. Emma Dorothy Eliza Nevitte Southworth (1819–99). Georgetown was settled late in the 17th century, was laid out as a town in 1751, chartered as a city in 1789, merged in the District of Columbia in 1871, and annexed to the city of Washington in 1878. In the early days of Washington it was a social centre of some importance, where many members of Congress as well as some cabinet officers and representatives of foreign countries lived and the President gave State dinners; and here were the studio, for two years, of Gilbert Stuart, and "Kalorama," the residence of Joel Barlow.

See R. P. Jackson, *The Chronicles of Georgetown, D.C. from 1751 to 1878* (1878); H. T. Taggard, Old *Georgetown* (Lancaster, Pa., 1908); W. A. Gordon, "Old Homes on Georgetown Heights," *Columbia Hist. Soc. Rec.*, vol. xviii, pp. 70–91 (1915); and W. Tindall. "The Executives and Voters of Georgetown," ib., vol. xxiv., pp. 89–117 (1922).

GEORGETOWN, a town of Kentucky, U.S.A., 65 mi. E. of Louisville; the county seat of Scott county. It is on federal highways 25, 62 and 227, and is served by the Frankfort and Cincinnati and the Southern railways. The population was 4,229 in 1930 and 4,420 in 1940. It is the seat of Georgetown college (Baptist), chartered in 1829 as the successor of an academy founded in 1789. A remarkable spring in the centre of the town has a flow of 200,000 gal. an hour, and furnishes power for various factories, as well as the municipal water supply. Georgetown was settled in 1775, and was called at first McClellan's and then Lebanon, until in 1790 it was incorporated under its present name in honour of George Washington.

GEORGETOWN, a city of South Carolina, U.S A.. at the head of Winyah bay, 14 mi. from the ocean; a port of entry and the county seat of Georgetown county. It is served by the Seaboard Air Line railway and by river and ocean steamers. The population was 5,082 in 1930; 1940, 5,559. The world's largest pulpboard mill was erected there in 1937. There are 28 large plantations in Georgetown county. Georgetown is the centre of fishing and hunting grounds. The Inland Waterway passes there. The first settlement there was made about 1700, and the town was laid out before 1734. In 1757 the Winyah Indigo society (growing out of a social club organized about 1740) was founded by a group of planters interested in the cultivation of indigo. During the Revolution Georgetown was the scene of several skirmishes, and here Gen. Lafayette first landed on American soil (June 13, 1777). The town was incorporated in 1805 and was chartered as a city in 1895.

GEORGETOWN, a city of central Texas, U.S.A., 2; mi. N. of Austin, on federal highway 81; it is served by the Missouri-Kansas-Texas and the Missouri Pacific railways; the county seat of Williamson county. The population in 1940 was 3,682. Williamson is one of the leading cotton counties of the state. North and west of the city are extensive forests; to the east is the black-land belt; and there are mineral springs and large deposits of building stone near by. Georgetown is primarily an academic centre, the seat of Southwestern university (Methodist Church), formed in 1873 by the consolidation of four pioneer Methodist institutions of the state, founded in 1840, 1844, 1848 and 1856 respectively. The first settlement here was made in the year 1848.

GEORGETTE. The name of a textile fabric, also sometimes described as "crêpe georgette." It is a light and gossamer-like tissue of silk of the plain weave, used for ladies' dresses, blouses, millinery, etc., and for other purposes when refinement and delicacy of texture are advantageous.

A georgette fabric has a somewhat subdued sheen, without being dull, and also a crêpe-like texture without the crimped surface of a true crêpe. This lustre and texture of georgette result from the employment both of warp and weft threads of "reverse" twist yarn spun and woven in the "gum," the yarn being subsequently "de-gummed" by boiling-off prior to dyeing and finishing. The warp and weft threads of "reverse" twist may be disposed either alternately, *i.e.*, with an "end-and-end" disposition in the warp series of threads, and a "pick-and-pick" disposition in the weft series; or in alternate pairs, *i.e.*, with a "two-and-two" disposition either in one or in both series of threads. The employment, in the same fabric, of threads of "reverse" twist in the manner described gives the threads the tendency to untwist in reverse directions and so develops the crêpe or crimp effect, which is also for the same cause a distinctive feature of a true voile texture (*q.v.*).

Georgine is the description of a very light silk tissue having the general appearance and characteristics of the true "crêpe georgette" but without the same degree of elasticity. (H. N.)

GEORGIA (Russian *Gruzia*, Armenian *Vrastan*), formerly an A.S.S.R., since the constitution of Dec. 1936 a state member of the U.S.S R. occupying the western part of Trans-Caucasia. Area 69,900 square kilometers; population (1939) 3,542,289. Its boundaries are west, the Black sea, north, the main ridge of the Caucasus, fringed by the Karachaev, Kabardine-Balkarsk, North Ossetian, Ingushetian, Chechen and Daghestan autonomous areas and republics, south-east, Azerbaijan, and south, Armenia and Turkey. It is a mountain and plateau region, including the southern slopes of the Caucasus, with glaciers and lofty peaks, and the northern slopes of the Armenian plateau, sometimes called the Anti-Caucasus or lesser Caucasus. Between them lie the valleys of the Rion flowing into the Black sea and the Kura and its tributaries flowing into the Caspian, and along these valleys goes the railway linking Poti to Baku.

The Suram or Meskhiysk range, a spur from the Caucasus to the Armenian plateau, not only forms the watershed between the Black sea and Caspian drainage, but also markedly influences the climate. To the west is a Mediterranean region, with a maximum winter rainfall and a luxuriance of sub-tropical vegetation. To the east is a climate of greater extremes of temperature with a scanty rainfall having its maximum in Spring, while between the Alazan and the Kura rivers is bare steppe only cultivable if irrigated. The eastern region is exposed to the winds from Central Asia. The broad coastal plain, with its luxuriant vegetation and malaria infested swamps, extends from Batum to Sukhum and continues inland almost to the Suram range, along the western slopes of which lies Imeretia. Eastwards from the Black sea, on the higher slopes of the Caucasus are the wild and inaccessible valleys of Swanetia, with Mingrelia below. Further east is the trachytic cone of Razbek, 16,541 ft., towering above the Dariel gorge along which goes the Georgian military road. West of the Mamison pass, as far as Klukhor, the only passes are glacial, used occasionally by the mountain peasants, but eastward are grassy passes where horses can cross the chain in many places, and this key region between the sources of the Terek and the Ardon on the north and those of the Rion and the Kura on the south, has been held by the Ossetes from time immemorial. There is no plain in eastern Georgia, but from Gori a plateau slopes south eastward, with the Alazan river on the north, the Kura on the south and the valley of the Yora in the centre. Round the Alazan, with its numerous left bank mountain tributaries, is the fertile vine-growing Kakhetian region. In addition to the sharp east and west climatic division in Georgia, there are vertical climatic zones, ranging from the warm valleys, through the leafy forest and pine forest zone to the Alpine pastures with their short, hot summer and long cold winter, and to the region of perpetual snow and glaciation.

This complexity of relief and climate has led to the development and preservation of scattered populations, each with its own language and culture, remote from communication with one another and the outside world. There are three main linguistic Georgian groups, Karthelian or Georgian proper now the administrative language, Mingrelian and Mingrelian-Lazi and Swanetian. In western Georgia are the historic divisions of Imeretia, Racha, Lechkhum, Swanetia, Guria and Mingrelia and in eastern Georgia,

Kartalinia, Kakhetia, Meskhetia, Dzhavakhetia, Mtskheta, Khevsuria, Pshavia, Borchalo and South Ossetia. Elements of the population from other regions include Russians, Armenians, Persians, Tatars, Turks and Jewish colonies of ancient date in the hill regions. Near Tiflis are German settlements dating from the 18th century. The population in 1926 was 2,666,388, and the Georgian element with its varied dialects, formed about 65%. The greater part of the population, especially in the rural areas, is illiterate, and the new republic thus has to face great difficulties.

Agriculture, mostly of a primitive kind, is the chief occupation. In western Georgia, in the absence of grass for working cattle, the leaves and stalks of maize are used, and maize flour is the common food. In Guria, Mingrelia and Imeretia, the spring floods spread alluvium on the fields and maize can be sown year after year. Cotton production in the two latter areas has almost reached pre-war level (1928). Tobacco for export is grown in Ozurgeti district. Orchard fruits, berries, peaches, apricots, vines, pomegranates, citrous fruits, tomatoes, cucumbers, beetroot, melons and vegetables are cultivated, but so unscientifically that they have little export value, and preserve-making is primitive. Bamboo and various narcotic and medicinal plants are also grown, and tea cultivation has markedly increased. Silkworm breeding flourishes in the Kutais district, where the mulberry is better cultivated. In eastern Georgia irrigation is often necessary; cotton, rice, wheat and barley are the chief crops. The fertile regions of Kakhetia and West Kartalinia are noted for their vines and fruits, though hailstorms often ruin the crop, and phylloxera is a constant scourge. Beekeeping is everywhere profitable. Wheat and barley are grown on the hills and foothills, the latter in Racha and Suanetia where wheat cultivation is impossible. On the high hills summer wheat, and in the valleys winter wheat is grown. All three varieties, the hard yellow and red and the soft white are found, and every variety of culture, one, two, three and many field, manured and fallow. Only the German colonists carry on an intensive system which provides them with winter food for their cattle, and allows or' dairy produce for export. Nomad cattle and sheep breeding is going through a crisis. An unforeseen result of the creation of autonomous republics and of the cession of the south to Turkey has been an interference with the balance between the Alpine summer pastures, and the lowland winter grazing. In Georgia there are 641,000 hectares of summer pasture, and only 234,000 of winter, while in Azerbaijan the proportions are reversed. An added difficulty is that the lowland pastures have an inadequate water supply and late spring snow may cause damage to the flocks as in 1924 and 1927. The insanitary habits of the nomads bring plague in their train and their low cultural grade will make it long before scientific provision of winter food can remedy the present difficulties. Buffaloes are used as working cattle in the wet west, and have not diminished much, but the number of sheep, goats and horses is markedly less than in pre-war times, and there is still a deficiency of working cattle. Irrigation problems are also complicated by the division of the republics, since the upper and lower courses of the rivers lie in different units and, though a federal committee is considering policy, no agreement has been reached. Local irrigation canals were ruined in a lesser degree than the larger mechanical schemes; the Karayask plant, built in 1867, was destroyed in 1917 and has not yet been replaced. A new mechanical irrigation plant is in course of construction in Kakhetia. The general level of agriculture is also lowered by the paucity of means of communication and the absence of towns to create a demand. Moreover widespread malaria in the plains has lowered the vitality of the workers.

Georgia is heavily timbered with forests of many varieties, but the timber industry is little developed, partly because of the inaccessibility of the region and the lack of communications and partly because the streams are not suitable for floating the logs. Its development will need great care, for the forests on these steep slopes regulate the river flow and prevent landslides. Boxwood for spinning shuttles, greeknut, beech, oak and pine are the chief commercial varieties. For an account of the forests, see CAUCASUS.

Minerals, etc.—The chief mineral product is manganese in the Chiatura district. This was being worked by an American firm, the Harriman manganese concession whose advent was considered to be a most important thing for Russia financially but which has since been liquidated as it proved to be impossible to work it on a profit for a variety of reasons. Coal of poor quality is mined at Tkvibuli on the Kvirila river, and at Gelati, north of Tiflis, and iron at Chataksk, south of Tiflis. Naphtha exists north of the Yorak. Mineral springs are numerous; Tiflis, Abbas-tuman and Borzhom are noted spas. Georgia has vast possibilities of hydro-electric development, and in 1926–27 the Zemo-Avchal station on the river Kura near Tiflis was completed, with a production of 13,000 kw.; the power is to be used for electrification of the railway and for irrigation works on the steppe, as well as for the Tiflis factories. Another station on the Abasha river in the Novo-Senaka district west of Kutais is being constructed and should supply Poti, Kutais and Chiatura. Manufactures are little developed, the only industrial centres being Tiflis, Kutais and Poti (*qq.v.*); the chief are foodstuffs, tobacco, leather and bricks. *Koustar* (peasant) industries are widespread, and include the weaving of carpets in the Borchalinsk district, of silk and dyed stuffs in Imeretia, the making of wooden and iron goods for daily use and the artistic silver work of the south western district. There is at present (1928) no railway crossing the Caucasus from Georgia, and no direct railway link with the north, but a coastal line to link Poti with Tuapse is under construction.

HISTORY

Georgia existed as a kingdom for 2,000 years. Its earliest name was Karthli or Karthveli from Karthlos, an eponymous king, whose son Mtskhethos founded Mtskhetha, the modern Mtskhet; the Persians knew it as Gurjistan, the Romans and Greeks as Iberia, though the latter placed Colchis also in the west of Georgia. Kakhetia and Karthli formed the nucleus of a kingdom which varied much, including at different times Guria, Mingrelia, Abkhasia, Imeretia and Daghestan. Georgia was conquered by one of Alexander's generals, but Pharnavaz or Pharnabazus (302 to 237 B.C.) shook off the Macedonian yoke. At the end of the 2nd century B.C. the last Pharnavazian prince was dethroned by his own subjects and the crown given to Arsaces, king of Armenia, thus founding the Arsacid dynasty. The Romans under Pompey in 65 B.C. and under the emperor Trajan, A.D. 114, invaded the country with little success. The Sassanian dynasty began with Mirhan or Mirian (265–342), son of a Persian king and a princess of the Arsacid dynasty. Christianity was introduced and the first church erected at Mtskhet. In 379 a Persian general built Tphilis (Tiflis) as a counterpoise to Mtskhet. Tiridates (393–405) freed the country from Persian rule. In 446–499 Vakhtang, surnamed Gurgaslan or Gurgasal (the "wolf lion"), established a patriarchate at Mtskhet and made Tphilis his capital. After conquering Mingrelia, Abkhasia, the Ossetes and part of Armenia, he joined Persia in an attack on India. His son Dachi or Darchil (499–514) permanently transferred the seat of government to Tphilis (Tiflis).

In 571 the Georgians, while Persia was being attacked by Turks and Byzantine Greeks, appealed to the Byzantine emperor, Justin II., who placed Guaram, a prince of the Bagratid family of Armenia on the throne. The Bagratid dynasty ruled until 1803. Byzantine influence was strong in the Georgian church until the Arab invasions in the 7th and 8th centuries, when Islamism was repeatedly imposed on the Georgians at the point of the sword. Under Bagrat III., who built in Kutais in 1003 a fine cathedral, peace was restored and his kingdom extended from the Black Sea to the Caspian. In the 11th century the Seljuk Turks overran the country, but David II. (1089–1125), the Renovator, with the help of the Kipchak Mongol horde, forced them back over the Armenian mountains. Under George III. (1156–1184), Armenia was in part conquered and Ani, one of its capitals, taken. His daughter Tamara or Thamar succeeded him and extended her power over Trebizond, Erzerum, Tovin and Kars, while her son George IV. (1212–1223) conquered Ganja and repulsed the Persians. In 1220 and 1222 the Mongol hordes under

a son of Jenghiz Khan overran the country and under his sister Rusudan, Tiflis was twice captured by the Persians and in 1236 Georgia was devastated by the Mongols. After a recovery under George V. (1318–1346), who reconquered Imeretia, the Mongols under Timur (Tamerlane) laid the country waste until 1403. Alexander I. (1413–1442) freed the country from the Mongols, but divided it among his three sons, whom he made sovereigns of Imeretia, Kakhetia and Karthli (Georgia) respectively; Imeretia remained a separate state till its annexation by Russia (1810).

In 1492, the king of Kakhetia sought the protection of Ivan III. against the Turks and Persians. In the 17th century, Theimuraz (1629–1634), king of Georgia, appealed to Michael, the first of the Romanov tsars of Russia, against Shah Abbas of Persia, as did Imeretia and Guria. In 1638 the prince of Mingrelia took the oath of allegiance to the Russian tsar, and in 16jo the prince of Imeretia took the same step. Vakhtang VI. of Georgia put himself in the 18th century under the protection of Peter the Great. After the 18th century Afghan conquest of Persia, the Turks captured Tiflis and compelled Vakhtang to abdicate, but in 1735 withdrew their claim. Peter the Great in 1722 extorted from Persia her prosperous Caspian provinces, but left her the predominating power in Georgia. Heraclius II. of Georgia (1783) declared himself a vassal of Russia and in 1795 appealed to Russia for help against Agha Mohammed, shah of Persia, who had laid Tiflis in ruins. George XIII., the next king of Georgia, renounced his crown in favour of the tsar and in 1801 Georgia became a Russian province. Guria submitted to Russia in 1829.

Under the tsars Georgia was divided between the Russian provinces of Tiflis and Kutais (see TRANSCAUCASIA). After the Oct. 1917 revolution a period of civil war followed in Georgia, which ended in 1921, upon the creation of the Georgian A.S.S.R.

In spite of her illiterate masses, Georgia has a cultural heritage which should prove a valuable asset to the new Georgian university. Her language is of the Caucasian group, and has a sacerdotal and an ordinary alphabet. The extant version of the Georgian bible dates from the eighth century, and the famous national poem "The man clothed in the panther's skin," by Roustaveli, memorized by many Georgians to-day, dates from the reign of Queen Tamara in the 11th century. An English translation of it has been published by the Royal Asiatic Society.

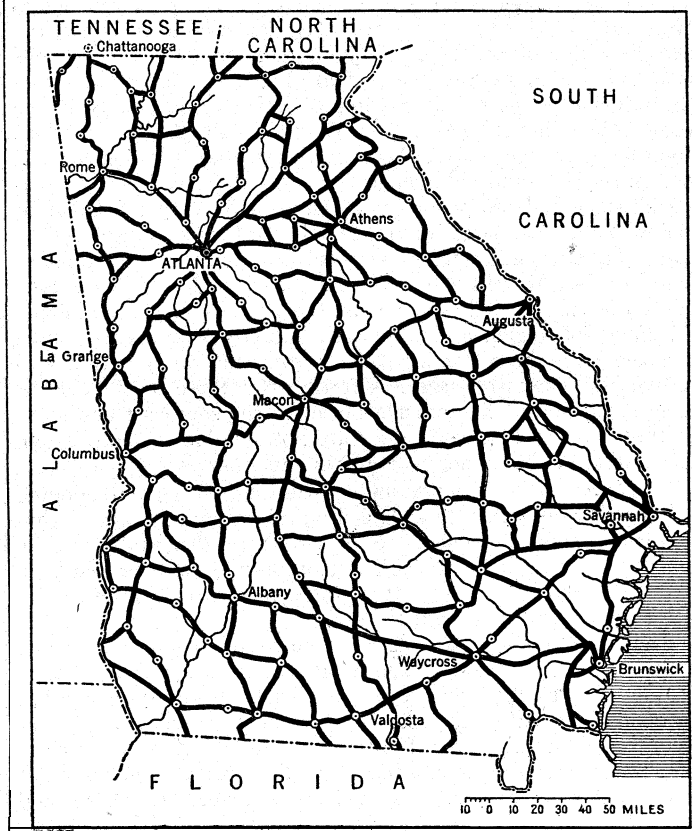
GEORGIA, popularly called the "Empire State of the South," is a southern State of the U.S.A., and one of the 13 original States. It is situated between 30° 31' 39" and 35° N. and between 81° and 85° 53' 38" W. Georgia is bounded on the north by Tennessee and North Carolina, east by South Carolina and the Atlantic ocean, south by Florida and west by Alabama. The extreme length and width of the State are 320m. and 254m. respectively. Its total area is 58,876 sq.mi. ,

Physical Features. — The surface of Georgia is divided into five physical zones. From the sea coast, which is skirted by fertile, semi-tropical islands, a plain of 35,000 sq.m., known as South Georgia, extends northward to the "fall-line" passing from Augusta, through Milledgeville and Macon, to Columbus. This is a part of the great Atlantic coastal plain. The average elevation for the entire region is about 250 feet. North of the line mentioned, and collectively known as North Georgia, are the four other regions, each with well-defined characteristics. The largest and southernmost is known as the Piedmont belt or plateau, being a region of faint relief eroded on highly complicated crystalline rocks. The Blue Ridge escarpment, a striking topographic feature in Virginia and the Carolinas, extends into Georgia along the north-eastern border of this belt, but is less strongly developed here than elsewhere, dying out entirely towards the south-west. North of the Piedmont belt lie the Appalachian (Blue Ridge) mountains region and the Great Valley region, the former to the east, the latter to the west of a dividing line from Cartersville northward. The former region consists of detached mountain masses of crystalline rocks, not yet eroded down to the level of



MAP OF THE ROADS OF GEORGIA

the Piedmont belt. In Towns county, in the Appalachian region, is the highest point in the State, Brasstown Bald (4,768 ft.); the approximate mean elevation of the State being 600 feet. The Great Valley region consists of folded sedimentary rocks, extensive erosion having removed the soft layers to form valleys, leaving the hard layers as ridges, both layers running in a north-east to south-west direction. In the extreme north-west corner of the State is a small part of the Cumberland plateau, represented by Lookout and Sand mountains. On the Blue Ridge escarpment near the north-east corner of the State is a water-parting separating the waters which find their way respectively north-west to the Tennessee river, south-west to the Gulf of Mexico and south-east to the Atlantic ocean. West of where the escarpment dies out, the Great Valley region and a considerable portion of the Appalachian mountains region are drained by the Coosa, the Tallapoosa and their tributaries, into Mobile bay; but the Cumberland plateau, like that part of the Appalachian mountains region which lies directly north of the Blue Ridge escarpment, constitutes a part of the Tennessee basin. The principal rivers of the State are the Chattahoochee and the Flint, which unite in the south-west corner to form the Apalachicola; the Ocmulgee and the Oconee, which unite in the south-east to form the Altamaha; and the Savannah, which forms the boundary between Georgia and South Carolina. All these rise in the upper part of the Piedmont plateau, through which they pursue a rapid course over rocky beds, and are navigable only south of the "fall-line."

The climate of Georgia is mild. Mean annual temperatures range from about 57" to 68° F. January averages are about 40° in the mountains and 54° on the south coast; July averages range from about 74" to 82°. Mean annual rainfall is almost 50 inches

a year, but varies from about 70° in the extreme northeast to 45° or 46° between Macon and Augusta. Snowfall averages 7 to 10 inches a year in the mountains, about 3 in Atlanta and becomes negligible on the coast plains.

Georgia is also notable for the variety of its soils. In the Cumberland plateau and Great Valley regions are a red or brown loam, rich in decomposed limestone and calcareous shales and sandy or gravelly loams. In the Piedmont plateau and Appalachian mountain regions the surface soil is generally sandy, but in large areas the subsoil is a red clay derived largely from the decomposition of hornblende. By far the greatest variety of soils is found in that part of the coastal plain region extending from the fall line as far south as a line bisecting Early county in the west and passing through Baker, Worth, Dooly, Dodge, Laurens, Johnson, Jefferson and Burke counties; a sand, forming what is known as the sand-hill region; red clay derived from silicious rock in the red hills; and grey, sandy soils with a subsoil of yellow loam. Southwest of this belt is the lime sink region. The soft limestone underlying this region is covered, in the uplands, with grey, sandy soils, which have a subsoil of loam; in the lowlands the surface soils are loams, the subsoils clays. Adjoining the lime sink region are what were formerly known as the pine barrens. Here the prevailing soils are grey and sandy with a subsoil of loam, but they are less fertile than those of the regions mentioned above. The coast counties of the southeast and some of those on the Florida frontier are not suitable for cultivation, on account of the numerous marshes and swamps.

Government. — The present constitution, which was adopted in 1877 and subsequently arnended, provides for a system of government similar in general to that of the other states of the union. An amendment to the constitution may be proposed by a two-thirds vote of the legislature, and comes into effect on receiving a majority of the popular vote.

The state executive officers are a governor, secretary of state, controller general and treasurer, all elected for a term of two years. Other elected administrative officials are the state superintendent of education, the attorney general, a commissioner of agriculture, a commissioner of commerce and labour, a prison commission of three members and a public service commission of five members. There are also numerous appointive officers and boards.

In case of the governor's "death, removal or disability" the duties of his office devolve, in the first instance, upon the president of the senate, and in the second upon the speaker of the house of representatives. The governor's power of veto extends to separate items in appropriation bills, but in every case his veto may be overridden by a two-thirds vote of the legislature. The legislature, consisting of a senate and house of representatives, meets in regular session at Atlanta, the capital, biennially in January in odd-numbered years. The senate consists of 52 members, elected from senatorial districts for a term of two years. Representatives, 205 in number, are likewise elected for two years. They are apportioned one to each county, except the eight more populous, which have three each, and the 30 of next greatest population, which have two each. The judicial power is vested in a supreme court, a court of appeals in two divisions, 33 circuit courts, about 80 city and county courts, a court of ordinary and probate for each county and a justice of the peace for every militia district. All judges are elected: those of the supreme court and the court of appeals, for six years; all others, for four years.

Each judicial circuit has a solicitor general elected for a term of four years. The counties, 159 in number, are the chief units of local government; and their more important affairs are managed as a rule by boards of commissioners, though each county normally elects also a clerk of court, a coroner, a sheriff, a tax collector, an ordinary, a county agent, a board of education and a county school superintendent.

Before 1909 there was no constitutional discrimination aimed against the exercise of suffrage by the Negro; but, in fact, the Negro vote had in various ways been reduced. By a constitutional amendment adopted by a large majority at a special election in Oct. 1908, new requirements for suffrage, designed primarily to exclude paupers and illiterates, especially illiterate Negroes, were imposed, the amendment coming into effect on Jan. 1, 1909. While this provision is still a part of the constitution, it is of little present significance. The only restriction actually enforced is the payment of the poll-tax of $1 per year. There is no specific race discrimination in this requirement, but it probably bears more heavily on the Negroes than on the whites because of the greater poverty of the Negro element. The poll-tax is cumulative for seven years, and it is this cumulative character of the tax which makes it so onerous, for if the citizen neglects paying it he cannot register for voting until he has paid the total amount accumulated. The practical disfranchisement of Negroes is, however, effected by the white primary system. There is in Georgia only one numerically strong political party, the Democratic. Its rules require that there shall be a primary election, confined to white members of the Democratic party, for the purpose of nominating candidates for all offices. When the general election is held, the voters, whether white or black, have no choice, since opposing political elements do not usually put up candidates. Of course, if there were an active Republican or other party, there would be no restriction upon the exercise of the suffrage by Negroes in the general elections. As the result of a general campaign against child labour, an act was passed in 1906 providing that no child under ten years of age should be employed or allowed to labour in or about any factory, under any circumstances.

This law was soon amended, raising the age and conditions of employment, and by an act of 1914 the employment of children under 14 years of age was prohibited. Factory inspectors were provided in 1916 and in 1920 an Employer's Liability act, which provided for compensation for industrial accidents, became operative. By another act of the same year, rehabilitation of persons disabled in industry or otherwise was undertaken by the state, with federal aid. On June 8, 1937, were ratified 26 constitutional amendments, which liberalized the powers of the legislature particularly with respect to state co-operation in the social program of the New Deal.

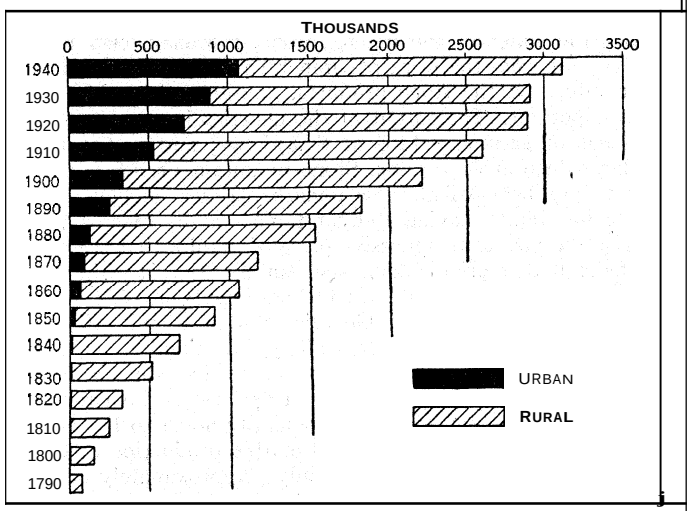
The four years of the Rivers administration, culminating with the inauguration of Governor Talmadge in Jan. 1941, have been called the Little New Deal period in Georgia. During that time the state fell in line with the national security program and a new charge, for public assistance, entered the budget. This new cost of $2,500,000 is for old-age pensions and subsidies to other dependent classes. During the same period the length of the school term was greatly increased, the state guaranteeing a seven months' term in the common schools. This undertaking involved a great increase in state costs. The general appropriation for common school education jumped from $4,000,000 in 1936 to nearly $10,000,000 in 1940. The appropriations for the health department grew from $100,000 in 1936 to $600,000 in 1940. The plants of the eleemosynary institutions were either renovated or rebuilt, at a cost of some millions of dollars. These heavily increased expenditures precipitated a crisis in state finances. While income receipts increased from $30,000,000 in 1936 to $46,000,000 in 1940, there is still a serious gap between charges and income. This situation is in a measure caused by the practice of earmarking or allocating certain types of income to specific charges. The most important source of revenue is the tax on motor fuel, and this revenue has always been largely earmarked for highway construction. The highways have, therefore, developed rapidly, and other services have suffered. The first general assembly under the Talmadge administration handled this problem by authorizing the governor to transfer funds from one department to another, and he used some millions of highway funds for educational purposes.

Population. — The population of Georgia in 1790 was 82,548; in 1820 it was 340,989; in 1850, 906,185; in 1880, 1,542,180; in 1910, 2,609,121; and in 1940, 3,123,723. This last figure represents an increase of 7.4% over the population in 1930. The population per square mile was 53.4, as compared with 44·2 for the United States as a whole. The population of the state and of

its principal cities is summarized in the following table:

Area	Population			Per cent of increase	
	1940	1930	1920	1930–40	1920–30
The State	3,123,723	2,908,506	2,895,832	7·4	0·4
Urban	1,073,808	895,492	727,859	19·9	23·0
Rural	2,049,915	2,013,014	2,167,973	1·8	−7·1
Per cent urban	34.4	30·8	25·1		
Principal cities:					
Atlanta	302,288	270,366	200,616	11·8	34.8
Savannah	95,996	85,024	83,252	12·9	2·1
Augusta	65,919	60,342	52,548	9·2	14·8
Macon	57,865	53,829	52,995	7·5	1·6
Columbus	53,280	43,131	31,125	23·5	38·6
Rome	26,282	21,843	13,252	20·3	64.8

Of the 1940 population, 1,073,808, or 34·4%, lived in urban places, that is, in cities, towns and villages of 2,500 or more. The number of occupied dwelling units returned in the housing census of 1940 was 752,286, which is approximately the same as the number of families. The average population per family (occupied dwelling unit) declined from 4·5 in 1930 to 4·2 in 1940. The number of males per 100 females in the population of the state



BY COURTESY OF THE U.S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF GEORGIA. 1790–1940

was only 96.9. The white population of Georgia formed 65·3% of the total in 1940, as compared with 63.2% in 1930, practically all the nonwhite population being Negro.

Finances. — The constitution of Georgia limits the tax rate on property to $5 per $1,000; but this limit is not now a matter of much significance, since less than 10% of the revenue of the state comes from property taxes. The most important source of revenue is the sales tax on motor fuel, which in 1940 yielded $21,841,623. The other important sources of revenue in 1940 were: the income tax, $5,668,184; the property tax, $4,995,013; the motor vehicle licence tax, $2,053,692; the cigar and cigarette tax, $3,127,225. The total revenue from taxes was $44,694,137. Grrnts from the United States for the year amounted to $10,961,991, which with other sources of revenue brought the total of receipts for the year to $64,531,949. Principal disbursements were as follows: highway department, $22,506,438; department of education, $14,004,474; university system, $6,911,000 (the larger part being fees and earnings of the institutions and U.S. grants); eleemosynary institutions, $7,472,911. Fixed debt (1940) was $27,088,616.

Education. — Georgia's system of public instruction was not instituted until 1870, but as early as 1817 the legislature provided a fund for the education, in the private schools of the state, of children of indigent parents. The constitution of 1868 authorized "a thorough system of general education, to be forever free to all children of the state," and in 1870 the first public-school law was enacted. The constitution, as amended in 1904, empowered counties and school districts within counties to supplement by local taxation the state appropriation for schools. Many school districts, however, continued to have poor schools because they failed to levy the local school tax. To remedy this defect in the former amendment, another was adopted in 1919 by which the counties were required to levy local taxation of not less than one mill or more than five mills for the support of elementary schools as a supplement to the state appropriation. Already (1910) the constitutional clause limiting the taxing power of the counties to taxation for elementary schools only had been removed, and in 1912 the high schools were made a part of the public-school system of the state. The state board of education, hitherto composed of state officials, was made a professional board (1911), and a uniform textbook law passed, the duty of selecting the books being placed upon the board. In 1937 the general assembly set up a-free textbdok system for the elementary and high schools and guaranteed a seven-months' term for the elementary schools at state expense. Compulsory education dates from 1916. The law, as amended by the new school code of 1919, required attendance between the ages of 8 and 14 at least through the seventh grade.

To encourage the consolidation of small schools, the legislature appropriated (1919) $100.000, from which the state offered to pay annually a bonus of $500 to any county which combined small schools into larger ones, and where a four-year high school was provided, an additional bonus of $1,000 was authorized. This fund was later increased to $400,000. An illiteracy commission was established (1919) to make a study of adult illiteracy, and in 1920 local taxation for the support of schools for adult illiterates was authorized. Noteworthy progress has been made in the eradication of illiteracy. Enrolment in the public schools in 1939 was 784,512, as compared with 713,290 in 1930, and the average daily attendance was 583,875. The number of public-school teachers in 1939 was 22,779, as against 19,071 in 1930. Expenditures for the public schools rose from a total of $18,677,000 in 1930 to a total of $26,432,915 in 1939; and the amount per capita of enrolment increased from $26.05 to $33.68. Teachers' annual salaries advanced from $690 in 1932 to $715.61 in 1939.

In addition to the public schools, the state also supports the university system of Georgia. The University of Georgia, at Athens, was chartered in the year 1785, and it is the oldest of the state-supported institutions in Georgia. With the passage of time the state established many other higher institutions, including the medical college at Augusta, the Georgia School of Technology at Atlanta, two four-year women's colleges, at Milledgeville and Valdosta, respectively; a college of agriculture at Athens, quite a number of teachers colleges and a half dozen junior colleges. All these were for white students only. In addition there were three or four Negro state colleges. All these institutions were independent, each with its own board of trustees and all competing for the small annual sum available for higher education. In 1933 the general assembly created the university system of Georgia, bringing under one board of regents all institutions of higher learning supported by the state and three experiment stations. A half dozen or more of the existing institutions were discontinued, and one new institution established. The officeof the regents is in the state capitol at Atlanta. The regents control these institutions as a unit, receiving a lump sum from the state and apportioning it according to needs to the units. The regents have set up a council of the university system. It comprises the presidents, deans, other administrative officers and some members of the teaching staffs of the units, and it has come to wield large influence in the curricula of the units. A somewhat uniform curriculum has been arranged for the two lower classes in most of the units, the purpose being to facilitate transfer of students from one unit to another (especially from the junior colleges to the senior colleges), and to provide a basis for comparison of the quality of work being done in the several units. Outside the state system are: Agnes Scott college (Decatur), Berry college (Mount Berry), Bessie Tift college (Forsyth), Emory university (near Atlanta), La Grange college (La Grange), Mercer university (Macon), Oglethorpe university (Oglethorpe), Piedmont college (Demarest), Shorter college (Rome), Wesleyan college (Macon).

Charities and Corrections.— One result of the reorganization act of 1931 was to bring under a single board of control, appointed by the governor, all eleemosynary institutions maintained by the state. In 1940 this board of control was abolished, and the institutions were placed under the public welfare department. These included, in 1940, a training school for boys, at Milledgeville; a training school for girls, at Atlanta; a Confederate soldiers' home, at Atlanta; an academy for the blind, at Macon; a school for the deaf, at Cave Spring; a state hospital for the insane, at Milledgeville; a training school for mental defectives, at Greenwood; and a tuberculosis sanatorium, at Alto. The state constructed a great central penitentiary at Tattnall county, where male and female convicts are kept. The former convict farm at Milledgeville has been made a part of the reformatory school for boys there. The custom of using able-bodied male convicts on the county roads has almost disappeared, most of the prisoners being sent to Tattnall penitentiary.

Industry, Trade and Transportation.— Agriculture is the principal occupation in Georgia, but its economic pre-eminence has been supplanted by manufacturing, the gross farm income being less than half the value of the manufactures of the state. The farm population in 1920 was 1,685,213 or 58.2% of the entire population; in 1940 it was 1,369,719 or 43.8%. The number of farms and acreage suffered a similar decrease. In 1920 there were 25,441,000 ac., or 67.7% of the total land surface in farms; in 1930 the figures were respectively 22,079,000 ac. and 58.7%; but by 1935 they had recovered to 25,297,000 ac. and 67.3%. The value of all farm property rose abnormally from $580,546,000 in 1910 to $1,356,685,000 in 1920, but fell to $686,673,000 by 1925 and $683,435,000 by 1930. Of the total number of farmers in 1935, 177,259 were white and 73,285 Negro.

The chief product is cotton, to which about one-sixth of the cultivated land was devoted in 1940. It is grown in all counties of the state except Rabun, Towns and Fannin in the extreme northern part of the state. Georgia has at times ranked second only to Texas as a cotton producer; but in 1940 with 905,088 standard bales, its rank was third among the states of the union. This crop was equalled in quantity by that of Alabama, but in value it stood slightly above the latter. Georgia's cotton production in 1940 was worth $48,450,000.

The principal cereals cultivated are Indian corn, wheat and oats. In 1940, the 4,259,000 ac. devoted to Indian corn produced 45,892,000 bu., valued at $31,857,000. The cultivation of wheat, formerly remunerative, declined on account of the competition of the western states. The product in 1940 was 1,630,000 bu.. valued at $1,524,000. In 1940, 190,280 ac. planted in oats produced 8,638,000 bu. Both white and sweet potatoes are produced; the latter, in 1940, amounting to 7,507,000 bu. The sugar-cane crop declined in value after 1890, and each year more of it was made into syrup. In 1940, 4,531,882 gal. of syrup were produced from a total of 35,000 ac. of cane. Tobacco and peanuts have been the most remunerative of the new crops. The tobacco crop in 1940 was 94,408,000 lb., worth $12,437,000. The acreage (766,000) devoted to peanuts in 1940 yielded a crop worth $17,715,000. Truck farming and the cultivation of orchard fruits have long been lucrative occupations. The Georgia peach crop of 1940 sold for $4,625,000. Pecans are an increasingly important crop. The gross income from all farm crops in 1940 was $143,629,000; while livestock and livestock products brought a gross income of $33,851,000. The livestock on Georgia farms, Jan. 1. 1940, consisted of 35,469 horses, 316,006 mules, 803,357 cattle (all kinds), 16,582 sheep and lambs, 1,125,337 swine.

The forests of Georgia, next to the fields, furnish the largest amount of raw materials for manufactures. The yellow pines of the southern part of the state yielded in 1939, 15,289,550 gal. of turpentine and 1,016,645 500-lb. barrels of rosin, a product not exceeded by any other state. From the same source was derived most of the 864,962,000 board feet of lumber cut in 1938.

The chief features of the state's industrial activity are its early beginning and steady development. As far back as 1850 there were 1,522 manufacturing establishments (35 of which were cotton mills) in the state, whose product was valued at $7,082,075 In 1939 there were 3,150 industries giving employment to 170,161 wage earners with a product valued at $677,402,657. The chief product of the factories was cotton goods, which had a value in 1937 of $211,102,858. In the quantity of cotton consumed Georgia was exceeded by North Carolina and South Carolina only. This growth in cotton manufacturing is due to various causes, among them being the proximity of raw material, convenient water power, favourable taxation and an abundance of cheap labour. Other important manufacturing industries and their products in 1933 were as follows: food products, $33,524,469; knit goods, $14,468,155; clothing, $12,642,628; cotton-seed oil, meal, and cake, $8,962,592 ; fertilizer, $8,826,861; construction and repair in steam railway shops, $8,507,016; printing and publishing newspapers and periodicals, $7,756,126; lumber and other timber products, $6,950,436; nonalcoholic beverages, $5,237,848; bags other than paper, $4,309,578; printing and publishing books, music, etc., $3,732,561; foundry and machine-shop products, $3,639,869; stone products, $3,367,173.

The mineral resources of Georgia are varied, but because of the absence of petroleum and coal in great quantities the total product is relatively low. In 1938 minerals were produced to the value of $11,598,421, an amount which gave Georgia the rank of 35th among the states of the union. Stone, raw clay, clay products and cement were the principal mineral products in the order of their value Of the stone products, granite and marble are the most important. The output of the quarries in 1939 was 1,582,660 tons of granite, valued at $2,878,289; and 59.620 tons of marble valued at $1,487,985. Stone mountain (1,686 ft.) in Dekalb county, near Atlanta, is a remarkable mass of light-coloured muscovite granite, having a circumference at its base of 7 miles. It is on the face of this massive piece of granite that the gigantic Confederate memorial is being sculptured. Georgia white marble. first quarried on a large scale in Pickens county in 1884, was used in the capitol buildings of Georgia. Rhode Island. Mississippi, Minnesota, in the Corcoran Art Gallery, Washington, D.C., and in other well known buildings. Other colours than the snowy white are found in the main marble belt of the state, which runs from Canton, Cherokee county, 60 mi. generally north to the northern boundary of the state. The annual marble production of Georgia is exceeded by that of Tennessee only. Approximately one quarter of all the barytes produced in the United States comes from Georgia, chiefly from Bartow county. Clay products, principally brick and tile, had in 1938 a value of $1,980,943; raw clay in 1939, 512,214 tons, valued at $4,135,727. The coal fields of Georgia are situated in the Allegheny region in Dade and Walker counties. Iron ore, bauxite, gold, manganese, talc, sand and gravel are other products of commercial importance.

Means of transportation are furnished by the rivers, which are generally navigable for light-draught boats as far north as the fall line; by ocean, steamship lines which have piers at St. Marys, Brunswick, Darien and Savannah; and chiefly by railways, whose mileage on Dec. 31, 1938, was 6,700, a decline from the 7,427 mi. in operation in 1915. The most important of the railways are the Central of Georgia, the Southern, the Atlantic Coast Line, the Seaboard Air Line, the Georgia and the Georgia Southern and Florida. The state highway department, created in 1916 and reconstituted in 1919, had under its control on Dec. 31, 1938, 10,740 mi. of roadway.

The total motor vehicle registration for 1940 was more than 500,000.

History.— Georgia, the last to be established of the English colonies in America, derived its name from King George II of Great Britain. Its formation was due to a desire of the British government to protect South Carolina from invasion by the Spaniards from Florida, and by the French from Louisiana, as well as to the desire of James Edward Oglethorpe (*q.v.*) to found a refuge for the persecuted Protestant sects and the unfortunate but worthy indigent classes of England. A charter was granted in 1732 to "the trustees for establishing the colony of Georgia in America," and parliament gave £10,000 to the enterprise. The first settlement was made at Savannah in 1733 under the personal supervision of Oglethorpe. The early colonists were English,

German Lutherans (Salzburgers), Piedmontese, Scottish Highlanders, Swiss, Portuguese and Jews; but the main tide of immigration, from Virginia and the Carolinas, did not set in until 1752. As a bulwark against the Spanish the colony was successful, but as an economic experiment it was a failure. The trustees desired that there should be grown in the colony wine grapes, hemp, silk and medical plants, for which England was dependent upon foreign countries; they required the settlers to plant mulberry trees, and forbade the sale of rum, a chief commercial staple of the colonies. They also forbade the introduction of negro slaves. The industries planned for the colony did not thrive, and as sufficient labour could not be obtained, the importation of slaves was permitted, under certain conditions, in 1749. About the same time the House of Commons directed the trustees to remove the prohibition on the sale of rum. In 1753 the charter of the trustees expired and Georgia became a royal province.

Under the new régime the colony was so prosperous that Sir James Wright (1716–85), the last of the royal governors, declared Georgia to be "the most flourishing colony on the continent." The people were led to revolt against the mother country through sympathy with the other colonies rather than through any grievance of their own. The centre of revolutionary ideas was St. John's parish, settled by New Englanders (chiefly from Dorchester, Mass.). The Loyalist sentiment was so strong that only five of the 12 parishes sent representatives to the first provincial congress, which met on Jan. 18, 1775, and its delegates to the continental congress therefore did not claim seats in that assembly. But six months later all the parishes sent representatives to another provincial congress which met on July 4, 1775.

The war that followed was really a severe civil conflict, the Loyalist and Revolutionary parties being almost equal in numbers. In 1778 the British seized Savannah, which they held until 1782, meanwhile reviving the British civil administration, and in 1779 they captured Augusta and Sunbury; but after 1780 the Revolutionary forces were generally successful. Civil affairs also fell into confusion. In 1777 a State Constitution was adopted, but harmony was not secured until 1781.

Georgia's policy in the formation of the U.S. Government was strongly national. In the Constitutional Convention of 1787 its delegates almost invariably gave their support to measures designed to strengthen the Central Government. Georgia was the fourth State to ratify (Jan. 2, 1788), and one of the three that ratified unanimously, the Federal Constitution. But a series of conflicts between the Federal Government and the State Government caused the growth of States rights theories. First of these was the friction involved in the case, before the U.S. Supreme Court, of *Chisholm* v. Georgia, by which the plaintiff, one Alexander Chisholm, a citizen of South Carolina, secured judgment in 1793 against the State of Georgia (see 2 Dallas Reports. 419). In protest, Georgia resolved that any Federal marshal who should attempt to execute the court's decision would be "guilty of felony, and shall suffer death, without benefit of clergy, by being hanged." No effort was made to execute the decision, and in 1798 the 11th amendment to the Federal Constitution was adopted, taking from Federal courts all jurisdiction over any suit brought "against one of the United States by citizens of another State, or by citizens or subjects of any foreign State."

The position of Congress and of the Supreme Court with reference to Georgia's policy in the Yazoo frauds also aroused distrust of the Federal Government. In 1795 the legislature granted, for $500,000, the territory extending from the Alabama and Coosa rivers to the Mississippi river, and between 35° and 31° N. lat. (almost all the present State of Mississippi and more than half of the present State of Alabama) to four land companies, but in the following year a new legislature rescinded the contracts, on the ground that they had been fraudulently and corruptly made. In the meantime the U.S. Senate had appointed a committee to enquire into Georgia's claim to the land in question, and as this committee pronounced that claim invalid. Congress, in 1800, established a territorial government over the region. The legislature of Georgia remonstrated, but expressrd a willingness to cede the land to the United States, and in 1802 the cession was ratified, it being stipulated, among other things, that the United States should pay to the State $1,250,000, and should extinguish "at their own expense, for the use of Georgia, as soon as the same can be peaceably obtained on reasonable terms," the Indian title to all lands within the State of Georgia. In 1824 the State remonstrated in vigorous terms against the dilatory manner in which the National Government was discharging its obligation, and the effect of this was that in 1825 a treaty was negotiated at Indian Springs by which nearly all the Lower Creeks agreed to exchange their remaining lands in Georgia for $5,000,000 and equal territory beyond the Mississippi. But President J. Q. Adams, learning that this treaty was not approved by the entire Creek nation, authorized a new one, signed at Washington in 1826, by which the Creeks kept certain lands west of the Chattahoochee. The Georgia Government, under the leadership of Governor George M. Troup (1780–1856), had proceeded to execute the first treaty, and the legislature declared the second treaty illegal and unconstitutional. In reply to a communication of President Adams, early in 1827, that the United States would take strong measures to enforce its policy, Governor Troup declared that he felt it his duty to resist to the utmost any military attack which the U.S. Government should think proper to make.

BY COURTESY OF TALLULAH FALLS INDUSTRIAL SCHOOL

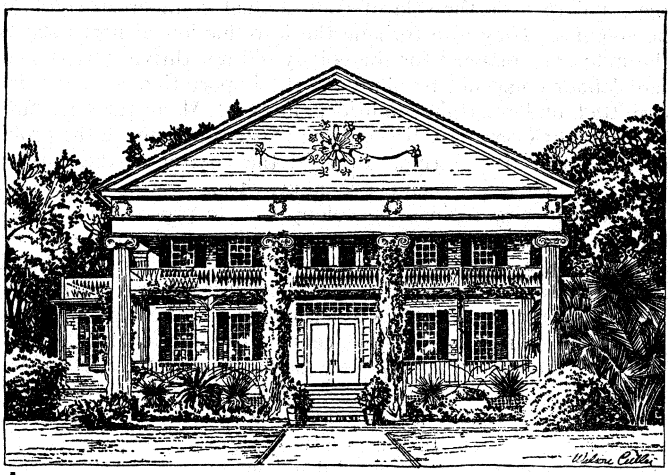
A TYPICAL SHACK IN THE MOUNTAINS OF GEORGIA

There was similar conflict in the relation of the United States and Georgia with the Cherokees. In 1828 the legislature extended the jurisdiction of Georgia law to the Cherokee lands. Then President Jackson, holding that Georgia was in the right on the Indian question, informed the Cherokees that their only alternative to submission to Georgia was emigration. Thereupon the chiefs resorted to the U.S. Supreme Court, which in 1832 declared that the Cherokees formed a distinct community "in which the laws of Georgia have no force," and annulled the decision of a Georgia court that had extended its jurisdiction into the Cherokee country (Worcester v.' Georgia). But the governor of Georgia declared that the decision was an attempt at usurpation which would meet with determined resistance, and President Jackson refused to enforce the decree. The president did, however, work for the removal of the Indians, which was effected in 1838. On account of these conflicts a majority of Georgians adopted the principles of the Democratic-Republican Party, and early in the 19th century the people were virtually unanimous in their political ideas. Local partisanship centred in two factions; one, led by George M. Troup, which represented the interests of the aristocratic and slave-holding communities; the other, formed by John Clarke (1766–1832), and his father Elijah, found support among the non-slave-holders and the frontiersmen. The Troup faction, under the name of States Rights Party, endorsed the nullification policy of South Carolina, while the Clarke faction, calling itself a Union Party, opposed South Carolina's conduct, but on the grounds of expediency rather than of principle. On account, however, of its opposition to President Jackson's hostile attitude toward nullification, the Troup Party affiliated with the new Whig Party, while the Clarke Party was merged into the Democratic Party led by Jackson. The anti-slavery and nationalistic views of the Whig Party during the '50s caused its members in Georgia to shift to the Democratic Party.

The activity of Georgia in the controversy was important. As early as 1835 the legislature adopted a resolution which asserted the legality of slavery in the Territories, a principle adopted by Congress in the Kansas-Nebraska bill in 1854, and in 1847 ex-Governor Wilson Lumpkin (1783–1870) advocated the organization of the Southern States to resist the aggression of the North, but his views were considered untimely by many of the party leaders. Popular opinion at first opposed the Compromise of 1850, and some politicians demanded immediate secession from the Union. Others contended that the Compromise was a great

victory for the South, and in a campaign on this issue secured the election of such delegates to the State convention (at Milledgeville) of 1850, that that body adopted, on Dec. 10, by a vote of 237 to 19, a series of conciliatory resolutions, since known as the "Georgia Platform." The approval in other States of the Georgia platform in preference to the Alabama platform (see ALABAMA) caused a reaction in the South against secession. The reaction was followed for a short interval by a return to approximately the former party alignment, but in 1854 the rank and file of the Whigs joined the American or Know-Nothing Party while most of the Whig leaders went over to the Democrats. The Know-Nothing Party was nearly destroyed by its crushing defeat in 1856 and in the next yeas the Democrats, by a large majority, elected for governor Joseph Emerson Brown (1821–94), who, by three successive re-elections, was continued in that office until the close of the Civil War. The Kansas question and the attitude of the North toward the decision in the Dred Scott case were arousing the South when he was inaugurated the first time, and in his inaugural address he clearly indicated that he would favour secession in the event of any further encroachment on the part of the North. On Nov. 7, following the election of President Lincoln, the governor, in a special message to the legislature, recommended the calling of a convention to decide the question of secession, and Alexander H. Stephens was about the only prominent political leader who contended that Lincoln's election was insufficient ground for such action. On Nov. 17 the legislature passed an act directing the governor to order an election of delegates on Jan. 2, 1861, and their meeting in a convention on the 16th. On the 19th this body passed an ordinance of secession by a vote of 208 to 89. Already the 1st Regiment of Georgia Volunteers, under Col. Alexander Lawton (1818–96), had seized Ft. Pulaski at the mouth of the Savannah river, and now Governor Brown proceeded to Augusta and seized the Federal arsenal there. Toward the close of the same year, however, Federal warships blockaded Georgia's ports, and early in 1862 Federal forces captured Tybee island, Ft. Pulaski, St. Marys, Brunswick and St. Simon island. Georgia had responded freely to the call for volunteers, but when the Confederate Congress had passed. in April 1862, the Conscript law which required all white men (except those legally exempted from service) between the ages of 18 and 35 to enter the Confederate service, Governor Brown, in a correspondence with President Davis, offered serious objections.

In 1863 north-west Georgia was involved in the Chattanooga campaign. In the following spring Georgia was invaded from Tennessee by a Federal army under Gen. William T. Sherman; the resistance of Gen. Joseph E. Johnston and Gen. J. B. Hood proved ineffectual; and on Sept. 1 Atlanta was taken. Then Sherman began his famous "march to the sea," from Atlanta to Savannah, which revealed the weakness of the Confederacy. In the spring of 1865, Gen. J. H. Wilson, with a body of cavalry, entered the State from Alabama, seized Columbus and West Point on April 16, and on May 10 captured Jefferson Davis, president of the Confederacy, at Irwinville in Irwin county. In accord with President Andrew Johnson's plan for reorganizing the Southern States, a provisional governor, James Johnson, was appointed on June 17, 1865, and a State convention reformed the Constitution to meet the new conditions, rescinding the ordinance of secession, abolishing slavery and formally repudiating the State debt incurred in the prosecution of the war. A governor and legislature were elected in Nov. 1865, the legislature ratified the 13th amendment on Dec. 9, and five days later the governor-elect was inaugurated. But both the convention and legislature incurred the suspicion and ill-will of Congress. Georgia was placed under military government, as part of the third military district, by the Reconstruction Act of March 2, 1867. Under the auspices of the military authorities registration of electors for a new State convention was begun, and 95,168 negroes and 96,333 whites were registered. The acceptance of the proposition to call the convention, and the election of many conscientious and intelligent delegates, were largely due to the influence of ex-Governor Brown, who was strongly convinced that the wisest course for the South was to accept quickly what Congress had offered. The convention met in Atlanta on Dec. 9, 1867, and by March 1868 had revised the Constitution to meet the requirements of the Reconstruction Acts. The Constitution was duly adopted by popular vote, and elections were held for the choice of a governor and legislature. Rufus Brown Bullock, Republican, was chosen governor, the Senate had a majority of Republicans, and in the house of representatives by the close vote of 76 to 74, a Republican was elected speaker. On July 21, the 14th amendment was ratified, and as evidence of the restoration of Georgia to the Union the congress-



A SOUTHERN COLONIAL PLANTATION HOME, BUILT BEFORE THE CIVIL WAR

As was the case with many of the houses erected during the days of slavery, the bricks for this building were made by Negroes on the plantation. The timber came from pine forests, also on the plantation, and the rest of the material was hauled by wagon from Savannah, a distance of 500 miles

men were seated on July 25 in that year. In September of the same year the Democrats in the State legislature, being assisted by some of the white Republicans, expelled the 27 negro members and seated their defeated white contestants. In retaliation the 41st Congress excluded the State's representatives on a technicality, and, on the theory that the Government of Georgia was a provisional organization, passed an act requiring the ratification of the 15th amendment before the admission of Georgia's senators and representatives. The War Department now concluded that the State was still subject to military authority, and placed Gen. A. H. Terry in command. With his aid and that of congressional requirements that all members of the legislature must take the test oath and none be excluded on account of colour, a Republican majority was secured for both houses, and the 15th amendment was ratified. Georgia was now finally admitted to the Union by act of Congress, July 15, 1870.

The reconstruction period in Georgia is remarkable for its comparative moderation. The explanation lies in the fact that there were comparatively few "carpet-baggers" or adventurers in the State, and that a large number of conservative citizens, under the leadership of ex-Gov. Brown, supported the reconstruction policy of Congress. The election of 1871 gave the Democrats a majority in the legislature; Governor Eullock, fearing impeachment, resigned, and at a special election James M. Smith was chosen to fill the unexpired term. After that the control of the Democrats was complete.

The recent history of Georgia has been one of social and economic progress. In 1907 was passed a statewide prohibition law. Many reforms in the educational policy, additional appropriations and a constitutional amendment, adopted in 1926, providing for a fund of $3,500,000 to be expended for public school teachers' salaries, hare helped much to raise the State's educational standards. Laws seeking to protect labour in the State's growing industries are among the most notable measures adopted. To encourage further industrial development, a constitutional amendment was adopted in 1924 giving the electors of a county or municipality the power to exempt from taxation for a period of five years certain new industrial establishments. Politically the state has stood firmly Democratic, even in 1928. In 1932 Roosevelt's popular majority was 11 to 1, and in 1936 it was nearly 8 to 1. In 1940 the state cast 85% of its vote for Roosrvelt.

BIBLIOGRAPHY.—The most complete bibliography of materials bearing upon all phases of Georgia history is *The Catalog of the W. J. DeRenne Georgia Library* (1931) 3 vols. compiled by Leonard L. Mackall.

See also Ella *M*. Thornton, state librarian, *Finding-List of Books Relating to Georgia and Georgians* (1928); also R. P. Brooks, "A Preliminary Bibliography of Georgia History," in *University of Georgia Bulletin* (vol. x., no. 10a, 1910).

Works covering the entire field of Georgia history are: E. M. Coulter, *A Short History of Georgia* (1933); Amanda Johnson, *Georgia as Colony and State* (1938).

Works devoted to special periods or subjects are: W. B. Stevens, *History of Georgia to* 1798 (1847 and 1859); C. C. Jones, *Antiquities of the Southern Indians, Particularly of the Georgia Tribes* (1873); *R*. H. Shryock, *Georgia and the Union in 1850; U*. B. Phillips, "Georgia and State Rights" (Amer. Hist. Assoc. *Annual Report for 1901*); R. P. Brooks, *Agrarian Revolution in Georgia, 1865–1912* (1914); C. M. Thompson, *Reconstruction in Georgia, 1865–72* (1915); J. R. McCain, *Georgia as a Proprietary Province* (1917). The Georgia Writers' Project, under the auspices of the Works Progress administration, published in 1940, through the University of Georgia Press, *Georgia, A Guide to its Towns and Countryside.*

Source material may be found in: *The Colonial Records of the State of Georgia* (1904–13); *The Confederate Records of the State of Georgia* (1909–10); and the *Georgia Historical Society Collections* (1840–1916)

See also list in vol. ii, of the *Report of the Amercian Historical Association for 1905.*

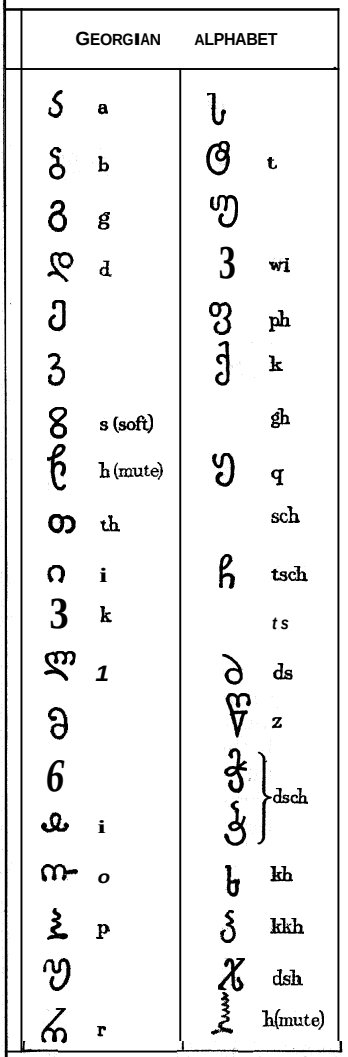
The principal sources for public administration are the annual reports of state officers and institutions, the *Georgia Official Register,* and the revised code of Georgia.

Valuable information concerning the resources and products of the state is given in the publications of the department of agriculture, the reports of the *Sixteenth United States Census,* the biennial census of manufactures, and the reports of the U.S. geological survey.

(R. P. Bs.)

GEORGIAN BAY, the north-east section of Lake Huron, separated from it by Manitoulin island and the Saugeen, or Bruce, peninsula. It is about 100 m. long and 50 m. wide. It receives numerous rivers draining a large extent of country; of these the chief are the French river draining Lake Nipissing, the Maganatawan, the Muskoka draining the Muskoka chain of lakes, the Severn draining Lake Simcoe and the Nottawasaga. The Trent valley canal connects Georgian bay with the Bay of Quinte and Lake Ontario, and a canal system has been projected to Montreal by way of the French and Ottawa rivers and Lake Nipissing.

GEORGIAN LITERATURE. The earliest extant Georgian literature dates from soon after the conversion of Georgia by St. Nino, early in the 4th century, and the oldest mss. known are biblical, liturgical and hagiological; all of great value. They show a stage of linguistic development, a wealth of words and grammatical forms which prove that the language must already have had an ancient literary history. There were early translators of the Greek classical authors, and one of these says, in a preface, that he has endeavoured to give so exact a rendering of the text that he has converted philosophical terms syllable by syllable, a method which has endowed Georgia, from the 12th century, with a metaphysical terminology of great exactitude. The folk-lore *(cf*. vol. i. of the Grimm library, London, 1894) is of deep interest for comparative purposes, and its views of the under-world may throw light on the religions of Egypt and Assyria. One folk-tale, *Et'heriani,* in prose and verse, the theme of which has been used for a successful opera in our own day, evidently assumed a literary form before the Christian era, and there is reason to believe that this may also be the case with the cycle of poems about Tariel, the hero of the greatest masterpiece of Georgian literature, attributed to Shot'ha Rust'haveli, an epic of over 1,500 rhyming quatrains written in the reign of Queen T'hamar (1184–1212). This has been rendered into English prose *(The Man in the Panther's Skin, a Romantic Epic,* Roy. Asiat. Soc., 1911), and it gives Georgia a high place in the literature of the world. The T'hamarian age has also left us a large number of odes of great rhythmic variety, full of allusions to Greek and oriental writers, and translations or adaptations of foreign works, such as the *Story of the Loves of Vis and Ranzin* (*Visramiani,* Eng. trans. published by Roy. Asiat. Soc., 1914), a romance of ancient Persia. Persian influence in Georgian literature was strong in the 17th century, and among the poets may be mentioned King T'heimuraz I. (lyrics and translations). In the 18th century a revival of nationalism was aided by the founding of a printing press at Tiflis, where, in 1712, King Vakhtang VI. published, with an elaborate commentary, the work of Rust'haveli; he also compiled a Code of Laws in which the ancient customary laws are of special interest. Of this period also are compilations on the history and geography of Georgia (by Prince Vakhusht), both texts with a vast amount of other matter, published and translated by M. F. Brosset, by far the greatest, as he was the first, of Western students of the literature. A great name is that of Prince Sulkhan Orbeliani (1655?–172j?), who in 1714 was Georgian envoy at Versailles. He kept a diary of his travels in Europe (partial French and Latin trans. in *Journ. Asiat.,* Paris, 1832 and 1834), and among his published works are a valuable dictionary of the language (Tiflis, 1884), and a rhymed translation of parts of the Persian Anvar-i-Suhaili. His *Book of Wisdom and Lies* (Eng. trans., 1894) is, after Rust'haveli, the most popular of Georgian books; in the form of interwoven apologues it highly recommends a sporting and Spartan education. In the early part of the 19th century the influence of Europe grew, and in the lyrics of A. Chavchavadze (1786–1846) and N. Barat'hashvili (1816–46) there is a Byronic strain, but G. Erist-'havi the first dramatist and founder of the national theatre, who translated poems of Petrarch, Schiller, Mickiewicz and others, had a steadying effect. The oppression of an alien rule (Russia, since 1801) inspired the patriotic verse of G. Orbeliani (1801–23) and Ilia Chavchavadze (1837–1907), who was the greatest Georgian of his generation in all branches of literature and public life. Acaci Tseret'heli (1840–1915) was the popular lyric poet of the century. I. Machabeli and D. Qiphiani translated Shakespeare into Georgian.



THE GEORGIAN NATIVE ALPHABET
The Georgian, together with the majority of other Caucasian languages, composes a group fundamentally distinct from the Indo-European linguistic family

BIBLIOGRAPHY.—A general history of Georgian literature was published in 1895–1901 by A. Khakhanov (in Russian). M. F. Brosset's translation of the Georgian chronicles was published in St. Petersburg (1849–1858). There is a good Georgian library at the Bodleian in Oxford and another at Harvard. At Oxford there is a fund for the encouragement of the study of Georgian literature.

GEORGSWALDE, a small town in northern Bohemia in the district of Schluckenau. occupied in 1938 by Germany. It has a long history of industrial prosperity based upon textile manufactures, mainly linen, supported in recent times by engineering industries and the manufacture of pianos. Pop. (1930) 7,942.

GEPHYREA, the name used for several groups of worm-like animals with certain resemblances but of doubtful affinity. W. C. McIntosh followed the accepted view in associating in this group the *Echiuridae, Sipunculidae,* and *Priapulidae.* E. Ray Lankester, in the preface to the English translation of C. Gegenbaur's *Comparative Anatomy* (1878) added the *Phoronidae* to these forms. The old group *Gephyrea* is now broken up into *Echiuroidea* (*q.v.*), which are modified Annelids; the *Sipunculoidea* (*q.v.*), an independent group of doubtful affinity; the *Priapuloidea* (*q.v.*), also of doubtful affinity; and the *Plzoronidea.*

GERA, a town of Germany in the *Land* of Thuringia, on the banks of the White Elster, 45 mi, S.S.W. of Leipzig. Pop. (1939) 83,047. Gera (in ancient chronicles *Geraha)* became a town in the 11th century, and in the 12th century it came into the possession of the lords of Reuss. It was sacked by the Bohemians in 1450, was burned down by the Swedes in 1639, and suffered from fires in 1686 and 1780, after which it has been mostly rebuilt.

Its educational establishments include a weaving school. Osterstein, the former residence of the princes of Reuss, stands on the site of a 9th century castle. Gera is noted for its industrial activity. Its industries include wool-weaving and spinning, dyeing. iron-founding, the manufacture of textiles, machinery, musical instruments, leather and tobacco, and printing (books and maps) and flower gardening.

GERALDTON, a town in the district of Victoria, West Australia, on Champion bay, 306 m. by rail N.W. of Perth. Pop. (1939) 4,725. It is the seat of a Roman Catholic bishop, an important seaport carrying on a considerable trade with the surrounding gold-fields and agricultural districts, the centre of a considerable railway system and a seaside resort. The harbour is safe and extensive; the chief exports arc gold, copper, lead, wool and sandalwood.

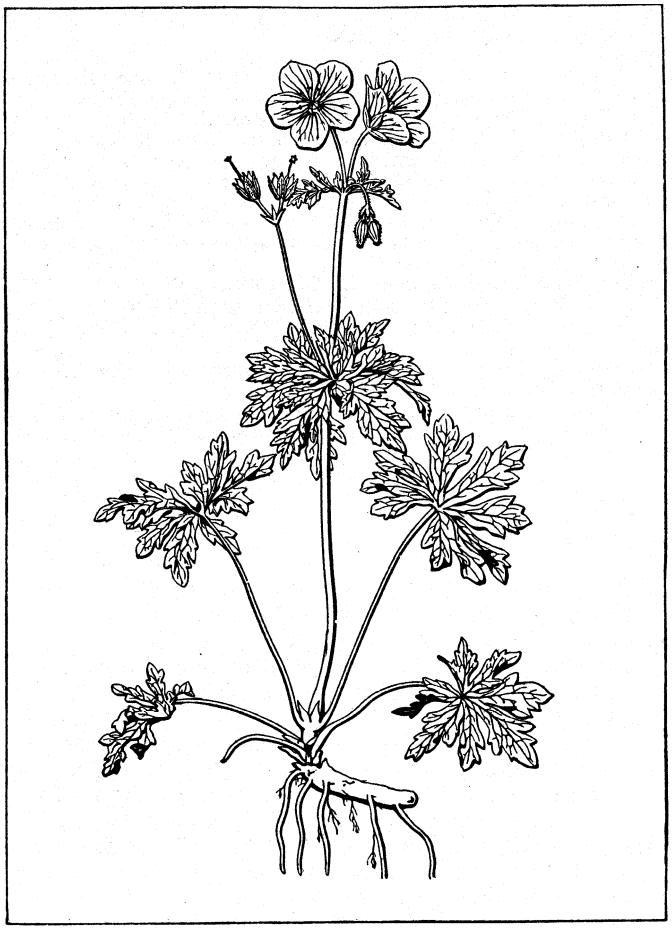
GERANIACEAE, a small but widely distributed family of Dicotyledons belonging to the Archichlamydeae, containing about 700 species in 11 genera. The family is represented in Britain by two genera, *Geranium* (cranesbill) and *Erodium* (storksbill), to which belong nearly two-thirds of the total number of species. The same two genera are the only representatives of the family in North America. The plants are mostly herbs, rarely shrubs, with generally simple glandular hairs on the stem and leaves. The opposite or alternate leaves have a pair of small stipules at the base of the stalk and a palminerved blade. The flowers, generally in a cymose inflorescence, are hermaphrodite, hypogynous, and, except in *Pelargonium,* regular. The parts are arranged in fives. There are five free sepals, overlapping in the bud, and, alternating with these, five free petals. In *Pelargonium* the flower is zygomorphic with a spurred posterior sepal and the petals differing in size or shape. In *Geranium* the stamens are obdiplostemonous, *i.e.,* an outer whorl of five opposite the petals alternates with an inner whorl of five opposite the sepals; at the base of each of the antisepalous stamens is a honey-gland. In *Erodium* the members of the outer whorl are reduced to scale-like structures (staminodes), and in *Pelargonium* from two to seven only are fertile. There is no satisfactory explanation of this break in the regular alternation of successive whorls. There are five, or fewer, carpels, which unite to form an ovary with as many chambers, in each of which are one or two, rarely more, pendulous anatropous ovules, attached to the central column in such a way that the micropyle points outwards and the raphe is turned towards the placenta. The long beak-like style divides at the top into a corresponding number of slender stigmas.

The larger-flowered species of *Geranium* are markedly protandrous, the outer stamens, inner stamens and stigmas becoming functional in succession. For instance. in the meadow cranesbill. G. *pratense,* each whorl of stamens ripens in turn, becoming erect and shedding their pollen; as the anthers wither the filaments bend outwards, and when all the anthers have diverged the stigmas become mature and ready for pollination. By this arrangement self-pollination is prevented and cross-pollination ensured by the visits of bees which come for the honey secreted by the glands at the base of the inner stamens.

In species with smaller and less conspicuous flowers, such as *G. molle,* self-pollination is possible, since the divisions of the stigma begin to separate before the outer stamens have shed all their pollen; the nearness of the stigmas to the dehiscing anthers favours self-pollination.

In the ripe fruit the carpels separate into five one-seeded portions *(cocci),* which break away from the central column, either rolling elastically outwards and upwards or becoming spirally twisted. In most species of *Geranium* the cocci split open on the inside and the seeds are shot out by the elastic uptwisting *(see* fig.); in *Erodium* and *Pelargonium* each coccus remains closed, and the long twisted upper portion separates from the central column, forming an awn, the distribution of which is favoured by the presence of bristles or hairs. The embryo generally fills the seed, and the cotyledons are rolled or folded on each other.

Geranium is the most widely distributed genus; it has 300 species and is spread over all temperate regions with a few species



MEADOW CRANESSILL (GERANIUM PRATENSE), AN ENGLISH HERB. WHOSE COMMON NAME IS DERIVED FROM ITS LONG-BEAKED FRUIT. THE DOUBLE-FLOWERED VARIETIES ARE FREQUENTLY GROWN IN GARDEN BORDERS.

in the tropics. Three British species—G. *sylvaticum,* G. *pratense* and *G. robertianum* (herb-Robert) reach the arctic zone, while G. *patagonicum* and *G. magellanicum* are found in the antarctic. *Erodium* contains 6; species (two are British), most of which are confined to the Mediterranean region and west Asia, though others occur in America, in South Africa and West Australia. *Geranium* is represented in eastern United States by 11 species, 7 of which are introduced. In this region *Erodium* is represented only by two species introduced from Europe. In the western United States there are 5 species of *Geranium,* and *Erodium* is represented by one native species which extends throughout the whole region west of the Rocky Mountains, where it is known as "pin-clover" and "pin-grass." *Pelargonium,* with 250 species, has its centre in South Africa; the well-known garden and greenhouse "geraniums" are species of *Pelargonium (see* GERANIUM).

For a monographic treatment **of** the family **see** R. Knuth, Geraniaceae. Pflanzenreich 53 (iv 129): 1–640. fig. 1–80 (1912).

GERANIUM, the name of a genus of plants, the type of the family Geraniaceae, commonly called cranesbill; but also the common name of the garden geraniums, all of which belong to the South African genus *Pelargonium.* Formerly the genus *Geranium* comprised most of the family Geraniaceae.

The species of *Geranium* consist mostly of annual or perennial herbs, dispersed throughout the temperate regions of the world. They number about 250 and bear a considerable family resem-

blance. The leaves are for the most part palmately-lobed, and the flowers are regular, consisting of five sepals, five imbricating petals, alternating with five glandules at their base, ten stamens and a beaked ovary. Fourteen species are natives of the British Isles. G. *robertianum* is herb-Robert, a common plant in hedge-banks. G. *sanguineum,* with flowers a deep rose colour, is often grown in borders, as are also the double-flowered varieties of *G. pratense.* Many others of exotic origin form handsome border plants in our gardens of hardy perennials.

In North America about 25 species of Geranium are found, inclusive of several naturalized from the old world. Of the native species well-known representatives are the spotted cranesbill or wild geranium (G. *maculatum*), common in woods from Newfoundland to Manitoba and southward to Georgia and Nebraska, with handsome rose-purple flowers, 1 in. to 1½ in. broad; the Carolina cranesbill (*G. carolinianum*), found in barren soil across the continent from Nova Scotia to British Columbia and southward to Florida and Mexico, with pale pink or white flowers about ½ in. broad; and the herb-Robert mentioned above, which is native to rocky woods from Nova Scotia to Manitoba and southward to New Jersey and Missouri.

Pelargonium, though agreeing with *Geranium* in certain points of structure, differs in that the flowers are irregular, the two petals which stand uppermost being different—larger, smaller or differently marked—from the other three, which latter are occasionally wanting. This irregularity the modern florist has done much to annul, for the increased size given to the flowers by high breeding has usually been accompanied by the enlargement of the smaller petals, so that a near approach to regularity has been in some cases attained. Another well-marked difference, however, remains: the back or dorsal sepal in *Pelargonium* has a hollow spur, which is adnate, *i.e.,* joined for its whole length with the flower-stalk; while in Geranium there is no spur. This peculiarity is best seen by cutting through the flower-stalk just behind the flower, when in *Pelargonium* there will be seen the hollow tube of the spur.

The various races of pelargoniums have sprung from the intermixture of some of the species obtained from the Cape of Good Hope. The older show-flowered varieties have been gradually acquired through a long series of pears. The fancy varieties, as well as the French spotted varieties and the market type, have been evolved from them. The zonal or bedding race, on the other hand, has been more recently perfected; they are supposed to have arisen from hybrids between *Pelargonium inquinans* and P. *zonale;* perhaps better considered as belonging to *P. hortorum,* for the hybrid origin of many garden geraniums is obscure.

In all the sections the varieties are of a highly ornamental character, but for general cultivation the market type is preferable for indoor purposes, while the zonals are effective either in the greenhouse or flower garden. Some of the Cape species are still in cultivation—the leaves of many being beautifully subdivided, almost fern-like in character, and some of them are deliciously scented; P. *quercifolium* is the oak-leaf geranium. The ivy-leaf geranium, derived from *P. peltatum,* has given rise to an important class of both double- and single-flowered forms adapted especially for pot culture, hanging baskets. window boxes and the greenhouse. The common household geranium can be wintered over by hanging, roots up, in a cool, frost-free place.

The best soil for pelargoniums is a mellow fibrous loam with good well-rotted stable manure or leaf-mould in about the proportion of one-fifth; when used it should not be sifted, but pulled to pieces by the hand, and as much sand should be added as will allow the water to pass freely through it. All are readily increased by cuttings made from the shoots when the plants are headed down after flowering, or in the spring, when they will root freely in a temperature of 65° to 70° F. They must not be kept too close, and must be very moderately watered.

GERARD (d. 1108), archbishop of York under Henry I., began his career as a chancery clerk in the service of William Rufus. He was one of the two royal envoys who. in 1095, persuaded Urban II. to send a legate and Anselm's pallium to England. Gerard was rewarded for his services with the see of Hereford (1096). On the death of Rufus he at once declared for Henry I., by whom he was nominated to the see of York. He made difficulties when required to give Anselm the usual profession of obedience, and took the king's side on the question of investitures. He pleaded Henry's cause at Rome with great ability, and claimed that he had obtained a promise, on the pope's part, to condone the existing practice of lay investiture. But this statement was contradicted by Paschal, and Gerard incurred the suspicion of perjury. About 1103 he wrote or inspired a series of tracts which defended the king's prerogative and freely attacked the oecumenical pretensions of the papacy. In 1105, he became a stanch friend and supporter of Anselm. Gerard was a man of considerable learning and ability; but the chroniclers accuse him of being lax in his morals, an astrologer and a devil worshipper.

See the Tractatus Eboracenses edited by H. Bochmer in Libelli de *lite* Sacerdotii et *Imperii,* vol. iii. (in the Monumenta *hist.* Germaniae, quarto series), and the same author's Kirche und Staat in England und *in der Normandie* (Leipzig, 1899). **(I-I.** W. C. D.)

GERARD (c. 1040–1120), variously surnamed TUM, TUNC, TENQUE or THOM, founder of the order of the Knights of St. John of Jerusalem (*q.v.*), found his way in some capacity to Jerusalem, where a hospice existed for visitors to the holy places. Of this institution Gerard became guardian about 1100, and he organized that religious order of St. John which received papal recognition from Paschal II. in 1113, by a bull which was confirmed by Calixtus II. shortly before the death of Gerard in 1120.

GÉRARD, ÉTIENNE MAURICE, COUNT (1773–1852), French general, was born at Damvilliers (Meuse), on April 4, 1773. He joined a battalion of volunteers in 1791, and served in the campaigns of 1792–1793 under Generals Dumouriez and Jourdan. In 1795 he accompanied Bernadotte as aide-de-camp. In 1799 he was promoted chef *d'escadron,* and in 1800 colonel. He distinguished himself at the battles of Austerlitz and Jena, and was made general of brigade in November 1806, and for his conduct in the battle of Wagram he was created a baron. He won distinction in the Spanish campaign (1810–XI), the expedition to Russia, and the campaign of 1813. In the campaign of 1813, he commanded a division, and after the battle of Bautzen he was created by Napoleon a count of the empire. After the first restoration he was named by Louis XVIII. grand cross of the Legion of Honour and chevalier of St. Louis. In the Hundred Days Napoleon made Gérard a peer of France and placed him in command of the IV. corps of the Army of the North with which he took a brilliant part in the battle of Ligny (see WATERLOO CAMPAIGN). He retired to Brussels after the fall of Napoleon, and did not return to France till 1817. He sat as a member of the chamber of deputies in 1822–1824, and again in 1827. He took part in the revolution of 1830, after which he was appointed minister of war and a marshal of France. He resigned the office of war minister in October, but in 1831 he took the command of the northern army, and drove the army of Holland out of Belgium. In 1832 he commanded the besieging army in the famous scientific siege of Antwerp. He was again chosen war minister in July 1834, but resigned in October. From 1838 to 1842 he was commander of the National Guards of the Seine. He became a senator under the empire in 1852, and died in the same year.

GÉRARD, FRANÇOIS, BARON (1770–1837), French painter, was born on May 4, 1770, at Rome, where his father occupied a post in the house of the French ambassador. His mother was Italian. At the age of twelve Gérard obtained admission into the Pension du Roi at Paris. From there he passed to the studio of Pajou (sculptor); he left at the end of two years for that of the painter Brenet, whom he left almost immediately to place himself under David. In 1789 he competed for the Prix de Rome, which was carried off by his comrade Girodet. In the following year (1790) he again presented himself, but the death of his father prevented the completion of his work, and obliged him to accompany his mother to Rome. In 1791 he returned to Paris. David at once availed himself of his help, and one of that master's most celebrated pictures—Le Pelletier de St. Fargeau—may owe much to the hand of Gérard. This painting was executed early in 1793, the year in which Gérard, at the request of David, was named a member of the revolu-

tionary tribunal, from the fatal decisions of which he, however, invariably absented himself. In 1794 he obtained the first prize in a competition, the subject of which was "The Tenth of August," and, further stimulated by the successes of his rival and friend Girodet in the Salons of 1793 and 1794, Gérard produced in 1795 his famous "Bélisaire." In 1796 a portrait of his generous friend, Isabey the miniaturist (in the Louvre) obtained undisputed success, and in 1797 he executed his "Psyché et l'Amour." In 1799, his portrait of Madame Bonaparte established his position as one of the first portrait-painters of the day. All the leading figures of the empire and of the restoration, all the most celebrated men and women of Europe, sat to Gérard. This extraordinary vogue was due partly to the charm of his manner and conversation, for his *salon* was as much frequented as his studio; Madame de Stael, Canning, Talleyrand, the duke of Wellington, have all borne witness to the attraction of his society. Loaded with honours—baron of the empire, member of the institute, officer of the legion of honour, first painter to the king, he died on Jan. 11, 1837.

See C. Lenormant, *Essai de biographie et de critique sur François Gérard* (1846); Delécluze, *Louis David, son tcole et son temps* (1855).

GERARD, JAMES WATSON (1867–), American lawyer and diplomat, was born at Geneseo, N.Y., on Aug. 25, 1867. Educated at Columbia university and at the New York law school, he was admitted to the bar in 1892 and began to practise in New York city. In 1908 he became associate justice of the supreme court of New York, resigning in 1913, on being appointed ambassador to Germany. At the outbreak of the World War in 1914 he assumed the care of British, Japanese, Rumanian and Serbian interests in Germany. On Feb. 3, 1917, diplomatic relations were broken off by America and he was recalled. On his return to America he resumed the practice of law in New York city. In 1917 he published *My Four Years in Germany* and in 1918 *Face to Face with Kaiserism.*

GERARD, JEAN IGNACE ISIDORE (1803–1847), French caricaturist, generally known by the pseudonym of Grandville—was born at Nancy on Sept. 13, 1803. He received his first instruction in drawing from his father, a miniature painter, and at the age of 21 came to Paris, where he soon afterwards published a collection of lithographs entitled *Les Tribulations de la petite propriété.* He followed this by *Les Plaisirs de toutâge* and *La Sibylle des salons;* his success was made with *Métamorphoses du jour* (1828), *a* series of 70 scenes in which individuals with the bodies of men and faces of animals play the human comedy. Gérard contributed drawings to many periodicals, illustrated several classic works, and issued from time to time series of lithographs. He died on March 17, 1847.

A short notice of Gérard, under the name of Grandville, is contained in Théophile Gautier's *Portraits contemporains. See* also Charles Blanc, *Grandville* (1855).

GERARD, JOHN (1545–1612), English herbalist and surgeon, was born at Nantwich, Cheshire. He was educated at Wisterson or Willaston and, setting up in London, acted as superintendent of the gardens of Lord Burghley. In 1597 appeared his well-known *Herball* which was really an adaptation of the *Stirpium historiae pemptades* (1583) of Rembert Dodoens. Its illustrations are mostly impressions from the wood blocks employed by Jacob Theodorus Tabeknaemontanus in his *Icones stirpium,* published at Frankfurt in 1590. He died in London in Feb. 1612.

See preface to the 1633 edition of the *Herball* by I. Johnson; *A Catalogue of Plants cultivated in the Garden of John Gerard in the years 1596–1599, with a Life of the Author, by B. Daydon Jackson, F.L.S.* (1876), and *Gerard's Herball, the essence thereof distilled by Marcus Woodward* (1927).

GÉRARDMER, a town of north-eastern France, in the department of Vosges, 33 mi. E.S.E. of Epinal by rail. Pop. (1936), 5,210; of the commune, 9,312. Gérardmer is situated at a height of 2,200 ft. at the eastern end of the smali Lake of Gérardmer. It is the chief summer resort of the French Vosges and is a centre for excursions. The town itself carries on cloth-weaving, bleaching, wood-sawing and the manufacture of wooden goods, felt hats and paper; there is trade in the cheeses (*géromé*) manufactured in the neighbourhood. Gérardmer is said to owe its name to Gérard of Alsace, 1st duke of Lorraine, who in the 11th century built a tower on the bank of the lake near which in 1285 a new town was founded.

GERARD OF CREMONA (*c.* 1114–1187), the famous mediaeval translator, was born at Cremona. He spent most of his life at Toledo in the college of translators established by Archbishop Raymond (d. 1151).

At an uncertain date he returned to Cremona, where he died in 1187. The most important of his Latin translations from the Arabic are the *Post. Anal.* (with the commentary of Themistius), the *Physics,* the *De Caelo,* the *De Gen. et Corr.* and the *Meteorologic~*(bks. 1–3) of Aristotle, the famous *Liber de Causis,* the *Almagest* of Ptolemy, the *De Somno et visione,* the *De Intellectu* and the *De quinque essentiis* of Alkindi, the *De Syllogismo* of Alfarabi, the *De Crepusculis* of Alhazen, the *De Motu Accessionis et recessionis* of Thabit, the *Canon* of Avicenna, the *Algebra* of Al-Khowarizimi, the *De Sphaeris* of Theodosius, the *De Diffinitionibus* and the *De Elementis* of Isaac Israeli, the *Elements* and the *Data* of Euclid, and works by Galen and Hippocrates.

See A. Jourdain, *Recherches sur . . . Porigine des traductions latines d'Aristote* (1843); Boncompagni, *Della vita e delle opere di Gherardo Cremonese e di Gherardo da Sabbionetta* (1851); L. Thorndike, *Hist. of Magic, etc.* (2 vols., 1923).

GERASA, an ancient city of Palestine in the highlands of Gilead, 20 m. N of ʿAmmān (Philadelphia) and 20 m. E. of the Jordan (mod. Jerāsh). The city, now ruined, is pleasantly situated in a valley through which runs a perennial stream, the Chrysorrhoas of the Greeks, to fall into the Zerka (Jabbok) 6 m. to the south. The site is undulating and strewn with knolls offering excellent positions for public buildings, a circumstance of which the Roman architects took full advantage, as their structures, magnificent even in ruin, testify. Since 1878 a colony of Circassians has occupied the site, or rather a small portion of it. The building materials for their village on the eastern bank of the stream have been extracted from the ruins, the bulk of which lie on the western bank. The delightful orchard gardens of Jerāsh make it one of the pleasantest towns in all Palestine.

History.—Nothing, up to the present at any rate, is known of the history of the city in Old Testament times or earlier, although the site was very probably occupied, unless, indeed, it represents Ramoth Gilead, as has been suggested. Iamblichus asserts that it was originally colonized by veterans of Alexander the Great. Josephus tells us that it was captured by Alexander Jannaeus (*c.* 83 B.C.), rebuilt by the Romans (*c.* A.D. 65), burned by the Jews, and subsequently desolated and burned by Vespasian's captain, Annius. From the time of Trajan it belonged to the Roman province of Syria, but about A.D. 160 it was allotted to the province of Arabia, and during the peaceful reign of the Antonines (130–180), it was adorned with magnificent buildings and rose rapidly in importance and prosperity. It was the second city of the Decapolis and early in Christian times became the see of a bishop. To the Talmud and Jerome Gerdsa and Gilead were synonymous, and similarly Mukkadsi calls Jebel ʿAjlūn, Jebel Jerāsh, Tughtakin, the atabeg of Damascus, had here a castle which was taken and destroyed by Baldwin II. (1121). The Arabic geographer, Yākūt, on the evidence of an eye-witness, reports it in ruins at the beginning of the 13th century. The "Gerasenes" of Matthew viii. 28 were not natives of Gerasa, as might be thought, but must be sought elsewhere (Khersa?).

Archaeology.-Of the many beautiful architectural monuments beyond Jordan, the fruit of Roman administration, the ruined grandeur of Gerasa supplies the finest. Laid out on a definite scheme with colonnaded main and cross streets, we find in it an early example of enlightened town planning. The city was surrounded by walls, 8 ft. thick, with a total circuit of 3,000 yd., and had six gates, the principal ones being north and south. The stream, near to which and roughly parallel to it ran the main street, divided the city in two, but the main public buildings were on the western bank and on the western side of the road. The approach to Jerāsh from the south passes a triumphal arch 300 yd. from the south gate. Between this and the gate on the left hand side are the ruins of a *naumachia* or tank for naval displays (170 yd. by 60 yd.) and contiguous to it a

stadium (100 yd. by 60 yd.). Within the walls the main objects of interest are a fine peripteral temple, a theatre (south) in a good state of preservation, a colonnaded loop in the road, generaliy, but doubtfully, regarded as the forum, a basilica or senate house, the great sun temple, a tetrapylon at the cross-roads, and a theatre (north). But the outstanding feature of the site is undoubtedly the profusion of columns, of which over zoo still stand. "A catalogue of the visible monuments alone can convey little impression of their supreme beauty from the point of view of classical art, and not only are the buildings in themselves triumphs of architecture, but they are strikingly placed so that each one meets the eye as a distinct feature, while from the distance they compose themselves readily into a single harmonious picture." The decay of the city is partly due to changed climatic conditions bringing lack of water, partly to political vicissitudes and partly and especially to seismic disturbances.

The Trans-Jordan Government in 1926 cleared the main street and retrieved and consolidated dangerous parts of the ruins. Excavation has begun on the temple area, and tourists are given facilities to visit Jerāsh by the Government.

See Sir C. Warren, in Hastings' *Dictionary of the Bible;* and *F.* Bull, in *Encyclopaedia of Islam* (bibl.); *E.* Huntington, *Palestine and its Transformation* (1911); H. Guthe, *Das Land der Bibel,* ii. 1, 2 (1919); J. Garstang, in Cook's *Handbook for Syria and Palestine* 478 *seq.* (1924). (E. Ro.)

GERBA: *see* JERBA.

GERBIL or GERBILLE, the name of a group of small, elegant, large-eyed, jumping rodents typified by the North African *Gerbillus aegyptiacus* and forming a special sub-family, *Gerbillinae,* of the rat tribe or *Muridae.* They are found over the desert districts of Asia and Africa. They have elongated hind-limbs and long hairy tails and progress by leaps, in the same manner as jerboas, from which they differ in having five hind-toes. Gerbils dwell in burrows furnished with numerous exits, and containing large grass-lined chambers. The Indian *Tatera indica* produces at least a dozen young at a birth. All are nocturnal.

GERENUK, a long-necked aberrant gazelle, commonly known as Waller's gazelle *(Lithocranius walleri),* and ranging from Somaliland to Kilimanjaro. The gerenuk is a large species with long neck and limbs. The horns of the bucks are heavy, and have a peculiar forward curvature at the tips; the coat is red-fawn, with a broad brown band down the back. Gerenuk, in Somaliland, are found in family parties, and feed by browsing on the branches and leaves of trees and shrubs. *(See* ANTELOPE.)

GERGOVIA (mod. *Gergovie),* in ancient geography, the chief settlement of the Arverni, situated in the Auvergne, 8 m. from the Puy de Dôme, France. Julius Caesar attacked it in 52 B.C., but was beaten off; some walls and earthworks, probably of this period, survive. Later, when Gaul had been subdued, the place was dismantled and its Gaulish inhabitants resettled 4 m. away in the plain at the new Roman city of Augustonemĕtum (mod. Clermont-Ferrand).

GERHARD, JOHANN (1582–1637), Lutheran divine, was born in Quedlinburg on the 17th of October 1582, and studied at Wittenberg, Jena and Marburg. He was general superintendent of the duchy of Coburg until 1616, when he became theological professor at Jena, where the remainder of his life was spent. Here, with Johann Major and Johann Himmel, he formed the "Trias Johannea." Gerhard had already come to be regarded as the greatest living theologian of Protestant Germany; in the numerous "disputations" of the period he was always protagonist, and his advice was sought on many public and domestic questions touching on religion or morals. He died in Jena on the 20th of August 1637.

Of his many works the most important is the *Loci communes theologici* (1610–22), in which Lutheranism is expounded with a fulness of learning, a force of logic and a minuteness of detail that had never before been approached. His devotional work, *Meditationes sacrae* (1606), has been frequently reprinted and has been translated into most of the European languages, including Greek. The English translation by R. Winterton (1631) passed through at least nineteen editions. There is also an edition by W. Papillon in English blank verse (1801). His life, *Vita Joh. Gerhardi,* was published by E. R. Fischer in 1723, and by C. J. Bottcher, *Das Leben Dr. Johann Gevhards,* in 1858. *See* also W. Gass, *Geschichte der protestantischen Dogmatik* (1854–67).

GERHARDT, CHARLES FRÉDÉRIC (1816–1856), French chemist, was born at Strasbourg on Aug. 21, 1816. After attending the gymnasium at Strasbourg and the polytechnic at Karlsruhe, he was sent to the school of commerce at Leipzig, where he studied chemistry under Otto Erdmann. Later he worked for some time with Liebig at Giessen and became professor of chemistry at Montpellier in 1644, and in 1855 at Strasbourg, where he died on Aug. 19, 1856. Although Gerhardt did some noteworthy experimental work—for instance, his preparation of acid anhydrides in 1852—his contributions to chemistry consist not so much in the discovery of new facts as in the introduction of new ideas that vitalized and organized an inert accumulation of old facts. In 1839 he revived the old radicle theory of organic compounds under the title of the "theory of residues." He first suggested that many organic substances were "conjugated" or "copulated" compounds formed by the union of two residues. In 1842 he attempted the first definite classification of organic compounds, but owing to the obscurity of sorne of his concepts, little progress was made until he co-operated with Laurent (*q.v.*). Eventually Gerhardt introduced the idea that all substances were based on four main types; viz., hydrogen, hydrochloric acid, water and ammonia. Although these ideas were later abandoned they play an important part in the development of structural organic chemistry *(see* CHEMISTRY: *Organic).*

His chief works were *Précis de chimie organique* (1844–45), and *Traitt de chimie organique* (1853–56).

See *Charles Gerhardt, sa vie, son oeuvre, sa correspondance,* by his son, Charles Gerhardt, and E. Grimaux (Paris, 1900).

GERHARDT, ELENA (1885–), German singer, was born at Leipzig on Nov. 11, 1885. She studied music at the Leipzig conservatorium, where her voice was trained by Madame Hedmondt, and afterwards received invaluable help in interpretation from Nikisch, who frequently accompanied her at concerts. As a Lieder singer, and especially as an interpreter of Schubert, she has set a standard of purity and simplicity which is not likely to be surpassed.

GERKARDT, PAUL (1607–1676), German hymn-writer, was born at Grafenhainichen on March 12, 1607. After tutoring in Berlin, in 1657 he became "diaconus" to the Nicolaikirche there. Owing to his uncompromising Lutheranism he refused to accept the Elector Frederick William's "syncretistic" edict of 1664, and was deprived of his office in 1666. In spite of a public petition in 1667, he refused to resume an office which, he thought, implied at least a tacit repudiation of the Formula Concordiae. In 1668 he was appointed archdeacon of Liibben, Saxe-Mersburg, where he died on June 7, 1676. Gerhardt is the greatest German hymn-writer of the 17th century. Many of his best-known hymns first appeared in church hymnbooks, as for example in the Brandenburg hymnal in 1658; others in Johann Criiger's *Geistliche Kirchenmelodien* (1649), and *Praxis pietatis melica* (1656). The first complete set is the *Geistliche Andachten* (1666–67), edited by Ebeling, music director in Berlin.

The life of Gerhardt bas been written by Roth (1829), by Langbecker (1841), by Schultz (1842), by Wildenbahn (1845), by Bachmann (1863), and by H. Petrich (1914); also by Kraft in Ersch u. Gruber's *Allg. Encycl.* (1855). The best modern edition of the hvmns, published by Wackernagel in 1843, has often been reprinted (Eng. trs. by Kelly, *Paul Gerhardt's Spiritual Songs,* 1867). *See* also T. *B.* Hewitt, *Paul Gerhardt as a hymn-writer and his influence on English Hymnody* (New Haven, *U.S.* 1918).

GERICAULT, JEAN LOUIS ANDRE THEODORE (1791–1824), French painter, the leader of the French realistic school, was born at Rouen on Sept. 26, 1791. In 1808 he entered the studio of Carle Vernet, from which, in 1810, he passed to that of Guérin, whom he drove to despair by his passion for Rubens, and by the unorthodox manner in which he persisted in interpreting nature. At the Salon of 1812 Géricault attracted attention by his "Officier de Chasseurs à Cheval" (Louvre), a work in which he personified the cavalry in its hour of triumph. Two years later (1814) he exhibited the "Cuirassier blessé" (Louvre); in both subjects he called attention to the interest of contem-

porary aspects of life, and exhibited that mastery of and delight in the horse which was a feature of his character. In 1815 Géricault gave way to his enthusiasm for horses and soldiers, and enrolled himself in the *mousquetaires.* During the Hundred Days he followed the king to Bethune, but, on his regiment being disbanded, left France for Italy in 1816, and at Rome illustrated his favourite animal by his great painting, "Course des Chevaux Libres." Returning to Paris, Géricault exhibited at the Salon of 1819 the "Radeau de la Méduse" (Louvre), illustrating a shipwreck, a subject which not only enabled him to prove his zealous and scientific study of the human form, but contained those elements of the heroic and pathetic, as existing in situations of modern life, to which he had appealed in his earliest productions. The appearance of this work marks the beginning of the struggle between the classicist and Romantic movements. Easily depressed or elated, Géricault took to heart the hostility which this work excited, and passed nearly two years in London, where the "Radeau" was exhibited with success, and where he executed many series of admirable lithographs now rare, and painted the three versions of the Derby now in the Louvre. At the close of 1822 he was again in Paris, and produced a great quantity of projects for vast compositions, models in wax, and a horse *écorché,* as preliminary to the production of an equestrian statue. He died from the consequences of a fall from his horse on Jan. 26, 1824.

See Charles Clement, Th. *Géricault,* Etude biographique et critique, avec *le* catalogue *raisonné* (1879 second edition).

GERIN-LAJOIE, ANTOINE (1824–1882), Canadian writer, was born at Yamachiche in 1824, and died at Ottawa on Aug. 4, 1882. He was educated at the Collège de Nicolet. In 1844 he was employed as proof-reader on *La Minerve,* and soon rose to be its editor. At the same time he pursued legal studies, and was called to the bar, afterwards entering the civil service. In 1856 he was made librarian to the parliament. At Quebec, where the parliament was held after 1859, he was one of the founders of *Soirées* Canadiennes (see CRÉMAZIE, OCTAVE), and of the *Foyer Canadien;* in these magazines he published his Jean Rivard (1862–64), a novel of pioneer life. He also wrote *Dix ans d'Histoire du* Canada (1888). But he is best known for the almost national poem, *Un* Canadien, written at a time when many Canadians were being forced, by the upheavals of 1837, to emigrate to the United States.

GERIZIM, a mountain in Samaria (mod. Jebel et-Tiir), 2,849ft. above sea-level. With its companion mountain, Ebal, it flanks the valley in which lies Nāblus (Neapolis), the ancient Shechem.

History.— It was on Ebal and Gerizim that the tribes assembled under Joshua to hear the curses and the blessings connected with the violation and observance of the law (Deut. xi.). The distance from Ai and the position of Ebal and Gerizim in the midst of a hostile country have constituted difficulties which Eusebius, Epiphanius and others met by associating Ebal and Gerizim with hillocks in the lower Jordan valley—a solution that has never found favour. From Gerizim—a prominent rock is still pointed out as his pulpit—Jotham addressed his parable to the treacherous elders of Shechem (Judges ix.). This mountain is the holy place of the Samaritan community. About 432 B.C., following on the refusal of the Jews returned from the Exile to recognize the Samaritans, the latter erected on the mount a temple as rival to that at Jerusalem. This was probably destroyed by John Hyrcanus (c. 110 B.C.). The Samaritans were expelled from Gerizim by the emperor Zeno, who built a church (484). In the course of his struggle with the Samaritans, Justinian surrounded this church with a fortress.

Archaeology.— A small level plateau near the summit marks the site of the schismatic temple and an important link with the past is the celebration near this spot of the Passover by the Samaritans, now a small body of about 150 souls. "As the sun sets on Passover eve the seven lambs are slain, ceremonially examined and roasted in the oven pit. At midnight the covering is removed and the flesh Is eaten by the standing elders with their families in the improvised tents. Anything left over is scrupulously collected and consumed, so that the letter of the commandment may be kept." Recently (1928) excavations carried out by the German Archaeological Institute have uncovered Zeno's basilica. This building (121ft. by 98ft.), which was built over the ruins of the Samaritan temple, exhibits a well-preserved octagonal ground plan. Two side chapels with handsome mosaics have also been disclosed. The abundance of fragments suggests that it will be possible to determine accurately the details of architectural design. (E. Ro.)

GERMAN BAPTIST BRETHREN, the legal name until 1908 of The Church of the Brethren, whose members are popularly nicknamed Dunkers or Dunkards.

Origin.— The Church of the Brethren began in Schwarzenau, Germany, in 1708, in the county of Witgenstein, province of Westfalen. It was the result of the Pietistic Movement. The Pietists became dissatisfied with the formal religion of the state churches, and being persecuted for their faith, withdrew from other parts of Germany, from Switzerland, France and England to the mountains of Witgenstein. After years of Bible study and prayer, some of these Pietists were convinced that they could not be true Christians without being organized into a church. Alexander Mack was their leader. They took the New Testament as the "Rule of Faith and Practice," following it literally, and where it was not clear, they interpreted it by the practices of the early church. Eight persons formed the nucleus of the church in Schwarzenau, which grew rapidly, and soon two other churches were formed, at Marienborn, and at Krefelt.

Migrations.— The treaty of Westphalia (1648) gave religious liberty only to the Lutherans, Calvinists and Catholics. The new church had no right, and was persecuted. In 1719 the church at Krefelt under the leadership of Peter Becker, came to Germantown, Pa. The same year the mother church at Schwarzenau, forty families, two hundred members, moved to Westfriesland, Holland. In 1729 this group, with Alexander Mack, also came to Pennsylvania. Within the next decade the scattered members who were left found their way to America.

In America.— In 1723 the first new converts in America were baptized in the Wissahickon Creek, Philadelphia. The first Love Feast was also held then, and Becker was made the bishop. Soon after, a missionary tour resulted in new converts and a second church, the Coventry church, near Pottstown, Pa. The church spread rapidly west and south so that in 1929 there were members in every state of the Union except in New England. The communicants numbered 135,000.

Doctrines.— The New Testament being the only creed of the church, its teachings were set forth as the rule of faith and practice. (1) The Doctrine of Peace; there is to be no force in religion; only willing believers are to be baptized; no one is to have any part in war. (2) The Doctrine of Temperance. (3) The Doctrine of the Simple Life, as against luxury and worldliness. (4) The Doctrine of Brotherhood; no member ever held slaves; all caste and class distinctions are wrong. (5) Religion means obedience to the teachings of Christ, rather than creeds and cults; right living has always been emphasized more than forms. Baptism is by triune immersion, as in the early church. The Agape is held, following literally John 13:1–17. After the Lord's Supper, the Communion service of the Broken Bread and the Cup is administered.

Organization.— The Church is democratic, each member has a vote. The country is divided into fifty districts, which hold confererices annually. The General Conference meets annually with delegates from each district and from each local church. The decisions of the General Conference are the unifying and directing ideals for church government.

Educational Interests.— In Germantown, the two Christopher Sowers, father and son, were printers. The elder Sower printed the first Bible, in a European tongue, in America. Three editions of the German Bible were printed, 1743, 1763, 1776. He also published the first religious magazine on the continent, and as early as 1740 organized a Sunday School for religious education, and printed portions of the Bible as lesson leaves.

Many efforts have been made to establish colleges. In 1929, the church owned and controlled the following educational institutions: Juniata College, Pa., founded. 1876; Mt. Morris College, Ill., 1879; Bridgewater College, Va., 1880; McPherson College, Kansas, 1887; Daleville Academy, Va., 1890; La Verne College, Calif., 1891; Manchester College, Ind., 1895; Elizabethtown College, Pa., 1898; Blue Ridge College, Md., 1899; Bethany Bible School, the Theological Seminary, Chicago, 1901. The Headquarters of the church is the Brethren Publishing House, Elgin, Ill. The Gospel Messenger, the church paper, and all other publishing for the church, is done there.

Missionary Work. — In 1876 missionaries were sent to Denmark. The real interest in missions began in 1894 when work was started in India, at Bulsar. In India the church had, in 1929, eleven stations with fifty-four missionaries. In 1908 work was started in the Shansi Province, China. In 1929 there were four stations with thirty-four missionaries in China. In 1922 a field was opened in Nigeria, Africa, where are two stations with eighteen missionaries. There is also much home missionary work done, especially in the mountains of Virginia and Tennessee.

Divisions. — In 1732 the Ephrata Society was founded by Conrad Beissel, a former member of the Church of the Brethren. But the ideals, organization, and methods of this Society have almost no similarity to the church from which the founder came. In 1881 a small group left the church who were more conservative and called themselves The Old Order Brethren. They do not believe in missions, Sunday Schools, or higher education. They number about 3,000. In 1882 a larger body, about 10,000 left the church who were more progressive than the mother church. They were popularly known as the Progressive Brethren, but their legal name is the Brethren Church. Their number is about 25,000.

GERMAN CATHOLICS (Deutschkatholiken), the name assumed in Germany towards the close of 1844 by certain dissentients from the Church of Rome. The most prominent leader of the German Catholic movement mas Johann Ronge, a priest who in the Sachsische Vaterlandsblatter for the 1jth of October, 1844, made a vigorous attack upon Wilhelm Arnoldi, bishop of Trier since 1842, for having ordered (for the first time since 1810) the exposition of the "holy coat of Trier," alleged to be the seamless robe of Christ, an event which drew countless pilgrims to the cathedral. It was intended to demonstrate that the Roman Catholic population would render unconditional obedience to the leadership of their clergy; and the intention was fully realised. But this celebration had also the effect of a challenge on circles which in spirit had outgrown the tutelage of the clergy. Ronge, who had formerly been chaplain at Grottkau, was then a schoolmaster at Laurahiitte near the Polish border. The article made a great sensation, and led to Ronge's excommunication by the chapter of Breslau in December 1844. The ex-priest received a large amount of public sympathy, and a dissenting congregation was almost immediately formed at Breslau with a very simple creed, in which the chief articles were belief in God the Father, creator and ruler of the universe; in Jesus Christ the Saviour, who delivers from the bondage of sin by his life, doctrine and death; in the operation of the Holy Ghost; in a holy, universal, Christian church; in forgiveness of sins and the life everlasting. The Bible was made the sole rule, and all external authority was barred. Within a few weeks similar communities were formed at Leipzig, Dresden, Berlin, Offenbach, Worms, Wiesbaden and elsewhere; and at a "council" convened at Leipzig at Easter 1845, twenty-seven congregations were represented by delegates, of whom only two or at most three were in clerical orders.

Even before the beginning of the agitation led by Ronge, another movement fundamentally distinct, though in some respects similar, had been originated at Schneidemuhl, Posen, under the guidance of Johann Czerski (1813–1893), also a priest, who had come into collision with the church authorities on the then much discussed question of mixed marriages, and also on that of the celibacy of the clergy. The result had been his suspension from office in March 1844; his public withdrawal, along with twenty-four adherents, from the Roman communion in August; his excommunication; and the formation, in October, of a "Christian Catholic" congregation which, while rejecting clerical celibacy, the use of Latin in public worship, and the doctrines of purgatory and transubstantiation, retained the Nicene theology and the doctrine of the seven sacraments. Czerski had been at some of the sittings of the "German Catholic" council of Leipzig; but when a formula somewhat similar to that of Breslau had been adopted, he refused his signature because the deity of Christ had been ignored, and he and his congregation continued to retain by preference the name of "Christian Catholics," which they had originally assumed. Of the German Catholic congregations which had been represented at Leipzig some manifested a preference for the fuller and more positive creed of Schneidemuhl, but a great majority continued to accept the comparatively rationalistic position of the Breslau school. The number of these rapidly increased, and the congregations scattered over Germany numbered nearly 200. External and internal checks, however, soon limited this advance. In Austria, and ultimately also in Bavaria, the use of the name German Catholics was officially prohibited, that of "Dissidents" being substituted, while in Prussia, Baden and Saxony the adherents of the new creed were laid under various disabilities, being suspected both of undermining religion and of encouraging the revolutionary tendencies of the age. Ronge himself was a foremost figure in the troubles of 1848; after the dissolution of the Frankfort parliament he lived for some time in London, returning in 1861 to Germany. He died at Vienna on the 26th of October 1887. In 1859 some of the German Catholics entered into corporate union with the "Free Congregations," an association of free-thinking communities that had since 1844 been gradually withdrawing from the orthodox Protestant Church, when the united body took the title of "The Religious Society of Free Congregations" (*Religionsgesellschaft freier* Gemeinden). Before that time many of the congregations which were formed in 1844 and the years immediately following had been dissolved. including that of Schneidemuhl itself, which ceased to exist in 1857. Both movements were deficient in the power to proceed from negative criticism of the faults of the Roman Church to the formation of a purer Catholic Church.

Kampe, *Das Wesen des Deutschkatholicismus* (1860); Findel, *Der Deutschkatholicismus in Sachsen* **(189;)**; Tschirn, *Zur 60-jahrigen Geschichte der Freireligiosen Bewegung* (1904).

GERMANDER, the name given to plants of the genus *Teucrium* (family Labiatae), comprising some 100 species distributed all over the world. Both common British species (T. *Scorodonia*) and the common North American forms (T. *canadense* and T. occidentale) are frequently known as wood sage. The European species were formerly used medicinally; T. *marum,* the cat thyme of southern Europe, is still so used. The plants are small, with small flowers remarkable for the slight development of the upper lip. T. Chamaedrys is wall-germander.

GERMAN EAST AFRICA. By agreements with Great Britain, in 1886 and 1890, and by other agreements with Portugal and the Congo Free State the east central part of Africa was recognized as a German possession. At that time the coast lands of what became German East Africa were held by Seyyid Bargash, the Sultan of Zanzibar, who also made vague claims to the interior as far as Lake Tanganyika. At Zanzibar British influence was then predominant and Bargash had in 1877 made an offer to a British merchant, William MacKinnon, to lease to him all his mainland territory. In consequence of the opposition of the British Government the offer was declined, but when in 1884 the German Colonization Society sought to secure for its country territory on the east coast it deemed it prudent to act secretly, so that both Great Britain and Zanzibar might be confronted with accomplished facts. Making their way inland, three young Germans, Karl Peters, Joachim Count Pfeil and Dr. Juhlke, concluded a "treaty" in Nov. 1884 with a chieftain in Usambara who was declared to be independent of Zanzibar Other treaties followed, and on Feb. 17, 1885, the German emperor granted a char-

ter of protection to the Colonization Society. The German acquisitions were resented by Zanzibar, but were acquiesced in by the British Government. The sultan was forced to acknowledge their validity, and to grant a German company a lease of his mainland territories south of the mouth of the Umba river. On Oct. 28, 1890, the sultan ceded to Germany the mainland territories, receiving as compensation £200,000.

Meanwhile, on Aug. 16, 1888, the German East African Company, the lessee of the mainland strip, took over the administration from the Arabs. This was followed, five days later, by a revolt of all the coast Arabs against German rule—the Germans, raw hands at the task of managing Orientals, having aroused intense hostility by their brusque treatment of the dispossessed rulers. It was not until the end of 1899 that the revolt was crushed, through the efforts of Maj. Hermann von Wissmann, who was sent out by the German Government. Wissmann remained in the country until 1891 as commissioner, and later (1895–96) was for 18 months governor of the colony—as the German sphere had been constituted by proclamation (Jan. 1, 1897). Towards the native population Wissmann's attitude was conciliatory, and under his rule the resources of the country were developed. Equal success did not attend the efforts of other administrators; in 1891–92 Karl Peters had great trouble with the tribes in the Kilimanjaro district and resorted to very harsh methods, such as the execution of women, to maintain his authority. In 1896 Peters was condemned by a disciplinary court, for a misuse of official power, and lost his commission.

The extension of German authority in the interior met with much opposition, several revolts occurred and a rebellion of the Wangoni in 1905–6 entailed the loss of 120,000 lives. Material development was slow, partly because the Reichstag was niggardly in supplying funds, partly because of the inexperience of the Germans in dealing with Africans. A change came about after 1907, when Herr B. Dernburg, then colonial secretary, visited the colony and boldly advocated the adoption of British colonial methods in administration. From that time better conditions prevailed and much good work was done in the scientific study of the resources of the country. Flourishing German settlements grew up in the Usambara highlands, which were linked to Tanga by railway. From Dar es Salaam a trunk railway was built to Ujiji-Kigoma on Lake Tanganyika. Partly owing to the energy of Dr. Albert Schnee, the last German governor, this line was completed, two years before scheduled time, in Feb. 1914. The World War followed, ending in the conquest of German East Africa by British and Belgian troops. By the Treaty of Versailles Germany renounced her sovereignty over the colony, which came for the most part under British mandate *(see* TANGANYIKA TERRITORY). Part came under Belgian mandate *(see* RUANDA-URUNDI).

BIBLIOGRAPHY.—S. Passarge and others, *Das Deutsche Kolonialreich*, the first volume (Leipzig, 1909), deals with East Africa; Vice Consul Norman King wrote a valuable report (Annual Series No. 5171), published by the British Foreign Office, 1913; *A Handbook of East Africa* (1916), prepared for the British Admiralty, and *Tanganyika (German East Africa)* (1920), a Foreign Office Handbook, are complementary volumes, each with a list of authorities. *See* also under TANGANYIKA TERRITORY. (F. R. C.)

GERMANIC LANGUAGES: *see* TEUTONIC LANGUAGES.

GERMANIC LAWS, EARLY. After the foundation of the great kingdoms of the Teutonic tribes on the soil of Roman civilization, the necessity for a written codification of the inherited tribal laws arose. This necessity evidently arose out of permanent intercourse with a native population which had been living under different laws. Thus the Visigoths, Burgundians and Salic Franks had already, at the turn of the fifth and sixth centuries, codified their law. One and a half centuries later the Lombards did the same. The Teutonic tribes, living in the interior, owe their codification to the influence of the Frankish suzerainty; the Ripuarians, Alemans and Bavarians to the Merovingians; the Chamavic Franks, Saxonians, Thuringians and Frisians to Charlemagne. For the edict of Theodoric I. *see* ROMAN LAW.

The leges germanorum are codifications of the valid criminal law and the law of procedure, but do not offer an exhaustive regulation of these and are not, on the other hand, solely confined to them. In substance they consist partly of already existing customary law and also partly of new statutory laws. Whether it is possible to distinguish among such varied forms, contained within a lex, the different strata of text is a question not definitely settled. It was thought, but has not as yet been proved, from the tradition of the Salic Law that it was originally composed of primitive tariffs of composition, to which, later, constitutions were added with the intention of creating a new law. Moreover such constitutions (capitularia) are preserved to us partly as amendments (novellae) to older leges and partly as special laws. The capitularies of Charlemagne and of his son Louis were of particular importance in the development of the law. All *leges* and *capitularia* are in Latin, but in most cases there is also an admixture of Germanic legal terminology. We possess fragments of the Lex Salica and of the Carolingian capitulary in an old High-German translation.

For the whole body of the Germanic laws *see* P. Canciani, *Barbarorum leges antiquae* (Venice, 1781–1789); F. Walter, *Corpus juris germanici antiqui* (Berlin, 1824); *Monumenta Germaniae historica, Leges.* For further information on the codes in general *see* J. E. O. Stobbe, *Geschichte der deutschen Rechtsquellen* (Brunswick, 1860–1864); Paul Viollet, *Histoire du droit civil français* (2nd ed., Paris, 1893); H. Brunner, *Deutsche Rechtsgeschichte* (2nd ed. Leipzig, 1906); Brunner-Heymann, *Grundzüge der deutschen Rechtsgeschichte* (7th ed., Leipzig, 1925).

Leges **Visigothorum.**—It is now certain that the earliest written code of the Visigoths dates back to King Euric (466–485). Of this code, fragments of chapters cclxxvi. to cccxxxvi. have been discovered in a palimpsest ms. in the Bibliothèque Nationale at Paris (Latin coll., No. 12161). The *lacunae* in these fragments have been filled in by aid of the law of the Bavarians, where the chief provisions are reproduced. Euric's code was used for all cases between Goths, and between them and Romans; in cases between Romans, Roman law was used.

Euric's code remained in force among the Visigoths of Spain until the reign of Leovigild (568–586), who made a new one, improving upon that of his predecessor. This work is lost, and we have no direct knowledge of any fragment of it. In the 3rd codification, however, many provisions have been taken from the 2nd, and these are designated by the word "antiqua"; by means of these "antiqua" we can reconstruct the work of Leovigild.

After the reign of Leovigild the legislation of the Visigoths underwent a transformation. The new laws made by the kings were declared to be applicable to all the subjects in the kingdom, of whatever race—in other words, they became territorial, and this principle of territoriality was gradually extended to the ancient code. Moreover, the conversion of Reccared I. (586–601) to orthodoxy effaced the religious differences among his subjects, and all subjects, *qua* Christians, had to submit to the canons of the councils, which were made obligatory by the kings. After this change had been accepted, Recessvind (649–672) made a new code, which was applicable to Visigoths and Romans alike. This code, known as the *Liber judiciorum*, comprises 324 constitutions taken from Leovigild's collection, a few of the laws of Reccared and Sisebut, 99 laws of Chindasvind (642–653), and 87 of Recessvind. A recension of this code of Recessvind was made in 681 by King Ervig (680–687) and is known as the *Lex Visigothorum renovata;* and finally some additamenta were made by Egica (687–702). The texts of the *Leges Visigothorum* have been published by K. Zeumer in the 40 series of the *Mon. Germ. hist.* Cf. Zeumer's articles in the *Neues Archiv.*, vols. xxiii., xxiv. and xxvi.; H. Brunner, *Deutsche Rechtsgeschichte* (2nd ed., Leipzig, 1906); Ureña y Smenjaud, *La Legislacion Gotico-hispana* (Madrid, 1905); E. de Hinojosa, *Das germanische Element im spanischen Rechte* (*Zeitschrift der Savigny-Stiftung*, vol. 31).

Lex **Burgundionum.**—This code was compiled by King Gundobad (474–516), very probably after his defeat by Clovis in 500. Some additamenta were subsequently introduced either by Gundobad himself or by his son Sigismund. This law bears the title of *Liber Constitutionum*, which shows that it emanated from the king; it is also known as the *Lex Gundobada* or *Lex Gombata.* It was used for cases between Burgundians, but was also applic-

able to cases between Burgundians and Romans. The law of the Burgundians shows strong traces of Roman influence. It recognizes the will and attaches great importance to written deeds, but, on the other hand, sanctions the judicial duel and the *cojuratores* (sworn witnesses). The vehement protest made in the 9th century by Agobard, Bishop of Lyons, against the *Lex Gzindobada* shows that it was still in use at that period. So late as the 10th and even the 11th centuries we find the law of the Burgundians invoked as personal law in Cluny charters, but doubtless these passages refer to accretions of local customs rather than to actual paragraphs of the ancient code.

The text of the *Lex Burgundionum* has been published by F. Bluhme in the *Mon. Germ. hist., Leges,* iii., 525; by Karl Binding in the *Fontes rerum Bernensium* (vol. i., 1880); by J. E. Valentin Smith (Paris, 1889 *seq.);* and by von Salis (1892) in the 4to series of the *Mon. Germ. hist.,* cf. *R.* Dareste, "La Loi Gombette," in the *Journal des Savants* (July 1891); K. Zeumer in the *Neues Arclziv.,* vol. xxv.; Petot, "Un nouveau manuscr. de la loi Gombette, *Nouv. Rev. hist. de Droit,* 1913.

Leges **Langobardorum.**—We possess a fair amount of information on the origin of the laws of the Lombards. The first part, consisting of 388 chapters, is known as the *Edictus Langobardorum,* and was promulgated by King Rothari at a diet held at Pavia on the 22nd of November, 643. This work, composed at one time and arranged on a systematic plan, is very remarkable. The compilers knew Roman law, but drew upon it only for their method of presentation and for their terminology; and the document presents Germanic law in its purity. Rothari's edict was augmented by his successors: Grimoald (668) added nine chapters; Liutprand (713–73j), fifteen volumes, containing a great number of ecclesiastical enactments; Ratchis (746), eight chapters; and Aistulf (755), thirteen chapters. After the union of the Lombards to the Frankish kingdom, the capitularies made for the entire kingdom were applied to Italy. There were also special capitularies for Italy, called *Capitula Italica,* some of which were appended to the edict of Rothari.

At an early date compilations were formed in Italy for the use of legal practitioners and jurists. Eberhard, Duke and Margrave of Rhaetia and Friuli, arranged the contents of the edict with its successive additamenta into a *Concordia de singulis causis* (829–832). In the 10th century a collection was made of the capitularies in use in Italy, and this was known as the *Capitulare Langobardorum.* Then appeared, under the influence of the school of law at Pavia, the *Liber legis Langobardorum* also called *Liber Papiensis* (beginning of 11th century) and the *Lombarda* (end of 11th century) in two forms — that given in a Monte Cassino ms. and known as the *Lombarda Casinensis,* and the *Lombarda Vulgata.*

There are editions of the *Edictus,* the *Concordia,* and the *Liber Papiensis* by F. Bluhme and A. Boritius in the *Mon. Germ. hist., Leges,* iv. Bluhme also gives the rubrics of the *Lombarda,* which were published by F. Lindenberg in his *Codex legum antiquarum* in 1613. For further information on the laws of the Lombards *see* J. Merkel, *Geschichte des Langobardenrechts* (1850); A. Boritius, *Die Kapitularien im Langobardenreich* (1864); Schupfer, *Manuale di storia del diritto italiano* (2nd ed. 1895); Solmi, *Diritto longobardo e diritto nordico* (1898); C. Kjer, *Edictzu Rotari* (Copenhagen, 1898), *C.* Kjer, *Dansk og langbardisk Arveret* (1901); J. Ficker, *Das langobardisclze und die skandinavischen Rechte* (Mitteilungen des Instituts fiir oesterreichische Geschichtsforschung, vol. xxii.); Cf. R. Dareste, in the *Nouvelle Revue historique de droit français et étranger* (1900, p. 143).

Pactus Alamannorum and Lex **Alamannorum.**—Of the laws of the Alamanni we possess two different texts. The earlier text, of which five short fragments have come down to us, is known as the *Pactus Alamannorum,* and from the persistent recurrence of the expression "et sic convenit" was most probably drawn up by an official commission. The reference to affranchisement *in ecclesia* shows that it was composed at a period subsequent to the conversion of the Alamanni to Christianity. There is no doubt that the text dates back to the 7th century. The later text, known as the *Lex Alamannorum,* dates from a period when Alamannia recognized the theoretical suzerainty of the Frankish kings but was ruled by national dukes and may be placed between the years 717 and 719.

The two texts have been published by J. Merkel in the *Mon. Germ. hist.,* Leges, iii., and by Karl Lehmann in the 4to series of the same collection. Cf. Heinrich Brunner, "Uber das Alter der Lex Alamannorum" *(Berliner Sitzungsberichte,* 1885); Karl Lehmann, in the *Neues Archiv.,* vol. x.; Bruno Krusch, *Die Lex Bajuvariorum,* mit zwei Anhangen: *Lex Alamannorum* und *Lex Ribuaria* (1924); Franz Beyerle, in the *Savigny-Zeitschrift fur Rechtsgeschichte,* vol. xxxv.; Bruno Krusch, Neue Forschungen uber die drei oberdeutschen Leges: *Bajuvariorum, Alamannorum* und *Ribuariorum* (1927).

Lex **Baiuvariorum.**—The law of the Bavarians has, in some parts, been taken directly from the Visigothic law of Euric and from the *Lex Alamannorum* and the *Lex Salica.* The Bavarian law, therefore, is later than that of the Alamanni. It dates, probably, from a period when the Frankish authority was very strong in Bavaria when the dukes were vassals of the Frankish kings. The date of compilation may be placed between 740 and 748.

The text of the *Lex Baiuvariorum* has been published by J. Merkel in the *Mon. Germ. hist., Leges,* iii. 183; by E. von Schwind (1927) in the 4to series of the same collection, and by Konrad Beyerle (Munchen, 1926). Cf. von Schwind's articles in the *Neues Archiv.* vol. xxxi., xxxiii. and xxxvii.; H. Brunner, Uber ein verschollenes merowingisches Konigsgesetz des. 7. Jahrhunderts *(Berliner Sitzungsberichte,* 1901); V. Kralik, Die deutschen Bestandteile der *Lex Baiuwariorum (Neues Archiv.* vol. xxxvii.); Bruno Krusch, *Die Lex Bajuvariorum,* Textgeschichte, Handschriftenkritik und Entstehung (1924); Franz Beyerle, in the *Savigny-Zeitschrift fiir Rechtsgesclzichte,* vol, xlv., Ernst Heymann, Zur Textkritik der *Lex Bajuwariorzim (Kehr-Festschrift,* 1925); Bruno Krusch, Neue Forschungen uber die drei oberdeutschen Leges (1927); Karl August Eckhardt, *Die Lex Baiuvariorum,* eine textkritische Studie (1927).

Lex Saxonurn.--The *Lex Saxonum* has come down to us in two mss. and two old editions (those of B. J. Herold and du Tillet). The law contains ancient customary enactments of Saxony, and, in the form in which it has reached us, is later than the conquest of Saxony by Charlemagne. It is preceded by two capitularies of Charlemagne for Saxony — the *Capitulatio de partibus Saxoniae,* which dates undoubtedly from 782, and is characterized by great severity, death being the penalty for every offence against the Christian religion; and the *Capitulare Saxonicum,* of the 28th of October 797, in which Charlemagne shows less brutality and pronounces simple compositions for misdeeds which formerly entailed death. The *Lex Saxonicum* apparently dates from 802, since it contains provisions which are in the *Capitulare legi Ribuariae additum* of that year. The law established the ancient customs, at the same time eliminating anything that was contrary to the spirit of Christianity; it proclaimed the peace of the churches, whose possessions it guaranteed and whose right of asylum it recognized. There is an edition of the *leges Saxonum* by Karl v. Richthofen in the *Mon. Germ. hist., Leges,* and another by Cl. von Schwerin in the 8vo series of the same collection (1918). Cf. von Schwerin, in the *Savigny-Zeitschrift fiir Rechtsgeschichte,* vol. xxxiii.; Martin Lintzel, in the *Savigny-Zeitschrift für Rechtsgeschichte,* vol. xlvii.

Lex **Thuringorum.**—A collection of laws has come down to us, in one ms. and one old edition, bearing, in the ms., the name *Lex Thuringorum* and in the edition the name *Lex Angliorum et Werinorum, lzoc est Thuringorum.* In early times there dwelt, south of the river Unstrut, the Angli, who gave their name to the *pagus Engilin* or *Englide,* and to the east, between the Saale and the Elster, the *Warni* (*Werini* or *Varini)* whose name is seen in *Werinofeld.* Cf. Hoops, *Reallexikon,* 1, 86, iv., 483. This text is a collection of local customs arranged in the same order as the law of the Ripuarians. Parts of it are based on the *Capitulare legi Ribuariae addituvn* of 803, and it seems to have been drawn up in the same conditions and circumstances as the law of the Saxons.

There is an edition of this code by Karl von Richthofen in the *Mon. Germ. hist., Leges,* v. 103, and another by Cl. v. Schwerin in the 8vo series of the same collection (1918).

Lex **Frisionum.**—This consists of a medley of documents of the most heterogeneous character. Some of its enactments are apparently pagan. Thus one paragraph allows the mother to kill her new-born child, and another prescribes the immolation to the gods of the defiler of their temple; others are purely Christian such as those which prohibit incestuous marriages and working on Sunday. The law abounds in contradictions and repetitions and the compositions are calculated in different moneys. From this it would appear that the documents were merely materials collected from various sources and possibly with a view to the compilation of a homogeneous law. These materials were apparently brought together at the beginning of the 9th century, at a time of intense legislative activity at the court of Charlemagne.

There are no mss. of the document extant; our knowledge of it is based upon B. J. Herold's edition (*Originum ac Germanicarum antiquitatum libri,* Basel, 1557), which has been reproduced by Karl von Richthofen in the *Mon. Germ. hist., Leges,* iii. 631 and by de Geer (1866). Cf. Patteta, *La Lex Frisionum* (1892); Hugo Jaekel, in the *Neues Archiv.,* vol. xxxii.; Siegfried Rietschel, Das *Volksrecht der Friesen* (Gierke-Festschrift, 1911); Philipp Heck, *Die Entstehung der Lex Frisionum* (1927).

(C. PF.; K. A. EcK.)

GERMANICUS CAESAR (15 B.C.–A.D. 19), a Roman general and provincial governor in the reign of Tiberius. The name Germanicus, the only one by which he is known in history, he inherited from his father, Nero Claudius Drusus, the famous general, brother of Tiberius and stepson of Augustus. His mother was the younger Antonia, daughter of Marcus Antonius and niece of Augustus, and he married Agrippina, the granddaughter of the same emperor. It was natural, therefore, that he should be regarded as a candidate for the purple. Augustus, it would seem, long hesitated whether he should name him as his successor, and as a compromise required his uncle Tiberius to adopt him, though Tiberius had a son of his own. Of his early years and education little is known. Suetonius and Ovid allow him a reputation as an orator.

At the age of 20 he served under Tiberius, and received the triumphal insignia for crushing the revolt in Dalmatia and Pannonia. In A.D. 11 he accompanied Tiberius in his campaign on the Rhine. In 12 he was made consul, and increased his popularity by appearing as an advocate in the courts of justice, and by the celebration of brilliant games. Soon afterwards he was appointed by Augustus to the command of the eight legions on the Rhine. The news of the emperor's death (14) found Germanicus at Lugdunum (Lyons), where he was superintending the census of Gaul. Close upon this came the report that a mutiny had broken out among his legions on the lower Rhine. Germanicus hurried back to the camp, which was now in open insurrection. The tumult was with difficulty quelled, partly by concessions, for which the authority of the emperor was forged, but chiefly owing to his personal popularity. Some of the soldiers suggested that he should claim the empire for himself, but he refused. In order to calm the excitement Germanicus determined at once on an active campaign. Crossing the Rhine, he attacked and routed the Marsi, and laid waste the valley of the Ems. In the following year he marched against Arminius, the conqueror of Varus, and performed the last rites over the remains of the Roman soldiers that still lay there unburied, erecting a barrow to mark the spot. Arminius, however. favoured by the marshy ground, was able to hold his own, and it required another campaign before he was finally defeated. A masterly combined movement by land and water enabled Germanicus to concentrate his forces against the main body of the Germans encamped on the Weser, and to crush them in two obstinately contested battles.

The success of Germanicus had already stirred the jealousy and fears of Tiberius, and he was reluctantly compelled to return to Rome. On May 26, 17 he celebrated a triumph. The enthusiasm with which he was welcomed, not only by the populace, but by the emperor's own praetorians, was so great that the earliest pretext was seized to remove him from Rome. He was sent to the East with extraordinary powers to settle a disputed succession in Parthia and Armenia. At the same time Gnaeus Calpurnius Piso, one of the most violent and ambitious of the old nobility, was sent as governor of Syria to watch his movements. Germanicus proceeded by easy stages to his province, halting on his way in Dalmatia, and visiting the battle-field of Actium, Athens, Ilium and other places of historic interest. When he reached his destination, he found little difficulty in effecting the settlement of the disturbed provinces, notwithstanding Piso's violent and persistent opposition. At Artaxata Zeno, the popular candidate for the throne, was crowned king of Armenia. To the provinces of Cappadocia and Commagene Roman governors were assigned; Parthia was conciliated by the banishment of the dethroned king Vonones.

After wintering in Syria Germanicus started for a tour in Egypt, but he was warned by Tiberius that he was thereby transgressing an unwritten law which forbade any Roman of rank to set foot in 'Egypt without express permission. On his return to Syria he found that all his arrangements had been upset by Piso. At Epidaphne near Antioch he was attacked by a fatal illness which he himself and his friends attributed to poison administered by Plancina, the wife of Piso, at the instigation of Tiberius. His ashes were brought to Rome in the following year (20) by his wife Agrippina, and deposited in the grave of Augustus. He had nine children, six of whom, three sons and three daughters, survived him, amongst them the future emperor Gaius and the notorious Agrippina, the mother of Nero. The news of his death cast a gloom over the whole empire.

He possessed considerable literary abilities; his speeches and Greek comedies were highly spoken of by his contemporaries.

In addition to monographs by A. Zingerle (Trent, 1867) and A. Breysig (Erfurt, 1892), there are treatises on the German campaigns by E. von Wietersheim (1850), P. Hofer (1884), F. Knoke (1887, 1889), W. Fricke (1889), A. Taramelli (1891), Dahm (1902). *See* Tacitus, *Annals,* i.–iv. (ed. Furneaux); Suetonius, *Augustus, Tiberius;* J. C. GERMANIUM, a chemical element included in the same natural family as tin and lead (*see* PERIODIC LAW), was discovered in 1886 by C. Winkler in the argyrodite (a silver thiogermanate) of Freiburg in Saxony. (Symbol Ge, atomic number 32, atomic weight 72.6.) The properties of this element and its compounds indicated that it was identical with the hypothetical element, ekasilicon, the properties of which had been predicted by D. Mendeléeff in 1871. It is still a very rare metal, although a promising source has been found in the concentrate from certain residues obtained in the smelting of American zinc ores, G. H. Buchanan having reported that such residues contain 0·25% of germanium dioxide. This source has been exploited by L. M. Dennis and his collaborators in Cornell university. U.S A., who have thereby increased very considerably our knowledge of germanium and its compounds. The following data are largely collected from these researches.

Germanium is separated from other metals by fractional distillation of its volatile tetrachloride and is isolated in the metallic state by reduction of its dioxide with aluminium, carbon or hydrogen.

Germanium is a greyish-white metal of crystalline structure and so brittle that it cannot be drilled; it has the specific gravity 5·35/20° C, melts at 958·5° C, and is not volatile at 1,250° C. When heated in oxygen at 730° C it is partially oxidized to dioxide, GeO_2, a dense white powder (specific gravity 4·70 at 18°). When acted on by the halogens, germanium yields the corresponding tetrahalides, GeX_4. The tetrachloride is a colourless liquid boiling at 83° C (melting point −49·5° C). The tetrabromide is a colourless crystalline solid (octahedra) melting at 26·1° C and boiling at 186·5° C. The tetraiodide is an orange powder or coral-red solid; it melts at 144° C and has specific gravity 4·3215 at 20° C. A germanium-magnesium alloy when decomposed by dilute hydrochloric acid yielded a mixture of germanium hydrides from which the following were isolated: — monogermane or germanomethane. GeH_4, a gas with nauseating odour, melting point, −165° C, boiling point −90° C; digermane or germanoethane,

Ge_2H_6, a colourless volatile liquid boiling at 29° C and melting at −109° C; and trigerrnane or germanopropane, Ge_3H_8, a colourless liquid boiling at 110·5° C with melting point −105·6° C.

Germanium resembles silicon and tin in forming organic derivatives: — germanium tetramethyl, $Ge(CH_3)_4$, and tetraethyl, $Ge(C_2H_5)_4$, are colourless liquids boiling respectively at 43.4 and 163·5° C. Tetraphenylgermane, $Ge(C_6H_5)_4$, and hexaphenyldigermane, $Ge_2(C_6H_5)_6$, are crystalline solids melting at 235° C and 340° C respectively (G. T. Morgan and H. D. K. Drew, 1925; C. A. Kraus and L. S. Foster, 1927), and homologous alkyl and aryl derivatives of germanium have been prepared in the Cornell laboratories. Just as carbon and silicon give respectively chloroform, $CHCl_3$, and silicochloroform, $SiHCl_3$, so germanium furnishes germanochloroform, $GeHCl_3$, a liquid boiling at 75° (melting point −71° C). Germano-bromoform and -iodoform are also known. The three compounds $GeHX_3$ are prepared by adding the halogen hydride to the corresponding germanium dihalide: $GeX_2+HX=GeHX_3$. The three germanium dihalides are solids the fusibility of which diminishes with increase in the atomic weight of the halogen; they possess strong reducing power similar to that of the stannous halides (F. M. Brewer, 1927). Germanium compounds when fused with alkaline carbonates and sulphur form thiogermanates which on decomposition with acid give white germanium disulphide. This substance, which is useful in the analytical separation of germanium, is also formed by passing hydrogen sulphide into acid solutions of germanium dioxide. In its general chemical reactions, germanium disulphide resembles stannic sulphide.

When silica is replaced by germanium dioxide in flint and crown glasses, an increase in refractive index is observed. Germanium compounds have been suggested in treating anaemia.

A further analogy between germanium and tin is seen in the interactions of their tetrachlorides or tetrabromides with acetylacetone. The products, germanium bisacetylacetone dichloride, $[GeA\check{c}_2Cl_2]$, and dibromide, $[GeA\check{c}_2Br_2]$, are non-ionized metallic complexes corresponding closely with the similar tin bisacetylacetone dihalides. When, however, germanium tetrahalides are condensed with copper acetylacetone, the final products are germanium trisacetylacetone cuprohalides, $[GeA\check{c}_3]Cu^{I}X_2$. In this respect germanium shows its relationship to silicon which gives rise to similar complex salts (Morgan and Drew, 1924).

GERMAN LANGUAGE. Together with English and Frisian, the German language forms part of the West Germanic group of languages, to which belongs also Langobardian, a dialect which died out in the 9th or 10th century.

Leaving English and Frisian aside, we understand by Deutsche *Sprache* the language of those remaining West Germanic tribes who, at their earliest appearance in history, spoke a Germanic tongue, and still speak it. The chief of these tribes are: the Saxons, the Franks, the Chatti (Hessians), Thuringians, Alemannians and Bavarians. This definition naturally includes the languages spoken in the Low Countries, Flemish and Dutch, the offspring of the Low Franconian dialect, mixed with Frisian and Saxon elements; but the Netherlands have built up an independent literary language of their own, excluded from the present survey.

MODERN STANDARD "DEUTSCH"

Phonetics. — An important feature is the "glottal stop" preceding every initial vowel in simple words *Eiche* (*'aiçə*) and though not always in compounds *Erinnerung* (ĕr'ĭnarŭn). Further characteristics are: the very full lip-articulation (rounding) in the pronunciation of u, *o; ü, ö;* lingual and guttural *r;* the *p, t,* k are slightly aspirated and the b, d, *g* become voiceless in the offsound; the ich sound (ç) and the ack (x) are sharply distinguished. The German w is a bi-labial spirant. Quantity determines the quality of the vowels, so that long vowels which are never diphthongized are tense, short vowels lax, and their articulation is always dorsal (upper surface of the tongue).

There are no nasalized vowels except in words borrowed from French (*Entrée, Parfum,* etc.). The diphthongs (Teil, Main; *Häuser, Teufel; Haus,* laufen) are falling; rising diphthongs occur only in words borrowed from Romance languages (Familie, Union, adieu, etc.).

The difference between strong and weak stress (Silbendruck) is marked, the voice in general is loud, at least when compared with English.

Accidence. — Standard German retains four cases out of the six in Old High German, but the weakening of the final vowels has often levelled out the different forms (cf. declension of Leben and Mensch), so that it is now the article — not the noun itself — which shows the difference in the cases. Other Germanic languages (English, Dutch) as well as the German dialects have lessened the number of specific case-forms, with the latter the loss of the genitive is especially noticeable (cf. [1] *dem* Vater *sein Haus,* [2] das *Haus von* dem Vater).

The distinction of *grammatical* gender as masc., fem. and neuter — a heritage from the Indo-European — is still retained. The declensions, when compared with older stages of the language, are much simplified and represent three types: strong (vocalic), weak (consonantal) and mixed declension. Many changes in gender as well as in declension have taken place and the -er plurals masc. (Manner, Geister) in addition to neuters have greatly increased in number, The qualifying adjectives (but not the predicative) all follow the strong and weak declension, but the strong shows pronominal forms (*guter,* -em, -en).

The verb — strong, weak (only one class as compared with three in Old High German) and some irregular (gehen, stehen, tun, sein, *wollen*) — has two tenses as in Germanic; viz., Present and Preterite (corresponding to the Indo-European Perfect), other tenses being formed, as in English, by combination of the auxiliary verbs *haben,* sein, *werden* with the past part., or, for the formation of the future, of werden with the inf. (the latter only since the late Middle High German period from an original werden plus pres. part. with future or present meaning.)

The old vocalic distinction between sing. and plur. in the preterite of the strong verb (cf. ward, wurden) has been levelled out. Sometimes the sing. prevails (*schwamm, schwammen*), sometimes the plur. (*griff, griffen*). Some forms have been influenced by the past participle (erlosch), others have arisen through the accordance of homophones due to phonetic processes; *e.g.,* Middle High German *rîze, reiz, rizzen, gerizzen,* which should normally give ich *reisse,* reiss, *rissen, gerissen,* but has substituted the preterite *riss* to avoid confusion of present and preterite (in English write *<writan,* wrote< *wrāt* there is no interference).

Word Formation. — Compounds of two or more independent words (*Kĭrchtúrmspítze, Fĕlddiébstàhl, Altwĕibersómmer*) and derivations by means of *affixes* (prefixes and *suffixes*), some of which originally were independent words such as *-lich* (Engl. *-ly*), *-tum* (*-dom*), *-heit* (-hood), *-schaft* (*-scape, -ship*), -haft, have played an important part in enriching the vocabulary from the oldest period. The great modification in the original meaning of a word by these affixes which are mostly of Germanic but for a part also of Classical or Romance origin, may be shown by such examples as *sitzen: ersitzen;* Wetter: *Gewitter;* Eigenschaft: *-tum: -heit; eigentlich;* Weib: *weibisch:* weiblich; England: Englander: *Engländerei.* As an important feature for the growth of the vocabulary loan-translations (calques, *Übersetzungslehnwörter*) deserve mention. They occur throughout the whole period, cf. Old High German bigiht (confessio, *Beichte*), *arm herzi* (*misericors, barmherzig*), gifatero (conzpater, Gevatter) and *Wasserflugzeug* (hydroplane), Volkerbund (*Société* des Nations, League of Nations), the last examples showing very strikingly the inherent power of forming compounds.

Vocabulary. — Besides loan-translations the German vocabulary contains a very large number of foreign words (Fremd- and *Lehnwörter*). Latin contributes from the time of Rome's contact with the Teutons, through the mediaeval church, humanism and the Renaissance. the rise of the grammar-schools and the study of medicine and science French influence was strong in the period of knighthood, in the baroque period and the Thirty

Years' War, then again under Frederick the Great and the Revolution. Italian, Spanish and Eastern languages are also contributors and English supplies many loans, especially sporting terms. In the 17th century German academies *(Sprachgesellschaften)* fought against this invasion, in the 19th century. J. H. Campe, H. Stephan and since 1885 the "Allgemeine Deutsche Sprachverein." That the battle still rages is shown by an article of H. Bojunga, "Werden und Wesen der deutschen Sprache in alter Zeit" in *Germanische Wiedererstehung*, ed. by H. Nollan (Heidelberg, 1926).

Syntax. — In German the order of words in the sentence presents some difficulty. Its rigidity has gradually become more pronounced owing chiefly to the influence of the grammarians and schoolmasters. Examples taken from the great preacher Berthold von Regensburg (about 1250) and from Martin Luther will prove this with regard to the rule of the final position of the verb in dependent clauses when introduced by a rel. pronoun or a conjunction.

B.v.R.: . . . *daz ir immer erlost muget werden; . . . daz sie ir muoter ie getruoc an diese werlt.*

Luther: . . . *den Got selbst hat erkoren; . . . dass wir uns yhe fursehen mit grossem ernst.*

Examples of this kind, however, may easily be paralleled from the writings of Goethe and Schiller and many others. *Sprachgefühl* and other psychological factors must decide where and how far the rigid rule can be relaxed, but it would not be advisable to accept as a pattern K. Sternheim's sovereign disregard of the acknowledged rules of word-order. General usage puts an infinitive with *zu* behind the verb (. . . *der mich bittet, ihm zu schreiben*) and the same holds good with comparisons: . . . *den ich hoher halte als meine anderen Freunde.*

An inflexible rule, on the other hand, is the inversion of subject and predicate when an adverbial clause or dependent sentence precedes: *dann kam er,* then he came; *als er kam, sagte ich,* when he came I said. English alone among the Germanic languages lacks this feature. The inversion frequently met with, especially in business letters where principal clauses are joined by the conjunction *and* (ex.: *ich danke Ihnen und werde ich . . .*) is unnecessary and should be avoided.

Style. — German style has often been accused of intolerably long and intertwined periods, of excessive use of mere expletives and of overburdened adjectival (participial) clauses placed between the article and noun; *e.g., "der in dem von der Sonne gedorrten Grase liegende Knabe."* There are, indeed, many learned publications, books and treatises on scientific, philosophical, historical or philological subjects which cause the reader to despair.

The long domination of Latin in the humanistic schools had certainly its influence on such execrable "Schachtel" sentences, but the predilection for periodic style corresponds to certain features of the national character. The successful use, therefore, depends on the author's personality. Few will complain of the harmonious, lucid and rhythmical periods in the writings of Goethe, Nietzsche and Thomas Mann. However, a preference for clear terse sentences under the influence of French and English style had repeatedly shown itself; *e.g.,* in the writings of the great literary historian, W. Scherer, based on Macaulay and in the historical writings of F. Ranke. In lyrics, novel and drama this is now the ruling tendency and is often carried to extremes in the works of the expressionists.

THE DEVELOPMENT OF THE GERMAN LANGUAGE

The history of the German language falls into three great sections: (1) Old High German *'(Althochdeutsch)* and Old Low German (Old Saxon; *Altniederdeutsch, Altsächsisch*); (2) Middle High German (*Mittelhochdeutsch*) and Middle Low German (*Mittelniederdeutsch*); and (3) Modern High German and Modern Low German *(Neuhochdeutsch* and *Neuniederdeutsch).*

Old High German Period.——The first or Old High German period is commonly regarded as extending to about the year 1050. The principal characteristic of the change from Old High German to Middle High German is the weakening of the unaccented vowels in final syllables (cf. O H G. *tagā, gesti, geban, gābum* and M.H.G. *tage, geste, geben, gāben*). This process began tentatively as early as the 10th century in Low German, whilst long, unaccented vowels are preserved in the Alemannic dialect as late as the 14th century and even later. With regard to the division between the second and third periods, some date Modern High German from the time of Luther, from about 1500. But certain characteristics attributed to the Modern German vowel system, such as lengthening of Middle High German short vowels, the change from Middle High German *ī, ū, iu* to Modern High German *ei, au, eu (ou),* of Middle High German *ie,* uo, *üe* to Modern High German *ī, ū, ü,* made their appearance long before 1500. Others, therefore, distinguish a period of classical Middle High German extending to about 1250, and a period of transition (sometimes called *Frühneuhochdeutsch,* or Early Modern High German) from 1250 to 1650. The principal characteristics of Modern High German are then the greater stability of the grammatical and syntactical structure, due to the efforts of earlier grammarians, such as Schottelius, Gottsched and others, and the levelling out of the vowels of the singular and plural of the preterite of strong verbs *(cf.* above) which was carried through consistently.

The middle ages did-not produce a Schriftsprache or literary language in the modern sense, so that the history of the language in its earlier stages is the history of different dialects. With the scientific study of the German language there arose a keen interest — not only on the part of scholars — in the dialects which were long held in contempt.[1]

A movement during the last three decades has bestowed great care on many of the existing dialects. Phonological questions have received most attention, but problems of syntax have also not been neglected. Monumental works like Wenker's *Sprachatlas des deutschen Reiches* and dialect dictionaries are either in course of publication or preparation[2] and many monographs[3] have appeared.

In the Old High German period the East Middle German, spoken mostly on territory colonized later, is therefore not represented in literature. In that period are found Old Low German and Old High German dialects, the latter divided into Upper High German and Franconian dialects.[4]

Low German. — The chief characteristic of Low German is the absence of the High German sound-shift; *i.e.,* the phonological process starting about A.D. 500 in the South by which the voiced and unvoiced stops b, *d,* g; *p, t, k* were affected: *b>p, d>t, g>k;* according to position *p>pf or ff, t>z* (=affricate *tz)* or *zz* (double spirant, now written *ss), k>ch (i.e., kh* or *χ)* or *hh.* Low German therefore agrees in this respect with Frisian and English. Independently of this sound-shift another consonantal shift starts from Upper Germany in the 8th century; *i.e.,* the change of the spirant *th*(þ)*>d: werthan: werdan; theob: deob (Dieb);* it soon spread to Middle German dialects and finally in the 11th and 12th centuries to Low German, so that *th* (þ) is only preserved in English. On the other hand the *i* -Mutation (Umlaut) found in Anglo-Saxon in the 6th century, had a firmer grip on Old Saxon in the 8th century than on Franconian and

[1] Of writers who have made extensive use of dialects, it must suffice to mention here the names of J. H. Voss, Hebel, Klaus Groth, Fritz Reuter, Usteri, G. D. Arnold, Holtei, Castelli, J. G. Seidl, Anzengruber, John Brinckmann, in our own days G. Hauptmann, and a Low German group as J. H. Fehrs, A. Wibbelt, F. Stavenhagen, K. Wagenfeld.

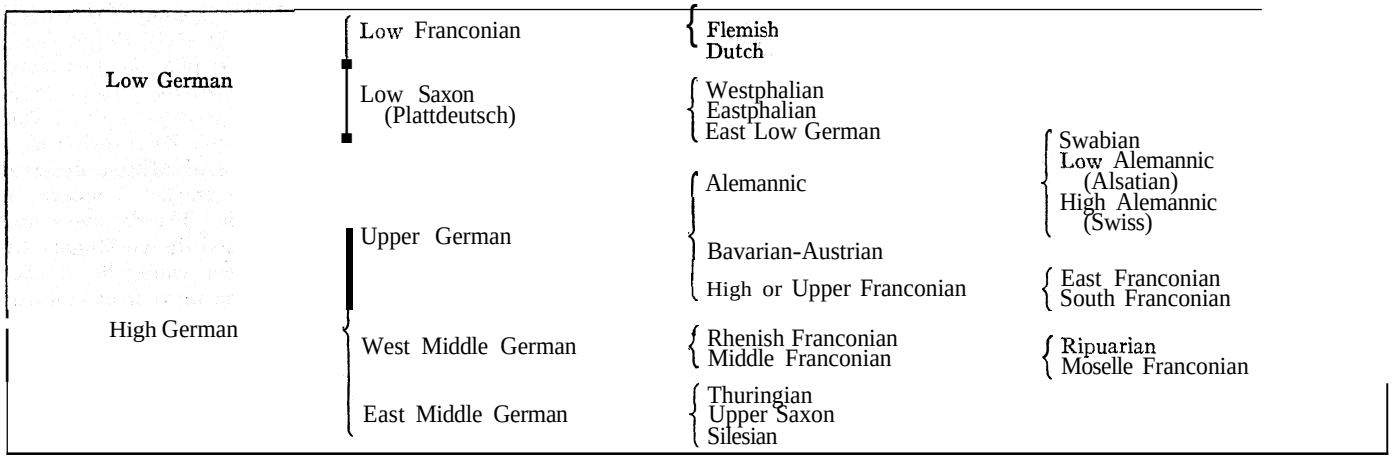
GERMAN DIALECTS IN THE MIDDLE HIGH GERMAN AND MODERN GERMAN PERIODS



especially on Upper German dialects of the same period. In Low Saxon—not in Low Franconian and East Low German (colonial territory)—the plural present of all three persons ends in -et (originally the ending of the 2nd pers., Old Saxon *-ath*): *wi, ir,* sie *stirwet;* b, d, g and *s* (medially) are always voiced, short *i* and *u* are rather open sounds tending towards e and o.

Upper German.—The Upper German dialects have carried the sound-shift farthest, especially the Old Bavarian, cf. *Kāpamēs* (wir *gaben*); in the Tyrol we still find *k*=>*kch* (the affricate sound): *kchind* and in High Alemannic (Swiss) kh (χ spirant): chilche. In the Bavarian-Austrian dialect—in the second half of the 12th -century—the first traces of that diphthongization of i, 1, *īū* (*ü*) to ei, au, eu can be seen which, even at the present day, is foreign to the greater part of the Alemannic, to the Ripuarian, (Low) Hessian, West-Thuringian and Low German dialects: *frili* (Swiss), is (Eis, Cologne), etc. Bavarian-Austrian forms the diminutives in -el, *-erl* (*Mädel, Hunderl*), High Franconian, Alemannic in *-la, -le* (*Mädla*) as opposed to *-chen* and -ken in Middle and Low German dialects. Bavaria has preserved the old dual form of the personal pronoun as es and enk. Characteristic of Aleinannic is the pronunciation of -st- and *-sp-* as scht and schp (Lascht, Haschpel).

West Middle German.—The principal characteristic of the West Middle German dialects is unshifted initial *p,* not *pf* as in the Upper German dialect. Middle Franconian shows -f, for *-b* (*wiif*=Weib), j- for g- (*jolden*=*Gulden*), has preserved the old t in the pronominal forms dat, *wat,* dit, it, *allet;* -rp for *rf* (*dorp*), rd for rt, at least in the north, in Ripuarian (centre Cologne), where *up*=*auf* has also escaped the sound-shift.

East Middle German.—The East Middle German group shows initial f<p- first in Thuringian, which dialect marks the transition between West and East Middle German. This change. then spread eastwards; *e.g.,* Ferd, Fund, Feife, Fennig *flücken,* etc. A feature of the Thuringian dialect is the loss of the final *-n* in the infinitive; *e.g.,* (*ge*)*lerne,* in Southern Thuringia even (*ge*)*lern.* This is not shared by the other East Middle German dialects They pronounce the old *hs* in *wachsen,* etc., ks as in the literary language, whilst Thuringia and the West Middle German dialects speak *s*(*s*).

THE DIALECTS TO STANDARD MODERN GERMAN

The language spoken during the Old High German period is remarkable for the fullness and richness of its vowel sounds in word-stems as well as in inflexions. Cf. *elilenti, Elend; luginari, Lügner; karkari, Kerker; menniskono slahta, Menschengeschlecht; herzono, Herzen* (gen. pl.); *furisto, vorderste; hartost,* (am) *härtesten; sibunzug, siebzig; ziohemes,* (*wir*) *ziehen; salbota,* (*er*) *salbte,* gaworahtos, (du) *wirktest,* etc.

Literary Use.—Of the dialects enumerated above, Bavarian and Alemannic, High and Rhenish Franconian as well as Old Saxon are more or less represented in the literature of this peroid. *Cf.* the *"Hildebrandslied"* (mixture of High and Low German), the Old High German *"Isidor"* (Rhenish Franconian), *"Tatian"* (East Franconian), Otfrid's *"Evangelienbuch"* (South Rhenish Franconian), *"Muspilli"* (Bavarian), *"Heliand"* (Old Saxon), Notker's prose (Alemannic). There was no recognized literary language (Schriftsprache) during this period; though the schools in the large monasteries, such as Reichenau, St. Gall, Murbach and Fulda, contributed to the spread and acceptance of certain orthographical rules. Nor did the next period—that of classical Middle High German—give birth to a Schriftsprache. At this period the German language made great advance as a vehicle of literary expression; it acquired a lucidity, flexibility and beauty of style hitherto unknown; although the language lost in richness of sounds owing to the weakening of unstressed vowels to neutral *-e* or their complete disappearance (cf. O.H.G. aro: *ar*[*e*] Aar; *zala: zal:* Zahl; *salida:* saelde). This was the period of the Minnesang (Walther von der Vogelweide) and the great heroic and court epics (*Nibelungenlied,* Hartmann von Aue, Wolfram von Eschenbach and Gotfrid von Strassburg); when literature enjoyed the fostering care of the courts and the nobility (court of Vienna and of Eisenach in Thuringia). At the same time German prose celebrated its first triumphs in the sermons of Berthold von Regensburg, and later in the 14th century in the mystic writings and sermons of Meister Eckhart, Tauler and others. History (Eike von Repkow's Weltchronik) and law (*Sachsenspiegel, Schwabenspiegel*) used the vernacular, and from about the middle of the 13th century German became the language of deeds and charters.

How far did this period aspire after a *Schriftsprache?*[1] About the year 1200 there was undoubtedly a marked tendency towards a unification of the literary language by poets like Walther von der Vogelweide, Hartmann von Aue and Gotfrid von Strassburg, who avoid dialectic peculiarities more particularly in their rhymes, and do not make use of archaic words or forms. There was thus, if not a Middle High German literary language in the widest sense of the word, at least a Middle High German Dichtersprache or poetic language, on an Alemannic-Franconian basis. Whether or how this affected the ordinary speech of the nobility or courts is a matter of conjecture; but it had an undeniable influence on Low German poets, who endeavoured at least to use High German forms in their rhymes. But the efforts of the High German poets to form a uniform language were short-lived. By the end of the 13th century the Dichtersprache disappeared, and the dialects again reigned supreme: yet the desire for a certain degree of uniformity was never again entirely lost. At the close of the 13th century literature had passed from the nobility to the middle classes of the towns; the number of writers who used the German tongue rapidly increased; later the invention of printing, the increase of the schools, the progress of commerce and travel, and above all the religious movement of the Reformation, awakened a desire to be understood by a wider community. A certain amount of uni-

[1] *Cf.* H. Paul, Gab es *eine mhd.* Schrijtsprache? (Halle, 1873); A. Socin, Schriftsprache und Dialekte (Heilbronn, 1888); O. Behaghel, Schrijtsprache und Mundart (Giessen, 1896); S. Singer, Die mhd. *Schriftsprache* (1900); C. Kraus, *Heinrich von Veldecke und die mhd.* Dichtersprache (Halle. 1899); G. Roethe, Die Reimvorreden des *Sachsenspiegels* (1899); H. Tümpel, *Niederdeutsche* Studien (1898).

formity could be found in the language used officially by the great chanceries (Kanzleien), the imperial chancery (first under Charles IV. [1347–78] at Prague, then from Frederick III. [1440–93] at Vienna) and that of the Saxon electorate. About the year 1500 there was no essential difference between the languages of the two chanceries and others soon followed suit.

Luther. — In the midst of this development arose the imposing figure of Luther, who; although by no means the originator of a common High German speech, helped very materially to establish it. He deliberately chose (cf. the often quoted passage in his *Tischreden,* c. 69) the language of the Saxon chancery as the vehicle of his Bible translation and subsequently of his own writings. The differences between Luther's usage and that of the chancery, in phonology and inflection, are small; still in his writings after 1524 he shows more pronounced tendency towards East Middle German. The adoption of the language of the chancery gave rise to the mixed character of sounds and formas which is still a feature of the literary language of Germany. Thus the use of the monophthongs, *ī, ū* and *ü* instead of the old diphthongs *ie,* uo and iie, comes from Middle Germany; the forms of the words and the gender of the nouns follow Middle rather than Upper German usage, whereas, on the other hand, the consonantal system (*p,* to *pf;* d to t) betrays in its main features Upper German (Bavarian-Austrian) origin.

The language of Luther no doubt shows greater originality in its style and vocabulary (cf. its influence on Goethe and the writers of the Sturnt *und* Drang), for in this respect the chancery could obviously afford him but scanty help. His vocabulary is drawn to a great extent from his own native East Middle German dialect. However, it would be a mistake to infer that his language in the orthography given to it by the correctors of the Wittenberg printing presses made any rapid conquest of Germany. It was immediately acceptable to the eastern part of the Middle German district (Thuringia and Silesia), and it found no great difficulty in penetrating into Low Germany, at least into the towns and districts lying to the east of the Sale and Elbe (Magdeburg, Hamburg), thus crushing the aspirations of Low Germany to have a literary language of its own. Protestant Switzerland, on the other hand, resisted the "uncommon new German" until well into the 17th century. The Catholic Lower Rhine (Cologne) and Catholic South Germany held out against it, for to adopt the language of the reformers would have helped their ideas. At the same time, geographical and political conditions, as well as the pronounced character of the Upper German dialects, formed an important obstacle to any speedy unification, in spite of the ever-increasing number of printing presses in all parts of Germany.

Thus in the 16th century Germany was still far from real unity in its language. During the 17th century men like M. Opitz (Buch von der deutschen Poeterey) and J. G. Schottelius (Teutscfze *Sprachkunst,* 1641, and Von der' teutschen *Sprachkunst,* 1663), insisted on the claims of the vernacular to a place beside and even above Latin (in 1687 Christian Thomasius held for the first time lectures in the German language at the University of Leipzig), and established a firm grammatical basis for Luther's common language which, especially in the hymnals, had become modernized and more uniform. About the middle of the 17th century the disparity between the vowels of the singular and plural of the preterite of the strong verbs practically ceases; under East Middle German influence the final e is restored to words like Knabe, Jude, Pfafle, which in South German had been Knab, etc.; the mixed declension (*Ehre,* Ehren; *Schmerz, Schmerzen*) was established, and the plural in -er was extended to some masculine nouns (*Wald,* Walder); the use of the mutated sound has now become the rule as a plural sign (Vater, Baume). Thus the unification of word-forms and the agreement in the vocabulary made great strides, but the exclamation of the Swiss A. von Haller (1708–77) "I am a Swiss, the German language is strange to me," or the language used by the great preacher Abraham a Sancta Clara (1709) are characteristic of the backwardness of the South.

Eighteenth Century Developments. — In the 18th century the Leipzig Professor J. C. Gottsched (Deutsche *Sprachkunst,* 1748) insisted on the claims of the spoken language (*Umgangssprache*) of the educated classes of Upper Saxony (Meissen); *i.e.,* the East Middle German dialect which since the Reformation had much esteem throughout the greater part of Germany, and J. C. Adelung published his Grammatisch-kritisches *Wörterbuch der hochdeutschen Mundart* (1774–86). Later came Bodmer and Ereitinger, the Swiss writers, and Klopstock (*Messias,* 1748), who, partly under the influence of Milton, opposed Gottsched's pedantic conception of the standard language in favour of a more poetical and flexible diction. The "*Stürmer* and Dranger" like the Romanticists later, enriched the vocabulary by many an archaic or vigorous word, and then came the classics Wieland, Herder, Schiller, Goethe, when the movement towards a standard literary language reaches its culmination. But this unification did not imply the creation of an unalterable standard; for, just as the language of Opitz and Schottelius differed from that of Luther, so — although naturally in a lesser degree — the literary language of our day differs from that of the classic writers of the 18th century. Local peculiarities are still to be met with, as in modern German literature from Switzerland or Austria.

But this imperfect unity is limited to the literary language. The differences are much more sharply accentuated in the *Umgangssprache,* the language spoken by educated people throughout Germany: with regard both to pronunciation, where it is naturally most noticeable, and to the choice of words and the construction of sentences. Compared with the times of Goethe and Schiller a certain advance undoubtedly has been made, but the differences between north and south are still great. The question as to whether a unified pronunciation (*Einheitsaussprache*) is possible or even desirable has occupied the attention of academies, scholars and the educated public during recent years, and in 1898 a commission of scholars and theatre directors drew up a scheme of pronunciation for use in the royal theatres of Prussia,[1] which has been recommended to all German theatres by the German Biihnenverein.

GERMAN LAW. (I.) General. — In Germany those questions, the settlement of which primarily concerns the interests of the public, are dealt with under public law, whose chief components are constitutional law and administrative law. The latter, however, does not embrace all the legal principles governing administrative procedure; indeed, private law also partially governs the actions of the Administration. To administrative law appertain only such rules as lay down special regulations for public administration. "Administrative law is therefore that law adapted to the requirements of public administration." (Cf. Fleiner, *Institutionen* des deutschen *Verwaltungsrechts,* p. 61.) It is thus essentially a question of this distinction in content between private and public law; and it is not correct to state that administrative law is that law "which is administered by administrative courts," although administrative courts do exist. (See G. Lassar, *Administrative* Jurisdiction *in* Germany.) But there are also important rules of administrative law, of which the courts have no

[1] *Cf.* Th. Siebs, *Deutsche* Biihnenaussprache (14th cd., Köln, 1927).

cognizance, and their application in the event of disputes is determined by the ordinary courts. While the competence of the administrative courts to decide questions of law extends properly only to questions involving administrative disputes, such questions constitute only a fraction of those matters with which administrative law has to deal.

(II) The fields of activity in which public administration is carried out, preferably under the rules of administrative law, are numerous. Historically the oldest and formerly the most important department is that of the police. In principle the police is competent to act when the public is endangered. There are numerous legal provisions dealing with the prevention of such dangers. They deal, among other things, with the regulation of traffic, combating of dangerous diseases, rules affecting associations, public meetings and the press, also certain industrial activities and the structure of buildings.

A special importance attaches to social insurance (sickness, accident, old age, disablement and unemployment insurance). Closely associated therewith are the provisions for the care of veterans of World War I and of those in need of assistance. The laws for the protection of workmen also come within this province. Moreover, since 1919, legislation relating to taxation has increased enormously as a result of the considerable increase in public expenditure. Furthermore, administrative law regulates public roads, rivers and lakes and the military establishment, while a considerable proportion of the law of communications also falls within its province; also a part of agricultural and forest law (*e.g.*, game, hunting and settlement regulations), as well as the whole field of education, including the universities in so far as the latter are not autonomous. Moreover, public officials are subject in the whole of their relations to administrative law.

(III) Federal Law and State *Law.*—Germany is a federal state with the result that German administrative law is partly federal law and partly state law (*Landesrecht*). Historical development has determined the boundary between the tno. To-day the organization of state departments and the regulations regarding state officials belong to the sphere of the law of the several states, and so do considerable portions of police, agricultural, mining, game and education law, together with the law of water rights. as also the whole sphere of state taxation. On the other hand the federal government (the "Reich") has dealt with the law regarding federal taxation, industrial and labour law, also with matters affecting federal officials, the army, the railways and waterways and other communications and the postal service. The line dividing them is, however, by no means uniform, since in the course of development the empire has frequently encroached on state law or, *e.g.*, in dealing with education, has laid down general rules only, their detailed application being left to the states. The extent and importance of federal law has steadily increased as against the law of the states, a process which, in view of the tendency to greater uniformity in all the relationships of life, is likely to continue in the future.

(IV) *The* General Problems of *Administrative* Law.—In Germany common (gemeines) administrative law exists only as federal law. All other administrative law is general (*allgemeines*) law. There is no general section corresponding to the general section of the civil code. Only with regard to certain special domains, which have been dealt with within recent years. has codification of general rules of law been effected. (See *German* Codes.) However, general principles and rules of law also exist, and these recur in the individual fields of administration. The *nucleus is* the *authority* of the *"rule* of *law"* the principle of which is recognized, but its application to individual cases is still the subject of controversy. It is an inherent characteristic of the bureaucracy that they strive as far as possible to extend the range of their operations to the utmost possible limits left undefined by law; such, at any rate, has been the experience of all modern states, and in the case of Germany there are special historical reasons encouraging such a development. In Germany it was not until the period of 1818–50 that the absolutist system was superseded by a constitutional system. Since in the absolutist state no separation of powers exists, the bureaucracy was, at that time, not bound in practice by principles of law; and it only gradually became accustomed to such subordination. The question of the rule of law accordingly plays an important part in the interrelations of the executive and the legislative.

As in Engiand and the United States, so in Germany the legislature has, to an increasing degree, empowered administrative departments to make regulations. The problems connected with the scope and investiture of such authority, and the question as to whether any particular regulation is or is not ultra *vires,* are of great importance. In their consideration special interest attaches to the determination of the powers of the administration with regard to persons and property. In this connection, particularly in recent years, the fundamental rights embodied in the Federal constitution of 1919 have gained in importance. Among these may be mentioned liberty of the person, inviolability of property. equality before the law, freedom of association, meetings and religion. It is unnecessary to observe that the law cannot prescribe rigid rules to the administrative departments but must necessarily allow them a certain freedom of action. The agency would be powerless to act unless it had a certain discretion (*pouvoir discrétionnaire*). It occasionally happens, however, that departmental action is ultra *vires* and, in practice, particularly with regard to the administrative courts, it is part of the daily work to determine the limits of their conduct. The determining of compensation, due in respect of administrative acts, is also an important branch of administrative law. In recognizing government responsibility in tort the German law differs notably from that of England. If in the exercise of official activity a public servant exceeds his official duty, the private citizen has a claim for compensation against the state. These provisions are interpreted very liberally by the courts and therefore afford satisfactory protection to the citizen.

An important section is devoted to administrative organization. In Germany, too, public administration is either departmental or self-governing. As a result of the federal articulation of Germany the former is either federal administration or state administration. Self-government is, to a very great extent, on a municipal basis. To such belongs the administration of the communes, municipal unions and other organizations which may be compared with that of the counties (Grafschaft). Furthermore, the legislature has to an increasing degree transferred to newly formed self-governing bodies the carrying out of public services, *e.g.*, in the domain of insurance, public health and settlement schemes. The main questions appertaining to organization are concerned with the competence of the administrative departments to deal with the individual problems of public administration, the interrelation of different agencies and the state control of self-governing bodies.

German law does not provide a legal remedy for all administrative disputes. The system is a complicated one. The ordinary courts are competent to deal with some few disputes, defined by the law, but apart from the categories so defined they have no competence to deal with disputes involving public law. Moreover, the administrative courts are competent to act only in such cases as are explicitly defined. If a case does not fall within the definition the only remedy is to lodge a complaint with the department concerned. The administrative courts are, however, always competent to act in matters of practical importance, *e.g.*, in matters affecting the police and taxes, as provided by the so-called general clause. A new movement is in progress in consequence of the example of individual German states to introduce this general clause generally. The administrative courts may not give opinions; their functions are limited to deciding questions of law.

GERMAN CODES

By codification we understand the exhaustive arrangement of a particular subject matter (*e.g.*, commercial or criminal law) according to a uniform plan in a book of law.

The Nature and History of ,Codification. — Modern codifications have only been carried out in Germany since the 18th century. As a result of the adoption of Roman law the Corpus *Juris Civilis* came to be applied in Germany as a whole, subject

to the glosses which had been incorporated by the Bologna school of law. It was a code regulating all legal relationships except in so far as particular rights were otherwise provided for. Moreover, the *Corpus Juris Canonici* had a wide application. There were thus two great code systems in existence. Their validity was profoundly shaken at the beginning of the modern era for the following reasons: The Reformation had very much limited the extent to which the ecclesiastical law could be applied; while the mental attitude toward the question of social relationships had been profoundly modified as a result of a philosophy of enlightenment and the idea of natural law. Moreover, the changes in political, social and economic conditions required new principles of law, since the Roman text books had become archaic and unmanageable, while in the matter of social dynamics they were not sufficiently adapted to the conditions of the modern world. Finally the general conception of law at the time was that all valid law was exclusively state-made law, and by codification it was possible to give effect to this point of view. In the 18th century the German empire broke up into a series of independent states. When the legal constitutional connection between the individual states disappeared, they began to feel the want of a new and independent arrangement of their systems of law. Codification was often a means of confirming a state's reality; and the individual German states set about the task of introducing systems of law that would answer to their national and practical requirements. The most extensive codification of the end of the 18th century, which embraces every branch of law is the *Allgemeine Landrecht fuer die preussischen Staaten* of Feb. 5, 1794. The other individual states all codified the law separately; they dealt specially with private law, with criminal law and with procedure. These collections of laws incorporated much from the general law of the land, and also many special German laws, so that in spite of a certain modernization the general tradition was observed. Moreover, on passing from an absolutist to a constitutional system in Germany, the form of a written constitution was adopted, so that constitutional law itself was codified. The political circumstances of the time, however, were such that this was only done for the individual German states except in the case of the law incorporating the German federation. It was not until the North German confederation and the German empire came into being (in 1866 and 1870 respectively) that the constitutional conditions for the general codification of law obtained. The need for a uniform system of law, especially in the field of commerce, was so strong that a common form had already been arrived at by the individual states in their system of commercial law. Under its constitution the North German federation was already competent to frame laws which should be commonly valid in the individual territories. As this competence increased in scope a number of codifications were effected over a considerable period of years. The scheme which they followed was determined both by the keen need that was felt for rationalizing a constantly growing, and therefore increasingly unmanageable, legal material and by the simplification of all political and commercial relationships and the closely related evolution of the federal constitution of Germany into that of a single individual state.

In order to understand the German codes, it is essential to realize that they apply not to a state of a unitary character, but to a federal state. Even in the case of those parts of the law which had been codified, the empire was not wholly successful in assuming full control of residual legislation (*e.g.*, in questions of police and the law of real property). There are therefore in many codes provisions allowing for assigning certain matters to the legislatures of the individual states. Such are especially matters which had been previously dealt with by the states individually. On the other hand such exceptions are of small scope or nonexistent in those codes which deal with matters which had from the start fallen within the province of the imperial legislature, such as the law relating to national insurance. The importance of reservations in favour of territorial jurisdiction has been greatly diminished in those cases where they still exist.

Apart from this limitation of codes in favour of territorial law, their scope is limited in another direction. When, upon a subject being codified, new legal regulations are required, these are often promulgated as *novellae* to the codes. But frequently independent laws are passed, especially where the code is antiquated. Thus there are about 300 subsidiary laws to the penal code.

THE CIVIL CODE

The German civil code is arranged in five books. It has been largely influenced in its scheme by the general law and by the Prussian general law of real property. The general regulations and the provisions dealing with relationships between debtors have been largely derived from Roman law, while the law of property and of inheritance is Germanic in origin. Its technique does not derive from casuistic theory; indeed the provisions are of a very general phrasing and often conceived in a highly abstract manner. It bears the mark of the individualistic, and in economics of the capitalistic, outlook of the end of the 19th century. Collectivist ideas have had but little influence upon it. Even when it first came into force it was partly inadequate, since it does not deal with the special conditions under which the labouring classes live, although the proletariat already constituted a substantial portion of the population. In theory the code was intended to cover all la s affecting the rights of private individuals excepting commercial law. Moreover, since it came into force, important fields have been regulated by separate federal laws, as for instance motor insurance, contracts for service, the laws relating to young persons. In matters appertaining to the law of things the old territorial law has been largely retained and the competence of territorial jurisdictions for further dealing with matters in this province has been maintained.

As for the separate portions of this code, the general section includes the rules of law laying down what subjects fall within the scope of the legislature and deals with the manner of conducting the business of the courts. It includes regulations regarding interpretation, the statute of limitations, contempt of court, etc.

The law of obligations which is contained in the second book is based upon the principle of freedom of contract. In the first and general section, this book contains the maxims regarding the nature, origin and extinction of the obligation. Its guiding principle is that all obligations are to be carried out in a manner consonant with a true and loyal observation of the generally accepted rules of human intercourse. The special portion of the book deals with individual cases of obligation, such as sale, lease, barter, unjustifiable enrichment, unconscionable actions. This code contains only a few provisions affecting contracts of service and such provisions are of little practical significance. The legal position of workmen and servants is in fact dealt with to a much greater extent by subsidiary laws, especially the wages agreements regulations. These provisions are generally no longer included in the law of persons; together with allied regulations they have been amalgamated into a labour law, the codification of which was completed by the republic.

The law of things of the civil code deals with the law as it affects movable and immovable things, especially ownership, possession and assignable rights. The recent advance of the social idea has profoundly modified the contents of this book. The ownership and user of the land is dealt with in a series of supplementary laws of the postwar period, dealing with usufruct. occupation and life estates.

The law of domestic relations regulates marriage, relationship and guardianship. Reforms affecting divorce and the position of illegitimate children are under consideration. Public interest in child welfare has invalidated the original provisions of the code in several directions (the Juvenile Welfare law of July 9, 1922; the Juvenile Courts law of Feb. 16, 1923). Finally, the fifth book deals with the law of inheritance. It is based on the principle of free disposition over property, with due consideration to be paid, for ethical reasons, to the next-of-kin.

The Commercial Code.—This was of special importance as being the first codification of private law; it was the predecessor of the civil code, into which a large number of the general provisions were subsequently incorporated. It was revised on the

promulgation of the civil code and is now valid as the commercial code for the German empire (May 10, 1897). Since that date numerous *nooellae* have been passed and in addition a series of subsidiary la s of various dates are operative, as for instance the laws governing limited liability companies and unfair competition. On the other hand any isolated reservations by territorial jurisdiction are without practical significance. The private special law of merchants, in so far as it is applicable, is therefore of higher validity than the civil code. It deals more particularly with the problem of assuring liberty of contract and of form, there being also numerous provisions to ensure the revelation of essential facts and to secure good faith (*e.g.*, those dealing with the trade register and *bona fide* acquisition) as well as for the accurate estimation of time and money (suggestions as to the value of commercial services). It is divided into four books. The first contains the legal definitions affecting commerce and such activities as can be practised commercially. The book dealing with commercial associations treats of the legal position of partnerships, joint stock corporations, limited liability companies, et~ The commercial code does not contain any special provisions affecting trusts and cartels, these being dealt with separately. The third book on commercial transactions contains general regulations dealing with them as well as provisions dealing with a series of individual trades, as for instance the purchase of businesses, warehousing and agency matters. The fourth book deals with admiralty law.

The Criminal Code.—The reforming movement of the 18th century left its mark in the field of criminal law. The individual German states codified their criminal law, Bavaria being the first to do so. in 1751. The federal criminal code was not issued until after the unification of Germany (the criminal code of April 16, 1871). This falls into a general and a particular section. The first section contains the general legal definitions regarding the essential nature of crime, its various forms and degrees, explaining what constitutes attempt, complicity and consummation of the act, as well as the system and measure of punishment, preventive arrangements and some further general matters. The special section deals with individual crimes and penalties. The code is, however, far from dealing with every individual criminal action; it is therefore only the general section that is of importance as a code. A revised code was prepared and with regard to certain highly important matters already has been carried into effect. The principle of fines has been adopted as a substitute for short terms of imprisonment, while youthful offenders are dealt with educationally rather than penally, the reformatory principle having been adopted from the French model. New principles are applied for carrying punishment into effect. These reforms, which have been introduced by means of *novellae,* are indicative of the general trend. The distinguishing features will be greater detail in specifying crime, as well as special preventive measures and a considerable widening of judicial discretion, both in the matter of imposing penalties and applying preventive measures and in the matter of granting probation and parole. The military code (draft of April 30, 1926) is in force concurrently with the criminal code. It provides for a number of special military crimes and misdemeanours.

Organization of the Courts and Procedure.—The law relating to the organization of the ordinary courts is codified in the code of judiciary organization. This deals with the office of judge and the organization of the courts, as well as laying down certain general rules for the conduct of their business. In addition, there are two codifications of the procedure to be adopted by ordinary courts, viz., the rules of civil procedure (Jan. 30, 1879) and the rules of criminal procedure. The law of criminal procedure has been codified in the individual states since the middle of the 19th century. On Feb. 1, 1877, the rules of criminal procedure for the German empire were promulgated. Moreover, since World War I, the taxing power in almost all cases has passed from the provincial to the federal government. Here too, codification had been effected through the tax regulations of Dec. 23, 1919.

The importance of the codes is variously estimated in Germany. They have served to crystallize the ideas of law current at the time of their promulgation. The danger is that the law of the state and the law as applied tend to be identified. Codifications in Germany had therefore in the earlier period after their promulgation often tended to make the law rigid and to encourage a cult of the legal system for its own sake. When, however, society and an economic system have outgrown a code, new propositions of law arise in a liberal administration of the law, so that codes suffer the fate of all written legal propositions Moreover, as has already been indicated, individual codifications do not represent an exhaustive treatment of the subject, owing to subsidiary laws that are passed from time to time. In the further course of their development the emphasis of codes tends more and more to be restricted to the general principles. Nevertheless the codes played a highly important role in the development of German law. Every code has tended to make the law more uniform and, in spite of their traditional content, to modernize it. Moreover, the codifications embody to so large a degree those elements of national tradition which are inherent in German legal thought that it is certain they will continue in the future to be an essential part of the German legal system.
