Basic Aspects of National Socialist Law — The political, social and moral revolution which began with the seizure of power on January 30, 1933, by Adolf Hitler and the German National Socialist Workers' party (Nationalsozialistische Deutsche Arbeiterpartei — NSDAP) could not fail to affect deeply the principles of law as well as the techniques used for their application in the administration of justice. As the most striking feature therein appeared that private law, traditionally conceived as the sum total of generally determined and universally valid rights and duties of the individual citizen, was subordinated to the requirements of the state. The borderline between private and public law became obliterated. Private law was wholly superseded by public law, or at least private action was free from state control only if no political considerations were involved. Many activities, considered heretofore in a liberal-democratic milieu as of a purely private and personal character, were converted into public duties and functions. This phenomenon appeared as the consequence and corollary of the limitless expansion of what the regime called the "political" sphere. The term had nothing in common with the pragmatic concept of the "public interest." "Political" in the national socialist system of values defies an exact definition. Signifying the mystical and transcendental power and policies of the state-community', it superseded, paralyzed and destroyed private interests and rights. The content of the "political" was interpreted by national socialist world outlook (*"Weltanschauung"*) and carried into effect by both the state and the party as the instrument of the state.[1]

Such a complete dominance over the members of the community, reducing them from the status of active participants in the national sovereignty, as under the republic, to that of mere subjects or addressees of state power, could be accomplished only by abolishing and eradicating the institutions of individual liberties, due process and the rule of law which the regime stigmatized as antiquated notions of the liberalistic era. This result is all the more remarkable since the German people possess an ingrained tradition of the rule of law *("Rechtsstaat")* which, binding citizens and officials alike, determined the relations between the people and public authorities. That such a revolution could be

[1]Gesetz ueber **die Einheit von Partei und Staat,** Dec 1. 1933 (*Reichsgesetzblatt* I [first part], p. 1016).

accomplished within less than a year after the national socialists had attained the monopoly of political control was due to the legalized application of systematic violence and scientific terror, symbolized by the concentration camp and the executioner's axe, which no present-day people, after centuries of humanized justice, was able to withstand.

The ethical concepts of the regime, in no wise distinguished by constructive originality, were dictated mainly by opportunism and basic opposition to the principles of bourgeois liberalism and humanitarian progress prevailing under the republic. Although obscured by skillful semantics, they may be summarized thus: For the concept of equality and liberty, the western heritage of Roman law, Christian morality and the French Revolution were substituted the new values of the race and racial superiority, social duty and blind obedience to the leader (Fuehrer). Through the medium of an unparalleled propaganda and indoctrination the racial, predominantly anti-Semitic prepossessions of the ruling élite were forced upon the people under the label of "folkish world outlook" (*"Voelkische Weltanschauung"*). With these tenets individual assertion and judicial protection of individual rights were incompatible; their continued existence would have thwarted the monopoly of political power of the national socialist party. The loss of liberty, never highly prized in Germany, was compensated for by temporary economic security, achieved at first by public works, rearmament and state employment. However, it should be understood that the notion of the "master race," which later on served for justifying aggression, had little meaning in the daily life of the people. So abstract and vague a notion as the "superiority" of the "Nordic race" did not penetrate, in spite of its propagandistic over-simplification, into the mind of the average German. Chained to the leviathan of a gigantic war machine, he soon found himself submerged by a new and artificial feudalism. The only visible and tangible result of the racial myth and the "folkish dogma" was that it placed the German people over and above at least one segment of the community, namely, the Jews. Consequently, in volume and intensity the anti-Semitic legislation, at first called "Aryanization," exceeded by far that in any other field.

Much emphasis, for similar reasons of racial regeneration and war preparedness, was placed on populationist aims. Resultant therefrom were many changes in the fields of the law of domestic relations, sexual morality and established values of Christian ethics. While the racial myth and the folkish dogma were likewise responsible for eugenic innovations, some of these seemed valuable enough to deserve retention after the fall of the regime.

Furthermore, a considerable amount of national socialist legislation was conditioned by the political interest of the regime in the economic welfare of sections of the population which, because they were considered as basically favourable to its rule, were favoured at the expense of others. This explains the volume of legislation which, at least prior to the outbreak of World War II, protected the lower middle classes, the consumer and the small debtor, whom the regime had inherited from the preceding years of depression. However, war demands on manpower degraded these classes mercilessly to the status of dispossessed proletarians. Likewise the farmer, another favoured child of the regime, lost during the war his previous prosperity and economic security by the most stringent system of control of production and distribution.

Of the anticapitalistic ingredients of the national socialist program, which had so much contributed to Hitler's early electoral successes, few if any traces remained by 1943. The services of the capitalist organization, into which relatively few party officials and political interlopers had penetrated, proved indispensable for the preparation and the conduct of the war. Capitalism is too technical to allow its operation by party dilettantes. Moreover, the formerly ruling bourgeois class was easily reconciled to the regime by huge profits derived from rearmament.

Private property—one of the two pillars of a liberal society—was preserved by the regime at least in a nominal sense. The classes of the entrepreneurs and the farmers were permitted to retain the legal title to such means of production as the regime deemed essential for its military aims. However, title to ownership was substantially eroded by state regulations as to its use. This was accomplished mainly by incorporating both the industrialist and the farmer into a large-scale planning process. The entire economic structure was covered by a densely woven, highly bureaucratized system of pseudocorporative control by the so-called estates (*"Staende"*) and professional organizations as their affiliated subdivisions. Controlled by party officials, they regulated all phases of production, distribution and consumption. This new professional bureaucracy operated side by side and frequently at cross purposes with the older bureaucracy of the civil service and a new competitive bureaucracy of the national socialist party.

It is obvious that in this system of complete state regulation over the entire social life no place was left for freedom of contract, that other basic principle of a liberal society. Contractual processes were supplanted by state dictation. Free disposition over finance capital was restricted by the state through maximum limits on dividends and revenue, compulsory levies and general insecurity of long-term investments. Contractual freedom was hedged in by the compulsory membership of practically all persons in professional groups and associations which dictated the conditions of contract in all essentials of price, quality, quantity and markets.

The Position of the Courts of Law.—In conformity with the preponderance of the political interest in the administration of justice the position of the judge was fundamentally changed. No longer was he the incorruptible dispenser of objective justice according to established law, irrespective of the persons affected and hence subjecting also the officials of the state to the law of the land. He became a political tool of the regime who, under the pretext of defending the "folkish" values, was little more than a sort of exalted policeman or executive agent of the state. The composition of the bench changed less within the first decade of national socialist rule than might have been expected. The majority of the older judges and public prosecutors consisted of the men trained under the republic, retained by the regime if for no other reason than that a sufficient number of competent party members was not yet available. However, the top positions of the judicial hierarchy were assigned to partisans whenever feasible, and the new system of legal education, based entirely on compliance with national socialist doctrines and techniques, barred access to the magistrature for all except reliable party members. Judicial subservience was accomplished by a vigorous purge of the bench in 1933 and after. The Public Officials act of January 30, 1937,[2] though paying lip service to the principle of the merit system, held the threat of dismissal over the nonconformist judge as over all public officials. Potential denial of tenure and weakening of the protection of other vested rights could not but bend the bench wholly under the political will of the regime. Nonetheless, the supreme court (*Reichsgericht*) and one or the other court of appeals showed a remarkable resilience and, in isolated cases, even a latent defiance of some of the crudest abuses of the administration of justice for party aims.

On the other hand, the bar, purged at an early date of political opponents as well as of most non-Aryans, submitted voluntarily. It paid for it by the loss of much of its former social prestige.

On the whole a regime as anti-intellectual as national socialism had little use for the legal profession.

In the following summary of national socialist law only the salient features are presented, without aiming at completeness or exhaustiveness of the subjects treated.

Constitutional and Administrative Law.—In the pattern of a present-day dictatorship political power and governmental control are achieved by the concentration of legislative and executive functions in the hands of the one ruling man who, in nazi Germany, was styled "Der Fuehrer." He is assisted by a relatively small group of superior officers acting as ministers and party bosses, appointed by and accountable to him alone. The judiciary became equally integrated into the

[2] Deutsches Beamten-Gesetz, Jan. 26, 1937 (*Reichsgesetzblatt* I, p. 39).

unity of command and obedience of the "leadership state" (*Fuehrerstaat*). While the Weimar constitution was never repealed formally, and at times some of its more innocuous articles were still referred to by the courts as valid positive law, the instrumentalities created by it were hollowed out into meaninglessness. The Reichstag, rarely convened and acting as a legislative body only in a few exceptional cases (Nuremberg laws of 1935 and subsequent extensions of the Enabling act of 1933), was used only for political demonstrations. The federal council (Reichsrat) and the economic council (Reichswirtschaftsrat) were abolished at an early date. The Reich-presidency, after von Hindenburg's death in 1934, was merged with the function of the Reich-chancellor and Fuehrer who officially assumed also the role of the "supreme law lord" (Oberster *Gerichtsherr*), claiming for himself paramount jurisdiction, without the formalities of a regular trial, over life and death of civilians and military persons alike.

Probably the most important and perhaps a lasting reform initiated by the regime was the transformation of Germany's federal form of government into a full-fledged unitary state. Beginning in 1933 the elimination of the states (Liinder) proceeded at a rapid pace. As representative of the Reich in each state a Reich-regent was established, accountable only to Hitler; his political importance, however, was virtually eclipsed by that of the party boss, called the *Gauleiter*.[3] On this groundwork subsequently all public services heretofore operated under the responsibility of the Lander were reorganized under unified central control of the Reich by a vast procedure called unification of the law (*"Verreichlichung"* and *Rechtsvereinheitlichung*). This legal reform, levelling down the astounding diversity of many administrative branches, was considered beneficial by many who believed that a widely differentiated system of administration was incompatible with the technological exigencies of a modern state, while it was deplored by those for whom the traditional social and cultural diversification is a positive value. Next to nothing, however, was accomplished in the field of the territorial regrouping of the historically determined boundaries of the political subdivisions of the Reich (*Reichsreform*). The annexation of adjacent lands acquired by aggression (Austria, Memel, Sudetenland, Bohemia and Moravia, Danzig, Poland, Alsace-Lorraine) imposed upon the regime the enormous task of co-ordinating them administrationally and integrating them into the system of German law. This process, called "legal assimilation" (*"Rechtsangleichung"*), absorbed most of the time of the ministry of justice which might otherwise have been devoted to more constructiye tasks.

Racial Legislation. — Racial legislation (Rassengesetzgebung) served mainly though not exclusively for the elimination of the Jewish population. While formally belonging to the realm of private law, by virtue of its political significance it became a branch of law in its own right. The basic regulations are found in the so-called Nuremberg laws of 1935, the best known single statute of the Third Reich and well deserving its sinister reputation as the most flagrant violation of the principles of civilized society, namely, Act on "the Protection of Blood and Honor," and Reich Citizens act (Gesetz *zum Schutz* des *Blutes und* der *Ehre; Reichsbuergergesetz* of Sept. 15, 1935).[4] Followed by a stream of exerutory ordinances, they gave rise to a vast volume of a novel kind of jurisprudence dealing with the new crime of "race defilement" (*Rassenschande*) (sexual intercourse between Jews and non-Jews) and similar situations of an amazing variety. Jews are defined as persons with four or three Jewish grandparents. A Jew is also a person with only two Jewish grandparents, provided he practises the Jewish religion or is married to a Jewish partner. Marriage between Jews and Aryans is a punishable crime and illegal. Jews are excluded from German citizenship. The gruesome story of the subsequent complete outlawry of the Jews, the exclusion from the professions as well as from economic life, the spoliation of their entire property, the expulsion to the ghettos of the East and their final extermination by fire and sword at the behest of Hitler was perhaps the most revolting single episode in the career of the Third Reich.

Civil Law. — Surprisingly little was accomplished by the regime concerning the much advertised basic reforms of the civil law proper. Most of the actual changes occurred in connection with the racial dogma. Others aere already planned Ly the Weimar republic, whose findings the regime utilized in claiming exclusive credit for the accomplishment.

(a) Succession Law. — In 1938 a reform[5] of the last book of the civil code facilitated the establishment of last wills, a measure which might well be considered beneficial, since the excessive formalism of the civil code frequently invalidated testamentary dispositions for purely formal violations of the procedure of drafting However, even this reform was not devoid of political implications in that a testamentary provision is void not only if in conflict with legal provisions but, beyond that, if it grossly disregards the duties toward his family and the common weal incumbent on the testator from the viewpoint of the "healthy sentiment of the people."

Objections by the family against testamentary provisions which appear politically or racially objectionable were encouraged Permitted was disinheriting of Jews and of persons considered politically undesirable.[6]

(b) Law o j Domestic Relations –A number of new provisions, most of them unobjectionable and laudable, introduced certain hygienic and eugenic requirements for the conclusion of the marital bond. Marriage between persons affected by hereditary sickness was to be prevented.? A certificate of health (*Ehetauglichkeitszeugnis*) must be obtained prior to the marriage ceremony. Contracts of marriage and adoption were voidable[8] if the maintenance of the family relationship appeared morally unjustified, that is, in case the institutions of marriage and adoption were abused only to confer the name of the husband to a wife, or of the adopting person to the adoptee. The civil register of vital statistics (*Personenstandsverzeichnis*), which, serving in Germany for the identification and control of persons, had a considerable political significance, was modernized and centralized[9] It introduced the family book, into which all facts concerning the civil status are entered officially. However, the most incisive reform in the law of domestic relations occurred in 1938 when the situation in newly annexed Catholic Austria, where divorce had become practically unobtainable, was used as a leverage for drastically recasting the divorce law for all Germany.[10] It had been under fire for a long time because it made custody of the children, as well as alimony of the divorced wife, dependent on the attribution of guilt to one or both partners by judicial declaration in the divorce decree. The result of this unsound procedure was that the parties, in contravention of the law, frequently agreed on a conventional or prearranged procedure, openly or tacitly tolerated by the courts. After 1933, the number of divorce cases rose sharply. The courts granted divorce for racial and political reasons; "Aryan" partners were subjected to pressure to seek annulment under the pretext that they had committed an error in not realizing the implications of "diversity of race" at the time of the conclusion of the marriage. Although the act did not eliminate altogether guilt of a partner as ground for divorce, it allowed dissolution of the marital bond also on the ground of what was called "objective disruption of the marital relations" without resorting to the artificial concept of guilt. Thus, three grounds for divorce were legalized, namely, (a)

those based on guilt, such as adultery; persistent and unreasonable refusal to beget or to bear offspring; other conduct which makes the continuation of the marriage unbearable for the copartner; (b) medical or eugenic grounds, such as mental or contagious disease and premature sterility; (c) objective disruption, evidenced by not having lived together for three years. The reform, incorporating much of the demands of the liberal era, was on the whole, commendable. However, it was not devoid of political and racial connotations, such as the effort to increase the birth rate; moreover, by attempting to eliminate the so-called "sick" marriages it opened the door to grave injustice to an innocent wife.

The planned legal reform of the position of the child born out of wedlock was not accomplished; but illegitimate birth was officially encouraged for military reasons by propaganda, indoctrination and support of mother and child by the state. Consequently, sexual morality reached an all-time low. Political motives were also responsible for one of the most absurd enactments of the regime," which permitted contesting ex *officio* the legitimacy of a child by the public prosecutor. Intended to enable prominent party members to rid themselves of the stigma of Jewish ancestry, it was widely abused by the device of falsely imputing intercourse with a Jewish partner to a living or dead parent.

Other Fields of Civil Law.—In spite of the hectic legislative activities no basic changes of other branches of civil law were recorded. In accordance with the establishment of the unitary state since April 1936, a uniform real estate and mortgage register[12] was in use all over the Reich. Entails (*Familienfideikommisse*) were abolished after Jan. 1, 1939.[13] If this law had been vigorously enforced against the latifundia in the regions east of the Elbe it would have gone a long way in destroying the economic power of the Junkers class, still prominent in governmental and military positions, although the feudal landowner had benefited from the creation of the "hereditary farm" (see below).

No important changes occurred in the law of associations (Vereinsrecht) and of co-operatives (Genossenschaftsrecht) except that they were brought under the ubiquitous political control of the regime. Nor were any changes made in the text of the second book of the civil code, the law of obligations (*Schuldrecht*); contractual self-determination was superseded and eroded by the device of compulsory membership in professional groups and associations endowed with far-reaching and practically monopolistic regulatory powers. Much theorizing about a new "folkish" approach to the law of contract and the fulminations against the "Roman-Jewish" Pandectist tradition induced substantive changes neither in the code nor in its interpretation by the courts. The main features of reform in this field were economic facilities and privileges granted for political reasons to the small debtor, a phenomenon well known in most accomplished revolutions. Old debts and mortgages were liquidated;[14] interest rates were reduced;[15] the debtor should be in a position to carry only debts in accordance with his income. Already in 1933 special tribunals for debt reductions and debt release were established.[16] Similar protective purposes served the rent control law which made rent increases dependent on judicial authorization.[17] Soldiers causing damage in the fulfilment of their duties are not liable personally except in case of wilful or negligent action.[18]

Farm Law.—Perhaps the most important innovation in the field of civil law was the legal recognition of the farmer as a separate and privileged class by the Hereditary Farm act of 1933.[19] A new nobility of middle-class farmers was created as the manifest fruition of the "blood-and-soil" doctrine of the regime. All estates up to about 300 acres, with the exception of dwarf farms, became entails in the hands of a member of the family as a hereditary homestead. Upon his death it passes undivided to the oldest (or youngest) son, or the nearest male relatives. It cannot be sold in whole or in part nor mortgaged without previous authorization of the newly created Hereditary Farm tribunal. The other disinherited children are compensated on paper only by a claim to "support" on the farm. The dilemma of these dispossessed groups was easily solved by the manpower demands under rearmament and war. The Hereditary Farm tribunals developed a vast body of a new law called farmer law (*Bauernrecht*), as a result of the deep inroads the privileged class had made into the ordinary common law, particularly into immovables, obligations and succession.[20] After the conquest of Poland and the western districts of Russia the German farmer benefited from the wholesale confiscation, without compensation for the lawful owner, of enemy property. All agricultural land not previously (that is, before Sept. 1, 1939) owned by a German (*Volksdeutscher*) could be taken under what was boldly styled "public administration" and was transferred to a suitable partisan of the regime.[21] This statute was the legal basis of making Lebensraum for the Herrenvolk.

Commercial Law.—The regime gave little attention to commercial law, evolved as the instrument of mobile capital and monied property. Since it was considered of no "folkish" significance for an economy based internally on compulsory distribution and marketing and externally on strict exchange control and large-scale bartering, the commercial code was not subjected to basic modifications. The most important measure of legislative reform referred to the joint stock corporation (*Aktiengesellschaft*). Although the statute of 1937[22] was boldly proclaimed as "realizing basic postulates of the economic philosophy" of the regime, it was rather more a concession to big business, management and the owners of controlling packets of shares than one which would conform to the anticapitalistic ingredients of the national socialist program. On the whole the Aktiengesellschaft lost under the nazis much of the popular magic the preceding liberal era bestowed upon it. The minimum capital was fixed at 500,000 Reichsmark, thus making the joint stock corporation the exclusive instrument of big business, inaccessible to small enterprises. The manager was given more responsibility in conformity with the leadership principle; the rights of individual stockholders were considerably curbed. The board of directors was under an obligation to consider, in the conduct of business, the common welfare. No effective curbs on salaries were introduced. However, since the regime did not believe in the anonymity of commercial transactions, the transformation of stock companies into partnerships was encouraged[23] and even imposed. The conversion proceeded at a rapid pace. The complementary reform of partnerships and corporations with limited responsibility (Gesellschaft *mit* beschraenkter Hajtung) was not undertaken. The formidable task of establishing a new register for all commercial firms was successfully accomplished,[24] separating the registers for partnerships and for each other legal form of business enterprise.

Protection of the small shop owner and merchant, one of the basic economic demands of the national socialist program of 1920, was only temporary.[25] Decimation of this class by the combing-out process of the manpower drive broke the backbone of the lower middle class more effectively than the inflation of 1923, and possibly beyond reconstruction after the war. Likewise the dogmatic attack against cartels and trusts, serving at first for the protection of the small and independent businessman against the

encroachment by big concerns,[26] was soon halted. In due course the mammoth cartels were permitted to swallow completely what little the state had left of the small entrepreneur. The cartels proved indispensable for the Four Years plan of 1936.

On the credit side of the regime was the rewriting of the more or less obsolete law of patents, trade marks and protected samples.[27] The reform of the patent law fulfilled postulates which antedated the regime, by breaking down excessive protection of the individual inventor and making the invention, under safeguard of his financial interests, more accessible to use by the community and for the common welfare.

The Law **of Civil** Procedure.— The German code of civil procedure of 1877 (Civilprocessordnung) had not escaped the basic dilemma of all procedural codes, namely, to reconcile the postulates of thoroughness and speed without sacrificing one to the other. If it was true that the "technicality" of the German procedural code frequently delayed decisions it was no less true that, in the hands of well-trained lawyers, it permitted an effective administration of justice. Once more the nazis benefited from previous proposals of the Republic when they enacted, in 1933, what purported to be a basic reform of procedure.[28] Evidence was taken before the entire court instead of before the single judge or a judge-referee. Such "immediateness of evidence" led to a considerable acceleration of the trial and permitted in most cases (86% to 92% in 1938) to concentrate it, after due preparation by motions and pleadings, into one hearing. In addition, the presiding judge now was given more power over pleadings—a move which again contributed to shortening the average trial. An act of 1935[29] released the *Reichsgericht* from the binding force of such of its own precedents as had occurred prior to the advent of national socialism. As far as can be judged in view of the general decline in the number of cases on the dockets of the courts, the reform of the procedure gave beneficial results although the acceleration of the trial is not necessarily conducive to a better decision of the case.

In the course of the unification of the administration of justice, the entire judicial personnel was made subject to control by the Reich.[30] Centralization applied also to all affiliated legal professions, such as the bar[31] and public notaries.[32] Lawyers, judges and public prosecutors have to undergo a training and indoctrination in camps before being admitted to the state examinations. All applicants must be members of the NSDAP or its affiliated organizations.[33] It should be noted here that the practising lawyers also became quasi-public officials and were admitted to practice only on probation. On Oct. 1, 1937 only 17,381 lawyers were registered as being admitted to practice, a figure which is the lowest since the foundation of the German Reich in 1871.

Labour Law.—Labour was another privileged child of the regime, in consonance with the socialist ingredients of the national socialist program. A new, and as the nazis chose to call it, an "ennobled" status was bestowed on the working class, exempting it substantially from the common law. The trade unions were eliminated by force at the earliest possible moment (May 2, 1933); their substantial properties, accumulated during many years of workingmen's contributions, were confiscated and transferred to the German labour front, the huge single labour union permitted. Thereafter the German labour front was the only legally recognized labour union in Germany, a leviathan of some 30,000,000 members whose operation by the party was perhaps the greatest organizational achievement of the regime during its peacetime existence. A new labour code of 1934,[34] the basic charter of capital and labour, proclaimed the leadership principle in business. The owner of the plant, factory or business was the "leader of the enterprise," while the employees were the "followers." The new feudality was reflected by the new concept of labour, which was converted from an individual right into a social duty. Loyalty to the "shop community" was rigorously demanded from all concerned and enforced by the local labour trustee appointed by the ministry of labour.[35] A shop council had consultative voice in the management, but the leader of the enterprise was the undisputed master in determining labour relations. The shop councils were to be elected by all employees; but this very last vestige of elective procedures was abolished in 1934. The social honour courts[36] heard complaints on alleged violations of the social principles governing the code of business Controversies affecting individual employees were decided by the regular labour courts instituted by the social legislation of the republic.[37] The panels of employers and employees from among whom the lay assessors of these courts were chosen were prepared by the labour front. Only loyal party members were summoned to serve in the judicial positions. Questions arising from collective contracts, however, were no longer under the jurisdiction of the labour courts. On the whole, the legal security of the individual worker suffered gravely by the competitive interference of other agencies, namely, the social honour courts and the party courts, the officials of the labour front and the quasi-judicial organizations of the various "estates." Though the complexity of overlapping and conflicting jurisdictions resulted in the complete control of the state over labour, it may be contended as evidenced by the decisions of the labour courts and other authorities, that labour fared better than the employer except, of course, for the fact that the biggest employer happened to be the state.

Some observations on the position of labour under national socialism may be in order. The regime prided itself on having created what the doctrine praised as "German socialism." Productive society rested on three pillars, namely, labour, to which the highest value is accorded; soil, in which the farmer is rooted; and finally, capital, for which the entrepreneur (Unternehmer) is responsible. Control of the interplay of these three forces by the state was the essence of German socialism. By allegedly having weeded out the purely acquisitive character of capital and by making the work of the labourer and the farmer both a personal honour and a national duty, a socialistic millennium of typically German flavour was said to have been established. Of this so much at least is true, that both capital and labour were equally under the heel of the regime. But it is equally true that labour was compensated for the complete loss of its rights by a visible increase in social prestige. Labour became sanctified as a national institution. The labour front operated the gigantic enterprise of "Strength Through Joy" (Kraft durch *Freude*), used less as a means of entertainment than of ever-present control and indoctrination of the labour element. "Dignity of work" and stimulating labour surroundings testified to the care of the labour front officials. But what improvements of labour conditions during the first years occurred were sacrificed after 1936 to the Four Years plan and to the requirements of economic and military mobilization. The 8 hour day, still valid on paper, gave way to 10, 12 or more hours in industries of "political importance for the state."[38] Universal labour conscription for all men and women was introduced as early as 1938.[39] Wages were frozen at about the lowest level of the depression and were bearable only by the most rigid price control which to date (1943) had prevented inflation. Distribution of labour was strictly regulated and controlled by the state authorities, the worker being compelled to take the job assigned to him under penalty of treason. The

tremendous strain placed on German economy by the war created an unprecedented situation. The entire nation slaved for the new Pharaoh called State. Labour especially became sullen and restless, kept in submission of serfdom only by the iron hand of the gestapo. Nonetheless, although labour organization was destroyed to its foundation, it is likely that the proud memory of labour self-government could be revived and that, after the fall of the regime, labour would find its balance more securely than the other classes of the people likewise levelled down by the steamroller of the regime.

Criminal Law.—Criminal law is the most essential legal mechanism for a dictatorship based on compulsion and force instead of on persuasion and voluntary consent of the people. Its primary function is that of maintaining and stabilizing the regime in power. In accordance with the anti-individualistic tenets of the regime the common criminal law was punctured by numerous political crimes and sanctions demonstrating the "virility" of the new society and of those directing it. Consequently, national socialism was characterized, though not distinguished, by what may be described as easily the most elaborate system of the defense of the state in existence anywhere.

Legislation for the Defense of the Political Order.

For obvious reasons of self-preservation the regime at the earliest moment equipped itself with the sharpest weapons of retaliation against its enemies, and in the following years intensified and applied them ruthlessly. The penological practice of all dictatorships is determined by the "virile" principles of determent and retribution; it breathes the spirit of harshness and brutality. Execution of the punitive measures was entrusted to the political police (*Geheime Staatspolizei*), popularly known as the gestapo, which under Himmler became an independent supreme Reich-authority; it was subordinated, only nominally for that matter, to Hitler and explicitly placed beyond judicial and administrative control.[40] The range of political crimes was considerably extended. Treason, confined in states under the rule of law to actual attempts at the sovereignty and integrity of the state, acquired under national socialism a ubiquitous and almost commonplace connotation. Of the more important enactments only the following may be mentioned: In 1933 two ordinances of the Reich-president were directed against treason and attacks against the government,"' supplemented by an even more stringent law of 1934.[42] In the daily life of the people the most dreaded act was the famous *"Heinztuecke"* (insidiousness) statute of 1934;[43] it penalized even harmless utterances if deemed detrimental to the stability of the regime, or if considered apt to "undermine the confidence of the people in its leaders." Acts of actual resistance as well as attempts at organizing or expressing political opposition were under heavy penalties. Those enemies of the state who escaped nazi terrorism by taking refuge abroad were struck by wholesale denaturalization and confiscation of their property.[44] Capital punishment threatened those venturing attacks on state or party officials and indulging in inimical propaganda, even if undertaken abroad, by a statute delicately styled "for the safeguarding of the peace of law."[45] Other enactments of similar content were the law against acts of political violence[46] introducing the death penalty or life term of penal servitude for many felonies at common law. This vast array of criminal sanctions was climaxed by a comprehensive act of 1934, redefining and extending the categories of treason and treasonable activities, conspiracy with foreign powers and other attacks against the internal and external security of the state.[47] With the conversion of Germany into a single-party state the NSDAP held the monopoly of political organization, incorporated in, and carrying the state." Reconstruction of dissolved, or formation of new, political parties, or attempts at such activities, were treated as treason.[49] Even reading or communication of prohibited foreign newspapers or listening to foreign broadcasts constituted treason. In September 1939, after the outbreak of the war, the measures for protecting internal security were again intensified. Acts which possibly could hinder the total war or which exploited the abnormal conditions created by the emergency were exposed to heavy penalties.[50] This Draconian enactment was directed against any anti-national combination (*volksfeindliche Verbindung*), against misuse of blackouts for looting, and against sabotage. It was followed by an even more severe ordinance against crimes committed by violence.[50a] On the basis of these laws numerous cases of capital punishment for activities on the black market, listening to foreign broadcasts, resistance to measures of economic mobilization, violation of currency regulations, were reported.

On the other hand, frequent amnesties[51] for criminal activities and quashing of prosecutions of party members and similarly privileged persons who had violated the law "in excessive zeal for the fight of national socialism" did not contribute to making the supporters of the regime more law-abiding. Party members when summoned as witnesses were granted the privilege of professional secrecy and must testify only with the authorization of their party superiors." For their crimes they were tried by special party courts, the ordinary courts being denied jurisdiction over them.[53] SS formations were exempted from the jurisdiction of the ordinary military tribunals.[54]

Common Criminal Law.—The substance of common criminal law, contained in the penal code, underwent fewer changes than might be expected in view of the grandiloquent announcements of leading lawyers of the regime to the effect that substantive criminal law must reflect the new philosophy of the regime. A full-fledged reform of the liberal criminal code of May 15, 1871, drafted by a commission of experts in the national socialist doctrine before 1936, was never passed by the Reichscabinet "owing to the pressure of events in foreign politics." The draft was never published; but its main purpose was to make honour and the mysteries of folkish values the keystone of criminal protection. Punishable no longer was the act as committed but the criminal intention on which it was predicated. On this "legal" presumption, operating on implied or imaginary psychological premises, and deliberately flouting the postulates of truth and evidence-proven truth, a new criminal law called *Willensstrafrecht* was to be established. However, what became revolutionized was rather the spirit of the administration of criminal iustice than criminal law proper. For practical purposes the regime rksorted to the technique of "administrative instructions for the internal service" (*Verwaltungsverordnungen fuer den Inneren Dienst*). Their legal character is obscure; but it appears that, addressed to the executory agencies only, they were beyond the jurisdiction of the courts. Such instructions were issued for procedure; exemption from punishment; dispensation of mercy; compensation for people innocently held in custody, the latter of course not applicable to persons subjected to protective custody (*Schutzhaft*).

Of minor additions inserted into the criminal code, without influence on either its system or its basic principles, may be mentioned punishment of highway robbery through motorcar traps" and kidnapping of children." The law against economic sabotage[57] penalized Germans who "wilfully and callously or for other depraved motives transfer property values abroad or fail to remove them therefrom."

Of a more basic importance because of their programmatic content were new statutes against what the reeime calls habitual criminals.[58] These measures, enacted for the otherwise commendable purpose of reducing professional crime, permitted custody in concentration camps and confinement to work with hard labour as retaliatory, as well as sterilization as preventive, measures. In practice, the program was vitiated by its extension to persons whose alleged inclination to crime consisted of political non-conformity. However, this legislation was in line with the eugenics policies of the regime.[59] Climaxing large-scale sterilization carried out currently, racial fanaticism led during the war to wholesale slaughter of allegedly incurable inmates of asylums under the pretext of mercy killings—a measure which deeply outraged even

the blunted conscience of the German people.

Spurning the liberalistic idea that the convicted criminal deserves humane treatment and that punishment should serve his re-education no less than retribution, harshness in meting out excessive penalties was matched and surpassed by utmost severity toward prisoners.[60]

On the whole commendable was the policy which provided for a special protection to youth. In addition to a uniform law for the training of youth of 1934, special courts for youth protection were created, dealing with criminal actions committed against young people (*e.g.,* sexual criminals; maltreatment of children; exploitation of young persons).

Whether the deliberate brutality of the criminal law and its application was instrumental in deterring potential criminals remains an open question in view of the lack of reliable statistics and of war conditions, which generally result in an increase of criminality.

Criminal Procedure. — Deep inroads into the time-honoured principles of the rule of law and due process, to whose evolution German legal thinking had contributed much in the past, were recorded in the field of criminal procedure. While civil procedure offered little opportunity for national socialist experimentations, political tenets of the regime were carried into the administration of criminal justice and distorted it beyond recognition. Most of these elements of procedure, which, in the process of humanizing the law, had been introduced in order to protect the accused against injustice and arbitrariness of the state, were whittled away. The burden of proof of his innocence was on the accused. Publicity of trial, rights of defense and appeal and of mercy were curtailed. Special courts (*Sondergerichte*) were established which, under a summary procedure, assumed jurisdiction over many matters previously assigned to the ordinary courts.[61] At first these special courts had to deal mainly with the defense of the state until under the reform of 1938 any offense at the discretion of the public prosecutor could be brought befcre this court.[62] The most dreaded extraordinary court, however, was the people's court (Volks*gerichtshof*),[63] truly a revolutionary tribunal of the Star Chamber type, formally incorporated in 1936 as a permanent court into the judiciary system.[64] Composed of a majority of lay assessors not trained in the law and selected for possessing "intimate knowledge of the political trends of the nation," it judged *in camera;* no appeal was permitted. Most of the traditional rights of the accused were abrogated. He mas not even allowed to choose his own counsel, who n-as assigned to him by the court from among a special group of trusted party lawyers. Preliminary investigation and the decree of commencement were granted only at the discretion of the court.

In numerous other cases the traditional principles of justice according to law were openly jettisoned. Statutes were made retroactive;[65] unusual punishments were introduced, such as hanging instead of decapitation. The most notorious break with the rule of law occurred in 1935[66] when the judge was formally freed from the observance of the positive law. Whenever the criminal code offered no basis for conviction he was authorized to apply a similar statute by way of analogy, a penological technique which had been rejected consistently by all civilized systems of lam. Legalized arbitrariness was carried even farther by the provision that in determining an act as punishable it is sufficient if, in the opinion of the court, the moral precepts of the "racial conscience" of "the average man" demand punishment. By thus abandoning the maxim of *nulla poena* sine lege, nazi Germany officially proclaimed justice without law. However, it appears that few judges were bold enough to resort to such devices, partly because the dense network of punitive provisions left hardly a chance for a conviction without an apposite provision, partly because the training of German judges makes them servants rather than masters of the written law. Simultaneously protective custody (*Schutzhaft*) without indictment and trial and of indefinite length, imposed and administered by the Gestapo, which heretofore had been applied more or less as a political measure outside the law, was made legal. The criminal courts were freed from most procedural restrictions concerning evidence and trial. The supreme court was authorized to abandon stare decisis. The prohibition of a more severe sentence on appeal (*reformatio in peius*) was lifted. This trend of rendering the accused defenseless and the judge supreme mas finally climaxed after the outbreak of the war in a decree[67] by which the public prosecutor of the *Reichsgericht* acting as delegate for the "judicial overlordship of the Fuehrer" (*Gerichtsherrlichkeit* des Fuehrers), was authorized to request that a special panel (*Senat*) of the supreme court set aside ex post facto any previous decision of any court, even if it had accrued to a res judicata. The special panel is obligated to reopen the case and to decide it according to instructions issued by the prosecuting authority. This procedure is called "ausserordentlicher Einspruch gegen reclztskraeftige *Urteile"* The motive behind this reform was that of overruling an undesirable, or undesirably mild, sentence. In view of such universal corruption of criminal justice it meant little that on various critical occasions, such as after the blood purge of June 1934 and again in 1942, Hitler had arrogated to himself supreme judicial functions, overriding all ordinary and special courts.[68]

GERMAN LITERATURE. The literary history of the German-speaking peoples of the continent of Europe may conveniently be divided into six main sections:

I. The Old High German period, from the earliest records to the middle of the 11th century.

II. The Middle High German period, from the middle of the 11th to the end of the 14th century.

III. The Transition period, covering the 15th and 16th centuries.

IV. The Period of Renaissance and Baroque, from the end of the 16th century to the middle of the 18th.

V. The Classical and Romantic period of modern German literature, from the middle of the 18th century to Goethe's death in 1832.

VI. The period from Goethe's death to the present day.

I. THE OLD HIGH GERMAN PERIOD (c.750–1050)

There are no records which can justify us in inferring that the continental Germanic tribes possessed a written literature before the age of Charlemagne. But the sagas out of which the German national epics of a later date were welded originated in the great upheaval of the 5th century known as the *Volkerwanderung,* or "Migration." Thus one might speak of an earlier period of unwritten poetry. When the vernacular literature began to emerge in the 9th century, it was merely a faint reflection of the activity of the monasteries; and this, with very few exceptions, Old High German literature remained. Translations of the liturgy, of Tatian's Gospel Harmony (*c.* 835), of fragments of sermons, form a large proportion of it. Rarely, as in the so-called *Monsee Fragments* and at the end of the period in the prose of Notker Labeo (d. 1022), does this ecclesiastical prose attain any kind of literary style. But it had no vitality of its own; it virtually sprang into existence at the command of Charlemagne, whose policy with regard to the use of the vernacular in place of Latin was liberal and far-seeing; and it docilely obeyed the tastes of the rulers that followed, becoming severely orthodox under Louis the Pious, and consenting to extinction when the Saxon emperors withdrew their favour from it. Of the poetic fragments the most interesting are the *Merseburg Charms* (*Zaubersprüche*), the *Wessobrunn* Prayer (*c.* 780), the *Muspilli,* an imaginative description of the Day of Judgment, and the *Ludwigslied* (881), the first German historical ballad. The Gospel Book (*Liber evangeliorum*) of Otfrid of Weissenburg (*c.* 800–870) is the earliest attempt to supersede alliteration in German poetry by rhyme; but for the only genuine poetry of this epoch we have to look to the Low German races. To Saxon tradition we owe the earliest extant fragment of a national saga, the Lay of *Hildebrand* (*Hildebrandslied, c.* 800),

[60] Verordnung ueber den Vollzug der Freiheitsstrafen und ueber Massregeln der Sicherung und Besserung, die mit der Freiheitsstrafe verbunden sind, May 14, 1934 (I, 383); Proclamation of April 25, 1933 (I, 233) concerning equally harsh treatment of prisoners who committed a crime in pursuance of their political convictions ("Ueberzeugungstaeter"). and a Saxon poet was the author of a vigorous alliterative version of the Gospel story, the Heliand (c. 830), which is worthy of being described as an epic. Of the existence of a lyric poetry we only know by hearsay; and the drama had nowhere in Europe yet advanced beyond an ecclesiastical function. Such as it was, the vernacular literature of the Old High German period enjoyed but a brief life, and the literature of the 10th and 11th centuries again reverted to Latin. The Lay of Walter (*Waltharilied,* c. 930), by Ekkehard of St. Gall, the moralizing dramas of the nun, Hrosvitha of Gandersheim, the Ecbasis captivi (c. 940), earliest of all the beast epics, and the romantic adventures of Ruodlieb (c. 1030), although not in German, foreshadow the future developments of German poetry.

II. THE MIDDLE HIGH GERMAN PERIOD (1050–1350)

The beginnings of Middle High German literature were slow and tentative after the set-back of the 11th century. The Church had no helping hand to offer, as in the more liberal epoch of the great Charles; for, at the middle of the 11th century, when the linguistic change from Old to Middle High German was taking place, a religious asceticism, originating in the Burgundian monastery of Cluny, cast a blight over secular poetry. Lugubrious in their asceticism are poems like Memento *mori* (c. 1050), Vom *Glauben,* a verse commentary on the creed by a monk Hartmann (c. 1120), and verses on "the remembrance of death" (*Von des tôdes* gehugede) by Heinrich von Melk (c. 1160). But in the Ezzolied (1063), a spirited lay by a monk of Bamberg on the life, miracles and death of Christ, and in the *Annolied* (c. 1080), a poem in praise of the archbishop Anno of Cologne, the tone is less monotonous.

A freer poetic spirit is to be seen, too, in the lyric poetry inspired by the Virgin, in the legends of the saints which bulk so largely in the poetry of the 12th century, and in the Kaiserchronik (c. 1130–50), a long, confused chronicle of world history. The national sagas begin to emerge in the popular literature. To the wandering *Spielleute* we owe the romance of *König Rother* (c. 1160), and the kindred stories of *Orendel,* Oswald and Salomon *und Markolf.* These poems bear witness to the influence of the crusades; as do also the Alexanderlied (c. 1130), and Herzog *Ernst* (c. 1180), which point the way to the court epic. The *Chanson* de Roland (Rolandslied) was, about 1135, reproduced in German by Konrad of Regensburg.

The court epic begins in Germany with the Tristrant (c. 1180) of Eilhart von Oberge, and a knightly romance of Floris *und Blancheflur.* In these years, too, the beast epic, already represented by the Latin Ecbasis captivi, was reintroduced into Germany by an Alsatian monk, Heinrich der Glîchezâre, who based his *Reinhart Fuchs* (*c.* 1180) on the French Roman de *Renart.* Lastly, the *Minnesang,* or lyric, burst out with extraordinary vigour in the last decades of the 12th century. Its origins are obscure, and it is debatable how much in it is indigenous and national, how much due to French and Provencal influence; but the freshness and originality of the early South German singers, such as Kürenberg, Dietmar von Eist, Friedrich von Hausen and Heinrich von Morungen, are not to be questioned. The satirical *Spruchdichtung* is represented by two poets who call themselves Herger and "Der Spervogel," and was less dependent on foreign models.

Mediaeval Poetry. — Such was the preparation for the extraordinarily brilliant although brief epoch of German mediaeval poetry which was contemporary with the reigns of the Hohenstaufen emperors, Frederick I. Barbarossa, Henry VI. and Frederick II. National epic, court epic and Minnesang — these three types of mediaeval German literature, to which may be added as a smaller group, didactic poetry, comprise virtually all that has come down to us in Middle High German. A Middle High German prose hardly existed, and the drama, such as it was, was still essentially Latin.

The first place among the National epics belongs to the *Nibelungenlied,* which received its present form in Austria about the end of the 12th century. Combining. as it does, elements from various cycles of sagas — the lower Rhenish legend of Siegfried, the Burgundian saga of Gunther and Hagen, the Gothic saga of Dietrich and Etzel — it is the representative epic of German mediaeval life. And in dramatic intensity and singleness of purpose it is the greatest of them all. Whoever the welder of the sagas may have been, he was clearly a poet of lofty imagination and high epic gifts (see NIBELUNGENLIED). Less imposing is the second of the German national epics, *Gudrun,* which, as it has come down to us, is the work of an Austrian; but the home of the saga is on the shores of the North sea. Dietrich von Bern (*i.e.,* of Verona), or Theodoric the Great, who had been looked upon for hundreds of years by the German people as their national hero, has been celebrated in no epic comparable to the *Nibelungen*lied, but he appears in the background of a number of romances— Die Rabenschlacht, *Dietrichs Flucht, Alpharts* Tod, Biterolf *und* Dietlieb, *Laurin,* etc.—which make up what is usually called the Heldenbuch.

The court epic, or romance of chivalry, the influence of which is apparent on all these popular epics, forms the second great group of German mediaeval poetry. The poet who established the court epic in Germany was Heinrich von Veldeke, a native of the lower Rhineland; his Eneit, written between 1175 and 1186, is based on a French original. Other poets of the time, such as Herbort von Fritzlar, the author of a Liet von Troye, followed Heinrich's example, and selected French models for German poems on antique themes. With the three masters of the court epic, Hartmann von Aue, Wolfram von Eschenbach and Gottfried von Strassburg — all of them contemporaries — the Arthurian cycle became the established theme of this type of romance. and the embodiment of the ideals of the knightly classes. Hartmann was a Swabian, Wolfram a Bavarian, Gottfried presumably a native of Strasbourg. Hartmann, in his Erec and Iwein, *Gregorius* and Der arme *Heinrich,* provided the Court epic of the age with its best models; he had, of all the mediaeval court poets, the most delicate sense of style. Wolfram and Gottfried, on the other hand, represent two extremes of poetic temperament. Wolfram's *Parzival* is filled with mysticism and obscure spiritual significance; while Gottfried's Tristan is as lucid in its style as Hartmann's Iwein.

Parzival and Tristan are the greatest of the German court epics, and the subsequent development of that literary form stands under the influence of the three poets, Hartmann, Wolfram and Gottfried. To the followers and imitators of Hartmann belong Ulrich von Zatzikhoven (*Lanzelet, c.* 1195); Wirnt von Gravenberg, a Bavarian (*Wigalois,* c. 1205); the versatile Spielmann, known as "Der Stricker"; and Heinrich von dem Tiirlin, author of an unwieldy epic, Die Krone ("the crown of all adventures," *c.* 1220). Wolfram's mysticism is to be seen in Der *jüngere* Titurel of a Bavarian poet, Albrecht von Scharfenberg (c. 1270), and in the later *Lohengrin* of an unknown poet; whereas Gottfried von Strassburg dominates the Flore und *Blanscheflur* of Konrad Fleck (c. 1220) and two chief poets of the later 13th century, Rudolf von Ems, who died in 12 j4, and Konrad von Wiirzburg, who lived till 1287. Of these, Konrad alone carried on worthily the traditions of the great age; he excels in short romances like Die *Herzemaere* and *Engelhard,* but becomes diffuse and wearisome in his enormously long Trojanerkrieg and *Partonopier und Meliur.*

The most conspicuous changes which came over the narrative poetry of the 13th century were, on the one hand, a steady encroachment of realism on the matter and treatment of the epic, and, on the other, a tendency to didacticism. Substituting the "fact" of the chronicle for the freer imaginings of the earlier poets is to be seen in the work of Rudolf von Ems; while the growth of realism appears in the *Pfaffe Amis,* a collection of comic anecdotes, the admirable peasant romance Meier Helnzbrecht, written about 1250 in Bavaria, and in the adventures of Ulrich von Lichtenstein (*Frauendienst,* 1255; *Frauenbuch,* 1257).

In a higher degree than any of these epic poets, Walther von der Vogelweide summed up in himself all that was best in the group of poetic literature with which he was associated — the *Minnesang* or lyric; in love song high and low, in religious poetry, in patriotic and political *Sprüche*—in all he was a master. He was born about 1170 and died about 1228; his art he learned in Austria — he calls the elegiac poet Reinmar von Hagenau his master — whereupon he wandered through South Germany, a wel-

come guest wherever he went although his championship of what he regarded as the national cause in the political struggles of the day won him foes as well as friends. Of all Germany's lyric poets, he exerted the deepest influence; and in the originality and purity of his inspiration he is one of her greatest (see WALTHER VON DER VOGELWEIDE).

Amongst Walther's immediate contemporaries, highborn poets, whose lives were passed at courts, naturally cultivated the conventional lyric; but the more gifted and original singers of the time availed themselves of the freedom of Walther's poetry of uncourtly love. This was Walther's most valuable legacy to his successors, the greatest of whom was Neidhart von Reuental (c. 1180–*c.* 1250). Neidhart sought the themes of his *Höfische* Dorfpoesie in the village, and, as the mood happened to dictate, depicted the peasant with humorous banter or biting satire. The lyric poets of the later 13th century were either echoes of Walther and Neidhart, or their originality was confined to some particular form of lyric poetry in which they excelled. On the whole, the *Spruchdichter* came best out of the ordeal of changing fashions; and the increasing interest in the moral and didactic applications of literature favoured the development of a new form of verse. The *Spruchdichtung,* was in fact, the connecting link between the Minnesang of the 13th and the lyric and satiric poetry of the 15th and 16th centuries.

A utilitarian and didactic spirit was gradually taking the place of the idealism of chivalry. In the early decades of the 13th century, Der *Winsbeke,* by a Bavarian, and Der welsche *Gast,* written in 1215–16 by Thomasin von Zirclaere, a native of Friuli, still inculcate the duties and virtues of the knightly life. But in the Bescheidenheit (c. 1215–30) of a wandering singer, who called himself Freidank, we find for the first time an antagonism to the unworldly code of chivalry and a sign of the changing social order, brought about by the rise of what we now call the middle class. Freidank is their spokesman. In Der *Renner* by Hugo von Trimberg, written at the very end of the century, the terseness and wit of Freidank have given place to diffuse moralizing and allegory. There is practically no Middle High German literature in prose.

III. THE TRANSITION PERIOD *(1350–1600)*

To the End of the 15th Century. — By the middle of the 14th century, knighthood was rapidly declining, and the conditions under which mediaeval poetry had flourished were passing. But the stories of chivalry still appealed as stories to the people, although the old way of telling them was no longer appreciated; the feeling for beauty of form and expression was lost. Signs of the decadence are to be seen in a continuation of *Parzival* by two Alsatians, Claus Wisse and Philipp Colin (c. 1335), and in an *Apollonius* von *Tyrus* by Heinrich von Neuenstadt *(c.* 1315). The story of Siegfried was retold in a rough ballad, Das Lied vom *hürnen* Seyfried, the Heldenbuch was recast in *Knittelvers* or doggerel (1472), and even the Arthurian epic was parodied. A no less marked symptom of decadence is to be seen in a large body of allegorical poetry analogous to the *Roman* de la Rose in France. As time went on, prose versions of the old stories became more general, and out of these developed the *Volks*biicher, which were the favourite reading of the German people for centuries. As the last monuments of the decadent narrative literature of the middle ages, we may regard the Buch der *Aben*teuer of Ulrich Fiietrer, written at the end of the 15th century, and Der *Weisskönig* and Teuerdank by the emperor Maximilian I. (1459–1519), printed in the early years of the 16th. At the beginning of the new epoch the *Minnesang* could still point to two poets of distinction, Hugo von Montfort (1357–1423) and Oswald von Wolkenstein (1367–1445); but as the lyric passed into the hands of the middle-class poets of the German towns, its emotional sensitiveness gave place to moral and religious dogmatism; and the simple forms of the older lyric were superseded by ingenious metrical distortions. Under the influence of writers like Heinrich von Meissen ("Frauenlob," *c.* 1250–1318), Heinrich von Miigeln and Michael Beheim (1416–*c.* 1480), the Minnesang passed over into the Meistergesang. In the later 15th and in the 16th centuries all the south German towns possessed flourishing Meistersinger schools in which the art of writing verse was taught and practised according to complicated rules.

The great lyric poetry of these transition centuries was not the Meistergesang, but the Volkslied. Never before or since has Germany been able to point to such a rich harvest of popular poetry as now. Every form of popular poetry is to be found in the old collections — songs of love and war, hymns and drinking-songs, songs of spring and winter and historical ballads. In prose the most popular form was the Schwank or comic anecdote. Collections of such *Schwänke* range from the practical jokes of Till *Eulenspiegel* (1515), and the coarse witticisms oi the Pfaffe vom Kalenberg (end of 14th century) and Peter Leu (1550), to the religious and didactic anecdotes of J. Pauli's *Schimpf* und *Ernst* (1522) and the more literary Rollwagenbiichlein (1555) of Jorg Wickram and the *Wendunmut* (1563 seq.) of H. W. Kirchhoff. Of the first importance is the *Narrenschiff* of Sebastian Brant (1457–1521), where the humorous anecdote became a vehicle of the bitterest satire. It appeared in 1494, and is a landmark on the way that led to the Reformation. The beast fable and beast epic appealed with peculiar force to the new generation. At the very close of the Middle High German period, Ulrich Boner revived the Aesopic fable in his Edelstein (1349), translations of Aesop in the following century added to the popularity of the fable (*q.v.*), and in the century of the Reformation it became, in the hands of Burkard Waldis (*Esopus,* 1548) and Erasmus Alberus (Buch von der *Tugend* und Weisheit, 1550), a favourite vehicle of satire and polemic. A still more popular form of the beast fable was the epic of *Reinke* de Vos, which had been cultivated by Flemish poets in the 13th and 14th centuries and has come down to us in a Low Saxon translation, published at Liibeck in 1498.

The drama, as we have seen, had practically no existence in Middle High German times. As in all European literatures, it emerged slowly and with difficulty from the Church liturgy. As time went on, the vernacular was substituted for the original Latin, and with increasing demands for pageantry, the scene of the play was removed to the churchyard or the market-place; the next step was an enlargement of the scope of the religious play to include legends of the saints, and finally we find a complete separation of the drama from ecclesiastical ceremony. The most interesting example of this encroachment of the secular spirit is the Spiel von Frau *Jutten* by an Alsatian, Dietrich Schernberg, in 1480. Meanwhile, in the 15th century, a beginning was made to a drama entirely independent of the Church. The mimic representations — originally allegorical in character — with which the people amused themselves at the great festivals of the year, were interspersed with dialogue, and performed on an improvised stage. This was the beginning of the *Fastnachtsspiel* or Shrovetide-play. Amongst the earliest cultivators of this type of play were Hans Rosenpliit (*fl.* c. 1460) and Hans Folz (*fl.* c. 1510), both of Nuremberg.

The Age of the Reformation. — The coming of the Protestant Reformation was prepared by mysticism and humanism. With Meister Eckhart (c. 1260–1327), the most original of all the German mystics, with Heinrich Seuse or Suso (c. 1300–66), and Johannes Tauler (c. 1300–61), mysticism was an essentially personal interpretation of Christianity, and, as such, naturally conducive to the individual freedom of Protestantism. To the mystics we owe the early translations of the Bible into German; one was printed at Strasbourg in 1466. Johann Geiler von Kaisersberg (1445–1510), a pupil of the humanists and a friend of Sebastian Brant, links up mysticism with humanism. The latter was transplanted to German soil with the foundation of the University of Prague in 1348 but its immediate influence was restricted by the fact that the pre-Reformation humanists despised the vernacular and wrote only in Latin. Thus although neither Johann Reuchlin of Pforzheim (1455–1522), nor the patriotic Alsatian, Jakob Wimpfeling (or Wimpheling) (1450–1528)—not to forget the great Dutch humanist Erasmus of Rotterdam (1466–1536) — has, strictly speaking, a place in the history of German literature, the battle of the humanists for liberalism in thought and scholarship cleared the way for a healthy national literature. Moreover, to

humanistic stimulus we also owe many translations from the Latin and Italian, prominent among the translators being Niklas von Wyl (died *c.* 1478), chancellor of Wiirttemberg, and Albrecht von Eyb (1420–75).

Martin Luther (1483–1546), Germany's greatest man in this age of intellectual new-birth, demands a large share of attention in a survey of its literature; for Luther's translation of the Bible (1522–34) is, like the English Bible, a great literary monument. Well aware that this Bible must be the keystone to his work, he gave himself endless pains to produce a work German both in language and in spirit. He chose, in respect of vocabulary and forms, his language so that it might be read without difficulty in wide circles of the population; and thus the Lutheran Bible became a factor of the first importance in unifying the speech of the nation. As a hymn-writer (*Geistliche Lieder,* 1564), Luther was equally mindful of the importance of adapting himself to popular needs; and his hymns form the starting-point for a vast development of German religious poetry which was to culminate in the following century.

The most virile literature of this age was inspired by religious strife. Amongst Luther's henchmen, Philipp Melanchthon (1497–1560), the "praeceptor Germaniae," and Ulrich von Hutten (1488–1523) were powerful allies in his cause, although their intellectual sympathies inclined to the humanists. The satirical dramas of Niklas Manuel (1484–ISSO), a Swiss Protestant, and the polemical fables of Erasmus Alberus *(c.* 1500–53) were, however, insignificant compared with the fierce assault on Protestantism by the Alsatian monk, Thomas Murner (1475–1537), the most ruthless of all German satirists. It was not until the following generation that the Protestant party could point to a writer who, in genius and power, was at all comparable to Murner, namely, Johann Fischart *(c.* 1550–*c.* 1591). His chief work, the *Affentheuerliche Naupengeheurliche Geschichtklitterung* (1575), a Germanization of the first book of Rabelais' satire, is a witty and ingenious monstrosity, a satirical comment on the life of the 16th century. Other satirists were Bartholomaeus Ringwaldt (1530–1599) and Georg Rollenhagen (1542–1609), author of the *Froschmeuseler* (1595).

On the whole, the form of literature which succeeded best in extricating itself from religious polemics in the 16th century was the drama. Protestantism proved favourable to its development, and the humanists, who had always prided themselves on their imitations of Latin comedy, introduced into it form and proportion. The Latin school comedy in Germany was founded by Wimpfeling with his *Stylpho* (1470) and by J. Reuchlin with his witty adaptation of *Maître Pathelin* in his *Henno* (1498). In the 16th century the chief writers of Latin dramas were Thomas Kirchmair or Naogeorgus (1511–63), Caspar Brulow (1585–1627), and Nikodemus Frischlin (1547–90). In Basle, Pamphilus Gengenbach produced moralizing *Fastnachtsspiele* in 1515–16; and in Berne Niklas Manuel employed the same type of play for anti-Catholic propaganda. The *Parabell vam vorlorn Szohn* by Burkard Waldis (1527), the many dramas on the subject of Susanna — notably those of Sixt Birck (1532) and Paul Rebhun (1535) — and Frischlin's German plays are attempts to treat Biblical themes on humanistic lines. In another important literary centre of the 16th century, in Nuremberg, the drama developed on more indigenous lines. Hans Sachs (1494–1576), the Nuremberg cobbler and Meistersinger, has left behind him a vast literary legacy, embracing every form of popular literature from *Spruch* and *Schwank* to complicated *Meistergesang* and lengthy drama. But in the progressive movement of the German drama he played an even smaller rôle than his Swiss and Saxon contemporaries; for his tragedies and comedies are little more than stories in dialogue. In the *Fastnachtsspiele,* where dramatic form is less essential than anecdotal point and brevity, he is at his best. At the close of the century the influence of the English drama — brought to Germany by English actors — introduced the dramatic and theatrical element which had hitherto been lacking in the German drama. This is to be seen in the work of Jakob Ayrer (d. 1605) and Duke Heinrich Julius of Brunswick (1564–1613). But unfortunately these beginnings had hardly made themselves felt when the full current of the Renaissance swept across Germany, bringing in its train the Senecan tragedy. Then came the devastation of the Thirty Years' War, which made the creation of a popular and national theatre impossible.

The novel was less successful than the drama in emancipating itself from satire and religious controversy; Fischart was too dependent on foreign models and too erratic to create a national form of German fiction. The most important novelist was a much less talented writer, the Alsatian Meistersinger and dramatist Jorg Wickram (d. *c.* 1560), who has been already mentioned as the author of a popular collection of anecdotes, the *Rollwagenbüchlein.* His *Der Knabenspiegel* (1554) and *Der Goldfaden* (1557), are in form, and especially in the importance they attach to psychological developments, the forerunners of the modern German novel. But Wickram stands alone. The old *Volksbücher* were the real novels of the Reformation age; and none of these affords clearer insight into its temper and spirit than the famous story of the magician *Doctor Johann Faust,* published at Frankfurt in 1587.

IV. THE RENAISSANCE (1600–1740)

The 17th century in Germany presents a complete contrast to its predecessor; the fact that it was the century of the Thirty Years' War, which devastated the country, crippled the prosperity of the towns, and threw back by many generations the social development of the people, explains much, but it can hardly be held entirely responsible for their intellectual apathy and slavery to foreign customs and foreign ideas.

There were, however, some branches of German poetry which escaped this foreign influence. The Church hymn, continuing the great Lutheran traditions, shows extraordinary richness both in quality and quantity. Paul Gerhardt (1607–76), the greatest German hymn-writer, was only one of many Lutheran pastors who in this age contributed to the German hymnal. On the Catholic side, Angelus Silesius (Johann Scheffler, 1624–77) showed what a wealth of poetry lay in the mystic speculations of Jakob Boehme, the gifted shoemaker of Gorlitz (1575–1624), while Friedrich von Spee (1591–1635), another leading Catholic poet of the century, cultivated the pastoral allegory of the Renaissance. The revival of mysticism associated with Boehme gradually spread through the whole religious life of the 17th century. Besides the hymn, the *Volkslied,* which amidst the struggles and confusion of the great war bore witness to a steadily growing sense of patriotism, developed in its own way. But all else — if we except certain forms of fiction — stood completely under the influence of the Baroque.

The first focus of the Renaissance literature was Heidelberg, where, under the leadership of J. W. Zincgref (1591–1635), a number of scholars carried into practice that interest in the vernacular which had been shown a little earlier by the German translator of Marot, Paul Schede or Melissus (1539–1602). G. R. Weckherlin (1584–1653), a native of Wiirttemberg who had spent the best part of his life in England, wrote *Oden und Gesänge* (1618–19) of great promise. But the greatest, or at least the most influential writer of this group was Martin Opitz (1597–1639). He was a native of Silesia and, as a student in Heidelberg, came into touch with Zincgref's circle; subsequently, in the course of a visit to Holland, a more definite trend was given to his ideas by the example of the Dutch poet and scholar, Daniel Heinsius. As a poet, Opitz experimented with every form of Renaissance poetry, and with his *Buch von der deutschen Poeterey* (1624) he gave the German Renaissance its theoretical textbook. In this tract, in which Opitz reproduced in German the doctrines of Scaliger and Ronsard, he not merely justified his own mechanical verse-making, but also gave Germany a law-book which regulated her literature for 100 years.

The work of Opitz as a reformer was furthered by another institution of foreign origin, namely, literary societies modelled on the *Accademia della Crusca* in Florence. These societies. of which the chief were the *Fruchtbringende Gesellschaft* or *Palmenorden* (founded 1617), the *Elbschwanenorden* in Hamburg and the *Gekronter Blumenorden an der Pegnitz* or *Gesellschaft*

GERMAN PHILOSOPHERS AND WRITERS

1. Martin Luther (1483–1546)
2. Immanuel Kant (1724–1804)
3. Gottfried Wilhelm von Leibnitz (1646–1716)
4. Gotthold Ephraim Lessing (1729–81)
5. Johann Wolfgang von Goethe (1749–1832)
6. Georg Wilhelm Friedrich Hegel (1770–1831)
7. Heinrich Heine (1797–1856)
8. Johann Christoph Friedrich von Schiller (1759–1805)
9. Arthur Schopenhauer (1788–1860)
10. Friedrich Nietzsche (1844–1900)
11. Gerhart Hauptmann (1862–)
12. Thomas Mann (1875–)

der Pegnitzschäfer in Nuremberg, were the centres of literary activity during the unsettled years of the war. Although they produced much that was trivial, these societies also did German letters an invaluable service by their attention to the language, one of their chief objects being to purify it from foreign and un-German ingredients. J. G. Schottelius (1612–76) wrote his important grammatical works to further the objects of the *Fruchtbringende Gesellschaft*. Meanwhile the poetic centre of gravity in Germany had shifted from Heidelberg to Königsberg, where a group of academic poets gave practical expression to the Opitzian theory. Chief among them were Simon Dach (1605–59), a gentle, elegiac writer on whom the laws of the *Buch von* der deutschen Poeterey did not lie too heavily, and the more manly and vigorous Paul Fleming (1609–40).

Satire was cultivated by two Low German poets, J. Lauremberg (1590–1658) and J. Rachel (1618–69), of whom at least the latter was accepted by the Opitzian school; but there is satire, too, in the powerful and scathing sermons of J. B. Schupp (1610–61), an outspoken Hamburg preacher, and in the scurrilous wit of the Viennese monk Abraham a Sancta Clara (1644–1709), who had inherited something of his predecessor Murner's gift. Most gifted of all the Silesian group of writers is Friedrich von Logau (1604–55), Germany's greatest epigrammatist. Logau's 3,000 epigrams (Deutsche *Sinngedichte,* 1654) reflect admirably the intellectual temper of their age.

The chief dramatist of the Renaissance movement is Andreas Gryphius (1616–64). Like Opitz, Gryphius was a Silesian, and a poet of no mean ability, as is to be seen from his lyric poetry; but his tragedies, modelled on the stiff Senecan pattern, suffered from his ignorance of the more highly developed drama of France, not to speak of England; his models were Dutch. In the field of comedy, he was less hampered; and his *Horribilicribrifax* and Herr Peter *Squentz*—the latter an adaptation, probably through a Dutch intermediary, of the comic scenes of the Midsummer Night's Dream—are the best German plays of the 17th century.

The German novel of the 17th century was largely a product of foreign influence, Spanish and French. Don *Quixote* had been partly translated early in the century and the picaresque romance had found its way to Germany still earlier; while H. M. Moscherosch (1601–69) in his Gesichte Philanders von Sittewald (1642–43) made the *Sueños* of Quevedo the basis for vivid pictures of the life of the time, interspersed with satire. The best German novel of the 17th century, Der *abenteuerliche Simplicissimus* (1669) by H. J. Christoffel von Grimmelshausen (c. 1625–76), is picaresque, but it owed little more than its form to the Spaniards. It is in great measure the autobiography of its author, and describes with uncompromising realism the social disintegration and the horrors of the Thirty Years' War. But this remarkable book stands alone. Christian Weise (1642–1708), rector of the Zittau gymnasium, wrote a few satirical novels, but his realism and satire are too obviously didactic. He is seen to better advantage in his dramas, of which he wrote more than 50 for performance by his scholars.

The real successor of *Simplicissimus* in Germany was the English Robinson *Crusoe,* a novel which, on its appearance, was immediately translated into German (1721); it called forth hundreds of imitations, the vogue of which is even still kept alive by Der schweizerische Robinson of J. R. Wyss (1812 seq.). With the exception of J. G. Schnabel's *Insel Felsenburg* (1731–43), the literary value of these imitations is slight; but they represented a healthier and more natural development than the "gallant" novels of French provenance, written by writers like Philipp von Zesen (1619–89), Duke Anton Ulrich of Brunswick (1633–1714), A. H. Buchholtz (1607–71), H. A. von Ziegler (1653–97)—author of the famous Asiatische Banise (1688)—and D. C. von Lohenstein (1635–83). The last mentioned and Christian Hofmann von Hofmannswaldau (1617–79) are regarded as the leaders of a "second Silesian school," opposed to the first school of Opitz. They cultivated the bombastic and Euphuistic style of the Italians Guarini and Marini, and of the Spanish writer Gbngora.

But this aberration of taste was of short duration. Although socially the recovery of the German people from the desolation of the war was slow and laborious, the intellectual life of Germany was rapidly recuperating. Samuel Pufendorf (1632–94), Christian Thomasius (1655–1728), Christian von Wolff (1679–1754) and, above all, Gottfried Wilhelm Leibnitz (1646–1716), the first of the great German philosophers, laid the foundations of rationalism; while German religious life was strengthened and enriched by a revival of pietism, under mystic thinkers like Philipp Jakob Spener (1635–1705), a revival which left its traces on religious poetry. The so-called "court poets"—Rudolph von Canitz (1654–99), Johann von Besser (1654–1729) and Benjamin Neukirch (1665–1729)—substituted the "good taste" of Boileau for the extravagance of Marini; and from their midst sprang one lyric poet, Johann Christian Giinther (1695–1723), of high gifts. In Hamburg, where the Italian opera kept the decadent Renaissance poetry alive, the incisive epigrams of Christian Wernigke (1661–1725) provided an effective antidote; and Barthold Heinrich Brockes (1680–1747), who had been deeply impressed by English nature-poetry, gave the artificiality of the Silesians its death-blow. Translations and imitations of the English Spectator, Tatler and Guardian—the so-called *Moralische Wochenschriften*—helped to regenerate literary taste, and implant healthy moral ideas in the German middle classes. Between 1724 and 1740 Johann Christoph Gottsched (1700–66) succeeded in establishing in Leipzig, then the metropolis of German taste, literary reforms in accord with French 17th-century classicism. He purified the stage by abolishing irrelevant buffoonery, and provided it with a repertory largely of French origin; and in his Kritische *Dichtkunst* (1730) he laid down the principles according to which good literature was to be produced and judged. With Gottsched the period of German Renaissance literature reaches its culmination and at the same time its close.

V. THE CLASSICAL AND ROMANTIC PERIOD (1740–1832)

From the Swiss Controversy to the "Sturm und Drang."—As in France, the next advance in German literature was achieved in a battle between the "ancients" and the "moderns," the German "ancients" being represented by Gottsched, the "moderns" by the Swiss literary reformers, J. J. Bodmer (1698–1783) and J. J. Breitinger (1701–76). The latter in his Kritische Dichtkunst (1739) maintained doctrines which were in opposition to Gottsched's in his treatise of the same name, and Bodmer supported his friend's initiative. Basing their arguments on Milton's Paradise Lost, which Bodmer had translated into prose (1732), the Swiss demanded room for the play of genius and inspiration; they insisted that the imagination should not be dominated by the reason. Their victory was due less to any skill with which they presented their arguments than to the fact that literature itself was in need of greater freedom. The effects of the controversy appear in a group of Leipzig writers of Gottsched's own school, the *Bremer* Beitrager as they usually are called after their literary organ. These men—C. F. Gellert (1715–69), author of graceful fables and tales in verse, G. W. Rabener (1714–71), mild satirist of Saxon provinciality, the dramatist J. Elias Schlegel (1719–49), and a number of minor writers—did not set themselves up in active opposition to their master, but they were in sympathy with many of the views which the Swiss had advocated. And in the *Bremer Beiträge* there appeared in 1748 rhe first instalment of an epic by F. G. Klopstock (1724–1803), Der Messias. These first cantos of Klopstock's epic, and in a still higher degree, his Odes, inaugurate the great age of German literature in the 18th century. His rhapsodic dramas have less value, but with Macpherson's Ossian, which in the '60s awakened a widespread enthusiasm throughout Germany, they were responsible for the so-called "bardic" movement. The leaders of this movement were H. W. von Gerstenberg (1737–1823), K. F. Kretschmann (1738–1809) and Michael Denis (1729–1800).

Under Frederick the Great, who, as the docile pupil of French culture, had little sympathy for unregulated displays of feeling, neither Klopstock nor his imitators were in favour in Berlin, but at the University of Halle considerable interest was taken in the new movement. Here, before Klopstock's name was known

at all, two young poets, J. I. Pyra (1715–44) and S. G. Lange (1711–81), wrote *Freundschaftliche Lieder* (1737) in rhymeless metres such as Klopstock advocated. The later Prussian poets, J. W. L. Gleim (1719–1803), J. P. Uz (1720–96) and J. N. Gotz (1721–81), who were associated with Halle, and K. W. Ramler (1725–98) in Berlin, cultivated mainly the Anacreontic and the Horatian ode; and Friedrich von Hagedorn (1708–54) in Hamburg showed to what perfection the lighter *vers de société* could be brought. The Swiss physiologist Albrecht von Haller (1708–77) was the first German poet to give expression to the beauty and sublimity of Alpine scenery *(Die Alpen,* 1734), and a Prussian officer, Ewald Christian von Kleist (1715–59), author of *Der Frühling* (1749), wrote admirable nature-poetry.

As Klopstock had been the first of modern Germany's inspired poets, so Gotthold Ephraim Lessing (1729–81) was the first critic who brought credit to the German name throughout Europe. Like his predecessor Gottsched, whom he vanquished more effectually than Bodmer, he had unwavering faith in classicism, but "classic" meant for him, as for his contemporary, J. J. Winckelmann (1717–68), Greek art and literature, not French pseudoclassicism. He went, indeed, still further, and asserted in his *Hamburgische Dramaturgie* (1767–68) that Shakespeare, with all his irregularities, was a more faithful observer of the spirit of Aristotle's laws, than were the French dramatists. He looked to England and not to France for the regeneration of the German theatre, and his own dramas were pioneer-work in this direction. *Miss Sara Sampson* (1755) is a *bürgerliches Trauerspiel* on the English model, *Minna von Barnhelm* (1767), a comedy in the spirit of Farquhar; in *Emilia Galotti* (1772), again, he remoulded the "tragedy of common life" in a form acceptable to the *Sturm und Drang;* and finally in *Nathan der Weise* (1779) he won acceptance for iambic blank verse as the medium of the higher drama. His two most promising disciples—J. F. von Cronegk (1731–58) and J. W. von Brawe (1738–58)—unfortunately died young; but another of his friends, C. F. Weisse (1726–1804) was the most successful playwright of his day. Lessing's name is associated with Winckelmann's in *Laokoon* (1766), a treatise which defines the boundaries between plastic art and poetry, and with those of the Jewish philosopher, Moses Mendelssohn (1729–86) and the Berlin bookseller C. F. Nicolai (1733–1811) in the famous *Literaturbriefe*. The last years of Lessing's life were embittered by conflict with Lutheran orthodoxy and intolerance.

To the widening of the German imagination C. M. Wieland (1733–1813) contributed by introducing the Germans to the lighter poetry of the south of Europe. With the exception of his verse-romance *Oberon* (1780), his work has fallen into neglect; he did, however, excellent service to the development of German prose fiction with his psychological novel, *Agathon* (1766–67), and with his humorous satire, *Die Abderiten* (1774). Wieland had a considerable following, particularly in Austria, where Aloys Blumauer (1755–89) and J. B. von Alxinger (1755–97) wrote travesties and epics under his influence. In Saxony, M. A. von Thümmel (1738–1817), author of a comic epic in prose, *Wilhelmine* (1764), belonged to Wieland's school. It was K. A. Kortum (1745–1824), however, who wrote the most popular comic epic of the time, the *Jobsiade* (1784). The German novel owed much to the example of *Agathon,* but the groundwork and form were borrowed from English models; Gellert had begun by imitating Richardson in his *Schwedische Gräfin* (1747–48), and he was followed by J. T. Hermes (1738–1821), Sophie von Laroche (1730–1807), A. von Knigge (1752–96) and J. K. A. Musaus (1735–87), the last mentioned being, however, better known as the author of a collection of *Volksmarchen* (1782–86). Meanwhile rationalism was spreading rapidly. Men like Knigge, Mendelssohn, J. G. Zimmermann (1728–95), T. G. von Hippel (1741–96), Christian Garve (1742–98), J. J. Engel (1741–1802), as well as the educational theorists J. B. Basedow (1723–90) and J. H. Pestalozzi (1746–1827), wrote books and essays on "popular philosophy" which were as eagerly read as had been the *Moralische Wockenschriften;* and with this group of writers must also be associated the most brilliant of German 18th-century satirists, G C. Lichtenberg (1742–99).

Such was the *milieu* from which sprang the most stimulating pioneer of the great epoch of modern German literature, J. G. Herder (1744–1803). The transition from the popular philosophers to Herder is represented by men like Thomas Abbt (1738–66) and J. G. Hamann (1730–88). The revolutionary nature of Herder's thought lay in the fact that he grasped, as no thinker before him, the idea of historical evolution, and awakened an interest—for which, of course, Rousseau had prepared the way—in the primitive conditions of mankind. He collected and published the *Volkslieder* of all nations (1778–79), and drew attention to those elements in German life and art which were, in the best and most precious sense, national. Herder is thus the real founder of the literary movement known as *Sturm und Drang.* New ground was also broken by a group of poets, who, under Klopstock's influence, founded in 1772 the Göttingen "Bund" or "Hain," and published their poetry in the *Gottinger Musenalmanach.* With the exception of the two brothers, Chr. zu Stolberg (1748–1821) and F. L. zu Stolberg (1750–1819), the members of this coterie belonged to the peasant class or the lower *bourgeoisie;* J. H. Voss (1751–1826), the leader of the "Bund," and author of the famous idyll, *Luise* (1784), was a typical North German peasant. L. H. C. Holty (1748–76) and J. M. Miller (1750–1814), again, excelled in simple lyrics in the tone of the *Volkslied.* Closely associated with the Gottingen group were M. Claudius (1740–1815), an even more unassuming representative of the German peasant in literature than Voss, and G. A. Burger (1747–94) who contributed to the *Gottinger Musenalmanach* the famous ballad of *Lenore* (1774).

But the Gottingen "Bund" was only a minor phase of *Sturm und Drang;* the main movement was intimately associated with Johann Wolfgang Goethe (1749–1832). As a student in Leipzig (1765–68), Goethe had written lyrics in the Anacreontic vein and dramas in alexandrines; but in Strasbourg, where he continued his studies in 1770–71, he made the personal acquaintance of Herder, who interested him in Gothic architecture, the *Volkslied* and Shakespeare. The pamphlet *Von deutscher Art und Kunst* (1773), to which, besides Goethe and Herder, the historian Justus Moser (1720–94) contributed, was a kind of manifesto of *Sturm und Drang.* The new ideas seemed at once to set Goethe's genius free, and from 1772 to 1775 he was extraordinarily fertile in poetic ideas. His *Gotz von Berlichingen* (1773), the first important drama of the *Sturm und Drang,* was followed within a year by the first novel of the movement, *Werthers Leiden* (1774); he dashed off *Clavigo* and *Stella* in a few weeks in 1774 and 1775, and wrote a large number of *Singspiele,* dramatic satires and fragments—including *Faust* in its earliest form (the so-called *Urfaust*)—not to mention matchless lyrics which more than fulfilled the promise of Klopstock's *Odes.* In all forms of literature he set the fashion to his time; the Shakespearian restlessness of *Götz von Berlichingen* found imitators in J. M. R. Lenz (1751–92), F. M. von Klinger (1752–1831), J. A. Leisewitz (1752–1806), H. L. Wagner (1747–79) and Friedrich Miiller, better known as Maler Müller (1749–1825). The dramatic literature of the *Sturm und Drang* was its most characteristic product—indeed, the very name of the movement was borrowed from a play by Klinger; it was inspired by the desire to present upon the stage figures of Shakespearian grandeur impelled by gigantic passions, all considerations of plot, construction and form being subordinated to character. The fiction of the *Sturm und Drang,* again, was in its earlier stages dominated by *Werthers Leiden,* as may be seen in the novels of F. H. Jacobi (1743–1819) and J. M. Miller, who has been already mentioned. Later, it was developed in a broader and less turbulent spirit by J. J. W. Heinse (1749–1803), author of *Ardinghello* (1787), Klinger and K. Ph. Moritz (1757–93), whose *Anton Reiser* (1785) foreshadows *Wilhelm Meister.*

With the production of *Die Rauber* (1781) by Johann Friedrich Schiller (1759–1805), the drama of the *Sturm und Drang* entered upon a new phase. Schiller's tragedy was more skilfully adapted than those of his predecessors to the exigencies of the theatre; it and the succeeding dramas. *Fiesco* and *Kabale und Liebe—all* three in prose—were masterpieces of high promise. In

his fourth drama, *Don Carlos* (1787), he abandoned prose for iambic blank verse. Other eminent dramatists of this period were O. von Gemmingen (1755–1836), an imitator of Diderot, F. L. Schroder (1744–1816) and A. W. Iffland (1759–1814), the two latter the greatest actors of their time. Germany owes to the *Sturm und Drang* her national theatre; permanent theatres were established in these years at Hamburg, Mannheim, Gotha and at Vienna, the Hofburgtheater was founded in 1776.

Classicism. — The *Sturm und Drang* soon exhausted itself. For Goethe this phase in his development came to an end with his departure for Weimar in 1775, while, after *Don Carlos*, Schiller turned aside from poetry to study history and philosophy; not until the very close of the century did he, under the stimulus of Goethe's friendship, return to the drama. The first ten years of Goethe's life in Weimar were comparatively unproductive; at the Weimar court, where classic or even pseudoclassic tastes prevailed, he was gradually finding his way to a new poetic form. But he did not arrive at clearness in his ideas until after his sojourn in Italy (1786–88), an episode of the first importance for his mental development. Italy was, in the first instance, a revelation to Goethe of the antique; here he conceived that ideal of a classic literature, which for the next 20 years dominated German literature. In Italy he gave *Iphigenie auf Tauris* (1787) its final form, he completed *Egmont* (1788) — like the exactly contemporary *Don Carlos* of Schiller, a kind of bridge from *Sturm und Drang* to classicism — and began *Torquato Tasso* (1790). *Wilhelm Meisters Lehrjahre* (1795–96), Goethe's most important novel, which had been originally concerned only with the theatre, becomes now a book on the conduct of life.

Before *Wilhelm Meister* appeared, however, German thought and literature had arrived at that stability in form and ideas essential to a great literary period. In the year of Lessing's death, 1781, Immanuel Kant (1724–1804), the great philosopher, had published his *Kritik der reinen Vernunft*, and this, together with the two later treatises, *Kritik der praktischen Vernunft* (1788) and *Kritik der Urteilskraft* (1790), placed the Germans in the front rank of thinking nations. Under the influence of Kant, Schiller turned to the study of aesthetics, the first fruits of which were his wonderful philosophic lyrics, and his treatises *Anmut und Würde, Ästhetische Erziehung des Menschen* (1795), and *Über naive und sentimentalische Dichtung* (1795). In the same way, German historical writing had in these years, led by men like Justus Moser, Thomas Abbt, I. Iselin, F. C. Schlosser, Schiller himself and, greatest historian of all, Johannes von Miiller (1752–1809), advanced from unsystematic chronicling to scientific method. G. A. Forster (1754–94), who had accompanied Cook round the world, and Alexander von Humboldt (1769–1859), gave Germany models of lucid descriptive writing. In practical politics and economics, once the unbalanced doctrines of Rousseauism had fallen into discredit, Germany produced much wise and temperate thinking which provided a basis for the reconstruction of her social and intellectual life. Prominent amongst such builders was Wilhelm von Humboldt (1767–1835).

Meanwhile the years 1794–1805, when in Jena and Weimar Goethe and Schiller were united by a close friendship, mark the culmination of literary classicism. Schiller's treatises provided a theoretical basis; his new journal, *Die Horen*, and his *Musenalmanach* — in which the two poets published their magnificent ballad poetry — were its literary organs. Goethe, as director of the ducal theatre, influenced the whole dramatic production of Germany. Under his encouragement, Schiller turned from philosophy to poetry and wrote the splendid series of classic dramas, the trilogy of *Wallenstein*, *Maria Stuart*, *Die Jungfrau von Orleans*, *Die Braut von Messina*, *Wilhelm Tell*, closing with the fragment of *Demetrius;* while to Goethe we owe the idyllic epic of *Hermann und Dorothea;* his severely classical plays *Die natürliche Tochter* and *Pandora* are less important; but it was chiefly owing to Schiller's stimulus that in those years Goethe brought the first part of *Faust* (1808) to a conclusion.

Although acknowledged leaders of German letters, Goethe and Schiller met with considerable opposition, representatives of the once dominant rationalistic movement being particularly obnoxious. But, apart from the two great poets, literature was in no very healthy condition; the stage was dominated by the extraordinarily popular plays of A. von Kotzebue (1761–1819); and there is a wide gap between Moritz's *Anton Reiser* or the philosophic novels which Klinger wrote in his later years, and Goethe's *Meister;* nor can the once so warmly admired novels of Jean Paul Friedrich Richter (1763–1825) stand very high. In lyric and epic poetry, it is impossible to regard poets like the gentle F. von Matthisson (1761–1831), or the less inspired G. L. Kosegarten (1758–1818) and C. A. Tiedge (1752–1841), as worthy of an age that produced Goethe and Schiller. Thus when we speak of the greatness of Germany's classical period, we think mainly of the work of her two chief poets. Moreover, at the very close of the 18th century a new unclassical movement set in, and to this movement, which took definite form in the Romantic school, the sympathies of the younger generation turned.

The Romantic Movement. — The first Romantic school was founded in 1798, not so much as a protest against the classicism of Weimar, with which its leaders were in essential sympathy, as against the utilitarian rationalism of Berlin. Ludwig Tieck (1773–1853), a leading member of the school, was in reality a belated *Stürmer und Dranger*, who in his early years had chafed under the tastes of the Prussian capital. Friedrich Holderlin (1770–1843), one of the most gifted poets of this age, demonstrates no less clearly than Tieck the essential affinity between *Sturm und Drang* and Romanticism. The theoretic basis of Romanticism was laid down by the two brothers, August Wilhelm and Friedrich Schlegel (1767–1845 and 1772–1829), who, accepting, in great measure, Schiller's aesthetic conclusions, adapted them to their own needs. While the. older school had insisted on the critic's right to sit in judgment according to a definite code of principles, these Romantic critics maintained that the first duty of criticism was to understand and appreciate; the right of genius to follow its natural bent was sacred. The *Herzensergiessungen eines kunstliebenden Klosterbruders* by Tieck's school-friend W. H. Wackenroder (1773–98) contained the Romantic art-theory, while the hymns and fragmentary novels of Friedrich von Hardenberg (known as Novalis, 1772–1801), were, with the dramas and fairy tales of Tieck, the representative products of this phase of Romantic literature. The universal sympathies of the movement were exemplified by the many admirable translations — greatest of all, Schlegel's *Shakespeare* (179;–1810) — which were produced under its auspices. J. G. Fichte (1762–1814) and to a much greater extent, F. W. J. von Schelling (1775–1854) were the exponents of the Romantic doctrine in philosophy, while the theologian F. D. E. Schleiermacher (1768–1834) demonstrated how vital its individualism was for religious thought.

The first Romantic school was of short duration; Wackenroder and Novalis died young, and by the year 1804 the other members were widely separated. Two years later, however, another phase of Romanticism was initiated in the town of Heidelberg. The leaders of this second Romantic school were Klemens Brentano (1778–1842), L. A. von Arnim (1781–1831) and J. J. von Gorres (1776–1848); their organ, corresponding to the *Athenäum* of the first school, was the *Zeitung fur Einsiedler*, or *Tröst-Einsamkeit*, and their most characteristic production the collection of *Volkslieder*, published under the title *Des Knaben Wunderhorn* in 1805–08. Compared with the earlier school, the Heidelberg writers were more practical; they, too, were interested in the German past, but they put aside the idealizing glasses of their predecessors and kept to historic fact; they wrote historical novels, not stories of an imaginary mediaeval world as Novalis had done, and they collected *Volkslieder* and *Volksbücher*. Their immediate influence on German intellectual life was consequently greater; they stimulated the interest of the German people in their history; and we owe to them the foundations of the study of German philology and mediaeval literature, both the brothers Jakob and Wilhelm Grimm (1785–1863 and 1786–1859) having been in touch with this circle in their early days. Again, the Heidelberg poets strengthened the national and patriotic spirit of their people; they prepared the way for the rising against

Napoleon in 1813, which produced an outburst of patriotic song, the chief voices being those of E. M. Arndt (1769–1860), K. Th. Korner (1791–1813) and M. von Schenkendorf (1783–1817).

The subsequent history of Romanticism stands in close relation to the Heidelberg school, and when, about 1809, the latter broke up, and Arnim and Brentano settled in Berlin, the Romantic movement followed two clearly marked lines of development, one North German, the other associated with Württemberg. In the north Heinrich von Kleist (1777–1811), Prussia's greatest dramatic poet, created a Romantic drama of high poetic achievement; while Zacharias Werner (1768–1823), an undisciplined and unbalanced dramatic genius, sounded depths of mysticism and fatalism. But Berlin was no favourable soil for the development of Romantic ideas, and the circle of poets there were not free from elements of decadence. Friedrich de la Motte Fouqué (1777–1843), for instance, shows how easy it was for the mediaeval tastes of the Romanticists to be satisfied with mediocre novels and plays; and E. T. A. Hoffmann (1776–1822), novelist of indubitable genius though he was, cultivated with preference in his stories a morbid supernaturalism. The lyric was less sensitive to this decadence; and the North German Romantic circle could point to one lyric poet of the very first rank, the Silesian, J. von Eichendorff (1788–1857); while A. von Chamisso (1781–1838), French-born although he was, developed into a German poet of the purest water. Others again, like Friedrich Ruckert (1788–1866), sought new inspiration in the poetry of the East; and Wilhelm Miiller (1794–1827) following Byron's example, stirred German sympathy for the oppressed Greeks and Poles.

The last phase of Romanticism is represented by the Swabian school. Its chief representative, Ludwig Uhland (1787–1862), himself a disciple of the Heidelberg school, grafted the lyricism of the Roinantic school on to the older traditions of German poetry, and as a ballad-poet is second only to Schiller in popular esteem. One might say that the mission of the Swabian circle, the chief members of which were J. Kerner (1786–1862), G. Schwab (1792–1850), W. Waiblinger (1804–30), W. Hauff (1802–27) and, most gifted of all, E. Morike (1804–75) was to preserve the Romantic traditions from the disintegrating influences to which their North German contemporaries were exposed in the next generation.

Meanwhile, in the background of these phases of Romantic evolution stands the majestic figure of Goethe. Personally he had in the early stages of the movement been opposed to that reversion to subjectivity and lawlessness which the first Romantic school seemed to him to represent; to the end of his life he regarded himself as a "classic," not a "romantic" poet. But, on the other hand, he was too liberal-minded a thinker and critic to be oblivious to the fruitful influence of the new movement. His own works, above all, the first part of *Faust* (1808), *Die Wahlverwandtschaften* (1809), *Dichtung und Wahrheit* (1811–14, a final volume in 1833), *Westostlicher Divan* (1819), *Wilhelm Meisters Wanderjahre* (1821–29) and the second part of *Faust* (published in 1832 after his death), stood in no real antagonism to the Romantic ideas of their time. One might rather say that Goethe was the link between the two great literary groups; and that his work represented reconciliation between "classic" and "romantic" ideas.

VI. GERMAN LITERATURE SINCE GOETHE (1832–1928)

Young Germany. — With Goethe's death a great age in German poetry came to a close. Long before 1832 Romanticism had begun to lose ground, and the French July revolution of 1830 virtually brought the movement to an end. In philosophy Schelling had given place to G. W. F. Hegel (1770–1831), now the dominant force in German philosophy; and the Hegelian metaphysics proved a less fruitful influence on literature than that of Fichte and Schelling. The transference of Romantic ideas to religion and politics had led to reaction; Romanticism became the cloak for a kind of Neocatholicism, and Romantic politics, as enunciated by men like F. von Gentz (1764–1832) and Adam Miiller (1779–1829) was an apology for the Metternich régime in Austria. Only at the universities — in Gottingen, Heidelberg and Berlin — did the movement continue, in the best sense, to be productive; German philology, German historical science and German jurisprudence benefited by Romantic ideas, long after Romantic poetry had been superseded. The day of Romanticism was over; but a return to the classic and humanitarian spirit of the 18th century was impossible. The social condition of Europe had been profoundly altered by the French Revolution; the rise of industrialism had created new economic problems, the march of science had overturned old prejudices. The leadership in literature passed to the un-romantic school of "Young Germany."

The new school was called into existence by political persecution: in Dec. 1835 the German "Bund" issued a decree suppressing the writings of Heinrich Heine, Karl Gutzkow, Ludolf Wienbarg, Theodor Mundt and Heinrich Laube. Of these men, Heine (1797–1856) is by far the most famous. He had made his reputation in 1826 and 1827 with *Die Harzreise* and his *Buch der Lieder,* both of which show how deeply he was immersed in the Romantic traditions. The *Buch der Lieder* is, in fact, one of the greatest of German song-books. But Heine felt more acutely than any other man of his time how the ground was slipping away from beneath his feet; he hailed the July revolutions as the first stage in the "liberation of humanity"; and sought in France the freedom and intellectual stimulus which Germany withheld from him. But these sympathies were always counteracted by doubts whether, after all, life had not been better in that old Romantic Germany of his childhood for which, to the last, he retained so warm an affection. To these doubts were added bitter disappointments and the excruciating tragedy of his "mattress grave"; the gifted poet and satirist were often overshadowed by the cynic.

Heine's contemporary and fellow-fighter, Ludwig Borne (1786–1837), was a more whole-hearted representative of the "Young German" point of view; and his brilliant *Briefe aus Paris* (1830–33) form a landmark in the development of German prose style. Karl Gutzkow (1811–78) had become a man of letters under the influence of the July revolution, and in an early novel, *Wally, die Zweiflerin* (1835), then regarded as atheistic and immoral, he fought for the new ideas. His best literary work was the comedies with which he enriched the German stage of the '40s, and the long novels *Die Ritter vom Geiste* (1850–51), and *Der Zauberer von Rom* (1858–61). Heinrich Laube (1806–84), also the author of social novels and *Reisenovellen* in the style of Heine's *Reisebilder,* was another of the leaders of the new movement; but he is best remembered as Germany's greatest theatre manager: his directorship (1850–67) of the Burgtheater of Vienna forms one of the most brilliant periods in the history of the modern stage. The scholarship and learning of this period were strongly infused with Hegelianism, the leading spirits being D. F. Strauss (1808–74), author of the *Leben Jesu* (1835), the historians G. G. Gervinus (1805–71) and W. Menzel (1798–1873), and the philosopher L. A. Feuerbach (1804–72).

Outside the circle of "Young Germany," efforts were being made to keep alive the Romantic tradition, or provide a surrogate for it. The historical novel, for instance, which Romanticists like Arnim had cultivated, fell at an early date under the influence of Sir Walter Scott; Wilhelm Hauff, Heinrich Zschokke (1771–1848) and K. Spindler (1796–1855) were the most prominent amidst the many imitators of the Scottish novelist. The drama, too, was endeavouring to adapt itself to the new horizons. In Germany its representatives were either unbalanced geniuses such as C. D. Grabbe (1801–36), or poets with too little theatrical blood in their veins like K. L. Immermann (1796–1840), or with too much, like E. von Raupach (1784–1852), K. von Holtei (1798–1880) and Adolf Miillner (1774–1829)—the last named being the chief representative of the so-called "fate-tragedy." But in Austria the developments were more promising. For Austria possessed one dramatic poet of the highest rank, Franz Grillparzer (1791–1872). More successfully than any other dramatist of his time, Grillparzer carried out that task which Kleist had first seriously faced, the reconciliation of the classicism of Goethe and Schiller with the Romantic and modern spirit. His *Sappho* (1818), *Das goldene Vliess* (1820), *Konig Ottokars Glück und Ende* (1825), *Der Traum, ein Leben* (1834) and *Des Meeres und der Liebe Wellen* (1831), are works of high rank. E. F. J. von Miinch-Bellinghausen (1806–71), Grillparzer's more popular con-

temporary, who wrote under the pseudonym of Friedrich Halm, is now unread. Other Austrian dramatists are E. von Bauernfeld (1802–go), who wrote some admirable comedies, and F. Raimund (1790–1836) and J. Nestroy (1801–62), who cultivated the popular Viennese fairy-play and farce.

The transitional character of the age is best illustrated by K. L. Immermann, already mentioned, and A. von Platen-Hallermunde (1796–183j). Immermann's dramas had little success in the theatre, but one at least, *Merlin* (1832), is a dramatic poem of great beauty. In his novels, however, *Die Epigonen* (1836) and *Münchhausen* (1838–39), Immerinann reflected the spirit of his time. Platen is a poet who stands peculiarly alone; he was an antagonist both of Romanticism and "Young Germany"; even with Immermann he came into sharp conflict. He, the least subjective of all German lyric poets, began as an imitator of oriental poetry, and soon attained an extraordinary mastery of poetic form; his *Sonette aus Venedig* (1825) are the finest sonnets in the German tongue.

Meanwhile the political ideas of the "Young German" movement, gained ground in the unsettled conditions prevailing between the revolutions of 1830 and 1848. The early '40s were in German literature marked by an outburst of political poetry, which may be compared with the national and patriotic lyric of 1813. Initiated by mediocre talents like N. Becker (1809–45) and R. E. Prutz (1816–72), the movement found a vigorous champion in Georg Herwegh (1817–75), who in turn succeeded in winning Ferdinand Freiligrath (1810–76) for the revolutionary cause. Others joined in the revolutionary cry—F. Dingelstedt (1814–81), A. H. Hoffmann von Fallersleben (1798–1874), and a number of Austrians, who had more reason for discontent than the North Germans. But the best Austrian political poetry, the *Spaziergänge eines Wiener Poeten* (1831), by "Anastasius Grun" (Graf A. A. von Auersperg, 1806–76), belonged to a decade earlier. The political lyric came to an end in 1848; the revolutionists of the '40s were, if not appeased, at least silenced by the ineffective risings of that year. If Freiligrath be excepted, the chief lyric poets of this epoch stood aside from the revolutionary movement; E. Geibel (1815–84) was only temporarily interested in the political movement, and his best work is purely lyrical. M. von Strachwitz's (1822–47) promising talent did not feel at home in the political atmosphere; while Annette von Droste-Hulshoff (1797–1848), Germany's greatest poetess, and the Austrian, Nikolaus Lenau (1802–so), are imbued with that pessimistic resignation which is characteristic of the best German literature between 1850 and 1870.

Mid-century Literature.— When once the revolution of 1848 was over, a spirit of tranquillity came over German letters; but it was without confidence or hope in the future. The literature of the middle of the century was not wanting in achievement, but it lacked enthusiasm and initiative; it was slow to respond to the new ideas of the time. The so-called "Hegelian Left" had advanced so far as to have become incompatible with the original Hegelianism; the new social and economic theories did not fit into the scheme of Hegelian collectivism; the interest in natural science—fostered by the popular books of J. Moleschott (1822–93), Karl Vogt (1817–95) and Ludwig Biichner (1824–99)—created an effective antidote to the Hegelian metaphysics. In literature Hegel's influence gave place to that of the chief exponent of philosophic pessimism, Arthur Schopenhauer (1788–1860). Schopenhauer's chief work, *Die Welt als Wille und Vorstellung,* had appeared, it is true, as far back as 1819; but the century was more than half over before pessimism became a dominant force in German intellectual life.

The 20 years between 1850 and 1870 were pre-eminently an age of prose fiction. Friedrich Spielhagen (1829–1911) followed in Gutzkow's footsteps, and in a series of excellent novels from *Problematische Naturen* (1860) to *Sturmflut* (1876), held the mirror up to the social problems which agitated the German mind in these decades. Gustav Freytag (1816–95), although an older man, freed himself more successfully from the "Young German" tradition; his romance of German commercialism, *Soll und Haben* (1855), is the masterpiece of mid-century fiction of this class. Less successful were *Die verlorene Handschrift* (1864) and his series of historical novels, *Die Ahnen* (1872–So). As was, however, only natural in an age of social and political interests, the historical novel occupies a subordinate place. The influence of Scott, which in the earlier period had been strong, produced only one writer of distinction, Wilhelm Häring ("Willibald Alexis," 1798–1871). In the series of six novels, from *Der Roland von Berlin* to *Dorothe,* published between 1840 and 1856, Alexis gave Germany, and more particularly Prussia, a historical fiction which has been compared with the *Waverley Novels.* But Alexis had no successor, and the historical novel soon made way for a type of fiction seen in the "antiquarian" novels of ancient Egyptian life by Georg Ebers (1837–98), and the historical romances of Felix Dahn (1834–1912), in which the accurate reproduction of remote conditions was held of more account than poetic inspiration or artistic power. Under Fenimore Cooper's influence American life and adventure came into vogue. The chief German writers who made these their theme, were K. A. Postl, who wrote under the pseudonym of Charles Sealsfield (1793–1864) and Friedrich Gerstacker (1816–72).

Of greater importance was the novel of peasant and provincial life, of which Immermann had given an excellent example in *Der Oberhof,* a short story embedded in his *Münchhausen.* A Swiss pastor, A. Bitzius, better known by his pseudonym "Jeremias Gotthelf" (1797–1854), was, however, the real founder of the peasant romance; and his simple, unvarnished stories of Swiss life were followed not long afterwards by the more famous *Schwarzwalder Dorfgeschichten* (1843–54) of Berthold Auerbach (1812–82). These village stories seem to us now lacking in naïveté, but they enjoyed a wide popularity in their day, and were the forerunners of a large body of peasant literature dealing with South German village life. With this group of writers may also be associated A. Stifter (1805–68), who has given us unforgettable pictures and impressions of the life and scenery of Bohemia.

Meanwhile, the Low German peoples benefited by this revival of interest in dialect and peasant life; Fritz Reuter (1810–74) brought honour to the Plattdeutsch of the north, with his Mecklenburg novels, especially *Ut de Franzosentid* (1860), *Ut mine Festungstid* (1863) and *Ut mine Stronztid* (1862–64), books which have a place beside the best High German fiction of the period; what Reuter did for Plattdeutsch prose, his contemporary, Klaus Groth (1819–99), the author of *Quickborn* (1852), did for its verse. Another north German, Theodor Storm (1817–88), is the author of short stories of delicate, lyric inspiration, steeped in that elegiac Romanticism which harmonized so well with mid-century pessimism. In Switzerland Gottfried Keller (1819–90), a native of Zurich, was a modern Romanticist of a robuster type; his magnificent autobiographical novel, *Der grüne Heinrich* (1854–55), might be described as the last in the great line of Romantic fiction that had begun with *Wilhelm Meister,* and his volumes of short stories, *Die Leute von Seldwyla* (1856–74) and *Züricher Novellen* (1878) contain masterpieces of the first rank.

In the German theatre of these decades French influence was predominant; and the successful German playwrights, such as R. Benedix (1811–73) and Charlotte Birch-Pfeiffer (1800–68), have small literary interest. Gustav Freytag's admirable comedy, *Die Journalisten* (1852), was one of the few exceptions. But the German drama of this epoch is not to be judged by the theatres. At the middle of the century Germany could point to two writers who, each in his way, contributed to the development of the modern European drama: Friedrich Hebbel (1813–63) and Otto Ludwig (1813–65). Hebbel is the most original German dramatist of the 19th century. His first tragedy, *Judith,* appeared in 1840, his masterpieces, *Herodes und Marianne, Agnes Bernauer, Gyges und sein Ring,* and the triiogy of *Die Nibelungen* between 1850 and 1862. They inaugurate the psychological drama, while Ludwig's *Der Erbforster* (1850) is a forekunner of modern realism.

Between 1852 and 1860 King Maximilian II. of Bavaria gathered round him in Munich some of the most distinguished writers of the day. A leading spirit of the group was Emanuel Geibel. F. von Bodenstedt (1819–92), revived the Oriental interest with his *Mirza Schaffy;* and J. V. von Scheffel (1826–86),

won wide popularity with his historical novel *Ekkehard* (1857) and his verse-romance, *Der Trompeter von Sackingen* (1854). This kind of light epic, which had been cultivated earlier by O. von Redwitz (1823–91) and G. Kinkel (1815–82), was, in fact, one of the favourite forms of poetry at this time, its most successful exponents being J. Wolff (1834–1910) and R. Baumbach (1840–1905); while others, such as H. Lingg (1820–1905) and R. Hamerling (1830–89) devoted themselves to the more ambitious epic. The pessimism of the age is deeply engrained in the verse of H. Lorm (pseudonym for Heinrich Landesmann, 1821–1902) and H. Leuthold (1827–79). The most important prose-writer of the Munich group is Paul Heyse (1830–1914), the best of whose "Novellen" or short stories give him a place beside Storm and Keller. He is also the author of two important long novels, *Kinder der Welt* (1873) and *Im Paradiese* (1875).

From 1870 to 1900.—The Franco-German War had little or no immediate effect on literary development. The interest of the nation was engrossed, not by literature, but by the *Kulturkampf*, the financial difficulties due to unscrupulous speculation, and the rapid rise of social democracy as a political force. The intellectual basis of the latter movement was laid by Ferdinand Lassalle (1825–64) and Karl Marx (1818–83), author of *Das Kapital* (1867–94). The influence of Hegel was still strong, and the "historical" method was generally in vogue at the German universities. H. Lotze (1817–81) attempted to establish a compromise between science and metaphysics; while in his *Philosophie des Unbewussten* (1869), E. von Hartmann (1842–1906) aimed at reconciling pessimism with idealism. But in literature and art the dominant force was still the philosophy of Schopenhauer. In lyric poetry there was, however, some reaction to the war, and the singers of the revolution of 1848 were among the first to welcome the unification of Germany. At the same time, men of the older generation, like Herwegh, Freiligrath and Geibel could ill conceal a certain disappointment with the new régime; the united Germany of 1871 was not what they had dreamed of in their youth, when all hopes were set on the Frankfurt parliament.

The novel continued to be what it was before 1870, the most popular form of German literature, hut the novelists who enjoyed favour in the early '70s were all older men; while the drama was even less promising. The iambic tragedy was cultivated by the Munich school, by A. Wilbrandt (1837–1911), A. Lindner (1831–88), by the Austrian F. Nissel (1831–93), and A. Fitger (1840–1909); but it was characteristic of the time that Halm was popular, while Hebbel and Grillparzer were neglected. The most gifted German dramatist between 1870 and 1880 was an Austrian, Ludwig Anzengruber (1839–89), who produced a series of powerful plays dealing with the life of the Austrian peasant. But the popular playwrights of this epoch were either writers who cultivated the *bourgeoise* comedy—G. von Moser (1825–1903), O. Blumenthal (1852–1918)—or who, like P. Lindau (1839–1919), imitated French models. The only encouraging sign in the dramatic history of this period is the marked improvement of the German stage, an improvement due to the artistic reforms introduced by the duke of Meiningen in his Court theatre and to the ideals of a national theatre realized at Bayreuth by Richard Wagner (1813–83). The first performance of Wagner's tetralogy *Der Ring des Nibelungen* at Bayreuth in the summer of 1876 was a significant event in the history of the German drama.

In marked contrast to all this, the last 15 years of the 19th century were a period of intense literary activity. Among the younger generation, growing up as citizens of the united German empire, a more hopeful spirit prevailed. The influence of Schopenhauer was on the wane, and at the universities Kant was taking the place of Hegel. L. von Ranke (1795–1886) was still the dominant force in German historical science, and between 1881 and 1888 nine volumes appeared of his last great work, *Weltgeschichte*. Other historians of the period were H. von Sybel (1817–95) and H. von Treitschke (1834–96), the latter a vigorous and inspiring spokesman of Germany's political aspirations; while J. Burckhardt (1818–97), author of the masterly *Kultur der Renaissance in Italien* (1860), exerted an influence on German thought which was not confined to academic circles. Literary criticism perhaps benefited most of all by the new outlook. It became more cosmopolitan in spirit, a change which is more particularly noticeable in its attitude to Goethe whose greatness had been hitherto overshadowed by Schiller's.

The thinker who embodies the spirit of this period was Friedrich Nietzsche (1844–1900). Nietzsche had begun as a disciple of Schopenhauer and a friend of Wagner, but his mature thought is militantly individualistic, and in its optimism the sharpest contrast to mid-century pessimism. The individual, not the race, the *Herrenmensch,* not the slave, self-assertion, not self-denying renunciation—are the pivotal ideas round which his ethics turn. Nietzsche looked forward to the human race emerging from the effete culture of tradition, and re-establishing itself on a basis in harmony with man's primitive instincts. Like Schopenhauer before him, Nietzsche was a stylist of the first rank, and his literary masterpiece, *Also sprach Zarathustra* (1883–91), is one of the most important works of its epoch.

The German lyric reacted most quickly to the individualism of Nietzsche—himself a lyric poet of considerable gifts. Detlev von Liliencron (1844–1909) was the first to break, in his *Adjutantenritte* (1883), with the traditions of the past; and an anthology, *Moderne Dichtercharaktere* (1885) by W. Arent (b. 1864), may be regarded as the manifesto of the new movement. Representative lyric poets of this period are G. Falke (1853–1916), A. Holz (1863–1929), K. Henckell (1864–1929), F. Avenarius (1856–1923), K. Busse (1872–1918) and Richard Dehmel (1863–1920). Heinrich Hart (1855–1906), a critic of the new school, was also the author of an ambitious *Lied der Menschheit* (vols. 1–3, 1888–96); but the master of the epic in this age, and one of its greatest poets, is a Swiss, Karl Spitteler (1845–1924). His *Olympischer Frühling* appeared in two parts in 1900 and 1906. The lighter side is represented by the poetry of the so-called *Überbrettl* or cabaret; its chief exponent was O. J. Bierbaum (1865–1910), whose lyrics are collected in *Irrgarten der Liebe* (1901).

Nietzschean individualism was only one of many factors which contributed to the vitality of this new literature. The realistic movement, as it had developed in France, Russia and Scandinavia, now became a dominant force in Germany. The centre of this movement was Berlin, which, since it had become the imperial capital, was rapidly also becoming the literary metropolis. The novel reacted quickly to this new realism, more especially as some of the older and established writers, such as F. Spielhagen and A. Wilbrandt, regarded it with sympathy. Theodor Fontane (1819–98), wrote between 1880 and 1898 a series of novels in which the finer elements of French realism were grafted on the German tradition. To the older school belong Wilhelm Jensen (1837–1911), and that fine humourist, Wilhelm Raabe (1831–1910), with whom may be associated as other humourists of this period, H. Seidel (1842–1906) and W. Busch (1832–1908). Two eminent Austrian authors, Marie von Ebner-Eschenbach (1830–1916), and Ferdinand von Saar (1833–1906), both excel as writers of short stories. An Austrian, too, is Peter Rosegger (1843–1918), who won popularity with his many novels of peasant life. German prose in Switzerland is represented pre-eminently by Konrad Ferdinand Meyer (1825–96), who turned to literature comparatively late in life. Meyer resembles his compatriot Keller in being not merely a master of the short story—for his themes he turns with preference to the period of the Renaissance—but also a writer of virile, original verse.

Realistic novels were written by H. Conradi (1862–90), Max Kretzer (b. 1854), M. G. Conrad (1846–1927), K. Bleibtreu (1859–1928), K. Alberti (pseudonym for Konrad Sittenfeld, 1862–1918) and Hermann Sudermann (1857–1928), whose *Frau Sorge* (1887) and *Der Katzensteg* (1889) are among the best of this period. His later and longer novels *Es War* (1894) and *Das hohe Lied* (1908), are marred by a crass sensationalism. Realistic, too, in its origins was the so-called *Heimatskunst,* the cultivation of the province, which was responsible for many excellent novels. Here may be mentioned as representative of widely different areas of the German-speaking world H. Lons (1866–1916) and Otto Ernst (1862–1926) in the north; H. Stehr (b. 1864) in

Silesia; F. Lienhart (1865–1929) and E. Zahn (b. 1867) in the south-west. Particularly popular were the novels *(Jorn Uhl,* 1901) of G. Frenssen (b. 1863). Studies of child life and educational problems proved particularly attractive to later writers, such as Hermann Hesse (b. 1877), Emil Strauss (b. 1866), Rudolf Huch (b. 1862) and Friedrich Huch (1873–1913). Mention ought also to be made of W. von Polenz (1861–1903), G. von Ompteda (1863–1931), W. Hegeler (b. 1870) and G. Hermann (b. 1871). On the whole, the greatest novel of this epoch is *Buddenbrooks* (1902) by Thomas Mann (b. 1875), who is also the author of masterly short stories. Some of the best fiction was the work of women, the most distinguished being Helene Bohlau (1859–1919), Gabriele Reuter (b. 1859), Clara Viebig (C. Cohn-Viebig, b. 1860) and Ricarda Huch (b. 1867).

The theatre, however, was the arena in which the decisive literary battles of the day were fought out. In Oct. 1889 Hauptmann's play, *Vor Sonnenaufgang,* was produced on the then recently founded *Freie Bühne* in Berlin; and a month later, *Die Ehre* by Sudermann met with a more enthusiastic reception in Berlin than had fallen to the lot of any German play for more than a generation. Before that date, Ernst von Wildenbruch (1845–1909) had attempted to revive the historical tragedy, and other dramatists, such as Richard Voss (1851–1918), had experimented with realism.

Gerhart Hauptmann (b. 1862) is the most eminent of contemporary German dramatists. His early plays, the most powerful of which is *Die Weber* (1892), were works of uncompromising realism; but in *Hanneles Himmelfahrt* (1893) he combined realism with the poetic mysticism of a child's dream, and in *Florian Geyer* (1895) he adapted the methods of realism to an historical theme. In 1896 he, to all appearance, abandoned realism for poetic allegory in *Die versunkene Glocke.* Hauptmann's subsequent work is exceedingly varied and ranges from the frank naturalism of *Fuhrmann Henschel* (1898) and *Rose Berndt* (1903), to subtle psychological studies in *Der arme Heinrich* (1902) and *Kaiser Karls Geisel* (1908), and the poetic mysticism of *Und Pippa tanzt!* (1906). Hauptmann has also written some excellent comedies *(Der Biberpelz,* 1893). Hermann Sudermann (1857–1928) had a more immediate popularity with the long series of plays of modern life which opened with *Die Ehre.* Of these the best are perhaps *Heimat* (1893) and *Das Glück im Winkel* (1896). With less success Sudermann attempted in *Johannes* (1898) a tragedy on the lines of Hebbel. Sudermann's talent showed less capacity for development than Hauptmann's; he was a practical playwright rather than a dramatic poet.

Besides Hauptmann and Sudermann, the most talented dramatists of this period were Max Halbe (1865–), O. E. Hartleben (1864–1905), G. Hirschfeld (1873–), Ludwig Fulda (1862–1939), Max Dreyer (1862–), and especially Frank Wedekind (1864–1918). In Vienna, notwithstanding the influence of Berlin, the drama retained its Austrian characteristics, with writers like Arthur Schnitzler (1862–1931), Hermann Bahr (1863–1934) and Hugo von Hofmannsthal (1874–1929), the last-mentioned being one of the greater poetic forces of his time.

The 20th Century.—The movement of realism and impressionism had not progressed very far before it was plain that it was but a passing phase; even before the end of the century it had ceased to be the dominating force in German letters. The lyric, at all times the most sensitive expression of the German literary temperament, soon broke away; and under the influence of similar movements in France, it is to be seen feeling its way towards a new form, describable at one time as neo-classic, at another as neo-romantic, but in either case definitely opposed to the previous impressionism. The representative poet of this revolt was Stefan George (1868–1933), whose finely chiselled verse effected, from the early '90s on, a complete break with the past. But even here there was no permanence; a younger generation of poets came to the front who, while profoundly influenced by Stefan George's formal beauty, felt the need of more subjective and emotional expression. But there could be no question of going back; for by this time impressionism had been definitely discredited by new doctrines of "expressionism," in accordance with which the interpretation of the outside world by the poet, or indeed, the superimposition of his ego upon that world, was of the first importance. Prominent among the poets of this new phase are Max Dauthendey (1867–1918), Christian Morgenstern (1871–1914), Alfred Mombert (1872–), and Theodor Daubler (1876–1934), whose most notable work is an epic, *Nordlicht* (1910); nor must Georg Heym (1887–1912) be forgotten, whose early death deprived the lyric of a talent of great promise. The most gifted poet of this last phase of the German lyric is Rainer Maria Rilke (1875–1926), a native of Prague. Rilke's subtle spiritual mysticism and haunting cadences have made the deepest impression of all upon the present generation. The World War was, of course, responsible for much political and patriotic poetry of ephemeral value, and indeed, in no form of literature did the war bring about more confusion than just here; but on the other hand, the lyric responded more quickly to the new ideas awakened by the terrible tragedy and devastation which had overwhelmed Europe. The militarism of the war-poets was soon displaced by an intense pity for suffering humanity and a craving for the reconstruction of human society on the basis of a universal brotherhood. Among the new poets who have given voice to this aspiration towards spiritual and social regeneration the most significant is Franz Werfel (b. 1890).

The drama of the 20th century shows an even more surprising change of front, compared with the activity of the preceding generation. Here the doctrine of expressionism has full sway, and aided by the remarkable technical development of the German theatre, has produced a drama of extraordinary interest, which, whatever its ultimate value may be, represents the most complete repudiation of the old realism. Of the older writers only Hauptmann has in some measure kept abreast of the movement; his later dramas show an increasing tendency to dwell on subtle psychological problems of allegorical implication, and thus adapt themselves to the changing spiritual horizon; but the actual leadership has passed to younger hands. The drama of expressionism, which obviously owes much to the Swede Strindberg and the Belgian Maeterlinck, was inaugurated in 1912 by *Der Bettler* by Reinhard Sorge (1892–1916); but the new art did not assert itself until two years later, on the eve of the war, when *Die Bürger von Calais* by Georg Kaiser (b. 1878) and *Der Sohn* by Walter Hasenclever (b. 1890) were produced. Kaiser's talent is extraordinarily facile and prolific, and much of his work has consequently little abiding value. He began with satiric comedies which show clearly the influence of Wedekind, as do also those of Karl Sternheim (b. 1881); but in *Von Morgens bis Mitternachts* (1916), *Die Koralle* (1917), and the trilogy *Gas* (1918–20), he has given German expressionism some of its most characteristic works. A vigorous talent of the school mas Ernst Toller (1893–1939), while with Reinhard Goering (1887–1936), author of *Seeschlacht* (1917) and *Scapa Flow* (1919), Paul Kornfeld (b. 1889), Hanns Johst (b. 1890) and Johannes R. Becher (b. 1891), the expressionist drama seems in danger of dissolving in nebulous mysticism and losing all touch with the practical theatre. This, too, is true of the dramas *Ein Geschlecht* (1916) and *Platz* (1920) by Fritz von Unruh (b. 1885), a dramatist of real poetic gifts who, before the war, had written two effective dramas of military life, to become, in its course, a convert to anti-militarism.

Side by side with this expressionist drama there has been a considerable neo-romantic revival in the theatre; many of the younger poets have gone back to mediaeval and even ancient sagas and history for their themes, discovering in them modern implications and infusing into them a very modern psychology. The abiding value of this aspect of the contemporary drama seems, however, open to question. The chief poets who come in question here are Herbert Eulenberg (b. 1876), Ernst Hardt (b. 1876), K. G. Vollmöller (b. 1878), Wilhelm von Scholz (b. 1874) and Paul Ernst (1886–1933). Here. too. should be mentioned the spacious mystic trilogy *Aeon* (1907–11) by Alfred Mombert, and the fine drama *Spiegelmensch* (1920) by *F.* Werfel. Of the more recent dramatists in Austria, Karl Schönherr (b. 1869) and Anton Wildgans (1881–1932); in Switzerland Max Pulver (b. 1889), may be mentioned.

Of the German novel in the last period it is less possible to speak in positive terms. It has experienced the same difficulty as that of other lands in the post-war era, in reconciling literary quality with the demand for entertaining books that are of an immediate but transient appeal. Moreover, the new literary theories of the day have led to much experimenting of a psychological and expressionist kind, which, so far from being favourable to the novel, has accentuated those tendencies to formlessness and verbosity which have always been its weak side. Of the older writers Thomas Mann has concentrated his experience of the war years in an amorphous novel, *Der Zauberberg* (1925), which, however, has little of the imaginative strength of *Buddenbrooks*. His more prolific brother Heinrich (b. 1871), who contributed to the fiction of the decadence before the war, has satirized the old régime in a series of novels, *Das Kaiserreich* (1918–25). One of Hauptmann's several novels, *Emanuel Quint* (1910), has real literary significance, while Sudermann has redeemed the sensationalism of his earlier work with a volume of fine *Lithauische Geschichten* (1917). Of the newer writers of fiction Jacob Wassermann (1873–1934) and Bernhard Kellermann (b. 1879) have produced books of some distinction, while in the field of the historical novel E. G. Kolbenheyer (b. 1878) and Enrica Handel-Mazzetti (b. 1871) perhaps may retain a place in literary history.

The time has obviously not yet come for a summing-up of the significance of the last phase of German literary history. It may well be that the future will attach more importance to the ideas that lie behind it than to the actual production—that revival of mysticism in German thinking which has led alike to a revaluation of the past and to the reconstruction of the present; but it has at least borne out the old tradition of the unexpected which is characteristic of all new developments in the history of Germany's literature.

GERMAN OFFENSIVE, 1918. This great effort to obtain a military decision on the western front in France and Flanders before the intervention of American man-power could turn the scales, comprised four main acts, opening respectively on March 21 (*see* ST. QUENTIN, BATTLE OF, 1918); April 9 (*see* LYS, BATTLES OF THE, 1918); May 27 (*see* CHEMIN-DES-DAMES, BATTLE OF THE, 1918), and July 15 (*see* MARNE, SECOND BATTLE OF THE). Important attacks were also attempted, but with less success, on April 24 in front of Amiens, and on June 9 in the direction of Compiégne, the latter to break down the "buttress" between the salients made by the St. Quentin and Chemin-des-Dames offensives. These and the general course of the whole offensive are described under WORLD WAR.

GERMAN SILVER or **NICKEL SILVER,** an alloy of copper, nickel and zinc, prepared either by melting the copper and nickel together in a crucible, and adding piece by piece the previously heated zinc, or by heating the finely divided metals under a layer of charcoal. To destroy its crystalline structure and so render it fit for working it is heated to dull redness and then allowed to cool. German silver is harder than silver; it resembles that metal in colour, but is of a greyer tinge. Exposed to the air it tarnishes slightly yellow, and with vinegar affords a crust of verdigris. At a bright red heat it melts, losing its zinc by oxidation unless protected from the atmosphere. At a heat above dull redness it becomes exceedingly brittle.

German silver in various modifications of composition is much used in the arts. Alloys, of which about 50% is copper and the residue zinc and nickel in about equal proportions, take a fine polish and are used as imitation silver for knives and forks. With a somewhat higher proportion of copper an alloy is formed suitable for rolling and for wire. In Chinese *white silver* or *packfong* (paktong) the amount of copper is smaller, about 40%, with about 32% of nickel, 25 of zinc, and 2 or 3 of iron. German silver for casting contains 2 or 3% of lead, which like iron increases the whiteness of the alloy. German silver, having a high specific resistance and a low temperature coefficient, has been used for electrical resistance coils, and these qualities are possessed in a still greater degree in *manganin,* which contains manganese in place of zinc, its composition being 84% of copper, 12 of manganese and 4 of nickel. The addition of a trace of tungsten to German silver, as in *platinoid,* also largely increases the resistance.

GERMAN SOUTH-WEST AFRICA. A territory north of the lower course of the Orange river, which, owing to its proximity to Cape Colony, came to be regarded as a sort of depend-

ency of the Cape. This territory, bounded on the east by the Kalahari desert, was inhabited by Hottentot tribes who had migrated from the Cape, and was known as Great Namaqualand. A few Dutch and British farmers had settled in it, and from 1805 the London Missionary Society had agents—of German nationality—among the Hottentots, many of whom had a considerable strain of European blood. About 1840 the L.M.S. transferred its stations to the Rhenish mission. A few traders established themselves on the coast at Angra Pequena; in 1867 the small islands off the coast, which had valuable guano deposits, were annexed to Great Britain. The next year (1868), largely as the result of disputes between the Hottentots and their neighbours, the Herero, a tribe living in Damaraland, the Rhenish missionaries, seeking protection, asked Great Britain to annex the country. Although this appeal was supported by Prince Bismarck, on behalf of the Prussian Government, it was refused. In 1876, however, the Cape Government sent W. Coates Palgrave as "special commissioner to the tribes north of the Orange." Palgrave concluded treaties which placed the whole region up to the Portuguese colony of Angola under British control. Sir Bartle Frere, then high commissioner for South Africa, approved Palgrave's action, but the British Government refused to ratify the treaties, and it was with difficulty that Sir Bartle obtained consent (1878) to annex Walvis bay, the only good harbour along the coast, and the adjacent strip of territory.

Such was the position when, in July 1883, an agent of Adolf Liideritz (a Bremen merchant), obtained a cession of land at Angra Pequena, since known as Luderitz bay. Prince Bismarck, a late convert to belief in German colonial expansion, gave ample opportunity to Great Britain to act. The opportunity was neglected, both by the London and the Cape cabinets, and in Aug. 1884 a German protectorate was proclaimed. Treaties with Portugal (1886) and Great Britain (1890), fixed the limits of German territory.

A large part of the country thus obtained was barren. The most fertile and most thickly-inhabited part was the northern tropical region of Ovamboland; but in this remote district the Germans interfered little. Elsewhere, besides deserts, were large stretches of grazing ground, and certain areas where farming was possible. Moreover, South-west Africa was the only oversea possession suitable for white settlement which Germany had acquired. The Germans, almost from the outset, had much trouble with the Hottentots, but in 1894 Hendrik Witboi, the most redoubtable Hottentot leader, concluded peace and became an ally of the Germans. In that year von Leutwein became governor, and under his rule in the next ten years the country made much progress. Swakopmund was chosen as chief port, and from it a railway, 240m. long, was built (1897–1902) to Windhuk, a former Hottentot stronghold in the hill country which the Germans had made their capital. Another line was built going north to the copper mines of Otavi. Land was very freely appropriated by the white settlers from the natives; a cause of great discontent, though von Leutwein endeavoured to treat the natives with consideration.

In 1903 the Bondelzwart Hottentots, living near the Cape border, rose in revolt, and this developed into a long and ruthless struggle with the Herero and the Hottentots generally. Impatience of white rule, and the loss of their grazing grounds by the natives, were the main causes of the war. The Herero began hostilities (Jan. 1904) in the approved fashion of savage tribes—the murder of a number of German farmers and their families. Troops under Gen. von Trotha were sent from Germany. Von Trotha stormed the Herero stronghold in Aug. 1904, but the main body of the enemy escaped and thereafter kept up a harassing guerilla warfare. Von Trotha, exasperated, issued a proclamation in Oct. 1904 saying that every (man) Herero within the German frontier, "with or without a rifle," would be shot; no more women or children would be taken over. "I will either drive them back to your people or have them fired on." Later von Trotha ordered his soldiers to fire, not into, but over the heads of the women and children; while Prince Bulow, the then chancellor, ordered the general to repeal the whole proclamation. At this juncture (Oct. 1904) Hendrik Witboi broke with the Germans and was joined by other Hottentot tribes; the first act of the insurgents being the massacre of some 60 German settlers in the Gibeon district (British and Boer farmers were left in peace). Witboi was incensed because von Leutwein, for whom he had great admiration, had been recalled to Berlin, and by the harsh conduct of von Trotha. The Germans found that in the Hottentots they had to deal with an able, determined and elusive foe, and that in a country largely roadless and waterless. Von Trotha was in turn recalled towards the end of 1905. The new governor. von Lindequist, issued an amnesty to the Herero, who had lost some 30,000 men killed, while thousands, including women and children, had been driven into the Kalahari desert, there to perish. In Nov. 1905 Hendrik Witboi died, but other Hottentot chiefs continued the struggle, and it was not until 1908 that German authority was completely re-established. At the height of the campaign (1906) the Germans had 19,000 men in the field, while the cost of the wars (1904–08) to the Imperial Treasury was £23,000,000.

The native wars had resulted in the loss, in all, of some 100,000 native lives, and from 1908 the problem of getting labour was very difficult. But in that year diamonds were discovered along the coast by Luderitz bay, and a new and profitable industry quickly grew up. Europeans were attracted, and though settlers on the land were few, the white population in 1913 numbered nearly 15,000, of whom over 12,000 were Germans. The railway system was greatly extended, and the Government, though bureaucratic and expensive, did much to encourage farmers and pastoralists, while the settlers were given some voice in the administration. The country had never paid its way, but the grant-in-aid had been brought down to £500,000, and there appeared to be a fair future for this German colony when, in 1914, the World War began. A year later the country had been conquered by Gen. Botha, and it passed under the administration of the Union of South Africa. (See SOUTH-WEST AFRICA, CAMPAIGN IN.)

See South-west *Africa,* British Foreign Office handbook (1920), with bibliography. (F. R. C.)

GERMANTOWN, a residential district and former suburb, now a ward of Philadelphia, Pa., U.S.A., on Wissahickon Creek, in the northern part of the city. There are many old colonial houses along Germantown avenue (the old Main street). Prominent among the historic houses is Cliveden, or the "Chew House," built about 1761 by Benjamin Chew (1722–1810), who was chief justice of Pennsylvania in 1774–1777 and was imprisoned as a Loyalist in 1777, and whose home during the battle of Germantown was occupied by British troops. The well-preserved Morris House (1772) was the headquarters of General Howe at the close of the battle. Three doors above stood until 1904 the Ashmead House, used for a time by Count Nicholas Lewis Zinzendorf and his daughters for their Moravian school. In the same street is the old Wister Mansion, built as a country-seat in 1744 and occupied by British officers during the battle of the Revolutionary War. In another old house (now Nos. 5275–5277), John Fanning Watson (1779–1860), the annalist of Philadelphia, did most of his literary work. In this vicinity the first paper mill in America was erected in 1690. The King of Prussia inn, built about 1740, and the Mermaid hotel, as old or older, are interesting survivals of the inns and taverns of old Germantown. The Germantown Academy was built in 1760, and after the battle of Germantown was used by the British as a hospital. In Germantown are also a Friends' school, a Friends' free library, and the Germantown branch of the Philadelphia public library. The first school in Germantown was established about 1701. For the first 18 years it was under the mastership of Francis Daniel Pastorius (1651–1719), the leader in founding the town, who lived in a house that stood on the site of the present First Methodist Episcopal church. High street and Main street. He compiled a primer which was the first school book produced in the State. Later the same school passed to Christopher Dock (d. 1771), who in 1770 published an essay on teaching (written in 17jo), which is said to have been the first book on pedagogy published in America. The first Bible printed in America in any European language was published in Germantown in 1743 by Christopher

Sauer (d. 1758), who in 1739 established Germantown's first newspaper, *The High German Pennsylvania Historian, or Collection of Important News from the Kingdom of Nature and of the Church.* The Friends were the first sect to erect a meeting-house of their own (about 1686). The Mennonites built a log meeting-house about 1708, and their present stone church was built in 1770. Germantown manufactures textiles, knit goods and yarns.

Germantown was founded in Oct. 1683, by 13 families from Crefcld, Germany, under the leadership of Francis Daniel Pastorius. The borough of Germantown was incorporated in 1691. For many years it was a struggling village, but after 1750 its growth was more rapid. It was annexed to Philadelphia in 1854.

See Samuel W. Pennypacker, *The Settlement of Germantown, and the Beginning of German Emigration to North America* (Philadelphia, 1899); S. F. Hotchkiss, *Ancient and Modern Germantown, Mount Airy and Chestnut Hill* (Philadelphia, 1889); N. H. Keyser, "Old Historic Germantown," in the *Proceedings and Addresses of the Pennsylvania-German Society* (Lancaster, 1906); and Herbert Pullinger, *Old Germantown* (Philadelphia, 1926).

The Battle of Germantown. — This famous encounter in the American War of Independence was fought on Oct. 4, 1777. Following the battle of Brandywine (*q.v.*) and occupation of Philadelphia, the British force commanded by Sir W. Howe encamped at Germantown, where Washington determined to attack them. The Americans advanced by two roads, Gen. Sullivan leading the column on the right and Gen. Greene that on the left. Washington himself accompanied Sullivan, with whom were Stirling and Anthony Wayne. The right at first met with success, driving the British advanced troops back on the main body near the Chew House. Col. Musgrave, of the 40th Foot, threw a portion of his regiment into this house, and Gen. Agnew came up with his command. The Americans under Stirling attempted to dislodge Musgrave, thus losing time. Gen. Greene on the left was even less fortunate. Meeting with unexpected opposition at the first point of attack his troops were thrown into confusion and compelled to retreat. One of his brigades extended itself to the right wing, and by opening fire on the Chew House caused Wayne to retreat, and presently both of the American columns retired rapidly in the direction of their camp. The surprise had failed. Washington went into winter quarters at Valley Forge, 40m. W. of Philadelphia. The British wintered in and around the city.

GERMAN VOLGA REPUBLIC, an A.S.S.R. created in February 1924. It is situated between lat. 49° 50′ N. and 52° N. and long. 44° 45′ E. and 48° 5′ E. It is mainly bordered by the Saratov province, which it divides into two separate parts. Samara touches it on the north-east, and Stalingrad and the Kazakstan A.S.S.R. on the south and south-east. Its area is 26,753 sq km., one fourth lying on the right and three fourths on the left bank of the Volga river. The district on the left bank is a plain, with chestnut-coloured soil passing over into salt steppe in the south-east where it nears the Aralo-Caspian depression. The water supply is poor and the streams often salty. The right bank area is a plateau, cut by rivers into ravines which give it a hilly appearance, and it has some forest. The streams here are not salt, and the soil in the north is black earth; towards the south the transition zone to the salt steppe begins. Except for the Volga river the streams are shallow, liable to dry up, and not suitable for navigation or floating goods. The climate is distinctly continental, average July temperature 73°, January 11°. The rainfall in the south-eastern part rarely exceeds 300 mm. per annum, and even in the more favoured north-west only reaches 350 mm. per annum. The number of days with rain is rarely more than 100, and most of these are in the period October to March. This scanty rainfall cannot be relied on, and the region has always been liable to years of drought. An added drawback is the liability to late spring frost even at the end of May, and to early autumn frost in September. Dry winds from the desert to the south and east blow for more than half the year, and there are occasional severe storms. Precarious agriculture is the main occupation and the 1921 famine reached terrible proportions in this district; the population in 1920 was nearly 700,000, but in 1926 was 571,089. Further droughts and bad harvests occurred in 1922 and 1924, but since then varieties of seed have been selected for their drought-resisting qualities and better harvests have ensued. The chief crops are wheat, barley, rye, millet, maize and sunflower seed; in pre-1914 times wheat was largely produced for export, but the subsequent poverty and famine altered the balance of crops in favour of barley, rye, millet and sunflower seed; maize is also more widely grown than formerly. Irrigation, the only safeguard against recurrent drought, is proceeding as rapidly as local finance will allow, and in 1925–6 the irrigated area was 13,500 hectares. Irrigation works in progress of construction in 1928 cover an area of 40,000 hectares. Livestock diminished markedly during the famine period, but the balance is being gradually restored. Horses and working cattle are still much below pre-war numbers but oil-tractors are taking their place. Sheep, goats, pigs and camels are bred. The industries include flour-milling, tobacco-making from local makhorka, begun in 1922, a leather factory built at the town of Golom-Karamysh in the right bank district, bacon factories, and a factory built in 1926 at Markstadt (formerly Katherinestadt) on the left bank of the Volga, for the manufacture of oil tractors. There are small sawmills in the forest area, and a large one at Pokrovsk, the administrative centre on the left bank of the Volga opposite to Saratov. Peasant industries are widespread.

History. — About 27,000 German colonists were settled on the Volga river in 1760 and 1761 at the invitation of Catherine II. by special manifesto, when the population of Russia was so much less than today that the government was concerned for the development of uncultivated lands. The climatic difficulties of their new environment, lack of capital, oppression by officials and attacks by Kirghiz and Kalmucks diminished their numbers by 50% in the first ten years. They were at first given special privileges, including exemption from army service, but in the mid-nineteenth century these privileges were annulled. About 1870 the small measure of autonomy remaining to them was cancelled and the colonies broken up.

When war with Germany broke out, the German colonists were persecuted and in 1915 an Imperial ukase ordered their exile to Siberia.

Before this was carried out, the 1917 revolution took place. In early 1918, a commission was organized at Saratov to organize Soviet rule among the German Volga peoples, and at that town in June 1918 the first Soviet Congress of the Volga Germans expressed a wish for autonomous government.

In October the Autonomous German Volga district was created by decree, and it became a republic in Feb. 1924. Of its twelve cantons, 5 have purely German inhabitants, 4 mixed German-Russian or German-Ukrainian inhabitants and 3 are predominantly Russian or Ukrainian.

Its population was 605,542 (1939). The German Volga Republic has a permanent representative in Berlin.

GERMANY (*Deutschland*), from 1918 to 1933 the German republic; after 1933 known as the "Third Reich"; a country of central Europe, inhabited by the majority of the German-speaking peoples of Europe.

German groups are, however, old established in several other states beyond its borders, and the proportion of these has been increased as a result of changes of territory following World War I.

These terms reduced the area of the *reich* from 208,830 sq.m. to 181,714 sq.m., including the Saar district which was placed under a special régime.

By annexing Austria in March 1938, the Sudeten districts of Czechoslovakia in the following October, and the larger part of the rest of Czechoslovakia in March 1939, under the name of "German Protectorate of Bohemia-Moravia," Hitler created a "Greater Germany" larger than in 1914.

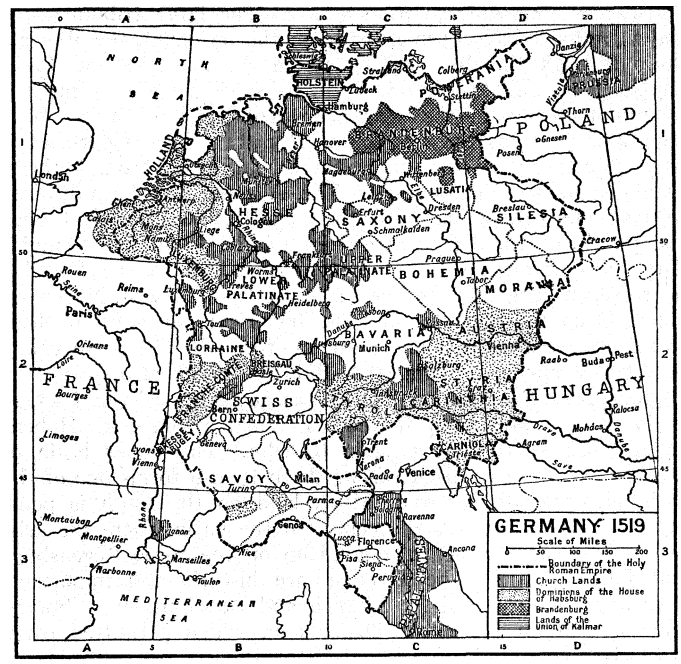
After invading Poland in Sept. 1939, he annexed Danzig, the Polish Corridor, Posen, and districts along the Silesian frontier; he also conquered about half of the rest of Poland, with a population of some 15,000,000, and placed it temporarily under a German governor.

Geology.--Germany consists of a floor of folded Palaeozoic rocks upon which rest unconformably the comparatively little

disturbed beds of the Mesozoic system, while in the north German plain a covering of modern deposits conceals the whole of the older strata from view, excepting sorne scattered and isolated outcrops of Cretaceous and Tertiary beds. The rocks which compose the ancient floor are thrown into folds which in the western half of Germany run approximately from west-south-west to east-north-east. They are exposed on the one hand in the neighbourhood of the Rhine and on the other hand in the Bohemian *massif*. With the latter must be included the Frankenwald, the Thiiringerwald, and even the Harz. The oldest rocks, belonging to the Archaean system, occur in the south, forming the Vosges and the Black Forest in the west, and the greater part of the Bohemian massif, including the Erzgebirge, in the east. They consist chiefly of gneiss and schist, with granite and other eruptive rocks. Farther north, in the Hunsriick, the Taunus, the Eifel and Westerwald, the Harz and the Frankenwald, the ancient floor is composed mainly of Devonian beds. Other Palaeozoic systems are, however, included in the folds. The Cambrian, for example, is exposed at Leimitz near Hof on the eastern side of the Frankenwald, and the important coal-field of the Saar lies on the southern side of the Hunsriick, while Ordovician and Silurian beds have been found in several localities. Along the northern border of the folded belt lies the coal basin of the Ruhr in Westphalia, which is the continuation of the Belgian coal-field, and bears much the same relation to the Rhenish Devonian area that the coal basin of Liége bears to the Ardennes. Carboniferous and Devonian beds are also found south-east of the Bohemian massif, where lies the extensive coal-field of Silesia. The Permian, as in England, is not involved in the folds which have affected the older beds, and in general lies unconformably upon them. It occurs chiefly around the masses of ancient rock, and one of the largest areas is that of the Saar.

Between the old rocks of the Rhine on the west and the ancient *massif* of Bohemia on the east a vast area of Triassic beds extends from Hanover to Basle and from Metz to Bayreuth. Over the greater part of this region the Triassic beds are free from folding and are nearly horizontal, but faulting is by no means absent, especially along the margins of the Bohemian and Rhenish hills. The Triassic beds must indeed have covered a large part of these old rock masses, but they have been preserved only where they were faulted down to a lower level. Along the southern margin of the Triassic area there is a long band of Jurassic beds dipping towards the Danube; and at its eastern extremity this band is continuous with a synclinal of Jurassic beds, running parallel to the western border of the Bohemian *massif*, but separated from it by a narrow strip of Triassic beds. Towards the north, in Hanover and Westphalia, the Triassic beds are followed by Jurassic and Cretaceous deposits, the latter being here the more important. As in the south of England, the lower beds of the Cretaceous are of estuarine origin and the Upper Cretaceous overlaps the Lower, lying in the valley of the Ruhr directly upon the Palaeozoic rocks. In Saxony also the upper Cretaceous beds rest directly upon the Palaeozoic or Archaean rocks. Still more to the east, in the province of Silesia, both Jurassic and Cretaceous beds are again met with, but they are to a large extent concealed by the recent accumulations of the great plain. The Eocene system is unknown in Germany except in the foothills of the Alps; but the Oligocene and Miocene are widely spread, especially in the great plain and in the depression of the Danube. The Oligocene is generally marine. Marine Miocene occurs in north-west Germany and the Miocene of the Danube valley is also in part marine, but in central Germany it is of fluviatile or lacustrine origin. The lignites of Hesse, Cassel, etc., are interstratified with basaltic lava-flows which form the greater part of the Vogelsberg and other hills. The trachytes of the Siebengebirge are probably of slightly earlier date. The precise age of the volcanoes of the Eifel, many of which are in a very perfect state of preservation, is not clear, but they are certainly Tertiary or Post-tertiary. Leucite and nepheline lavas are here abundant. In the Siebengebirge the little crater of Roderberg, with its lavas and scoriae of leucite-basalt, is posterior to some of the Pleistocene river deposits.

A glance at a geological map of Germany will show that the greater part of Prussia and of German Poland is covered by Quaternary deposits. These are in part of glacial origin, and contain Scandinavian boulders; but fluviatile and aeolian deposits also occur. Quaternary beds also cover the floor of the broad depression through which the Rhine meanders from Basle to Mainz, and occupy a large part of the plain of the Danube. The depression of the Rhine is a trough lying between two faults or system of faults. The broader depression of the Danube is associated with the formation of the Alps, and was flooded by the sea during a part of the Miocene period. (P. LA.; X.)



Physical Features.—Germany may be described broadly as the country from the Alps to the North and the Baltic seas, and it includes a number of very diverse zones and physical units; even less than many other countries does it approach any real unity of structure or physical geographical character. The country from the Alps to the Baltic may be divided into six sub-parallel zones: (1) the Alps which stretch across the south of Bavaria; (2) the upper Danube basin framed on the south mainly by the Alps and on the north by (3) the Alpine foreland or the Swabian Jura roughly parallel to the Alps, and the Franconian Jura turning northward as if in face of the resistance of the old block of Bohemia; (4) the basins of the Main and the Neckar between the Jura and (5) the broken highlands of mid-Germany running from the Ardennes to the northern side of the Bohemian block and (6) the broad northern lowland between the north edge of the broken highlands on the south and the coasts of the North sea and Baltic on the north. A seventh physical region stands apart from this series of sub-parallel zones; it is that of the Rhine rift valley, mainly Baden. It will be convenient to describe (7) after (4) rather than in its numerical order.

The Alps.—It is only the northern fringe of the Alps from Lake Constance to about Hallein that is in Germany, and the frontier here lies along the northernmost of the east-west ridges of the Alps (highest point in Germany—Zugspitze, 9,738ft.). None the less the Bavarian Alps are of great beauty, with some exquisite mountain lakes, and farther down the northward valleys long lakes behind morainic dams, one of which, the Wiirmer See, has given its name to a moraine held by Penck to mark one of the ice-maxima of the Pleistocene glaciation. The slopes towards the Danube have much boulder clay, and there are large swampy areas called Moose, but. the better drained valleys are relatively rich. The chief streams are the Iller, Lech, Isar and Inn, right-bank tributaries of the Danube.

The Upper Danube *Basin*.—The main river rises in the Schwarzwald (Black Forest) and the basin is framed by the lake of Constance and the Bavarian Alps on the south, and by the

Alpine foreland (Jura) and the south-west border of the Bohemian block on the north. The river flows near the northern side of its basin, and from its left bank arise the dip slopes of the Jura, the scarp slopes of which face north or north-west and are steep where they face the Neckar. The river follows the line of the Jura down to Regensburg (Ratisbon), beyond which it flows beneath and parallel to the granitic edge of the Bohemian block, and then onward past Passau. The large tributaries of the right bank have been named; on the left bank the Wornitz flows through the Jura zone between the Swabian and Franconian Jura, and the Altmiihl and its feeders utilize a number of minor breaks in the sharp curve of the Franconian Jura. The Wornitz joins the Danube at Donauworth, and parts of it may be called upon to help make the ship canal from Main to Danube which is being built. The Altmiihl has been utilized in parts in connection with the small Ludwigskanal through the passes of the Franconian Jura linking Main and Danube. The ways through the Franconian Jura lead to the Danube, near Regensburg, and to the basin of the Main at Niirnberg, which is on the Regnitz; and the historic importance of these two centres is thus to some extent interpreted. The Naab valley between Franconian Jura and Bohmer Wald also joins the Danube near Regensburg. The uppermost part of the Danube is in Baden, and then it crosses Wiirttemberg and Hohenzollern and Wurttemberg again to Ulm. The upper basin of the Danube from the Iller eastwards to Passau forms one of the main elements of Bavaria. Much land on the south is poor, but some areas towards the centre of the basin where the subsoil is loess are fertile. Though Ulm on the west, Regensburg and Passau, all on the Danube, are historic and important, they are far surpassed by Munich and Augsburg on tributary streams and on somewhat higher land which permitted early cross-river communication.

The Jura is built mainly of porous, Mesozoic rock dipping southward and the drainage is in many parts in deep cut valleys. The ridge exceeds 3,000ft. in only a few places in Germany. but the south-west border of Bohemia reaches nearly 4,900ft. in the Bohmer Wald, which has the lower Bayrischer Wald in front of it. The Swabian Jura is higher and less broken than the Franconian, and from the rawness of winter on it a large part is known as the Rauhe Alb, its ridge forming a part of the boundary between Bavaria and Wiirttemberg. Farther west, between the Neckar and the Danube, astride of the Jura lies the district of Hohenzollern, the early home of the late German reigning family, for which reason this territory is politically a part of Prussia though widely separated from the main area.

The Basins of Main and Neckar, right-bank tributaries of the Rhine, lie north and west of the Jura ridge, their basins being otherwise framed by the Black Forest on the west and the mid-German hills on the north. The Neckar escapes to the Rhine south of, and the Main north of, the Odenwald. The basin of the upper Neckar forms the essential Wiirttemberg, but that State has stretched across the Jura right away to Lake Constance to include a large area of high land. Though the upper Danube basin from Clm (a border city of Wiirttemberg) to Passau is the essential Bavaria, that political unit has grown across the broken Franconian Jura to include most of the Main basin. The lowest sections of Neckar and Main, under the influence of the Rhine, are excluded from Wurttemberg and Bavaria respectively. In the Neckar basin Stuttgart is the chief focus, and the basin has much loess in its subsoil; in that of the Main, so far as it is Bavarian, Niirnberg, Bamberg and Wurzburg are the great centres.

It is advisable to consider here No. 7 of the introductory list. *The Rhine from Basle to Mainz* flows through a remarkable rift valley, that is a block with parallel sides let down while the sections beyond its parallel edges remain upstanding. On the east the upstanding edge is the sharp western slope of the Schwarzwald (the Feldberg is 4,898ft. high) as far north as the latitude of Carlsruhe; recognizable again farther north is the Odenwald (*c.* 1,700ft.). West of the Rhine the upstanding edge is the Vosges (in France), becoming lower and smoother north of Saverne but rising again in the Hardt. The continuous block that once included Vosges and Black Forest was a Hercynian Massif, and the rift has given a section of the Rhine with a broad valley floor and parallel sides. The course of the river is rough in places, and a volcanic mass, the Kaiserstuhl, stands out in the middle; the banks of the rapid river are rough land with few towns in the south, but from Speyer northwards they abound. On the west side Alsace, now in France, is essentially the basin of the Ill, a left-bank feeder of the Rhine; on the east Baden is the land beneath the scarp edge of Schwarzwald which forms part of the boundary against Wiirttemberg. But the State of Baden extends north as far as the Odenwald, and in the region between Schwarzwald and Odenwald lies Carlsruhe, the capital of Baden, on a main express route eastwards from the Rhine to Munich, Vienna and beyond. West of the Rhine the country becomes more and more influenced by the Rhine as the Vosges weakens north of Saverne, and the Pfalz or Bavarian Palatinate is a political unit around the Hardt (2,240ft.).

THE MID-GERMAN HILLS

(5) The mid-German hills are mainly dissected plateaux of Palaeozoic rocks the history of which includes their folding into a mountain system in the Permo-Carboniferous phase, their planing down by long denudation and their uplifting as blocks in Tertiary times. In the western half the Palaeozoic rocks outcrop almost everywhere, but the eastern half, east of the Rhine basin. is largely floored by Triassic rock with blocks of Palaeozoics brought up by faulting to form the Thiiringer Wald and the isolated Harz mountains in the north. In the western half the plateau hills trend almost south-west to north-east, the main lines being sharply cut at right angles by the Rhine gorge from Bingen to Bonn. The Hunsriick (2,684ft.) west of the Rhine is in line with the Taunus (2,890ft.) east of it, and the Eifel (2,493ft.) is similarly in line with the Westerwald (2,155ft.). Hunsrück and Eifel are separated by the deep cut of the Moselle valley just as Taunus and Westerwald are by that of the Lahn. Beyond the eastern rim of the Rhine basin are large volcanic masses, the chief of which are the Vogelsberg (2,530ft.) and the Rhon (3,117ft.), and this is a zone of much faulting. It is drained mainly by the Weser and its tributaries and these last start close to the northern tributaries of the Main, so that there is a way through the mid-German hills from Frankfurt-am-Main in the south via Cassel to Hanover in the north, an important factor of the greatness of these cities. East of the Weser the hill lines of the Harz (highest point the Brocken 3,747ft.) and the Thüringer Wald (3,225ft.) trend nearly north-west to south-east and are outlined and cut by faults with the result that they, and especially the Harz, have long been famed for metalliferous mining.

The valleys of the Thuringer Wald are historically famous for their numerous small petty states, but under the German republic these have been grouped as a Thiiringian state.

The Prussian Rhine province includes land on both sides of the Rhine (below Coblenz on the east and below Bingen on the west) in so far as that land is dominated by the life of the river and its cities, *i.e.*, it consists of the Rhine gorge from Bingen to Bonn and of the bay of lowland to the north. From Mainz to Bingen the Rhine flows east to west, from the Rift valley to the gorge cutting through the mid-German hills. In this section and the last section of the Rift valley (Worms to Mainz) the land is relatively low and forms one part of the State of Hesse; the land in the bend has loess subsoil and is an area of ancient settlement, attested by rich finds of prehistoric objects of several periods.

The south-eastern end of the Thüringer Wald and the north-eastern end of the Franconian Jura approach one another and the mountains farther east (Erz Gebirge and Böhmer Wald) in the Fichtelgebirge (3,355ft.), which thus seem to be a centre of orographical and fluvial radiation. From them the Naab goes south between Franconian Jura and Bohmer Wald to the Danube, the Main goes west to the Rhine between the Thiiringer Wald and the Jura, the Saale and its tributaries flow north between

the Thuringer Wald and the Erz Gebirge, while, in Bohemia, the Ohre flows east between the Erz Gebirge and the Bohmer Wald. Eastward beyond the Thuringer Wald the hills trend north-eastwards once more in the Erz Gebirge (4,052ft.), the northern edge of the Bohemian block, as far as the sharp break, by which the Elbe passes from Bohemia to Germany, through a territory called from its scenery the Saxon Switzerland. Beyond the Elbe the hills trend once more south-eastward as the Riesengebirge (5,26oft.) and the Sudetes, forming the north-east side of the Rohemian block. In the middle belt of Germany the hill lines form two obtuse angles, broken in the one case by the Weser, in the other by the Elbe; the lines enclosing these angles in the two cases are sub-parallel. The resemblances between these lines and those of the Baltic coasts are a feature. Farther east than the Sudetes the zone of dissected plateau-hills hitherto followed sinks. The rocks concerned become buried under newer deposits, or where they outcrop, as in Upper Silesia and Lysa Gora, they form only moderate hills, entirely subordinate to the great Carpathian mountain arc, a part of the Alpine system, which dominates the orography of the region. Between Carpathians and Sudetes is the gesenke, the depression that gives communication between Oder and Danube via the March, or between Vienna and either Breslau (Oder basin) or Cracow (Vistula basin).

6. The *northern plain* is marked off from the hills by the lines forming the two obtuse angles mentioned above, but there are in addition irregularities which give nhat may be called the gulf of lowland that narrows up the Rhine beyond Cologne and the lowland bay east of the Harz, framed by the Thuringer Wald and Erzgebirge.

Beneath the hills the subsoil in the east is loess in large patches, a zone of early settlement for the most part not densely wooded. Meuse, Rhine, Weser, Saale, Elster, Elbe and Oder emerge from the hills on to the plain, and related to their emergence, though not always on them, are large historic cities of which one may mention Aachen, Cologne, Hanover, Halle, Leipzig, Dresden and Breslau. In Belgium and west Germany below the mid-German hills, running south-west to north-east, coalfields of great importance occur (Mons, Charleroi, Liège, Düsseldorf and the Ruhr).

At the Weser, as already said, the general hill line changes direction, becoming west-north-west to east-south-east, but hills taking this direction also stand out west of the Weser into the plain as the Teutoburger Wald. Between this on the north and the mid-German hills (Sauerland) on the south is the lowland of Westphalia, drained by Ruhr and Lippe, tributaries of the Rhine, and by the upper Ems. The Saxon lowland has coalfields, especially round Zwickau, and ore-veins in the Erz Gebirge (Ore mountains), etc. North-east of the Riesengebirge is another, but a smaller coalfield. In upper Silesia are still other coalfields, and also in west Poland, the latter annexed by Germany in Sept. 1939.

The northern plain, apart from the foothill zone (fall line) just mentioned, has, as its main features, morainic hills, most arranged in lines more or less parallel to the Baltic coast and usually less than 6ooft. high, though the Turmberg, west of Danzig reaches 1,086 feet. In the east one zone of morainic hills (including the Turmberg) stretches between Danzig and Stettin; south of it and parallel to it lies the Netze valley. South again another morainic zone may be traced eastward through the Masurian lake country at the back of east Prussia and westward in broken patches to Frankfurt-on-Oder. Its southern boundary is marked by the rivers Narew and (lower) Bug, the Vistula for some distance below Warsaw, the upper Warthe, and the east-west section of the Oder above Ratzdorf. South of this again the land rises in Poland and in Germany with, in the latter country, Nieder Lausitz between the Spree and middle Elbe basins and farther west the Flaming between the middle Elbe and the Havel. The morainic zones are rich in small lakes, and those of eastern Germany, and the composite river lines between them, more or less focus on Berlin.

West of the Berlin area (Mark of Brandenburg) the morainic belts trend on the whole west-north-westwards, one with many lakes, in Mecklenburg and Schleswig Holstein where its general direction becomes south-to-north, and one between the lower Elbe and the line of the Aller and Weser. This latter. practically a continuation of the Flaming, is called the Altmark towards its eastern end (west of the Elbe) and the Luneburger Heide in the centre; rising to 56oft. it dies down towards the North sea coast south of Cuxhaven. West of the Liineburger Heide towards the Dutch frontier the land lies low in Oldenburg and Ost-Friesland and marsh abounds in the latter. Post-Pleistocene land sinking has brought the sea up the river mouths, so that most of Germany's ports are river ports and have developed outports below themselves, as Bremerhaven below Bremen, Cuxhaven below Hamburg, Travemunde below Lubeck, Warnemunde below Rostock and Swinemunde below Stettin. A great difference, however, is to be remarked between the coasts of the North sea and those of the Baltic. On the former, where the sea has broken up the ranges of dunes formed in bygone times and divided them into separate islands, the mainland has to be protected by massive dikes, while the Frisian islands are being gradually washed away by the waters. On the coast of East Friesland there are now only seven of these islands, of which Norderney is best known. while of the North Frisian islands, on the western coast of Schleswig, Sylt is the most considerable. Besides the ordinary waste of the shores, there have been extensive inundations by the sea within the historic period, the gulf of the Dollart having been so created in the year 1276. Sands surround the whole coast of the North sea to such an extent that the entrance to the ports is not practicable without the aid of pilots. Heligoland is a rocky island, but it also has been considerably reduced by the sea. The tides rise to the height of 12 or 13ft. in the Jade bay and at Bremerhaven, and 6 or 7ft. at Hamburg.

The coast of the Baltic, on the other hand, possesses few islands, the chief being Alsen and Fehmarn off the coast of Schleswig Holstein, and Riigen off Pomerania. It has no extensive sands, though on the whole very flat. The Baltic has no perceptible tides; and a great part of its coastline is in winter covered with ice, which also so blocks up the harbours that navigation is interrupted for several months every year. Its *haffs* fronting mouths of large rivers are rather extensions of the rivers than sea-bays cut off, though coastal subsidence has contributed to their evolution. The Pommersche or Oder Haff is separated from the sea by two islands, so that the river flows out by three mouths, the middle one (Swine) being the most considerable. The Frische Haff is formed by the Nogat, a branch of the Vistula, and by the Pregel, and communicates with the sea by means of the Pillauer Tief. The Kurische Haff receives the Memel, called Niemen in Russia, and has its outlet in the extreme north at Memel. Long narrow alluvial strips, called *Nehrungen,* lie between the last two haffs and the Baltic. The Baltic coast is further marked by large indentations, the gulf of Lubeck, that of Pomerania, east of Rügen, and the semi-circular bay of Danzig between the promontories of Rixhoft and Brusterort.

The rivers of the great lowland are naturally navigable and need very few locks for their improvement for this purpose. Nearly every one of them has long east-west sections between morainic zones, and most of them cut through those zones in south-north sections, which sometimes have important towns such as Torun (Thorn) on the Vistula and Posen (Poznan) on the Warthe, and Frankfurt on the Oder.

The east-to-west sections of two rivers in different parts of one and the same low zone between morainic hills have been linked in many cases by canals; *e.g.,* the Vistula with the Netze, the Oder with the Spree and the Havel. Thus a system of river and canal communications supplementing railway and road connections focusses from a wide zone in the east upon Berlin and helps to account for the phenomenal growth of the city from insignificance in the mid-seventeenth century to a population of four millions at the present (1940). The Oder is navigable from Ratibor near the Bohemian frontier, and long stretches of the Warthe and Netze are also navigable, as is the Neisse, a left-bank tributary. Large sections of Havel, Spree and Saale are navigable,

and the Elbe itself can be navigated right up into Bohemia and its tributary, the Moldau, as far as Prague. By means of the river and canal systems combined there is thus continuous inland water communication from Ratibor on the upper Oder, or Torun on the Vistula, to Hamburg and the Elbe mouth.

The development of this system of communications and of its focus at Berlin may be said to have changed the face of Germany. Previously the great lowland had been on the whole of secondary importance with the Hanseatic cities along its coasts and the fall line cities above enumerated near the hills, and Magdeburg and a few others between. The growth of Berlin as a focus developed the political power of Prussia, which spread both to the coast and to the foothills and received a further impetus when the potato spread as a food plant, especially on the sandy soils of the north, and still more when coal came to be utilised for industry. Coal gave a new growth to many old cities along the foothills, thus making modern German industry in a considerable measure a new development of old cities as contrasted with modern British industry which mostly grew in places previously small. German industry has also brought many new towns to birth.

Climate. — The climate of Germany is to be regarded as intermediate between the oceanic and continental climates of western and eastern Europe respectively. The differences in the range of temperature and the amount of rainfall throughout Germany are not so great as they would be were it not that the elevated plateaux and mountain chains are in the south, while the north is occupied by low-lying plains. In the north-west no chain of hills intercepts the warmer and moister winds which blow from the Atlantic, and these accordingly influence at times even the eastern regions of Germany. The mean annual temperature of south-western Germany, or the Rhine and Danube basins, is about 52° to 54° F, that of central Germany 48° to 50°, and that of the northern plain 46° to 48°. In Pomerania and West Prussia it is only 44° to 45°, and in East Prussia 42° to 44°. The difference in the mean annual temperature between the south-west and north-west of Germany amounts to about 3°.

The valley of the Rhine above Mainz has the greatest mean heat, the mildest winter and the highest summer temperature. Arys, on the Spirdingsee, on the lake plateau of east Prussia, has a like winter temperature to the Brocken at 3,200 feet. The Baltic has the lowest spring temperature, and the autumn there is also not characterized by an appreciably higher degree of warmth. In central Germany the high plateaux of the Erz and Fichtelgebirge are the coldest regions. In south Germany the upper Bavarian plain experiences a harsh winter and a cold summer. The warmest districts are the Rheintal from Karlsruhe downwards, less than 300ft. above sea-level, and protected by mountains. The same holds true of the valleys of the Neckar, Main and Mosel. Hence the vine is everywhere cultivated in these districts. The mean summer temperature there is 66" and upwards, while the average temperature of January is above 32° F. The climate of north-western Germany is oceanic, the summers not being too hot (mean summer temperature 60° to 62°), and snow in winter remaining but a short time on the ground. West of the Weser the average temperature of January exceeds 32° (it is 34° at Cologne); to the east it sinks to 30°, and therefore the Elbe is generally covered with ice for some months of the year, as are also its tributaries. The farther one proceeds to the east the greater are the contrasts of summer and winter. While the average summer warmth of Germany is 60° to 62°, the January temperature falls as low as 26° to 28° in West Prussia, Posen and Silesia, and 22° to 26° in East Prussia and upper Silesia. The navigation of the eastern rivers is interrupted by ice.

Rainfall takes place at all seasons, but chiefly in summer. The rainfall is greatest in the Bavarian tableland and the hilly regions of western Germany. For the Eifel, Sauerland, Harz, Thuringian Forest, Rhön, Vogelsberg, Spessart, the Black Forest, the Vosges, etc., the annual average may be stated at 34in. or more, while in the lower terraces of south-western Germany, as in the Erzgebirge and the Sudetic range, it is estimated at 30 to 32in. only. The same average obtains also on the humid north-west coast of Germany as far as Bremen and Hamburg. In the remaining parts of western Germany, on the shores of farther Pomerania and in East Prussia, it amounts to upwards of 24 inches. In the best wine districts, *i.e.*, in the valley of the Rhine below Strasbourg, in the Palatinate, and also in the valley of the Main, no more than from 16 to 20in. fall. Mecklenburg, Brandenburg and Lusatia, Saxony and the plateau of Thiiringia, West Prussia, Posen and lower Silesia have an annual rainfall of only 16 to 20 inches. Thunderstorms are most frequent in July. The soils of Germany, in correlation with these facts of climate, are generally of the brown group (see EUROPE) moderately leached, save near the sea where the leaching has generally been more intense and where the glacial subsoil often includes much sand. The soils on the Jurassic rocks of the south are specially rich in humus

Vegetation. — Germany was largely covered with forests of oak and beech, with larch, birch and pine on the heights before man reduced it for his purposes, but it is none the less an error to think of it as pure forest. There were always patches of loess with a lighter tree covering that were available for early settlement and that have yielded abundant evidence of settlement at many periods, and there were other patches also more or less forest free for reasons usually connected with the nature of the rock. Of the "clear" areas one may mention the foothill region and the southern edge of the great plain from Hanover to Dresden, including much of the lowland bay around Leipzig, a part of the Oder basin from the frontier down to Breslau, the country in the bend of the Rhine near Mainz, the basin of the upper Neckar, the Danube from Regensburg down to Passau and many another smaller area. The lower mountains are often still covered with timber, and it is a feature of German civilisation that forest conservation has become a high art, the woods being largely of a more or less cultivated character with conifers dominant on account of their special utility. On the whole the north is less densely wooded than the south, the morainic hills often being ill adapted for great forests, though the lowlands of the north-east still have many trees. Areas specially rich in woodland include some between the Oder basin and the Elbe basin near the upper Spree, and in this forested area Wendish speech has survived Germanising influences, the Harz and the Thiiringer Wald, the Rothaargebirge, the hills in the great bend of the Main above Frankfurt-am-Main, the Fichtelgebirge, the frame of Bohemia, the Odenwald and the Schwarzwald. Woodland is practically absent in north-west Germany.

In the southern regions of warm summers where there is shelter the woods contain chestnut and walnut, and the fig, peach and apricot may be grown here and there. Latitude 51° is approximately the northern limit of the vine in Germany, and it is mostly grown near Rhine and Danube and as usual near the crops limit, it is only special varieties grown with care that are of much value. Reference has already been made to the potato which yields good crops in the sandy north, while the beetroot has also spread in the northern plain and mid-Germany. Flax grows chiefly in the north and hops chiefly in the south. Among the grains rye is important almost everywhere, with wheat, barley and oats as well; maize ripens only in the south; buckwheat mostly in the north. Concerning the wild animals of Germany, little needs to be added to what has been said for Europe; wolves are rare except at times in the east, bears survive in the Alps and the elk in the forests of East Prussia. The stork is seen for about 170 days, the house-swallow 160, the snow-goose 260 and the snipe 220; the period is 20–30 days shorter in the north than in the south.

Population. — In racial type the German population is very largely Alpine, that is broadheaded with medium to dark colouring, in Bavaria and parts of the mid-German hills, becoming markedly fairer and less broadheaded towards the north. Tall, fair and moderately broadheaded people are numerous, and the opinion has been advanced that they may represent a combination of Alpine (broadheads) and Nordic (fair hair) traits. There are areas with more longheads apparently in Oldenburg and in East Prussia, and doubtless elsewhere but the cephalic index seems to be higher than in Scandinavia or the British Isles. The Neckar

basin in Wurttemberg apparently contains more tall, fair elements in its population than do most other parts of south Germany. There has been considerable Slavonic immigration into industrial areas tending on the whole to increase the broad-headed elements. The Jewish type is strongly marked in many cities. (H. J. F)

The population of the German Empire at its establishment in 1871 was nearly 41,000,000. During the following 40 years it increased rapidly to 64,900,000, according to the last pre-war census of 1910, and to 67,800,000 at the outbreak of the World War. The population was severely reduced by the war in three ways: (1) the loss of men at the front and of other persons from war causes was estimated at 2,870,000; (2) the birth-rate during the war fell to the lowest point in history and remained low during the post-war years; and (3) nearly 7,000,000 were separated from Germany in the territories which she had to surrender by the Versailles Treaty.

Hitler's annexations of territory, hoaever, which earned for him among his admirers the new title of "Aggrandizer of the Reich," much more than compensated for the war losses Up to the summer of 1939 these additions, which created a "Greater Germany," according to the preliminary results of the census of May 17, 1939, are given in Table I.

TABLE I *Area and Population of Annexed Territories*

Territory	Annexation	Population	
	13, 1935	864,000	1,924
Austria	March 13, 1938	7,008,000	83,763
Sudetenland	1, 1938	2,945,000	28,971
	March 15, 1939	6,805,000*	
	March 22, 1939	153,6529	2,848

Territory	Date of Annexation	Population 1939	Area in sq. kil.
Saarland	Jan. 13, 1935	864,000	1,924
Austria	March 13, 1938	7,008,000	83,763
Sudetenland	Oct. 1, 1938	2,945,000	28,971
Bohemia-Moravia	March 15, 1939	6,805,000*	
Memelland	March 22, 1939	153,6529	2,848

*Estimated for 1939 on basis of 1939 census

These additions, totalling 197,700 sq. km., brought the population of Greater Germany in the summer of 1939 to a grand total of 86,400,000. However, Bohemia-Moravia was not completely integrated with the rest of the Reich like the other added territories. It formed a German "Protectorate" and to some extent was allowed to have its own laws and administration. The German conquest of Poland in Sept. 1939, brought some 15,000,000 persons under German rule; Danzig, the Polish Corridor, Posen, and small districts on the Silesian frontier were annexed as an integral part of the Reich; the remainder of the conquered Polish territory was placed temporarily under a German governor If the conquered Polish territory and the Bohemia-Moravia Protectorate are not included, the population of Greater Germany mas 79,727,000 in 1939. Its distribution and growth since 1925 may be seen in Table II. The table shows also the administrative divisions of the Reich, including the provinces of Prussia, and the Gaue (administrative districts, formerly provinces) of Austria, which is now known as the "Ostmark."

TABLE II *Growth of Population of Greater Germany*

Lands	Area in sq kil	Population	
		May 17, 1939	June 16, 1925
Prov East Prussia	36,991	2,496,000	2,256,349

Movement of Population. — The birth-rate in Germany 1871–1914, during the period of rapid industrial expansion. was, as under like conditions formerly in England, unusually high. It had averaged about 35 living births per 1,000 of the population in the 1850s; rose to more than 39 in the decade after 1871; and then fell slowly but steadily to 27·5 in 1913. During the war it fell sharply to 14·3 in 1918, rose again to 25·9 in 1920, but then fell steadily again to 14·7 in 1933. The close parallelism of the birth-rate per

In 1933 the National Socialist leaders were greatly alarmed at the low birth-rate. Together with the loss of population by the three war-causes mentioned above, the Nazis feared that Germany would soon have a stationary or even declining population. Furthermore, there was an abnormal excess of old men, owing to the loss of young men on the battle-field. Hitler and his leaders ardently desired a larger population in order to give the Third Reich greater industrial and military strength Therefore, several measures were adopted 1933–39 to promote population increase. The enforcement of the law against abortions was tightened. Young people were even taught that it was no social disgrace to have illegitimate children for the good of the Fatherland Generous tax exemptions were granted to families according to the number of their children. Unmarried persons had to pay a special additional tax. Most publicized, perhaps, was the Government's granting of marriage loans (Ehestandsdarlehen) of 1,000 marks to newly-married couples who applied for them. If the marriage was childless, the loan had to be repaid after a certain period; but for every child born alive one-fourth of the loan was cancelled. In the years 1933–35 the Government expended 523,000 marks (about $210,000) for these marriage loans. In 1936 28·1% of the newly-wed couples applied for and received a total of 171,640 marks; for 1937 the figures were respectively 29·7% and 183,556 marks; and in 1938 38·7% of newly-wed couples were aided. These measures brought a moderate increase in the population figures, as will be seen from the table on next page, but not as much improvement as the National Socialist leaders would have liked to see. In 1939 the birth-rate rose to 20 per 1,000 population.

The death-rate in the 1850s was 26.3 per 1,000 of the population After the Franco-Prussian war it fell pretty steadily to 15 per 1,000 in 1913 This decline in the death-rate was largely owing to improved medicine and especially to the Government's measures to reduce infant mortality by providing lying-in hospitals, milk dispensaries, and better protection for expectant mothers. After the war the death-rate again fell fairly steadily from 15·1 per 1,000 in 1920 to 11·7 in 1937. Consequently the excess of births over deaths from 1933 to 1939 in Old Germany (exclusive of territories added by Hitler) was 2,775,000 or about 465,000 per annum

Of the total population of Greater Germany (not including Bohemia-Moravia) in 1939, 38,700,000 were male, and 40,700,000 female The excess of females, as in all German population figures since the war, tended to decline. In 1919 for every 1,000 males there were 1,101 females; in 1925, 1,073; in 1933, 1,060; and in 1939, 1,050.

The number of divorces in National Socialist Germany declined from 54,744 in 1934 to 46,786 in 1937.

Emigration from Germany reached a high point of 220,000 in 1884, after which it declined sharply, and was largely offset by immigration, chiefly of Polish agricultural labourers in the eastern provinces and industrial workers in the Rhineland. For the post-war period no exact recent figures are available, but it is estimated that from 1925 to 1933 the emigration exceeded the immigration by 234,000 persons, and that the tide then turned, the immigration exceeding the emigration by 666,000 persons in the six years from 1933 to 1939.

The statistics of marriages, births, and deaths in the German Reich (including the Saarland but excluding Austria and the Sudetenland) in recent years may be seen in Table III.

TABLE III. *Vital Statistics*

Year	Marriages	Births	Deaths	Excess births over deaths	For every 1000 pop.	
					Births	Deaths
1893	401,234	1,865,715	1,248,201	617,514	36·8	24·6
1903	463,150	1,983,078	1,170,905	812,173	33·8	20·0
1913	513,283	1,838,750	1,004,950	833,800	27·5	15·0
1923	588,069	1,318,489	866,754	451,735	21·2	13·9
1924	446,445	1,290,763	766,957	523,806	20·6	12·2
1925	489,084	1,311,259	753,017	558,242	20·8	11·9
1926	489,685	1,245,471	742,955	502,516	19·6	11·7
1927	545,381	1,178,892	765,331	413,561	18·4	12·0
1928	594,631	1,199,998	747,444	452,554	18·6	11·6
1929	597,014	1,164,062	814,545	349,517	18·0	12·6
1930	570,241	1,144,151	718,807	425,344	17·6	11·0
1931	522,881	1,047,775	734,165	313,610	16·0	11·2
1932	516,793	993,126	707,642	285,484	15·1	10·8
1933	638,573	971,174	737,877	233,297	14·7	11·2
1934	740,165	1,198,350	724,758	473,592	18·0	10·9
1935	651,435	1,263,976	792,018	471,958	18·9	11·8
1936	609,770	1,278,583	795,793	482,790	19·0	11·8
1937	619,791	1,275,212	793,192	482,020	18·8	11·7

With these steadily increasing numbers, the density of population in Old Germany (*i.e.* including the Saarland but not the later annexations) increased from 124·2 per square kilometre in 1910, to 134·3 in 1925, 140·3 in 1933, and 147.6 in 1939. If Austria and the Sudetenland but not Bohemia-Moravia are included, the density of population in Greater Germany in 1939 was 131·3 per square kilometre. It is this growing pressure of population living within an area no larger than Texas which makes the National Socialists proclaim so loudly and insistently that they must have more elbow room or "living room" (Lebensraum).

The most rapid increase of density, of course, is to be found in the cities. Before the World War there was already such a strong shift from the country to the larger towns and cities, that it caused some alarm to the Government. After 1919 this trend continued, until by 1933 the percentage of people in urban districts had become greater than those in rural districts in 1871, as may be seen from the figures for Old Germany in Table IV.

TABLE IV. *Percent of Population in Towns*

Year	Under 2,000	Over 2,000
1871	62.6	37·4
1900	43'9	56·1
1910	38·3	61·7
1925	35·4	646
1933	32.8	67·2

The National Socialists tried in various ways to prevent this "flight from the country" (*Landflucht*) into the towns and cities. Much was done to improve the conditions of the peasant. He gets good prices guaranteed for his products, though he is subject, like everyone else doing any kind of business in the Third Reich, to a great many petty and vexatious regulations. Some peasants were elevated into a "peasant nobility," if they had no Jewish ancestors since 1800. They have hereditary peasant holdings which cannot be seized for non-payment of interest on mortgages or for any other cause except incompetence or dishonourable conduct on the part of hereditary peasant owner. Radios have been sold by the million to relieve the monotony of life on the farm—and to afford a medium for filling the peasant with all sorts of Nazi propaganda. Students, soldiers, white-collar workers, and others are urged or compelled to help the peasant get in his crops; in the early summer of 1939 the universities were closed earlier than usual so that the students could go into the country to aid in the harvesting. Some regulations were issued directly forbidding peasants to move into certain towns. But in spite of all this, the lure of the city seemed to be effective, and one of the social problems which was most frequently discussed in German newspapers in 1939 was how to counteract this "flight from the country."

By the census of May 17, 1939, 61 cities had each more than 100,000 inhabitants. The total population of these 61 cities was 23,900,000, or about 30% of the total population of Greater Germany. The 26 cities with more than 250,000 inhabitants in 1939, together with their population at the preceding census of 1933, are given in Table V.

TABLE V. *Cities with over 250,000 Population, 1933 and 1939*

City	1939	1933
Berlin	4,332,242	4,242,501
Vienna	1,918,462	2,001,541
Hamburg	1,682,220	1,673,703

Kiel	272,311	223,021
Stettin	268,915	270,747

Constitution of the Republic.—Germany was organized under a constitution given by a National Assembly at Weimar on August 11, 1919, on the basis of sovereignty of the people and of recognition of the rights of constituent lands or states. Administration and legislation, including financial legislation, relating to the whole republic were controlled by the organs of the constitution of the republic, but, in matters relating to a particular land or state, and not contravening the general law, power resided with the corresponding organs of the constitution of the land or state concerned. The republic as a whole had exclusive charge of foreign and colonial affairs, questions of citizenship and migration, customs dues, coinage, armaments, postal organization and telephones. It had to make laws relating to crime, passports, care of the poor, the press and public meetings, infant welfare, health services, protection of workers, war pensions, weights and measures, regulation of industry and transport by air, land and sea, insurance, theatres, protection of natural beauty, etc.

Each land may, in general, make laws on any other matters, but the Reich has large duties and powers of oversight. In case of dispute either the Reich or a land can appeal to the Supreme Court or to other authority as may be provided in special cases by law. Each land is required to have a constitution based on universal secret suffrage and the principles of proportional representation, and the same principles must be applied in the smaller units of local government. The division of the Reich into lands and any alteration of the scheme of division or of boundaries is held to be subject to the will of the people concerned and careful safeguarding articles are included. Disputes between lands are referred to the Supreme Court, and the president of the republic is required to carry out the decision of the Supreme Court. A feature of the constitution is that there is nothing to prevent any group of people now outside the republic from asking for admission to the status of a land within it.

The Government was under a president, who might be any German over 35 and was chosen by universal direct suffrage; he had, more or less, the powers and duties of a constitutional monarch; he held office for seven years and might be re-elected. The Government consisted of a chancellor and ministers appointed by the

president, and the chancellor and his ministers were responsible for the acts of the Government.

The *Reichstag* was the single-chamber legislature elected by proportional representation for the whole republic on the basis of party-lists; one seat in the *Reichstag* was allotted for every 60,000 votes. No by-elections took place between elections, any vacancy being filled by appointment of the next person on the party-list. The Ministry must have the confidence of the *Reichstag.*

Government of the Third Reich, 1933–39.—Adolf Hitler was leader (Fuehrer) of the National Socialist Party, the largest political party in Germany in 1932. No stable cabinet commanding a working majority in the Reichstag was able to exist so long as Hitler's party remained in opposition and was aided by two or three other opposition parties. Dr. Bruening, Herr von Papen, and General von Schleicher all were forced to resign as chancellors in the summer and winter of 1932. Therefore President von Hindenburg appointed Hitler as Chancellor on Jan. 30, 1933. This marked the beginning of the Third Reich, which was soon organized as a "Totalitarian State."

Chancellor Hitler quickly dissolved the Reichstag and called for elections on March 5 to choose a new one. Meanwhile, the burning of the Reichstag building, which National Socialists alleged was the act of Communists, gave Hitler's armed Brown Shirt followers a pretext for arresting and imprisoning Communists and many Socialists. The voters were terrorized by strong-arm methods. As a 'result, the National Socialists, together with their temporary Nationalist allies, secured a sufficient majority in the new Reichstag to pass a so-called Enabling Bill. This set aside many of the clauses of the Weimar Constitution, including the guarantees of personal liberty. and virtually gave dictatorial power to Hitler. He and his cabinet could issue decrees having the force of law. The Reichstag ceased to be of any importance except as a sounding-board to hear and give emphasis to Hitler's speeches. It was called together only occasionally when he had some important announcement to make, and sometimes went through the form, without any discussion, of giving approval to his decisions.

With complete power thus in his hands, Hitler proceeded to organize the Totalitarian State, that is, a State which should embrace and control every aspect of life. All other political parties except the National Socialist were dissolved. The 17 States of the Reich were gradually shorn of much of their former power of local government which was transferred to the central government of the Third Reich at Berlin. Prime ministers of the former States were replaced by governors (Statthalter) appointed by Chancellor Hitler or by his Reich Minister of the Interior, Dr. Wilhelm Frick. State legislatures ceased to exist. The States thus gradually came to be little more than administrative divisions of Reich central government at Berlin. Local executive boards were merged with, or replaced by, Reich boards.

The Government of the Third Reich is a sort of dual affair. Existing side by side are "Party" and "State." The former is the National Socialist Party, with a complete set of boards or ministries (treasury, foreign affairs, education, etc.) paralleling those of the State. The State consists of all the regular machinery of government, so far as it survived the changes made by Chancellor Hitler; these changes were mostly in the curtailing of the functions of the former States like Prussia, Bavaria, Saxony, etc.; the central administrative machinery of the Reich was not greatly modified except that it was given many new tasks. Tolerable harmony between the State and Party was secured by the fact that many important persons, like Hitler, Goering, Hess, Frick, Goebbels, Darré and others, were high officials in both organizations. There was much discussion as to the relation between Party and State. In general, it may be said that the Party was the more influential organization, according to the principle: "The Party directs the State."

The National Socialist Party grew rapidly in numbers before Hitler became Chancellor, because all new members were welcomed as increasing the political power of Hitler who hoped thereby to seize control of the Reich Government. But soon after he was appointed Chancellor, membership in the Party was "closed." The early members who had borne the burden and heat of the day from the beginning, that is, the "old fighters" with "low numbers," did not care to see their distinction dimmed by having the privilege of membership conferred on too great a number, after the goal of political power had finally been achieved in Jan. 1933. It was always a practice of the Party that, in awarding high office or in giving jobs and other advantages, preference should be given to Party members, and especially to '(old fighters." Therefore, soon after he became Chancellor, Hitler announced that no new members were to be admitted from among persons who might have sought membership but did not do so in the earlier days when the Party was making its hard struggle for power. The only large regular additions to membership after 1933 were from the ranks of the Hitler Youth who had reached maturity and shown that they would make reliable and worthy recruits to carry on the work of the Party. Occasional exceptions, however, were made to the rule closing the Party to non-members who were already of age in 1933, as when Hitler conferred membership on Dr. Schacht and all other non-member cabinet officials in Jan. 1937.

After 1933 the National Socialist Party varied in numbers as some were "purged" out of it and as others were taken in, but it probably approximated 3,000,000. Since the Party directs the State, Germany is ruled by a small highly organized minority, representing less than five per cent of the whole population. Or it might be said that Germany is ruled by the dictatorial power of one man, since Adolf Hitler as Fuehrer is the supreme authority in both Party and State.

In 1937 the members of the National Socialist Party were organized in 33 provinces, including the organization for Germans living abroad. Each province (Gau) was under a provincial leader (Gauleiter) appointed by the supreme Leader, Adolf Hitler. They were further organized in 760 districts (Kreisen), 21,345 local groups (Ortsgruppen), 74,091 "cells," and 397,040 "blocks." By 1940 these numbers were somewhat increased; a new Gau was created for the annexed Sudeten Germans, for each of the six former provinces of Austria, and for the Warthe (Polish Corridor) District.

The "block leader" is the lowest representative of the Party's sovereignty. He is assisted by "block wardens" of the German Labour Front, of the National Socialist Welfare Association, and of the National Socialist Women's Association. Together they are supposed to "advise national comrades on all problems of life, help them as far as possible in case of need, and in every way take care of them." For that purpose the block wardens must know everything about all the 40 to 60 families within their block, who in turn must answer all questions asked by the Party representatives. Germans deny that this is merely an efficient spying system, and insist that it is really a method of carrying out the principle: "The common good takes precedence over the individual good;" this is possible only "if a relation of mutual trust develops between the block leaders and the national comrades."

During the years following 1933 the Party steadily increased its control over the Totalitarian State. It was able to accomplish this by means of the four functions which it efficiently fulfilled: (1) It furnished from its membership nearly all the higher officials of the central and local governments of the State; (2) It maintained a wide-spreading network of directing bureaus and mass organizations. side by side with those of the State, as agencies for its functions of educating the people in National Socialist ideology, of caring for their welfare, and of enforcing the National Socialist view of life (Weltanschauung); (3) It developed and spread the dogmas that are the driving force of the National Socialist "Movement" and the Totalitarian State; (4) It protected the State against all internal German enemies—grumblers, critics, traitors, religious opponents and so forth—by a very active radio and press propaganda and by the ever-present Brown Shirts, Black Shirts, and secret police (Geheim-Staats-Polizei, commonly abbreviated as Gestapo), just as the regular army (Reichswehr) stood ready to protect Germany against all foreign foes.

Religion.—Historically what is now Germany became divided in the 16th century into regions in which nearly the whole population remained attached to the Roman Catholic church and regions

in which the population generally seceded from that church and became Protestant. Broadly the south and the Rhineland remained Catholic, with the exception of north Wurttemberg, while the north became Protestant except upper Silesia and parts of the east. There is and has long been a large Roman Catholic minority in Prussia and Oldenburg in the north, but Saxony, Brunswick, Thuringia, the Hanse Towns, Waldeck, Anhalt, Schaumburg-Lippe, Mecklenburg-Schwerin and Mecklenburg-Strelitz have only small numbers of Roman Catholics. Hesse is rather more than two-thirds Protestant. There are considerable Protestant elements in north Baden and north-east Bavaria. The distribution of religious adherence has not changed greatly since the Thirty Years' War save that immigrants from the west have altered a previous Roman Catholic into a present Protestant majority in several of the eastern regions of Prussia. The facts of religious adherence seem to depend largely on the adherence in the 16th or 17th century of the then reigning families to one form of religion or another. German Protestantism arose from two chief groups, the Lutheran and the Reformed, but, after 1815, a church union was developed, and in 1924 nearly all the Protestants of Germany became united in a German Evangelical Church Union. There are a few Old Lutherans who have stood out against union, and the Moravian communities, a few Quakers, Methodists, Baptists, etc., may be mentioned.

The Roman Catholic hierarchy in Prussia includes the archbishopric of Cologne with bishops at Miinster, Paderborn and Trier. The bishopric of Culm is still attached to the archbishopric of Gnesen and Posen, though the rest of that archdiocese was in Poland. Breslau, Meissen, Hildesheim and Osnabrück are directly subject to the Holy See. In south Germany the archdiocese of Bamberg includes the dioceses of Eichstatt, Speyer, Wiirzburg, the Bavarian archdiocese of München and Freising, those of Augsburg, Passau and Regensburg, and the archdiocese of Freiburg, those of Fulda, Limburg, Mainz and Rottenburg (in Wiirttemberg). There are vicars apostolic for Saxony, Anhalt and the Northern Missions The Old Catholics who seceded from the Roman Catholic church in consequence of the definition of the dogma of papal infallibility are a small group.

(H. J. F.; S. B. F.)

DEFENCE

Under the *Treaty* of *Versailles*, signed on June 28, 1919 by representatives of the United States, the British Empire, France, Italy and Japan as "Principal Allied and Associated Powers" and by twenty-two lesser Powers (but not subsequently ratified by the United States), Germany was given a period ending on March 31, 1920 to demobilize and reduce her army to 7 divisions of infantry and 3 of cavalry, the total number of effectives after that date not to exceed 100,000 including, a maximum of 4,000 officers, of whom not more than 300 were to be employed in the Ministries of War in the different states of Germany and in the administrations attached to them. The civilian personnel for army administration services was not to exceed one-tenth of the personnel in each class provided by the Budget of 1913. "The Great General Staff and all similar organizations shall be dissolved and may not be reconstituted in any form." State customs officers, forest guards, coast guards, gendarmes and local or municipal police might not be assembled for military training, and their numbers were to be limited. Up to the date when Germany should join the League of Nations her armaments, munitions and military material were strictly reduced, and after that date only to be increased with the sanction of the Council of the League. Importation of all such material was prohibited. The maximum (but not the minimum, as in the subsequent Treaty with Austria, *q.v.*) strength of army field formations was prescribed. No grouping of divisions under more than two 'army-corps headquarter staffs was permitted.

Universal compulsory military service was forbidden, only voluntary enlistment was permitted. Officers retained in the army must serve therein at least up to the age of 45 years. Newly-appointed officers must serve on the active list for at least 25 consecutive years, and not more than 5% of the total effectives must be discharged in one year for any reason before their time of service expired. Other ranks must serve for 12 years, the same 5% rule applying to their discharge. The number of military schools and of students therein was strictly to be limited. Educational establishments and societies and associations of every description were forbidden to occupy themselves with any military matters, to carry out any military instruction or to be connected with Ministries of War or with any other military authorities.

All measures of mobilization or appertaining to mobilization were forbidden, and Germany further agreed not to allow any military, naval or air missions to leave her territory; to prevent her nationals from leaving to join the fighting forces of other Powers (except the French Foreign Legion); or to be attached to such forces to give them instruction. All fortified works, fortresses and field works west of a line drawn 50 kilometres from the Rhine were to be demolished and no new ones constructed. Works of this nature on the southern and eastern frontiers of Germany were to be kept in their existing condition. Military (and naval) Air Forces were strictly forbidden.

Germany's Rearmament since 1933.—The limitations mentioned above, by which the victorious Allies had hoped to prevent Germany from again becoming a great military power, began to be secretly infringed as soon as the National Socialists came to power in 1933. Hitler's Government, to be sure, took part in disarmament conferences at Geneva. But when he found that the former Allied Powers would do little or nothing to carry out their implied obligation to reduce their own armaments, and would not give Germany "equality of treatment in practice as well as in theory," he withdrew in defiance from the disarmament conference. He also gave notice a few days later (Oct. 19, 1933) of Germany's withdrawal from the League of Nations. Prudence dictated that his rearmament measures should not be too noticeable until after the plebiscite in the Saar Territory in Jan. 1935. As soon as this region had been reunited to Germany by an overwhelmingly large vote (over 90%), Hitler could at last throw off his mask and tear up publicly the military clauses of the Versailles Treaty.

He startled the world on March 16, 1935, by announcing that he would reintroduce the forbidden system of universal military service. This created a conscript army of approximately 500,000, organized provisionally into 12 army corps and 36 divisions. Soldiers were to serve for one year and then enter the reserves who could be mobilized in time of war. This measure was quite universally popular in Germany for many reasons. It meant that another section of the hated Versailles "dictate" had been scrapped. It restored most of the military system under which Germany had overthrown Napoleon I. and grown steadily more powerful for a century thereafter. It helped solve the unemployment problem; besides the unemployed now enrolled for military service, much employment was furnished by the need for building new barracks and for furnishing all sorts of military equipment for the enlarged army. And even by many persons not particularly sympathetic with the Nazi regime, a stronger army mas welcomed as a dependable force which might save the country from chaos if the Hitler Government should suddenly come to an end.

Hitler's decree of March 16, 1935, was only the beginning of a series of measures enormously increasing every aspect of Germany's armaments. In July the General Staff, which according to the Versailles Treaty was to be dissolved but which had not really wholly disappeared, was officially reconstituted. In October the War Academy in Berlin was reopened under the command of General Adam, head of the Munich Army Corps. By a decree of Aug. 24, 1936, Hitler again took the world by surprise by extending the term of service from one to two years. This again increased the regular army to about 800,000 men, or approximately the size of the German army at the opening of the World War. This two-year service requirement did not meet with the same general enthusiasm as the one-year service law of the preceding year. It was felt that it would delay for a year the age at which men could become self-supporting and marry; that it would mean increased taxation and restriction of food imports; and that the European situation was not so dangerous as to necessitate this additional

measure of safety and self-defence. The people, nevertheless, resigned themselves to it.

During the next three years the army was further increased by enlarging the officer corps, by enrolling soldiers who for lack of equipment and officers could not be called up at once, and by incorporating in the German Army the forces of the former Austrian Republic. By the summer of 1939 the German Army was estimated to number about 1,000,000 officers and men Including the trained reservists who were mobilized on account of the strained relations with Poland, a total of nearly 2,000,000 were under arms. No exact figures were available, as Germany did not publish any statistics on this subject. This figure of nearly 2,000,000 did not include the police, the SA (Brown Shirts). the SS (Black Shirts), or the semi-military formations known as the Labour Service and Hitler Youth. Nor did it include the Slovakian Army of 30,000 regulars and 300.000 reservists which Hitler declared on Aug. 18, 1939, were henceforth to be under German command.

Naval and Air Forces.—The peace terms as they affected the German Navy were very severe. Within two months of the Treaty of Versailles coming into force the German naval forces in commission were not to exceed 6 battleships of the "Deutschland" or "Lothringen" type, 6 light cruisers, 12 destroyers, 12 torpedo boats, or an equal number of ships constructed to replace them. Germany was precluded from owning any submarines. The personnel of the navy, including fleet, coast defences, signal stations and administrative services was not to exceed 15,000 officers and men, of which the officers and warrant officers were not to exceed 1,500. The whole of the warships interned in the ports of the Allies under the conditions of the Armistice or in neutral ports were to be surrendered. In addition 8 battleships, 8 light cruisers, 42 destroyers, 50 modern torpedo boats, all submarines, submarine salvage vessels and docks for submarines were to be handed over or broken up. Germany was forbidden to construct or acquire any warships, except to replace the units she was permitted to have in commission, and such warships were not to exceed the following displacement:—armoured ships, 10,000 tons; light cruisers, 6,000 tons; destroyers, 800 tons; torpedo boats, 200 tons. Unless a ship had been lost it was not to be replaced until 20 years, in the case of battleships and cruisers, or fifteen years, in the case of destroyers and torpedo boats, had elapsed since the date of launching. Conscription was to cease entirely, and all recruiting was to be by voluntary engagement.

These treaty obligations were faithfully observed by Germany from 1919 to 1933. In building replacement battleships, however, as she was permitted to do by the treaty, she used such skill and ingenuity, by welding instead of riveting the plates and by other improvements, that the resulting "pocket battleships" like the "Deutschland" were really much more powerful and formidable than any 10,000-ton vessels in any foreign navies.

By the end of 1934 Hitler had secretly begun the construction of submarines, though these were forbidden to Germany by the treaty, and he even made a formal denial to the British that any submarine building was taking place. Six months later, by the Anglo-German Naval Pact of June 18, 1935 (anniversary of Waterloo when Germans and English had fought side by side against Napoleon I.), Hitler persuaded the English virtually to approve his nullification of the naval clauses of the Versailles Treaty. Great Britain had begun to realize that it would be difficult to prevent Germany from building up her navy again, and therefore judged it prudent to come to a friendly and timely agreement with her. Hitler, on his side, professed to want to avoid Tirpitz's great mistake before the World War of antagonizing Great Britain by any extensive naval program which might threaten British naval superiority. Accordingly, by this naval pact of 1935, Great Britain winked at the scrapping of the Versailles naval limitations, and Hitler promised not to build beyond 35% of the British fleet in each category of ships, except that in the case of submarines he might build up to 45% (to be offset by proportionate tonnage reductions in other classes of vessels). Furthermore, he might even build up to 100%, that is, to parity, of British submarine tonnage, if he felt that conditions had changed, and if he first gave Great Britain due notice.

In Dec. 1938, Hitler gave Great Britain due notice to this effect. Germany was already approaching the 45% submarine limit of the 1935 pact, and wanted to continue further submarine construction. The "changed conditions" which she noted were that the Soviet Union and the other European Powers had built, were building, or had appropriated moneys for the construction of submarine ships and tonnage as given in Table VI.

TABLE VI *Submarine Tonnage of World Powers, 1939*

Country	Ships	Tons	Country	Ships	Tons
Russia	160	85,000	France	98	96,101
Italy	130	114,000	England	73	75,904
U.S.A.	106	107,805	Germany	71	31,282

Though Germany had nearly as many submarines as Britain, their total tonnage was still below 45% of the British submarine tonnage, because many of the German U-boats were comparatively small: 31 were small 250-ton "minnows," designed primarily for coast defence or for use in the Baltic, although they had a cruising radius of 1,200m. and could be used in the North Sea and against British commerce; 11 were 517-ton vessels with a cruising radius of 3,000m.; 8 were "ocean-going" ships of 740 tons each; and the tonnage of the others was not accurately known. In building up to submarine parity with Great Britain, Hitler no doubt intended to use a large part of the available tonnage in building larger submarines of the ocean-going type. He hoped also, by sticking to the modified naval pact of 1935, still to avert Anglo-German naval rivalry and antagonism which had been so unfortunate before the World War and which he so vigorously condemned in his autobiography, *Mein Kampf*.

After the Munich Agreement of Sept. 1938, which began the dismemberment of Czechoslovakia, the British lost confidence in Hitler's honesty and professions of peace. Britain began rapidly to arm. Hitler was angered to find that he could no longer lull Britain into a passive and friendly attitude while he himself went forward re-making the map of Europe.

After his annexation of Bohemia-Moravia in March 1939, Britain's attitude stiffened still further, and she began to organize a "stop Hitler" front. Hitler thereupon denounced the Anglo-German Naval Pact of 1935 altogether, taking the singular attitude that, since Britain had changed from friendliness to unfriendliness. he was no longer bound by the treaty he had signed with her. He was now free to go ahead and build up his naval forces as fast as his resources would allow.

Meanwhile he had been proceeding with the building of large naval vessels. Germany had three of the "Deutschland," or "pocket battleship" class. The "Seydlitz" launched on Jan. 19, 1939, and a sister ship launched six months later in July are 10,000-ton ships, 199 metres long, 21·7 beam, and 4.6 draught; they have a speed of 32 knots, carry a catapult for aircraft, and are armed with eight 20·3cm. guns, twelve 10·5cm., twelve 3·7cm., and have twelve torpedo tubes. A new type of vessel, a kind of "carrier-cruiser" was launched at Kiel on Dec. 8, 1938. It has a 19,000 tonnage and a heavy armament of 16 large guns, but can carry at least 40 aeroplanes. A sister "carrier-cruiser" was under construction. Germany was also building two large battleships, probably of about 35,000 tons each, but the details were kept secret.

Military aircraft were forbidden to Germany by the Versailles Treaty. But Germany developed very rapidly and successfully her civil aviation both before and after Hitler came into power. The training which civil pilots received in the Lufthansa, which has a network of passenger lines all over Central Europe as well as to South America and Asia, was useful in preparing for the development of military aviation. The creation after 1933 of a great air-fleet of heavy bombers, pursuit and scout planes, and other types, was largely the result of the tremendous energy and driving force of General Hermann Goering, Hitler's minister of aviation. During 1935 he razed to the ground a whole block of buildings in the crowded centre of Berlin on the Leipzigerstrasse and put up within a year a gigantic building with 2,500 offices to house his subordinates. The Tempelhofer Field on the southern edge of Berlin was extended to he the largest airport in the world. Hangars, often concealed and protected against attacks from the air, were constructed in various parts of Germany. Special attractions were offered to young men to enter the air service. With the annexation of Austria and Bohemia-Moravia. the latter being especially important in this connection, a considerable addition was made to the German air forces. The exact number of Germany's various types of military planes is not known, but an estimate by an expert, taking into account numbers of planes and pilots, speed, replacement, morale and other factors, gave the following relative rat-

ing to European air forces in Feb. 1939: Germany 10, Italy 6, Great Britain 5, and France 2.

The manufacture of arms and ammunition for export was also forbidden to Germany by the Versailles Treaty. But *The League of Nations Armantents Year Book,* published on Nov. 30, 1936, showed that already in 193; Germany stood sixth among the chief exporters of arms in that year, the figures in U.S. dollars of the old standard being: Great Britain, $10,731,000; Czechoslovakia, $10,517,000; France, $6,548,000; United States, $3,354,000; Sweden, $3,300,000; and Germany, $2,462,000. Since 1935 Germany's exports of arms and ammunition have considerably increased, especially to the smaller States of southeastern Europe, South America, and, for a while, to China.

Higher Command.— Under the German Republic, 1919–1933, a fine training was given to the Reichswehr, the professional army of 100,000 men permitted by the Versailles Treaty. This training was largely the work of Generals Hans von Seeckt, Werner von Fritsch, and the other German officers of rigid Prussian discipline and high standards, who were taken over from the old Imperial Army which had fought the World War. They laid emphasis on the value of discipline and intelligence among the men, of rapid motorized equipment and of the element of sudden surprise *(Blitzkrieg* or "lightning war"). The highest possible efficiency in the Reichswehr was all the more necessary, in view of its limited numbers, because of the existence of various semi-military partisan organizations: the illegal monarchist "Black Reichswehr" or "Free Corps," composed of discontented ex-officers and demobilized soldiers, who perpetrated acts of violence against the Republic, as well as against the French and the Poles; the "Reichsbanner," made up of men who wanted to defend the Republic against its domestic enemies; the "Steel Helmets," a less demonstrative group of war veterans; and the Hitlerite Brown Shirts ("Sturm Abteilungen," known for short as "SA"), rapidly growing in numbers and in provocative acts of disorder which aimed at the ultimate overthrow of the republican parliamentary democracy. Thanks to General von Seeckt's organizing genius, it was generally reckoned that if it actually came to fighting or civil war, one Reichsmehr soldier would be equal to ten Brown Shirts. Thus, under the Republic, the old Junker landed aristocracy continued to dominate the higher command in the army. Though a majority of the officers were probably monarchist at heart, they on the whole stood aside from politics. They were negatively loyal to the Republic in the sense that they supported no attempts to overthrow it. In fact, they were ready, if need be, positively to defend it, as for example at the time of Hitler's Beer Hall Putsch on Nov. 9, 1923. But for the most part the Reichswehr stood aloof from politics as a non-political pillar supporting the existing State.

When Hitler became Chancellor in Jan. 1933, he made his personal friend, General, later Field Marshal, von Blomberg, one of his cabinet as minister of war. Von Blomberg was then a man barely past fifty, had visited Fort Leavenworth in the United States, and travelled about in the world. Though belonging to the old Prussian tradition by inheritance, he had become a convinced National Socialist. For many months he and the Reichswehr officers continued the tradition of keeping the army aloof from politics. At the same time they supported the measures by which Hitler began secretly to increase the Reichsmehr beyond the size stipulated in the Versailles Treaty.

With this increase of the Reichsnehr after 1933 there developed a conflict between it and the Nazi Brown Shirts, who were becoming increasingly numerous, powerful, and obstreperous. The Reichswehr officers wanted to preserve General von Seeckt's high efficiency, the two-century old predominance of the Junker families, and the non-partisan character of their organization, all of which they feared was threatened by the "plot" of Captain Roehm. This Brown Shirt leader, formerly an intimate friend of Hitler, aimed at getting a controlling influence over the Reichswehr by infiltrating his Brown Shirt followers into its ranks, increasing his personal power, and using it for Nazi political purposes. These purposes were in direct conflict with the ideals of the Reichswehr. Some of its officers therefore demanded that Hitler put an end to Roehm's activities. This was one of the elements of the terrible "Blood Purge" of June 30, 1934. By Hitler's personal intervention Roehm and his fellow "plotters" were shot, mostly without any trial. Seventy-seven were "executed" according to Hitler's statement in the Reichstag a few weeks later; in reality several times that number were killed—some estimates go as high as twelve hundred—because individual Nazis took advantage of this affair to murder private enemies or others whom they feared or disliked for one reason or another, like General Schleicher who had been Chancellor just before Hitler. Some unfortunates were murdered through mistaken identity. After this Blood Purge the remaining Brown Shirts were given a month's vacation and greatly reduced in numbers and importance, though in 1937 and thereafter they again were given by Hitler an important political and military role. As the other semi-military organizations (with the exception of the Elite Guard or Black Shirts) had also been dissolved or ceased to be of importance by the end of 1934, the Reichswehr was left in a stronger position than ever.

Hitler's startling decree of March 16, 1935, changing the Reichswehr from a professional army to one based on the old Prussian system of universal military service and enlareing it to about 500,000 men, as explained above, further increased its power. But it also brought the germs of a new conflict between the older officers and the more radical Nazis. A majority of the higher command disliked the methods and aims of the more radical Nazi leaders and even disapproved of some of Hitler's moves. In 1936 they advised against his decision for the military reoccupation of the Rhine valley and the demilitarized area west of it. They feared that this decision, which scrapped another of the humiliating limitations of the Versailles Treaty, might be opposed with force by the French, and they did not believe that even the enlarged Reichswehr would be a match for the French Army. But France did not march. Hitler won a bloodless triumph, both over the Versailles "dictate" and over his own more cautious generals.

Nazi persecution of Protestant and Catholic church organizations also added to friction between the older officers and the Nazi leaders. In Nov. 1937, the army chaplains addressed a long but dignified letter of protest to Hitler. They denounced in strong terms the tendencies that were undermining Christianity in Germany and dividing the German people against one another, yet were tolerated or actively furthered by Nazi officials and Government propaganda. They declared among other things: "Here is seen most clearly the breach in the German nation. One half believes enthusiastically everything that is officially announced; the other half holds that it is all a lie. This situation has been nurtured by the contradiction between the State's promises and its practices. The sense of injustice suffered is constantly growing. Protestant men and women, and not only pastors, who sought nothing more than to serve their church and their faith, have been arrested and held in concentration camps for months and are still there. The conscientious Christian in Germany today is wholly unprotected. The effect of this struggle on moral preparedness is evident. The full enthusiasm that has been natural to the Protestant German when the fate of the Fatherland was at stake will be lacking if matters go on as they are. The official war propaganda also will suffer because a not unimportant section of the population will believe not a single word after what they have experienced in the church struggle." In view of the strict discipline in the German Army, it is almost inconceivable that the chaplains could have drawn up this protest without the knowledge and probably the approval of the higher officers.

This protest of the chaplains was followed early in 1938 by another on the part of General von Fritsch and other officers, not on religious grounds, but on a social matter. General von Blomberg, a widower, married a woman beneath him in social rank. The old officers, with aristocratic and conservative traditions, insisted to Hitler that this was intolerable and that Blomberg must retire. The question was complicated by an intrigue on the part of Heinrich Himmler, the powerful head of the Secret Police and the Black Shirts, to become Blomberg's successor, just as Roehm in 1934 had sought to get control of the Army. Hitler had already decided at this time, according to the speech which he made at the opening of the new Chancellor's Palace in 1939, that he was soon going to intervene in Austria and annex it, as he did in March. With this military action in prospect, he did not want dissension and opposition in the Higher Command. He was also incensed that he and General Goering had been persuaded by Marshal von Blomberg to be witnesses at Blomberg's private wedding ceremony without being informed of the antecedents and character of the bride. Under all these circumstances he decided on another purge—this time a bloodless one. On Feb. 4, 1938, it was announced that Blomberg, Fritsch, and some 50 other high officers were retired "for reasons of health." Their places were filled with men on whom Hitler felt that he could depend without question. Again in November, after the Munich Agreement, there was another smaller and likewise bloodless purge of Army officers. General Ludwig Beck, who was reported to have warned Hitler against going to war with Czechoslovakia over the Sudeten crisis, was replaced as chief-of-staff by General von Halder. Several other high officers were, retired in favour of men who were politically more reliable.

While the Higher Command, cautious, conservative, and aloof from politics during the first years of the National Socialist regime, had been reckoned as a force for peace and a check on rash enterprises, this was less the case after Hitler's success in the Sudeten crisis. As the old officers were weeded out, they were naturally replaced by unquestioning supporters of Hitler's wishes. Likewise the new recruits were young men who had served in the ranks of the Hitler Youth organizations and the Labour Service, where they had been effectively exposed to thorough indoctrination in the Nazi *Weltanschauung.* So the Army became much more of a Nazi instrument than in the first five years of the Third Reich. In addition to the Army, much military, and a great deal of political power was exercised by the omnipresent secret police and by the Elite Guard or Black Shirts (Schutz-Staffel, or "SS"), both of which took a prominent part along with the Army in the seizure of Austria, the Sudetenland, and Bohemia-Moravia.

The German Army at the beginning of 1939 comprised 43 regular divisions, together with 4 light motorized divisions, 3 mountain divisions in Bavaria and Austria, 5 armoured-car or tank divisions, and *a* cavalry brigade in East Prussia. These forces were organized into 18 army corps or defence districts (Wehrkreise), each comprising about 60,000 men, and these in turn into 6 chief commands having their headquarters in Berlin, Frankfort-on-the-Main, Dresden, Leipzig, Vienna, and Hanover. The Czechs in Bohemia-Moravia were exempted from service in the German Army after their annexation in

March 1939. A decree of August 10, at the time of sharp tension between Germany and Poland over Danzig, ordered all Czechs to surrender all arms and explosives in their possession to the German authorities; cases of disobedience mere to be tried by German, not Czech, courts, and penalties of five years in the penitentiary or even death mere threatened.

The Commander in Chief of all the armed forces of every branch is the Fuehrer, Adolf Hitler. To secure complete unity of command he exercises his authority through his personal representative, General Wilhelm Keitel. Under him are the heads of the three chief branches of the military forces: General von Brauchitsch (Army), Admiral Kaeder (Navy), and General Milch (Air-forces).

Permanent Fortifications.— A brief résumé of the recent history of the fortification policy of the late German Empire will bring into prominence the importance of the provisions for the future laid down after the World War. The fixed defences maintained by the German Empire (apart from naval ports and coast defences) belong to two distinct epochs in the military policy of the state. In the first period (roughly 1871–1899), which is characterized by the development of the offensive spirit, the fortresses, except on the French and Russian frontiers, were reduced to a minimum. In the interior only Spandau, Ciistrin, Magdeburg, Ingolstadt and Ulm were maintained as defensive supporting points, and similarly on the Khine, which was formerly studded with fortresses from Basel to Emmerich, the defences were limited to Neu Breisach, Germersheim, Mainz, Coblenz, Cologne and Wesel, all of a "barrier" character and not organized specially as centres of activity for field armies. The French frontier, and to a less extent the Russian, were organized offensively. Metz. already surrounded by the French with a girdle of forts, was extended and completed as a great entrenched camp, and Strassburg, which in 1870 possessed no outlying works, was similarly expanded, though the latter was regarded an instrument of defence more than of attack. On the Russian frontier Konigsberg, Danzig, Thorn, Posen, Glogau (and on a smaller scale Boyen in East Prussia and Graudenz on the Vistula) were modernized and improved.

From 1899, however, Germany began to pay more attention to her fixed defences, and in the next years a long line of fortifications came into existence on the French frontier, the positions and strength of which were regulated with special regard to a new strategic disposition of the field armies and to the number and sites of the "strategic railway stations" which were constructed about the same time. Thus, the creation of a new series of forts extending from Thionville (Diedenhofen) to Metz and thence south-eastward was coupled with the construction of twelve strategic railway stations between Cologne and the Belgian frontier, and later an immense strategic railway station was undertaken at Saarburg, on the right rear of Thionville and well away from the French frontier, and many important new works both of fortification and of railway construction in Upper Alsace, between Colmar and Basel. In August 1914 the rapid construction of semi-permanent works, which helped so materially to defeat the French offensive against the left-centre of the German advance, brought into prominence the value of such works, as did their absence on the other flank which was left open to the German turning movement.

After the World War, Germany's 5,500km. of land frontier had for the most part no good protection from natural features or barriers. To the west Germany was faced by the powerful French defensive fortifications known as the Maginot Line which was built after the war, and by strengthened defensive works in Belgium. To the south and west Switzerland has a good natural defence in her mountains. On the south the Alps form something of a barrier between Germany and Italy, but railway lines through the Brenner and Semmering passes, and the existence of other passes make the Alpine boundary not insuperable for modern mechanized armies. Mussolini, by rapidly sending Italian troops to the Brenner frontier in 1934, helped to prevent Hitler from seizing Austria at the time of the Nazi assassination of the Austrian Chancellor Dollfuss. Since 1936, when Hitler and Mussolini became friends and later formed the "Berlin-Rome Axis," Hitler no longer needed to worry about Germany's southern frontier and could afford to leave it unfortified. Nor were any fortifications needed to the southeast, after the annexation oi Austria, against weak and small States like Hungary and Yugoslavia, which are further weakened bv internal conflicts between Nazi and anti-Nazi elements.

To the east the problem of the frontiers against Poland and Czechoslovakia was more serious. Poland and Germany had been enemies for six centuries with bitter memories on both sides. By the Versailles Treaty Germany was deprived of the so-called Polish Corridor, so that East Prussia was cut off from the rest of the Reich and more than half surrounded by Polish territory. Nowhere was the Polish frontier well defined by any rivers, mountains or other good natural barriers. On both sides of the frontier there were discontented minorities—Poles in Germany, and Germans in Danzig and the Polish Corridor. Germany was permitted by the treaty to retain some pre-war fortifications, but these were antiquated and of little value, especially as Poland was in alliance with France. Under the German Republic therefore no effort was made to change the Polish frontiers, aside from the plebiscites provided for in the treaty. Hitler likewise saw that he could do nothing until he had rearmed Germany and fortified hi; western frontier against France. Therefore, in Jan. 1934, he signed with Pilsudslri a ten-year treaty of friendship, by which Poland and Germany agreed not to change their frontiers by force.

Czechoslovakia seemed a great obstacle to Hitler in his plans of pushing to the east, and also something of a potential military danger if he engaged in any war. Czechoslovakia had one of the greatest armament factories in the world, the Skoda works, which were partly controlled by French capital and were in close association with the French Schneider-Creusot armaments concern. She had also defensive alliances with France and Russia. Her territory, well defended by the natural mountain frontier and fortification works, might be an easy landing place for friendly Russian air forces and thus form the spear-head of the Communist attack on the Third Reich—at least so the Nazi propaganda proclaimed in trying to justify Hitler's seizure of Bohemia-Moravia in March 1939. By joining this former Austrian territory to Greater Germany, Hitler shortened most advantageously his eastern frontier and took possession of the Czech fortifications built with the aid and advice of French engineers. At the same time he extorted from tiny Slovakia the right to send German armies through her territory and to build German fortifications against Poland along the northern frontier of Slovakia; and in Aug. 1939, he decreed that the Slovakian Army should place itself under his command to be used against Poland in case of war.

Meanwhile, he had decided that before he could destroy Czechoslovakia and attack Poland, he must make an impenetrable barrier in the west which would prevent France from invading Germany in support of France's Polish and Czech allies. The order for the construction of this "Westwall" was secretly given on May 28, 1938, after Czechoslovakia had taken a somewhat defiant attitude by mobilizing part of her army a week earlier to prevent Hitler from making trouble in the Sudeten districts. The task was given to Dr. Todt, a very able engineer who had proved his genius and energy in constructing Germany's magnificent new auto-highways of concrete cement. He was told that the "Westwall" must be completed by October 1. Within the time specified it was practically finished—a line of fortifications stretching from the Belgian to the Swiss frontier. In some places it was as much as 50km. wide, if the anti-aircraft defences are included. In the triple line of protective works, which included not only gun emplacements but complete living quarters underground for the men, underground connecting railways, and closely set concrete barrier pillars, stupendous amounts of labour and material were employed with an extraordinarily feverish activity. According to official statistics published in July 1939, there were engaged in the work at the end of September nearly 500,000 men. Cement, gravel, steel, and other materials were brought daily in 8,000 railway cars in addition to what was transported by 15,000 trucks and many canal boats. Six million tons of cement—a third of Germany's total annual production—and 695,000 cubic metres of wood were used. The German engineers pronounced the barrier to be impassable. It contributed to Hitler's success in bluffing France and England into acceptance of the Munich Agreement and the beginning of Czechoslovalria's dismemberment. In the summer of 1939, when Hitler demanded that Danzig should return to the Reich and German-Polish relations became tense, Hitler ordered that a film of the "Westwall" should be shown in all German theatres and movie-houses to strengthen people's conviction that Germany was invincible in the west. If Poland did not yield to his demands and war came in the east, the German people need have no fear of invasion by the French.

ECONOMIC AND SOCIAL CONDITIONS

Germany After the World War was different in geographical extension as well as in economic structure from the Bismarckian empire of 1871. Though the country was not broken up in scattered parts, as seemed likely immediately after 1918, its area was considerably reduced. Alsace-Lorraine and a few outlying districts handed over to Belgium were lost on the western frontier; Posnania, parts of West Prussia and of Upper Silesia, went to Poland in the east; and a large area was joined to Denmark. In the west, the Saar area was separated from the German economic body for the time being. Germany, moreover, was no longer an unbroken territorial unit. Danzig and the Polish Corridor cut the connection between the Reich and East Prussia. This province thus became a kind of outlying dependency, enclosed by foreign customs frontiers, freely accessible from the mother country by sea only.

On the other hand, Hitler's annexations of territories between 1935

and 1939, which have been noted above under "Population" in Table I, more than made up for the territorial and population losses which Germany suffered as a result of the World War. The number of separate States forming the Bismarckian Reich was reduced from 26 to 17 by the amalgamation of smaller units, either with each other (Thuringia) or with Prussia and Bavaria. But the feature most characteristic of the German Union, the fact that Prussia is the predominant partner, has not been changed. The 18 other units, comprising not only the petty countries but Austria, Bavaria, Wurttemberg, and Saxony as well, cover but 312,000 sq.km. with 37,800,000 inhabitants, whilst the remaining partner, Prussia, controls 293,000 sq.km. and 41,700,000 inhabitants. In addition, there is the separately organized and governed German "Protectorate of Bohemia-Moravia" with 6,000,000 inhabitants, and the "General Government" of Poland with some 15,000,000 inhabitants.

After 1933 Hitler proceeded rapidly to complete the work of German unification. This had begun during the period of the French Revolution and Napoleon I, when some 300 States of the old Holy Roman Empire were consolidated into 69 in 1806, and to 39 in the German Confederation of 1815. Bismarck's annexations of territory to Prussia further reduced the number of States in the German Empire of 1871 to 25. The 17 States comprising the Weimar Republic of 1919 were so reduced in power and functions by Hitler after 1933 that his "Third Reich" became virtually a unitary, instead of a federal, form of government. Just as in the French Revolution the power of the old French feudal duchies and counties was swept away and France was made "one and indivisible," with power concentrated in the capital at Paris, so under Hitler the authority of the former German States was obliterated and his Third Reich became one of the most highly centralized and unified States in the world, with power concentrated in the capital at Berlin.

The Reich firmly grasped the financial sovereignty belonging to the States under the Bismarckian constitution. Whilst formerly the Imperial treasury was the pensioner of the States, the process has become inverted: the States, now called Lander, are restricted to such taxes as the Reich has seen fit to turn over to them; they draw most of their sustenance from the subsidies it is granting to them from proceeds of taxes assigned and collected by its authority. It is not a sound system as different authorities are responsible for the raising and for the spending of the revenues; there is a good deal of haggling about the shares. But the very shortcomings of the system drove all parties concerned towards greater unification, some of them conniving at it very much against their will. The Reich built up its own system of tax gathering over its entire area; it took over the separate financial services which the Lander so far had maintained for the assessment and the collection of taxes left to them for their own independent use. Germany became economically and financially a "united empire," somewhat like England, Wales, Scotland and Northern Ireland, whilst formerly she was a kind of union of the United States type.

Natural Resources. — Germany is not a rich country as far as natural resources go. Of her total surface of 586,000 sq.km. (Bohemia-Moravia and Poland area excluded) about 112,000 are unfit—at present—for cultivation, being covered by lakes, moors, river beds, hills and mountains, the latter rising on her south-eastern frontier to the level of eternal snow. A huge plain stretches from near her western boundary to her eastern frontier, fertile in some parts, it is true, but consisting elsewhere of thin sandy soils fit only to grow potatoes. rye and fir. Of the country's total area capable of being beneficially worked 154,000 sq.km. are covered with forest, 213,000 sq.km. are under the plough, 107,000 sq.km. are pasture and meadows. The climate, though severe in the extreme north and in the high lying mountain lands, is genial enough for viticulture in the river-valleys of the west, the Rhine, the Moselle, the Main and the Saar. The vintage of sheltered sites in favoured years is as unique as are the best French brands. In the Rhine valley and other sheltered spots an inferior tobacco is grown—whilst the rich lands of central Germany, especially of the Prussian province Saxony, are producing sugar-beets containing a very high percentage of sugar. Fruit growing is possible all over the country, the south-western and southern districts excelling in quality.

Germany's great natural assets are her coal mines. She is supposed to possess 80,000,000,000 metric tons. Coal exists in many districts; the main centres of the industry are, however, the Ruhr district, which is producing about 78% of the total German production, and the Silesian area, especially Upper Silesia. A large part of this area was handed over to Poland under the award of the League of Nations, resulting in a severe dislocation of the coal trade, but this area was reannexed to Germany in Sept. 1939. Many of the German coal seams are comparatively thin, especially in the Ruhr district where working costs are comparatively high. On the other hand their situation close to great natural waterways and to efficient canals is favourable to distribution. Upper Silesia, on the other hand, has been a land of very thick seams, and low working costs, but is rather badly situated for distributive purposes.

Within the last 40 years the exploitation of the huge lignite deposits has been taken up. The available German supply is estimated at 57,000,000,000 metric tons. As lignite is not mined, but rather scraped up by means of huge mechanical excavators, production is not dependent on an adequate supply of skilled miners The most important of these new lignite areas are close to existing industrial centres. Thus power plants in the lignite area of central Germany are generating the electric power needed in Berlin. Lignite, moreover, has been made the base for the production of synthetic nitrate and can be used as cheap raw material for producing oil. Germany's position as an iron-ore producing country was greatly changed by the Treaty of Versailles. The loss of Lorraine reduced her annual production from 28½ million tons in 1913 to 9,000,000 tons in 1937. Having lost her main supplies, she is now but the fifth of the iron-ore producing countries of Europe. However, by the annexation of Austria and by the exploitation of low grade ores in the Salzgitter district in central Germany near Hanover, Germany increased her iron production during the first six months of 1939 to 6,180,000 metric tons.

Apart from iron Germany's mineral wealth is not considerable. There are some spelter, copper, silver, lead and a little tin, and, of course, a good deal of bauxite. On the other hand the world's chief potash deposits are located in Germany. The distribution and estimated amount of Germany's principal mineral resources are given in Table VII.

TABLE VII. *Mineral Distribution and Tonnage*

Mineral	Areas	Million tons
Coal	Upper and Lower Silesia	5,240
	Saxeny, Hanover	480
	Ruhr, Krefeld, Aachen districts	65,520
	Saarland	9,205
	Austria	13
Lignite	Middle and Lower Rhine districts	18,199
	Brunswick, Thuringia, Saxony, Lusatia	27,789
	Eastern Germany	8,414
	Silesia	1,299
	Austria	600
	Scattered	1,066
Iron ore	*West:* Lahn, Siegerland, Eifel, Taunus	174
	Brunswick, Hanover (Salzgitter)	Much
	Harz, Thuringia	108
	South: Bavaria, Württemberg, Baden	Much
	Austria	Much
Lead	Harz, Saxony, Silesia, Austria	Much
Copper	Harz, Mansfeld, Hesse	0·6
Salt	Saxony, Rhine, and other districts	Immense
Potash	Harz, Saale, Halberstadt, Saxony	15,300
Petroleum	Hanover, Holstein, Austria	Some

The many mountain districts, distributed over many parts of the country, make it fairly easy to use and exploit water power. Southern and south-western Germany, which are far away from the coal areas, are favoured by easy access to water power.

Broadly speaking, apart from coal, Germany is not conspicuous amongst the countries of the world for the possession of natural resources. Invention and scientific management rather than natural wealth are the mainstays of German economic life. It is not by accident that she has become the home of applied chemistry.

AGRICULTURE

There are two main systems of landholding forming the basis of German agriculture, each of them predominating in different parts of the country. The east, especially the country to the right of the Elbe, is a land of big properties; some tracts like East Prussia and parts of Silesia being in the hands of comparatively few owners. These estates are rarely let to tenants; they are run like home farms under the management of the owners or their administrators by means of hired agricultural labourers. Of the 5,096,534 holdings only 1,373,625 are let to tenants, who farm but 12·4% of the total area used for agricultural purposes. Since migration to the industrial centres has set in, there is very often a scarcity of labour.

In the west, in the south and in most parts of central Germany the land is mainly held by peasant proprietors. Some of them, especially in the north-west, own fairly large farms, for the working of which they employ hired labour. Others again, especially in the Rhine valley, are small holders, running their farm or plot—some of them very intensively cultivated—with the help of their families. The distribution of the total 5,096,534 holdings enumerated is (1925 figures) given in Table VIII.

TABLE VIII Distribution of Holdings

Size of holdings	Number of holdings	Area covered
0·05–2 ha.	3,027,430	1,587,670 ha
2–20 "	1,850,608	12,082,485 "
20–100 "	199,825	6,768,629 "
100 and more ha	18,671	5,159,893 "

The total number of agricultural holdings in Greater Germany (not including Bohemia-Moravia) above one-half hectare (*i.e.* above 1·23ac.) in size was 3,471,904. Their distribution according to size is given in Table IX.

Agrarian Germany—outside certain districts—is a kind of peasant-democracy, dominated in some parts, it is true, by large estate owners, who farm on a large scale and who cling tenaciously to traditional and somewhat feudal social conceptions. This sway is slowly disappearing. Big estates are broken up, partly under the desire for closer settlement, partly as a result of the agricultural crisis which has hit the owners of big properties at least in certain parts of the country,

TABLE IX. *Agricultural* Holdings *in Greater* Germany

Size of holdings	Number of holdings	Area covered
0.5 to 2 ha.	931,091	1,050,000 ha.
2 to 5 "	894,824	2,937,000 "
5 to 20 "	1,223,065	12,267,000 "
20 to 100 "	382,955	13,678,000
Over 100 "	30,969	19,251,000
Totals	3,471,904	49,183,000 "

far more severely than the farmers working medium-sized and small holdings. Much was done, during the 20 years after the war, in Old Germany (including the Saarland but not later annexations) to create new peasant agricultural holdings by reclaiming swamp and other unused lands and by breaking up larger into smaller estates. Much of the land, however, was taken for barracks, airports, auto-highways, and other public purposes. These changes are shown in Table X.

TABLE X. *New* Peasant Settlements

Area of lands acquired, 1919–37		Number	Area
Swamp and unused land	58,256 ha.	..	..
State domains	162,849 "	..	..
Estates over 1 a	1,106,938 "	..	..
" under "	101,804 "	..	..
Total.	1,464,681 "	76,409	902,891

Of total area of the agricultural holdings above half a hectare in size in Old Germany (41,567,000ha.), about two-thirds (26,705,000ha.) were in active use: under tillage, 18,315,309ha.; meadow, 5,049,067ha.; and pasture, 2,929,966 hectares.

Germany soon after the Franco-Prussian War, with the rapid industrial development, was no longer able to raise enough grain to meet her food and fodder needs. In 1879 a tariff on grains was introduced to stimulate domestic production, but nevertheless Germany ever since has had to be a grain-importing country. By the use of artificial fertilizers and improved methods, however, she has considerably increased her production of grain and other crops above pre-war levels. The figures for recent years are shown in Table XI.

TABLE XI. Crop Production in Metric Tons (*000's omitted*)

Crop	1929	1930	1931	1932	1933	1934	1935	1936	1937
Rye	8,155	7,679	6,680	8,364	8,727	7,608	7,478	7,386	6,917
Wheat	3,349	3,789	4,233	5,003	5,604	4,533	4,667	4,427	4,467
Barley	3,181	2,860	3,018	3,215	3,468	3,202	3,388	3,399	3,638
Oats	6,793	5,186	5,709	6,075	6,334	4,826	5,386	5,618	5,919

Flax	..	..	..	..	16	27	69	149	169

The areas planted to different crops, and the relatively high kilogram yields per hectare as compared with Great Britain and the United States in 1937, which was a fair average year for Germany, were, according to the International Agricultural Institute in Rome, as shown in Table XII.

TABLE XII. Crop Production Comparison

Production	Wheat	Rye	Barley	Oats	Potatoes	Sugar beets
Area (1,000 ha.)	2,235	4,517	1,875	3,127	3,186	495
Kg per ha in:						
Germany	2,170	1,630	2,070	2,020	18,840	33,690
Great Britain	2,060	1,500	1,820	2,020	17,240	20,410
United States	910	810	1,190	1,170	8,280	26,080

Outside a few grazing districts, mixed farming is the rule. Nearly everywhere cattle must be kept indoors in winter, and in recent years there has been an increasing tendency to keep them indoors throughout the year in order to make more land available for raising crops by turning pasture into arable land. This being the case, stall feeding has become everywhere increasingly predominant, aiming at dairy produce rather than at stock-breeding or fattening and sheep farming. The diet of fodder beets and potatoes instead of grass appears to increase rather than diminish the yield of milk. The average yield per cow in 1937 was 2,521 kilograms. In the decade 1924–27 to 1934–37 it had increased by 670 litres or 37% on small farms, and by 510 litres or 18% on large estates, per cow per year. During 1937–38, however, cattle and dairy production suffered considerably from the hoof-and-mouth disease which swept across Germany from the Rhinetand to the eastern districts. The livestock and the dairy production in recent years is given in Table XIII.

TABLE XIII. *Livestock* and Dairy Production

(000's omitted)	1929	1931	1933	1935	1936	1937
Horses	3,617	3,451	3,397	3,390	3,410	3,434
Cattle	18,033	19,124	19,739	18,938	20,088	20,504

Since Germany cannot produce at home all the food she needs she has made increasing use of the limitless resources of the sea, catching more sea-fish herself, importing less, and carrying on an active propaganda for greater consumption of sea-foods in place of meat. These changes are shown in Table XIV.

TABLE XIV. Sea-Food Statistics

Year	German catch of sea-fish in tons	Imported fish in tons	Consumption *per adult (over 15) in kg.
1913	169,000	328,000	5·0
1933	387,000	227,000	8·9
1936	596,000	242,000	12·0
1937	672,000	224,000	12·4
1938	718,000	225,000	12·0

*Not including imported fish.

Viticulture is important on the sunny hillsides of the Rhine, the Main, the Neckar, the Moselle, and the Saar. The yield of the vine crop has varied during the past decade between 1,722,000 hectolitres in 1932 and 4,525,000 in 1934. Beer production fell from 58,078,000 hectolitres in 1929 to 33,570,000 in 1932, the year of the deepest depression; in the following years it rose steadily to 43,599,000 hectolitres in 1937. Mainly from the sugar beet, 232 factories produced 2,210,000 tons of raw sugar in 1937, enough to supply domestic consumption.

A little more than a quarter of Germany (27.5%) is covered with forests which yield timber as well as material for paper, wood-fibre, cellulose, and numerous artificial substitute ("Ersatz") products. But the wood supply is insufficient for Germany's needs, especially in recent years when she has been cutting wood one-and-a-half times as fast as it grows. The annexation of Austria, where forest covers 37·4% of the area, was a valuable addition to Germany's timber supply; the same is true in a less degree of the annexations of the Sudetenland and Bohemia-Moravia.

German agriculture was financially in a bad way under the Weimar Republic. Notwithstanding the fact that farmers had practically wiped out their heavy indebtedness during the inflation of 1923, their lands became heavily mortgaged again during the following years at high rates of interest. Agriculture was not a paying business. Prices of agricultural products varied with the movement of the world market; fluctuations could not be prevented as in the cartellized industries. Industrialists could stabilize prices at a level they considered profitable by a combination of protective duties with a centralized control of the market. Agriculturalists on the other hand had to pay greatly inflated prices for their equipment, whilst they received for their farm products prices by no means adequately raised. Furthermore, the wages of agricultural labourers rose considerably. They varied very greatly in different districts. They amounted in 1926 to about 0.48 mark per hour in the Rhineland, but were only 0.34 mark in East Prussia.

Under National Socialism great, and on the whole successful, efforts were made to improve and stabilize agricultural conditions. A Reich Food Bureau (*Reichsnährstand*) was created under the leadership of the minister of agriculture, Richard Walther Darré. In his books he had emphasized Blut *wnd* Boden—pure Aryan blood and German *soil* as the backbone of the Third Reich's strength. He tried to please some 600,000 peasant proprietors by making their holdings (*Erbhöfe*), hereditary and inalienable. and by declaring that they formed a "Peasant Nobility." Remembering Germany's painful food shortage during the World War and the post-war blockade, and conscious of her needs in case of a future war, he aimed to make Germany as far as possible self-supporting in the matter of food. His Reich Food Bureau was given very wide powers to help bring this about. Agricultural prices were rigidly fixed or controlled at levels sufficiently remunerative to the farmer. Prices therefore were no longer subject to the fluctuations of the world market. The profits of the middleman were largely eliminated, because the farmer must deliver his fixed quota of produce directly to the agents of the Food Bureau, which likewise fixed the prices for the consumer. The importation of food from abroad was also controlled by the granting or withholding of foreign exchange for payment, by trade agreements between the German Government and foreign governments, and by the provision that all importers of food must first offer it for sale to the Food Bureau. Darré's Food Bureau also distributed technical information and advice to peasants, called their representatives together once a year in a "Peasant Congress," and encouraged them in the use of labour-saving agricultural machinery and of fertilizers. In 1935 the Government compelled the chemical companies to reduce by 25% the price of artificial fertilizers.

Hitler's annexations of 1938–39 did not greatly alter German agricultural conditions, since the conditions in Austria, the Sudetenland, and Bohemia-Moravia were much the same as in Old Germany. As far as the food shortage was concerned, the annexations made Greater

Germany rather worse off than before, because the new territories were dependent to a larger extent than Germany on imported food. The figures for the Protectorate of Bohemia-Moravia were not available, but the principal agricultural statistics for Austria and the Sudetenland for 1937 are given in Table XV.

TABLE XV. *Agricultural Statistics for Austria and Sudetenland*

	Area in use in 1,000 ha.			Livestock in 1,000's		
	Arable	Meadow	Pasture	Horses	Cattle	Pigs
Austria	1,784	980	1 162	261	2,349	2,823
Sudetenland		323	1	121	1,164	782

	Crops in 1,000 tons					
	Rye	Wheat	Barley	Oats	Potatoes	Fodder beets
Austria	477	400	288	475	3,612	2,137
Sudetenland	383	194	211	375	2,438	1,602

INDUSTRY

More than 41% of the German people are engaged in industry. Though the old handicraft system is by no means extinct, more or less large industrial establishments employ an increasing proportion of the total number of industrial workers. Of the 1,917,793 industrial establishments in 1933, more than nine-tenths were small or handicraft establishments employing five or less persons each, while only one per cent were large industries employing over 50 men each. Yet two-fifths of all the industrial workers were concentrated in this one per cent of large industrial plants, as may be seen from the figures in Table XVI.

TABLE XVI. *Industrial Statistics for 1933*

1933	Establishments		Workers	
	Number	%	Number	%
Establishments with 1–5 workers	1,743,453	91	3,074,093	33
" " 6–50 "	154,650	8	1,975,138	27
" " over 50 "	19,690	1	4,102,970	40
Totals	1,917,793	100	9,152,201	100

An elaborate industrial census was taken on May 17, 1939, but its results were not immediately available. But earlier censuses show that in the half century between 1882 and 1933 there were considerable changes in the relative number of persons engaged in different forms of employment. While those in agriculture and forestry increased only very moderately, those in industry more than doubled; those in commerce and transportation more than quadrupled; those in public services nearly trebled; while those in domestic service actually declined. These changes, which are shown in Table XVII, proceeded at an accelerated rate during the six years after 1933.

TABLE XVII. *Distribution of German Employment, 1882–1933*

(Figures in 1000's)				1933
Agriculture and Forestry				9,388
Industry and Handicraft	6,050	10,118	13,667	13,235
Commerce and Transportation	1,427	3,464	5,240	5,994
Public Services		1,726	2,208	2,725
Domestic Services	1,364	1,473	1,407	1,280
Totals	17,005	25,378	32,329	32,622

The after-effects of the war and of the revolution greatly affected German industries. The revolution brought about a different attitude of the working classes. Labour's increased demands not only led to important changes in wages and hours of work; they greatly lessened the disparity between skilled and unskilled workers and made collective bargaining almost universal. Inflation has reduced the 43 to 5 milliard marks of bonded debt with which industrial concerns were saddled, to less than one milliard, if valorization is taken into account; —an advantage which was quickly lost when the Dawes plan placed five milliard marks representing an annual charge of 300 million marks, running for 38 years, on industrial concerns with the avowed object of equalizing the cost of production of German industries with those of competing countries.

On the other hand, inflation greatly dislocated the home market, the income of the large class formerly receiving interest on mortgages, debentures and other bonds, having been reduced by at least four-fifths. Moreover, the scarcity of capital following inflation cramped industrial reorganization. A contracted home market was not offset by expanding foreign markets. In many oversea countries industrialization set in to such a degree as to make the importation of manufactured goods more or less superfluous. Whilst Germany was precluded from the full enjoyment of the most favoured nations clauses in the former enemy countries, her selling agencies were destroyed permanently in many cases, owing to the expulsion or non-admission of her nationals.

Last, but not least, the Treaty of Versailles greatly dislocated some of the leading German industries, especially the mining industry, the iron and steel industry, the textile industry and, to a lesser degree, the chemical trade.

German statistics group industrial and handicraft establishments under 21 headings. The results of the industrial censuses of 1925 and 1933 are given in Table XVIII on the "Distribution and Development of German Industry, 1925–33." In 1925 Germany was starting forward again, after the disrupting effects of the war and inflation, in a great industrial recovery. This continued upward during the next four years when the adoption of the Dawes Plan for Reparations re-established German credit and allowed Germany to borrow very heavily abroad. Part of the money borrowed was spent in prompt payment of reparations obligations under the Dawes Plan; part was spent in public welfare improvements, in accordance with socialistic ideals, such as public parks, libraries, baths, and athletic fields and buildings for the masses; and a large part of the remaining money borrowed abroad was spent in the "rationalization of industry," that is, in the modernization of old plants and the construction of new ones with the most up-to-date labour-saving machinery. The use of hand-power was increasingly replaced by machine-power. The older forms of horse-power—wind, water, and steam-machines—were increasingly replaced by electric motor power, so that between 192; and 1933 the former declined 4·7%, and the latter increased 40·7%. The excessive rationalization of industry, or replacement of hand-power by machine-power, affected Germany adversely in two ways. It saddled Germany with an intolerable foreign debt at high rates of interest which could not be met when the world depression began in 1929. It also tended to increase the terrible unemployment conditions in Germany which were at their worst in 1932. The number of industrial employed persons had fallen from 13,000,000 in 1925 to 9,000,000 in 1933, a drop of over 30%. It was this frightful unemployment, with industrial depression and financial distress, which afforded the fertile ground in which National Socialism could sow its seeds and pave the way for Hitler's seizure of political power.

In 1933 another great industrial recovery began. It was stimulated by the National Socialist policy of reducing unemployment by spreading out work at short hours and fixed low wages to as many persons as possible (instead of allowing trade unions to force high wages for

TABLE XVIII.—*Distribution and Development of German Industry, 1925–33*

Industrial Groups	Persons Employed			Horse-Power Employed

the employed while great masses remained unemployed, as in the United States). The National Socialists also reduced unemployment by great Government expenditures on public works like auto-highways, roads, housing and repairs, and better barracks, and after 1935 by gigantic but unpublished Government expenditures on rearmament and fortifications. The statistics of this recovery after 1933 in some of the more important industries—coal and iron, chemicals, textiles, motor vehicles, and others—will be indicated in tables below.

By 1939 the feverish effort at rearmament had completely wiped out unemployment, and even created a severe labour-shortage, in spite of the 22,000,000 then employed. As German exports were insufficient to pay for all the needed raw materials irom abroad, Germany also began to suffer from a severe shortage of industrial raw materials. As she also wanted to be as far as possible "self-sufficient" in case of a future war and blockade, she developed a policy of "autarchy." Instead of manufacturing goods from imported raw materials she began to manufacture them as far as possible from her own domestic resources. These substitute (Ersatz) products,—gasoline from coal; textiles from wood-fibre, cellulose, or casein; artificial rubber or buna; etc.—required much more labour, capital investment, horse-power and domestic materials such as coal and timber, than goods formerly made from imported raw materials. As a result, the severity of the labour shortage and raw materials shortage was further intensified. By Aug. 1939, when German troops were mobilized on account of the Danzig crisis and tension with Poland, German industry was already suffering irom overstrain.

Coal mining, Germany's basic industry, lost about 16% of the production capacity of 1913, the ceded part of Upper Silesia having an output of 32,000,000 tons of the total German output of 193,000,000 tons. Moreover, 13,000,000 tons a year from the Saar were no longer available from 1919 to 1935. These losses could not be completely overcome even by 1939. The world's coal situation had changed; lignite had come into great importance, and oil and'electricity became serious competitors. Coal production increased to 163,000,000 tons in 1929, sank to 105,000,000 in 1932, and then rose again to 184,500,000 in 1937. But there the limit of further increase seemed to be reached, production for 1938 was only slightly above 1937, and only 94,060,000 for the first half of 1939. Two of the difficulties which coal mining encounters are shortage of labour and increasing taxes. Efforts were made in 1938–39 to overcome the first by increasing the compulsory workday for miners from 8 to 89 hours a day, cutting out all holidays, and paying higher wages and premiums to attract a larger number of young men into the industry; also by transferring miners from former Czechoslovakia to the Ruhr. But as to the second difficulty, under Nazi rule reduction of taxes was hardly to be looked for. The result is that coal mining has not been a profitable business since strenuous rearmament began, as may be seen irom the reports of nine large companies in Table XIX.

TABLE XX. *Statistic! of Coal Production, 1933–37*

Year	Persons employed	Volume 1000 tons	Value 1,000 M.	Exported coal 1000 tons
1933	310,469	104,740	1,175,286	26,435
1934	331,468	124,856	1,305,482	30,883
1935	386,741	143,003	1,505,901	36,408
1936	393,780	158,283	1,687,605	39,071
1937	450,276	184,513	2,045,438	51,383

Lignite (Braunkohl) production increased rapidly after the war and almost exactly equalled coal production in tons. Compared with coal, lignite has a relatively low caloric content, but it requires far less labour to exploit, since it lies close to the surface and can usually be dug up by giant scoops in open air operations. It is largely used in the form of briquettes in private houses and apartments. It is also largely used for generating energy in electric power plants and in industry generally.

TABLE XXI *Lignite Production and Consumption in 1933 and 1937*

Year	Persons employed	Production		Consumption (1000 tons)	
		Volume, tons	Value, marks	Houses	Power plants
1933	49,636	126,794,000	316,155,000	22,651	18,050
1937	55,962	184,709,000	449,743,000	26,327	33,049

Of Germany's total coal production in 1937, about 10% was used in private house consumption; another 10% was used by railroads and ships; 8% furnished energy in electric power plants; 28% was exported; and 3470 was used for coking and distillation. The coking process produced coke for smelting iron ore, gas which was piped for hundreds of kilometres, gasoline, coal-tar, dyes and thousands of other derivatives invaluable for the chemical industry and for the manufactuie of many "substitute" (Ersatz) products.

Iron and steel, another of Germany's basic industries suffered an even greater dislocation as a result of the war and the cession of Alsace-Lorraine to France. The production of iron ore had been 28,600.000 tons in 1913; of this output the districts remaining to Germany produced but 7,300,000 tons—a reduction of 74·5%. This production did not increase at first; in 1932 it even fell to 1,300,000 tons. The number of separate undertakings was reduced from 328 to 115, and the number of people employed from 43,000 to 13,802. Amongst other losses there were 23 concerns with 114 blast furnaces, 21 steel works with 50 Thomas converters, 70 Martin hearths and 30 rolling mills. These works were expropriated by the French Government, the German Government being bound to pay compensation, which was used for the re-election of new plants in German territory. The former German owners, being in most cases owners of coal and coke in the Ruhr district, could easily start new works on the basis of their ownership of coal, whilst their French successors depended for the profitable running of their newly acquired Lorraine steel works, on coal from the Ruhr and on the market of south-western Germany. When the struggle for the Ruhr was over and when Germany regained her liberty of tariff legislation, the German iron and steel industries again began to acquire a strong position. By importing iron ore and by the use of scrap, Germany had enough raw material to start again.

After 1933 Germany's iron and steel production recovered rapidly. Her great lack is iron ore to make up for the ores lost in Lorraine. To overcome this lack of domestic iron ore Germany in 1937 imported 20,600,000 tons—9,100,000 from Sweden, 5,700,000 from France, 1,500,000 from Belgium and Luxembourg, 1,100,000 from Spain, 800,000 from Newfoundland, 700,000 from Algeria, 500,000 from Norway, and a little from other countries. Her own domestic production of iron ore rose from 2,600,000 tons in 1933 to 9,700,000 tons in 1937. The annexation of Austria, which produced 1,800,000 tons in 1937, and of part of Czechoslovakia which produced about 1,000,000, were welcome additions to Germany's iron ore supply.

The total of imported and domestic iron ore in 1937 (30,300,000 tons), however, was not enough for Germany's rearmament and other needs. Therefore there was formed, as part of the Four-Year Plan, the Hermann Goering Reich Company for Ore Mining and Iron Smelting. By the use of a new acid smelting process discovered by Mas Paschke and Eugen Peetz this company is to exploit Germany's low grade ores which lie in the Hanover-Brunswick regions and elsewhere. They have a low iron content of only 14 to 30%, as compared with an average of 60% or more in Swedish ores, and 30 to 40% in German ores already being exploited by private enterprise i n Germany. It is estimated that there are 1,000,000,000 tons of this low grade ore, but hitherto it had been unprofitable to develop by the old processes, and private enterprise would not touch it. But the Goering company, supplied partly with State funds and partly with private capital which was encouraged to participate, and using the new Paschke-Peetz acid smelting process, was expected to produce 1,000,000 tons of crude steel by 1940 in the new plant being erected in the Salzgitter district near Hanover. Inasmuch as the new steel plant was erected on the ore deposits themselves, the necessary coal and coke will have to be transported to it, but this was held to be cheaper than moving the low grade ore to the coal in the Ruhr district. It had also the strategic advantage that, being further from the frontier, it would be less in

TABLE XXII. *German Industrial Production in 1933 and in 1937*

Industry	1933	1937
Iron and steel:		
Pig iron	5,247,000 tons	15,960,000 tons
Raw steel	7,492,000 "	19,387,000 "
Rolling mill production	5,558,000 "	14,179,000
Chemicals:		
Sulphuric acid	1,206,000 "	2,050,000 "
Benzin	293,000 "	1,260,000 "
Coal-tar distillations	208,000 "	464,000 "
Textiles:		
Woollens	138,000 "	170,000 "
Cottons	350,000 "	369,000 "
Rayon	28,800 "	57,200 "
Artificial textiles	1,500 "	99,400 "
Motor vehicles:		
Passenger cars	92,200	264,600
Trucks, omnibuses'	13,300	64,404
Motorcycles	53,500	(1938) 190,018
Tractors	(1937) 33,505	" 41,192
Food and luxuries:		
Beetroot sugar	1,428,000 tons	2,210,000 tons
Beer (hectolitres)	34,144,000	43,599,000
Cigars (millions)	7,268	9,019
Cigarettes "	33,688	42,531
Miscellaneous:		
Leather industry	126,400 tons	127,100 tons
Cement "	3,820,000 "	12,605,000 "
Electricity (million kwh.)	25,654,000	48,969,000
Ships over 100 tons	(1934) 57	174
" " 100 "	(1934) 73,723	435,606

danger of being bombed in case of war than if concentrated with the other steel plants in the Ruhr. After the annexation of Austria the Goering company began the erection of another iron and steel plant at Linz on the Danube for the more rapid exploitation of Austrian ores.

Some of the principal other industries, besides coal and lignite, and their recent development may be seen in Table XXII.

German business life is highly organized. Joint stock companies and limited liability companies increased in number and importance after the World War.

Organization did not stop at the formation of joint stock companies.

TABLE XXIII.—*German Business Corporations*

	Joint stock companies		Limited liability companies
	No.	Nominal capital (million marks)	No.
1913	5,139	16,527	26,790
1926	12,343	20,055	57,338
1937	6,094	18,407	30,454

During the days of inflation the concentration of industries in a few bands by all sorts of combines was highly popular. Shrewd business men borrowed money to buy shares and plants, and repaid the loans in valueless paper money. Some of the new combines collapsed when credit became dear. Others chose the so-called "vertical" combination, trying to concentrate in one hand works representing the different stages of production. For some time the "integral" combination became the industrial ideal. It was a self-sufficient industrial unit, which raised its own raw material and distributed its own finished produce by its own selling agency, after having sent the raw material through all manufacturing stages, in works under control of the management.

The scarcity of credit which followed the stabilization of the mark dealt unkindly with these undertakings, but many survived. It has been estimated that of the 12,000 joint stock companies existing Oct. 31, 1927, 2,100 were controlled by such concerns, whilst the nominal capital invested in these 2,100 undertakings was estimated to be about three-fifths of the nominal capital of the existing joint stock companies:

TABLE XXIV. *Combine Control of Stock Companies, 1927*

	No. of companies	Nominal capital in million gold marks	
		Maximum	Minimum
Joint stock companies	12,008	18·117	17·476
In combines	2,106	11·455	10·814

The relation between the companies was sometimes maintained by means of a holding company, in other cases interlocking directorates were supposed to be sufficient.

The other form of combination, the "horizontal" combine, the object of which is to unite all works producing similar goods in some sort of union with the object of controlling prices, is more firmly established than ever. Some of these combines, popularly called "cartels," do not go farther than to standardize contracts, conditions of payment and so on; others distribute the markets—at home or abroad, by more or less loose agreements; others again—they are mostly called syndicates--created central selling agencies, which fix a uniform price and regulate the output of the participating members with a view to maximum profits for the industry in the long run.

Most of the basic industries, coal, lignite, pig iron, steel making, potash mining and many others, adopted this highly centralized organization, securing a kind of co-operative monopoly for their members. By raising prices above the competitive rates they succeeded in keeping unprofitable works going at a profit charged to the home consumer; but they tried at the same time to eradicate them either by buying their quota or by forcing technical progress and business efficiency upon them through a kind of compulsory education. The available surplus which could not be disposed of at monopolistic prices at home was sold abroad at competitive prices, thus providing foreign countries with half finished produce or raw material at a cheaper rate than the German manufacturers.

In some cases, the producer of finished goods was compensated by a kind of drawback, to enable him to meet his foreign competitors on equal terms.

In a few cases organization went beyond the "cartel" stage and a real trust was formed, when all the enterprises concerned were completely fused. This was done in steel-making by the fusion of big steel works, and, more completely, in the chemical industry, where, in some branches at least, there is a kind of natural monopoly. The trust is a far more efficient form of organization than the cartel, if its stock has not been watered at formation, as it need not pay any regard to backward concerns. It has not succeeded in getting real control of the industry in most cases. Even the steel trust is but an extremely powerful unit of the steel cartels.

It has been estimated that there were in 1928 about 3,000 of such cartels, some extremely weak, while again, others were strong enough not only to run their own affairs but to wield a decisive influence on the fate of their customers. There was a change visible in the attitude of the Government, which acted firmly when powerful combines tried to raise prices.

The Question of Nationalization.— Immediately after the World War when Socialism was rife many plans were made for the nationalization of German industry. The nationalization of the mining industry seemed imminent, for the centralistic control existing in these syndicalized enterprises made the process easy enough. Foreign difficulties—the property of the Reich and the States was hypothecated for reparation payments—and the very close interlacing of the mining industry with the different phases of steel making prevented any immediate legislation. Government did not nationalize, but a cumbersome public control of prices in mining and iron and steel making was established.

The complete breakdown of government and government finance during the last phase of the inflation period in 1923 practically ended all schemes for nationalization. The existing government and municipal works like the government railways and municipal tramways did not pay, as it was impossible to raise the rates of public utilities as quickly as the depreciation of the currency demanded. Government undertakings seemed doomed; even where they had existed for a long time they were organized as private companies, the shares of which were held by the government or the municipality. All the mining interests of the Prussian government, for example, were detached from the general administration and put into a separate company, owned by the Prussian State. Technical developments, in some ways, worked in the same direction. Of 45 cities with more than 100,000 inhabitants but five by 1926 depended entirely on electrical power generated in their own municipal plants; 20 others got their main supply from their own works, whilst 20 others got it entirely or mainly from other concerns. There were 42 cities that drew 58.670 (1.783 million kw.) from their own plants. Whilst municipalization and nationalization had received a setback in these directions, the credit stringency following the stabilization of the mark forced the government into many enterprises. At times government was the only agency possessing cash. Industrial concerns in difficulties asked for State loans and subsidies and in this way the government became their silent partner when faith in government enterprise had completely gone.

TABLE XXV.—*German Government Holdings of Companies* (1927)

I. Holdings of the Reich

	Marks
(1) Vereinigte Industrie Aktiengesellschaft, called "Viag." This is a holding company embracing banks, electrical undertakings, aluminium works, nitrate works, engineering shops, etc., totalling	208,200,000
(2) Holdings of different departments:	
(a) Home Office: publishing, wireless, etc.	90,000
(b) Labour Office: building companies, etc.	536,000
(c) Food Ministry: grain company, etc.	21,000,000
(d) Transportation Ministry	6,000,000
(e) Ministry of Finance	58,800,000

II. Holdings of the States

Prussia:	
(a) Preussag (holding company for mines)	4,500,000
(b) Electrical concerns:	
Majority in six companies	
Participation in seven companies	
Totalling over	53,000,000

During the years 1924–29 German industries were completely overhauled. American experience and American capital were drawn upon freely to rationalize German industry and to bring about greater efficiency. Results were excellent from a technical point of view, but not an unqualified economic success. In 1937 joint stock companies numbering 3,000 and having a capital of 17 milliard marks, had debts amounting to 35 milliard marks. Average dividends were but 4·7%.

Transportation.— Since Prussia nationalized her railways in 1876–79, other German States have followed suit. Before the war nearly all German railways were State-owned; there were but a few hundred kilometres in private hands when the Reich took over the railways from the States in 1919 by paying them 39.5 milliard marks (inflated) money, besides taking over the debts incurred by the States when building or acquiring railways. Notwithstanding this excellent bargain, the newly unified railways did not pay. The wear and tear of the war, the struggle for the Ruhr, the havoc of inflation, saddled them with heavy deficits, although formerly the Prussian railways contributed handsomely to the expense of the State. Under the London agreement which embodied the main features of the Dawes plan, the German railways were reorganized. A company, called Deutsche Reichseisenbahngesellschaft, was formed, with a capital of 11 milliard gold marks in ordinary shares and three milliard gold marks in preference shares. The ordinary shares remained the property of the Reich. The preference shares (divided between the Reich and the company) were to be sold to the public, when the need for cash arose; up to 1928, 481 million gold marks had been sold. Debenture bonds to the value of 11 milliard gold marks bearing 5% interest and 1% sinking fund were issued and handed over to the Reparation Commission, the annuity of 660 million gold marks attached to their service being a substantial part of the obligations payable under the Dawes plan.

Since this reorganization the German railways have done well. Thev have earned the income on the bonds issued and the dividend due-on the preference shares sold They have not yet rarned a divi-

dend on the common shares, but they have been able to transfer to capital account quite a considerable surplus.

Whilst railway and postal matters are affairs of the Rcich, roads and canals largely were built and maintained by State and municipal authorities. The total length of the roads is about 213,394,523 kilometres. The splendid new auto-highways (*Reichsautobahnen*), built since 1933 with the engineering skill and organizing ability of Dr. Todt, totalled 3,051km. open to traffic at the end of 1938; 2,000km. more were under construction, and a further 1,500km. mere planned. These auto-highways of concrete cement are usually 76 metres wide and provide for two lines of traffic in each direction separated from one another by a central strip of grass. There are no cross-roads,—only bridges over, or passes under, the auto-highway. They circle the large cities and thus avoid delay and congestion for through traffic. They are of great economic value to the country; a truck going at 3om. per hour over their direct smooth surface consumes less gasoline than one going only 20m. per hour over the old rougher roads. They are also of great strategic value for the rapid concentration of troops and the moving of military supplies. They have somewhat increased motor competition with the railways, but this has been to some extent avoided by working agreements between the two systems of transportation.

The number of motor vehicles in Greater Germany on July 1, 1938, was 3,364,503. They included 1,305,608 passenger cars, 20,792 motor buses, 250,403 trucks, 1,582,872 motor cycles, 54,943 tractors, and some thousands of other motor vehicles like fire-engines and street cleaning machines. In 1938 there began the construction of a gigantic automobile factory at Fallersleben near Hanover, which the Nazis claimed would be the biggest in the world. It was to begin by 1940 to turn out by mass production an inexpensive "people's car" (Volksauto). The car was officially baptized by Hitler as "The Strength-through-Joy Car," and was expected to do for Germany what the early Ford car did to popularize the automobile in the United States. It was scheduled to cost ggo marks (about $400). which was about half the price of the cheapest car in Germany hitherto. The motor would be in the rear and would develop 24 horse-power with a speed of 64m. per hour. Early in 1939 it was ordered that all other automobile manufacturers should cut drastically the variety of styles of cars in order to save materials and reduce costs of manufacture by approaching mass-production methods.

German shipping was greatly affected by the World War. Of the marks, of which only a comparatively small amount (750,000,000 tonnage, very little was left to Germany, as 2,500,000 tonnage had to be handed over to the Reparations Commission. The value of these surrendered ships was estimated by the Germans at four milliard marks, of which only a comparatively small amount (750,000,000 marks), was admitted by the Reparations Commission. Nearly the whole mercantile marine had to be rebuilt, a severe financial loss, no doubt, but not without some redeeming features, inasmuch as the ages and types of the new ships fitted existing conditions far better than an old established fleet could have done. The "Bremen," for instance, still one of the largest and fastest transatlantic liners, on her maiden trip in 1929 broke all previous records for the Atlantic crossing and continued to hold the Blue Ribbon for almost a decade. She and her sister ship, the "Europa," were popular and profitable. By 1939, Germany, by intensive ship construction, had reached fourth place among the world's largest mercantile marine countries, with 2,459 steam and motor registered vessels having a total tonnage 4,482,682. She u-as surpassed only by Great Britain (17,900,000 tons), the United States (11,500,000), and Japan (5,600,000).

Postal administration was completely unified. There were in 1938 about 65,000 separate post-offices and 397,890 employees. They handled in a year 166,278,000,000 letters, 307,000,000 packages, and 21,128,000,000 telegrams. Postal expenses were 1,906,000,000 marks, but revenues more than covered the expenses and left a profit of 65,000,000 marks for the Reich. The postal administration has also become an influential financial organization by creating a system of postal cheques which can be cashed all over the country.

Radio receivers in 1939 numbered 12,600,000, or 63 for every 100 households, a percentage not exceeded by any country except the United States. As the Nazis lay great stress on political propaganda it was their policy to encourage the mass manufacture, and sale at low price, of as many radio receiving sets as possible. These are weak long-wave sets, able to hear all broadcasts in Germany, but less suited to receive foreign long-wave broadcasts and incapable of receiving any foreign short-wave broadcasts. In 1938 Germans were forbidden to listen in to Moscow broadcasts. In Sept. 1939, after the German invasion of Poland, they were forbidden under severe penalties, even including death under certain circumstances, to listen to any broadcasts from abroad at all, and short-wave receiving sets were ordered to be confiscated. From the early years of Nazi rule Germans were forbidden to pawn their radio sets, since it would diminish their opportunities for hearing official propaganda.

TRADE AND FINANCE

Commerce.—German commerce was paralyzed by the World War. Abroad the blockade cut short its activities, at home the control of food and of other necessities greatly reduced its sphere of usefulness. The loss of the German colonies, the confiscation of German property and the expulsion and non-admission of German traders from many countries, prevented a quick recovery.

At home, government control of economic life was continued after the war in many spheres, as inflation made it impossible to re-establish the free play of natural economic forces. The fixing of prices in a quickly deteriorating currency not only hampered free movements. As there were no means of maintaining the value of liquid capital, traders invested either in commodities, often on a speculative basis, or in industrial assets or in foreign currencies. When stabilization set in, Germany had become an empty shell. Whilst industrialists and agriculturists had saved parts of their fortunes by putting them into plants, the merchant class as a whole was practically bankrupt. They and the investing public had borne the brunt of the catastrophe. There always had been a tendency amongst German industrialists to set up selling agencies of their own. This tendency was greatly strengthened by the reduced financial capacity of the merchants and by the growth of cartels and organized concerns. In pre-war days these tendencies were greatly facilitated by the industrial policy of the German banks. As the banks were often the promoters as well as the partners (by holding shares) of industrial concerns, the ties connecting banking and industry were very close. The merchant as a financier could easily be dispensed with, when the big joint stock banks were willing not only to finance the goods produced but to take up shares with the object of selling them to the public after the concern was properly nursed. Relations between banks and industrial companies were very close; there was a successive interchange of directors to sit on the respective boards. In times of great industrial prosperity the influence of the manufacturers on the banks was enormous; they became sometimes nearly independent of their support and influenced their policy by being their most important "depositors." In times of stringency, on the other hand, the banks regained control.

Inflation nearly ruined the banks. They realized far too late the wisdom the industrialists had very early exhibited: that inflation is the borrowers' heaven and the creditors' hell. The assets of all joint stock banks which had amounted to nearly 18 milliard gold marks on Dec. 31, 1913, had fallen to 3.5 milliard gold marks on Jan. 1, 1924. At the same dates the assets of the mortgage banks had fallen from 13.5 milliard gold marks to a little over one-half a milliard gold marks. Since then there has been a quick recovery. But. the total share capital of all joint stock banks, which was a little over four milliard marks (without reserves), has not yet grown to three milliard marks.

Banking.— Before the World War Germany had the gold standard. The notes of the Reichsbank were legal tender; they were covered to one-third by a gold reserve, whilst the remaining two-thirds were secured by bills of exchange conforming to certain standards. The country's total circulation was estimated at about 6 milliard marks. During the war the bank was authorized to issue notes against treasury bills. As a result of this overissue of notes the mark depreciated until in July 1923 during the struggle for the Ruhr the amount of treasury bills outstanding was 57.8 milliard marks and the total note issue 43.6 milliard marks. In Dec. 1923 the bank's available gold reserves, which had stood at about one milliard marks a year earlier. had fallen to 467 million marks. The value of the gold mark had risen to one milliard of paper marks. By midsummer 1923 the mark as medium of circulation was doomed. An emergency currency such as "gold certificates" was suggested. To stave off the crisis, whilst currency discussion went on, taxation was put on a gold basis; for the first time for many years the landed interest had to bear its share. The Reichsbank, which had not been willing to risk its gold in 1922 when there was a fair chance of success, had thrown away half of its holdings in the hopeless endeavour to raise the course of the mark at a time when the printing of marks proceeded at fantastic speed. A foreign loan, to ensure success, could not be had; a home loan, it was supposed, was out of the question.

A plan for the issue of a new money, to be guaranteed by mortgage bonds, funded on real estate, was broached. These notes—they were later called the rentenmark—were to be secured by interest-bearing bonds; they could be automatically converted into them. The interest was to be a first charge on real estate. The total issue of the new money was to be limited to 4.2 milliards. 2.3 milliards of which were to be lent to the government; the rest to private concerns. The plan which was to provide the government with funds to carry on the struggle in the Ruhr would have failed lamentably if the Stresemann government had not had the courage to stop, the fight, thus doing away with the main cause for unlimited expenditure. It cut down the total issue to 2.3 milliards and greatly modified the whole scheme. The government succeeded, against all expectations, in floating a gold loan, which gave it a breathing space; it was echeloned in such small points that it could be used as stable currency during the period of transition. When Luther became chancellor of the exchequer the new currency, the rentenmark, was issued, and the work of stabilization began. It succeeded completely.

A little later the Reichsbank was reorganized according to the Dames plan. Its capital was fixed at 300,000,000 marks, 120,000,000 marks more than the capital of the old bank. Of the 300,000,000 marks capital only 177,000,000 were at first called. Part of the capital shares were handed over to foreigners, and the Reparations Commission was given certain control over the management of the Reichsbank. After 1930 this foreign control was done away with, and in 1939 all foreign holders of Reichsbank shares were forced to surrender

them and given compensation of a sort. Before the war, and by the reorganization of 1924, the Reichsbank was required to cover its issue of paper money by a gold reserve of at least 40%. This was considered the minimum for financial safety. This requirement was abandoned after 1930. By 1939 the gold had so largely disappeared and the paper money had so enormously increased, as a convenient method of finding money for rearmament and other Nazi expenditures, that the gold reserve sank to less than 1% of the note circulation. The Reichsbank was also formerly independent of the political control of the Reich Government, being under the management of an independent board of directors. Dr. Hjalmar Schacht, president of the Reichsbank for more than a dozen years, was a very able financier. In spite of some very questionable methods he still enjoyed some confidence among foreign bankers, but he was never popular with the Nazis, especially with the more radical members of the Nazi Party. When he was forced, in Nov. 1937, to retire as president of the Reichsbank, the bank lost whatever was left of its independent position. By a decree of June 15, 1939, it was placed directly under the control of Hitler, who exercised his control through Dr. Walther Funk, who held the double position of Reich economics minister and president of the Reichsbank. Its unsound financial condition in 1939 as compared with a decade earlier may be seen by a comparison of the principal items of two of the bank's weekly statements.

TABLE XXVI *Weekly Statements of the Reichsbank in 1928 and 1939*

Assets	1000 Marks	
	Feb. 29, 1928	July 31, 1939
Gold and bullion	1,888,350	76,721
Reswve in foreign currency	281,953	
Bills of exchange, cheques, Gov't I.O.U.'s	2,336,275	8,460,711
Silver and other coin	67,666	121,055
Investments	94,239	289,190
Otherassets	551,823	1,510,713
Liabilities		
Capital	123,000	150,000
Paper banknotes in circulation	4,268,220	8,989,006
Other daily maturing obligations	491,035	1,293,698
Other liabilities	221,285	424,558

State governments, government departments, provinces and municipalities were accustomed to charter banks of their own with the object of doing their own business, independently of the Reichsbank and the private banks. These public banks did not issue notes. Though their capital was but a third of that of the big Berlin banks much competition took place between them and the private joint stock banks. Moreover, the savings banks tried to enlarge their activities. The saving banks, like all other institutions dealing with liquid money, were almost cleared out by 1924. Deposits in the savings banks had fallen from 19 milliard marks (1914) to 1.25 milliard marks (1924). Since then savings have grown considerably, reaching 4.665 milliard marks by the end of 1927, and 15·7 milliard marks in 1937.

FOREIGN TRADE

The vicissitudes of Germany's economic fate since the World War years are expressed in her foreign trade, and they show wide fluctuations.

Germany before the war had an unfavourable balance of commerce which was compensated by German shipping, by services of German banks and insurance companies and especially by German investments abroad. These investments were variously estimated between 20 and 25 milliard marks. For the decade 1914–24 no satisfactory figures for German foreign trade are available. During the years of the Dawes Plan from 1924 to 1929 German imports greatly exceeded exports, because Germany was buying raw materials and equipment to replenish her diminished stocks and to rationalize her industries; these imports were largely paid for with money borrowed abroad. From 1929 to 1933 foreign loans ceased; Germany with her replenished raw materials and her up-to-date machinery was able to export much more than she imported in spite of the world depression. After 1933 the balance of trade again became increasingly unfavourable to Germany. This was owing to many causes. The Nazi persecution of the Jews led to a boycott of German goods in foreign countries. The Nazi efforts at "autarchy," that is, to make Germany as far as possible self-sufficing in case of war or blockade; her dwindling supply of gold; her gradual loss of the Russian market owing to her violent anti-Communist propaganda—all these factors caused Germany to introduce a great variety of trade and foreign exchange controls which further throttled German foreign trade. With some countries Germany established barter agreements, "clearing agreements," and other trade arrangements; these, however, usually resulted in partial failure and in growing resentment in the countries with whom the agreements were made, as these countries gradually realized that they were disadvantageous to themselves. These fluctuations in German foreign trade during the past 60 years are outlined in Table XXVII.

As Germany depends for foodstuffs and most of her raw material on supplies from abroad, she has to export finished goods. Most of her exports in that line are goods which can be produced elsewhere. Outside potash and a few chemicals she does not export non-competitive goods. Most of the chief exports depend on previous imports.

TABLE XXVII. *German Imports and Exports, 1880–1939*
(in millions of marks)

Year	Imports	Exports	Balance	Year	Imports	Exports	Balance
1880	2,803	2,933	+ 130	1929	13,447	13,483	+ 36
1885	2,922	2,854	− 68	1930	10,393	12,036	+1,643
1890	4,146	3,327	− 819	1931	6,727	9,599	+2,872
1895	4,121	3,318	− 803	1932	4,667	5,739	+1,072
1900	5,766	4,611	−1,155	1933	4,204	4,871	+ 667
1905	7,129	5,732	−1,397	1934	4,451	4,167	− 284
1910	8,934	7,475	−1,459	1935	4,159	4,270	+ 111
1925	12,362	9,290	−3,072	1936	4,218	4,768	+ 550
1926	10,002	10,415	+ 413	1937	5,468	5,911	+ 443
1927	14,228	10,801	−3,427	1938*	5,348	5,236	− 112
1928	14,001	12,276	−1,725	1939**	2,755	2,814	+ 59

*Partly estimated and not including Austria or Sudetenland.
**First six months; includes Austria and Sudetenland but not Bohemia-Moravia.

German exports really amount to a finishing goods industry on a huge scale; an industry working on a fairly narrow margin. As Herr Hitler tersely stated to the Reichstag on the sixth anniversary of his accession to power on Jan. 30, 1939: "Germany must export or die." Germany needed to import raw materials for her armaments and exporting industries as well as food for her people, but these imports could be paid for only by increased exports. Herr Hitler could of course have easily increased the much-needed food imports if he had been willing to cut down on the imports for manufacturing armaments. But he was emphatic in declaring that "it is the supreme task of the National Socialist leadership to do absolutely everything that is humanly possible toward strengthening our armaments." It was the policy summed up in the Nazi slogan: "Cannon rather than butter."

The relative importance of the principal groups of goods comprising Germany's imports and exports remained fairly constant throughout all the vicissitudes through which the country passed after 1913, in spite of great changes in the total volume of goods imported and

exported, as may be seen in Tables XXVIII and XXIX. Food steadily averaged about 40% of the total imports, but almost vanished from the list of exports. Correspondingly, the proportion of total exports represented by finished goods increased by about 15% between 1913 and 1937.

TABLE XXIX. *Exports, 1913–37 (relative importance of groups of goods)*

Medicines	139·8	2·4	Brazil (10·0); Argentine (7·7)

While the relative importance of the various items of German imports and exports remained fairly stable, the direction of German trade changed greatly as a result of the World War and other post-war factors. Before the World War nearly one-fourth of Germany's total trade was with Great Britain and the United States. After the war the trade with both steadily declined, until in 1937 it was scarcely more than one-tenth of Germany's total foreign trade. Germany's exports to Russia, following the years of Germany's great economic recovery during the Dawes Plan, at a time when Russia was developing her resources with imported machinery during the first Five-Year Plan, increased to more than a tenth of Germany's total exports in 1932. But these soon declined again sharply owing to the political antagonism between the National Socialist and Bolshevist regimes. The large increase of German exports to the Netherlands after the war was partly for re-sale by the Dutch to small overseas countries, before Germany had rebuilt her own merchant marine and carrying trade to replace the vessels which she had to surrender to the Allies by the Treaty of Versailles.

Germany's loss of trade with Great Britain and the United States, caused in part by the tariffs, currency changes, and strong bargaining position of these countries, and in part by Germany's own restrictions of foreign exchange, tariffs, and "clearing agreements," was partly made up by increased German exports to South American and other smaller countries which were willing to accept Germany's trade stipulations; these trade stipulations, however, were often far from being wholly advantageous to the smaller countries, and usually ended in causing resentment in them and in a consequent decline in German exports to them in the years 1937 to 1939. Furthermore, in South America, the United States was growing as a successful competitor.

The countries in which Germany's trade increased most successfully in these last years were the smaller States in Southeastern Europe—Hungary, Rumania, Bulgaria, and Yugoslavia. The commercial pressure which Germany was able to exert upon them was considerably increased by her annexations of Austria and Czechoslovakian territory in 1938 and 1939. Some of the changes in the direction of German trade in the past quarter of a century are seen in Table XXXII.

TABLE XXXII. *Direction of German Trade, 1913–37*

SOCIAL CONDITIONS

Of the total population of 62.5 million people living in Germany on June 15, 1925, 5.7 millions exercised no calling. Of the remaining 56.7 millions 32 millions were engaged in some gainful occupation; whilst the remaining 28.7 millions depended on these breadwinners, another 900,000 were attached to them as domestic servants. Of these 56·7 millions 13 millions—5.5 million breadwinners—were heads of businesses, proprietors, tenants, managers, etc. More than 10 millions—5.3 million breadwinners—were employees (clerks, gangleaders, foremen and so on); 26.6 millions—14.4 million breadwinners—were labourers of all sorts. Another 5·6 millions were members of the family helping in the work; nearly a million and a half consisted of non-attached domestic helpers.

Of 14·4 million people depending on agriculture, 2.2 million breadwinners were "heads"; of 26 million people depending on industry 1.8 million breadwinners were masters or managers; of 10.6 million breadwinners engaged in commerce 1.2 millions were in this position. The percentage of people in a position of economic independence or responsibility of some sort or other, varied between one-sixth and one-fifth of the numbers counted.

Amongst the breadwinners in agriculture the number of labourers (2.6 millions) was little more than the number of heads (2.2 millions); but in this case 4.8 millions of family helpers—largely female—swelled the numbers of the employed class. In industry 1.8 million heads were confronted by over 11 million employees of some sort, very nearly two millions being women. With few exceptions the modern system of working for a wage spread all over Germany. Over seven million people worked in shops with more than ten workers each and subject to factory legislation.

German National Income.—The number of salaried people in Germany was 21·4 millions on June 16, 1925. From these, the administrators, managers, directors and others drawing comparatively high salaries must be deducted. Or the number of wage earners in a more limited sense can be obtained from the statistics of social insurance. The income of 17·7 million insured people calculated from premiums paid to social insurance, amounted to 24·1 milliard marks. The 3.7 million people included in the first figure of 21.4 millions were not insured; they comprised government officials and salaried persons earning more than 6,000 marks a year. Their income may be estimated at 14.2 milliard marks a year. The total "earned" income was thus valued at 38.3 milliard marks. The different estimates of the national income are more or less guesswork. The national income is supposed to have risen to more than 70 milliard marks in 1937.

The German Working Class.—When the working-class leadership in the winter 1918–19 threw its weight into the scales against bolshevism, it was clearly realized that some sort of participation of the working class in the control of industry was unavoidable. The various schemes of nationalization were more or less abandoned, though a coal council and a potash council were created, on which working-men were represented. A system of work councils was, however, created, which enabled the workers in each factory, employing more than 20 persons, to choose representatives, participating in what was supposed to be the control of the management. Members of these work councils—Betriebsrate—were entitled to sit on the board of the companies. This new move was regarded with high hopes by the workers and correspondingly with great fears by the management. Both parties were disillusioned. The presence of the representatives of the working class was used as a pretext by the management to keep from the public and its shareholders many things which really need not he considered confidential. A similar disillusion was produced by the Economic Council (Reichswirtschaftsrat) which was supposed to be an economic parliament in which the producer's wisdom got the better of the consumer's folly. Though workers and employers were equally represented upon it, it had no power, the real power, being in the hands of the great associations of the manufacturers (Reichsverband der Deutschen Industrie), the Land Union and the General Commission of Trade Unions, who exercised their influence directly on parliament. The Reichswirtschaftsrat was not meant to be a conciliation board, but rather a super-parliament. As such it failed completely.

Organized Labour in Germany.—The position of the working class as such changed enormously after the revolution of 1918. When Prince Bismarck started his scheme of compulsory social insurance, one of his objects had been to wean the working class from the trade union movement by taking away the benefits from these organizations. In that respect the plan of what is now called the "Corporate State" was not successful. Trade unionism grew by leaps and bounds. In the days of the revolution the number of trade unionists grew from 2.5 millions in 1913 to 8 millions in 1920. There was a great falling off later on; inflation nearly ruined many organizations (membership had fallen to 4 millions in 1924). In 1927 it had grown again to 8.2 millions. Over half of them were organized (4.6) in the General German Trade Union Association, whose members

were leaning towards the Social Democrats; over 600,000 were within the Christian trade unions who were antagonistic to socialism and rather conservative; 150,000, called Hirsch-Duncker'sche, had what might be called liberal leanings. There were communistic unions and unions subsidized by the "masters." Organization spread amongst clerks, technical employees, foremen and so on—nearly 1.5 millions were in these organizations in 1927.

In the spring of 1933, soon after the National Socialists came to power, all the trade unions were crushed. Many of their leaders were arrested and thrown into prison or concentration camps, or managed to escape into exile. The large trade union funds were confiscated and were supposed to be turned over to use of the German Labour Front (Deutsche Arbeitsfront or "DAF"). This so-called labour organization, run by the National Socialist leader, Dr. Robert Ley, was henceforth the only labour organization which was tolerated. Virtually all workers joined it, because it was practically impossible to get a job or hold one without such membership. Later, the Labour Front even swallowed up all the employer associations, on the general principle that all persons, employers and employees alike, belonged to a single community, which was to be guided by the slogan: "The common good before the individual good."

The hours of labour, factory conditions, and all similar matters were regulated after 1933 by the 13 (later 17) all-powerful Trustees of Labour appointed by the Reich minister of economics. Since employers and employees could have only the one common aim—the welfare of the German community—there could be no strikes and no lock-outs. In every business of 50 or more employees, the "employer-leader" nominated from his "worker-followers" a committee or shop-council. This nominated committee was then elected by the employees to confer with the employer and look after the interests of the workers. If the workers did not like the list of men nominated, they could reject it and call for other nominations. Any disputes were ultimately settled by the authority of the regional Trustee of Labour. In general, wages remained fixed as they were in 1933. But the Trustee of Labour had authority in special circumstances to raise or lower them. He could also forbid employers to dismiss employees. In 1937 and thereafter, when unemployment began to end and to be replaced by a labour shortage under the pressure of work for rearmament, labourers were forbidden to leave one job and take another without the consent of the authorities.

The German Labour Front, which collects considerable fees from its members, did a great deal to try to make life brighter and happier for the German workingman and his family. It created a dozen subsidiary organizations to provide him with better library facilities, to give him tickets to concerts, plays, and movies at reduced rates, and to advise him on the healthy and refreshing use of his leisure time. One of the most active of these organizations was "Strength Through Joy" (*Kraft durch Freude*). It sent scores of thousands annually from the great cities and industrial areas on a two weeks' holiday trip at very low cost to the mountains, to the seashore, or-on sea trips on fine large new steamers along the Norwegian waters or in the Mediterranean. Another organization was "Beauty of Work" (*Schönheit der Arbeit*). It interested workers in brightening up and improving life at the factory by getting flowers planted in the yards and driveways. and by getting better dressing rooms, shower-baths, rest rooms, lunch rooms, and other comforts installed for the worker.

For the further advantage of the worker the National Socialists created industrial "Courts of Honour." Here might be brought any cases in which it was charged that either the employer or the worker had acted contrary to the dictates of human brotherhood and German honour. An employer who improperly mistreated one of his workers might be suspended from the management of the business which belonged to him, or even be deprived of it altogether.

The consumers' co-operative movement had an even more phenomenal development. From 1914 to 1925 consumers' co-operative societies grew from 2,416 with 1.8 million members to 2,474 with 3.2 million members. Employers, in their turn, were equally well organized. There were at least 1,611 employers' associations covering the whole Reich, to which must be added a few hundred associations limited to individual countries or districts. This broadly-spread system of organization made collective bargaining fairly easy when the revolution had demonstrated the power of the organized working class. Before the war (1914) only one and a half million of workers enjoyed the benefits of collective bargaining. On Jan. 1, 1926, 7,533 separate agreements, binding 788,755 different establishment*, were in force; 11,140,511 million workers were included in them.

Unemployment has varied considerably. It was practically non-existent during the inflation days, when the investing public's capital, so to speak, was spent on keeping the working class busy. Manufacturers and traders were relieved of the necessity of paying interest on their debts; as rents were practically non-existent their wage bills were about 20% below what they would have been if the working class had had to pay full rent. New credits for business people and for the government were extremely cheap; even after the bank raised its discount rate to 18% it was still extremely profitable to borrow money with the certainty of being able to return it when it had lost 50% of its value.

The Ruhr crisis and stabilization put an end to all that. Trade-unions reported that 13.5% of their members were out of work on an average in 1924, against 2.8% and 1.5% for 1921 and 1922; 15.3 were working short time against 5.4 and 2.8%. The situation improved in 1925 when the percentage of totally unemployed fell to 7.1%; but it rose again to 18.3% 1926 and to 13.6% 1927. It has been estimated that the total number of unemployed, including short time workers, was as follows:

Jan. 1, 1927	2,350,000
Dec. 1, 1927	1,049,000
Jan. 1, 1928	1,763,000

The great reduction in 1927 was, no doubt, due largely to the spending of loans foreign as well as domestic in the reorganization of industries. By the middle of 1926 2.8% of the resident population were on relief; by the end of 1927 this had fallen to 1.3%.

Originally the local authorities were charged with the relief for the unemployed, the central authorities coming to their aid. Later on a programme of productive works was entered upon, on which at certain times over 150,000 people were kept busy. A regular system of insurance was introduced, employers and employees contributing up to 3% of basic wages.

After 1929 unemployment conditions again grew rapidly worse. No more capital could be borrowed abroad. The improved labour-saving machinery which had been introduced tended to limit the number of workers who could be employed. Worst of all, the general world economic depression which set in affected Germany as well as other countries very seriously. As a result, unemployment increased rapidly, so that in Feb. 1932, no less than 6,128,429 persons were on the rolls of the unemployed. This meant that one-third of Germany's wage earners were on a pitifully small relief or in serious distress. From the summer of 1932 a slight improvement began.

It was one of Chancellor Hitler's greatest achievements that he reduced this very serious unemployment more rapidly than was done in any other large industrial country. Under his direction the Third Reich undertook extensive public works; spread out work for as many workers as possible by shortening hours of those who worked; and withdrew women from industry in order to make places for heads of families. After he began his active rearmament program in 1935, unemployment was further reduced by drawing off some young men from the labour market by putting them at two years' service in the armed forces. Others found employment in working in the iron and steel plants making munitions, in the textile factories making uniforms, and in all the other industries which were created or stimulated to make things which would be used directly or indirectly by the armed forces and the new fortifications. As a result, by 1938 unemployment had almost disappeared. The few thousands still counted as unemployed were in most cases persons who were only temporarily unemployed because they were moving from one occupation to another, or persons who had been so long unemployed that they had lost their skill and should really be classed as unemployable rather than unemployed.

In fact, Germany's difficulty by 1938 was no longer unemployment, but an actual labour shortage. This became serious in 1939. It caused the Government to comb out the population for all persons who might be compelled to take up work whether they wanted to or not. The period of school training was shortened by a year and the university courses were cut down by a year or more, in order that men might more quickly be drawn into productive work. By these and other rigorous measures the number of actively employed wage earners, most of them working full time and in many cases working overtime, was increased by June 1939, to 21,840,000. Of these, almost exactly two-thirds were men and one-third women. This remarkable change accomplished by National Socialism, from serious unemployment to a country working at full capacity, within a period of half a dozen years is shown in Table XXXIII, giving the average figures for each year.

TABLE XXXIII *Employed and Unemployed in Germany, 1932–39*

Year	Employed	Unemployed
1932	12,518,000	5,603,000
1933	13,016,000	4,804,000
1934	15,041,000	2,718,000
1935	15,949,000	2,151,000
1936	17,106,000	1,593,000
1937	18,354,000	912,000
1939*	21,840,000	

*Figures are for the month of June 1939, and do not include any of the territories annexed to the old Reich except the Saarland in 1935.

Wages and Standard of Living.—Wages fluctuated widely in the decade after the World War. After the exceptional conditions of the inflation period, average wages per hour rose, and in Oct. 1927 were: male skilled workers, 1.02 marks; male unskilled workers, 0.74

TABLE XXXIV. *Weekly Wages*

	Skilled workers	Unskilled workers
	Marks	Marks
1913	35·33	23·50
Jan. 1924	28·45	21·18
Jan. 1926	45·98	34·05
Jan. 1927	46·36	34·46
Jan. 1928	49·82	37·43

mark. With fairly full employment this meant that weekly wages had risen as shown in Table XXXIV.

When the economic depression and unemployment set in after 1929, wages per hour soon declined and even the employed were generally unable to work as many hours per week as formerly, so that the industrial workers were doubly worse off. It is also difficult to determine under these conditions what their weekly wages were. From 1930 to 1933 wages per hour declined and thereafter remained almost unchanged, being rigidly fixed by the National Socialist Government authorities. Women's wages were about two-thirds the wages of men. As more persons were employed every year after 1933, and as the number of working hours per week increased, the total industrial wages earned more than doubled in five years.

TABLE XXXV *Industrial Wages per Hour and Total Wages per Year*

Wages per hour	1930	1932	1933	1935	1936	1937
Skilled workers, male	1·03	0·82	0·78	0·78	0·78	0·78
" female	0·65	0·53	0·52	0·52	0·52	0·52
Unskilled workers, male	0·81	0·64	0·62	0·62	0·62	0·62
" " female	0·54	0·44	0·43	0·43	0·43	0·43
Total wages, million marks	..	..	5,921	8,031	10,580	12,127

An accurate estimate of changes in the standard of living of the German industrial worker under the National Socialist regime is difficult to make, owing to the many complex factors involved. It is also unsatisiactory to use averages for the whole German people to give an idea of individual persons or households. In general, it may be said that, taking the German workers as a whole, their material condition improved from 1933 to 1939, because the 6,000,000 unemployed had secured full employment; in 1939 they were getting some wages, small to be sure, whereas earlier they had been getting nothing at all, or at best a small Government dole.

On the other hand, comparing those workers in 1933 who were so fortunate as to be employed with their condition six years later, one finds that their material condition had grown much worse. Their standard of living had deteriorated, because their wages had remained virtually the same (except so far as they may have worked more hours a week), while the cost of living had risen. In other words, the purchasing power of their wages had declined.

TABLE XXXVI. *Index Figures of Cost of Living and of Wholesale Prices*

1913=100	1925	1928	1931	1933	1934	1935	1936	1937
Cost of living	142	152		118	121			125
Wholesale prices	142	140		93	98			106

The cost of living index figures for 1938–39 were not available, but they continued to rise somewhat parallel to wholesale prices, the index for which rose to 107·1 in June 1939. The Government, in its zeal for building public works and for rearmament, spent a great deal more in stimulating the production of producers' goods than consumers' goods. While the index for producers' goods, which include armaments, rose from 45·7 in 1932 to 145·3 in April 1939, the index for consumers' goods, such as food, clothing, and household goods, increased only from 74 in 1932 to 112.8 in April 1939.

The standard of living was also affected by several other factors. The amount of paper money in circulation doubled between 1936 and 1939. This would normally have tended to have an inflationary effect on prices and the cost of living. But the Government sought to control prices so that, in the interests of the workingmen, fixed wages and fixed prices should go hand in hand and form a single stable economic structure. With this in view the so-called "price-stop" decree of Nov. 1937 rigidly forbade any manufacturer or retailer to charge more than the price prevailing at the date of the decree. Nevertheless, in 1938–39, because of the labour shortage and other factors, the Trustees of Labour tended more and more to make "exceptions" to the fixed wages and fixed prices, and to allow them to be pushed up here and there. This began to threaten the successful continuance of the Government's regulated economic structure.

Even if prices had remained absolutely fixed, the worker's standard of living would have been adversely affected, because the quality of the goods which he received at h e fixed prices had deteriorated. The new substitute (Ersatz) products were inferior in quality to the old goods made from natural raw materials which had formerly been largely imported but which Germany could no longer afford to buy. A workingman, for instance, might pay in 1938–39 the same fixed price for a suit of clothes that he had paid three or four years earlier. but the new suit, being made of wood-fibre, casein, or other substitute materials, did not wear as well, and he had to replace it sooner, thus increasing his cost of living in a way that did not show in the cost of living index. Similarly, he might pay in 1939 the same price for a cigar that he had paid in 1933, but it had less tobacco in it and was more quickly consumed. His litre of gasoline might cost the same, but it had less power because it was diluted with more potato spirits. Thus, in the case of a great many other articles of consumption, the inferior quality of the goods decreased the real purchasing power of wages and resulted in a lowered standard of living.

Furthermore, the worker had to pay an increasingly larger proportion of his earnings in taxes, which had more than trebled, having increased from 6 milliard marks in 1932–33 to 22 milliard in 1939–40. Finally, he had to pay a great deal more out of his wages, in addition to taxes, in the shape of numerous contributions to the National Socialist Party organizations: membership fees to the Hitler Youth and the Labour Front, subscriptions to Party publications, and "voluntary" contributions to various welfare organizations like the Winter Help Work, the Large Families League, and the Air Raids Precaution Association. In addition, young men were virtually deprived of earning any wages at all during the compulsory half year of service in the Work Service and the two years of service in the armed forces.

Social Insurance. — An extensive system of compulsory social insurance has existed in Germany for half a century. In 1937, 22 million people (33% of the population) were insured against sickness, 27 million against accidents (40% of the pop.) and 19 million (28% of the pop.) were entitled to benefit, when incapacitated for work, to old age pensions, or widows' and orphans' pensions. Outside the working class proper, employees (clerks, etc.) are subject to separate compulsory insurance, when drawing a monthly income below 400 marks. (They number about 4.4 millions.) They are also subject to insurance against sickness, when drawing an income below 300 marks monthly. For the working class, the insurances, old-age insurance as well as insurance against sickness and against accidents, are absolutely compulsory.

Apart from insurance against accidents, which is exclusively financed by the employers. social insurance is mainly contributory. Two-thirds of the premium for insurance against sickness are contributed by the workers, one-third by the employers. Outside the miners' special organization (Reichsknappschaft), of nearly 800,000 members, there are four different types of insurance agencies against sickness, organized in 7,667 separate "units." The administration of these units is in the hands of the contributors, employers and employees.

The total regular income of the insurance against sickness organizations in 1936 was 1,533 million marks, of which 1,489 million were contributions; expenditure reached 1,523 million marks. The average contribution per member was 69 marks; the cost of sickness benefit per member 62.5 marks, whilst administration costs swallowed up 6.7 marks per member. Insurance against accidents is non-contributory for workers. The employers are liable; they are organized compulsorily in 63 employers' societies, one for each trade for industry and 35 for agriculture. They dealt with about 622,500 cases and spent over 350 million marks in 1936.

The third great group, insurance against invalidity (widows' and orphans' benefit). is contributory in equal parts from employers and employees. Workers are classified in six standard classes. Rents are paid when the insurer is incapable of work or when he has reached 65 years of age, or, after his death, to his widow and children. Rents are supplemented by a government grant of 72 marks a year for invalids and their widows and of 36 marks for orphans. Marks disbursed were 885 millions.

The employees' (clerks) insurance was organized for a class of wage earners whose conditions of life were in pre-war days rather different from those of the working class proper. Since then there has been a certain assimilation, in so far as clerks in banks, factories and counting houses are quite as little likely to become employers of labour as are the skilled working-men. Moreover, the discrepancy in wages is no longer very marked in many cases, apart from the fact that clerks are supposed to draw monthly wages. Insurance is compulsory for employees drawing less than 400 marks monthly; it is contributory, employers and emplayees sharing in the contributions. Their chief object is old age pensions, widows' and orphans' benefits. Their revenue was 692 million marks for 1936.

To the three old-established groups of insurance—accident, sickness, and old age or invalidity — there was added, during the deep depression which began after 1929, insurance against unemployment; its financial importance was more than one-third of all other social insurance, as is indicated in Table XXXVII for the year 1937.

TABLE XXXVII *Revenue and Expenditure of All Branches of Social Insurance*

Ordinary Revenue (in millions of marks)

Year	Total income	Contributions	State grants	Interest
1913*	1,553·7	1,295·7	58·5	199·5
1926*	3,018·0	2,571·9	248·1	198·0
1936*	4,457·2	3,441·6	541·0	474·6
1937*	4,708·9	3,770·7	516·5	421·7
1937†	1,708·7	1,701·1‡	..	..
1937, total	6,417·6	5,471·8	..	..

Ordinary Expenditure (in millions of marks)

Year	Total expenditure	Benefits	Administration cost	Surplus
1913*	1,088·8	956·2	111·8	464·9
1926*	2,520·0	2,306·0	214·0	498·0
1936*	3,750·2	3,362·2	273·4	707·0
1937*	3,815·5	3,486·2	282·3	893·4
1937†	1,461·3	394·0	1,067·3‡	247·4
1937, total	5,276·8	3,880·2	1,349·6‡	1,140·8

*Includes workers' sickness, accident and invalidity insurance, and white-collar workers' insurance.

†Insurance against unemployment.

‡Includes 834·4 million marks diverted from the unemployment insurance funds to the general expenses of the Reich.

Housing. — Rent control and inflation were jointly responsible for the very serious state of the housing of the people. Before the war about 200,000 new dwellings (each for a new household) were built annually, whilst another 50,000 old dwellings were replaced by new ones—scarcely sufficient to accommodate the growing population. Most of the dwellings for the mass of the people were flats. The average owner of houses who let the flats to tenants rarely had enough money to build the house. He had borrowed the necessary capital on mcrtgages; in many cases his income from rent was just sufficient to pay him for his work as administrator of the house after repairs and interest had been deducted. Inflation wiped out his obligations, but rent control plus inflation wiped out his income as well. Rents were fixed by law; they became purely nominal. Only after July 1926 did they reach the pre-war level. They soon went up to 120% of the pre-war rent—which does not take into account the depreciation of money. This was a great boon for existing tenants, who enjoyed a (decreasing) consumer's rent for many years. It enabled them to sell their tenant right or to let furnished apartments at competitive prices. It indirectly enabled all employers of labour to save on wages. But it made it very hard for new tenants to find apartments. Building was very costly. Few people were able to pay the rents necessary to make building possible. The supply of new buildings did not reach the pre-w-ar level before 1926.

It has been estimated that about 950,000 German households were without proper dwellings in 1926. This figure plus a yearly increase of 200,000 new houses up to 1935 must be reached if the truly abominable state of the housing situation was to disappear. This development could not be left to free competition. Having once destroyed the equilibrium of supply and demand by planting in the existing capitalistic world a kind of bureaucratic socialistic oasis, a simple return to the ways of private capitalism was impossible. Rents of new houses built on a purely business basis would be three times the pre-war rent, the cost of capital being prohibitive. Whilst old rents were slow to correspond with the general run of prices, new rents were artificially lowered to 150–170% of pre-war rents. The different State governments and municipalities collected about 50% of the old rents as a kind of house tax. Parts of these proceeds, reaching about 1,430 million marks in 1926, were used for general government purposes, whilst at least 17%–27% (Prussia and Bavaria) of the present rents were given at cheap rates as building loans. Up to April 1926 1,638 million marks from the proceeds of the house tax were spent for this purpose. The rents of the existing tenants were thus partly used for the construction of new dwellings

After 1929, efforts were made to reduce the housing shortage by building both apartment houses and small one-family or two-family houses. The number of these buildings constructed annually and the resulting number of family household accommodations which they afforded are given in Table XXXVIII.

TABLE XXXVIII. *Housing, 1929–37*

New Construction	1929	1933	1934	1935	1936	1937
Housing buildings	170,783	91,909	128,574	143,185	155,112	168,090
Families accommodated	317,682	178,038	283,995	211,032	310,490	320,057

The general character and cost of apartments in recent building may be seen from the 500 buildings which Munich was planning in 1939 to afford accommodation for 3,214 families. They included 149 apartments with two rooms, 1,356 with three rooms, 1,387 with four rooms, 223 with five rooms and 99 with six rooms. The rent was to be 40 marks a month for 813 of the apartments, 40–50 for 642, 50–90 for 1,576, and over 90 for 183.

With the general depression, rents were lowered by the Government in 1931 to a low level known as "crisis rents." These generally prevailed during the following years, being strictly regulated by the National Socialists. The "stop-price" principle of 1937 was also applied to rents, and forbade any increase of rents. But a decree of April 19, 1939, allowed the owner, if the local Board of Rents gave its approval, to terminate existing leases and thereafter charge an increased rent. No such approval was needed in 1938–39 for terminating the leases of Jewish tenants and forcing them to vacate their apartments.

Finance, 1919–29.—Government functions are divided between at least three authorities: (1) The Reich (2) the States and (3) the local government bodies (districts and municipalities). In the bigger States, like Prussia and Bavaria, provinces and government-district stood between the local government bodies and the central government. Notwithstanding a great deal of self-government, German government was bureaucratic on its administrative side. Representatives of the Central Government were the resident heads of the various local units, entrusted with administrative functions, for which they were responsible to the Central Government as well as to the representative local bodies with which they have to co-operate. Administration proper in this sense was in the hands of the Lander (States.)

Administrative systems varied considerably, not only between the different Lander, some of them, like Prussia, comprising nearly 40 million inhabitants, others, like Mecklenburg-Strelitz, counting scarcely over 100,000. Even in Prussia there was an enormous difference in the various provinces. Until lately the Reich had no proper administration, outside the foreign office and the navy—the army was a Prussian or a Bavarian service. This was greatly changed since the revolution. The services are both "Imperial" to-day, so is the inland revenue and the administration of customs and excises and a good deal of labour administration. Administration proper (police), education in its various forms, justice, public health, the supervision of industry and so on, were matters appertaining to the Lander. The Lander, moreover, had a tax-collecting service of their own, though some of the smaller ones entrusted the authorities of the Reich with the collecting of State taxes. There was a good deal of overlapping in many cases between Reich authorities and State authorities.

Of the total 12 milliards spent in 1927 about eight milliard marks were collected by the Reich. But two and a half milliards were handed back to the State and local government units, so that the expense of the Reich came to about 5½ milliard marks. As to the revenue, the Reich to-day is the chief taxing authority in Germany. It has ousted the States from their former privileged position. It controls not only customs and excise but the income tax, the corporation tax, the inheritance and the property tax as well. In fact, there are no longer any taxes exclusively reserved to the States. The Reich can take up whatever taxes it likes. It has, however, allowed the States and the municipalities to levy certain taxes on land, buildings, business and so on.

As the States cannot carry out the tasks left to them with the proceeds of the taxes subject to their own control, they are entitled to participation in the Reich's most important taxes: the income tax, the corporation tax and some minor taxes. Three-quarters of the income tax and of the corporation tax are handed over to the States from the Reich. The States again have to share the refunds they receive from the Reich with the municipalities

At the beginning of the stabilization period, the Reich, like other debtors, was practically free from debt, inflation having wiped out all the debtors' claims. A very strong popular movement arose, however, forcing the government to some kind of revalorization,—notwithstanding the fact that the Peace Treaty practically invalidated the home debt by giving all reparation claims priority over home debts. The capital value of the valorized debt was 5,373.3 million marks. A loan was issued in Jan. 1927 to provide for certain productive works. It realized 452·5 million marks. To this must be added the external loan of 1924 of 932·5 million marks (redemption value), bringing the funded debt newly issued to nearly seven milliard marks. There was additional new debt arising from bank loans during the end of the inflation period (loans from the Rentenbank or the Reichsbank) which averaged another milliard marks, and a few small claims. The entire debt was over eight milliard marks or nearly double the pre-war issue (4.9 milliard marks, 1913).

As to the States, their financial position changed enormously. They not only lost their financial sovereignty to the Reich, but got rid of their chief assets, the railways, which were taken over by the Reich and afterwards used as one of the chief pledges for the, purposes of reparation. Whilst Prussia drew from her railways a minimum income of 210 million marks, available for general government purposes, the interest payable on the bonds and sinking fund (660 million marks) and the dividend on the preference shares practically swallowed up the railway revenue, so that the Reich did not yet receive an income from its property.

The States still have some property, but its importance has fallen considerably in comparison to pre-war days. Their mainstay is the tax refunds from the Reich. They were always trying to get them raised, and there was some justice in their claims, for the Reich forced upon them certain standards of expenditure (salaries) and set them certain tasks without giving them adequate means for defraying them.

The States had to revalorize their debts in the same way as the Reich. As they were interested in development work, they were forced to contract many new loans. The outstanding loans of Prussia for the year 1928–29 amounted to 333 million marks. The total interest and sinking fund needed for 1928 came to 57 million marks (17 million marks of which were for repayment, 21 million for interest on the above mentioned loans, and 19 million for repayments of treasury bills).

The total tax income of Prussian cities and local corporations (1925) was 1,421,506,000 marks. Of this sum 796,237,000 marks came from municipal taxes on property, 112,324,000 marks from municipal taxes on consumption, luxury and so on and 33,420,000 marks from taxes on transportation, etc. The share of the Prussian municipalities in the taxes of the Reich was 479,524,000 marks.

Under the Treaty of Versailles Germany was saddled by the London ultimatum with a reparation liability of 132 milliard marks. Of these 132 milliards 50 milliards were to be issued in bonds paying 5% interest and 1% sinking fund. The remaining 82 milliards were to be issued when Germany was in a position to pay interest and sinking fund on them. These liabilities have never yet been cancelled formally. The London agreement of summer 1924, however, rearranged Germany's financial obligations in accordance with the main line of the Dawes plan. Germany was to pay two and a half milliard marks yearly—after an interim period which came to an end on Aug. 31, 1928. Of these two and a half milliard marks 960 million marks were supposed to be extra-budgetary charges. The railways were charged with 660 million marks a year and German industrial concerns with another 300 million marks. These 960 million marks were the equivalent,

at 5% interest and 1% sinking fund, of a capital sum of 16 milliard marks. Bonds of that amount were issued to the representatives of the creditor powers who were supposed to float them later on the markets. As these moneys did not reach the exchequer, they were supposed to be outside Germany's budgetary contribution. They took away, so to speak, an income, which was not an actual, only a potential, part of the German revenue system.

The remaining 1,540 million marks were to be defrayed from customs, excise and the railway transportation tax. The revenue arising under this head went into the account of the commissioner for controlled revenues up to the amount of 1,540 million marks (and a reserve fund). The surplus of these revenues was handed back to the German exchequer. It amounted to nearly another milliard and a half. The German budget was thus divided into two separate parts: a controlled budget and a free budget. When Germany had paid her share of controlled revenues, she could do with the rest as she liked. She was free to spend as much money as she liked—provided she had paid up, and she could levy as much additional taxation as seemed good to her. She was even free to borrow as much money as she might think advisable. But it was insisted upon by the Reparation commission that the service of the new loans must rank behind the service of the reparation obligations. Outside the "External Loan" issued in 1924 to start the Dawes plan, no reparation loan properly so-called was made; for the railway and industrial bonds were debentures issued by private corporations. They were not placed abroad, as the Dawes plan insisted upon safeguarding the German currency by preventing too heavy a pressure on foreign exchange. For the same reason neither the number of years for which the 1,540 million marks were to run, was fixed, nor the capital value attached to them. In case the transfer of payments abroad were to disturb the stability of the German exchange, an adjustment was provided for. And as long as this adjustment was possible, it was impossible to capitalize the annuities which might or might not be subject to it. Assuming that the Reich retained about 5–5½ milliard marks of taxes collected by it, it had to hand over nearly 30% of them; its own free revenue was reduced to a little over 4 milliard marks.

Finance, 1929–39.—The financial burden of reparations was somewhat lessened in 1930 when the Dawes Plan was replaced by the Young Plan. But this "New Plan" soon proved economically impossible and was suspended at President Hoover's suggestion in 1931 by a general moratorium for a year on all war debts. Thereafter reparations obligations were virtually nullified. But Germany still had a very heavy foreign debt because of the large sums borrowed abroad from 1924 to 1929 for the payment of reparations and for the reconstruction of German industry and other purposes. As the general economic depression and unemployment grew more serious from 1929 to 1932, the Government made drastic cuts in the salaries of officials and in other expenditures in efforts to balance the budget and avoid bankruptcy.

Under National Socialism the Government borrowed vast sums from the German people by selling Government obligations to savings banks, insurance companies, and other financial institutions, so that the total public debt of the Reich, the States, and the larger towns and cities rose from 24 milliard marks in 1932 to an estimated 64 milliard in 1939. This latter figure is probably too low, but no exact statement can be made; the National Socialists in 1935 ceased publishing the annual budget and so avoided revealing the true state of their shaky financial structure. Herr Hitler did announce on Sept. 1, 1939, that he had spent 90 milliard marks in building up the army; this enormous sum was considerably more than twice the amount of all the taxes and customs collected by the Reich in the years 1933–37 (38.5 milliard marks).

From 1933 to 1938 the total taxes collected by the Reich and local authorities more than doubled, rising from 10·5 milliard marks in 1933 to an estimated 22 milliard in 1939. The progressive increase in Reich and local taxes from the low depression point in 1932 to 1937 is shown in Table XXXIX.

TABLE XXXIX. *Federal and Local Revenues, 1929–38* (in millions of marks)*

Reich taxes	1929–30	1933–4	1934–5	1935–6	1936–7	1937–8
Property	6,347·1	4,096·9	5,013·0	6,229·3	7,903·6	9,894·3
Excise	1,803·4	1,714·6	2,100·6	2,225·4	2,315.8	2,541·8
Customs	1,095·2	1,065·1	1,148·6	1,249·4	1,333·4	1,595·2
Total	9,245·7	6,876·6	8,262·2	9,704·1	11,552·8	14,031·3
Local taxes	4,213·0	3,684·8	3,613·8	3,652·2	3,964·6	4,567·8
Total taxes†	13,458·6	10,571·1	11,894·7	13,366·1	15,537·4	18,599·1

*The German financial year runs from April 1 to March 31.
†Figures take account of certain equalization funds, and consequently are not the precise sum of the Reich and local taxes.

The fact that the Reich taxes doubled from 1933 to 1937, while the local taxes appeared to remain much the same, was caused by the centralizing policies of the National Socialists. They transferred to the central Reich the collection of many taxes which formerly were collected in whole or in part by the local States and the larger towns and cities; a part of the taxes collected by the Reich was then turned over to the States and towns for local needs.

Income, corporation, and sales taxes were among the taxes which were pushed up most sharply by the National Socialists. They also imposed a variety of new small taxes. The principal sources of Reich revenues are given in Table XL.

TABLE XL. *Principal Sources of Reich Revenues, 1928–38* (in millions of marks)

Taxes	1928–29	1932–33	1937–38
Income	2,900·0	495·3*	4,059·1
Corporation	550·0	..	2,219·1
Property	520'0	330·3	366·3
Succession	100·0	61·7	94'5
Sales	1,050·0	948·1	2,753·5
Tobacco	760·0	762·0	912·0
Sugar	140·0	285.8	353'7
Beer	370·0	177·5	314·9
Spirit-monopoly	378·8	137·8	279·0
Customs	1,058·8	1,106·0	1,595·2
Various	982·0	2,378·3	1,084·0
Total	8,692·0	6,682·8	14,031·3

*Includes corporation tax.

ETHNOLOGY AND EARLY HISTORY

Our direct knowledge of Germany begins with the appointment of Julius Caesar as governor of Gaul in 59 B.C. Long before that time there is evidence of German communication with southern civilization, as the antiquities prove, and occasional travellers from the Mediterranean had made their way into those regions (*e.g.* Pytheas, towards the end of the 4th century), but hardly any records of their journeys survive. The first Teutonic peoples whom the Romans encountered were the Cimbri and Teutoni, probably from Denmark, who invaded Illyria, Gaul, and Italy towards the end of the 2nd centurv B.C.

Julius Caesar in Germany.— When Caesar arrived in Gaul the Rhine practically formed the boundary between Gauls and Germans, though one Gaulish tribe, the Menapii, is said to have been living beyond the Rhine at its mouth, and shortly before the arrival of Caesar an invading force of Germans had seized and settled down in what is now Alsace, 72 B.C. At this time the Gauls were being pressed by the Germans along the whole frontier, and several of Caesar's campaigns were occupied with operations,

either against the Germans or against Gaulish tribes set in motion by the Germans. During the period of Caesar's government he succeeded in annexing the whole country as far as the Rhine. (For the campaigns see CAESAR, JULIUS.)

Later Campaigns — After peace had been established in Italy by Augustus, attempts were made to extend the Roman frontier beyond the Rhine. Nero Claudius Drusus (*q.v.*) in the year 12 B.C. annexed what is now the Netherlands and constructed a canal (Fossa Drusiana) between the Rhine and the Lacus Flevus, which partly corresponded to the Zuider Zee, though the topography of the district has altered. He also penetrated into regions beyond and crossed the Weser, receiving the submission of the Bructeri, and also of the Chatti and Cherusci (*qq.v.*). After Drusus' death in 9 B.C., the German command was twice undertaken by Tiberius, who in A.D. 5 received the submission of the Chauci and the Langobardi. A Roman garrison was left in the conquered districts between the Rhine and the Elbe. About the same time a Roman fleet voyaged along the northern coast as far as the north of Jutland and received the nominal submission of the Cimbri (*q.v.*) and the Charudes. In A.D. 9 Quintilius Varus, the successor of Tiberius, was surprised in the *Saltus* Teufobergensis between the Lippe and the Weser by a force raised by Arminius (*q.v.*), a chief of the Cherusci, and his army, consisting of three legions, was annihilated. Germanicus Caesar made repeated attempts to recover the Roman position in northern Germany and exact vengeance for the death of Varus, but without real success, and after his recall the Rhine formed for the greater part of its course the boundary of the Empire. A standing army was kept up on the Rhine, divided into two commands, upper and lower Germany, the headquarters of the former being at Mainz, those of the latter at Vetera, near Xanten. A number of important towns grew up, among which we may mention Trier (Augusta Trevirorum), Cologne (Colonia Agrippinensis), Bonn (Bonna), Worms (Borbetomagus), Spires (Noviomagus), Strasbourg (Argentorate), and Augsburg (Augusta Vindelicorum).

At a later date the frontier of upper Germany was advanced beyond the Rhine, and a fortification, known in its northern part as the Pfahlgraben, constructed to protect it. It led from Hönningen on the Rhine, about half-way between Bonn and Coblenz, to Mittenberg above Aschaffenburg on the Main, thence southwards to Lorch in Wiirttemberg, whence it turned east to the Danube just below Hienheim. (See LIMES GERMANICUS.)

During the wars of Drusus, Tiberius, and Germanicus the Romans had ample opportunity of getting to know the tribal geography of the western part of Germany. It will be convenient, therefore, to give an account of the tribal geography of Germany in the time of Augustus, as our knowledge of the subject is more complete for his reign than for several centuries later.

THE GERMAN TRIBES'

Of the Gaulish tribes west of the Rhine, the most important was the Treveri, inhabiting the basin of the Moselle, from whom the city of Trier (Trèves) derives its name. The Rauraci occupied the south of Alsace. To the south of the Treveri lay the Mediomatrici, and to the west of them lay the important tribe of the Sequani, who had called in Ariovistus. The Treveri claimed to be of German origin, and the same claim was made by a number of tribes in Belgium, the most powerful of which were the Nervii. There is some obscurity concerning the origin of the name Germani. It appears to be a Gaulish term, and there is no evidence that it was ever used by the Germans themselves. Caesar records that four Belgic tribes, namely, the Condrusi, Eburones, Caeraesi, and Paemani were collectively known as Germani. These tribes were all linguistically Celtic, and it is the prevailing opinion that they were not of German origin ethnologically but came from over the Rhine (Caesar, De *Bello Gallico* ii. 4). The name Germani originally denoted certain Celtic tribes to the east of the Rhine, and was then transferred to the Teutonic tribes which subsequently occupied the same territory.

Tribal Movements. — There is little doubt that, during the last century before the Christian era, the Celtic peoples had been pushed considerably farther west by the Teutonic peoples, a process which was still going on in Caesar's time. The Boii (*q.v.*) were expelled from their territories in Bohemia by the Marcomanni (*q.v.*) in the time of Augustus. Caesar also mentions a Gaulish tribe named Volcae Tectosages as living in Germany in his time. The Volcae Arecomici in the south of France and the Tectosages of Galatia were in all probability offshoots of this people. The name of the tribe was adopted in the Teutonic languages as a generic term for all Celtic peoples (O.H.G. *Walha*, A.S. *Wealas*). Ptolemy mentions a number of place-names which are certainly Celtic, *e.g.*, Mediolanion, Aregelia, Lougidounon, Lokoriton, Segodounon. There is, therefore, a probability that a large part of western Germany east of the Rhine was formerly occupied by Celtic peoples.

Tribes in the ***West and*** North. — Coming to the Germans proper, we find the basin of the Rhine between Strasbourg and Mainz inhabited by the Tribocci, Nemetes, and Vangiones, farther down by the Mattiaci about Wiesbaden, and the Ubii in the neighbourhood of Cologne; beyond them were the Sugambri, and in the Rhine delta the Batavi and other smaller tribes. All these tribes remained in subjection to the Romans. Beyond them were the Tencteri, about the basin of the Lahn, and the Usipetes about the basin of the Ruhr. The basin of the Lippe and the upper basin of the Ems were inhabited by the Bructeri, and in the same neighbourhood were the Ampsivarii. The upper basin of the Weser was inhabited by the Chatti, whose capital was Mattium (Maden on the Eder). To the north-west of them were situated the Marsi (*q.v.*), while the central part of the basin of the Weser was inhabited by the Cherusci, who seem to have extended considerably eastward. The lower part of the river-basin was inhabited by the Angrivarii. The coastlands north of the mouth of the Rhine were occupied by the Canninefates, by the Frisii as far as the mouth of the Ems, thence onward to the mouth of the Elbe by the Chauci. The basin of the Elbe was inhabited by Suebic tribes, the chief of which were the Marcomanni, who settled on the Saale during the latter part of the 1st century B.C., but moved into Bohemia before the beginning of the Christian era, where they became a formidable power under their king Maroboduus. (See SUEBI, etc.) The Quadi were settled somewhat farther east about the source of the Elbe. The Hermunduri in the basin of the Saale were in alliance with the Romans and occupied northern Bavaria with their consent. The Semnones dwelt below the junction of the Saale and Elbe. The Langobardi (see LOMBARDS) possessed the land between the territory of the Semnones and the mouth of the river. Their name is preserved in Bardengau, south of Hamburg. The province of Schleswig (perhaps only the west coast) and the islands adjacent were inhabited by the Saxons, while the east coast was occupied by the Angli. The coast of Mecklenburg was inhabited by the Varini (the later Warni). The eastern part of Germany was much less known to the Romans; the Rugii inhabited the eastern part of Pomerania, where a trace of them is preserved in the name Riigenwalde. The lower part of the basin of the Oder was occupied by the Burgundiones, and tlie upper part by a number of tribes collectively known as Lugii, who seem to correspond to the Vandals of later times. Among the Lugii we may include the Silingae, who afterwards appear among the Vandals in Spain, and whose name is preserved in Slavonic form in that of the province Silesia. The Goths (Gotones) inhabited the basin of the Vistula about the middle of its course, but the lower part of the basin was inhabited by non-Teutonic peoples, among whom we may mention the Galindi, probably Prussians, and the Aestii, either Prussian or Esthonian, in the coastlands at the mouth of the river, who are known especially in connection with the amber trade.

WARS OF THE GERMANS

In the time of Augustus the most powerful ruler in Germany was Maroboduus, king of the Marcomanni. His supremacy extended over all the Suebic tribes (except perhaps the Hermunduri), and most of the peoples of eastern Germany, including the Lugii and Goths. But in A.D. 17 he became involved in an unsuccessful campaign against Arminius, prince of the Cherusci, in which the Semnones and Langobardi revolted against him, and

LARGE INDUSTRIAL PLANTS IN GERMANY: STEEL, COAL AND SHIPBUILDING WORKS

1. View of steel and roiling mills in the Ruhr District, one of the greatest iron and steel producing regions in the world, converted largely into munitions making by Adolf Hitler before and during World War II
2. Blast furnaces at Mülheim, near Essen, in the Ruhr District, subjected to heavy bombing in World War II
3. Interior of cast steel plant, Fried. Krupp works, Essen, showing extra large ingot weighing 100 tons being lifted from casting pit by an overhead crane which carries the ingots to annealing pit
4. View of railway spring shop, Krupp works. showing stacks of completed springs for railway-cars and locomotives
5. Typical scene showing workings in an open pit lignite mine at Liegnitz, Silesia. The most important of these new brown coal areas have been developed near to existing industrial centres. Power plants in lignite area of central Germany generate electricity used in Berlin. Lignite is also used for making synthetic nitrates and is a cheap raw material from which oil is obtained
6. Launching an ocean freighter at the Bremen shipyards, which are among the largest in the world. After World War I Germany's merchant marine was largely rebuilt and many vessels for foreign owners were constructed, the one shown being for a Greek line

two years later he was deprived of his throne by a certain Catualda. The latter, however, was soon expelled by Vibilius, king of the Hermunduri, and his power was transferred to Vannius, who belonged to the Quadi. About the same time Arminius met his death while trying to make himself king of the Cherusci. In A.D. 28 the Frisians revolted from the Romans, and though they submitted again in 47, Claudius immediately afterwards recalled the Roman troops to the left bank of the Rhine. In 58 the Chatti suffered a serious disaster in a campaign against the Hermunduri. They recovered very soon, and at the end of the 1st century had extended their power at the expense of the Cherusci. During the latter part of the 1st century the Chauci were enlarging their territories: as early as 47 we find them raiding the Roman lands on the lower Rhine, and in 58 they expelled the Ampsivarii. During the last years of the 1st century A.D. the Angrivarii are found moving westwards probably under pressure from the Chauci, and the power of the Bructeri was almost destroyed by their attack. In 69 the Roman territory on the lower Rhine was disturbed by the revolt of Claudius Civilis (*q.v.*) a prince of the Batavi who had served in the Roman army. He was defeated by Petillius Cerealis at Vetera and arranged a capitulation in A.D. 70.

After the time of Tacitus our information regarding German affairs becomes extremely meagre. The next important conflict with the Romans was the Marcomannic War (166–180), in which all the Suebic tribes, together with the Vandals (apparently the ancient Lugii) and the Sarmatian Iazyges, seem to have taken part. Peace was made by the emperor Commodus in A.D. 180 on payment of large sums of money.

The Alamanni, the Goths, and the Franks.—About the beginning of the 3rd century we find a forward movement in south-west Germany among a group of tribes known collectively as Alamanni (*q.v.*), who came in conflict with the emperor Caracalla (*q.v.*) in the year 213. About the same time the Goths made their appearance in the south-east and soon became the most formidable antagonists of Rome. In the year 251 they defeated and slew the emperor Decius, and in the reign of Gallienus their fleets, setting out from the north of the Black Sea, worked great havoc on the coast of the Aegean (*see* GOTHS). About the middle of the 3rd century the name Franks (*q.v.*) makes its appearance, apparently a new collective term for the tribes of north-west Germany from the Chatti to the mouth of the Rhine.

The Huns.—In the 4th century the chief powers in western Germany were the Franks and the Alamanni, both of whom were in constant conflict with the Romans. The former were pressed in their rear by the Saxons, who at some time before the middle of the 4th century invaded and conquered a considerable part of north-west Germany. The Burgundians made their appearance in the west shortly before the end of the 3rd century, settling in the basin of the Main, and some portions of the north Suebic peoples, perhaps the ancient Semnones, had already moved westward. By the middle of the 4th century the Goths had become the dominant power in eastern Germany, and their king Hermanaric held a supremacy which stretched from the Black Sea to Holstein. At his death, the supremacy of eastern Germany passed to the Huns (*q.v.*), an invading people from the east, whose arrival produced a complete displacement of population in this region. With regard to the course of events in eastern Germany we have no knowledge, but during the 5th century several of the peoples previously settled there made their way into the lands south of the Carpathians and Riesengebirge, amongst whom (besides the Goths) may be mentioned the Rugii and the Gepides. We do not know how far northward the Hunnish power reached in the time of Attila (*q.v.*), but the invasion of this nation was soon followed by a great westward movement of the Slavs.

The Burgundians and other Tribes.—In the west the Alamanni and the descendants of the Marcomanni, now called Baiovarii (Bavarians), had broken through the frontiers of the Roman provinces of Vindelicia and Noricum at the beginning of the 5th century. About 435–440 the Burgundians were overthrown by Attila, and their king Gunthacarius (Gundahar) killed. The remains of the nation shortly afterwards settled in Gaul. About the same time the Franks overran and occupied the modern Belgium, and in the course of the next half-century their dominions were enormously extended towards the south (see FRANKS). After the death of Attila in 453, the power of the Huns soon collapsed.

THE FRANKS AND THE SAXONS

In the 6th century the predominant peoples are the Franks, Frisians, Saxons, Alamanni, Bavarians, Langobardi, Heruli, and Warni. By the beginning of this century the Saxons penetrated almost, if not quite, to the Rhine in the Netherlands. The old land of the Chatti was included in the kingdom of Clovis and Northern Bavaria was occupied by the Franks. To the east of the Franks, between the Harz, the Elbe, and the Saale, lay the kingdom of the Thuringi. The Heruli also had a powerful kingdom in the basin of the Elbe, and to the east of them were the Langobardi. The Warni now dwelt in the regions about the mouth of the Elbe, while the whole coast from the mouth of the Weser to the west Scheldt was in the hands of the Frisians. By this time all the country east of the lower Elbe was Slavonic. Theodoric, king of the Ostrogoths, endeavoured to form a confederacy with the Thuringi, Heruli and Warni against Clovis in order to protect the Visigoths in the early years of the 6th century, but very shortly afterwards the king of the Heruli was slain by the Langobardi and their existence as an independent power came to an end. In 531 the Thuringian kingdom was destroyed by the Frankish king Theodoric.

During the 6th and 7th centuries the Saxons were intermittently under Frankish supremacy, but their conquest was not complete until the time of Charlemagne. Shortly after the middle of the 6th century the Franks were threatened with a new invasion by the Avars. In 567–568 the Langobardi, who by this time had moved into the Danube basin, invaded Italy and were followed by those of the Saxons who had settled in Thuringia. Their lands were given by the Frankish king Sigeberht to the north Suebi and other tribes who had come either from the Elbe basin or possibly from the Netherlands. About the same time Sigeberht was defeated by the Avars, and they were followed by a movement of the Slavs, who occupied the basin of the Elster and penetrated to that of the Main.

By the end of the 6th century the whole basin of the Elbe, except the Saxon territory near the mouth, had become Slavonic. The Warni now disappear from history, and from this time the Teutonic peoples of the north as far as the Danish boundary about the Eider are called Saxons. The conquest of the Frisians by the Franks was begun by Pippin (Pepin) of Heristal in 689 and practically completed by Charles Martel, though they were not entirely brought into subjection until the time of Charlemagne. The great overthrow of the Saxons took place about 772–773, and by the end of the century Charlemagne had extended his conquests to the border of the Danes. By this time the whole of the Teutonic part of Germany had been brought under his government.

MEDIAEVAL HISTORY

When the Western empire came to an end, the region afterwards called Germany was divided into five main districts, and its history for the succeeding three centuries is mainly the history of the tribes inhabiting them. In the north-east, dwelling

between the Rhine and the Elbe, were the Saxons (*q.v.*), to the east and south of whom stretched the extensive kingdom of Thuringia (*q.v.*). In the south-west the Alamanni occupied the territory afterwards called Swabia (*q.v.*), and extended along the middle Rhine until they met the Ripuarian Franks, then living in the northern part of the district which at a later period was called after them, Franconia (*q.v.*); and in the south-east were the Bavarians, although it was some time before their country came to be known as Bavaria (*q.v.*).

The history begins with the wars of Clovis and his successors against the Alamanni, conquered by Clovis, the Thuringians, and the Bavarians. On the death of Clovis (511) his kingdom was divided, and the Ripuarian, or Rhenish, Franks, together with some of the Alamanni, came under the rule of his eldest son Theodoric I. This was the first of the many partitions which ultimately divided the kingdom of the Franks into an eastern and a western portion, that is to say, into divisions which eventually became Germany and France respectively, and the district ruled by Theodoric was almost identical with that which afterwards bore the name of Austrasia. In *531* he killed Hermannfried, king of the Thuringians, conquered his kingdom, and added its southern portion to his own possessions. His son and successor, Theodebert I., exercised a certain supremacy over the Alamanni and the Bavarians, and even claimed authority over various Saxon tribes between whom and the Franks there had been some fighting. After his death in *548*, however, the Frankish power in Germany sank to very minute proportions, a result due partly to the spirit of tribal independence, which lingered among the German races, but principally to the paralysing effect of the unceasing rivalry between Austrasia and Neustria. From *548* the Alamanni were ruled by a succession of dukes who soon made themselves independent; and in *555* a duke of the Bavarians, who exercised his authority without regard for the Frankish supremacy, is first mentioned. In Thuringia, which now consisted only of the central part of the former kingdom, King Dagobert I. set up in *634* a duke named Radulf who soon asserted his independence of Dagobert and of his successor, Sigebert III. The Saxons for their part did not own even a nominal allegiance to the Frankish kings, whose authority on the right bank of the Rhine was confined to the district actually occupied by men of their own name, which at a later date became the duchy of Franconia. During these years the eastern border of Germany was constantly ravaged by various Slavonic tribes. King Dagobert sent troops to repel these marauders from time to time, but the main burden of defence fell upon the Saxons, Bavarians and Thuringians. The virtual independence of these German tribes lasted until the 8th century. The ducal office was then abolished in Thuringia, a series of wars reduced the Alamanni to strict dependence, and both countries were governed by Frankish officials. Bavaria was brought into subjection about the same time; the Bavarian law, committed to writing between *739* and *748*, strongly emphasizes the supremacy of the Frankish king, whose authority it recognizes as including the right to appoint and even to depose the duke of Bavaria.

After all, however, even the most powerful Frankish conquerors had but imperfect success in Germany. Their power was only secure when they and their armies were actually in the land. One of the chief causes of their ill-success was the continued independence of the Saxons. They were still heathens, cherishing bitter hatred towards the Franks, whom they regarded as the enemies both of their liberties and of their religion; and their hatred found expression, not only in expeditions into Frankish territory, but in help willingly rendered to every German confederation which wished to throw off the Frankish yoke. Hardly any rebellion against the dukes of the Franks, or against King Pippin, took place in Germany without the Saxons coming forward to aid the rebels. This was perfectly understood by the Frankish rulers, who tried again and again to put an end to the evil by subduing the Saxons. They could not, however, attain their object. An occasional victory was gained, and some border tribes were from time to time compelled to pay tribute; but the mass of the Saxons remained unconquered until the reign of Charlemagne.

It was during the time of Pippin of Heristal and his son and grandson that the conversion of the Germans to Christianity was mainly effected. Some traces of Roman Christianity still lingered in the Rhine valley and in southern Germany, but the bulk of the people were heathen, in spite of the efforts of Frankish and Irish missionaries and the command of King Dagobert I. that all his subjects should be baptized. Rupert, bishop of Worms, had already made some progress in the work of converting the Bavarians and Alamanni, as had Willibrord among the Thuringians, when St. Boniface appeared in Germany in *717*. Appointed bishop of the Germans by Pope Gregory II., and supported by Charles Martel, he preached with much success in Bavaria and Thuringia, notwithstanding some hostility from the clergy who disliked the influence of Rome. He founded or restored bishoprics in Bavaria, Thuringia and elsewhere, and in *742* presided over the first German council. When he was martyred Christianity was professed by all the German races except the Saxons, and the church, organized and wealthy, had been to a large extent brought under the control of the papacy.

The Work of Charlemagne.—The reign of Charlemagne is a period of great importance in the history of Germany. The long struggle, which ended in *804* with the submission of the Saxons, together with the extension of a real Frankish authority over the Bavarians, brought the German races for the first time under a single ruler; while war and government, law and religion, alike tended to weld them into one people. The armies of Charlemagne contained warriors from all parts of Germany; and although tribal law was respected and codified, legislation common to the whole empire was also introduced. The general establishment of the Frankish system of government and the presence of Frankish officials helped to break down the barriers of race, and the influence of Christianity was in the same direction. With the conversion of the Saxons the whole German race became nominally Christian; and their ruler was lavish in granting lands and privileges to prelates, and untiring in founding bishoprics, monasteries and schools. Measures were also taken for the security and good government of the country. Campaigns against the Slavonic tribes, if sometimes failing in their immediate object, taught those peoples to respect the power of the Frankish monarch; and the establishment of a series of marches along the eastern frontier gave a sense of safety to the neighbouring districts. The tribal dukes had all disappeared, and their duchies were split up into districts ruled by counts (*q.v.*), whose tendencies to independence the emperor tried to check by the visits of the *missi dominici* (*q.v.*). Some of the results of the government of Charlemagne were, however, less beneficial. His coronation as Roman emperor in 800, although it did not produce at the time so powerful an impression in Germany as in France, was fraught with consequences not always favourable for the former country. The tendencies of the tribes to independence were crushed as their ancient popular assemblies were discouraged; and the liberty of the freemen was curtailed.

The reign of the emperor Louis I. was marked by a number of abortive schemes for the partition of his dominions among his sons, which provoked a state of strife that was largely responsible for the increasing weakness of the empire. The mild nature of his rule, however, made Louis popular with his German subjects, to whose support mainly he owed his restoration to power on two occasions. When in *825* his son Louis, afterwards called "the German," was entrusted with the government of Bavaria and from this centre gradually extended his authority over the Carolingian dominions east of the Rhine, a step was taken in the process by which East Francia, or Germany, was becoming a unit distinguishable from other portions of the empire. The process was carried farther by the treaty of Verdun in Aug. *843*, by which Louis obtained the bulk of the lands east of the Rhine together with the districts around Mainz, Worms and Spires on the left bank. Although not yet a single people, the German tribes had now for the first time a ruler whose authority was confined to their own lands, and from this time the beginnings of national life may be traced. For 50 years the main efforts of Louis were directed to defending his kingdom from the inroads of his Slavonic neigh-

bours, and his detachment from the rest of the empire necessitated by these constant engagements towards the east, gradually gave both him and his subjects a distinctive character, which was displayed when, in ratifying an alliance with his half-brother, the West-Frankish king, Charles the Bald, the oath was sworn in different tongues. The East and West Franks were unable to understand each other's speech, so Charles took the oath in a Romance, and Louis in a German dialect.

Important as is the treaty of Verdun in German history, that of Mersen (*q.v.*), by which Louis and Charles the Bald settled, 870, their dispute over the kingdom of Lothair, second son of the emperor Lothair I., is still more important. The additional territory which Louis then obtained gave to his dominions almost the proportions which Germany maintained throughout the middle ages. They were bounded on the east by the Elbe and the Bohemian mountains, and on the west beyond the Rhine they included the districts known afterwards as Alsace and Lorraine. His jurisdiction embraced the territories occupied by the five ancient German tribes, and included the five archbishoprics of Mainz, Treves (Trier), Cologne, Salzburg and Bremen. When Louis died in 876 his kingdom was divided among his three sons, but as the two elder of these soon died without heirs, Germany was again united in 882 under his remaining son Charles, called "the Fat," who soon became ruler of almost the whole of the extensive domains of Charlemagne. There was, however, no cohesion in the restored empire, the disintegration of which was hastened by the ravages of the Northmen, who plundered the cities in the valley of the Rhine. It was mainly in the interest of national defence that Arnulf, an illegitimate son of Carloman, the eldest son of Louis the German, led an army of Bavarians against Charles, and obtained recognition as German or East-Frankish king (887). He was successful in freeing his kingdom for a time from the ravages of the Xorthmen, but was not equally fortunate in his contests with the Moravians. After his death in 899 his kingdom came under the nominal rule of his young son Louis "the Child," and in the absence of firm rule and a central authority became the prey of the Magyars and other hordes of invaders.

During these wars feudalism made rapid advance in Germany. The different peoples compelled to attend to their own defence appointed dukes for special military services (see DUKE); and these dukes, chosen often from members of the old ducal families, succeeded without much difficulty in securing a more permanent position for themselves and their descendants. In Saxony, for example, we hear of Duke Otto the Illustrious, who also ruled over Thuringia; and during the early years of the 10th century dukes appear in Franconia, Bavaria, Swabia and Lorraine. These dukes acquired large tracts of land of which they gave grants on conditions of military service to persons on whom they could rely; while many independent landowners sought their protection on terms of vassalage. The same process took place in the case of great numbers of freemen of a lower class, who put themselves at the service of their more powerful neighbours in return for protection. The dukes became virtually independent, and when Louis the Child died in 911, the royal authority existed in name only.

While Louis the Child lived the German dukes were virtually kings in their duchies, and their natural tendency was to make themselves absolute rulers. But, threatened as they were by the Magyars, with the Slavs and Northmen always ready to take advantage of their weakness, they could not afford to do without a central government. Accordingly the nobles assembled at Forchheim, and by the advice of Otto the Illustrious, duke of Saxony, Conrad of Franconia was chosen German king. The dukes of Bavaria, Swabia and Lotharingia were displeased at this election, probably because Conrad was likely to prove considerably more powerful than they wished. The two former dukes yielded, but the duke of Lotharingia transferred his allegiance to Charles the Simple of France; and it was in vain that Conrad protested and despatched armies into Lorraine.

On the other hand, the rise of the dukes had been watched with extreme jealousy by the leading prelates. They saw that their independence would be much more imperilled by powerful local governors than by a sovereign who necessarily regarded it as part of his duty to protect the church. Hence they had done everything they could to prevent the dukes from extending their authority, and as the government was carried on during the reign of Louis the Child mainly by Hatto I., archbishop of Mainz, they had been able to throw considerable obstacles in the way of their rivals. They now induced Conrad to quarrel with both Swabia and Bavaria, and also with Henry, duke of Saxony, son of the duke to whom he chiefly owed his crown. In these contests the German king met with indifferent success, but the struggle with Saxony was not very serious, and when dying in Dec. 919 Conrad recommended the Franconian nobles to offer the crown to Henry, the only man who could cope with the anarchy by which he had himself been baffled.

Henry the Fowler.—The nobles of Franconia acted upon the advice of their king, and the Saxons were very willing that their duke should rise to still higher honours. Henry I., called "the Fowler," who was chosen German king in May 919, was one of the best of German kings. Almost immediately he overcame the opposition of the dukes of Swabia and Bavaria; some time later, taking advantage of the troubled state of France, he accepted the homage of the duke of Lorraine, which for many centuries afterwards remained a part of the German kingdom. Having established internal order, Henry was able to turn to matters of more pressing moment. In the first year of his reign the Magyars raided Saxony. In 924 they returned, and this time by good fortune one of their greatest princes fell into the hands of the Germans. Henry restored him to his countrymen on condition that they make a truce for nine years; and he promised to pay yearly tribute during this period. The barbarians accepted his terms, and faithfully kept their word in regard to Henry's own lands, although they occasionally invaded Bavaria, Swabia and Franconia as before. The king made admirable use of the opportunity he had secured, confining his efforts, however, to Saxony and Thuringia, the only parts of Germany over which he had any control.

In southern and western Germany towns and fortified places had long existed; but in the north, outside the sphere of Roman influence, they had not yet arisen. As a provision for the defence of the land Henry began the construction of fortresses and walled towns. Of every group of nine men one was compelled to devote himself to this work, while the remaining eight cultivated his fields and allowed a third of their produce to be stored against times of trouble. The necessities of military discipline were also a subject of attention. Hitherto the Germans had fought mainly on foot, and, as the Magyars came on horseback, the nation was placed at an immense disadvantage. A powerful force of cavalry was now raised, while at the same time the infantry were drilled in new and more effective modes of fighting. Before turning his new troops against their chief enemy, the Magyars, Henry used them to punish refractory Slavonic tribes; and he brought under temporary subjection nearly all the Slavs between the Elbe and the Oder. He compelled the duke of the Bohemians to do homage, and he recovered the land between the Eider and the Schlei from Gorm, king of the Danes. His greatest single achievement, however, was the victory which he won on March 15, 933, over the Magyars, which freed Saxony and Thuringia from an ever present danger.

Notable as it was, Henry's work concerned the duchy of Saxony rather than the kingdom of Germany. He concentrated all his energies on the government and defence of northern and eastern Germany, leaving the southern and western districts to profit by his example, while his policy of refraining from interference in the affairs of the other duchies tended to diminish the ill-feeling which existed between the various German tribes and to bring peace to the country as a whole. It is in these directions that his reign marks a stage in the history of Germany. When he died in July 936 every land inhabited by a German population formed part of the German kingdom, and none of the duchies were at war either with him or among themselves.

Otto the Great.—Before his death Henry obtained the promise of the nobles to recognize his son Otto as his successor, and Otto was chosen German king in July 936. More ambitious than his father, he gave excuse for a rebellion by insisting on the

reality of his authority over the great dukes. On its suppression, the duchies of Franconia and Lorraine were at his disposal. He kept the former in his own hands and granted Lorraine to Conrad the Red, an energetic and honourable count, whom he still further attached to himself by giving him his daughter for his wife. Bavaria, on the death of its duke in 947, was placed under Otto's brother Henry, who, after an unsuccessful rebellion, was a loyal subject. The duchy of Swabia was also brought into Otto's family by the marriage of his son Ludolf with Duke Hermann's daughter, and by these means Otto made himself master of the kingdom. For the time, feudalism in truth meant that lands and offices were held on condition of service; the king was the genuine ruler, not only of freemen, but of the highest vassals in the nation.

Otto's reign is important for the relations of Germany with external powers. He intervened in the affairs of France where King Louis IV. and his greatest subject, Hugh, duke of the Franks, had each married one of his sisters. His wars with his northern and eastern neighbours were more important. The duke of Bohemia, after a long struggle, was brought to submission in 950. Among the Slavs between the Elbe and the Oder the king was represented by Margrave Gero, who conquered much of the country north of Bohemia between the Oder and the upper and middle Elbe. Margrave Billung, who looked after the Abotrites on the lower Elbe, was less fortunate, mainly because of the neighbourhood of the Danes, who, after the death of King Henry, often attacked the hated Germans, but some progress was made in bringing this district under German influence. Otto, having profound faith in the power of the Church to reconcile conquered peoples to his rule, provided for the benefit of the Danes the bishoprics of Schleswig, Ripen and Aarhus; and among those which he established for the Slavs were the important bishoprics of Brandenburg and Havelberg. In his later years he set up the archbishopric of Magdeburg, which took in the sees of Meissen, Zeitz and Merseburg.

Having secured peace in Germany and begun the real conquest of the border races, Otto was by far the greatest sovereign in Europe. The latter part of his long reign was largely occupied with his intervention in Italy and its consequences. About 951 Adelaide, widow of Lothair, son of Hugh, king of Italy, having refused to marry the son of Berengar, margrave of Ivrea, was cast into prison and cruelly treated. She appealed to Otto; other reasons called him in the same direction, and in 951 he crossed the Alps and descended into Lombardy. He displaced Berengar, and was so fascinated by Queen Adelaide that within a few weeks he was married to her at Pavia. But Otto's son, Ludolf, who had received a promise of the German crown, saw his rights threatened by this marriage. He went to an old enemy of his father, Frederick, archbishop of Mainz, and the two plotted together against the king, who, hearing of their proceedings, returned to Germany in 952, leaving Duke Conrad of Lorraine as his representative in Italy. Otto, who did not suspect how deep were the designs of the conspirators, paid a visit to Mainz, where he was seized and was compelled to take certain solemn pledges which, after his escape, he repudiated. War broke out in 953, and the struggle was the most serious in which he had been engaged. Conrad the Red hurried from Italy and joined the rebels; in Swabia, in Bavaria, in Franconia and even in Saxony, the native land of the king, many sided with them. The rapidity and strength of the movement is extremely remarkable. Otto was, in fact, only saved by the presence of external peril. The Magyars were as usual stimulated to action by the disunion of their enemies; and Conrad and Ludolf made the blunder of inviting their help. The great battle against the Magyars was fought on Aug. 10, 955, on the Lechfeld near Augsburg. The Magyars were defeated, and from this time, they began to settle in the land they still occupy.

Entreated by Pope John XII., who needed a helper against Berengar, Otto went a second time to Italy, in 961; and on this occasion he received from the pope at Rome the imperial crown. The significance of this event is discussed elsewhere (*see* EMPIRE). It gave to Otto certain definite advantages, a general increase of prestige, and new authority over the Church in Germany. Otto had been led into Italian enterprises by considerations which no one in his position could have resisted, and his coronation was their inevitable consequence. Events were to prove that the association of Germany and Italy thus established would prevent the creation of a united monarchy in either country. In Otto's time the condition of Italy invited the intervention of a ruler who felt himself competent to establish order and reform the Church.

By the policy of his later years Otto did much to prepare the way for the process of disintegration which he rendered inevitable by restoring the empire. With the kingdom divided into five great duchies, the sovereign could always have maintained at least so much unity as Henry the Fowler had. Yet Otto threw away this advantage. Lorraine was divided into two duchies, Upper Lorraine and Lower Lorraine. In each he appointed a count palatine, whose duty was to maintain the royal rights; and after Margrave Gero died in 965 his territory was divided into six parts, and placed under margraves, each with the same powers as Gero. Otto gave up the practice of retaining the duchies either in his own hands or in those of relatives. Even Saxony, his native duchy and the chief source of his strength, was given to Margrave Billung, whose family kept it for many years. To combat the power of the princes, Otto greatly increased the importance of the prelates. He undoubtedly felt that, as church lands and offices could not be hereditary, their holders would necessarily favour the Crown. He forgot that the passion for the rights of an order may be not less intense than that for the rights of a family.

During the reigns of Otto II. (973–983) and Otto III. (983–1002) much of the work of Henry the Fowler and Otto I. was undone. Otto II. had married Theophano, daughter of Romanus II., the eastern emperor, and his main ambition was the conquest of southern Italy. Otto III. hoped to achieve the unity of Christendom under his authority, and was little interested in the problems of the German kingship. It is not strange that this period is marked by a reaction on the part of the kingdoms on the German border over which Henry and Otto I. had extended their influence and by revolts within Germany itself. The reign of Henry II., the successor of Otto III. (1002–24), was mainly occupied by an attempt to restore the royal authority over Germany and the border kingdoms, of which Poland (*q.v.*) was the most dangerous. In this last respect his work was continued by his successor Conrad II., a Franconian noble (1024–39), under whom the eastern border was materially strengthened. In the west, Conrad received the kingdom of Arles by the bequest of its king, Rudolph III. (1032), and in Germany itself he was remarkably successful in regaining control over the duchies. Franconia was under his own rule, and he was able to acquire Bavaria and Swabia for his son Henry. His power was greater than that of any other king since the death of Otto I., and he founded a notable dynasty.

Henry III.—Henry III., who had been crowned German king and also king of Burgundy during his father's lifetime, took possession of his great inheritance without opposition in June 1039. During the late king's concluding years a certain Bretislaus, who had served Conrad with distinction in Lusatia, became duke of Bohemia, and made war upon the disunited Poles, easily bringing them into subjection. Thus Germany was again threatened with the establishment of an independent Slavonic State upon her eastern frontier. To combat this danger Henry invaded Bohemia, and after two reverses compelled Bretislaus to submit at Regensburg. He also gained the goodwill of the Poles by helping to bring about the return of their duke, Casimir I., who willingly did homage for his land. The king of Denmark, too, acknowledged Henry as his feudal lord, and by several campaigns in Hungary the German king brought that country into the position of a fief of the German Crown. This war was occasioned by the violence of the Hungarian usurper, Aba Samuel, and formed Henry's principal occupation from 1041 to 1045.

In Germany itself Henry was successful. Under him Germany enjoyed a period of internal quiet such as she had probably never experienced before, but even he could not permanently divert from its course the main political tendency of the age, the desire of the great feudal lords for independence. For various reasons, the southern duchies, Swabia, Bavaria and Carinthia, passed from under his own immediate control. His position was becoming

gradually weaker when in 1051 he invaded Hungary, where a reaction against German influence was taking place. After a second campaign in 1052 the Hungarian king, Andrew, was compelled to make peace and to own himself the vassal of the German king. On Henry's return, Andrew, encouraged by the support of disaffected German nobles, repudiated the treaty and the German supremacy in that country came to a sudden end. Among the causes which undermined Henry's strength was the fact that the mediate nobles, who had stood loyally by his father, Conrad, were not his friends.

With Henry's reign, the relations between kmpire and papacy entered on a new phase. It was largely through him that the papacy was enabled to extend its authority over western Europe. In 1046 he entered Italy at the head of an army and secured the deposition of the three contemporary claimants to the papal see. He then bestowed it on Suidger, bishop of Bamberg, who, as Pope Clement II., crowned him emperor; and after Clement three other German popes—Damasus II., Leo IX. and Victor II.—owed their elevation to Henry. Under them a new era began for the Church, and in thus reforming the papacy Henry III. fulfilled what was regarded as the noblest duty of his imperial office, but he was preparing difficulties for his successors. The last years of his reign form a turning-point in German history. Great kings and emperors came after him, but none of them possessed the direct, absolute authority which he freely wielded; even in the case of the strongest the forms of feudalism more and more interposed themselves between the monarch and the nation, and at last the royal authority virtually disappeared. During this reign the towns entered upon an age of prosperity, and the Rhine and the Weser became great avenues of trade.

When Henry died in Oct. 1056, the decline of the royal authority was accelerated by the fact that his successor was a child. Henry IV., who had been crowned king in 1054, was at first in charge of his mother, the empress Agnes, but a succession of revolutions at court placed him under the control of Adalbert, archbishop of Bremen. Adalbert's rule was very successful. Compelling King Solomon to own Henry's supremacy he restored the influence of Germany in Hungary; but in Germany itself and especially in Saxony he made many enemies, and in 1066 Henry, who had just been declared of age, was compelled to dismiss him.

The Investiture Controversy.—Henry IV. assumed the duties of government soon after the fall of Adalbert. The first ten years of his actual reign were marked by a great revolt in Saxony (*q.v.*) which ended in the submission of the duchy. In the later part of his reign began the dispute between empire and papacy commonly known from one of the questions at issue as the Investiture Controversy. Its origin and history are discussed in other articles (see EMPIRE; PAPACY). The present article is only concerned with its effect on Germany, which from any point of view was disastrous. It destroyed whatever possibility existed of an effective kingdom of Germany. The authority of later kings like Frederick I. or Henry VI. is more artificial than that of Otto I. or Conrad II., it depends more obviously on the personality of the reigning king, and its sanction has evidently been weakened. Henceforward the German kingship was on the defensive against the papal claim to universal dominion, and the papacy could generally obtain the support of the disaffected elements within Germany. The resistance actually made by Henry IV. to the new claims advanced by the papacy is a testimony to the work of Henry's predecessors. They had made the German kingship a political force, had compelled the most powerful of their princes to show it at least formal respect, and above all had identified it with the security of the German people against attack from the alien peoples of the East. In this their work was never wholly undone. The defence of the eastern borders was always a royal duty, and the marks which were created for their protection were for many years under far more definite subjection to the king than the ancient duchies had ever been. The real damage which Germany suffered through the investiture controversy came through the papal challenge to the respect which had hitherto been accorded to the royal authority implicitly, without speculation as to its origin or sanction.

Henry IV. died in Aug. **1106.** The first years of his successor Henry V. were spent in campaigns in Flanders, Bohemia, Hungary and Poland and in the establishment of his power in Germany. His chief supporters were his nephews, the two Hohenstaufen princes, Frederick and Conrad, to whose father Frederick the emperor Henry IV. had given the duchy of Swabia when its duke Rudolph became his rival. The younger Frederick succeeded to this duchy in 1105, while ten years later Conrad was made duke of Franconia, a country which for nearly a century had been under the immediate government of the Crown. The two brothers were enthusiastic imperialists, and with persistent courage they upheld the cause of their sovereign during his two absences in Italy.

The investiture controversy—the great outstanding question at issue between pope and emperor—was settled in 1122 by the concordat of Worms, a compromise by which the right of electing prelates was granted to the clergy, and the emperor surrendered the privilege of investing them with the ring and the staff. On the other hand it was arranged that these elections should take place in the presence of the emperor or his representative, and that he should invest the new prelate with the sceptre, thus signifying that the bishop, or abbot, held his temporal fiefs from him and not from the pope. The settlement gave material advantage to the emperor, and he was able to establish good order in Germany before his death in 1125.

Decay of **the** Royal Power.—The Franconian dynasty was now extinct, and after a protracted contest Lothair, duke of Saxony, the candidate of the clergy, was chosen king His first enterprise was a disastrous campaign in Bohemia, but before this occurrence he had aroused the enmity of the Hohenstaufen princes by demanding that they should surrender certain lands which had formerly been the property of the Crown Lothair's rebuff in Bohemia stiffened the backs of Frederick and Conrad, and in order to contend with them the king secured a powerful ally by marrying his daughter Gertrude to Henry the Proud, a grandson of Welf, whom Henry IV. had made duke of Bavaria, a duchy to which Henry himself had succeeded in 1126. Henry was perhaps the most powerful of the king's subjects, nevertheless the dukes of Swabia and Franconia withstood him, and a long war desolated south Germany. This was ended by the submission of Frederick in 1134 and of Conrad in the following year. Lothair's position, which before 1130 was very weak, had gradually become stronger. He had put down the disorder in Bavaria, in Saxony and in Lorraine; a diet held at Magdeburg in 1135 was attended by representatives from the vassal States of Denmark, Hungary, Bohemia and Poland; and in 1136, when he visited Italy for the second time, Germany was in a very peaceful condition. In June 1133, during the king's first visit to Italy, he had received from Pope Innocent II. the imperial crown and also the investiture of the extensive territories left by Matilda, marchioness of Tuscany; and at this time the pope seems to have claimed the emperor as his vassal, a statement to this effect being inscribed in the audience hall of the Lateran at Rome. Nothing could indicate more clearly than this fact how much of their old power the German kings had lost.

Henry the Proud was confident that he would succeed Lothair, who had died on his return from Italy in Dec. 1137; but, by a hasty and irregular election, Conrad of Hohenstaufen, duke of Franconia, was chosen king in March 1138. Henry the Proud rebelled and was declared to have forfeited his two duchies, Saxony and Bavaria, the former being given to Albert the Bear, margrave of Brandenburg, and the latter to Leopold IV., margrave of Austria. Henry defended his rights with vigour and once again Germany was ravaged by war, for although he was unpopular in Bavaria he was strongly supported by the Saxons, who, since the time of Henry IV., had always been ready to join in an attack on the monarchy, and he had little difficulty in driving Albert the Bear from the land. However, in Oct. 1139 Henry died suddenly, but his young son, Henry the Lion, was recognized at once as duke of Saxony, while his brother, Welf, upheld the fortunes of his house in Bavaria. The struggle went on until May 1142, when peace was made at Frankfurt. Saxony, with the assent of Albert the Bear, was granted by Conrad to Henry the Lion, and Bavaria was given

to Henry Jasomirgott, who had just succeeded his brother Leopold as margrave of Austria. But this was only a lull in the civil strife, which was renewed after the king had made a successful expedition into Bohemia. The princes clerical and lay were fighting against each other, and the Bavarians were at war with the Hungarians who gained a great victory in 1146. Notwithstanding the many sources of confusion Conrad was persuaded by the passionate eloquence of Bernard of Clairvaux to take part in the second crusade; he left for the East in 1147 and returned to Germany in 1149, to find Welf again in arms and Henry the Lion claiming Bavaria. The king had done nothing to stem the rising tide of disorder when he died at Bamberg in Feb. 1152. During this reign the work of conquering and Germanizing the Slavonic tribes east of the Elbe was seriously taken in hand under the lead of Albert the Bear and Henry the Lion, and the foundation of the margraviate of Brandenburg by Albert tended to make life and property more secure in the north-east of Germany.

Frederick **Barbarossa.**—After Conrad's death Germany passed under the rule of one of the greatest of her sovereigns, Frederick I., called Barbarossa, nephew of the late king and son of Frederick, that duke of Swabia who had fought along with Conrad against Henry the Proud. Frederick himself had also been closely associated with Conrad, who advised the princes to choose his nephew as his successor. This was done, and the new king was crowned at Aix-la-Chapelle in March 1152. Allied through his mother to the Welfs of Bavaria, and anxious to put an end to the unrest which dominated Germany, especially to the strife between the families of Welf and Hohenstaufen, Frederick began his reign by promising to secure for Henry the Lion the duchy of Bavaria, and by appeasing Henry's uncle, Count Welf, by making him duke of Spoleto and margrave of Tuscany. But the new king had another, and perhaps a more potent, reason for wishing to see peace restored in Germany. For his adventurous and imaginative spirit Italy and the imperial title had an irresistible charm, and in 1154, two years after he had ascended the throne, he crossed the Alps, being crowned emperor at Rome in June 1155. After this event the best years of his life were spent in Italy, where, in his long and obstinate struggle with the Lombard cities and with Pope Alexander III., he chiefly acquired his fame. Although on the emperor's side this struggle was conducted mainly with German troops it falls properly under the history of Italy.

The promise that Bavaria should be granted to Henry the Lion was not easily fulfilled, as Henry Jasomirgott refused to give up the duchy. At last, however, in 1156, after his return from his first expedition to Italy, Frederick reconciled the latter prince by making Austria into a duchy with certain special privileges, an important step in the process by which that country became the centre of a powerful State. Henry Jasomirgott then renounced Bavaria, and Henry the Lion became its duke. It was, however, in his other duchy of Saxony that the latter duke's most important work was done. Although he often gave offence by his haughty and aggressive disposition, few German princes have earned so thoroughly the goodwill of posterity. Since the death of Otto the Great the Slavonic lands to the east of the Elbe had been very imperfectly held in subjection by the Germans. Devoting himself to the conquest of the lands lying along the shore of the Baltic, Henry succeeded as no one before him had ever done. But he was not only a conqueror. He built towns and encouraged those which already existed; he founded and restored bishoprics in his new territories; and between the Elbe and the Oder he planted bodies of industrious colonists. While he was thus at work a similar task was being performed to the south-east of Saxony by Albert the Bear, the first margrave of Brandenburg, who, by his energetic rule was preparing this country for its great destinies. Already under Henry V. Pomerania had come under the influence of Christianity, introduced mainly by Otto, bishop of Bamberg (1103–1139).

Early in his reign, by settling a dispute over the Crown of Denmark, Frederick brought the king of that country once more into the position of a German vassal. Having spent the year 1156 in settling the Bavarian question and in enforcing order in the Rhineland and elsewhere, the emperor marched into Poland in 1157, compelled its ruler, Boleslaus IV., to do the homage which he had previously refused to perform, and in return for services rendered during the campaign and for promises of future aid, raised the duke of Bohemia to the rank of a king, a change which in no way affected his duties to the German Crown, but which gave him a certain precedence over other vassal princes. The king of Hungary, too, although no attempt was made to subdue him, became a useful ally. Towards the west, Frederick asserted his authority in Burgundy or, as it was sometimes called, Franche Comté. In Germany itself internal order was established by a strict appliance of the existing laws against those who broke the peace, fresh orders for its observance were issued, and in Frederick the robber nobles found a most implacable enemy. The cities, too, flourished during this reign. The emperor attached them to himself by granting to many of them the very liberties which, by a strained interpretation of his imperial rights, he withheld from the cities of Lombardy. Yet, notwithstanding his policy, in these directions the German nobles appear to have been enthusiastically devoted to Frederick. Time after time they followed him to Italy, enduring serious losses and hardships in order that he might enforce claims which were of no advantage to them, and which, previously, had been a curse to their nation. Their loyalty is well illustrated by the famous scene at Besançon in Oct. 1157. During a meeting of the diet a papal legate read a letter from Pope Adrian IV., which seemed to imply that the empire was a papal fief. Indignant murmurs rose from the assembled nobles, and the life of the legate was only saved from their fury by the intervention of the emperor himself.

The central years of his reign were mainly occupied with an attempt to enforce his rule upon Italy. To these years belong his quarrel with Pope Alexander III. and his wars with the cities of northern Italy *(see* PAPACY; LOMBARD LEAGUE). In his later years his interests were devoted to German affairs. Here, his chief enemy was Henry the Lion. Rendered arrogant by success and confident that his interests were in northern, and not in southern Europe, the Saxon duke refused to assist Frederick in the campaign which ended so disastrously at Legnano. Ascribing his defeat to Henry's defection, Frederick returned to Germany full of anger against the Saxon duke and firmly resolved to punish him. The immediate cause of Henry's downfall, however, was not his failure to appear in Italy, but his refusal to restore some lands to the bishop of Halberstadt, and it was on this charge that he was summoned before the diet. Three times he refused to appear, and early in 1180 sentence was pronounced against him; he was condemned to lose all his lands and to go into banishment. For some time he resisted, but at length the emperor in person marched against him and he was forced to submit; the only favour he could secure when peace was made at Erfurt in Nov. 1181 was permission to retain Brunswick and Luneburg, which have remained in the possession of his descendants until our own day. Bavaria was granted to Otto of Wittelsbach, but it lost some of its importance because Styria was taken from it and made into a separate duchy. The extensive duchy of Saxony was completely dismembered. The name was taken by the small portion of the former duchy which was given to Bernard, son of Albert the Bear, the founder of a new Saxon line, and the extensive western part was added to the archbishopric of Cologne. The chief prelates of Saxony and many of the late duke's most important feudatories were made virtually independent of all control save that of the Crown. Frederick's object in thus breaking up the two greatest duchies in his kingdom was doubtless to strengthen the imperial authority. But in reality he made it certain that the princes would one day shake off the imperial power altogether.

Less serious than the struggle with Henry the Lion was Frederick's struggle with Philip of Heinsberg, archbishop of Cologne (d. 1191), on whom he had just conferred a great part of Saxony. When the emperor went to Italy in 1184 he left the government of Germany to his son Henry, afterwards the emperor Henry VI., who had been crowned German king in 1169. On all sides, but especially in the north-west, Henry was faced with incipient revolution, and while he was combating this the quarrel between Frederick and the papacy broke out again in Italy. At this juncture Philip of Cologne united the German and the Italian oppositions. Several princes rallied to his standard and foreign powers promised

aid, but although very formidable in appearance the combination had no vestige of popular support. The greater part of the German clergy again proved their loyalty to Frederick, who hurried to Germany only to see the opposition vanish before him. In March 1188, Philip of Cologne submitted at Mainz. Germany was now at peace. With the accession of Gregory VIII. pope and emperor were reconciled, and by the marriage of his son Henry with Constance, daughter of Roger I., king of Sicily, the emperor had reason to hope that the empire would soon include Naples and Sicily. In 1189 he started with a great army for the Holy Land. In June 1190 he was drowned in Cilicia.

Henry VI.—His son Henry VI. became for a short time stronger than even Frederick had been. Having in 1190 reduced Henry the Lion once more to submission, the new king set out to lake possession of his Sicilian kingdom, being on the way crowned emperor at Rome. At the end of 1191 he returned to Germany, where he overcame dangerous risings in the lower Rhineland and in Saxony, Thuringia and Meissen. His success against the Saxon rising was partly due to his use of the influeace possessed by his prisoner Richard I. of England with Henry the Lion and his family. The latter made his peace in 1194, when his son Henry was promised the succession to the Rhenish Palatinate. Returning from another visit to Sicily, the emperor was now so powerful that, in pursuance of his plan for making himself the head of a great world monarchy, he put forward the suggestion that the imperial crown should be declared hereditary in his family. This proposal aroused much opposition, but Henry persisted with it; he promised important concessions to the princes, many of whom were induced to consent, and but for his sudden death, which occurred in Sicily in Sept. 1197, it is probable that he would have attained his end.

Great as was Henry's authority, many of the princes refused to recognize his son, Frederick, who had been chosen king of the Romans in 1196. This attitude was probably due to fear that the German princes would be entangled in Italian politics. The friends of the house of Hohenstaufen, convinced that Frederick's kingship was not possible, chose the late emperor's brother, Philip, duke of Swabia, to fill the vacant throne; soon afterwards the enemies of the house found a candidate in the person of Henry the Lion's son, Otto of Brunswick. Thus the struggle between Welf and Hohenstaufen was renewed and civil war broke out at once. Philip's supporters were the nobles of southern and eastern Germany, while a few cities in the west owned his authority; Otto's friends were found mainly in the north and the north-west of the country. If Germany had been unconnected with the papacy, or even if the papacy had been as weak as in the days of Henry VI., the issue of the strife would almost certainly have been an early victory for Philip. Most of the princes and Philip II., king of France, were on his side. But Innocent III. declared for Otto in 1201, and civil war was only ended by Philip's murder in June 1208.

Otto was now again chosen German king, and to mark the general reconciliation he was betrothed to Philip's daughter Beatrix. Nearly all the princes acknowledged him, and as pope and king were at peace, Germany enjoyed a period of comparative quiet. This, however, did not last long. Having secured his coronation at Rome in Oct. 1209, Otto repudiated the many pledges he had made to Innocent and began to act in defiance of the papal wishes. To punish him the pope put forward his own ward, Henry VI.'s son Frederick, who was living in Sicily, as a rival king. While Otto was warring in Italy a number of influential princes met at Nuremberg, at the instigation of Innocent and his ally Philip Augustus of France, and invited Frederick to come to Germany. Otto then left Italy hurriedly, but he was quickly followed by his young rival, who in the warfare which had already broken out proved himself a formidable opponent. Seeking to mend his failing fortunes, Otto went to France to support his ally, the English king John, against Philip Augustus, and at the battle of Bouvines (July 27, 1214) his fate was sealed, although until his death in May 1218 he maintained a desultory warfare against Frederick.

Frederick II.—Frederick II. was, if not the strongest, certainly the most brilliant of German kings. For outward splendour his position was never surpassed, and before he died he possessed six crowns, those of the empire, Germany, Sicily, Lombardy, Burgundy and Jerusalem. But Germany profited neither by his gifts nor by his prestige. After Bouvines he purchased the assistance of Valdemar II., king of Denmark, by ceding to him a large stretch of land along the Baltic coast; and, promising to go on crusade, he secured his coronation at Aix-la-Chapelle in July 1215. Then being generally recognized as king he was able to do something to quell disturbances in various parts of the country, and, in April 1220, to bring about the election of his young son Henry as king of the Romans. But for this favour he had been compelled to pay a high price. Seven years before, at Eger in July 1213, he had made extensive concessions to the church, undertaking to take no part in episcopal elections, thus surrendering the advantages gained by the concordat of Worms, and to allow to German bishops the right of appeal to Rome. Proceeding a step farther in the same direction, he now promised to erect no new toll-centre, or mint, on the lands of the spiritual princes and to allow no towns to be built thereon. Thus the prelates possessed nearly all the rights of sovereigns, and regarded the pope in Italy and not the king in Germany as their head, a state of affairs which was fatal to the unity, nay, even to the existence of the empire.

Having made peace with Henry, count palatine of the Rhine and brother of Otto IV., and settled a dispute about the lands of the extinct family of Zahringen in the south-west of the country, Frederick left Germany in Aug. 1220; engaged in his bitter contest with the papacy and the Lombard cities, in ruling Sicily, and, after several real or imaginary delays, in fulfilling his crusading vow, he did not return to it for 15 years. During this period he was represented by his son Henry, in whose name the government of Germany was carried on by the regent Engelbert, archbishop of Cologne. While Englebert lived the country was in a fairly peaceable condition, although, thanks to the emperor's concessions, the spiritual princes were predominant, and all possible means were taken to check the growth of the towns, whose interests and aspirations were not favourable to this state of affairs. There was, moreover, a struggle between Valdemar of Denmark and some neighbouring German nobles. But after Engelbert's murder (Nov. 1225) there was a change for the worse, and the only success which can be placed to the credit of the German arms during the next few years was the regaining of the lands ceded to Denmark in 1215, lands which included the cities of Hamburg and Liibeck. Under the rule of the new regent, Louis I., duke of Bavaria, confusion reigned supreme, and civil war prevailed in nearly every part of the country.

After the treaty of San Germano, which was made with Pope Gregory in 1230, and the consequent lull in the struggle with the papacy, Frederick was able to devote some little attention to Germany, and in 1231 he sanctioned the great Privilege of Worms. This was a reward to the princes for their efforts in bringing about the peace, and an extension of the concessions made in 1220. The princes, now for the first time referred to officially as *domini terrae*, were given full rights of jurisdiction over their lands and all the inferior officers of justice were made subservient to them. Practically they became independent sovereigns, and to make their victory more complete serious restraints were laid upon the freedom of the towns. Before this date King Henry had begun to take a personal part in the government and was already involved in a quarrel with Otto II., duke of Bavaria. He disliked the Privilege of Worms and, favouring the towns against the princes, his policy was diametrically opposed to that of the emperor; however, in 1232 he went to Italy and promised to obey his father's commands. But in 1234, at a time of great and increasing disorder in Germany, he rebelled; he appealed publicly to the princes for support, gained some followers, especially in his own duchy of Swabia, and made an alliance with the Lombard cities. Confident of his strength Frederick entered Germany with a few attendants in the middle of 1235, and his presence had the anticipated effect of quelling the insurrection; Henry was sent a prisoner to Italy and disappeared from history. Then, in Aug. 1235, amid surroundings of great splendour, the emperor held a diet at Mainz, which was attended by a large number of princes. This diet is very important in the legal history of Germany, because here was issued that great "land peace" *(Landfrieden)* which became the model for all subsequent enactments of the

kind. By it private war was declared unlawful, except in cases where justice could not be obtained; a chief justiciar was appointed for the empire; all tolls and mints erected since the death of Henry VI. were to be removed; and other provisions dealt with the maintenance of order.

In 1236, during another short stay in Germany, Frederick led the imperial army against Frederick II., duke of Austria, who had defied and overcome his representatives; having taken possession of Vienna and the Austrian duchies he there secured the election of his son Conrad, who had already succeeded his brother as duke of Swabia, as king of the Romans (May 1237). But in spite of these imposing displays of power the princes looked with suspicion upon an emperor who was almost a stranger to their country and who was believed to be a renegade from their faith, and soon after Frederick's return to Italy the gulf between him and his German subjects was widened by his indifference to a great danger which threatened them. This came from the Mongols who ravaged the eastern frontiers of the country, but the peril was warded off by the efforts of Henry II., duke of Silesia, who lost his life in a fight against these foes near Liegnitz in April 1241, and of Wenzel I., king of Bohemia.

The emperor's attitude with regard to the Mongol invasion is explained by events in Italy, where Frederick was engaged in a new and, if possible, a more virulent struggle with the Lombard cities and with Gregory IX. As usual, the course of politics in Germany, which at this time was ruled by King Conrad and by the regent Siegfried, archbishop of Mainz (d. 1249), was influenced by this quarrel. Frederick of Austria had allied himself with Wenzel of Bohemia, and spurred on by the papal emissary had tried to set up a rival king; but both the Danish and the French princes who were asked to accept this thankless position declined the invitation, and Frederick and Wenzel made their peace, the former receiving back his duchies. After the defeat of the Mongols, however, there was again the danger of a rebellion based upon a union between the princes and the pope. Siegfried of Mainz deserted his master, and visiting Germany in 1242 Frederick found it necessary to purchase the support of the towns by a grant of extensive privileges; but, although this had the desired effect, Conrad could make but little headway against the increasing number of his enemies. At last the papacy found an anti-king. Having declared Frederick deposed at the council of Lyons in 1245, Gregory's successor, Innocent IV., induced a number of princes to choose as their king the landgrave of Thuringia, Henry Raspe, who had served as regent of Germany. This happened in May 1246, and the conduct of the struggle against the *Pfaffenkönig*, as Henry was called, was left to Conrad, who was aided by the Bavarians, until Feb. 1247, when the anti-king died. The papal party then elected William II., count of Holland, as Henry Raspe's successor, and during the state of anarchy which now prevailed in Germany the emperor died in Italy in Dec. 1250.

Upon his father's death Conrad IV. was acknowledged by many as king in Germany, but in 1251 he went to Italy, where he was fully occupied in fighting against the enemies of his house until his death in May 1254. The struggle to maintain the position of the Hohenstaufen in Italy was continued after this event; but in Oct. 1268, by the execution of Conrad's son Conradin, the family became extinct. After Conrad's death William of Holland received a certain allegiance, especially in the north of the country, and was recognized by the Rhenish cities which had just formed a league for mutual protection — a league which for a short time gave promise of great strength and usefulness. In Jan. 1256, however, William was killed, and in the following year there was a double election for the German Crown, Alphonso X., king of Castile, a grandson of Philip of Swabia, and Richard, earl of Cornwall, brother of Henry III. of England, being each chosen by parties of electors. Neither obtained permanent recognition in Germany.

Expansion and **Disunion.**—The 13th century saw a notable expansion of Germany. Prussia was occupied by the knights of the crusading Teutonic order, and the allied Knights of the Sword pushed farther east into Courland and Livonia. Yet it was in this age that the German people lost the possibility of political unity. The dissolution of the ancient duchies had given virtual independence to a great number of counts, barons and ecclesiastics of different rank and power. During the war between Otto IV. and Philip there was much encroachment upon the lands and prerogatives of the Crown, and the pre-occupation of Frederick II. with Italian affairs prevented him from asserting any effective power in Germany. In 1220 he formally confirmed the spiritual princes in their usurpations; 11 years later he granted still more extensive advantages to the princes both spiritual and secular, and these formal concessions were the legal basis of the independence of the princely class. Frederick's immediate successors could not exercise any real authority, and they lost control over the border countries which had hitherto been dependent on or connected with Germany. Denmark and Poland thenceforward rendered no homage to the German king. Nevertheless the disunion of Germany should not be regarded as an unmixed evil. It was only in small countries, such as England, that effective centralization could be established under mediaeval conditions. Germany was far too large to be governed as a whole, and premature attempts in this direction could only lead to anarchy. Against the dreary tale of local wars which fills much of German history should be set the impulse given to architecture, art, letters and education by princes who tried to earn reputation by the patronage which they gave to artists and scholars.

The period from the death of Conrad IV. to the election of Rudolph of Habsburg in 1273 is generally called the Great Interregnum, and it was used by the princes to extend their territories and to increase their authority.

Until this time the territories of a prince were rarely divided among his descendants, the reason being that, although the private fiefs of the nobles were hereditary, their offices — margrave, count and the like — were in theory at the disposal of the king. There was now a tendency to set this principle aside. Otto II., duke of Bavaria, a member of the Wittelsbach family, had become by marriage ruler of the Rhenish Palatinate, and after his death these extensive lands were ruled in common by his two sons; but in 1255 a formal division took place and the powerful family of Wittelsbach was divided into two branches. About the same time the small duchy of Saxony was divided into two duchies, those of Wittenberg and Lauenburg, and there were similar divisions in the less important States. It was thus practically settled that the offices and territories, as well as the private fiefs, of the princes were hereditary, to be disposed of by them at their pleasure. The process of division and subdivision which steadily went on broke up Germany into a multitude of principalities.

Rudolph of **Habsburg.**—The end of the interregnum was brought about by the pope, who realized the necessity for some central power which could protect the interests of the Church in Germany. In Sept. 1273, at the instigation of Pope Gregory X., the electors raised to the throne a Swabian noble, Rudolph, count of Habsburg. The situation on the eastern border was critical, owing to the power and aggressive policy of Ottakar II., king of Bohemia (*q.v.*). The victory won by Rudolph over Ottakar at Diirnkrut (Aug. 1278) for a time saved eastern Germany from disintegration. By the annexation of all Ottakar's possessions except Bohemia, Rudolph became one of the chief territorial princes in the empire, and his energies were largely spent in providing for the interests of the family of which he was the head. He has often been called the restorer of the German kingdom, but he has little real claim to this title. He had all the sympathies and prejudices of the noble class, and his policy of territorial aggrandizement was perhaps justified by the condition of the German kingdom, the ruler of which had little strength save that which he derived from his hereditary lands. Four years after the fall of Ottakar Rudolph obtained from the princes a reluctant assent to the granting of Austria, Styria and Carniola to his own sons, Rudolph and Albert. In 1286 Carinthia was given to Meinhard, count of Tirol, on condition that when his male line became extinct it should pass to the Habsburgs. If Rudolph was not the restorer of the empire, he was the real founder of the house of Habsburg.

On Rudolph's death the electors, fearing the new power which

he had founded, passed over his son Albert and elected Adolph, count of Nassau (July 1291). Like his predecessor, Adolph wished to secure an extensive territory for his family. Meissen, which he claimed as a vacant fief of the empire, and Thuringia, which he bought from the landgrave Albert II., seemed to offer a favourable field for this undertaking, and he spent a large part of his short reign in a futile attempt to carry out his plan. Naturally he sought to isolate Albert of Habsburg, who was treating with Philip of France, and this led to an alliance with Edward I. of England. But many of the princes were disgusted with him and at Mainz in June 1298 he was declared deposed. He resisted the sentence, but Albert of Habsburg, who had been chosen his successor, marched against him, and in July 1298, at Gollheim near Worms, he was defeated and killed.

After Adolph's death Albert was again chosen German king, and was crowned at Aix-la-Chapelle in Aug. 1298. Like his father Rudolph, the new king made it the principal object of his reign to increase the power of his house, but he failed in his attempt to add Bohemia and Thuringia to the hereditary lands of the Habsburgs, and he was equally unsuccessful in his endeavour to seize the countries of Holland and Zealand as vacant fiefs of the empire. In other directions he was more fortunate. He recovered some of the lost crown lands and sought to abolish new and unauthorized tolls on the Rhine; he encouraged the towns and took measures to repress private war; he befriended the serfs and protected the persecuted Jews. His greatest danger came from a league which was formed against him in 1300 by the four Rhenish electors, who disliked his foreign policy and resented his action with regard to the tolls. Albert, however, supported by the towns, was victorious; and the revolting electors soon made their peace.

After Albert's murder in May 1308, Henry, count of Luxembourg, a brother of Baldwin (1307–1354), archbishop of Trier, became king as Henry VII. Although fortunate enough to obtain for his son John the crown of Bohemia, the aggrandizement of his family was not the main object of this remarkable sovereign, the last German king of the old, ambitious type. His interest was not in his territory but in the empire; from the beginning of his reign he looked forward to securing the Lombard and imperial crowns. His purpose to cross the Alps at the head of a great force was hailed with delight by the Ghibellines, whose aspirations found utterance in Dante's noble prose, but his life was too short for him to fulfil the hopes of his friends. In the autumn of 1310 he went to Italy, and remained there until his death in Aug. 1313. As in former times, the Italian interests of the emperor meant a weakening of royal authority in Germany and Henry's expedition produced some of the difficulties which confronted his successor, Louis of Wittelsbach.

Louis IV.—His son, John king of Bohemia, was under age in 1313. After a year's delay there was a double election to the empire when the larger party chose Louis IV., duke of Upper Bavaria, and the smaller party chose Frederick, duke of Austria, the son of the emperor Albert I. After a war of eight years, Frederick was defeated at Miihldorf in Sept. 1322. The success of Louis was to some extent due to the imperial cities, which supported him from the first. But he was perhaps still more indebted for his victory to the outbreak of war between the Swiss and the Habsburgs. The position of the Habsburg family was sensibly weakened by the defeat of Leopold of Austria at Morgarten in 1315, and thus this struggle for freedom, although belonging properly to the history of Switzerland, exercised much influence on the course of German history. The long reign of Louis has a distinctive character owing to a conflict with the papacy which lasted until the emperor's death. The nature of the struggle is described in the article PAPACY. Here it need only be noted that Louis, unlike earlier emperors, was supported by the great body of the German princes, lay and ecclesiastical, in his resistance to the papal claim to supremacy. In asserting the independence of the empire he could rely on a national feeling which was intensified by the general opinion that the pope, now established at Avignon, was using his position in the interest of the French Crown. The most significant incident in the struggle is the definite assertion by the diet at Frankfurt in 1338 that the imperial power proceeded from God alone and that an emperor, duly elected, needed no papal confirmation. For the moment, it seemed as if the new national consciousness of Germany might find expression in the empire. Nevertheless the reign of Louis was not marked by any serious attempt at centralization. Louis, like the Habsburg emperors before him, put the interests of his house before other considerations, and before the end of his reign his family policy had brought a majority of the princes into opposition to him. In July 1346, five of the electors met, and, having declared Louis deposed, they raised John's son Charles, margrave of Moravia. to the German throne. For a time no serious steps were taken against Louis, but after King John had met his death at Crécy Charles, who succeeded him as king of Bohemia, began to make vigorous preparations for war, and only the sudden death of the emperor (Oct. 1347) saved Germany from civil strife.

In 1349 Charles of Moravia, son of King John of Bohemia, obtained recognition as king of the Romans. His reign is important in the history of Bohemia (*q.v.*). In the empire his chief achievement was the issue of the Golden Bull (*q.v.*). Apart from this, the true interest of the reign lies in the movements beyond the range of the emperor's influence. It is significant that at this time the Femgerichte, or Fehmic Courts (*q.v.*), vastly extended the sphere of their activities, and that in the absence of a strong central authority they were respected as a check upon the lawlessness of the princes. The cities, notwithstanding every kind of discouragement, formed new associations for mutual defence or strengthened those which already existed. The Hanseatic League carried on a successful war with Valdemar, king of Denmark. and his ally, the king of Norway, while its commerce extended to nearly all parts of the known world. In 1376 some Swabian towns formed a league which, in spite of the imperial prohibition, soon became powerful in south-west Germany and defeated the forces of the count of Wurttemberg at Reutlingen in May 1377. Meanwhile, the emperor who, unlike his predecessor, avoided conflict with either the papacy or the princes, was steadily increasing the power of his house. When he died in Nov. 1378, he wore the crowns of the empire, of Germany, of Bohemia, of Lombardy and of Burgundy; he had added Lower Lusatia and parts of Silesia to Bohemia; he had secured the mark of Brandenburg for his son Wenzel in 1373; and he had bought part of the Upper Palatinate.

After the death of Charles, his son Wenzel, who had been crowned German king in July 1376, was recognized by the princes as their ruler. His reign is marked by a confused struggle between the German towns and princes in which the emperor was unable or unwilling to take any consistent part. In the struggle the towns were driven to form associations for mutual support, which anticipate the greater town leagues of the next century (see SWABIAN LEAGUE).

Towards the close of the century the discontent felt at the incompetent and absent German king took a decided form. The movement was led by the four Rhenish electors, and after some preliminary proceedings these princes met in Aug. 1400; having declared Wenzel dethroned they chose one of their number, the elector palatine Rupert III., in his stead. Rupert was an excellent elector, and under more favourable circumstances would have made a good king, but so serious were the jealousies and divisions in the kingdom that he found little scope for his energies outside the Palatinate. Having secured a certain amount of recognition in the south and west of Germany, the new king turned aside from the pressing problems of government and in 1401 made a futile attempt to reach Rome. After his return to Germany he had to face the hostility of many of the princes, and this contest, together with vain attempts to restore order, occupied him until his death in May 1410.

Sigismund.—His successor, Sigismund, king of Hungary, is the most interesting figure among the emperors of the later middle ages. He played a part in all the movements of his time—the crusade against the Turks, the reform of the Church, the creation of territorial principalities in Germany. The religious rising in Bohemia which developed into the Hussite war (*see* HUSSITES)

distracted Sigismund's attention from Germany, into which the war often extended. It was an unfortunate distraction, for Sigismund had many of the qualities of a radical reformer, and under other circumstances would have done much to adapt the imperial constitution to the conditions of his time. As it was, the part which he played in the history of the council of Constance gave to the empire a prestige which had not belonged to it since the interregnum. In all his plans for the well-being of the empire Sigismund relied on the support of Frederick of Hohenzollern, burgrave of Nuremberg, and made a permanent impression on German history by establishing his ally in the mark of Brandenburg (1415). But the persistent opposition within Gesmany to any schemes of imperial centralization compelled Sigismund to concentrate on his territorial interests, and his historical importance lies in the fact that he is the real creator of the dominion which when inherited by the house of Habsburg, gave a new significance to the imperial title.

Sigismund, who died in Dec. 1437, was succeeded on the German throne and also in Hungary and Bohemia by his son-in-law Albert of Austria, and from his time, although remaining in theory elective, the German crown was always conferred upon a member of the house of Habsburg until the extinction of its male line in 1740. The reign of Albert II. was short. Like the electors he observed neutrality in the dispute between the council of Basle and Pope Eugenius IV., and he put forward a scheme to improve the administration of justice. He died in Oct. 1439, and was succeeded by his kinsman Frederick, duke of Styria, who in 1452 was crowned at Rome as the emperor Frederick III.

The importance of Frederick's reign lies in the steady disintegration of Germany. In the west, the dukes of Burgundy were steadily consolidating their dominion at the expense of the empire, and the Swiss were achieving virtual independence. In the east the Teutonic order was losing ground against the Poles, and in the north Schleswig and Holstein fell under Danish rule. In Germany itself the greater families such as the Hohenzollerns and Wittelsbachs were turning their possessions into territorial principalities and Frederick himself followed their example. Despite all discouragements, he foresaw the great destiny which lay before his house, and he did much to turn his dreams into reality by securing the marriage of his son Maximilian with the heiress of the Burgundian dukes. To this obscure emperor the later Habsburgs owed the territories on the western border of Germany which gave them for centuries a unique influence in European politics.

Maximilian I.—Maximilian, Frederick's son, came to the throne in 1486 with exceptional advantages. He was heir to the extensive Austrian lands, and as the widowed husband of Charles the Bold's daughter Mary he administered the Netherlands. Although he soon gave up these provinces to his son Philip, the fact that they were in the possession of his family added to his influence, and this was further increased when Philip married Joanna, the heiress of the Spanish kingdoms. From Maximilian's accession the empire exercised in the affairs of Europe an authority which had not belonged to it for centuries.

The reign of Maximilian I. is important in many ways. The emperor himself is an interesting figure, erratic and ambitious, but intelligent, and fully aware of the contrast between his imperial position and his actual resources. His reign coincides with a strong movement among the princes for constitutional reform, led from within the electoral college by Bertold, archbishop of Mainz. Maximilian, in fact, was the first emperor to be confronted with a constitutional programme. Naturally he had no sympathy with the limitation of imperial authority implied by the plan proposed by Bertold and his adherents. Nevertheless the changes which were made in his time had great influence on the later imperial constitution (see EMPIRE; DIET; IMPERIAL CHAMBER) and in a sense the modern history of the empire begins with him. In the history of Germany his importance lies in his resistance to the French claim to the provinces which had formed part of the Burgundian dominion. In this he was only carrying out his father's dynastic policy, and he had little support from other German princes. Few at the time realized that the integrity of Germany was at stake in the struggle which Maximilian maintained with very slender resources.

In many respects the reign of Maximilian must be regarded as the end of the middle ages. The feudal relation between the king and the princes and between the princes and their vassals had become purely nominal. No real control was exerted by the Crown over the heads of the various States, and, now that war was carried on mainly by mercenary troops, the mediate nobles did not hold their lands on condition of military service. The princes were sovereigns, not merely feudal lords; and by the institution of local diets in their territories an approach was made to modern conceptions of government. The age of war was far indeed from being over, but men were at least beginning to see that unnecessary bloodshed is an evil, and that the true outlet for the mass of human energies is not conflict but industry. By the growth of the cities in social, if not in political, importance the products of labour were more and more widely diffused; and it was easier than at any previous time for the nation to be moved by common ideas and impulses. Many causes contributed to effect a radical change in the point of view from which the world was regarded; and the strongest of all mediaeval relations, that of the nation to the Church, was about to pass through the fiery trial of the Reformation. This vast movement in the later years of Maximilian definitely severed the mediaeval from the modern world.

The Reformation.— The seeds of the Reformation were laid during the time of the great conflict between the papacy and the empire. During the struggle of Louis IV. with the popes of his day the feeling revived with fresh intensity. At the same time the spiritual teaching of the mystics awakened in many minds an aspiration which the Church, in its corrupt state, could not satisfy, and which was in any case unfavourable to an external authority. The Hussite movement further weakened the spell of the Church. Still more powerful, because touching other elements of human nature and affecting a more important class, was the influence of the Renaissance, which, towards the end of the 15th century, passed from Italy to the universities of Germany. The men of the new learning did not sever themselves from Christianity, but they became indifferent to it; its conceptions seemed to them dim and faded, while there was a constantly increasing charm in literature, in philosophy and in art. No kind of effort was made by the Church to prepare for the storm. At last Leo X., by his incessant demands for money and his unscrupulous methods of obtaining it, awakened universal hostility.

The popular feeling for the first time found expression when Luther, on All Saints' day 1517, nailed to a church door in Wittenberg the theses in which he contested the doctrine which lay at the root of the scandalous traffic in indulgences carried on in the pope's name by Tetzel and his like. This episode, derided at first at Rome as the act of an obscure Augustinian friar intent on scoring a point in a scholastic disputation, was in reality an event of vast significance, for it brought to the front, as the exponent of the national sentiment, one of the mightiest spirits whom Germany has produced. Under the influence of Luther's strong personality the most active and progressive elements of the nation were soon in more or less open antagonism to the papacy.

HISTORY FROM 1519 TO 1648

Charles V.—Maximilian died in Jan. 1519. After a long contest for the succession between his grandson, Charles I. of Spain and Francis I. of France, the former was elected in June, 1520, and in the following October was crowned at Aachen as the Emperor Charles V. The religious conflict had reached a critical stage, the bull of excommunication against Luther having just been published in Germany. Some of the Reformers cherished a hope that the new emperor's policy might be to act as a mediator for peace, not unfavourable to their leader. But though Charles showed later that he would not hesitate to oppose the pope in the sphere of politics, he held that he owed him entire allegiance in that of faith, and the protection of the Church had always been regarded as a chief function of the emperors. Moreover the peoples under his direct sway were adherents of the old faith. He was king of Spain, Naples, Sicily and Sardinia, lord of the

Netherlands, the county of Burgundy and the Austrian archduchies and of the new lands beyond the Atlantic—by far the most important ruler of his time. He hoped to add north Italy to his dominions, and this was another motive for standing well with the Holy See. It was not surprising therefore that at the diet of Worms, in Jan., 1521, he issued the edict drawn up by Cardinal Aleandro denouncing the reformer. This was accepted by the diet, and Luther was placed under the ban of the empire.

At his election Charles had been required to accept a *Wahlkapitulation* (electoral agreement) embodying the conditions on which he was to receive the crown—a precedent followed at subsequent elections. This was confirmed by the diet. Charles, regarded as a foreigner by the princes, undertook to respect the ireedom of Germany, use the German language and convene the diets on German soil. He was not to bring foreign troops into Germany or place German troops under foreign command. An administrative council, the *Reichsregiment* (State board of control) was to be set up, and after some debate between Charles and the princes it was settled that it should consist of 22 members with a president nominated by the sovereign. It was to govern Germany in his absence; at other times its functions would be only advisory. There was an undertaking to aid the emperor by raising and paying an army. In April, 1521, Charles invested his brother Ferdinand (afterwards emperor) with the Austrian archduchies and then left Germany to deal with disturbances in Spain and renew his struggle with Francis I.

The Civil Wars.—Serious trouble arose in his absence, making Germany the scene of civil wars. There the *Ritterschaft*, the knighthood of the empire, were a discontented class, which had suffered by the substitution of Roman law for the old feudal law, under which they were tenants-in-chief of the crown. They had now no share in government, and the suppression of private wars had deprived them of active employment. Two of their leaders, Ulrich von Hutten and Franz von Sickingen, had become supporters of Luther, hoping the coming changes in Germany would improve their position. Hutten held that there could be no reform in church and state while the country was divided into a number of small princedoms, and he planned a revolution to be effected with the help of Sickingen, who had got together a small army, with which in Aug., 1522, he besieged Trier (Treves), the city of a prince archbishop and elector of the empire. The place made a good defence, and on the approach of an army levied by the princes the siege was abandoned. The revolt ended with the defeat and death of Sickingen at Landshut in May, 1523. Hutten, broken in health, took refuge in Switzerland, where he died a few weeks later. Luther and his friends had stood apart from the movement, though the knights had proclaimed the freedom of Germany from papal influence as one of their aims.

A more serious revolt was the rising in south and central Germany known as the Peasants' War (Bauernkrieg). The small farmers and peasants had real grievances, partly the outcome of changing economic conditions, but largely of the grasping policy of the princes and great landowners. Like the knights, they had lost many of their traditional feudal privileges by the introduction of the new system of Roman law. In many districts there were obstacles to migration and re-settlement which led to their small holdings being subdivided till, with an increasing population, they became too small to support a peasant family. Since 1461 there had been a recurrence of minor local outbreaks. The first movements of a rising on a wide scale took place in 1522 while the revolt of the knights was still in progress. As in former movements the standard of revolt was the Bundschuh, a peasant's clog upon a pole. As the rising spread many knights and adventurers joined the peasants, and they found friends among the poorer workers of the towns. A new feature of the revolt was that the rebels put forward a religious as well as a social programme, one of their claims being that each village should elect its pastor. There were appeals also to scriptural prophecies interpreted to predict the coming of a new era of freedom and prosperity. Some of the lords granted the more moderate claims of the peasants, amongst these peace-makers being the elector palatine, the bishops of Bamberg and Speyer and the abbots of Fulda and Hersfeld. Luther wrote a pamphlet warning the princes that their oppression had caused the rising, and that the reasonable claims of the peasants should be granted, but telling the latter that their grievances did not justify their violence, and they should negotiate for peace. Meanwhile the rising spread along the Rhine and across the Main into Thuringia. It was not till the summer of 1525 that the war ended, and ended in disaster for the rebels. After their first successes they had indulged in reckless outrages on life and property, and the princes, when their forces got the upper hand, wreaked a ferocious vengeance on them. Luther encouraged these reprisals in a pamphlet "On the Murderous Peasant Hordes," urging that the rebels deserved no mercy.

Rival Forces in the Diets.—During the civil wars the *Reichsregiment* had proved an inefficient organ of government, soon to disappear from German history. Meeting at Nuremberg in 1522, it had voted supplies for defence against the Turks, but many of the cities resisted its levy of taxes, and on an appeal to Charles its scheme was vetoed. It had left to a group of princes the suppression of the revolts. It had declined to enforce the edict of Worms, and a new meeting of the diet only ventured to direct that it should be enforced "if possible." The party of the reformers was gaining ground and had the support of several of the princes. There was much secularization of church property, suppression of monasteries and the introduction of the Lutheran service in numerous churches. A notable event of 1525 was the action of Albert of Hohenzollern, grand master of the Teutonic order, who, supported by most of its knights, declared for Luther, secularized the property of the order and made himself the personal ruler of its territory between Poland and the Baltic—a first step towards the building up of the future Prussian kingdom. All over Germany men were falling into line on one side or the other of the religious conflict. Charles vetoed a proposal for a national assembly to decide the questions at issue. The Catholics under the archduke Ferdinand and Cardinal Campeggio met at Regensburg to concert measures against Lutheranism, while on the other side assemblies at Speyer and Ulm declared their intention of forwarding the teaching of the new doctrines. In 1525 the Catholic princes formed a defensive league at Dessau, and the reformer princes took a similar step next year at Gotha.

In the diet that met at Speyer in June 1526 the reformers were the stronger party. A message from Charles in Spain, calling on the diet to forbid innovations and enforce the edict of Worms, was rejected, on the ground that when the emperor wrote it, three months earlier, he and the pope were at peace, but were now at war. The diet decreed that pending a national council each prince should regulate the religious affairs of his own dominions. After this wherever the reformers were in power—notably in Saxony, Brandenburg, Hesse and the Palatinate, and in Strassburg, Niirnberg, Ulm and Augsburg—the religious changes went forward. But when the diet met again three years later at Speyer under the presidency of the archduke Ferdinand, the Catholic party was stronger, and a message from Charles required the repeal of the decree of 1526. But the Catholics were anxious for a truce, and with the approval of Melanchthon, who was also striving for peace, secured the adoption of a decree that until a Council met the reformers should abstain from further changes, but that in their states the Catholic minority should have freedom to practise their religion. Philip of Hesse with four other princes and the delegates of several cities protested against any limitation of their powers, and declared their resolve to disobey the decree. Melanchthon wrote of this rejection of the *modus vivendi* as "a terrible affair." The protest was the origin of the new name of "Protestant," soon applied to and accepted by the reformers.

Charles V., having this year made peace with the Pope and Francis I., was crowned by Clement VII., at Bologna in Feb. 1530, and then went to Germany to make a personal effort to settle its troubles. The Protestant forces were now divided by the conflict between the Lutherans and the followers of the Swiss reformer Zwingli, whose influence extended to the south German cities. In June, 1530, the diet was convoked at Augsburg. By the emperor's invitation, as a basis for discussing a religious peace, the Lutherans presented a statement of their position, drawn up by Melanchthon, its articles accentuating points of agreement with the Catholics and dealing cautiously, and even vaguely, with

points of controversy. It is known as the "Confession of Augsburg," and forms still the confession of faith of the Lutheran Evangelical Church. It led to long debates which ended, as was to be expected, in failure to effect an agreement. Four of the Zwinglian cities at once protested against it. Numbers of the Lutherans themselves denounced its guarded statements. A conference between Catholic and Lutheran theologians only accentuated points of vital difference. Several of the Lutheran princes and their friends left Augsburg. In November the diet ended with a decree issued by Charles giving the Lutherans till the following April, to reconsider their position, calling for submission to a settlement, and leaving it to the imperial courts to insist on the restoration of confiscated Church property, and referring to the hope of a final peace being effected by a General Council.

In Jan. 1531 at Cologne Charles secured the election of his brother, the archduke Ferdinand, to the dignity of king of the Romans, which implied succession to the empire. Meanwhile Ferdinand would act as his representative in Germany instead of the discredited *Reichsregiment*. In April the Lutheran leaders formed at Schmalkalden in Hesse the defensive alliance known as the "League of Smalkald," which was joined by nine princes and eleven cities. It entered into relations with Denmark, the Zwinglians of Switzerland and the emperor's rival Francis I. Tension with France and the Turkish peril made the emperor hesitate to go to extremes. The latter danger was serious. The Turks had conquered Serbia and overrun Hungary, and only an outbreak of pestilence in their army had saved Vienna. Early in 1532 the emperor convoked a diet at Regensburg. The Lutherans absented themselves, and though the Catholics voted supplies for the Turkish war they opposed the emperor's policy of concessions to their opponents. Charles then entered into direct negotiations with the Protestant princes, which resulted in July in "the peace of Nuremberg," granting temporary toleration to the Lutherans, which was renewed in the following years. His reward was immediate and substantial. His subjects vied with each other in hurrying soldiers to his standard and the advancing Turkish army was soon in full retreat.

Internal Affairs of Germany. — Protestantism now made considerable progress especially in Anhalt and Pomerania, and thanks chiefly to the energy of Philip of Hesse, and the support of Francis I., the Lutheran claimant to Wiirttemberg, Duke Ulrich, was forcibly restored to his duchy. Ferdinand found himself obliged to recognise the restoration and to promise that he would stop all proceedings of the imperial courts against the members of the Smalkald League. Other events were less favourable to the supporters of the new religion. The mad outbreak of the fanatical Anabaptists at Miinster, though suppressed, caused widespread alarm, and there was an abortive attempt at a revolution by the extremists at Liibeck. A renewal of the war between the empire and France in 1536 was followed by an enlargement of the League of Smalkald and its prolongation for ten years. Amongst its new members was Christian III. of Denmark. About the same time Bucer arranged the friendly agreement between the Lutherans and Zwinglians, known as the concord of Wittemberg (May 1536). Thus strengthened the Protestant princes declared against the proposed General Council at Mantua. In June 1538 the Catholic princes formed a new defensive alliance, the League of Nuremberg, but though he had made a truce with France in this same month Charles was more conciliatory towards the Protestant princes than some of his supporters, and in April, 1539 he came to terms with them, without, however, granting all their demands. This year the Lutheran Prince Henry succeeded his Catholic brother as duke of Saxony. Ducal and electoral Saxony were thus won to the Protestant party, and with its gains under the elector Joachim II. in Brandenburg, it was now practically dominant throughout North Germany.

In 1542 Charles was again involved in war with both France and Turkey, and the League of Smalkald took advantage of his troubles to expel its opponent Henry, duke of Brunswick-Wolfenbiittel, from his duchy and establish Protestantism therein. The citizens of Regensburg declared for Lutheranism, and Hermann von Wied, prince archbishop of Cologne, and William, duke of Gelderland, announced their secession from Rome. The Protestants were now at the height of their power, but their ascendancy was soon to be destroyed more by their own division and the folly and imprudence of their leaders than by the skill and valour of their foes. The unity and power of the League of Smalkald was undermined by dissensions between John Frederick, the ruler of electoral Saxony, and Maurice, who had succeeded Henry in ducal Saxony, and the bigamy of Philip of Hesse, carried through under a dispensation signed by Luther and several of his colleagues, made him many enemies and endangered his legal status, so that in June 1541 he saved himself by coming to terms with the emperor. Thus the League lost its most important leader. In 1543 it looked on helplessly while Charles crushed Duke William of Gelderland and added his duchies to the lands of the Habsburgs. Charles, however, hesitated to make a general attack on the Protestants, and in accordance with the promises made in 1539 at Frankfurt, arranged conferences between the two religious parties, which, however, gave no result. The diets held at Regensburg and Nuremberg failed to give any solution of the religious question, and made grudging votes for the war; but at the diet of Speyer in 1544 lavish promises to the Protestants obtained supplies with which a new army was placed in the field. In September of that year Charles concluded the treaty of Crépy with Francis I. and had his hands free to deal with the affairs of Germany.

Victory of Charles. — Charles was influenced by political even more than religious considerations. He regarded Protestantism as a movement that had divided and disorganised Germany, and endangered both the system of the empire and the supremacy of the Habsburgs. He now meant to break up the League, and at the same time use his influence for the convocation of a General Council, which would deal with the abuses of discipline that had weakened the Catholic Church. Pope Paul III., not without hesitation, summoned the Council which met at Trent in Dec. 1545, and Charles prepared for war. He made peace with Turkey, and secured the neutrality of Bavaria and the support of Maurice of Saxony. He detached from the League those who were too timid or too lacking in zeal to face a conflict. Meanwhile its members were divided in policy, and neglected war preparations in the hope that another religious truce would be patched up. Luther, lamenting in his last days the Protestant divisions, died at Eisleben on Feb. 18, 1546. It was not till the diet met at Regensburg in June that a group of the Protestant princes, headed by Philip of Hesse, and John Frederick, the ruler of electoral Saxony realised the peril and at last began preparations for defence. In July they were placed under the ban of the empire and war began in the south. Charles had brought reinforcements from Italy and the Netherlands. Several cities, with Ulrich of Wiirttemberg and the elector Palatine submitted to him. The Leaguers were forced northwards from Saxony along the Elbe valley. At Miihlberg on April 24, 1547, Charles forced the crossing of the Elbe with hardly a show of resistance, and scattered the army of the League. John Frederick was taken prisoner and Philip of Hesse soon after surrendered.

Maurice was rewarded by the Saxon electorate being added to his duchy; more than one of the Lutheran princes hastened to court the conqueror's good will; and Charles met the diet at Augsburg in Sept. 1547 confident in his power to remodel German affairs.

But his over-confidence led to mistakes of policy. The princes evaded his chief demands by prolonged debate, and were soon encouraged by news that he was quarrelling with the pope over the proposed removal of the Council from Trent (in the empire) to Bologna (in the Papal States). Charles imagined he could settle the religious question himself. He proposed the acceptance of a compromise set forth in a decree known as the "Interim," as it was to be in force till the decisions of the Council were known. His critics, both Protestant and Catholic, spoke of it as "the Interim religion." Only a minority of both parties were ready to accept it. He did not satisfy either earnest Lutherans or orthodox Catholics, by slurring over points of difference in vague formulae.

Revolt of Maurice of Saxony. — Maurice of Saxony began

to prepare to change sides once more. He built up a secret alliance with several of the Lutheran princes and obtained promises of help from Henry II. of France, with whom a secret treaty was signed in Jan. 1552. Charles was off his guard when the storm suddenly burst in March. Henry II. invaded Western Germany, declaring he came as the defender of German freedom. Maurice seized Augsburg, and with his friends marched on Innsbruck, where the emperor was residing. Charles fled across the Brenner, and in May negotiations were opened with the revolted confederates, and by July the peace of Passau was arranged. Charles set at liberty John Frederick and Philip of Hesse, and agreed that the Lutherans should have full religious liberty.

Maurice then went to help Ferdinand against the Turks, but his ally, Henry II. of France, continued the war against Germany. He had seized Metz, and Charles failed in an attempt to recover it. Another of Maurice's allies, Albert of Brandenburg, after "living on the country" in Franconia, was for awhile with the emperor's army against France, and then resumed his bandit raids, which became such a terror that a league of the princes, formed by Maurice, united in driving him out of Germany Maurice iost his life in this campaign.

The Peace of Augsburg.—In Feb. 1555 the diet met at Augsburg to settle a final peace on the general basis of the treaty of Passau. Ferdinand presided for his brother. It was agreed that Catholics and Lutherans should be placed on an equal footing in the empire but Calvinists were excluded by both parties from this settlement. The Lutherans were to retain all church property they held at the date of the peace of Passau. But the peace of Augsburg did not really establish either religious freedom or individual toleration. The principle of State supremacy—*cuius* regio *eius* religio—was accepted.

The treaty was published in Sept. 1555. Charles had left the settlement entirely to his brother. His health was failing, he was tired of the troubled affairs of Germany, and anxious chiefly to consolidate his Spanish dominions in the hands of his son Philip (now the husband of Mary Tudor). He abdicated, in January 1556, entrusting Spain, the Netherlands and his oversea empire to Philip, while Ferdinand took over the conduct of German affairs, though it was not until after the death of Charles (1558) that he was formally installed as emperor.

Ferdinand I.—During his short reign Ferdinand I. devoted himself to enforcing the peace of Augsburg. War with the Turks went on till 1562, and he had to deal with local troubles in Hungary, Bohemia and north Germany. Efforts were made, with no result, to compose the growing differences among the Protestants. In his Catholic dominions he supported the reforms decreed at Trent in matters of ecclesiastical discipline. The Catholics were now gaining ground thanks largely to the reforms in clerical training ordered by the Council, and the missionary and educational work of the Jesuits. Before Ferdinand died in July 1564 the Counter-Reformation had begun. Some changes had been introduced in the empire. Lutherans now sat among the judges in the imperial courts; and the Aulic Council or *Hofrat*, established by Maximilian I. for the Austrian lands, extended its authority over the empire and was known as the Reichskojrat.

Ferdinand's son and successor, Maximilian II. (1564–1576), was a man of tolerant views, had even been at one time suspected of an inclination to Lutheranism. He secured his election by a declaration of fidelity to the old faith, but for awhile cherished optimistic but misleading dreams of effecting a peaceful religious reunion in Germany. His first diet at Augsburg in 1566 gave no encouragement to these hopes. The Catholics stood firmly for the decrees of Trent, and the Protestants gave new proof of their divisions by an attempt to exclude the Calvinist prince palatine, Frederick II. from the advantages of the peace of Augsburg. This led to Frederick and the Calvinists entering into closer relations with France and the Dutch Netherlands, while the Lutherans, now led by Augustus of Saxony, courted the friendship of the emperor. But even they were divided, while the Catholics were still gaining ground. Albert of Bavaria boasted that without force or strife most of his people had been won to the Catholic cause, The emperor now abandoned his reunion projects and was for awhile occupied with a Turkish campaign. The new diet at Speyer in 1570 was chiefly engaged in debates on the abuses resulting from the enlistment of Germans by foreign agents as mercenaries, but nothing practical was done. It is to Maximilian's credit that he tried to mediate between his cousin Philip II. and the revolted Netherlands. He was engaged in negotiations with a Polish party, which wished to elect him as King of Poland, when he died in October 1576.

Rudolph II.—He was succeeded by his son Rudolph II. (1576–1612). The drift of events during his long reign can be explained by noting as the chief factors the growing strength of the Catholics, not only in the Habsburg territories but also in south Germany and wide tracts of the Rhineland and Westphalia; the efforts of the Protestant leaders, now no longer prominent divines but politicians and princes, to obviate the divisions that weakened them, by sinking sectarian differences in a common alliance against the house of Habsburg, which they regarded as the chief protector of the Counter Reformation; finally the formation of opposing Catholic and Protestant leagues—the prelude to the Thirty Years' War. The first effort at a Protestant union was made in the very month of Rudolph's accession (Oct. 1576), when Augustus of Saxony drew up a moderately worded Lutheran profession of faith, the *Formula* Concordiae, which was accepted by a large number of princes and cities; but an influential minority refused it, and it only accentuated existing divisions. In the years that followed the Catholics secured not a few successes. An immigration of refugees from the Netherlands into north-west Germany led to troubles, and the local Catholic government was driven from Aachen in 1581. The Reichshojrat declared the movement a rebellion, but it was not till 1598 that Protestant worship was abolished at Aachen and the Catholic government restored. At Cologne in 1582 the prince archbishop, Gebhard von Truchsess, became a Calvinist, married and declared his intention to retain both his see and its territory. He was placed under the ban of the empire, and numbers of his subjects took up arms against him, aided by troops from Bavaria. This local conflict, the "War of Cologne," lasted for nearly five years. The Protestant princes stood neutral except John Casimir, a zealous Calvinist, with some military experience, who was acting as regent of the palatinate in the minority of his nephew. He gave some help to Gebhard, who was finally driven from his see and took refuge at Strassburg, where he instigated an unsuccessful rebellion. Meanwhile the Catholics succeeded in establishing their faith in several of the dioceses they had lost.

After the death of Augustus of Saxony there was another brief alliance of the Protestant princes, under the leadership of his successor Christian I. and of John Casimir. An opposition party was organised in the diet, but with little practical result, and the deaths of the two leaders in 1591–92 put an end to the alliance between Lutherans and Calvinists for a time. But in the diets held at Regensburg in 1593 the Protestant princes drew togethei-. Under the leadership of Christian prince of Anhalt they put forward demands for new concessions and in the latter assembly tried to hinder or delay the payment of subsidies for a new war with Turkey. In 1598 they advanced a theory that in the diet the decisions of a majority did not bind the minority, and in the diet of 1603 they asserted the same position, protested against various decisions of the Reichslzojrat and finally withdrew from the diet in a body. The war with Turkey lasted from 1593 to 1606, when peace was negotiated not by the emperor but by his brother Matthias, who, on account of Rudolph suffering from attacks of mental failure, had been declared head of the house of Habsburg. Rudolph resented this indignity and his relations with his brother were strained till his death in January 1612.

During the latter years of his reign the leader of the Catholic party in Germany was Maximilian, the duke of Bavaria. In 1607 he was given an imperial mandate to deal with a religious riot in the free city of Donauworth, and after suppressing it retained the city under his government. Alarmed by this arbitrary act, the Protestant princes formed, in 1608, the Evangelical Union, and in response the Catholics, led by Maximilian, united in a similar confederation, afterwards known as the Catholic League. As the

Union was headed by the Calvinist elector palatine, Frederick IV., many of the Lutherans were slack in supporting it, but it became very important by an alliance with Henry IV. of France, who was ready to profit by German quarrels and was interfering in a disputed accession to the duchies of Cleves and Julich. War between the two confederations on this question seemed imminent, but after the murder of Henry IV. in May 1610, the Union did not venture to fight.

The Thirty Years' War.—Rudolph II. was succeeded by his brother Matthias (1612–19). He had no children, and the Habsburgs selected as his heir the archduke Ferdinand of Styria. During the brief reign of Matthias the Union and the League jealously watched each other. It was a time of dangerous tension. Matthias died in March 1619, and in the following August the Habsburg archduke of Styria obtained the imperial crown as Ferdinand II. (1619–37). He had already practically eradicated Protestantism in his archduchy, and was determined to secure the triumph of his church in the empire. On his accession he found himself faced with troubles, troubles in his hereditary dominions, arid a serious crisis in Bohemia, the conflict which was the first phase of the Thirty Years' War. Its beginning is usually dated from the revolt of the Protestant nobles in Bohemia in 1618. There had since the days of Huss been a strong party in the kingdom opposed both to Rome and Vienna. When Ferdinand's accession was announced, the revolted Bohemians refused to acknowledge him and elected as their king, the elector palatine, Frederick V., a son-in-law of James I. of England. Ferdinand, on both dynastic and religious grounds, was determined to subdue the Bohemians. At first troubles in his other hereditary states made it difficult to take decisive action. But Spain promised help by invading the Palatinate, and early in 1620 it was arranged that Maximilian of Bavaria should send the army of the League under the famous Tilly to assist the emperor. Frederick received little help from the Protestant princes, most of the Lutherans disliking the alliance with a Calvinist leader. He had hoped for English support, but James I. went no further than allowing volunteers under Vere to take part in defending the Palatinate. Tilly marched into Bohemia and on November 8, 1620, routed Frederick's army in the decisive battle of the Weissenberg (the White Hill) near Prague. Frederick fled only to find Spinola's Spanish veterans and a Bavarian force overrunning the Palatinate, so that he was obliged to leave Germany. His hereditary lands were declared forfeit, and handed over to Maximilian. The war died down into mere desultory fighting against Frederick's only remaining adherents, Christian of Brunswick and Count Mansfeld.

The war blazed up again on a larger scale in 1623. The emperor's successes and the rising power of Maximilian of Bavaria alarmed the Lutheran princes, and a new Protestant combination was formed, of which the leading member was King Christian IV. of Denmark, who as duke of Holstein was a prince of the empire. Two confederate armies were soon in the field, the princes accepting for them the leadership of King Christian and Count Mansfeld. Unwilling to depend entirely on Maximilian and the League, and unable to raise a large force of his own, Ferdinand accepted the offer of the celebrated Wallenstein to raise, equip and maintain in the field at his own cost an army of 20,000 men, mostly veteran troops, on condition that he should command them and have a free hand He was a wealthy Czech noble, who had seen service in the Turkish wars, and had a real military genius with the mentality of a soldier of fortune. A Catholic, at least by profession, and serving the Catholic emperor, his levies were made up of a mixture of Catholics, Protestants and all kinds of adventurers ready to fight under any successful leader. He meant to pay and supply his army by levying contributions on the country in which it operated. As the war went on many of the armies in the field were not unlike Wallenstein's. In April 1626 with his hard fighting mercenaries he defeated Mansfeld at Dessau, and in August Tilly with the army of the League defeated Christian of Denmark at Lutter. The victors united their armies and invaded Denmark. Wallenstein now formed in union with the Spaniards an ambitious scheme for cutting off the supplies of the Netherlands and controlling those of North Germany by seizing the North sea and Baltic ports. He was only partly successful, and after five months' siege had to abandon the attempt to seize Stralsund. But Denmark was at the mercy of the imperialists, and in May 1629 had to conclude the peace of Liibeck.

Intoxicated by success, Ferdinand had only two months before issued the ill-advised "edict of restitution," ordering the restoration of all ecclesiastical lands taken over by the Protestants since the peace of Passau in 1552. This stirred up widespread opposition. While it was still being debated, Maximilian and his colleagues of the Catholic League united in demanding the dismissal of Wallenstein, now duke of Friedland, governor of the conquered territories of Mecklenburg and Pomerania, and rightly suspected of dangerous personal ambitions. Ferdinand had to yield just when new dangers were arising. In the summer of 1630 Gustavus Adolphus of Sweden declared himself the champion of the Protestant cause in Germany, and established himself with a strong force in Pomerania. How political rather than religious motives were now influencing events is shown by the fact that he had the promise of subsidies for the support of the war from the France of Cardinal Richelieu.

Gustavus, probably the ablest soldier of his day, had already extended the Swedish power to several of the Baltic lands, and at first the Protestant princes were slow in uniting with him, suspecting his real object was further Swedish conquests on the Baltic shores. But they soon welcomed his aid. He pushed forward to the Elbe gathering strength with success. He captured Frankfort-on-Oder, added the Saxon army to his own and defeated Tilly and the main army of the League at Breitenfeld near Leipzig in September 1631. Then while the Saxons won Silesia and invaded Bohemia, Gustavus marched triumphantly through Central Germany and established his headquarters at Mainz. In April 1632 he invaded Bavaria; Tilly was killed in a lost battle on the Lech; and Gustavus occupied Augsburg and Munich. Ferdinand now appealed to Wallenstein to take command again. Wallenstein only consented on being given control of all the imperial forces and the right of making treaties and granting pardons. He then drove the Saxons out of Bohemia, repulsed an attack made by Gustavus on the entrenched camp near Nuremberg, but was defeated by the Swedes at Lutzen (November 16, 1632). It was for them a costly victory, for Gustavus was killed leading a cavalry charge. The crown passed to his daughter Christina, but, under the government of the Chancellor Oxenstjerna, the Swedes continued the war.

In April, 1633, at Heilbronn the Swedes and their German allies agreed to arrangements for the conduct of the war. The military command was divided between Bernhard, duke of Saxe-Weimar and the Swedish general Horn. France was still supplying money to the allies. The war went on in the Rhine and Danube valleys, the Swedes entering Alsace and Bernhard capturing Regensburg. Wallenstein showed no longer his former vigorous leadership. There was enough reason for dissatisfaction to evoke a movement for his dismissal. Ferdinand yielded and in January 1634 declared Wallenstein deposed from command. He tried, however, to retain control of his army, but next month, as a result of a conspiracy among his officers, he was assassinated.

Commanded now by the archduke Ferdinand, king of Hungary (later the emperor Ferdinand III.), the Imperialists began a successful campaign by recapturing Regensburg and Donauworth and then, aided by Spanish troops, winning a complete victory over the Swedes and their allies at Nordlingen (Sept., 1634). The fortunes of the confederates were at a low ebb, but France presently came to their aid. Richelieu signed an alliance with Sweden at Compiègne in April, 1635, and next month France declared war and put her armies in motion. But by this time there was a movement for peace in Germany. Men of all classes were tired of the long conflict, in which they saw their country wasted and ruined as the cockpit for contending armies which levied contributions on city, town and countryside, and whether they were friends or foes left a trail of misery in their track. John George, the Lutheran elector of Saxony, took the lead in the movement, and despite Swedish opposition signed in May, 1635, the Treaty of

Prague with the emperor. The vexed question of Restitutions was settled by fixing November, 1627, as the date up to which their possession would be recognised and even later occupations were to stand for 40 years to come, during which amicable arrangements might be made. The elector agreed to assist the emperor to recover territories occupied by the Swedes, and to place the Saxon army at his disposal, receiving in return a small increase of his own dominions. The elector of Brandenburg, the duke of Württemberg and several of the cities soon adhered to the treaty.

In this last phase the war became a struggle between the Bourbon and the Habsburg interests. The Swedes won some successes in north Germany but in these campaigns after France came in the important field of operations was in the west and south. The French armies on one side drove the Spaniards back in Flanders, and on the other crossed the Rhine, and under Condé and Turenne, with some help from Bernhard and the Swedish general Wrangel penetrated far into south Germany. (On Bernhard's death in 1639 his army was taken over and paid by the French.)

The Treaty of **Westphalia.**—While these operations were in progress preliminary negotiations for a general peace had already begun at Hamburg and Cologne, before the death of the emperor Ferdinand II. in 1637. But it was not till Dec., 1641, that under his successor, Ferdinand III., a treaty was signed at Hamburg, by which it was agreed that peace conferences should meet at Munster and Osnabriick in March, 1642, the emperor treating with France at the former and with Sweden at the latter. The Catholic princes of the empire were to be represented at Munster and the Protestants at Osnabruck. The conferences did not actually begin till 1645, when the elector of Brandenburg had made, and the elector of Saxony was about to make, a truce with Sweden. In three years many controversial questions were settled, with much diplomatic playing for advantages, but at last in Oct. 1648 the treaty of Westphalia was signed, ending the Thirty Years' War.

France gained possession of the "three bishoprics"—Metz, Verdun and Toul, with the Austrian territory in Alsace. Sweden was granted Western Pomerania, Stettin, Verden and Bremen, and in virtue of this cession became a member of the empire. Hanover, Brandenburg and Saxony received some increase of territory, and the Rhenish palatinate was divided between the electoral house and Bavaria. Switzerland and Holland, long actually independent, were formally recognized as independent nations. The German states of the empire were accorded a measure of independence by the recognition of the right to make alliances even with foreign powers, with the nominal proviso that these should not be injurious to the emperor or the empire. The princes were to regulate the religious affairs of their territories, and though there was a stipulation for individual religious freedom, practically for long after in many states those who did not belong to the officially established religion were under some disabilities. To the imperial diet was left the settlement of treaties and laws affecting all Germany. By a compromise 1524 was fixed as the date for settling the question of the ecclesiastical lands. This left to the Catholics recent gains in the Habsburg territories. The general effect of the treaty was to relax the connection between the Habsburg and the other German lands. The empire survived, but there was a foreshadowing of the future change when the Habsburg emperor at Vienna would be no longer emperor of a "Holy Roman Empire," but emperor of Austria. But for another century and a half he was to represent the dignified tradition of some of the greatest memories of European history. (A. H. A.)

GERMANY AFTER 1648

The condition of Germany after the conclusion of the Peace of Westphalia was indeed tragic. The population had decreased in the course of the Thirty Years War from about 30 millions to 20 millions; the greatest decrease was shown in the rural population on whom the hardships of the war fell heaviest, causing them to migrate in large numbers to the cities. Many villages were totally deserted, and the old conditions were not completely restored until the middle of the 18th century.

Agriculture was almost at a standstill; large numbers of the land workers had been killed, or enrolled as mercenaries in the armies; stock had been destroyed, and houses burnt to the ground. Without capital and credit, the peasants were reduced to utter dependence upon the great nobles and land-owners who only furnished them with the money to rebuild their houses and replenish their stock on extremely hard terms. Everywhere their dues were increased and their rights of tenure diminished. A peasant without capital could not hope to improve the state of his holding. In consequence of the depopulation of the land the demand for agricultural produce had decreased, prices of livestock and grain had fallen and the area of land under cultivation had steadily diminished.

Nor did the great landowners fare any better. They suffered in like manner with the peasants, and in order to maintain their estates were forced to raise mortgages on their properties at a high rate of interest. If, in spite of these conditions the nobility succeeded for the most part in maintaining their properties, it was chiefly due to the administrations of the different States, who came to their help by declaring moratoriums or by the remission of interest. By the establishment of a *Fidei-kommiss* the aristocracy sought to preserve their landed property to their families' estates; the same object prompted the prohibition of the sale of noble estates to townsmen which survived in many cases until the beginning of the 19th century. The great landlords were also seldom in a position to carry out any agricultural development, and it was only gradually that a certain number of them, at the instigation of the ruling princes, began to cultivate the potato, which had been newly imported from America, and other food-crops and to plant fruit trees and tobacco.

Industry and commerce had been equally ruined by the wars. The disorganization of industry had favoured the import of foreign goods; the lack of purchasing power and skilled labour made recovery difficult. The country was flooded with French and English goods through the agency of the Dutch merchants. The once flourishing German trade in products of industrial art had almost entirely ceased; the South German linen and cloth industry decreased and the quality too, deteriorated. Official regulations were of little avail, and it was only the immigration of the French Huguenots in the second half of the 17th century that gave new life to German industry. The ancient organizations of the handicraft workers, the gilds, had become rigidly occupational associations; bad trading conditions and want of capital hindered the introduction of the factory system which was already developing widely throughout western Europe. German trade suffered specially from the fact that the mouths of the great German rivers were in foreign hands; the Dutch held the mouth of the Rhine; the Swedes and Danes the Weser, Elbe and Oder and the Poles the Vistula. German participation in world commerce was very restricted; German merchants were confined to internal trade and were often only agents for foreign investors.

Germany had been a wealthy country in the second half of the 16th century, but now money was scarce and furniture, art treasures and other valuables had been looted in large quantities by foreign armies. The crushing levies which the towns had to pay to preserve themselves from the hand of the invader had brought them to the verge of ruin. The mineral wealth, which had formerly been a main contributory source of German prosperity, especially the silver mines, was partly exhausted and partly diminished in value through the growing imports of precious metal from America. This loss of national wealth could only be replaced in the course of centuries.

Intellectual life had also suffered severely. Hard conditions had made material interests and the struggle for daily bread predominant. The striving after wealth and material comfort obsessed the nation, impoverished and demoralized by war. The sense of nationality was at a low ebb and the generation that had grown to manhood during the war had no other conception than that Germany was predestined to be ill-used by her neighbours. Confidence in the national strength had vanished and even patriotic pride and the culture that springs from it had been sorely diminished. A vast number of Spanish and French words had

been introduced into the German language, while court life and ceremony, fashion, and all social intercourse came more and more under French influence. This foreign culture descended from the court and the city patricians into the ranks of the middle-classes until the peasant class alone remained untouched by it.

Organization. — The political life of Germany was in a no less deplorable state. The imperial authority had become utterly powerless, lacked an administrative system, and was possessed of only a very limited revenue. When the Peace of Westphalia gave to the individual States the right to form associations among themselves or with foreign powers in so far as such alliances were not directed against the emperor and the empire, the emperor was reduced in fact to the position of president of an aristocratic republic. He was unable to make laws or levy taxes without the consent of the Reichstag, which since 1663 had been permanently established at Regensburg. It was composed of representatives of all the mediatized estates and was divided into the three chambers — electoral princes, princes and cities. The first chamber consisted of representatives of the eight electors of the empire — the archbishops of Mainz, Cologne and Treves, the king of Bohemia, the dukes of Saxony and Bavaria, the margrave of Brandenburg and the count-Palatine of the Rhine; in 1693 a ninth was added, the elector of Hanover. The second chamber was composed of representatives of all the greater princes whilst the lesser counts and lords were combined in separate bodies each possessing a single vote. The third chamber consisted of the representatives of the mediatized cities; their right to a casting vote when the other two houses disagreed was however disputed, and they were virtually condemned to insignificance. The working of this assembly was rendered very difficult by the fact that the representatives of the different estates had to obtain the consent of their principals on every vote. As communications were difficult and slow, the proceedings were often dragged out interminably and it became excessively difficult to obtain consistent decisions.

Apart from the Reichstag, there existed a further general imperial organization, the *Reichskammergericht,* the supreme judicial body of the empire. It met first at Speyer and later at Wetzlar, and was financed by the estates. Its effectiveness was seriously impaired, however, because the greater principalities were exempt by special imperial privileges from its jurisdiction. In addition the emperor maintained a separate Reichshofgericht at Vienna which was in perpetual conflict over questions of competence with the Reichskammergericht. Moreover, as the procedure was very complicated the hearing of processes was almost incredibly prolix, and at times a decision was never reached. An enquiry held in 1772 revealed that no less than 61,233 suits were still awaiting judgment by the *Reichskammergericht.*

The empire was unable either to take precautions to safeguard its territory, or to preserve law and order among its citizens and protect the interests and lives of its subjects abroad. There existed no regular taxation, and the empire possessed no army or police force. The necessary duties were collected on the basis of a register in which each constituent estate of the empire was assessed at a definite rate. These amounts, however, were regularly diminished in consequence of the protest of the different estates that their ability to pay was rated too highly; and payment into the imperial treasury was very irregular. When the empire went to war each estate had to furnish a stated quantity of troops and ordnance also recorded in a register. When the numerous small contingents did assemble at the oppointed date and place, which very rarely happened, the troops were variously armed and for the most part were made up of raw levies. The organization of larger forces was very difficult because no estate would permit its soldiers to be placed under foreign command. When it is also remembered that the troops were never trained together, it is easy to understand that an imperial army composed in such a manner rarely possessed any real military effectiveness.

It can therefore be said with truth that since the Peace of Westphalia there had never been a common political life in Germany. For administrative measures were carried out not by the empire but by the individual territories that had grown up within it and had practically attained to the status of independent States. The number of these States was extraordinarily large, and has been estimated at some 1800 including some amazing examples. The smallest territories were the dominions of the knights of the empire, numbering some 1,475. These were nearly all situated in south-west Germany and their joint population amounted to about 500,000. Each individual territory averaged about 300 inhabitants. These territories therefore, were no more than properties which. since their owners were free knights of the empire, were not under the dominion of a prince, but directly dependent on the emperor and the empire. In this instance the capacities of land-owner and sovereign lord were united in the same person, who administered the law and exercised police-rights over his little territory. These knights of the empire were unrepresented in the Reichstag.

Then there were 51 free imperial cities with a total population estimated at about 750,000, and, included in their number, were certain of the more important ancient commercial towns such as Hamburg, Bremen, Nuremberg, Augsburg, Ulm, Strasbourg and Frankfurt-am-Main; but the vast majority were small and insignificant country towns of 2–3,000 inhabitants in south-west Germany who had had the good fortune, like the knights, to be protected by their ancient privileges from coming under the rule of a prince. For the most part these towns and cities were governed by a small number of patrician families who monopolized all positions of influence and profit and often gained a reputation for devoting the revenue of the town more to their own special interests than to those of the citizens at large. With certain exceptions, these towns were little animated by civic spirit and the desire for economic progress. Moreover they were overshadowed by the capitals rising round the residences of the princes — although these had not the advantages enjoyed by the free cities.

The 63 ecclesiastical principalities (archbishoprics, bishoprics, abbacies) with their population of some three millions, had special characteristics. Here the supreme lord was a bishop or abbot elected by the cathedral chapter with whom he shared the administration of the district. The chapter was almost entirely composed of the nobility of the neighbourhood, since these religious foundations and orders afforded the nobles a convenient opportunity of providing for their younger sons in a manner befitting their rank. For the most part the administration was bad, and it was not until the 18th century that a few of the ecclesiastical princes were sufficiently enlightened to introduce important reforms. Many bishops used their high position to further the interests of their families by making over to them ecclesiastical estates and by fill. ing the chapters with their relatives.

The temporal principalities and countships numbered between 170 to 200; the number varied because the estates were often divided among different lines of the same family, or many principalities united by inheritance under one prince. A patriarchal form of government characterized the smaller principalities, in which the prince was personally acquainted with the majority of his subjects, concerned himself in their family affairs, and expected them to take a similar lively interest in the joys and sorrows of his own family. Nearly all these lesser princes maintained a magnificent court and employed a number of officials out of all proportion to the size of their principalities; they were especially inventive in introducing fresh methods of taxation by which they sought to obtain the money for the upkeep of their courts. A true political life was naturally impossible in all these miniature states, and was only to be found in the few larger principalities. Of these, the greatest was in the possession of the house of Habsburg which ruled over a vast territory in south-east Germany composed of the kingdoms of Bohemia, Austria. Styria, Carinthia, Carniola and Tirol with, in addition, a number of scattered possessions in southern Suabia stretching to the banks of the Rhine. These territories could not be regarded as constituting a single State, for from time to time they were divided among various branches of the ruling house, and it was only in 1665, after the failure of the Tirolese line, that Leopold I. finally united all the possessions of the Habsburgs. The individual States, however, retained their own administration and diets and the central authority for the whole territory, which Maximilian I. had begun

PROVINCIAL TYPES IN NATIVE COSTUME

1. Women of the Spreewald, a marshy wooded district near Berlin, inhabited by a Wendish people who retain the speech, customs and picturesque costumes of centuries ago. The women wear a wide-winged headgear, richly embroidered neck cioths, wide skirts and aprons
2. Characteristic dance of peasants of the Bavarian mountains, in the costume of the region; the men in knee-length leather breeches with embroidered suspenders and girdles, and felt hats adorned with goat's beard or eagle's feather; the women in wide skirts and aprons and embroidered neck cloths
3. Five "Wandervogel" (wandering birds), a name popularly applied to the young men and women of Germany, largely students, who travel on foot through the picturesque regions of the country, singing folk-songs
4. Bavarian "Wandervögel," in the costume of the province, photographed in Bremerhaven. They are travelling as a "Klampfe," or a guitar-and-violin band, in order to earn their living as they tour the country
5. A bridal couple, natives of the Schwalm district of Hesse, and a well-wisher congratulating them, according to custom, on the threshold of their new home. They are wearing the elaborate and multi-coloured festive costume of that district
6. A bridal party of Hanauer Land, a Black Forest district in Baden, in Peasant costume. In the background is a typical Black Forest house

CASTLES OF THE RHINELAND, CENTRAL AND EASTERN GERMANY

1. An aerial view of Heidelberg castle, near Heidelberg on the Neckar
2. Lion's castle near **Cassel,** Hesse-Nassau, built in the 15th century
3. **Wartburg** castle, Thuringia, founded 1070. Here the ***minnesingers*** held their contests in 1207 and Luther translated the Bible in 1521
4. **Marienburg** castle, East Prussia. built in 1192
5. "The Cat," left bank of the Rhine above St. Goarshausen, erected 1393 by the Counts **Katzenelnbogen**
6. **Castle Eltz on the Moselle, built by the Counts von Eltz in 1157**
7. Castle Rheinstein, 260 feet above the river on the left bank of the Rhine. Built in the 13th century and restored in the 19th

to establish, was still very unwieldy and exercised little control.

Next in importance came the territories of the house of Hohenzollern. The margrave of Brandenburg had inherited in the 18th century the district of East Prussia which had hitherto owed allegiance to Poland. At the same time he inherited from the last duke of Jiilich the district of Cleves in western Germany together with the countship of Mark and Ravensberg in Westphalia. After the death of the last Pomeranian duke, the Treaty of Westphalia gave to the Hohenzollerns Lower Pomerania and, as compensation for Upper Pomerania, ceded to Sweden the former bishoprics of Magdeburg, Halberstadt and Minden. The centre of their territory extended from the Elbe and the Hartz mountains almost to the bank of the Vistula: while East Prussia, which was cut off from the central territory by Polish West Prussia, and their territories on the Rhine and in Westphalia, formed districts loosely joined to the main body. The individual districts maintained substantial independence and did not look upon themselves as forming part of a single united territory, but rather as districts that had by chance come into the hands of the same ruler. After the Habsburgs and Hohenzollerns, came the house of Wettin which was divided into so many branches that the head of the house, the elector of Saxony, only ruled personally over a portion of its territories. The same was true of the house of Wittelsbach of which the most powerful member was the elector of Bavaria, ruling over the largest and most compact territory, whereas the widely-scattered lands in the Palatine were divided among numerous cadet branches of the family. In north-western Germany the leading rôle fell to the house of Guelf, whose lands in Hanover and Brunswick were shared among innumerable members of the family. If account be taken of the duchy of Wiirttemberg and the margravate of Baden in the south, and the lands of the house of Hesse in central Germany, all the more important territories then existing will have been considered. In these greater states there existed estates in which the land-owning aristocracy exerted the predominant influence, but in which the civil population of the towns was also represented. These diets claimed that no new legislation could be enacted, no fresh taxation introduced, and no burden of loans laid upon the State without their consent having first been obtained. While the princes endeavoured to reduce the old established power of the estates, they did not dare to suppress it outright. With the assistance of their paid officials, and supported by the standing armies which had been maintained in all the greater States since the Thirty Years' War, the princes succeeded in the course of the 17th and 18th centuries in permanently augmenting their power, until in fact they became absolute rulers; while the rights of the estates dwindled away more and more.

Administration and justice were far better in these greater States than in the smaller territories, and by developing the police system the princes ensured peace and order within their States. Political life in Germany was confined to these larger States. The only question was whether they would not gradually become wholly independent, and thus destroy the last traces of that national alliance of all the Germanic peoples that still existed in the old Imperial State Union (Reichsverband). In that event, Germany would have been divided into a number of independent States, each of which would have pursued its own special interest, and one could then have spoken of a German nation in so far as the inhabitants of the different States possessed in common a similar language and certain common elements of intellectual culture. Such a collapse of the empire could only be avoided either by strengthening the power of the empire to such a degree that the central authority could bring the individual territories into submission, or by one of these territories becoming so strong that the remainder would be forced to submit to its leadership.

THE AGE OF LOUIS XIV.

The sovereign princes of the German States were not sufficiently gifted to construct a real Government in the midst of the difficulties then prevailing in Germany. Ferdinand III. (1637–57) had been brought up in a strictly religious atmosphere and was dominated by his confessors. He had never given evidence of any special qualities. His eldest son, Ferdinand, who during his father's life-time had been chosen as his successor by the imperial electors, died before him in 1654, and, notwithstanding all his endeavours, the emperor was unable before his death to bring about the election of his younger son, Leopold, as king of the Romans. Hence when Ferdinand died in 1657 an interregnum ensued that lasted for almost a year, until finally the electoral princes united to elect Leopold (Aug. 18, 1658) who, however, was compelled to sign a capitulation by which the imperial rights were still further reduced.

Leopold I.—Leopold, who until 1705 was to be the head of the German peoples, was 18 years old at the time of his election He had originally been destined for the church; he was a thorough theologian, and a pious and bigoted churchman. Very reluctantly he abandoned his religious life in order to assume the duties of a temporal ruler. He invariably regarded the promotion of the interests of the Catholic Church as his first duty, while those of the house of Habsburg and of his Austrian territories had for him a quite secondary importance. He had little sympathy for the empire and its needs. Under the influence of his Spanish mother, his education had been entirely Spanish, and in his immediate circle Spanish alone was spoken. Though kindly, well-intentioned. benevolent, and even weak by nature, Leopold was pitiless and unyielding in all matters involving either interest of the Church or his own sovereign rights. His firm conviction that he was an instrument and agent for the execution of the Divine will endowed him with an almost unshakable spiritual equanimity. Although he was not a man of action, Leopold was exceedingly tenacious in maintaining his own point of view and in guarding his own interests.

In the first decade after the Peace of Westphalia, the primary concern of all the estates was the maintenance of peace. As the war between France and Spain lasted until 1659, and as grave issues were arising in north and east, Germany could easily have been involved again in a general war. As no one believed in the ability of the emperor to safeguard the empire from this danger, there grew up a network of alliances between the different estates for mutual defence. The elector Johann Philipp of Mainz succeeded in uniting the most important Catholic and Protestant princes in a great defensive alliance. The Confederation of the Rhine was signed on August 16, 1658 for three years, and had for its object the full execution of the Peace of Westphalia, the prevention of foreign wars and the defence of its own territories. But, in fact this alliance, which the emperor regarded as directed against his authority, very soon became largely dependent on France. It was frequently renewed and lasted until 1667.

During the first northern war (1656–60), the emperor in the Catholic interests supported the Catholic king of Poland; whilst the elector of Brandenburg, who at the outset supported Sweden, later entered into an understanding with Poland and the emperor. These wars, however, were waged for the most part outside the territory of the empire, and Germany was far more deeply disturbed by the course of events on her western frontier.

The French Wars.—Since 1661 Louis XIV. had personally governed France, and, in accordance with the traditional French policy, which had been built up under Richelieu and Mazarin, he sought to advance the French frontier to the Rhine and to include Belgium within the French kingdom. Belgium and the Franche-Comté still belonged to Spain, and hence Louis' policy led in 1668 to a renewal of war between France and Spain. The intervention of England, Holland and Sweden brought the war to a conclusion after a few months by a peace which Spain purchased at the cost of the surrender of certain fortresses in southern Belgium. As Louis XIV. was unable to dissolve this Triple Alliance, he endeavoured by means of a sudden invasion to crush Holland and succeeded in winning over the archbishop of Cologne, the elector Palatine, and the bishop of Miinster, to allow the passage of his armies through their territories. The neighbouring States who feared that they would be involved in the war, witnessed these intrigues with great disfavour and invoked the assistance of the emperor and the empire. As moreover, Louis XIV. had, without any legal grounds, driven the duke of Lorraine, who was a prince of the empire, out of his duchy, the empire had good cause

to intervene.

But Leopold still hesitated to take any action against Louis XIV. In view of the anticipated extinction of the Spanish branch of the Habsburgs, his main policy was to unite the Spanish monarchy with his own territories. This policy depended for its success upon the acquiescence of the French king. and since Louis was clever enough to dangle before the emperor the hope that he would help him to fulfil his desires, Leopold did not feel himself at liberty to oppose Louis in his schemes. Hence the Dutch found their sole support in the elector of Brandenburg, who had grown up in Holland and whose first wife had been a princess of Orange. By cutting the dykes and flooding the country, the Dutch were able with great difficulty to avert the French attack in 1672. At the urgent request of the estates, Leopold determined to send an army under General Montecucoli for the defence of the imperial frontier on the Rhine, but with instructions to maintain the defensive. The empire declared war on France at the same time as Spain. The war was chiefly waged in Belgium and on the Rhine. Louis XIV. allied himself with Sweden, who, at his request, invaded Brandenburg from Pomerania in order to restore the elector Frederick William, who was participating in person in the war against France. At the same time, Louis XIV. entered into relations with Poland, Turkey and Hungary which was discontented with the Habsburg rule. The emperor then found himself threatened in the rear. By his victory at Fehrbellin on June 28, 1675, the elector of Brandenburg drove the Swedes out of his territory and occupied nearly the whole of Swedish Pomerania. The French, on the other hand, were for the most part victorious in Belgium and on the Rhine. As the war dragged on without any definite decision being reached Louis was able to induce first Holland and then Spain to conclude a separate peace. When the emperor saw that he could no longer hope to obtain any success by carrying on hostilities, he concluded the peace of Nijmwegen with France in Feb. 1679. The greater part of Alsace and Lorraine, as well as the former Austrian territory of Breisgau, remained in French possession. The elector of Brandenburg, who was required by the peace to give up all his acquisitions in Pomerania, was unwilling to subscribe to such terms and for a short time carried on alone a forlorn fight. In the following year, however, he too was compelled to conclude peace.

In consequence of these events, Louis XIV. became convinced that the weakness of the empire was such that he could encroach upon its territory with impunity. He established in the French law courts in Metz, Breisach and Besançon, so-called chambers of reunion (*Reunionskammern*) for the purpose of determining what lands had at any former time belonged to the districts which had now been ceded to him. As the result of these investigations, he declared that the countship of Mompelgard, the whole of Alsace and certain districts in the Palatine and Trier, belonged by right to France; and he sent his armies to occupy these districts. The imperial city of Strasbourg, which was included in these districts, was on Sept. 28, 1681, forcibly seized and at once erected into a powerful French fortress. The emperor and the *Reichstag* contented themselves with ineffectual protests against these acts of violence.

That the emperor did nothing to safeguard the integrity of the empire at this crisis is partly accounted for by the fact that his own immediate territories were menaced by many grave dangers. The Turks in Hungary were planning a desperate attack on Austria, and in the spring of 1683 appeared with a powerful army before the walls of Vienna. But the valiant Count Rudiger von Starhemberg managed to defend the city until the arrival, of an army under the king of Poland and the electors of Bavaria and Saxony, which defeated the Turks and freed Vienna.

When Louis XIV., on grounds that had no legal justification whatever, sought to bring the Palatinate within his grasp, claiming it as the inheritance of Elizabeth Charlotte, the wife of his younger brother, war once more broke out in the west. The French armies invaded the Palatinate, and ravaged it with fire and sword. The magnificent palace of the elector Palatine at Heidelberg was destroyed and in face of this outrage the emperor felt impelled to resume the war in alliance with Holland and England. This new war lasted for nine years, inflicted severe losses on the French, but did not result in any decisive victory. Once more Louis was able to sow dissension among his enemies and to isolate Germany, and the emperor was forced to conclude the Peace of Ryswick in 1697, with but small gain to himself. Louis abandoned his claim to the Palatinate, and the districts outside Alsace that had been declared to have once formed part of it. Further he had to restore his duchy to the duke of Lorraine, but he retained the whole of Alsace and also Strasbourg.

Meanwhile the war between the emperor and the Turks continued in the east; two-thirds of Hungary remained in Turkish hands. Prince Eugene of Savoy, one of the greatest generals of the age was appointed to command the Austrian army and defeated the Turks in a decisive victory at Zenta (Aug. 29, 1697). Prince Eugene invaded Serbia and Bosnia, and forced the Turks to conclude the Peace of Carlowitz on Jan. 26, 1699, by which the entire kingdom of Hungary, with the exception of the Banat of Temesvar, was restored to the emperor. It was the conquest of Hungary that paved the way to the later Habsburg monarchy and its position as a great Power.

The Spanish Partition Treaties.—Shortly after this Charles II. of Spain died (Nov. 1, 1700), the last Habsburg to occupy the Spanish throne. The question of succession, which had already occupied the European diplomats for decades, had now to be settled. The claim of the Emperor Leopold was based not only on the fact that he was the nearest male blood-relation of the dead king, but also that his mother and his first wife had been Spanish princesses, and at the time of their marriage it had been expressly agreed that, in event of the failure of a male heir to the Spanish house, their children should be regarded as the heirs. But Louis XIV. was also the son and husband of Habsburg princesses, who married into the House of France, though it had been stipulated that they should renounce all their rights to the Spanish inheritance. Louis, however, declared that this renunciation was invalid because the promised dowries of the princesses had never been paid in full. Louis had frequently endeavoured to come to an agreement with Leopold concerning the partition of Spain, but without definite result. These projects for a partition had aroused great uneasiness in Spain, and Charles II. determined to make a will. By his first marriage with the princess Margaret Theresa, Leopold had only one daughter, who was married to the elector Max Emanuel of Bavaria; the only child of this marriage, the crown prince Joseph Ferdinand, then six years of age, was designated in 1698 by Charles II. heir to all his possessions, but the young prince died in the following year. Then Charles II., under pressure from the French party at the Spanish Court was persuaded shortly before his death to draw up a second will in which he named as his sole heir Philip, duke of Anjou, a grandson of Louis XIV. and Maria Theresa of Spain, who was then 17. Acting on this last will, Louis XIV. despatched his armies into Spain directly he learnt of Charles's death, and sent his grandson to Madrid where, under the title of Philip V., he assumed the reins of government.

The **War** of the Spanish Succession.—It remained to be seen, however, whether the success of this sudden and violent measure would be lasting. First there was the danger that the emperor would refuse to recognize the validity of Charles's will and attempt, if necessary, to support his own claim by force of arms. Further, the interests of the other European States were deeply involved in this question. England and Holland, old enemies of Louis XIV., had as little desire as the emperor, to see the great Spanish kingdom with Belgium, Naples, Sicily, Milan and the rich Spanish possessions overseas, pass into the hands of the French king, whose power was already a sufficient menace to them. William III. of Orange, Stadtholder of the Netherlands and, since 1688 also king of England, believed that this must be prevented in the vital interests of both the countries over which he ruled. He was the first to stress the theory of a European balance of power, and was the soul of the Great Alliance concluded on Nov. 7, 1701, between the emperor, England and Holland. Among his supporters Louis XIV. reckoned Hungary, which was anxious to throw off Austrian domination; in England the supporters of

King James II. who had been dethroned in 1688, then very numerous; and a number of German princes, chief of whom was the elector of Bavaria. He possessed a seasoned army led by skilled generals, and already held the greater part of the objects of the dispute. It is true that his finances were in a bad state because the frequent wars of these latter years and the extravagance of his court had involved him in heavy debt. Among the allies there existed points of dispute especially after the death of William III. (1702) when the close relationship maintained between England and Holland was dissolved and opposition to the war gained strength in England. But they had at the head of their armies two generals of outstanding military ability, Prince Eugbne and the duke of Marlborough, whose harmonious co-operation was rarely broken by differences of opinion. In the first years of the war the advantage lay with the French. Her position was such that she was able to strike a deadly blow at Austria by a concerted attack from the Rhine and Italy. This danger was averted by the union of prince Eugbne and Marlborough, and the allied armies won a decisive victory at Hochstadt on Aug 13, 1704. The French general Tallard was taken prisoner and the French army forced to retreat across the Rhine. Bavaria, the elector of which was allied with Louis XIV., was occupied by the imperial troops and the elector Max Emanuel was forced to fly to Brussels. On May 5, 1705 the emperor Leopold died, and was succeeded by his eldest son, Joseph I., then 27 years old. His arrogant bearing aroused great resentment in Germany, and greatly impeded the prosecution of the war.

Meanwhile a fleet of the maritime Powers attacked Spain. The younger brother of the emperor Joseph, the archduke Charles, who was the imperial claimant to the Spanish throne, accompanied this fleet which seized Gibraltar, sailed along the east coast of Spain and effected a landing at Barcelona. Catalonia rose in support of the archduke, and by the summer of 1706 he was able to enter Madrid. In that year Marlborough gained a great victory over the French at the battle of Ramillies (May 23), and occupied almost the whole of Belgium. Eugbne took command of the allied forces in Italy, and by his victory at Turin (Sept. 7) relieved the army of the duke of Savoy, which had been surrounded and drove the French out of Italy. A year later he occupied the kingdom of Naples.

The French, after failing in a renewed attempt to cross the Rhine into Suabia, concentrated their main military strength in the Netherlands. Eugbne hastened thither with the imperial troops and again joined forces with Marlborough. After their victory at Oudenarde (June 11, 1708), the Allies captured Lille. Louis XIV. expressed his readiness to renounce, on behalf of his grandson, all claims to the Spanish throne and to agree to a restoration of the Franco-German frontier to the line laid down in the Peace of Westphalia in 1648. This entailed the restoration of Strasbourg. The Allies, however, thought that he was only playing for time, and demanded that he should place his troops at their disposal to aid in the expulsion of his grandson from Spain. When he refused to do this, they broke off negotiations.

Once more the Allies were victorious at Malplaquet (Sept. 11, 1 jog), and captured the fortress of Mons. Louis again sued for peace, and now declared his willingness to concede to Germany the frontier of 1521, that is to say to relinquish Alsace, Metz, Toul and Verdun. He further offered to pay a sum of money to be used in driving his grandson out of Spain. Intoxicated by victory the Allies stood firmly by their former demands, and negotiations once more broke down.

A change now occurred in the general political situation which threatened to rob the allies of all the fruits of their victories. In England the Tories, who had long considered that the interests of England did not demand a continuance of the war came into power and entered into negotiations with France for a separate peace. The other allies, too, were disturbed when on April 17, 1711, the Emperor Joseph I. died, and, as he left no son his younger brother Charles was elected emperor. If Spain, Austria and the empire were all to be united under one ruler there was danger that such a disproportionate concentration of power in the house of Habsburg would threaten the European balance of power more seriously than the establishment of a second French dynasty in Spain. Neither England nor Holland nor Savoy felt disposed to prosecute the war for such an object. Hostilities were suspended and the peace congress assembled at Utrecht in 1712, resulted in the Peace of Utrecht (April 11, 1713). The emperor was awarded only a portion of Lombardy and the Neapolitan mainland: no mention was made of a restoration of the old Franco-German frontier. The emperor and the Reichstag prosecuted the war for some time longer. When Landau and Freiburg-im-Breisgau, however, had been captured by the French, they were forced, in the treaties of Rastatt and Baden (March 7 and Sept. 7, 1714), to assent to the terms of the Peace of Utrecht. The frontiers of the German empire remained as laid down in the Treaty of Ryswick (1697). The prospect of winning back the old German territories in the south-west, which a few years before had seemed so near realization now completely disappeared. Moreover the emperor was forced to agree to the restoration of his territories to the elector of Bavaria. Thus the War of the Spanish Succession had overthrown the supremacy enjoyed by France in Europe in the early years of Louis XIV.'s reign without yielding any profit to Germany. (*See* also SPANISH SUCCESSION, WAR OF THE; UTRECHT, TREATY OF, etc)

The Northern War.—At the same time another long-standing quarrel came to a head in the North and the East. The accession to the Swedish throne of the young king Charles XII. (1697) afforded an opportunity for Sweden's enemies to unite in an attempt to oust her from the position of power in which she had been placed during the Thirty Years' War by Gustavus Adolphus. In 1697 the elector Frederick Augustus of Saxony, after his conversion to Catholicism, was elected king of Poland. In alliance with Denmark and the Russian tsar, Peter, he began a war in the summer of 1700 which was to last for almost 20 years. By the spring of 1706, Charles was in possession of the greater part of Poland and the capital, Warsaw, and, in agreement with a section of the Polish nobility, had set up Stanislaus Leszczynski as king in opposition to Frederick Augustus. But Charles conceived the plan of overthrowing his chief enemy by seizing his German lands, and so rendering it impossible for him to receive money and reinforcements from Germany. To effect his purpose, he marched through Silesia towards Saxony, occupied a great part of the elector's domains, and established his headquarters during the winter of 1706–07 in Altranstadt, near Leipaig. But the peace which he compelled Augustus to sign, and in which the latter renounced his claim to the Polish throne, did not long remain in force. In the meanwhile Peter the Great had organized an efficient army with which he threatened to occupy Poland. Charles marched to oppose him and was completely defeated at Pultawa (1709) and forced to take refuge in Turkish territory. The Swedes were driven from Poland, and their allied enemies invaded Swedish territory on all sides. The elector of Brandenburg, who, with the Emperor's consent, had assumed the title of king of Prussia in 1701, also took part in this attack upon his old enemy. The Swedish possessions in Germany, Upper Pomerania, Bremen and Verden were seized, and when Charles returned from Turkey he found himself powerless to give a more favourable turn to the war.

After Charles had been shot at Frederikshall on the Norwegian frontier, the conclusion of peace was possible. Sweden was forced to surrender Bremen and Verden to Hanover, and Upper Pomerania south of the Peene to Prussia. Of greater importance as regards the future relations of Germany and Russia was that Estonia, Livonia and Ingermanland fell into the hands of the tsar: for Russia gained a firm foothold on the shores of the Baltic and thereby acquired a position that became more and more threatening to Germany. The Northern War made an end to Sweden as a Great Power, although she retained the German districts of New Pomerania and Riigen until they were joined to Prussia in 1815.

THE 18TH CENTURY

Charles VI.—From his earliest youth, the Emperor Charles VI. had been regarded as the future king of Spain and had been brought up in the spirit of Spanish Jesuitism. Throughout his **life**

his dearest wish was to secure as large a share as possible of the Spanish possessions for the house of Habsburg, and Austrian policy became more and more obviously inspired by the desire to govern Italy and extend the Habsburg rule to the lower reaches of the Danube. The emperor had little in sympathy with the interests of the rest of Germany which lay, above all, in safeguarding her western and north-eastern frontiers. He exercised but limited influence in the empire and the individual States were practically independent. There was no common political history in Germany at this period. On the other hand Germany's destiny was deeply influenced in the following decades by international affairs.

While prince Eugene was leading the imperial troops to fresh victories in the course of a new war against Turkey (1715–IS), and by the Peace of Passarowitz (1718) compelled the Sultan to cede the Banat and the greater part of Serbia and Wallachia, complications arose in Italy mainly caused by the dynastic ambitions of the Spanish queen. The lack of a male heir was the source of much anxiety to the emperor. He devoted his energies to assuring the succession to his eldest daughter, Maria Theresa, and as his action was contrary to the provisions of earlier compacts between the members of the house of Habsburg, which gave the precedence to the daughters of his eldest brother, he spared no trouble to ensure that, after his death, his wishes respecting the succession would be carried out. These wishes he embodied in a special law, the "Pragmatic Sanction," for which he secured the approval of the diets in all the territories of his empire. As Charles did not consider this was sufficient security in itself against the probable attempts on the part of the other heirs to secure the throne, he sought to have it guaranteed by the great Powers and approved by the *Reichstag*. The approval of the *Reichstag* was especially difficult to obtain, because two of the most powerful princes in Germany, the electors of Bavaria and Saxony, had married his brother's daughters and so had an immediate personal interest in frustrating the execution of the emperor's wishes. In these circumstances, the emperor was particularly anxious to secure the consent of the king of Prussia to his plan. King Frederick William was quite willing to fall in with the emperor's wishes but demanded in return his assistance in prosecuting his claim to a part of the inheritance of the duties of Jiilich and Berg in the Lower Rhine. The emperor appeared to assent to his wish and so secured the consent of Prussia to the Pragmatic Sanction by the Treaty of Berlin (Dec. 23, 1728). But since it soon appeared that the emperor had made contrary promises to the rival claimants the courts of Vienna and Berlin became estranged, and King Frederick William allied himself with the emperor's enemies.

On the death in 1733 of King August the Strong of Poland, who was also elector of Saxony, fresh troubles arose in the east. While Austria and Russia declared themselves in favour of the succession of his son August III., a number of Polish nobles, who were in relations with France, chose August the Strong's former opponent, Stanislaus Leszczynski, whose daughter was married to the young French king, Louis XV. Out of this quarrel arose the War of the Polish Succession (1733–35), which was chiefly fought in Italy and the Upper Rhineland and which ended unfavourably for Austria; the emperor being forced in the Peace of Vienna (1738) definitely to abandon Sicily and Naples, which were placed under the rule of one of the young Spanish princes whilst the duchy of Parma was ceded to Austria. Of special significance to Germany was the consent of the emperor to the cession of Lorraine. This duchy which had long been in the possession of France was made over to Stanislaus Leszczynski, as compensation for his abandonment of all claim to the Polish crown. After his death Lorraine was to be restored to France. The reigning duke of Lorraine, Francis Stephen, who was married to princess Maria Theresa, was compensated for the loss of his ancestral inheritance by the grand duchy of Tuscany. France, in return, recognized the Pragmatic Sanction with the important reservation that she only did so in so far as it did not conflict with established third party rights.

In the evening of his days the emperor was once more called upon to engage in war with Turkey — a war that ended disastrously for him. By the Peace of Belgrade (1739), he was forced to restore a great part of his former conquests, and the frontier in Serbia and Wallachia then laid down remained essentially the same until the outbreak of the World War.

The Silesian Wars. — When the Emperor Charles VI. died on Oct. 24, 1740, his daughter Maria Theresa at once assumed the reins of government in the countries belonging to the house of Habsburg. The electors of Saxony and Bavaria protested against her accession, and were supported by France who desired to see a partition of the Austrian territories; a still more pressing danger threatened the young princess when the new Prussian king joined her opponents. Frederick William I. of Prussia had died a few months before the emperor and his son Frederick II. thought that by virtue of certain old family compacts he could lay claim to a part of Silesia, namely the duchies of Liegnitz, Brieg, Wohlau and Jagerndorf. These claims had never been recognized by Austria, nor had they ever been completely settled. At one time, indeed, compensation had been offered but no final agreement was reached on the matter. Frederick now claimed the cession of a portion of Silesia and in return promised the young archduchess his aid against her enemies. When Maria Theresa rejected his proposal Frederick determined to occupy the disputed lands by force. In Dec. 1740 he crossed the Silesian frontier, advanced as far as Breslau, and defeated an advancing Austrian army near Mollwitz on April 10, 1741. As at the same time, the Bavarians supported by a French army, invaded Austria, advanced as far as Linz and even seized Prague with the help of the Saxons, Maria Theresa found herself in an extremely critical situation. Finally the German electors, under French and Prussian influence, did not elect as emperor her husband, duke Francis Stephen, but the elector Charles Albert of Bavaria (Jan. 24, 1742). He assumed the name of Charles VII., but throughout his three years' reign (1742–45) he never received full recognition in Germany nor succeeded in setting up a working Government. When Frederick invaded Moravia in 1742, after he had secured possession of all Silesia, and defeated an Austrian army at Chotusitz, Maria Theresa thought it prudent to open negotiations. Her troops had regained Linz, and even invaded Bavaria, but she thought a complete victory over her other enemies impossible, so long as the Prussian army threatened her flank. Frederick expressed his readiness to conclude a separate peace. England, also at war with France over colonial questions, acted as intermediary and thus the Peace of Breslau (June 11, 1742) was concluded. Austria ceded the greater part of Silesia, along with the countship of Glatz, to Prussia; and received only the principalities of Troppau and Teschen. In return, Frederick promised his neutrality. The first Silesian War, which ended with this peace established the military reputation of Frederick the Great. It was the first armed contest between the two greatest German States which had developed out of the old empire and had long regarded each other with common distrust and jealousy.

After the withdrawal of Prussia, the struggle for the inheritance of Charles VI. continued until the Austrian army captured Prague, freed Bohemia from the invaders, and even captured Munich, the capital of the Bavarian emperor. England had also despatched an army to the continent, led by George II. in person, which, after a victory at Dettingen in the summer of 1743, advanced from Hanover as far as the Rhine. The Austrians, under the leadership of Prince Charles of Lorraine, were advancing from southern Germany with the intention of crossing the Rhine, when Frederick decided to intervene again in the war. He feared that Maria Theresa, after a complete victory over her other enemies (as now seemed possible) would attempt to wrest Silesia back from him. Having signed a new alliance with France, Frederick invaded Bohemia and advanced by forced marches by way of Prague to Budweis. But as the expected simultaneous advance of the French army did not take place, Frederick found himself forced to retire to Silesia before the oncoming Austrians. During the winter the Emperor Charles VII. died (Jan. 20, 1745), and his son, the Elector Max Joseph, at once made peace with Maria Theresa. He received back his ancestral domains in return for the renunciation of all his claims to

the Austrian throne as grandson of the Emperor Joseph I. As the elector of Saxony had already abandoned his claims and made peace with Austria, and as the French were fully occupied with the campaign in Belgium, Frederick found himself alone opposed to the main force of Austria. Strengthened by Saxon troops, the Austrians attacked Silesia in the summer of 1745, but were defeated near Hohenfriedberg on June 4. Once more Frederick was able to invade Bohemia, and by the end of the year a great part of Saxony was in his possession. On Dec. 15 his chief general, Leopold von Dessau, won a fresh victory over the Austrians and Saxons at Kesselsdorf, near Dresden.

The majority of the electors had in the meantime at Frankfurt-on-Main, elected Francis Stephen of Lorraine as emperor. As Francis I. he was the nominal head of the German empire from 1745 to 1765. Maria Theresa, who perceived from the events of the last few years that it would not be so easy to retake Silesia, and who laid great stress on the recognition of her husband as emperor by Frederick, signified her willingness to reopen negotiations. On Dec. 25, 1745, the Second Silesian War was brought to a close by the Peace of Dresden, by which Frederick retained Silesia and recognized Francis I. as emperor.

The War of the Austrian Succession (*q.v.*) lasted for yet another three years, and was chiefly fought in Belgium. Because the French victories on land were more than offset by the English victories at sea, each of the contestants began to doubt the possibility of a decisive victory, and the dispute was finally settled by the Peace of Aix-la-Chapelle (Nov. 13, 1748) which recognized Maria Theresa as sole heiress of her father, gave certain frontier districts in Lombardy to Savoy, and the duchy of Parma to prince Philip of Spain.

Kaunitz.—Although peace was thus outwardly restored, the tension between Austria and Prussia remained, since Maria Theresa had never abandoned her hopes of regaining Silesia on the first favourable opportunity. Her hopes were shared in by her chief minister, count Kaunitz, who looked upon Prussia as the natural enemy of Austria. Neither party, however, wished to resume the contest without the help of powerful allies. Kaunitz had already established relations with Russia, and his special concern was to induce France to lend her support to his schemes. This was an especially difficult task to accomplish, because for a century and a half Paris had been accustomed to regard Austria as the particular foe of France. At the same time the French viewed the growing power of Prussia with dislike and feared that French influence in Western Germany would be prejudiced. After laborious negotiations, Kaunitz was successful in winning over the French statesmen from their mistrust of Austria and then in bringing about a defensive alliance between Austria and France. It is possible that the French would not have entered into this alliance, if Frederick the Great had not allied himself with England. Frederick, for his part, was convinced that he would again be called upon to defend Silesia from an Austrian attack. Since he was himself allied with France, whereas in earlier wars England had supported Austria, he was anxious to attempt to separate England from Austria without imperilling his good relations with France. At this time English policy was governed by growing colonial rivalry with France, especially in America. In the autumn of 1754 French and British settlers in North America had already come to blows. It was obvious that the mother countries would also become involved in the conflict. As it was feared in England that in such an event France would attack Hanover, and, since Austria showed herself unwilling to undertake the protection of Hanover against a French attack, the English Government sought an undertaking to this effect from Prussia. Being a question of a purely defensive agreement Frederick considered that he could enter into it without breaking faith with France. On Jan. 16, 1756, Frederick concluded with England the Convention of Westminster the main stipulations of which were that Prussia should help England in the event of an attack on Hanover and that England should support Frederick in the event of an attack on Silesia. When the news of this treaty reached Paris, it was regarded as a defection on the part of Frederick; and on May 1, 1756, the French concluded the defensive alliance with Austria for which Kaunitz had so long laboured.

While Kaunitz, with the zealous support of Russia, set to work in Paris to turn this defensive alliance into an offensive alliance, and to secure the consent of France to the complete destruction and partition of Prussia, Frederick the Great learnt of the conclusion of the Versailles Treaty. As at the same moment he received intelligence that Russia was arming on his eastern frontier and from intercepted letters perceived that an attack on Prussia by Austria, Russia and France was being planned for the coming spring, Frederick determined to anticipate the plans of his enemies before their negotiations had been completed. Austria having collected a great military force in Bohemia, Frederick enquired of Maria Theresa whether her military preparations were directed against Prussia, and whether she would be ready to give him her assurance that in this and the following year no attack would be made upon him. On receiving an evasive answer Frederick gave the order to his troops to cross the Saxon frontier.

The Seven Years' War (1756–63).—Thus began the Seven Years' War (*q.v.*), in which Frederick the Great fought against Austria, France, Russia, Saxony, Sweden and the empire. His sole ally was England, whose support consisted mainly in a subsidy of four million talers a year. It was only his pre-eminent generalship and his resolute determination, even in the most difficult circumstances, to lose everything rather than to consent to any diminution of his State, which made it possible for him to survive these perilous years.

During the autumn of 1756 Frederick occupied Saxony, and after he had first defeated a relieving Austrian army at Lobositz, compelled the Saxon army to surrender at Pirna. In the following year he invaded Bohemia, defeated the Austrians near Prague, and invested the Bohemian capital. When, however, he sought to turn back the advancing Austrian army under General Daun, he was himself heavily defeated at Kolin on June 18, 1757, and forced to withdraw from Bohemia. At the same time the Russian troops invaded East Prussia, the French attacked Hanover, and the English army that was stationed there to protect the country was put out of action. Hanover was occupied by the French. A second French army, in conjunction with an imperial army advanced from Thuringia upon Berlin. Frederick immediately attacked this army and won a brilliant victory at Rossbach on Nov. 5. As the Austrians had in the meantime invaded Silesia and seized Breslau, Frederick hastened thither and recaptured by his victory at Leuthen (Dec. 5) the capital of Silesia.

The following year saw a dangerous attack on the part of the Russians, who occupied Königsberg. The Austrians advanced to the south-west to join the Russians and besieged Küstrin. Frederick, who had again attempted an attack on Moravia, was forced by this to return in order to avert this pressing danger and to prevent a junction of the enemy armies. He defeated the Russians at Zorndorf on Aug. 25, although himself sustaining very heavy losses. The Russian forces now retreated into Pomerania and besieged Kolberg. The Austrians, however, had entered Lusatia and, in an attempt to expel them, Frederick was defeated by Daun at Hochkirch, near Bautzen, on Oct. 14. Notwithstanding this defeat Frederick was able, on the whole, to maintain himself in Silesia and Saxony, while in the west, duke Ferdinand of Brunswick, who commanded the English and Prussian forces held the line of the Rhine.

The year 1759 brought Frederick to the verge of irretrievable disaster. Whilst the French advanced in the west as far as the Weser, Frederick, who this time had been unable to prevent a junction of the Austrian and Russian armies, was heavily defeated by them at Kunersdorf on Aug. 12. His army seemed to be well-nigh exterminated. Frederick himself almost despaired and it was only the bad use made of their victory by his opponents that gave him time to collect his troops again. He was indeed, unable to prevent the imperial army from entering Dresden and occupying a part of Saxony. But, since in this year, they had not succeeded in completely overpowering Frederick, his enemies began to weaken in their attack. The illness of the tsarina Elizabeth hindered the operations of the Russians, since it was a matter of common knowledge that the sympathies of the heir-

apparent were with Frederick. Although a Russian advance guard did on one occasion (Oct. 1760) reach Berlin, Frederick was able more or less to retain possession of his kingdom. But, in 1761, the Austrians captured Schweidnitz and the Russians Kolberg and it became daily more and more difficult for Frederick to obtain reinforcements and money with which to pursue the war. English financial support was no longer forthcoming after the fall of Pitt's ministry, when the new Government began to negotiate for peace with France. No decisive change in the situation took place until the death of the Tsarina Elizabeth of Russia on Jan. 5, 1762. The new tsar, Peter III., immediately made peace with Frederick and entered into an alliance with him. Although he was murdered a few months later, his successor Catherine II. was also of the opinion that neither a strengthening of Austria nor the destruction of Prussia would serve the true interests of Russia. She withdrew her military support from Frederick although she did not renew the alliance with Austria. Since the conclusion of peace with England, France had lost all interest in the war with Prussia and had withdrawn her troops across the Rhine. Hence Maria Theresa found herself deprived of all hope of a decisive victory and compelled to enter into negotiations for peace. Peace was signed at Hubertusburg on Feb. 15, 1763. Frederick evacuated Saxony but retained Silesia. Both parties renounced all claims to a war-indemnity.

The importance of the Seven Years' War in the history of Germany lies in the failure of Austria's attempt to destroy Prussia before the power of the latter was consolidated. But the hostility between the two greatest German States continued to exist and to influence powerfully the whole future political development of Germany.

The Emperor Francis I. died (1765) very soon after the conclusion of peace, and was succeeded by his son Joseph II. (1765–90) who was appointed by Maria Theresa co-ruler in the Austrian possessions. As long as his mother was alive, however, he exercised a very limited influence upon Austrian policy. His ambition therefore led him to invest the imperial position with new significance to reform the *Reichshofrat* and the *Reichskammergericht*, and to restore many imperial rights that had fallen into disuse. He was a man of quick perception, and steeped in the ideas of the *Aufklärung*, and endeavoured to introduce them into public life. A doctrinaire rather than a man of action, Joseph was too ready to seek to enforce his ideas without regard to existing circumstances. Frederick the Great said of him that he invariably took the second step before he had taken the first; and from the very first his projects aroused the deep distrust of the German princes. Another principal concern of the emperor Joseph was the wish to extend the frontiers of his empire on all sides. This was first evident when Polish affairs called for interference on the part of the neighbouring Powers.

The First Partition of Poland.—When August III. died in 1763, he was succeeded on the throne of Poland by a king of Polish birth, Stanislaus Poniatowski. He had many enemies, however, in Poland, and the Russian empress, Catherine II., sought to use these internal disputes to make herself mistress of the whole of Poland. This policy affected nearly the interests of the neighbouring German States and, especially, Austria and Prussia Although Frederick the Great believed it to be impossible to check the expansion of Russian influence in Poland, he hoped that at least Austria and Prussia might obtain a share in the spoil. When the Emperor Joseph in the course of a personal visit to Frederick at Neisse in 1769 gave expression to his desire for an understanding with his former enemy, a concerted action on the part of Austria and Prussia in the Polish Question seemed to be possible. Joseph II. devoted all his energy to the task of bringing this about, despite the disapproval of the old empress Maria Theresa, and even took the initiative of occupying Zips.

His action led to the first partition of Poland by the Treaty of Aug. 5, 1772. Russia received all the land lying to the east of the Dvina and Dnieper; Austria received Eastern Galicia; while Prussia was given the former Polish province of West Prussia, with the exception of Danzig and Thorn, the bishopric of Ermland, and the district of the Netze. Though Prussia's share was the smallest, it was of the greatest importance for Prussia in that it restored the territorial unity between East Prussia and the main body of the kingdom. West Prussia had formerly belonged to the Teutonic knights, and was for the most part inhabited by German peasants and townsmen. When the rule of the Teutonic knights came to an end in the 15th century, their lands were lost to Poland.

War of the Bavarian Succession.—Joseph II. had designs on Germany also. In 1777 the elector Max Joseph of Bavaria died, and with him the Bavarian branch of the Wittelsbachs came to an end. According to the principles of the German law of inheritance, Bavaria fell to the head of the younger branch of the Wittelsbach house, Charles Theodore, the elector Palatine. The emperor, who maintained that he himself had claims on Bavaria, succeeded in forcing the elector Palatine to make a treaty by which the elector, in return for the emperor's recognition of his rights to the remainder of Bavaria, ceded to the latter the district of Lower Bavaria, which was at once taken possession of by Joseph. The remaining German princes, especially Frederick the Great, saw a menace to themselves in this extension of the Habsburg power. The emperor's action seemed especially questionable because his claim was entirely unfounded and the heir to the childless elector Charles Theodore, Count Palatine Charles von Zweibrucken, whose assent to these proceedings had not been obtained, had protested to the *Reichstag* against the injury done to his rights. When the emperor sought to extend his claim to include Upper Bavaria, and proposed to compensate the elector Palatine with the scattered Austrian possessions in Suabia and the Upper Rhineland, the count Palatine again protested to the *Reichstag*. Frederick the Great promised his protection to the Count Palatine Charles, and after he had assured himself of the co-operation of the elector of Saxony, invaded Bohemia in June 1778. The War of the Bavarian Succession came to an end without a decisive battle. The Empress Maria Theresa, who from the beginning had disapproved of her son's actions, at once initiated negotiations with Frederick that led to the Peace of Teschen (May 13, 1779). Austria received only a small district in Bavaria, the so-called Innviertel, and renounced all claims to the Bavarian inheritance.

The League of Princes.—Empress Maria Theresa died on Nov. 29, 1780. Joseph II. now became sole ruler in Austria, Bohemia and Hungary. Whilst he sought, by far-reaching laws, to transform these States into a single unitary state under German rule, to free the peasants and to reduce the influence of the Church, he pursued his old schemes in foreign policy. He purchased the support of the empress of Russia by promising her his help in forwarding the realization of her Eastern policy, and he resumed afresh his negotiations with the elector Charles Theodore for the cession of the whole of Bavaria to Austria. This time he offered him in compensation Belgium and the title of king of Burgundy. Charles Theodore was not unwilling to accept the emperor's offer; but once again the Count Palatine Charles raised objections and called upon Frederick the Great for aid. Frederick seized the opportunity to put into execution a long cherished plan. He had had sufficient experience of the unreliability of foreign alliances, and he now thought to increase the status of Prussia by means of an alliance with the more powerful German princes. As these all felt themselves threatened by the emperor's action, Frederick found them more sympathetic to his idea than before. On July 23, 1785 the League of German Princes was concluded between Prussia, Saxony and Hanover, to which were later added Saxe-Weimar, Saxe-Gotha, Palatine-Zweibrucken, Brunswick, Baden, Hesse-Cassel, Anhalt, Ansbach, Mecklenburg, the elector of Mainz and some other smaller States. The preservation of the integrity of the imperial constitution was the aim and object of this league. When the emperor saw that the majority of the German princes had united to oppose his projects, he was obliged to abandon them.

The German League of Princes was an important forerunner of the subsequent development, since this was the first occasion on which an alliance of the majority of the German States under the leadership of Prussia and in opposition to Austria, had been

successfully concluded, yet it was not regarded by Frederick the Great and the majority of its members as a permanent institution. It was called into being by the menace of Joseph II.'s projects for adding to his possessions and lost its significance with the complete abandonment of those projects by Joseph's successors. Of all its members, only Duke Charles August of Saxe-Weimar sought to give it a more far-reaching character. He thought to endow the League with a permanent constitution and to establish a common legal, financial and customs administration, supported by a joint army. The League would then have taken the place in German political life of the old empire now crumbling into ruins. His plans, however, awakened no response in the other members of the League.

The establishment of the League of Princes was the last political act of Frederick the Great. He died at Sans Souci on Aug. 17, 1786, lonely as he had lived, feared and admired by his contemporaries but not loved. The Emperor Joseph II. in the last years of his reign threw himself into vast undertakings in the East. The war against Turkey into which he entered in alliance with Russia, ended disastrously for Austria and threatened to involve the empire in a European war, when Joseph II. died on Feb. 20, 1790. As his successor, the Electors chose his younger brother, Leopold II., grandduke of Tuscany, who ruled for only two years. A peaceable, prudent and farsighted man, Leopold at once sought to restore peace in the East; to bring about friendly relations with Prussia; to overcome the mistrust aroused in the German princes by the adventurous schemes of his brother; and to quiet the disorder that had arisen within his dominions in consequence of the hasty reforms introduced by Joseph II.

THE REVOLUTIONARY AND NAPOLEONIC PERIODS

After the outbreak of the French revolution, the ideas of Liberty, Equality and Fraternity also became popular among the educated classes in Germany. In Germany the proceedings of the first National Assembly were regarded as an attempt to put into practice in political life the great principles of reason; but public opinion was sobered and disillusioned when the Reign of Terror followed and complete anarchy and insecurity of life and property seemed to be the immediate and the inevitable consequences of revolution. As yet the lower classes were not sufficiently independent to take a lively interest in these questions. Only in the Rhineland, which was soon afterwards invaded by the French, was there any real agitation.

There was at first friction between the new rulers in France and the neighbouring German princes when the National Assembly wished to put the decree abolishing feudal rights into practice in Alsace, where many German princes had extensive estates. The princes called on the emperor and the empire for help against the execution of the French law. But the farseeing prudent emperor had little desire to be involved for such a cause in a war with France. Day by day the bands of French emigrks seeking refuge in Germany grew in number. They found asylum at the courts of the west German princes who permitted them to enlist and arm volunteers. The French saw in this a threat to their territory and demanded the disbandment of these troops. But even this dispute would not have led to an outbreak of war, if it had not been that the course taken by the Revolution and the attempted flight of Louis XVI. in 1791 placed the lives of the French royal house in danger. Queen Marie Antoinette was the sister of the Emperor Leopold, and long ago she had entreated her brother to support her and her husband. But Leopold considered that this would only be possible if concerted action were taken by all the great European Powers. He invited the sovereigns of Europe in a circular note of July 6, 1791, to make common cause with him on behalf of the French king and queen. His proposal was energetically supported by Frederick William II. of Prussia, who met Leopold at Pillnitz on Aug. 27, to discuss what further measures should be taken. The representatives of the French emigrks and especially Count d'Artois, the younger brother of Louis XVI., came to Pillnitz to solicit help. They were informed that the German States could only contemplate taking measures which would permit the king to decide as to the acceptance of the new constitution in complete freedom if the non-German Great Powers also promised their support. When, however, the National Assembly, after it had completed the drafting of the constitution, set the king at liberty, and when he accepted the constitution without any outward signs of intimidation, Leopold declared in a circular note of Nov. 12, addressed to all the Great Powers, that he considered the king's acceptance to have been a voluntary act and that the necessity for intervention by the Great Powers no longer existed.

Meanwhile the earlier Declaration of Pillnitz had become known in France through emigrés, and had there aroused fierce resentment. In consequence of the threatening speeches delivered in the National Assembly, and the growing influence of the extreme elements, the emperor found it necessary again to contemplate the assembling of a European congress. After he had concluded a defensive alliance with the king of Prussia for the maintenance of the integrity of their respective dominions, Leopold despatched a sharply-worded note to the French Government in which he announced that the growing disorder in France and the steadily increasing influence of the war-party, compelled him to take defensive precautions on the frontiers of the empire. The Gironde, which had now taken complete control of the Government, demanded that the emperor should cease all military preparations immediately and abandon explicitly the European congress. But when this reply reached Vienna, the Emperor Leopold had just died (March 1, 1792). His son, Francis II., at once returned the answer that he could not grant either request until the complaints of the Alsatian princes had been settled and a Government had been set up in France able and willing to carry out treaty obligations. On receipt of this reply, the French Government declared war on April 20.

War with France. — It is therefore not true to say that Prussia and Austria united to make war for the purpose of crushing revolutionary ideas; on the contrary, they desired to avoid war, whilst the Girondists in Paris were loudly demanding it. Obviously, when such a war once broke out, it would of necessity be a war for the principles of Government, for the enforcement of the ideas prevailing in the age of absolutism against the new ideas born of the revolution.

The Austro-Prussian campaign against France did not begin until the autumn of 1792. From the very outset, its progress was crippled by the fear that the Empress Catherine would seize the opportunity presented by the preoccupation of the allies in France to annex the whole of Poland. The chief command was entrusted to the old duke of Brunswick, who increased the resentment of the French by issuing an imprudent and tactless manifesto to his armies. But since the French troops were ill-equipped and badly led, the German armies succeeded in capturing Verdun and advancing as far as the passes of the Argonne. But here the Duke of Brunswick delayed his attack so long that the French were able to bring up reinforcements for the defence of the passes. The bombardment of the Heights of Valmy (Sept. 20) had no decisive result. Brunswick did not dare to attempt a general assault, or to advance any further since his line of retreats might be threatened. Since moreover differences of opinion had meanwhile arisen between the Austrian and Prussian commanders and news had arrived that a Russian army had, in fact, marched into Poland, Frederick William II., who was present with the army in person, decided to order a retreat. The Allies' attack on France was thus frustrated. As Goethe rightly says Valmy marks the beginning of a new epoch in history.

While it was yet winter the French took the offensive, and occupied Speyer, Worms and Mainz, but failed to obtain more than a temporary grip upon Frankfurt-on-Main. Wherever the French troops came they set up Jacobin clubs and sought to win over the population to revolutionary ideas. In this they were at first successful; but it was soon clear that the Paris Government was more concerned in plundering the financial resources of the occupied districts than in their liberation. As soon as the inhabitants realized this public opinion turned against the French The threatening advance of the French on the Rhine again forced the two German Powers to take vigorous steps. During 1793 the

French were again driven out of Belgium, the greater part of which they had occupied. Mainz was recaptured and the German troops entered Alsace. It was not until the following year that the French were able by their victory at Fleurus to reconquer Belgium. to regain possession of Alsace, and to advance on the Lower Rhine even as far as Aix-la-Chapelle and Cologne. They were able to do this chiefly because Prussia had virtually retired from the war because Polish affairs demanded her whole attention.

The Second and Third Partitions of Poland.—In the autumn of 1792 negotiations were initiated between Russia and Prussia for a new partition of Poland. On Jan. 23, 1793 a treaty was signed by which Prussia obtained Danzig, Thorn, Posen and an important share of Poland; Russia receiving the greater part of Lithuania. Austria obtained nothing but was promised assistance in reconquering Belgium. The Emperor Francis felt that he had been cheated; and his distrust of Prussia steadily increased from that time. Of the former Polish kingdom, only a small and unimportant part remained in existence. The opposition displayed by the Poles to the occupation of the partitioned districts was forcibly crushed by Russia and Prussia. Both these States henceforth believed that the only security against a repetition of such occurrences lay in a complete partition of Poland. But this time Austria had to be given a share of the plunder, and, after lengthy negotiations, the Third Partition Treaty was signed, in Aug. 1795. Prussia obtained the Polish capital, Warsaw with the district up to the Bug and Memel; Austria got West Galicia and Cracow; and Russia received all eastern Poland together with Courland. The treaty was immediately put into force, and thereby the old Polish kingdom erased from the map of Europe without any attempt having been made to consult the wishes of the inhabitants. The partition was a simple act of violence characteristic of the *Kabinetspolitik* of the 18th century.

Basle, Campo Formio and **Lunéville.**—Shortly before this Frederick William of Prussia had signed at Basle (April 5, 1795) a separate peace with France in order to leave him free to deal with affairs in the East. By this treaty the left bank of the Rhine was given over to France, while Frederick William reserved the right to demand in compensation for Prussia's possessions that North Germany, north of a line drawn from the Rhine to Silesia, should be declared neutral; the French troops were not to enter this area, in return for which Prussia guaranteed to use her influence to prevent the North German princes from supporting the emperor against France. Thus Prussia once more resumed the anti-Austrian policy which she had for some years abandoned to make common cause with Austria against France.

Austria continued to carry on the war, with the financial support of England, for a further two years until she was compelled, as a result of Napoleon's masterly Italian campaign, to conclude the Peace of Campo Formio (Oct. 1797). The emperor was forced to surrender Lombardy and Belgium to France and received in return Venetia, Istria and Dalmatia. He was also forced to agree to the cession of the left bank of the Rhine to France. The German princes who suffered a loss of territory in consequence of this cession were to be compensated on the German right bank of the Rhine, and their claims were to be dealt with individually by a congress which was to meet at Rastadt.

This congress actually met. But before it had completed its labours, war had broken out anew. On the death of the Empress Catherine II. (1796) her son Paul I. had succeeded to the throne; he was a bitter enemy of the revolution. Since Austria, too, was eager to throw off the hard terms of the treaty of Campo Formio, the English minister, Pitt, was able to build up a new alliance against France. The greatest of the French generals, Bonaparte, had embarked on his expedition to Egypt, and the moment therefore seemed specially favourable for a renewal of the war. Under the leadership of the Russian General Suvarov, the allied army drove the French out of Italy in 1799; but an attempt to expel them from Switzerland miscarried. Before Suvarov had arrived with Russian reinforcements, the Austrian army had been defeated near Zurich. The French were also victorious over the English troops in the Netherlands, and, when Napoleon returned from Egypt in the autumn of 1799 and took over the supreme command, the French armies again resumed the offensive. By their victory at Marengo (June 14, 1800), they won back Italy. They also advanced victoriously into southern Germany. Under these circumstances, the allies decided to treat for peace with Bonaparte, who had in the meantime become head of the French republic as first consul. By the Peace of Lunéville (Feb. 9, 1801) the cession of the left bank of the Rhine to France was confirmed. Peace between France and England was signed in the following year at Amiens.

Napoleon and the German princes.—Negotiations now began in Germany for the compensation of the German princes who had incurred losses on the left bank of the Rhine. The *Reichstag* appointed a special commission for this purpose, but the settlement really lay in the hands of the great Powers, especially France. Napoleon came to an understanding with Russia and Prussia to divide up the ecclesiastical states and the majority of the imperial cities among the injured princes. Bavaria, Württemberg, Baden and Hesse were won over by promises of especially large compensation; finally, Austria was drawn in, since although she was reluctant to assent to such a great diminution in the Catholic elements in the *Reichstag* she gave up her opposition as unavailing. On Feb. 25, 1803 the results of the negotiations were embodied in the final decision of the commission (*Reichsdeputationhauptschluss*): 112 states were apportioned, out of which in the first place certain foreign princes who had sustained losses elsewhere, had to be compensated. Thus the hereditary Stadholder of the Netherlands who had been driven from his dominions, was given the abbacy of Fulda and certain adjoining districts; the duke of Modena the Breisgau; and the grand duke of Tuscany, the archbishopric of Salzburg. Prussia was indemnified by the bishoprics of Munster, Paderborn and Hildesheim in addition to Erfurt and a number of imperial cities in central Germany; Bavaria received the bishoprics of Wurzburg, Bamberg, Augsburg and Freising with a number of South German imperial cities; Württemberg, Baden, Hanover and Oldenburg were similarly greatly increased in area. The map of Germany was entirely altered by these political changes which marked only the beginning of a transformation that was to be carried still further three years later.

The Confederation of the Rhine and the Fall of the Empire.—Meanwhile war had again broken out between France and England. Russia and Austria made common cause with England; Prussia remained neutral. Napoleon's great victory at Austerlitz on Dec. 2, 1805 decided the war in his favour. The tsar withdrew to Russia, and Prussia, which in consequence of a violation of its territory by French troops was on the point of declaring war on France, again entered into an understanding with the emperor. Austria, however, was forced to sign the unfavourable Peace of Pressburg on Dec. 26, 1805, to surrender Venetia to the kingdom of Italy recently founded by Napoleon, Tirol to Bavaria, and her remaining Suabian lands to Württemberg and Baden. As compensation, she received only the archbishopric of Salzburg; its former possessor, the grand-duke of Tuscany, being compensated by Würzburg. The emperor was also forced to recognize the elevation of Bavaria and Württemberg to the status of kingdoms. Napoleon set up in the Rhineland a new grand-duchy of Berg for his brother-in-law General Murat.

Napoleon now resolved to unite the States which he had created, or enlarged, in a permanent confederation, and on July 12, 1806 he founded the Confederation of the Rhine, which, apart from some small states, included Bavaria, Wiirttemberg, Baden, Hesse-Darmstadt, Nassau and Berg. The territories of the counts and knights of the empire, which lay between these states, were divided up among them. Thus, the boundaries of the South German States were laid down by Napoleon much as they exist in the 20th century. Their rulers feared therefore lest Napoleon's defeat would involve them in the loss of all that they had gained The States of the Confederation of the Rhine remained independent for internal administration, but could not pursue an independent foreign policy and were required to place their troops at any time at the disposal of Napoleon, who had been nominated

the official protector of the Confederation. The members of the Confederation informed the emperor and the *Reichstag* that they regarded themselves as having ceased to be members of the empire, and that this had ceased to exist (Aug. 1, 1806). The emperor therefore laid aside the German Imperial crown on Aug. 6, having already assumed the title of emperor of Austria in 1804. The old German empire, in existence for almost 1,000 years, wholly disappeared, and the complete independence of the individual States which had grown up on its territory was legally recognized. Germany became a geographical expression, and lacked any political unity.

Napoleon's War with **Prussia.**—Napoleon now thought that his day of reckoning with Prussia had come. Thanks to his too cautious and wavering policy, Frederick William III. found himself without support before the might of the French emperor. Frederick William was indeed able to conclude a defensive alliance with Russia, when Napoleon's threatening speeches left no doubt as to his intentions, but, except for Russia, Prussia had as supporters only electoral Saxony and certain small North German States. When Napoleon occupied certain Prussian districts on the Rhine in order ro hand them over to rhe grand-duchy of Berg. and when he demanded that Prussia should recognize as valid this act of violence and completely disarm, Frederick William replied with an ultimatum in which he required Napoleon to evacuate Southern Germany. As Napoleon naturally refused to comply with this demand, war broke out between France and Prussia in Oct. 1806.

The defeat sustained by the Prussian armies at Jena and Auerstädt on Oct. 14, had in fact already decided the fate of the Prussian kingdom. Napoleon entered Berlin in triumph; Frederick William was compelled to fly to Königsberg. The whole of northern Germany was occupied by the French, and only a few Prussian fortresses put up a successful resistance. The elector of Saxony made peace with Napoleon and entered the Confederation of the Rhine in return for the conferment of the royal title. If the tsar had not at this moment come to her aid, Prussia would have been wholly destroyed. The bloody contests on the battlefields of West and East Prussia during the early months of 1807 failed to bring about a decisive victory. Napoleon therefore thought the moment favourable to enter into peace negotiations with the tsar, which resulted in the Peace of Tilsit (July 7, 1807). Although Prussia continued to exist as a kingdom, she was forced to cede her entire possessions west of the Elbe in addition to the greater part of her acquisitions in the last partition of Poland. A vast war indemnity was demanded from her, and, until it had been paid in full, she was required to consent to the occupation of her most important fortresses by French troops and to undertake not to maintain an army of more than 42.000 men. Out of the territory between the Elbe and the Weser ceded by Prussia Napoleon created the kingdom of Westphalia, with which he incorporated the territory of the elector of Hesse-Cassel, who had been dispossessed. He made his brother, Jerome, king.

Germany Under Napoleon.—While the attention of Napoleon was fully engaged in the south during the next few years in dealing with the revolt of the Spaniards, Austria made another attempt in 1809 to regain her old position. As Russia refused her aid, and Prussia, after her defeat, was unable to help, the war once more ended in the total defeat of Austria (Wagram, July 6, 1809). The Peace of Vienna (Oct. 14) deprived Austria of Salzburg, Galicia, and Istria. Napoleon erected a grand-duchy of Warsaw out of the former Polish possessions of Austria and Prussia, and made the king of Saxony grand-duke, whilst Dalmatia (already ceded by the Treaty of Pressburg) and Istria were united to France under the name of the Illyrian Provinces.

Although he was victor in this war, Napoleon saw with anxiety the excitement these events aroused in the whole of Germany. Bodies of volunteers were formed in various districts to offer their assistance to Austria—such as those organized by Major von Schill and Duke Frederick William of Brunswick. Despite the fact that these movements met with no success, Napoleon deemed it necessary to unite the north of Germany still more closely with France, and, in 1810, with the exception of Holland, he annexed all the German districts lying northwest of a line drawn from Cologne to Lubeck and formed them into departments after the French model. He had now attained to the zenith of his power; while his marriage with the daughter of the Emperor Francis had brought his dynasty within the circle of the ancient ruling houses of Europe. But a change came over the scene with his Russian campaign in 1812, in which the French army was almost entirely destroyed, a miserable remnant alone surviving to reach Germany in the winter.

The War of Liberation.—It was only natural that Germany should seek to utilize Napoleon's heavy deieat to shake off his rule; but there was wanting a single directing will in a country that was governed in part by princes that were vassals of France and in part occupied by French garrisons. The population of North Germany, where the rule of the foreigner had been felt most strongly and oppressively, was filled with a wild hatred against the French; in the south, where native princes still ruled and no foreign troops or officials had penetrated, emotions were less violent. For the first time the educated classes in Germany became inspired by a feeling of world-citizenship and learnt to understand the importance of a national state in the common life of a people. The rulers of the greater States however, still hesitated to come to a definite decision. The Emperor Francis did not wish to fight against his son-in-law, and Frederick William of Prussia feared that he might lose the rest of his kingdom if the new war should prove unsuccessful. Only when the Russians seemed determined to pursue their fight with Napoleon on German soil, were the German princes forced to decide on which side they would fight. At Napoleon's bidding, Austria and Prussia had been forced to send reinforcements to help him against Russia. The commander of the Prussian contingent, General York, acting on his own responsibility, concluded a treaty of neutrality with the commander of the Russian forces opposing him. But it was only under pressure from the Emperor Alexander of Russia that Frederick William finally decided to address from Breslau the "Appeal to my People" (*Aufruf* an *mein* Volk) in which he declared war against France. This proclamation gave the signal for a general rising in Northern Germany against Napoleon. Volunteers enthusiastically rushed to arms, and the Russian and Prussian troops were already on the Saxon frontier while Austria still remained neutral.

Napoleon hastened to the defence of his German allies, defeated the Russians and Prussians at Grossgorschen and Bautzen, and forced them to retreat to Silesia. Feeling himself unable to prosecute the campaign to a final victory Napoleon concluded an armistice during which peace negotiations were opened at Prague through the intermediary of Austria. Napoleon, however, was unwilling to surrender any of his conquests, and so, after much hesitation the Emperor Francis finally made common cause with the allies and declared war on France on Aug. 12, 1813. Since England gave financial support to the allies, and the Spaniards, in conjunction with an English army, advanced from the south against France, Napoleon found himself opposed by almost the whole of Europe. After many changes of fortune, the campaign in Germany finally ended in the defeat of Napoleon at the "Battle of the Nations" at Leipzig (Oct. 16–19, 1813). The French army had to retreat over the Rhine, the allied forces followed them slowly: on New Year's Eve 1814. they crossed the Rhine and advanced into northern France. By the end of March 1814 the allies were in possession of Paris. Napoleon was compelled to abdicate his throne and appeal to the mercy of his enemies. He was banished to the island of Elba. The house of Bourbon was restored to power, and, by the First Treaty of Paris, France was forced to abandon all the conquests she had made since 1792. (See also NAPOLEONIC CAMPAIGNS, etc.)

The Reconstruction of Germany.—With the removal of the foreign rule of the French the difficult question of Germany's future organization arose. Austrian policy, now inspired by Metternich, aimed at preventing Prussia from becoming too powerful and desired to draw to itself the German princes who had been allied with Napoleon. The Emperor Francis signed the Treaty af

Ried with the king of Bavaria, by which the latter was assured of full sovereign rights in his former dominions, and similar treaties were concluded with Württemberg, Baden and the other states in the former Confederation of the Rhine. Thus it was no longer possible to regard these States as captured districts to be divided up among the victors. In northern Germany Hanover, whose ruler was the king of England, also remained intact. Moreover it seemed unjust to exclude from their territories the princes whom Napoleon had exiled whilst preserving the vassal states which he had created. Under these circumstances it became excessively difficult to find a means of giving expression to the political unity of Germany.

At the Congress of Vienna, which sat from Sept. 1814 to June 1815, the German question was one of the most difficult of the problems under consideration. Finally it was agreed that Austria should recover her former possessions in Germany, with the exception of the scattered territories in Suabia, and in addition Salzburg, Venetia, Milan and Dalmatia. In return she was forced to abandon Belgium and hand over to Russia all her Polish acquisitions with the exception of Galicia. Prussia obtained in eastern Germany only West Prussia and Posen, but received as compensation for the rest of Poland (given to Russia) Westphalia, the Rhine province and the former Swedish province of Upper Pomerania, in addition to a considerable portion of the Saxon electorate. She renounced the South German districts of Anspach and Bayreuth, which were given to Bavaria together with Wurzburg and the Palatinate lands lying on the left bank of the Rhine. The other territorial changes were of less moment. There now remained in Germany 39 different States, of which four were the free cities of Hamburg, Bremen, Lubeck and Frankfurt: the remainder possessed monarchical constitutions. The idea of a restoration of the empire was abandoned, and the 39 states formed a union of which the constitution was laid down in the Federal Act of June 8, 1815. The common organ of the Confederation was the diet at Frankfurt-on-Main of which Austria was given the presidency. The organization of a federal army and the construction of a number of federal fortresses was also contemplated. The chief aim of the Confederation was the common defence of the federal territory against foreign attack whilst the individual States retained full sovereignty in their internal affairs. Even the establishment of a supreme court of justice for the Confederation proved impossible. As any change in these basic principles could only be effected by an unanimous vote, an extension of the competence of the Confederation was practically impossible. The Prussian provinces of Prussia and Posen, and the Austrian territories in Galicia, Hungary, Milan, Venetia and Dalmatia, were not included in the Confederation. The Confederation could at the most prevent war between the German States and if necessary ward off foreign attack upon its territory, but it could never establish the principle of a German political entity.

Whilst the congress was sitting at Vienna, Napoleon escaped irom Elba to France and once more sought to win back his former empire. This danger forced the States which had up to that time been allies to hasten on their union to prepare themselves for common defence. Napoleon's defeat at Waterloo and his imprisonment on St. Helena set this new order of things on a firm basis. By the Second Peace of Paris (Nov. 20, 1815) France was compelled to cede Saarlouis and Saarbrucken to Prussia and Landau to Bavaria; but she retained possession of Alsace and Lorraine.

THE GROWTH OF PRUSSIA

After the restoration of peace the German Governments endeavoured to restore absolutism as far as possible and to efface the effects of the French Revolution: in this Austria took the lead. Prince Metternich who, as chancellor, was the leader of Austria, was the real exponent of reactionary principles. In his eyes the maintenance of monarchical authority was essential to political stability. He was therefore an enemy to all liberal and democratic ideas. Moreover in the conception of nationality he perceived a present danger to the stability of Austro-Hungary. At the moment of his accession to power the various peoples in the Danubian monarchy were striving for autonomy and even questioning the further existence of the Habsburg rule. A man of unusual ability, great diplomatic skill and inflexible will power, Metternich was able to persuade the other princes to accept his ideas. His programme was indeed, purely negative and ultimately amounted to no more than the retention of existing institutions no matter how outworn they might be.

Reaction. — Prussia had no cause to oppose national and liberal claims. But Frederick William's dislike for everything that reminded him of Jacobinism made him willing to listen to Metternich's proposals. Then, too, there was the instinctive dislike of the nobility living east of the Elbe, with whom the Prussian kingdom was in very close relations, to every concession to liberalism. Only the desperate state of affairs after the Prussian defeat at Jena had induced the king and the nobles to allow reforms to be introduced into the political life of the State. For these reforms Hardenberg and Stein had fought with the object of interesting the nation in public affairs and securing their co-operation in the work of government. Once the danger had passed, the reforms fell into abeyance. The freedom accorded to the peasants and the autonomy granted to the towns did, indeed, remain, but the idea of completing the work through the introduction of autonomy into the provincial administrations and through the creation of a popular representation, as had been intended by Stein, was bitterly opposed by the king, and Hardenberg was too old and too yielding to oppose him energetically. But the reforms that had been effected in the very foundations of the Prussian State had introduced an element of liberty that was capable of further development. On the outbreak of the War of Liberation the king had pledged his word that for the future he would not raise new taxes nor loans without the assent of the estates. The natural result of his promise would have been to revive the diet. Hardenberg indeed sought to revive it, but the king invariably postponed the fulfilment of his request, and, after Hardenberg's death, the influence of Metternich was so strong that the idea was wholly abandoned; it was considered sufficient to create in 1823 provincial diets in each individual province of the monarchy, who however, could deal only with provincial affairs and whose deliberations might not be published. By rigid economy, the king was up to the time of his death able to avoid the necessity for new taxes or loans and thus evade the fulfilment of his promise.

A complete return to absolutism in the South German states, where many institutions from France had been introduced in the days of the Confederation of the Rhine, appeared impossible. Bavaria and Baden received constitutions in 1818, and Württemberg in 1819. A general assembly had been instituted consisting of two chambers; the first chamber was mainly composed of the royal princes and great territorial nobility; the second chamber too, was on a very restricted franchise based on a tax qualification favouring the owners of landed estates, the lower classes in the community thus being wholly unrepresented. The assent of the diet was necessary in future for all legislation, yet this assent was only required for the imposition of new taxes whilst existing taxes continued to be levied without special consent. It had, therefore, only limited control of the budget. The ministers depended solely upon the pleasure of the king and could only be impeached in cases where it was proved that an infringement of the constitution had taken place. Similar constitutions were introduced in Nassau and Saxe-Weimar. But in the remaining German states absolutism prevailed.

The great German States were displeased with what they regarded as too far-reaching concessions on the part of the South German princes. They seized the opportunity presented to them by the manifestation of liberal tendencies at the festival on the Wartburg at which the German students celebrated the tercentenary of the Reformation (1817) and the murder of the Russian spy and popular novelist Kotzebue, to summon the representatives of the greater German States to a conference at Carlsbad for the purpose of consulting upon new measures against the revolutionary spirit manifested in these occurrences. This resulted in the Carlsbad Decrees establishing a censorship of books and newspapers and a drastic supervision of the universities. The decrees were adopted by the diet under pressure from the greater States,

and a resolution passed declaring that no German prince had the right to make concessions to his subjects that involved an infringement of his sovereignty. These decrees were also embodied in the final Act of the Vienna Congress in *1820* and thereby became a fundamental law of the German Confederation. At the same time a central commission was set up in Mainz to detect and suppress all democratic movements.

In foreign policy Prussia and Austria were also of one mind in the following years. Their object was to support the cause of established authority throughout the world and to combat the further dissemination of revolutionary ideas. In this they were in full agreement with the Tsar Alexander, acd in the Holy Alliance (*q.v.*), which was concluded in *1815* between the rulers of Austria, Prussia and Russia, their ideas were given very clear expression. The allied powers made common cause against the revolutionary movements in Italy and Spain, and at the congresses held at Aix-la-Chapelle, Troppau, Laibach and Verona (1818–23 *qq.v.*) the measures to be taken were discussed and determined. Only when differences of opinion arose between Austria and Russia at the time of the Greek revolt against Turkey, was the Holy Alliance loosened and ultimately dissolved; and for long afterwards its renewal was one of the basic principles of the policy pursued by the rulers of the three Eastern Powers.

1830.—For a decade after *1815* Germany enjoyed outward peace and internal order. Those elements which were striving for a more liberal form of constitution and stronger national unity did not dare openly to reveal their aims oppressed as they were by police supervision and continual persecution. After the great upheaval of the War of Liberation the mass of the population sank back into their old indifference. Even the July Revolution of 1830 in Paris had no important effect in Germany. The sole result of the small risings that broke out here and there throughout the country was the introduction of constitutional government in a few more of the small States. Saxony, Hanover and the electorate of Hesse received constitutions that differed but little from those already in operation in the South German States. Duke Charles of Brunswick, who was a violent despot, was driven out of his dominions, and his brother William became duke in his stead. Both the great German Powers remained undisturbed by the agitation, and under their influence the *Bundestag* at Frankfurt laid upon the individual States the duty of supporting each other against rebellious movements, and decreed that no *Landtag* had the right to refuse taxes to the ruler. Political associations and meetings were forbidden, the police system further developed, and the freedom of the Press still more curtailed. No printed matter of less than 20 pages could be published without the permission of the police. When the elector of Hesse withdrew the constitution which had recently been granted the *Bundestag*, to which the Hessian diet had appealed for protection, refused to intervene against this flagrant infringement of an established right by a German prince. A similar situation arose a few years later in Hanover. After the death of William IV. of England (1837), the personal union between Hanover and England was dissolved in consequence of the existence of a different law of succession in each kingdom. Whilst William was succeeded upon the throne of England by his niece Victoria, his successor in Hanover was his brother Ernest Augustus. The latter arbitrarily set aside the constitution granted by his brother and introduced another which gave to the *Landtag* considerably restricted powers. When seven professors of the university of Gottingen refused to take the oath to the new constitution because they deemed themselves bound by their oath to the former, they were deprived of their professorships. Against all these violations of the law no protection was to be found in the *Bundestag*. The increasing bitterness of the population did indeed find expression from time to time in speeches like those held on the occasion of the Hambacher Festival in *1832* and in the quickly suppressed rising at Frankfurt against the *Bundestag (1833)*. The only result of these unsuccessful efforts at revolt was the tightening up of police supervision; they did nothing to remedy the state of affairs.

While thus political affairs were in a state of complete paralysis, in intellectual life new forces were beginning to appear and found expression in the writings of the so-called "Young Germany" group. Heine, Borne, Gutzkow, and Laube were the literary protagonists of the younger generation who demanded greater intellectual and political liberty. Their writings, which were condemned by the *Bundestag* as dangerous to the State, nevertheless enjoyed a wide circulation and influenced to a steadily increasing degree the ideas of the educated classes. A new energy also became manifest in the sphere of economics, and a great step forward was taken with the founding of the German Zollverein in *1834*.

The Zollverein.—By the Customs Law of *1818* Prussia had already removed the customs tariff between the individual provinces; stopped the levying of taxes on the frontier; introduced a simple system of calculation based on the weight, and, finally, had removed or lowered the customs duties on many classes of goods. The inclusion within the Prussian State of many small political entities rendered it impossible to achieve a rational organization of the customs service unless these entities accepted that system. This was first done by Schwarzburg and Anhalt; but in *1828* one of the greater States, Hesse-Darmstadt, joined the system. Hesse-Darmstadt adopted the Prussian customs tariff; the revenue was to be paid into a common treasury and subsequently divided between the two States in proportion to their respective populations. Shortly afterwards Bavaria and Württemberg entered into a customs union. Prussia entered into negotiations with them also and the central German States, fearing that an agreement between North and South Germany would be reached over their heads, felt compelled to join the union. After Jan. *1*, 1834, with the exception of Austria, Hanover, Oldenburg and the three Hansa cities, Germany formed an economic entity. Internal communication was thereby immensely simplified; the price of goods lowered and a greater uniformity in prices achieved; and consumption and production stimulated. The introduction of a uniform system of weights, measures and currency was the natural consequence of this customs union. At first the establishment of the customs union exercised no important influence on political life. The States that formed the union under the leadership of Prussia felt no obligation to unite themselves with her in political questions. The existence of the customs union did not prevent the economically allied States in 1848 and 1866 from engaging in political and military strife with one another, and it was not until later that Bismarck was able to utilize the union for the furtherance of his schemes for national unity. Yet it was not without importance for the future overcoming of provincial differences that from this time forward at least a greater part of Germany formed an economic entity. The desire to form the German States again into a political entity was confined to the intellectual leaders of the middle classes and only occasionally found literary expression. In this connection the most important publication was *Briefwechsel zweier Deutscher* by Paul Pfizer of Wiirttemberg *(1831)* in which, for the first time, expression was given by a South German to the belief that such a union could only be initiated by Prussia, since Austria had ever since the Reformation been so estranged from German life and thought she was no longer in a position to become the leading power in Germany.

Frederick **William IV.**—In view of the predominating influence which Austria and Prussia possessed over Germany's destiny, it was of great importance for future developments that in both States there occurred, at this time, a change of rulers. On March *2, 1835*, the Emperor Francis I. of Austria died, and was succeeded by his mentally feeble son Ferdinand. The actual Government was carried on by a state council composed of the brother and uncle of the emperor together with Prince Metternich and count Kolowrat. As Metternich remained the guiding spirit of the administration, little real change took place in the policy of Austria. Of far greater importance was the change of ruler in Prussia. Frederick William III. died on June 7, *1840*, after a reign of *43* years. He was succeeded by his eldest son Frederick William IV. who was then *45* years old. A man of unusual ability and many-sided interests, he was both a brilliant orator and an original thinker; but he was less suited to the practical duties of a statesman. Frederick William IV. was steeped in the spirit

of that romanticism which in his youth had played the leading rôle in the intellectual life of Germany. As a fervent Christian, he regarded the execution of his kingly office as a religious duty, and believed it to be his duty to make the principles of Christianity a factor in politics. He regarded himself as the divinely appointed father and guardian of his people, and he saw in the desires and ideals of democracy and liberalism a revolt against God; an attempt on the part of mankind to substitute human intelligence for the divine laws as the highest guiding principle in the settlement of all national problems. His ideal was the old German *Starcdestaat*. He hated France as a source of godless revolutionary ideas, and considered that in foreign policy also the conservative States based on the old divinely appointed order must hold together in opposing revolutionary tendencies. He was indeed the embodiment of the basic principles of the Holy Alliance of 1815. He desired it is true to introduce certain reforms into Germany, for he sympathized with the national currents of feeling and wished to satisfy them; but even in this the existing order must be maintained in principle. Any diminution of the sovereign rights of the German princes seemed in his eyes to be a blow directed against the divine principle of legitimacy, and he hoped to achieve the necessary unity by means of voluntary co-operation on the part of the princes, under the moral leadership of Austria and Prussia.

His attempt to organize Prussia in accordance with his ideals culminated in the summoning of a national parliament (1847). The members of all the provincial diets were to assemble at Berlin in order to deliberate with the king on affairs of State, when called upon by him to do so. The final decision of all matters remained in the King's hands, and the *Landtag* was to have no definite rights nor any claim to be summoned at any regular intervals. In the speech from the throne with which Frederick William IV. opened the deliberations he declared that no power on earth would induce him in any circumstances to change the natural relation between prince and people into a conventional and constitutional one and he would never consent that "a written document should, like a second Providence, intervene between God in Heaven and this land, to rule us with its paragraphs and replace our ancient holy loyalty." The *Landtag*, however, refused to play this rôle. When the King desired its consent to a loan for the construction of a railway between Berlin and Konigsberg, the *Landtag* declared that, in accordance with the promise made by the late king, the true diets must be summoned for this purpose. It did not regard itself as the true diet because it had never been given the right to be summoned periodically. **A** number of representatives of the middle classes in the Rhineland like Hansemann, Camphausen, Mevissen and Beckerath came into prominence in the *Landtag* as the spokesmen of liberal aspirations. As the king refused to yield to these demands the assembly was dissolved without coming to any definite conclusion.

The First Political Parties.—Whilst Frederick William's political experiments in Prussia were unsuccessful a strong political agitation arose throughout Germany. The relaxation of the censorship had led to the strengthening of the desire for a freer political order and a closer alliance of the German States. In the parliaments of the individual States also these desires found vigorous expression. Political parties were gradually formed uniting groups of similar views in the different States. It is true that they still lacked organization and a definite aim. When in 1840 the international tension rendered the outbreak of war between France and the German great Powers a possibility, a strong national feeling was aroused in the people. This again made itself manifest in 1846 when the king of Denmark sought to include the German inhabitants of Schleswig and Holstein within the frontiers of the Danish State. The diets of Holstein, which was a member of the German Confederation, appealed for help to the *Bundestag* at Frankfurt. The *Bundestag*, however, contented itself with an expression of its belief that the king of Denmark would respect the rights of the Confederation and of the Holstein diets. It was everywhere felt that this supreme organ of the Confederation was not really capable of representing threatened German interests.

Feeling was further excited by the appearance of new revolutionary movements in France, Italy and Switzerland. In Sept. 1847 the leaders of the democratic groups in the various German States met at Offenburg and drew up a programme of which the chief points were: entire liberty of thought and association; universal and equal suffrage; disbandment of the standing army and the introduction of a militia; a progressive income tax; trial by jury in all cases of offences against the Press laws; abolition of all class privileges; comfort, education for all; equalization of the disproportionate conditions existing between capital and labour; ministerial responsibility and the assembling of a German parliament. Behind, and inspiring the entire programme, lay the ideal of a German united republic. In October the leaders of the moderate Liberals held a conference in Heppenheim at which they also demanded freedom of the Press, abolition of the feudal burdens, wider autonomy, an improvement in the system of taxation, and a closer union of the German States. The liberal ideal was the establishment of a constitutional federal state with monarchical rule in the individual States which should also be administered constitutionally. In Feb. 1848, in the diets of Baden and Hesse, the liberal representatives Bassermann and Heinrich von Gagern proposed the summoning of a German Parliament.

The Revolution of **1848.**—Feeling was thus already excited in Germany at the moment when the news arrived of the success of the February Revolution in Paris and gave the signal for action in Germany. The movement first affected the smaller states in south-western Germany. Rioting broke out everywhere, and the Governments, taken by surprise, at once yielded to the demands which were put forward by the people's assemblies. They appointed liberal ministers and promised freedom of the Press and a constitution. Within a few weeks the old ministries had been overthrown in Baden, Wiirttemberg, Bavaria, Hanover, Brunswick, Hesse, Nassau, Thuringia and Saxony, and a new order seemed about to begin. A conference of the Liberals met at Heidelberg on March 5, and demanded the immediate convocation of a German parliament. The terrified *Bundestag* agreed to this demand and requested the German governments to send trustworthy councillors to Frankfurt to draft a constitution for Germany. The success thus achieved, however, could only prove of more than temporary character in the event of the overthrow of the old order in both the great German States.

In Vienna the Government did not dare to put up any real opposition to the demands of a population which was daily becoming more incensed. Metternich was forced to resign and leave Vienna. A national guard was organized and the summoning of a *Reichstag* conceded (March *13)*. The Hungarians, Bohemians, Southern Slavs and Italians in Lombardy and Venetia, simultaneously demanded autonomy and the granting of constitutions for their provinces. It seemed as though the Danubian monarchy was about to be broken up into a series of separate states.

On the approach of the revolution Frederick William IV. had sought to pacify his subjects by certain concessions. By the decree of March 14, he once more summoned the united *Landtag*, to which he now conceded the right of periodic assembly, and announced his readiness to collaborate in reconstructing the German Coniederation. He hoped thereby not only to retain his own position, but to be able to support the other States in combating the spread of revolutionary ideas. But with the arrival in Berlin of the news of the occurrences in Vienna open revolt broke out. Although the troops were victorious in the street-fighting of March 18, the self-confidence and determination of the king was shattered by the unexpected conduct of his "dear Berliners." At the request of a deputation which promised to remove the barricades, the king ordered the troops to evacuate their position thereby at once losing control of the situation so completely that the troops, which had at first been concentrated on the square in front of the palace, retired to their barracks. The moment the troops disappeared a vast throng of people advanced before the palace, bearing with them the bodies of those killed in the defence of the barricades, and forced the king to uncover before the corpses. **A** citizen guard was then organized, and assumed sentry duty in the palace, while the troops received orders to retire from Berlin.

Thus the Revolution triumphed in Berlin also. The king prom-

ised to grant a constitution to Prussia to be drawn up by a National Assembly. On March 21, displaying the black-red-gold colours, the King went in procession through Berlin and announced that in these critical days he would assume the leadership of the German people and that Prussia in future would become part of Germany. The King himself never thought to strive in alliance with the Revolution for the overthrow of the individual States or their subjection to Prussia. But he had let himself be swept away by the tide of popular feeling and, from the moment he regained in some measure his self-confidence, he sought to avoid the consequences arising out of the concessions he had made in a time of excitement and danger. The new liberal ministry was headed by Camphausen, who had been one of the leaders of the opposition in the united *Landtag*.

The fail of the old regime in the separate States was to be followed by a political re-organization of Germany. A preliminary parliament met at Frankfurt and again demanded that a German National Assembly should be elected on a universal suffrage for the purpose of determining the future constitution of Germany. The *Bundestag* hastened to organize the elections, but, as the democratic leaders in South Germany feared lest in the ne parliament the moderate Liberals would be in the majority, they attempted to bring about the immediate establishment of a German republic by means of a great upheaval of the masses. Their attempt met with little support, and the volunteer bands of peasants that they had assembled were easily dispersed by the troops of the South German Governments.

The Frankfurt Parliament. — With the failure of the Governments in the course of the ensuing weeks to come to an agreement on the re-organization of Germany, the German parliament which assembled on May 18, in the church of St. Paul in Frankfurt was given the task of determining the basic principles of a German constitution. Heinrich von Gagern was elected president, and he induced the assembly on June 24, to set up a provisional central authority for Germany with an imperial regent *(Reichsverweser)* elected by parliament. The parliament elected archduke John of Austria, an uncle of the Emperor Ferdinand, whose election was recognized by the Governments. The *Bundestag* now declared that its work had come to an end, and demanded that its authority should be handed over to the regent. He, however, was never able to establish any real Government. His attempt to place the troops of the separate states under his command was defeated. In foreign politics, the two great German Powers refused to be influenced by Frankfurt; this was most clearly seen in the Schleswig-Holstein Question (*q.v.*).

In March 1848 Frederick VII. of Denmark attempted to include the whole of Schleswig within his kingdom. The inhabitants of Schleswig-Holstein protested against such a violation of their traditional rights and at the outset found support in Prussia and the National Assembly at Frankfurt. The Prussian general Wrangel, who was appointed to the chief command of the army of the Confederation, occupied Schleswig-Holstein and advanced into Jutland. But when England and Russia seemed ready to support Denmark, Frederick William IV., who had long had scruples about supporting revolutionary subjects against their legitimate sovereign, entered into negotiations with Denmark, without consulting the Frankfurt government, and signed the Treaty of Malmo (Aug. 26). By this treaty, it was agreed that the duchies should be evacuated by both German and Danish troops and the administration provisionally entrusted to a mixed commission of Germans and Danes.

The majority of the National Assembly were disposed to criticize sharply Prussia's arbitrary action; they determined to invalidate all measures taken in the execution of the treaty. When, however, the Frankfurt ministry found itself unable to bring Prussia to heel, the minister-president, prince von Leiningen, resigned and was succeeded by the Austrian, von Schmerling. The national assembly was finally compelled to ratify the Treaty of Malmo because a breach with Prussia would have rendered the drafting of a constitution impossible. The attitude of the national assembly was taken by the democrats for weakness. They organized a rebellion in Frankfurt. The ministers and the national assembly summoned to its aid the Austrian and Prussian troops from the federal fortress of Mainz. After fierce street fighting in the course of which two members of the assembly lost their lives, the troops crushed the rising (Sept. 18). In consequence of having yielded to the pressure of the Governments, and of having even invited their help against the people, the assembly in great measure lost its former popularity.

As time went on the difference between the parties in the assembly became more and more accentuated. Whilst the democrats desired a united German republic, or at the most the establishment of an empire that should be wholly dependent upon parliament, the liberal majority wished to set up an hereditary empire alongside and above, the separate States. In addition to the question of the form the State should take there was the equally important question as to whether the German possessions of Austria should belong to the new *Reich*. After the Austrian Government had suppressed the nationalist movement in Bohemia by seizing Prague, and also re-established order to some extent in Vienna, they had summoned an Austrian National Assembly to draw up a constitution for Austria. A complete collapse of the Austrian monarchy, which had seemed imminent in the spring, was no longer to be feared. That the emperor of Austria would consent to be subjected to the authority of a German emperor seemed no less improbable, while, if this dignity were to be conferred upon him, there was danger that the interests of the numerous non-German peoples within Austria would receive greater consideration than those of Germany. Moreover it was doubtful whether Prussia would obey the dictates of an Austrian emperor. If, however, the highest dignity were conferred upon the king of Prussia, German Austria would most certainly refuse to be included within the new empire. Nevertheless the constitution in its final form favoured the latter solution of the problem, by declaring that in the future no part of the German empire cauld be joined with non-German lands to form a State. The assembly then proceeded to lay down the fundamental rights of the German peoples and to declare that in future the army, foreign policy, economic affairs, posts and general legislation were matters for decision by the empire alone. The more difficult question of the election of an hereditary emperor and the definition of his rights in regard to the parliament, was further postponed since there was no prospect of an agreement between the parties.

Meanwhile the greater German States had recovered from the blow they had sustained in the spring. On Oct. 31 Vienna which had once more revolted was captured by Prince Windischgratz; the Austrian parliament was transferred to the little Moravian town of Kremsier. The Emperor Ferdinand was persuaded to abdicate on Dec. 2, and his nephew, Francis Joseph, who succeeded him appointed as minister-president Prince Felix Schwarzenberg, a man of ruthless will-power and strongly absolutist tendencies.

The liberal ministry of Camphausen in Prussia was also dismissed during the summer, and, after various attempts to form a ministry that would be able to reach an agreement with the national assembly in Berlin over the question of the future constitution of Prussia had failed, the king entrusted Count Brandenburg with the task of forming a conservative official ministry. The attempt on the part of the Berlin parliament to gain control over the army no less than its openly-avowed desire to base the constitution on democratic principles, had convinced the king of the impossibility of coming to an agreement with the assembly. When the parliament resolved to remove the words "by God's grace" from the royal title, and to abolish the nobility, the king felt it impossible to carry on further negotiations. He assembled 50,000 men under General Wrangel near Berlin, and informed the assembly on Nov. 9, through Count Brandenburg, that they were adjourned until Nov. 27, and would re-assemble in Brandenburg-on-the-Havel. The parliament building was closed and occupied by Wrangel's troops. When the king found that these measures did not arouse any serious opposition in the country, he determined to proceed still further. So few representatives appeared at Brandenburg that no quorum could be obtained; it was therefore dissolved and the king immediately promulgated a constitution for Prussia (Dec. 5). The task of revising and deliberating upon this

constitution was entrusted to a new parliament of two chambers. The constitution, indeed, contained far more concessions to liberal wishes than the king in the depths of his heart considered right; but his ministers had firmly insisted that the concessions promised in March should be carried out, at least to some extent. Henceforth the rulers of Austria and Prussia were once more in full possession of their power, and it was therefore doubtful whether they would now suffer the national assembly in Frankfurt to draw up laws assigning to them their future position in Germany. Both Vienna and Berlin sharply repulsed all attempts of the national assembly and the regent to interfere in their internal dissensions. The Austrian Government had even gone so far as to shoot two members of the Frankfurt parliament, who had taken part in the October Revolution, despite the fact that their parliamentary immunity was guaranteed in a law that had been recognized by that Government. Since the Frankfurt parliament had no means of compelling the obedience of the more powerful States to its decrees, the majority in the parliament, which had day by day come into closer union with the so-called "Hereditary Emperor Party" and moved further away from the party that favoured what was known as the "Small Germany" solution recognized that their task could only be achieved by gaining the agreement and help of the king of Prussia.

But Frederick William IV.'s whole view of life prohibited him from accepting the imperial crown from the hands of an elective assembly without the approval, or even against the will, of the other German princes. At the same time he also believed a reform of the existing conditions in Germany to be necessary, and, before making any decisive move, he wished to come to an understanding with Austria over the reconstitution of Germany. This proved more difficult than he had anticipated. Prince Schwarzenberg would have greatly preferred to dissolve the Frankfurt national assembly by force and to have set up a new German Confederation to include the whole Danubian monarchy. At its head there was to be a college of kings composed of the rulers of the six greatest German States: — Austria, Prussia, Bavaria, Wiirttemberg, Saxony and Hanover. The smaller states were to be entirely subjected to their authority. This would not have achieved the unification of Germany and would only have met liberal aspirations to a very limited extent. His main design was to diminish Prussia's influence by a constitution of this kind. For this very reason Frederick William IV. refused to accept this plan: if it was contrary to his principles to increase the power of Prussia at the expense of the other German States with the help of the Revolution, he was no less determined not to permit Prussia to suffer any curtailment of her power.

These differences of opinion between the Austrian and Prussian monarchs awoke in Ludolf Camphausen, who on his retirement from office had become Prussian representative in the central Government in Frankfurt, the hope that it might yet be possible to bring about an understanding between Frederick William and the Frankfurt parliament. He used the influence accruing to him from his position to pursue a policy of reconciliation and mediation. But every attempt at reconciliation was doomed to failure, in consequence of the sharp contrast between the desires of the majority in the parliament and the personal disposition and sentiments of the king.

In Frankfurt the Small Germany policy gained a complete victory when Schwarzenberg established (March 4, 1849) a joint constitution for Austria-Hungary, which was to serve as the basis for a closer union of the Habsburg State. At the same time he informed the national assembly that Austria could not permit her German provinces to break away from their close union with the rest of the monarchy, and could only recognize a constitution for Germany which would permit her to enter the confederation without sacrificing her own new constitution. The party in Frankfurt which had worked for the inclusion of German Austria within the new empire, felt itself mortally injured by this declaration by the Austrian minister-president; and it was forced to recognize that in face of such a policy on the part of the Austrian Government its object was rendered unattainable.

The German Constitution of 1849. — After the results of the debates on the first reading of the German constitution had been communicated to the German Governments in order to enable them to bring forward their amendments, the second reading was concluded in the national assembly on March 27, 1849. Thanks to the mediating influence of Camphausen, agreement was reached between Prussia and 28 smaller German States over a number of amendments. But little regard was paid to these amendments in the course of the second reading, and others were even adopted that were excessively unwelcome to these States, as, for example, the omission of the *Reichsrat* which was to have been composed of representatives of the different Governments and to have been endowed with definite rights alongside the supreme head of the empire. The Liberals, indeed, would gladly have met the wishes of the governments, but, in order to carry the constitution, they were obliged to rely upon the votes of the democrats to whom they were forced to concede universal suffrage, a large diminution in the rights of the emperor, and the abolition of the *Reichsrat.*

The parliament finally resolved on the establishment at the head of the empire of an hereditary "Emperor of the Germans" who should reside at the seat of the imperial Government: that seat to be determined by special decree. The emperor was to receive a civil list and to have the right to dissolve the second chamber and to veto the laws passed by the parliament. Should, however, the parliament pass a law at three succeeding sessions, it became operative without the assent of the emperor. Alterations in the constitution might be effected in the same manner, only in this instance a two-thirds majority in both houses was required. Thus no room for doubt was left that the final decisive authority rested in the parliament.

The executive authority of the emperor was to be exercised through ministers responsible to the parliament. The parliament was to consist of an upper house *(Staatenhaus)* and a lower house *(Volkshaus).* The members of the first house were to be chosen half by the Governments and half by the lower houses in the separate states. The members of the second house were to be elected on a universal, equal, secret and direct ballot of the entire population in such a manner that there should be one representative for every 50,000 of the population.

The *Reich* alone was to have charge of foreign policy, the army, and the regulation of economic questions. The separate States were no longer to maintain a separate and individual diplomatic representation. Customs and indirect taxation were to belong exclusively to the *Reich* and, if these did not suffice to defray expenses, the balance was to be obtained by contributions from the separate States. The *Reich* was also to have the right to levy direct taxes on*the entire population. In all matters of finance the *Volkshaus* was the deciding body while to the *Staatenhaus* was merely accorded the right of proffering advice in such matters. To achieve unity in judicial matters an imperial supreme court of justice was to be established to determine the disputes between the different States or between the Governments and the parliamentary bodies.

The States thus retained only their own administrative system, the jurisdiction in the lower courts and the care of spiritual matters, particularly religion and education. But in all these matters they were compelled to conform their actions to the general principles laid down in the Constitution, in which it was expressly declared that in all circumstances the law of the *Reich* had precedence over the law of the individual states.

The Constitution was adopted in this form on March 27, and on the following day the election of an emperor was held in which 290 votes were cast for Frederick William of Prussia whilst the remaining 248 representatives abstained from voting. The formal unanimous election followed, and, amidst the pealing of bells and the thunder of cannon, the result was announced to the people. A deputation of 32 members under the leadership of Edward Simson, the president of the national assembly, was sent to Berlin to announce the result of the election to the King.

Frederick William could now no longer assume an impersonal attitude. Up to the last moment his ministers sought to persuade him to accept the throne conditionally upon his election being confirmed by the German princes and with certain reservations

affecting the Constitution. If he had followed their advice, Frederick William's position would have been at variance with all his principles. Hence when on April 3, 1849, he received the deputation in a formal audience, he contented himself with saying that he was unable to come to a decision until he had received the assent of the German princes and free cities, and that the Governments in general had still to consider whether the constitution was likely to realise the hopes of the fatherland. He added that he would never be found wanting should Germany need Prussia's shield and sword against enemies at home or abroad. These words appeared to amount to a postponement of a decision but the parliament could scarcely regard them as other than a refusal, since the completed constitution was spoken of as though it were only a draft awaiting alteration and acceptance at the hands of the German princes. Nevertheless Camphausen did not yet regard the situation as irretrievably lost: for he hoped that if it proved possible to gain the assent of the other Governments, naturally with the exception of Austria, the king would still accept the crown. And he was successful in inducing the 28 smaller States, which had already made a common declaration on the subject, to unite in an unqualified acceptance of the constitution and the election of the emperor. Only Bavaria, Wurttemberg, Saxony and Hanover still hesitated. But in view of the strong public opinion existing in the parliaments and among the inhabitants of these states in favour of an acceptance of the constitution, it did not seem likely that their rulers, willingly or unwillingly, would hesitate to give their assent also, in event of Prussia's still maintaining a reticent attitude, because not one of them would be willing to incur the blame of having nullified the work of unification by a refusal. Frederick William IV., however, would not accept such a solution. He considered that the assent of the princes obtained in this way through fear of public opinion was worthless. Apart from this it seemed very questionable whether alterations of any consequence could be made in the constitution once it had received the assent of all the Governments. Hence Frederick William IV. decided to announce through Count Brandenburg in the second chamber of the Prussian parliament on April 21, that Prussia could not accept the constitution as it stood.

Thus the work of unification of the Frankfurt parliament was finally frustrated. Camphausen resigned. The German Governments announced that the mandate of the national assembly had expired, and summoned their deputies to leave Frankfurt. The majority obeyed these orders; a minority remained however, in Frankfurt, the so-called "Rump parliament," mainly composed of South German democrats, and sought to hold further sessions and to arouse public support for the constitution against the Governments. Since the municipality of Frankfurt forbade any further deliberations within its walls, the Rump parliament removed to Stuttgart. But the Wiirttemberg Government ordered its troops to occupy the building in which the Rump was meeting on June 18, and prevented any further sessions. Only in south-western Germany and the kingdom of Saxony did the summons to assist in the execution of the imperial constitution by force meet with a response from a section of the populace. For a time Dresden was in the hands of the rebels, and the Saxon troops were only able to subdue the rising with the help of Prussian regiments. At the request of the South German Governments, a Prussian army under the command of the king's brother, Prince William was despatched thither and quickly recaptured the fortress of Rastatt which had fallen into the hands of the rebels and speedily dispersed the ill-armed and badly led revolutionaries.

This first attempt to unite Germany under a constitution based on principles of liberty failed chiefly because the vast bulk of the population were still indifferent to the great political issues. When the Governments of the individual States recovered from the first shock they set to work to put down firmly all hostile attempts. As a result of Frederick William's refusal of the imperial throne, the alliance between Prussia and the German union movement, which alone afforded the possibility of establishing a new political order in Germany, was for the time being dissolved.

The Prussian Union. — After the failure of the attempt to achieve the unity of Germany through a great national movement, Frederick William IV. desired, with the help of the Governments, to bring it about in another form than that striven for by the Frankfurt parliament. His most important adviser in this task was General von Radowitz, and the object for which both now began to work in common was the establishment of a more extensive confederation to include the whole Danubian monarchy and within this a lesser confederation of the remaining States under the leadership of Prussia. From the outset it was extremely questionable whether the emperor of Austria and the remaining German princes, when they had been delivered from their fear of revolution, would entertain such a plan; and, Frederick William insisted that their assent must be wholly voluntary.

A conference of the representatives of the greater German Powers was summoned at Potsdam. Since the revolution in Saxony and South Germany had not yet been fully crushed, at least a few of these states displayed a willingness to comply with the wishes of Prussia. The Alliance of the Three Kings (*Dreikönigsbündnis*) was concluded on May 26, 1849, between Prussia, Saxony and Hanover having for its object the foundation of a still closer union. A diet was to meet at Erfurt to draw up the constitution; it was to be elected solely by the inhabitants of those states which were to be members of the Confederation. Nevertheless both Saxony and Hanover made the ominous reservation that they should only be obliged to participate if all the German States, with the exception of Austria, entered the narrower Confederation.

Most of the smaller States joined the smaller confederation within a short time; but Bavaria and Wurttemberg refused, and Prince Schwarzenberg very clearly intimated from Vienna that he would look upon the conclusion of such treaties as a blow directed against the foundations of the still existing German Confederation. When, nevertheless, the majority of the Governments of the States in the narrower confederation decided to hold elections for a confederation diet, Saxony and Hanover announced their withdrawal on the ground of their former reservations Saxony in collaboration with Bavaria and Wurttemberg, entered into close relations with Austria in return for her promise of protection.

The elections for a confederation diet were held in the rest of the German States, and the diet itself assembled at Erfurt on March 20, 1850. A constitution for this narrower confederation was passed on April 29, which greatly differed from the constitution drawn up by the Frankfurt diet, but reproduced to a large extent the ideas of the king of Prussia and the Conservatives. Whilst Frederick William IV. was still hesitating as to whether he should now regard the narrower confederation as definitely constituted, Schwarzenberg took the offensive.

Austria had in the meantime with Russian help completely broken the dangerous revolt in Hungary, and also re-established her authority in Italy. Thus her hands were free to take action in Germany. Austria demanded that all the German States should send representatives to Frankfurt where the confederation diet was to re-assemble under the presidency of Austria. If Prussia remained faithful to the lesser confederation, war between her and Austria might easily break out; and both States therefore sought to ascertain what would be the attitude of the tsar in such an event. Frederick William IV. restored Schleswig-Holstein to Denmark in order to gain the tsar's support. Nicholas I., however who looked upon himself as the champion of conservatism in Europe, disliked the concessions which the Prussian king had made to the Liberals in Prussia and in the lesser confederation, and definitely took the side of Austria. Austria began to make preparations for war and re-opened the sittings of the *Bundestag* with as many of the representatives of the German States as had already arrived in Frankfurt. A constitutional dispute arose in Hesse between the elector and the *Landtag*, and the elector, who thought he would receive greater support from Austria than from Prussia left the union and appealed for help to the *Bundestag*. The *Bundestag* resolved to send Bavarian troops to his aid. But Prussia contested his right to secede from the union, and, on the ground that in virtue of former treaties she possessed the right to occupy with her army the great military roads that crossed the

electorate, simultaneously despatched her troops into the country. Once again both sides sought to gain the support of the Tsar. The Prussian minister-president, Count Brandenburg, as well as the Emperor Francis Joseph, and Schwarzenberg, visited the Tsar at Warsaw. Nicholas pursued a policy of mediation but he let them clearly understand that in the German question his sympathies were with Austria. At Radowitz's suggestion general mobilization was ordered in Prussia, although the king still hesitated to take up arms against Austria. Frederick William IV. next resolved to dismiss Radowitz, and after the death of Count Brandenburg who had died shortly after his return from Warsaw, to entrust the formation of a ministry to Freiherr Otto von Manteuffel, who as a strong Conservative was strongly opposed to a war against Austria. Manteuffel was sent to Olmutz to enter into direct negotiations with Schwarzenberg and, as in the neighbourhood of Bronzell small encounters had already taken place between the Prussian and Bavarian troops, it was agreed that, until the conclusion of the negotiations, the troops on both sides should refrain from advancing.

On Nov. 29, 1850 the Convention of Olmutz was signed. Prussia opened the way to Cassel to the troops of the Confederation; in Holstein joint commissioners were appointed by Austria and Prussia; the future constitution of Germany was to be discussed in open conferences to which all the German States were to be invited to send representatives. Prussia also agreed to abandon her mobilization while Austria promised that as soon as this was done she would also disarm.

The conferences began at Dresden in December and lasted until March 1851. They proved fruitless, and there remained no other alternative than to bring the old Confederation once more into force and to summon the confederation diet in its old form at Frankfurt. Thus the Prussian union was completely shattered.

The Political Reaction. — Although the great movement for the unification of Germany in accordance with liberal principles seemed thus to be retarded, yet it had not failed of result. All its supporters had before them in the constitution drafted by the Frankfurt diet a common programme that would never again be forgotten. Moreover, if the majority of the concessions which had been granted by the Governments in the spring of 1848 had been erased from the constitutions of the individual states, there still remained in Bavaria and Württemberg certain small extensions of parliamentary rights. Austria alone fully re-established absolutism. The constitution for the whole Danubian monarchy which had been proclaimed in March 1849 was withdrawn in 1851. In Prussia a fresh dissolution of the second chamber and the proclamation of a new electoral law were necessary before an agreement could be achieved between the Government and the diet regarding the constitution. The oath to the new constitution was finally taken by the king on Feb. 4, 1850. A sufficient guarantee for the retention of the majority in the second chamber by the Conservatives, was believed to have been found in the introduction of the Three Class franchise. The upper chamber was converted in 1854 at the king's desire into the *Herrenhaus* composed solely of the hereditary nobility and of life members chosen by the king in addition to representatives of the universities and corporations of the greater towns. Manteuffel, who remained at the head of the ministry, endeavoured as far as was compatible with the new constitution, to restore the old bureaucratic system of government.

The example of the two great Powers was followed by the smaller States. At their request the Bundestag appointed a committee to see that no laws or institutions endangering the order and peace of the Confederation, should continue to exist in any State; and the committee took upon itself far-reaching powers of interference with the constitutional rights of the individual States. The committee also introduced new restrictions upon the liberty of the Press and forbade political bodies to form associations with one another.

The sole important advance made in these years was in the sphere of political economy. Hanover, Oldenburg and the Hansa towns were induced to enter the ***Zollverein*** which, after 1854, included the whole of Germany with the exception of Austria. Thus all plans for the reform of the Confederation introduced by the central States were wrecked by the opposition of the great German Powers to any extension of the competence of the Confederation, because in the diet they might be outvoted at any time by the smaller States. All this passed over the heads of the populace: deep despondency had replaced enthusiasm. The most fearless champions of the liberal and national movements were forced to fly from Germany to avoid persecution. Karl Schurz fled to America, and Karl Marx and Lothar Bucher sought safety in England. Those who remained at home could only keep silence and place their hopes in the future.

While political life was thus brought to a standstill, vast changes were occurring in the economic life of Germany. Industry prospered, factories increased, and Germany began gradually to lose its character of a purely agrarian country. A network of railways was constructed of which only the first beginnings had been made in 1848, and from 1850 to 1860 the mileage was almost doubled. A quantity of new limited companies and banks were founded; foreign trade increased; and the great industrial districts which were later to be the nerve-centres of German industrial life began to make their appearance: the great iron and coal fields in the Rhineland and Westphalia, the Saar and Upper Silesian coalfields, and the great textile industry in Saxony. As had already been the case in Western Europe, so now in Germany, great armies of workmen began to be formed in the industrial districts who in the succeeding decades provided the Government with fresh problems.

At this time Germany as a whole played little or no part in foreign politics. Austria and Prussia pursued their own individual policies that were not infrequently diametrically opposed to one another. On the outbreak of the Crimean War (1854) the German States remained neutral. Although they concluded a defensive alliance among themselves (April 20, 1854), they soon came into conflict with each other, for Austria, wishing to see Russian influence in the East curtailed, entered into closer relations with the Western Powers, whilst Frederick William IV., in conformity with the old traditional policy of Prussia, inclined towards Russia. Hence once more relations between Prussia and Austria underwent a change for the worse. The authority of Prussia had sunk very low since the conclusion of the Olmiitz Treaty and the failure of her plans for a union of the German states. At first the Powers contemplated excluding Prussia from the Paris Congress which ended the Crimean War. When a rebellion of Prussian sympathisers broke forth in 1856 in the little principality of Neuchatel, which had formerly belonged to Prussia but had been incorporated in the Swiss Confederation after 1848, Frederick William was only enabled to secure an amnesty for the rebels through the intermediary of the French emperor; and in return was forced finally to abandon all claim to Neuchatel.

The Prussian Regency. — In the autumn of 1857 the mental condition of Frederick William IV. made it necessary to appoint a substitute, and since he was childless, his brother Prince William, in accordance with the constitution, took over the regency on Oct. 26, 1858. As a younger son, Prince William had been destined for a military career and had rarely come into contact with politics. Like his brother, he was a Conservative, but he did not share his doctrinairism and sentimental policy. As a moderate and practical man, his first thought was always to take into consideration the actual state of things in so far as his fundamental principles would permit. A brief sojourn in England in the spring of 1848 had given him a greater understanding of parliamentary procedure. He had also a far stronger sense of the real interests of Prussia than his brother. He had strongly disapproved of Prussia's yielding to Austria at Olmutz and had ever since been in opposition to the foreign and home policy of the king. He further disapproved of the one-sided conservative party system existing under the ministry of Manteuffel, and at once constructed a new ministry, under the joint leadership of Prince Karl Anton of Hohenzollern-Sigmaringen and Rudolf von Auerswald. Some Liberal members were also included in the Cabinet. His idea was to unite all elements which were prepared to collaborate for the good of the country in a policy which, although resting on conservative principles, was not to be the mere expression of exclusively con-

servative-party interests. In his speech to the new ministry on Nov. 8, 1858 he declared that a prudent and considered policy must be followed if the position of Prussia in Germany was to be improved. He summarized this policy in the words: "Prussia must make moral conquests in Germany."

Since the new government refrained from influencing the elections, these resulted in a great increase in the Liberal representation in the Prussian house of deputies All over Germany these events were hailed as the precursors of a new era in Prussia that would afford greater opportunity for the rightful demands of Liberalism. In Bavaria and Baden too this led to the Government adopting a different attitude towards the parliaments. Soon after William became regent, war broke out between Austria, France and Sardinia (1859). Austria looked upon it as Prussia's obvious duty to support her in this conflict, but the prince regent was only prepared to open hostilities if he were given the sole command of the German troops opposing France on the Rhine. As Austria refused this, no agreement was reached. For Prussia in truth had no obligation to intervene, since Lombardy and Venetia did not belong to the German Confederation. After the defeat of the Austrian army at Magenta (June 4, 1859), the Emperor Francis Joseph signified his willingness to comply with Prussian demands; and the prince regent ordered the mobilization of six army corps., But before Prussia had intervened the Austrians had sustained a second severe reverse at Solferino (June 24). When the Emperor Napoleon offered her peace in exchange for the cession of Lombardy and surrender of the Austrian possessions in Italy, Austria agreed to his terms because she feared that if Prussia were victorious on the Rhine her influence in Germany would become predominant. But it was completely false to declare as did the Emperor Francis Joseph in a manifesto, that Austria had been forced to sign the peace because she had been left in the lurch by her natural allies. Peace was made rather to prevent Prussia from appearing as the saviour of Austria.

Public opinion in Germany was deeply stirred by the war and the resultant unification of Italy. On August 14, 1859 there assembled for the first time since the revolution a vast gathering of men to demand the unification of Germany on a liberal basis. Four weeks later the German National Union (*Deutscher Nationalverein*) was founded to establish a German Federal State on the basis of the imperial constitution of 1849. Notwithstanding minor persecutions by the governments, the Union developed a powerful propaganda in the course of the next few years. Its supporters were chiefly to be found in the upper ranks of the middle classes, and as yet the mass of the population took no part in its work. The German Governments under pressure from the growing national feeling once more considered the possibility of a reform of the Confederation. While the prince regent thought that a reform of the military constitution of the Confederation was most necessary, Austria was opposed to it as giving Prussia the command over the greater part of Germany's military resources in event of war.

The Constitutional Conflict **in Prussia.**—For a long time past the prince regent had been convinced of the necessity for a fundamental reform of the Prussian military system. He wished to introduce universal compulsory military service and to raise the yearly number of recruits from 38,000 to 63,000; while for the purpose of training these recruits the number of regiments in existence would have to be increased by 49. Moreover, the *Landwehr* was to be brought into closer relation with the standing army. These reforms would entail increased expenditure amounting to 10 million thalers yearly. With the assistance of the minister for war, von Roon, a definite programme was drawn up and laid before parliament (Feb. 1860). The majority in the parliament were prepared to agree to an enlargement of the army, but demanded that the period of service should be reduced to two years and the independence of the *Landwehr* maintained. Although the prince regent did not wish to agree to these conditions, the Parliament provisionally voted the sums demanded. The new regiments were formed and the reform of the army carried out. Then William, who hsd become king on the death of his brother (Jan. 2, 1861). again laid the bill for army reform before a newly-elected parliament to receive its final assent. Once more the same counter demands were put forward; but when Roon on behalf of the king declared (March 5, 1862) that it was impossible to concede the two years' service, the house of deputies threw out in *toto* the increase demanded for military purposes. The king had therefore either to cancel arrangements already made or to fight out the battle with the parliament. Five members of the ministry believing that surrender was unavoidable, handed in their resignations. The dissolution of the parliament brought about no change in its composition. The new parliament also refused to agree to the demands of the Government, and declared that, if the king still persisted in levying unauthorized taxes for the carrying out of his programme of military reform, he placed himself in opposition to the Constitution and broke the oath which he had sworn to it. The obvious duty—so it seemed--of the king was to summon a ministry having the confidence of the parliament and to put forward a budget in accordance with their views. The majority in the ministry were also of this opinion.

But the king was convinced that the choice of ministers was an inviolable royal prerogative, and that the conditions which the parliament sought to introduce into its assent to the military programme and military budget, were unacceptable in the interest of the maintenance of an efficient army. If he should prove unable to find ministers ready to support him in his fight against parliament, he would abdicate. In searching for men of this character von Roon, the minister for war, hit upon Bismarck, who had represented Prussia as ambassador to the *Bundestag* at Frankfurt, and then at St. Petersburg and Paris. Von Roon had already assured himself of Bismarck's readiness to serve, and now persuaded him to come to Berlin. The decisive interviews between the king and Bismarck took place on Sept. 22 and 23, 1862 in the park at Babelsberg. Bismarck expressed his willingness to prosecute the struggle with the parliament in defence of the royal prerogative; but refused to lay down a detailed home and foreign policy for the future. After some indecision, the king resolved to nominate him minister-president on Sept. 23.

Bismarck.—From the outset, Bismarck's aim was the unification of non-Austrian Germany under the leadership of Prussia. His experiences in Frankfurt had convinced him that Austria would never consent to accord Prussia a position of equality with herself in German affairs and that therefore there would not be room for Austria and Prussia in a political organization of Germany. He was convinced that the solution for which he strove could only be attained through an armed conflict with Austria. Yet none knew better than he how diffcult it would be to induce the Iring, now nearly 70 years old, whose love of peace caused him to oppose himself to every forcible solution, to give his consent to such a policy. The king himself was aware of this antagonism and therefore hesitated to appoint Bismarck head of the Government. He realized Bismarck's extraordinary political capacity, but abo his passionate and ruthless temperament. In practice, Bismarck was able, once he had taken over the direction of affairs, to lead the king step by step in the direction which he considered right.

An understanding with the parliament over the military budget of 1862 was clearly impossible. The house of deputies maintained their previous position whilst the *Herrenhaus* rejected the budget as received from the lower house and assented to the demands of the Government. Bismarck now declared that, since the two houses who had equal rights had been unable to reach an agreement, a valid money bill could not come into force. As the constitution had not made any provision for such an event, and as it was impossible for the business of the State to stand still, the Government were compelled provisionally to carry on the administration without a proper legal budget; to continue to levy taxes; and to continue the necessary expenditure. The house of deputies declared that such a proceeding was unconstitutional and that there existed no further means of attaining to an agreement with the ministry. The king replied to this declaration with a message in which he gave expression to his unalterable trust in his ministers and designated as unconstitutional the attempt of the house of deputies to increase its authority. The struggle was still further

embittered by the restrictions placed by Bismarck on the liberty of the Press and by his dismissal of liberal officials.

Upon Liberal opinion throughout Germany this intensification of the constitutional struggle reacted in a sense unfavourable to Prussia. Bismarck was looked upon as desiring to restore absolutism and as lacking all understanding of the desires and demands of the age. This view was false because Bismarck did not wish to set aside the constitution; he wished to interpret it in the sense which seemed right to himself and the king. But doubtless this feeling amongst the Liberals gave rise to extraordinary difficulties in carrying out Bismarck's German policy; for it was the Liberals themselves who had founded the National Union and who strove for the establishment of a small Germany under Prussian leadership. Nevertheless Bismarck was compelled to repel these natural allies since, unless he successfully carried through the fight for the constitution in Prussia to the bitter end, he could not retain the king's confidence and the direction of Prussian policy.

It is comprehensible that Austria should have sought to take advantage of this situation. The emperor Francis Joseph invited all the German princes to come in person to Frankfurt on Aug. 18, 1863, to confer upon a reform of the German Confederation. His plan was to place a directory of five persons at the head of the Confederation and next to them, an assembly of delegates elected from the diets of the separate states endowed solely with advisory powers. Bismarck persuaded the king to absent himself from this conference but the remaining princes assembled at Frankfurt, where the majority adopted the Austrian proposal, on the understanding that their agreement would only remain in force until Prussia had announced what her definite attitude was to be. Thereupon Bismarck replied that Prussia must demand as preliminary conditions to any reform, the alternation of the presidency of the Confederation between Austria and Prussia; a recognition of the right of Prussia to veto any declaration of war involving the Confederation; and the summoning of a German parliament elected on a general suffrage. By her refusal to accept these terms, Austria completely destroyed any hope of success that remained for her project of reform.

Schleswig-Holstein.—The insecure state of affairs in the duchies of Schleswig and Holstein led to the next step in this development. After the revolution of 1848 the European Powers assembled in conference in London to settle this difficult question. The result of their labours was the London Protocol of May 8, 1852 which was signed by all the great Powers. The Powers agreed that on the failure of the male line of the Danish royal house, the house of Holstein-Glucksburg, to whom the throne of Denmark passed, should also rule over the duchies although, in accordance with the German law of inheritance, these should pass to the house of Holstein-Augustenburg. Austria and Prussia added the proviso that the duchies should enjoy an autonomous administration and constitution within the Danish State, and that terms must be arranged with the duke of Augustenburg to induce him to renounce his claims. It was not until Denmark had promised the duchies their own autcnomous administration and diets, and Duke Christian of Augustenburg had announced his intention of refraining from creating any difficulties in the matter of the succession, in return for the payment of compensation for the territories thus taken from him by Denmark, that the two German Powers signed the London Protocol. But when the Danish king sought to escape from the fulfilment of his treaty obligations, and to introduce Danish administration into the duchies, the Holstein *Landtag* appealed for help to the Confederation. In Feb. 1858 the Bundestag decided that the Danish constitution was not valid in Holstein. The king of Denmark, threatened by the Confederation, exempted Holstein from this constitution without, however, granting the duchy a new one. Austria and Prussia thereupon demanded that Denmark should carry out her treaty obligations in their entirety, and the Confederation again threatening sanctions, called upon the king to grant a new constitution in accordance with the provisions of the treaty of 1852. Since Denmark hesitated, Hanover and Saxony were instructed to enforce a federal execution.

At this moment Frederick VII. of Denmark died (Nov. 15, 1863) and with his death the male line of the Danish royal house came to an end. Duke Christian of Glucksburg at once ascended the throne of Denmark and Schleswig-Holstein, as Christian IX., in accordance with the provisions of the London Protocol. Under the pressure of public opinion in Denmark he granted a new constitution that effected the complete incorporation of the duchy of Schleswig within the Danish kingdom. At the same time Prince Frederick of Augustenburg announced that he did not recognize his father's renunciation, and that therefore he looked upon himself as the rightful heir to the duchies of Schleswig and Holstein. He assumed the style of Frederick VIII. and found many supporters in the duchies, since the German population ardently desired separation from Denmark. From a legal standpoint the prince's actions could not be sustained because his father was still alive and bound by his pledge. Moreover, the fact that the father renounced his own personal claims in favour of his son, was only capable of being interpreted as an attempt to evade the fulfilment of the obligations he had taken upon himself.

In consequence of the growing tension, Austria and Prussia came to an agreement upon a plan of joint action (Jan. 16, 1864). They agreed that, in event of Denmark refusing the demand for a constitution, they would declare war upon her, and regulate the future relations of the duchies with Denmark only by joint agreement. From the outset Bismarck's intention was to bring the duchies into close union with Prussia in some form or other, if they were separated frorn Denmark, whilst Count Rechberg, as the inspirer of Austrian policy, wished to compel the Danish king to carry through a purely personal union of the duchies with the Danish crown. When Denmark rejected the ultimatum presented to her by the German Powers, Austrian and I'russian troops, under General Wrangel, invaded the duchies. After the storming of the fortifications at Düppel, and the advance of German troops into Jutland, Denmark decided to invite the mediation of the other Powers. Through their intervention an armistice was agreed to, and a conference held in London from April 25 to June 25 for the purpose of effecting a peace. In order to conciliate Austria Bismarck announced his willingness to accept her solution of a personal union; but Denmark refused to accept the Austrian proposal and relied for support on the non-German great Powers. Thereupon the German Powers proposed the complete separation of the duchies from Denmark, and their erection into an independent State under the Prince of Augustenburg. This was immediately rejected by Denmark. Austria and Prussia then declared that every hope of further negotiation was at an end, and the London Conference broke up without any result. The war was resumed, and the German army, having forced the passage to Alsen, advanced to the northernmost point of Jutland. When they appeared to be preparing to invade Fiinen, and all hopes of foreign support had vanished, Denmark determined to sue for peace.

The Treaty **of Gastein.**—Peace was signed at Vienna on Oct. 30, 1864 and Denmark was forced to cede the two duchies up to the river Konigsau, to Prussia and Austria. While these two German districts were thus completely set free from Danish rule, it was as yet uncertain what was to be done with them. **A** joint Austro-Prussian administration was at first established. Austria, however, was resolved that in no case should these lands become Prussian, and therefore inclined more and more towards the recognition of the Prince of Augustenburg as duke of Schleswig-Holstein; a solution which was also favoured by the majority of the other German States and public opinion throughout Germany. But Bismarck was determined not to agree to this, since a personal interview in the previous summer with Prince Frederick had shown him unwilling to make those concessions to Prussia which Bismarck thought it necessary to demand. These included the placing of the Schleswig-Holstein troops under Prussian command; the control by Prussia of the post, telegraph and railway systems; and the cession to her of points of military importance on the coasts of the North and Baltic Seas which would ensure Prussia's control of the canal to be constructed between the Baltic and North Seas. Since Austria, in spite of Prussian opposition, condoned the agitation in the duchies in favour of the prince of Augustenburg, and since an attempt to win the assent

of Prussia to the union of the duchies by the cession of the countship of Glatz was frustrated by King William's opposition it became more and more clear to Bismarck that an open conflict could not be avoided. If war came about, however, Prussia's greatest concern would be the attitude adopted by the Emperor Napoleon III. Napoleon, indeed, had already frequently made known his desire for an alliance with Prussia and his willingness to permit an extension of Prussian authority in northern Germany. The only question was what price he would demand for his assistance. A personal interview at Biarritz between the emperor and Bismarck decided nothing definite.

Under repeated pressure from Austria, Bismarck (Feb. 1865), announced the conditions on which he was prepared to recognize the prince of Augustenburg as duke. The Vienna Government thereupon declared that these conditions were unacceptable because they would make the new duchy nothing more than a vassal of Prussia. During the summer of 1865 the situation was still further complicated by the resolution passed by a majority of the *Bundestag* at Frankfurt in favour of the unconditional recognition of the prince of Augustenburg. In May, Bismarck proposed to send an ultimatum to Austria and on its rejection to declare war. Ring William, however, was not prepared to go so far and only agreed that Austria's consent to the expulsion of the prince from the duchies should be demanded. As Vienna too was averse to a conflict, Austria and Prussia once more came to an agreement; but it was of a very incomplete nature. On Aug. 14, 1865 the Treaty of Gastein was signed, which laid down that both Powers should provisionally continue to exercise joint sovereignty in the duchies, but that Austria should administer Holstein, and Prussia Schleswig. The fortress of Rendsburg and the port of Kiel were handed over to the Confederation under Prussian control. The duchies were to become members of the *Zollverein* and Prussia was given the right to construct the canal uniting the Baltic with the North Sea.

Bismarck never believed that this agreement formed a basis for a permanent solution of the Schleswig-Holstein Question (*q.v.*). After a further visit to Biarritz in which he again tried to ascertain Napoleon's intentions, Bismarck set to work to strengthen Prussia's position for the coming conflict by winning allies and guiding public opinion in Germany to believe that the approaching war with Austria would be fought for the establishment of new conditions in Germany rather than for the future of the duchies. It was not without difficulty that he concluded an alliance with Italy on April 8, 1866. Italy undertook to participate in the war against Austria should war be declared within the ensuing three months. The two allies agreed that neither would conclude an armistice nor make peace until Italy had gained Venetia and Prussia had an equivalent extension of territory. Napoleon advised the Italians to sign this treaty because he hoped to profit by an outbreak of war in Germany.

At the same time Bismarck laid before the *Bundestag* a proposal for the immediate convocation of a German parliament to carry out the reform of the Confederation in conjunction with the Governments (April 9). Soon afterwards he let it be known that in his opinion the authority of the Confederation must be extended to foreign economic and military affairs and that the parliament must be accorded an equal power of legislation.

Prussia's negotiations with Italy, and the proposal for a reform of the Confederation, were taken in Vienna to indicate that Prussia was resolved upon war. To avoid being taken by surprise Austria strengthened her military forces in Bohemia, and Prussia also began to arm. At this juncture, as the result of efforts at mediation on the part of Russia and England, King William consented to the abandonment of all preparations for war on both sides. But the Emperor Francis Joseph, on receiving news of the Italian preparations for mobilization, ordered on April 21, the mobilization of the Austrian southern army. Prussia regarded this action as invalidating the recent understanding, and commenced mobilization on a large scale. As war now seemed inevitable, Austria sought by the intermediary of Napoleon, to prevent Italy from participating in the conflict. In event of an Austrian victory over Prussia. Napoleon was promised Venetia with the right to make it over to Italy. Austria was to be compensated in Germany at the expense of Prussia and her allies; but with the proviso that her expansion should not be carried so far as to endanger the balance of power in Europe or to effect a complete subjection of the other German states. When it is remembered that at the same time Napoleon had promised Prussia his benevolent neutrality, and had given her to understand that he had nothing against an extension of her authority in northern Germany his policy stands revealed as highly dishonourable.

On June 1, Austria announced that she proposed to leave the decision of the Schleswig-Holstein Question to the *Bundestag*, and, when shortly afterwards she summoned the *Landtag* to meet in Holstein, Bismarck immediately declared that her action had violated the earlier treaties; for Austria in Jan. 1864 had undertaken not to take measures for the future of the duchies without Prussia's consent and the right of summoning the *Lnndtag* was undoubtedly one of the sovereign rights which, according to the Treaty of Gastein, were to be exercised jointly by both Powers. Bismarck therefore affirmed that Prussia too was no longer bound by these treaties, and was once more entitled to share in the administration and military occupation of Holstein. On the entry of Prussian troops into Holstein, Austria moved in the *Bundestag* that the troops of the Confederation should be mobilized against Prussia for the preservation of peace. Such a step was a contravention of the laws of the Confederation which only permitted of sanctions after the failure of a friendly attempt at reconciliation. Bismarck therefore intimated to the *Bundestag* that he would be forced to regard every State which voted in favour of the Austrian proposal as at war with Prussia, while at the same time he placed before it a plan for a new constitution which in fact included the fundamental propositions he had already made known to the *Bundestag*. The command of the south German troops of the Confederation was to be given to Bavaria whom Bismarck thus hoped to win over to his side. The diet adopted by g votes to 6 the Austrian proposal, which had been modified by Bavaria. The Prussian representative announced that his Government considered that this unconstitutional decision dissolved the Confederation and he called upon the other German States to join with Prussia in establishing a new Confederation on the principle of the earlier reform proposals (June 14, 1866).

The Austro-Prussian War.—War was now inevitable. With the exception of some small North German states, the German governments ranged themselves on the side of Austria. Italy supported Prussia. France remained neutral. At the battle of Langensalza (June 29) the entire Hanoverian army, which was about to march southwards, was captured by the Prussian troops. The Prussian armies then occupied Hesse, Nassau and Frankfurt, and advanced into Bavaria as far as Nuremberg. Meanwhile, in the south, the Austrians defeated the Italians at Custozza (June 24). It was obvious, however, that the decisive action must be fought in Bohemia. In accordance with General von Moltke's plan of campaign, three Prussian armies advanced from Saxony and Silesia into Bohemia. The Austrian commander. General von Benedek, had taken up a strong position at Koniggratz where, on July 3, he was attacked by the united first and second Prussian armies. The result of the battle hung in the balance, until the Crown Prince Frederick William arrived with the third Prussian army at the critical moment, when it ended in the utter defeat of the Austrians and the wholesale rout of their army. The road to Vienna seemed to lie open before the victors.

Napoleon had not expected so speedy a victory. On the contrary, he had hoped that both sides would be exhausted by a long campaign, thus enabling him to dictate a peace under the threat of intervention without using his own forces. Napoleon, fearing to be excluded from participation in the reconstruction of Germany offered his mediation to the belligerents (July 5), Austria having previously ceded Venetia to him. On the advice of Bismarck, although contrary to his own inclinations, King William accepted the proffered mediation on condition that the terms of peace should be determined before an armistice was concluded. As it was of the utmost importance to him that the war should not be prosecuted in spite of his intervention, Napoleon decided to

support the conditions of peace laid down by Prussia and to work for their acceptance in Vienna, Hanover, electoral Hesse, Nassau and Frankfurt were to be incorporated in Prussia. Further, Austria was to be excluded from Germany; the North German States were to form a North German Confederation under Prussian leadership, the southern States were however to remain independent and have the right to form a separate Confederation. Austria was to pay a war indemnity and definitely consent to the cession of Venetia to Italy. Only after a fierce struggle had Bismarck been able to secure King William's assent to these conditions. The king did not wish to absorb the hostile North German States but only to reduce them, but on the other hand wished to impose cessions of territory on Saxony and the South German States and force Austria to surrender the Austrian portion of Silesia. Bismarck thought these proposals imprudent because the princes who had been deprived of a portion of their dominions would never prove trustworthy allies. For this reason he wished to annex to Prussia those territories which interposed between the two halves of the kingdom, whilst leaving the remaining States untouched so that they might be the more ready to enter in the future into a German Confederation. Bismarck also thought that, if Prussia were to encroach in South Germany, it might still lead to Napoleon's entry into the war. To obtain peace would then mean that no cessions of territory could be exacted from Austria and that the kingdom of Saxony would also have to be left intact. King William, however, finally yielded, and a preliminary peace was signed on July 26, at Nikolsburg. Bismarck refused the Italian request for a cession of the South Tirol on the ground that this was not included in the treaty of alliance.

After the conclusion of peace Napoleon unexpectedly came forward with the demand for compensation for his acquiescence in the expansion of Prussia. At first he demanded the transference to France of the entire Bavarian Palatinate, Rhenish Hesse and the fortress of Mainz. When Bismarck replied with a complete rejection of these demands, Napoleon said there had been a misunderstanding and reduced his demand to a request for the restoration of the frontier of 1814, that is to say, for the cession of Landau and the Saar district. On receiving a further refusal from Bismarck, Napoleon attempted at least to secure Prussian support for the annexation of Luxembourg to France and for the future conquest of Belgium. Thinking it unwise to answer these propositions with a flat refusal, Bismarck dragged out the negotiations for months without giving any definite reply. But he made use of these demands on the part of Napoleon, to reveal to the South German States the danger to which they were exposed by the covetousness of the French emperor. Since peace had not yet been concluded between these States and Prussia, Bismarck was able to hold before them the hope both of an abandonment by Prussia of her demands for territory and a reduced war-indcmnity in return for their entry into an offensive and defensive alliance with Prussia. The South German States were ready to enter into his plans and themselves asked for such an alliance. Bavaria, Wurttemberg ahd Baden entered into a reciprocal agreement with Prussia to defend her with their entire military force against every attack and to place their troops under the command of the king of Prussia for the duration of any war thus waged in common. As the northern portion of the grand-duchy of Hesse was a member of the North German Confederation, no such treaty was concluded with Hesse.

The North German **Confederation.**—When the war had finally been brought to an end by the signature of the definitive Peace of Prague (Aug. 23, 1866), Bismarck's first care was to end the internal conflict in Prussia. The possibility of doing so had arisen during the war through an election which had materially altered the composition of the house of deputies. The Conservatives had won a great number of seats from the Liberals; while the feeling against Bismarck entertained by many Liberals had greatly altered. Many of them now saw in him the man who alone was in the position to accomplish that unification of Germany for which they were also striving. Bismarck persuaded the king to lay before the new *Landtag* a bill of indemnity to give retrospective assent to the taxes and the expenditures made by the Government since the beginning of the conflict which had not hitherto been authorized. At first the parliament showed a disposition to demand guarantees from the Government that it would abstain from similar measures in the future, but, when the king refused to agree to this, the majority finally passed the bill in the form in which it had been presented to them. A cleavage in what had been hitherto the Progressive Party resulted from these proceedings. Those Liberals who were prepared to support Bismarck's German policy, and to abandon the full achievement of their objects in home affairs for the sake of the greater aim of national unity, formed themselves into the "National Liberal Party" under the leadership of the Hanoverian deputy Rudolph von Bennigsen.

The termination of the constitutional struggle in Prussia left the way open for the construction of a constitution for the North German Confederation. With the help of a number of experts, Bismarck had himself prepared the groundwork of the draft which was first submitted to the individual Governments and then laid before the North German *Reichstag*. The *Reichstag*, which had been elected on a universal franchise, met in Berlin towards the end of Feb. 1867, and, after some not unimportant changes had been made in the draft of the constitution, this was finally adopted on April 17, 1867, by a majority of 230 votes to 52. The important features in this constitution, which with few alterations became that of the German Empire after 1871, were as follows: the federal sovereignty reposed in the hands of the federated governments whose organ was the *Bundesrat*, in which out of a total of 43 votes, Prussia held 17: thus she did not possess the majority although her territory composed by far the greatest part of the federal territory. The presidency was given to the king of Prussia, and the direction of the affairs of the Confederation was placed in the hands of a chancellor nominated by the president. Next to the *Bundesrat* came the *Reichstag*, chosen on a universal, equal, secret and direct franchise and thus representative of the mass of the population.

For its passage, a federal act had to receive the assent of a majority in both the *Bundesraf* and the *Reichstag*, whilst an alteration in the constitution could only be effected by a two-thirds majority in the *Bundesrat*. The authority of the Confederation extended to foreign policy, the army and economic affairs. Moreover the constitution made provision for a unified financial, penal, commercial, economic and judicial system. The laws of the *Reich* were to have precedence over the laws of the separate States. As in the constitution of 1849, the individual States retained their own administrative systems and the control of ecclesiastical affairs and education. The expenditure of the Confederation was to be met by the customs revenue, indirect taxes, and the post and telegraph revenue. If these proved insufficient, the individual States were to make supplementary grants proportionate to their population so long as federal taxes had not been introduced. The *Bundesrat* possessed the right, with the approval of the president, of dissolving the *Reichstag*. This constitution gave the individual States a greater measure of independence than the Frankfurt constitution of 1849 by permitting them to retain their own diplomatic representatives, while they exercised through their votes in the *Bundesrat* a stronger influence upon the government of the *Reich*.

The establishment of the North German Confederation marks the first step towards the re-organization of Germany. The Liberals indeed often feared that the cleavage of Germany into two halves along the line of the Main might prove permanent. But Bismarck, from the beginning had in view the inclusion of the South German States within the Confederation as soon as the feeling of animosity against Prussia, which prevailed in the south after the war, had disappeared and the international situation permitted it. Through the conclusion of the offensive and defensive alliance with the South German States. Bismarck had already provided that, in event of a hostile attack from without, the military resources of Germany would be collected together under one leader for the defence of her territory. He now sought to unite North and South still more closely in economic bonds.

The war had destroyed the *Zollverein*. Bismarck at once set to work to resurrect it, and in July 1867 he invited the representatives of all the German Governments to a conference at Berlin. He informed the conference that Prussia was only prepared to conclude a new treaty with those States which were willing to establish a customs-parliament. This parliament was to co-operate with the Governments in the work of the *Zollverein*, especially in determining the customs-duties; it was to meet at Berlin and consist of deputies to the North German Reichstag as well as of a corresponding number of South German deputies. Since the South German States were not prepared to sacrifice the advantages to be derived from membership in a greater economic entity, they were forced to accept these conditions. On July 8, 1867, the new *Zollverein* treaty was signed, and the customs parliament met for the first time in the following year. In this parliament South Germany and North Germany again became accustomed to co-operate in public affairs and although its activities were restricted to economic questions, it contributed not a little to the overcoming of the differences between the various States. Whilst Bismarck by these two treaties established good relations with the South, the Bavarian Government strove to bring about the establishment of a separate South German Confederation under its own leadership—fruitlessly because Wiirttemberg and Baden were less unwilling to place themselves under Prussian than Bavarian leadership.

The Luxembourg Question.—The crux of international affairs after 1866 lay in Prussia's relations with France. Napoleon still hoped to receive at least the grand-duchy of Luxembourg as a recompense for his neutrality during the Austro-Prussian War. The grand-duchy had belonged to the old German Confederation but had not joined the North German Confederation. But since the town of Luxembourg prior to 1866 had been a fortress occupied by Prussia, a Prussian garrison still remained there. Napoleon demanded that Prussia should withdraw this garrison and declare her consent to his acquisition of the grand-duchy by purchase from the king of the Netherlands. While Bismarck let Napoleon hope that by this means he might gain possession of Luxembourg, he from the outset made it clear that the Prussian garrison could only be withdrawn at the request of the king of the Netherlands or the inhabitants of Luxembourg, and further the whole affair must be very cautiously handled in order to avoid irritating German nationalist feelings. If this occurred it would make it impossible for Prussia to consent to the transfer of Luxembourg to France: for she could not risk incurring the reproach of having handed over to France, without urgent reasons for doing so, a land in which the population was, at least in part, German. Ignoring these warnings Napoleon entered into direct negotiations with the king of the Netherlands for the purchase of Luxembourg, although the Prussian garrison had not been withdrawn. The king of the Netherlands was not prepared to make so weighty a decision without first assuring himself of the agreement of Prussia; but Bismarck declared that he was unable to advise him in the matter. Meanwhile the French had already spread abroad a rumour that the purchase had been completed, and in Germany an intense feeling of indignation made itself apparent. Von Bennigsen brought forward an interpellation in the North German *Reichstag* and in reply Bismarck stated that he had no knowledge of the conclusion of any such treaty and that he hoped to be able to protect the rights of German States and German citizens from any injury without prejudicing the friendly relations with neighbouring States. The king of the Netherlands thereupon refused to sign the treaty, and Napoleon was placed in a difficult position. For a long time it seemed as though war would break out, but this danger was averted by a European congress which met in London. As a result of its deliberations, Prussia abandoned her right to garrison the fortress, which was destroyed, while the grand-duchy remained an independent State under its then ruler.

If Bismarck had desired war with France, he could easily have brought it about at that moment. Instead he chose this moment to publish the, hitherto secret, offensiveand defensive alliance with the South German States, as a warning to Napoleon that in event of an attack upon Prussia he need not hope to find thk South German States either fighting upon his side or maintaining an attitude of neutrality.

Napoleon regarded this fresh defeat as a deep personal humiliation. Henceforth he worked for an alliance with Austria and Italy that should be directed against Prussia, and he also began a great re-organization and re-armament of his army. But although Napoleon found that Austria and Italy were in general inclined to favour his plans, he was unable to bring about the conclusion of an actual alliance. After her severe defeat at the hands of Prussia, Austria was unwilling to become involved in a new war of which the result could not with certainty be forecast. If France first gained the upper hand in South Germany, Austria would then be prepared to intervene in the struggle. Napoleon's negotiations with Italy broke down over the Roman Question; for he could not hand over Rome to the Italians without offending clerical parties in France. These negotiations, coupled with the appointment of the avowed enemy of Prussia, the duke of Grammont, as minister for foreign affairs, showed clearly the direction of Napoleon's policy.

The Spanish Succession Question.—Although Bismarck was aware of the existence of these negotiations, he was uncertain whether they had produced any definite result; and in any case he believed it to be his duty to make use of every available means of defence against an imminent French attack. An opportunity for this was afforded him by the emergence of the Spanish succession question. After the expulsion of Queen Isabella in 1568, a regency had been set up in Spain. When various attempts to find a suitable occupant for the throne had failed, it was offered to Prince Leopold of Hohenzollern-Sigmaringen who was descended from the Catholic and Suabian line of the Hohenzollerns, and married to a Portuguese princess. At first the prince manifested little inclination to accept the proposal, but Bismarck favoured his acceptance from the outset on the ground that, in view of the state of Franco-Prussian relations, it would be useful to have a friendly government in Spain. The king, however, was unwilling to influence the prince in making a decision, and the prince declined the proposal. Since among the reasons for his refusal the prince had alluded to the instability of the situation in Spain, and the untrustworthiness of the Spanish army, Bismarck despatched two agents to Spain to obtain accurate information as to the position there. He also induced the head of the Spanish Government, Marshal Prim, to inform the prince that he did not look upon his refusal as a final one. When the agents reported in a sense favourable to his candidature, the question was once more laid before the prince; as in these circumstances his father, Prince Charles Anthony also favoured an acceptance, the prince reversed his previous decision. Bismarck thereupon informed Prim that he should again approach Leopold.

The prince announced his acceptance to Prim's ambassador on June 19, 1870, after King William had given his consent, on condition that he should be elected by a considerable majority. The whole affair was to remain a secret until a proposal had been brought forward in the *Cortes* for the election of Leopold. Through a misunderstanding, however, the *Cortes* had been adjourned before the receipt of Leopold's final answer, and Prim, believing that in these circumstances it was not possible to preserve secrecy any longer, informed the French ambassador of the position of affairs. A wave of indignation spread over France. A question was answered in the French Chamber on July 5, by Grammont, with the declaration that France could not without anxiety see the establishment by a foreign power of one of its princes on the throne of Charles V., and the consequent disturbance of the balance of power in Europe. He ended his speech with an open threat of war against Prussia, if she did not withdraw Prince Leopold's candidature, and he despatched Count Benedetti to Ems, where King William was taking the cure, with instructions to see that he ordered the prince to withdraw his candidature.

While he hesitated to give such an order, King William informed Prince Charles Anthony that he would be very glad if his son were to abandon his candidature in order to avoid bringing about a war with France over this question. The prince, believing

that the decision must await the re-assembling of the Cortes, had gone on a tour in the Alps and could not at the moment be reached. Prince Charles Anthony therefore took it upon himself in the name of his son to telegraph to Paris and Madrid that the latter withdrew his candidature. Meanwhile in Paris a feeling had grown up that a mere withdrawal of Leopold's candidature was not of itself enough, and that the opportunity should be utilized to inflict upon Prussia a humiliation similar to that inflicted upon France over Luxembourg. Grammont demanded of King William that he should write a letter of apology to the Emperor Napoleon and at the same time verbally informed him, through Benedetti at Ems, that he must promise not to permit the prince to resume his candidature.

But before Benedetti had had time to present these new demands on July 13, Bismarck had taken action. When the crisis arose, he had been on holiday on his Pomeranian estates; but, on reading Grammont's reply to the interpellation in the Chamber, he resolved at once not to give way before any threat on the part of France. He would personally have preferred that the King should refuse to receive Benedetti at Ems, and, when he did so, Bismarck determined to go to Ems himself. On arriving in Berlin on July 12, he learnt that Prince Charles Anthony had already renounced the candidature on behalf of his son, and, as he thought that it was now too late to alter the situation, he determined to remain in Berlin. But he sent Count Eulenburg to Ems to convey his views to the King. On his arrival, Eulenburg found that the interview with Benedetti had already taken place, and that the King had told the ambassador he could give no guarantee for the future. On Eulenburg's advice, the King decided to inform Benedetti that under the existing circumstances he could not again receive him in audience and that any further negotiations must be transacted with his ministers. The King at once telegraphed an account of what had taken place at Ems to Bismarck and further gave him permission to make known to the Press and the diplomatic corps the further French demands and the fact of their rejection. Bismarck made use of this authorization to publish the King's telegram with certain abridgements which did not affect its actual content. (See BISMARCK, PRINCE OTTO VON.)

The French Government was now confronted with the necessity of deciding whether or not to accept the Prussian reply. Napoleon would perhaps have been disposed to let the matter rest there, if Grammont and the Empress Eugénie had not advised him that such a policy would still further imperil the already insecure position of his dynasty in France. Thus he resolved to sign the declaration of war on July 15. If the French Government had contented itself with the withdrawal of the Prussian candidature, he could have concluded the whole affair with a diplomatic triumph for France; it was only when they took the fateful decision to seize the opportunity to inflict a personal humiliation upon the Prussian king, that war became inevitable.

The War with France.—The South German States at once recognized that the eventuality provided for in the offensive and defensive alliance with Prussia had arisen, and placed their troops under the command of King William in fulfilment of their treaty obligations. But Germany could not count upon the support of any other allies; Russia preserved a strict neutrality; Austria pursued a very indecisive policy, and if the French had gained a distinct success in the first weeks of the war, the party in Vienna which favoured participation in a war against Prussia would certainly have gained the upper hand; England desired to remain neutral, but at the same time to prevent Belgium being involved in the war. Gladstone, indeed, thought that the safety of Belgium was not sufficiently secured by the existing treaties and he therefore, concluded new treaties with France and Prussia in which both States undertook not to violate the neutrality of Belgium, whilst England bound herself to make war upon any State that should violate that neutrality.

In accordance with a plan of Moltke's, three armies were formed for the purpose of invading French territory from three different directions: General Steinmetz from the Moselle, Prince Frederick Charles from the Palatinate on Metz and the crown prince from the upper Rhine on Strasbourg. The French advanced into the Saar district and won a small victory at Saarbriicken. So confident were they of victory that they had already drawn up an elaborate plan for the partition of Prussia and a re-division of Germany, by which France was to receive the Saar district. The further progress of the campaign was to belie their confidence. On Aug. 4 and 6 the crown prince won two great victories over Marshal MacMahon at Worth and Weissenburg, forced the marshal to evacuate Alsace, invested Strasbourg and advanced against Nancy. The other two German armies surrounded the troops of Marshal Bazaine in Metz and in the bloody fights at Mars-la-Tour and Gravelotte (Aug. 16 and 18) repulsed his attempt to break through the Prussian lines. Metz itself was besieged and the advance towards Chalons begun. When Marshal MacMahon attempted to get round the northern flank of the German forces and press forward on Metz, he found the road already closed to him by numerically superior German forces. Nevertheless he attempted to break through, only to meet with a terrible defeat at Sedan on Sept. 1, where, on the following day, he was forced to surrender with all that remained of his army, including the Emperor Napoleon himself. The arrival in Paris of the news of this disaster brought about the overthrow of the empire and the establishment of a Government of National Defence under the leadership of General Trochu. This new Government asked for an armistice. But on the refusal of Moltke to grant this request before he had received the surrender of Strasbourg, Metz, Bitsch and Toul, the negotiations broke down. Whilst the main German army advanced against Paris, the fortresses of Metz and Toul capitulated in September, and Strasbourg fell into German hands in October: of the frontier forts, Belfort alone held out until the middle of Feb. 1871. Paris was completely encircled with German troops and the attempts at relief made from the north and the Loire were repulsed after fierce fighting. Finally Bourbaki's army—the sole efficient army left to France—was driven over the Swiss frontier on Feb. 1, 1871, and there disarmed.

Shortly before this, Paris had capitulated (Jan. 28), and thereby the resistance of France was virtually ended. An armistice was concluded for a period of 21 days, and during this time a national assembly was to be elected with whom negotiations could be carried on for the conclusion of peace. The national assembly met at Bordeaux on Feb. 13, and elected Thiers as president of the executive body. As his representative, Jules Favre appeared at the German headquarters in Versailles and, after long and difficult negotiations, the preliminary peace was signed there on Feb. 26, which was subsequently to form the basis for the final peace concluded at Frankfurt-on-Main on May 10. France had to cede Alsace and a portion of Lorraine with the city of Metz, as well as to pay a war indemnity of five milliards of francs. At the outset Bismarck had wished to demand the cession of Belfort, and he had only desisted from doing so when he had been assured by Moltke that the possession of this fortress was not of vital necessity for the defence of the south-west frontier of Germany. German troops occupied Paris, only to leave it again when the national assembly had ratified the peace treaty, and certain districts in Lorraine continued in German military occupation until the war indemnity had been paid in full. (See also FRANCO-GERMAN WAR)

The German Empire.—During the war public opinion throughout Germany had loudly demanded that one result of the war should be a permanent union of northern and southern Germany. Bismarck laid great stress upon the necessity of the Southern States seeking admission to the Confederation of their own volition. It might otherwise be said that Prussia had seized the opportunity afforded her by the trustfulness of these States in placing their troops under her command, to compel them to make unwelcome decisions. Ultimately, under pressure from public opinion in Bavaria, and acting on the pressing advice of the rulers of Saxony and Baden, the Bavarian Government determined to initiate a discussion upon the new organization of Germany. The conference met in Munich (Sept. 22 to 27, 1870), and Bismarck was represented by the president of the federal chancellory, Rudolph Delbriick. The conference was composed

solely of representatives of Prussia, Bavaria and Wiirttemberg. Complete unity was still not effected because the Bavarian minister, Count Bray, firmly maintained that the conference was not competent to deal with the entry of the South German States into the North German Confederation but had only to consider a new treaty of confederation, and moreover, he demanded far-reaching privileges for Bavaria.

Nevertheless the existing difficulties seemed capable of solution, and Bismarck therefore induced the grand-duke of Baden to effect the inclusion of his State in the North German Confederation and to send the minister for war, von Suckow, to Versailles for this purpose. Thereupon Bavaria and Württemberg also felt obliged to send representatives. On Oct. 25, began the final negotiations which were carried on with each of the South German States separately. In return for an assurance on the part of Bismarck that he was prepared to concede at least some of her special desires, Bavaria withdrew her opposition to entry into the North German Confederation, and by the end of November treaties had been concluded with all the South German States. Bavaria and Württemberg retained their own postal and telegraph services and the right to levy their own taxes on beer and brandy. Bavaria was further conceded the right to independent control of her army in time of peace; her troops were only to be placed under the command of the federal commander-in-chief in time of war. Further the Bavarian ambassadors were to have the right to represent the ambassadors of the Confederation should occasion arise. Finally a diplomatic committee of the *Bundesrat* was established under Bavarian chairmanship which was to give its opinion concerning important questions of foreign policy.

Even during these negotiations there arose the idea that it might perhaps be possible to renew the old German imperial dignity in connection with the re-establishment of a national German State. Lest this question should first be raised by anyone else, King Ludwig II. of Bavaria determined to take the initiative, and he addressed a letter to King William in which he invited him to accept the imperial title. The letter was drafted by Bismarck at Ludwig's own desire. When the remaining German rulers proclaimed their agreement with the request contained in the letter, and when the North German *Reichstag* despatched a special deputation to lay a similar request before him, the king decided to comply with the general wish although he personally was averse to seeing the Prussian royal title thus subordinated to the imperial dignity. But it was only after the acceptance of the Treaty of Versailles by the North German *Reichstag* and the South German *Landtags* that the idea could be put into execution. On Jan. 18, 1871, the Hall of Mirrors in Versailles beheld the ceremonial proclamation of William I. as German emperor.

In accordance with the provisions of the Treaty of Versailles the Constitution had to be remodelled to include the alterations necessitated by the transformation of the German Confederation into the German *Reich* and the president of the Confederation into the German emperor. In its new form the Constitution was laid before the *Reichstag* which had been elected by the whole population of the new *Reich*. The Constitution was almost unanimously adopted on April 14, 1871. The new *Reich* was composed of 25 States, the four kingdoms of Prussia, Bavaria, Saxony and Wiirttemberg; five grand-duchies; 13 duchies and principalities; and the three free cities of Hamburg, Bremen and Lübeck. Alsace-Lorraine was to be the common property of all the German States. It was designated a "*Reichsland*" and was given an imperial *Statthalter*. The main principles of the constitution followed that of the North German Confederation of 1867; the special rights of the South German States were embodied; and it was clearly laid down that they could not be annulled without their consent.

Thus the aim of the small German party in the Frankfurt parliament was finally attained. Germany once more possessed a common political organization, such as she had not in fact enjoyed since the Peace of Westphalia, although the old constitutional forms had nominally existed until 1806. But this unification of the greater part of the German peoples was purchased at the cost of the exclusion of German Austria. As long as the Habsburg empire existed, and as long as its German inhabitants felt that they owed allegiance primarily to this State, no other scheme for unification of Germany was possible.

THE GERMAN EMPIRE

The new German Empire had a territory of 541,000 square kilometres, and its population, including that of the newly acquired districts, was 41,000,000. The population had been increasing steadily and rapidly ever since 1815, when it was 25,000,000. By 1900 it had reached 56,000,000, and at the outbreak of war in 1914 it was nearly 68,000,000. In 1871 Germany was still mainly an agricultural country; the production of foodstuffs was sufficient to supply the needs of the home population and leave a surplus for export. From the middle of the 19th century onwards, however, the industrial districts rapidly grew in importance. Industry was the principal gainer by the period of economic prosperity which set in after 1871, and German manufactured goods gradually began to compete with British on the world market. German export trade steadily increased, and tended more and more to be carried in German-owned and German-built ships.

Since the rural population still constituted the majority of the nation, its political influence was naturally great. In the districts east of the Elbe the old landed aristocracy maintained its traditional predominance; but in other parts of the country too its power was considerable, for the peasants and agricultural workers were unorganized and tended to follow its leadership. In the industrial districts and the old commercial towns a wealthy middle class had grown up, but the industrial workers were rapidly becoming a numerous class and were making themselves felt as an important factor in political life.

Party Politics.—Party divisions in German political life developed on somewhat different lines from those which they followed in most other countries. This was due to the important part played by sectarian considerations. The stronghold of the Conservatives was in the north-eastern part of the country, where the influence of the landed aristocracy was predominant. Conservative views also largely prevailed among public officials. As the electoral system in force in most of the States constituting the empire was specially favourable to the land-owning classes, the Conservatives felt their political position much more secure in the States than in the empire, where there was no upper house and the suffrage was general and equal. Most of them were, therefore, more strongly attached to the State to which they belonged than to the empire. Many of them disapproved of the policy which Bismarck had followed since 1866. They regarded the dethronement of German dynasties as an offence against Conservative principles and the Indemnity Act as a concession to Liberal demands. The Conservatives in consequence split up into two groups: the Independent Conservatives or *Deutsche Reichspartei* found most of their supporters among the public officials and, generally speaking, followed Bismarck, while the *Deutsch-Konservative* adhered strictly to legitimist principles and stood for the interests of the great land-owners.

The chief strength of the Liberals was to be found in the larger towns and among the upper middle classes, especially in North-west and Central Germany and in the Rhineland. Ever since the beginning of the 19th century the Liberals had been the chief supporters of German unity and had opposed what they regarded as the unreasonable and reactionary views of those who clung to the system of small States. The fact that political power was in the hands of the Conservatives in the individual States led the Liberals to think of a united Germany as the destined field for the realisation of their ideas. If they had had the sole voice in the drafting of the new constitution, they would presumably have limited the powers of the individual States much more drastically. The new empire however was not their creation, but that of Prussian diplomacy and the Prussian army, and they could only obtain the realization of such of their demands as Bismarck was willing to grant. It may be said in general that German Liberalism has suffered greatly from the fact that it has never been able to attain a position of power and responsibility. It was never able to do more than carry through now one, now another isolated item of its policy by means of compromises wrung with difficulty

from the Government; and as a consequence it inevitably tended to adopt a negative and critical attitude. Even when the Liberals came to terms with Bismarck after 1866, they were obliged to leave the real direction of affairs in his hands. The Liberal Party, like the Conservative Party, split on the vote on the Indemnity Act; the Right wing became the National Liberal Party, while the Left wing retained the old name of the Progressive Party. The latter party remained in opposition because it refused to support any Government which did not take up its stand on the Liberal programme as a whole. The National Liberals on the'other hand supported Bismarck's foreign policy in the hope of obtaining concessions to Liberal policy in return. Liberalism was enormously weakened by the split, and has never fully recovered from its consequences.

The Democrats or Radicals had endeavoured to set up a United German Republic during the Revolution of 1848, but after the defeat which they then suffered they practically disappeared from public life. Separate democratic parties only continued to exist in the South German parliaments; the Democrats of the North were too weak to form a party of their own, and attached themselves to the left wing of the Liberal Party. They gradually acquired considerable influence in the Progressive Party.

Another important political group was that of the Clericals. Even before the middle of the 19th century there had been Catholic political groups in the various States. In the Frankfurt parliament the Catholic members had met separately for discussion. It was not however until after 1850 that they actually constituted a party. In 1852 a Catholic party was formed in the Prussian Chamber of Deputies, and in 1858 it took the name of the Centre Party. Its object was stated to be to combat unbelief and all the resultant phenomena in public life. The Catholic clergy tried to induce every good Catholic to vote only for deputies belonging to the Catholic parties. The Clericals were particularly influential in Bavaria. During the war with France, when it seemed inevitable that an empire consisting of the German States without Austria and with a Protestant monarch would be formed, all the Catholics of Germany—they represented about one-third of the population—combined to form a single German Centre Party, and this party succeeded in getting a considerable number of its candidates returned at the elections to the first *Reichstag.* The Centre Party endeavoured to induce Germany to enter the lists for the restoration of the temporal power of the Pope, and to introduce provisions in the constitution of the empire which would secure the Catholic Church against any form of State interference. In neither of these respects was it successful. The Centre did not actually work against the existence of the new empire, but rather tried to induce it to further the interests of the Catholics as far as possible. The party was strongest in those parts of the country where the population was predominantly Catholic and under the influence of the clergy—in Southern Bavaria, the Rhineland and Westphalia, Upper Silesia, Posen and West Prussia.

Side by side with the older parties there gradually grew up a socialistic workers' party. The first organization of this kind was the *Allgemeiner Deutscher Arbeiterverein,* founded in 1863, of which Ferdinand Lassalle was at first the head. After Lassalle's death the party split up into several groups, but they reunited at the party congresses of Eisenach (1869) and Erfurt (1875) and assumed the name of the Social Democratic Party. Their objects were based on the principles laid down by Karl Marx and Friedrich Engels in the communist manifesto of 1848: the abolition of the whole existing social, economic and political order in favour of a new order based on communal ownership of all the means of production (the land, factories and machinery). They regarded the existing State as nothing more than a capitalist organization, and therefore entirely repudiated it. Only the proletariat, they held, could bring the new social order into being, and therefore, since the interests of the proletariat of all countries were identical, the workers of all countries should be induced to unite in an international struggle against capitalism. They considered that wars between nations were caused entirely by economic rivalry between the ruling groups of capitalists, and would automatically cease in a socialist society. In 1871 the Socialist Party was still very small; it had only three members in the first German *Reichstag.* In the following decades however it grew rapidly.

There were also a number of political groups which were opposed to the new empire on principle. These included in the first place the representatives of the foreign nationalities which had been incorporated in the empire—the Danes in North Schleswig, the Poles in the eastern provinces of Prussia, and the inhabitants of Alsace-Lorraine whose sympathies were with France. In addition there were those elements which refused to recognize the forcible abolition of the North German States which had been annexed in 1866—the Guelph Party in Hanover and the *Rechtspartei* in the electorate of Hesse.

The fact that so many parties were in existence prevented any one of them from obtaining a solid majority in the *Reichstag.* The prime minister thus always had the difficult task of constituting a majority by negotiating with the leaders of the various groups which were prepared to support the measures which he was contemplating at the time. Bismarck's ideal was to combine the two Conservative parties and the National Liberals so as to form a permanent majority. This however was exceedingly difficult because the right wing of the Conservatives regarded him with distrust, and objected to any kind of collaboration with the Liberals. A coalition between these parties was moreover not at first absolutely necessary, because the National Liberals won so many seats at the elections of 1871 and 1874 that they were able to constitute a majority with the help of the Independent Conservatives and a few Progressive votes. Bismarck therefore found it necessary to work in close touch with the National Liberals; but as his personal views were nearer to those of the Conservatives, he took care from the outset to prevent the Liberals from becoming too powerful.

The Liberal Period.—In 1873 imperial legislation was extended to cover the entire field of civil law. The imperial court of justice was set up in Leipzig in 1879. Work was begun at the same time on the drafting of a civil code for the German empire. A uniform penal code and uniform rules for civil and criminal procedure were drawn up. Under the Constitution there was only one responsible minister of the empire, the federal chancellor (*Bundeskanzler)* or imperial chancellor *(Reichskanzler)* as he had been called since 1871. The secretaries of State, as the heads of the various departments were called, were entirely subordinate to the imperial chancellor. A new act of 1877 empowered secretaries of State to countersign, as representatives of the chancellor, those imperial decrees which related to their particular department. This gave them a greater degree of independence, though they were not placed on a footing of equality with the imperial chancellor, but remained his subordinates. The heads of the various departments had no collective responsibility for the general policy of the Government; such responsibility rested solely with the imperial chancellor.

On other questions also Bismarck did something to meet the views of the Liberals. The Imperial Press Act of 1874 finally abolished the censorship and the obligation of the publishers of newspapers to deposit'a guarantee; the freedom of the press was thus secured. In the economic sphere, new uniform standards for the whole empire were erected by legislation dealing with the currency and banks, the protection of trade marks and patents and inventors' rights, and by the foundation of the imperial bank. The reform of the administration which was carried out in Prussia from 1872 to 1875 was also a concession to Liberal views. The new municipal system gave the representatives of the nation a greater share in local government, freed the large towns from the supervision of the *Landrat,* and handed over the settlement of disputes arising out of the action of the administrative authorities to special administrative courts. These measures met with violent resistance from the Conservatives, and the king was obliged to appoint 25 new members to the *Herrenhaus* in order to get them adopted by that body.

Bismarck came into violent collision with the Liberals on military questions. The Government considered it necessary to make the maintenance of the army independent of the annual consent

of the *Reichstag*, and demanded that the credits necessary for the upkeep of an army of 400,000 men should be voted without limitation of time. The Liberals regarded this as an intolerable encroachment on the right of parliament to control the budget. A compromise was finally agreed upon at the proposal of Bennigsen—the so-called *Septennat*, according to which the military credits were voted for seven years. At the end of that period the amount of the credit was to be reconsidered. The sums required for the creation of an imperial navy and for coastal defences were voted without much difficulty. The navy was to be used for the protection of the German coasts and of German commerce; it was decided not to create a battle-fleet or high sea fleet, in order to keep military expenditure within bounds.

The Kulturkampf.—On the religious and educational side, the alliance between Bismarck and the Liberals found its expression in the conflict which came to be known as the *Kulturkampf*. The dispute originally arose out of the decrees of the Vatican Council of 1870, which declared the infallibility of the pope in matters of faith to be a dogma of the Catholic Church. Serious objection was felt to these decisions among the intellectual leaders of German Catholicism. Many of them regarded them as a departure from the traditional spirit of the Catholic Church. They therefore called themselves the Old Catholics, and they refused to recognize the new dogma. The Bavarian Government went so far as to prohibit the publication of the decisions of the council because they had not received the royal approval *(Regium placetum)*. The German bishops, however, though not without reluctance, recognized the Vatican decrees, and the great mass of the Catholic population remained quite indifferent to the question; consequently the Old Catholics remained a little group of leaders without followers. They were excommunicated by the pope, and were forbidden to teach or to undertake the cure of souls. The Church demanded that the Government of the States should dismiss from their posts all Old Catholics who were teachers in State educational institutions. Bismarck regarded this as an encroachment by the Church on the sovereignty of the State, and it seemed to him the more dangerous as the Centre Party was at the same time putting forward the demands in the Catholic interest which have already been mentioned. He was confirmed in his attitude by the fact that the leadership of the Centre Party was tending to fall into the hands of the former Hanoverian Minister Windthorst, who was a supporter of the Guelph movement and consequently an avowed opponent of the new order of things. He refused to dismiss the Old Catholic teachers, and abolished the special section which had previously existed in the Prussian ministry of public worship to deal with Catholic affairs. Foreseeing that the Catholic Church would resist these measures, he tried to introduce radical changes in the relation between Church and State in Germany as a whole. He proposed to take the registration of births, deaths and marriages out of the hands of the clergy, and to make the celebration of marriages an exclusive function of the State, as well as to abolish clerical supervision over schools and to alter the system of training of the Catholic clergy.

Bismarck's plans were warmly supported by the Liberals, while, as was to be expected, they were strongly opposed by the Centre Party, the Poles *(see* POZNAN) and the right wing of the Conservatives. The conflict began when the bishops forbade all Catholics to attend classes or lectures given by excommunicated Old Catholic teachers. Bismarck replied by expelling the Jesuits from Germany, and by demanding that all bishops should recognize the duty of implicit obedience to the laws of the State. He withheld their emoluments from all those who refused to make such a declaration. An imperial act was passed forbidding the clergy to make use of the pulpit or the confessional for purposes of political agitation. In May 1873 the Prussian *Landtag* passed a number of measures limiting the exercise of ecclesiastical disciplinary and penal measures. It was further decided that no cleric should in future be appointed to a benefice unless he had undergone a three years' course of study at a university or a seminary recognized by the State, and had passed a Government examination in philosophy, history and German and classical literature. The State was to have the right to veto the appointment of any priest to a benefice. A special State court of justice for Church matters was set up to try priests who failed to conform to this legislation. The court had power to remove them from their posts.

The German bishops protested against this legislation in Prussia and the similar measures adopted in Baden and Hesse, and called on the clergy and the population to engage in passive resistance. Government inspectors were refused admission to the seminaries, and appointments were made to ecclesiastical benefices without previous notification of the State. The clergy refused to appear before the State court of justice or to pay the fines which it imposed. The archbishops of Posen and Cologne and the bishop of Trier were consequently arrested, and the first-named was deposed by the State court of justice on the ground of contumacy.

A number of still more drastic measures were adopted in 1874 and 1875; the State was empowered to appoint its own commissioners to administer clerical posts which had not been regularly filled, and to withhold State grants from parishes which offered resistance. The article of the Prussian Constitution which conferred complete autonomy on the Catholic Church was revoked These measures aroused intense feeling among the German Catholics; indeed an attempt on Bismarck's life was made by a certain Kullmann at Kissingen in July 1874. Feeling ran still higher when the pope, on Feb. 15, 1875, declared the Prussian ecclesiastical legislation invalid and called on the people to resist it because they owed greater obedience to God than to men.

The Catholics felt it as a special threat to their position that the State was attempting to exercise its influence over the training of the clergy, to bring them into closer touch with secular culture and to prevent their education from remaining wholely in the hands of the Church. Bismarck and Dr. Falk, the Liberal minister of public worship who was his principal coadjutor in this affair, certainly underestimated the power of resistance of the Catholic Church. The Old Catholics had no influence with the nation at large, and the orthodox elements among the Protestants were inclined to support the Catholic point of view on the question of relations between Church and State. The question was whether in spite of this Bismarck would be able to carry the struggle through to the end. For him the main point at issue was always to maintain the strong political position of Germany, and to contrive such a state of affairs among the parties as would ensure that he could obtain the necessary resources. He had entered on the struggle because he regarded the alliance of the Catholic Church with the Centre and the Poles as a serious danger; but he himself repeatedly declared later that he had never really meant to go so far, and that the May laws were the work of Falk and the Liberal majority in parliament. Probably he began by demanding more than would really content him, so as to have a margin with which to offer concessions and thus finally arrive at agreement. Conditions soon became such as to make him very anxious that an agreement should be reached.

Financial Reform.—It soon became apparent that the revenues which the Empire derived from its own resources would not be sufficient to cover its expenditure. The imperial contributions of the States repeatedly had to be increased. Bismarck considered this undesirable, and tried to devise means of finding increased sources of revenue in the empire itself. His first idea was that the railways, which belonged partly to the individual States and partly to private companies, should be taken over by the empire. As a preparatory measure, an Imperial Railway Board was set up in 1873. The scheme broke down however owing to the resistance of the States, which were unwilling to part with so valuable a source of income. Bismarck next tried to increase the taxation of articles in common use, and to introduce a tobacco monopoly. In this he met with opposition from the Liberals, who objected to any increase in indirect taxation because they regarded it as an encroachment on parliament's right of control over the budget. The only other possible means of raising fresh revenue for the empire appeared to Bismarck to be an increase in customs tariffs. Here again opposition was to be expected from the Liberals, the vast majority of whom were believers in free trade; but on the other hand it was possible to reckon on a strong protectionist movement among the great manufacturers and landowners.

German industrialists regarded increased protective tariffs on foreign imports as an assistance to them in their struggle for the control of the home market. German agriculture was beginning to have difficulty in meeting the food requirements of the rapidly growing population; more and more cheap foreign grain was being imported, and this tended to depress the prices of agricultural products, while at the same time agricultural wages were rising. The landowners were convinced that increased import duties on grain were the only means of keeping prices at a level which would make farming pay. Bismarck accordingly felt sure of support from the principal economic elements of the country, and decided to undertake a complete revision of the customs tariffs.

Bismarck would very much have liked to win over the right wing of the National Liberals; the support of the Conservatives was not in doubt. He declared himself ready to include Bennigsen, the principal National Liberal leader, in the ministry if he could bring over the majority of his party to the side of tariff reform. Bennigsen however insisted that two other National Liberals, Forkenbeck and Stauffenberg, should also be given office, and the scheme broke down. Bismarck now saw that his plans for financial and tariff reform could not be carried out with Liberal aid.

Social Questions. — There was yet another question on which Bismarck and the Liberals had come to the parting of the ways. The Social Democrats had been gaining many adherents among the workers; they had won no less than 12 seats at the 1877 elections Bismarck regarded the growth of this movement, which was hostile to the existing political order, as a grave menace. He thought its development might be checked if satisfaction were given to some of the justifiable demands of the workers, while at the same time stern measures were taken to repress all extremist tendencies. It had for some time been in his mind that the State ought to find some means of protecting workers against destitution when they were no longer able to support themselves by their own earnings. Ideas of this kind had first been put forward in Catholic circles, and had found an ardent defender in Ketteler, archbishop of Mainz. Among the Protestants too there were many who thought that both Christian and general humanitarian considerations demanded that something should be done to improve the material and moral conditions of the workers. These tendencies found representation in the *Verein fur Sozialpolitik*.

Bismarck was no doubt indirectly influenced by these points of view, but it was mainly political considerations that he had in mind. He prepared a scheme for the insurance of worlrers against sickness, industrial accidents and old age, in which a considerable part of the necessary funds was to be contributed by the empire. At the same time he proposed to make it an offence to engage in agitation for revolutionary or republican objects, or for the subversion of the existing social order. As early as 1875 he attempted to introduce provisions into the act supplementing the penal code laying down penalties for public attacks on the principles of marriage and the family and of private property. The Liberal majority rejected the proposed clauses, and Bismarck then began to consider introducing exceptional legislation against Social Democratic agitation. The Liberals were however opposed both to the introduction of exceptional legislation against one particular political tendency, and to compulsory State insurance of the workers, which was in their view an unwarrantable interference of the State in economic affairs. Since these plans of Bismarck's also were opposed by those who had been his allies, he began to consider whether some other parliamentary majority could not be won over to his side. Such a majority could only be found among the Conservatives and the Centre Party; but no understanding with the Centre Party could be reached unless the *Kulturkampf* came to an end. This did not seem impossible, since Leo XIII., who had become pope on the death of Pius IX. in 1878, also manifested the desire to put an end to the regrettable state of affairs which prevailed in the Catholic districts of Germany as a result of the conflict between Church and State.

At the time when Bismarck was considering these possible changes in policy, a journeyman tinsmith, named Hödel made an attempt on the life of the Emperor Wilhelm I, on May 11, 1878. Although the emperor was not actually wounded, and although there was no evidence of any connection between Hödel and the Social Democrats, Bismarck thought that he might make use of the indignation aroused by the attempted assassination of the aged monarch to carry through exceptional legislation against the Social Democrats. The Liberal majority however again threw out the bill. A few weeks later, on June 2, a second attempt was made on the Emperor's life, this time by a certain Dr. Nobiling. The emperor was so seriously wounded that the crown prince had to be empowered to act as his representative for a time. Social Democratic publications were actually found in Nobiling's possession, and Bismarck thinking that fresh elections might result in a majority more favourable to his schemes, dissolved the *Reichstag* The Liberal parties in fact lost 42 seats, and the Conservatives gained 37.

Bismarck once more submitted exceptional legislation against Social Democratic agitation to the new *Reichstag*. Meetings, associations, funds and publications intended to promote Social Democratic propaganda were to be prohibited; professional agitators were to be liable to expulsion from the country; martial law might be proclaimed in districts where the movement manifested itself particularly strongly. The National Liberals, thoroughly alarmed by their failure at the polls, allowed themselves to be prevailed upon to vote for the bill with a few attenuating amendments; it was provisionally to remain in force for two and a half years. The Conservatives also voted for the bill, and it was adopted on Oct. 19, 1878 by 221 votes to 149. It did not produce the desired effect. The Social Democrats printed their journals in Switzerland and smuggled them into Germany in large quantities; as long as the act was in force (*i*.e., till 1890) they held their party assemblies abroad. Persecution simply resulted in making their organization stronger.

The New Customs Tariff. — Bismarck at first thought it would be possible to win over enough of the National Liberals to protection to enable it to be introduced by a similar majority. When however it became clear that this was hopeless, he decided to enter into direct negotiations with the Centre. On March 31, 1879 he had an interview with Windthorst which proved to be one of the turning points in the internal history of the German empire. The Centre expressed its willingness to accept an increase in customs duties and indirect taxation if the *Kulturkampf* were broken off. In order, however, to safeguard the *Reichstag's* control of the budget, it demanded that all revenue from the new taxation in excess of 130,000,000 marks a year should be divided among the individual States. The object of this was that if the Government should require more than this sum, it should be obliged to ask for matricular contributions, the amount of which had to be approved by the *Reichstag* every year. On this basis the new customs tariff and the increases in indirect taxation were adopted on June 12, 1879. Hamburg and Bremen were brought within the customs frontiers of Germany with the exclusion of a free harbour for goods in transit (1881); the customs barrier surrounding the empire thus became complete. The grant of imperial subsidies to certain great steamship lines (1885) also served to facilitate the application of the system by which the Government hoped to create better conditions for the economic activity of the country

The breach between Bismarck and the Liberals was now complete, and the Conservatives and the Centre began to make their influence more and more strongly felt in all spheres. Their task was the easier because Bennigsen failed in his efforts to prevent a split in the National Liberal Party; the right wing desired to regain its position of alliance with the Government, while the left wing joined with the Progressive Party, the two together forming the German Independent Party (*Deutsch-freisinnige Partei*). Both groups lost more and more of their adherents. The Conservatives became increasingly powerful, especially in Prussia. A ministerial order issued by von Puttkamer in 1882 instructed all officials to support the policy of the Government, and to exercise their influence in the elections for this purpose.

The End of **the Kulturkampf.**—Falk, the minister of public worship, had resigned while the *Kulturkampf* was still continuing. In 1880 Bismarck obtained powers from the *Reichstag* to dispense with the application of the May laws in individual cases.

The secular examination for candidates for the priesthood was abolished, the competence of the State ecclesiastical court was limited, and the payment of emoluments to the clergy in most cases resumed. Finally, in 1886, the State ecclesiastical court was abolished, together with State inspection of seminaries. The pope on his side induced the archbishops of Posen and Cologne, who had been the two most violent opponents of the State in the recent struggle and had been deposed by the State ecclesiastical court, to resign their office. Peace was finally concluded between Church and State in 1887. The pope recognised the right of the State to veto ecclesiastical appointments if there was any serious objection to them on doctrinal or moral grounds. In return, the State agreed to modify the formula of the oath required of the clergy, and readmitted the Catholic orders with the exception of the Jesuits. Civil marriage was maintained. Certain difficult questions of principle remained outstanding, but agreement was reached on the most pressing of the points at issue.

Social Legislation. — Bismarck now returned to his plan for far-reaching legislation on the insurance of the workers. In March 1881 he laid an Accident Insurance bill before the *Reichstag*. All workers were to be insured against industrial accidents by an Imperial Insurance Institution. The cost was to be borne partly by the employers and workers and partly by the State. As however the Liberals were opposed to compulsory insurance, while the Centre and the Conservatives disliked any extension of the sphere of influence of the central Government, the bill did not go through the *Reichstag* without drastic amendment. The principle of compulsory insurance was accepted, but the empire was not to make any contribution to the scheme, and it was decided to set up insurance institutions for each of the States instead of an Imperial Insurance Institution. One of Bismarck's main objects was to make the workers feel that they were receiving direct benefit from the Empire, and he regarded the amendment as so serious a mutilation of his scheme that he withdrew the bill for the time being. The 1881 elections showed a great decrease in the strength of the Conservatives, and an accession of power to the Liberals and Social Democrats. Bismarck submitted his bill to the new *Reichstag* in a modified form, and persuaded the emperor to take the almost unprecedented step of announcing it to the *Reichstag* by a special message. He said that the object of the new law, which was to be followed by others, was to promote peace between classes in a spirit of Christianity. Although Bismarck had made up his mind to give up the idea of an Imperial Insurance Institution and to set up a system of trade associations (*Betriebsgenossenschaften*) on a local and occupational basis under State control, there was still a great deal of opposition to the bill because the principle that 25 per cent. of the expense should be provided by an imperial subsidy was maintained. It was only after prolonged negotiations that the bill finally became law in March 1884, with an amendment substituting an imperial guarantee for the imperial subsidy. Bills were later introduced setting up sickness insurance funds and a system of old age and invalidity insurance, and these too gave rise to heated discussion and were only adopted after far-reaching amendment. Bismarck however succeeded in getting the principle of a subsidy from the empire adopted in the case of the old age and invalidity insurance system.

Whatever may have been its defects of detail, this body of social legislation represents a great achievement and has served as a model for the other countries of Europe. It did not however achieve Bismarck's object of bringing over a large proportion of the workers from the Social Democratic camp and winning their adherence to the existing political order. The workers regarded the concessions which it represented as a sort of payment on account which they were glad to accept because it meant an improvement in their material position; but it did not persuade them to give up the rest of their aims.

Foreign Politics. — In the sphere of foreign policy, Bismarck's principal object was to preserve peace, which Germany required in order to develop its economic activities and to consolidate its internal organisation. He was convinced that it was not to Germany's interest to extend its territories any further at the expense of its neighbours, and that therefore even a successful war could bring no real advantage.

The most serious menace to peace lay in the desire of France to recover Alsace-Lorraine. Within a few years France had paid off its war indemnity of five milliard francs, and it then began to reorganize and strengthen its army and to improve the fortifications on the German frontier. France alone would not however have been strong enough to reopen the struggle, and Bismarck therefore regarded it as his first duty to maintain friendly relations with all countries which might have become the allies of France. He endeavoured to strengthen the traditional ties of friendship between Germany and Russia, to bring Austria and Italy into closer relations with Germany, and to establish contact with Great Britain.

Conditions in the Balkan Peninsula constituted another great danger to peace. Here the interests of Russia and those of Austria were in sharp opposition. Russia was striving to establish its hegemony over the Slav states of the Balkans and Constantinople. Austria on the contrary was anxious that Russia should not gain complete control over the lower Danube and the way to the Aegean, and was therefore in favour of the maintenance of Turkey. England threw its weight into the same scale, in the hope of keeping Russia out of the eastern Mediterranean. The maintenance of Turkey however did not appear to be possible unless the Sultan carried out far-reaching reforms and granted full equality of rights to his Christian subjects But it was exceedingly doubtful whether this was feasible in a State the very foundation of which was the principle of the exclusive supremacy of Islam. From the point of view of Germany, which was not directly interested in Eastern questions, the main thing was to prevent a collision between Russia and the other Powers.

Bismarck's first idea was to renew the close alliance between Russia, Austria and Germany which had existed some decades ago. For some time this appeared to be successful. The revolt of Bosnia and Hercegovina against the Turks in 1875 however threatened the very existence of Turkey, and in consequence the danger of war between Austria and Russia once more became acute. The revolt spread to Serbia and Bulgaria; Russia intervened in favour of the Christian peoples of the Balkans and declared war on the Sultan in 1877. The tzar succeeded in averting the intervention of Austria, but in return he was obliged to leave the administration of Bosnia and Hercegovina to Austria. In the spring of 1878 England seemed to be on the point of entering the field, but this was avoided by Bismarck's mediation. At the Congress of Berlin, which took place from June 13 to July 13, 1878 and over which Bismarck presided, the Powers agreed upon a new settlement of Balkan affairs; but none of them received full satisfaction, and thus the seed was sown for future complications. Russia above all was discontented at the accession of territory to Austria, and at the fact that the foundation of a Greater Bulgaria had been prevented. It was resented that Bismarck had not supported Russian claims more warmly, and the tzar was actually betrayed into uttering open threats in a letter to the Emperor William.

This gave Bismarck an opportunity of beginning negotiations with Austria with a view to a defensive alliance. Count Andrássy, who was mainly responsible for Austrian policy, was in favour of the idea; but the Emperor William resisted the scheme because he disliked the idea of an alliance directed against Russia and because he thought it wrong that Austria should refuse to promise help to Germany in the event of an attack by France. The old emperor finally yielded to Bismarck's threat of resignation, though with great reluctance. The German-Austrian alliance was concluded on Oct. 7, 1879. It was laid down that either of the contracting parties would support the other with its whole power in the event of an attack by Russia on one of them. If either contracting party were attacked by any other Power, the other undertook to maintain benevolent neutrality. If, however. Russia should intervene in the struggle on the other side, the obligation to give the fullest assistance would at once come into play.

It was far from being Bismarck's object to adopt a permanent attitude of hostility towards Russia. In June 1881 he succeeded in bringing about a new treaty between the three emperors by

which they undertook to support one another against other Po ers, and agreed that no alterations of frontier should take place in the Balkans unless they had been previously agreed upon by Russia, Austria and Germany. In the spring of 1884 the treaty was renewed, with slight modifications, for a further period of three years.

Another feature of Bismarck's policy was the establishment of closer relations with Italy. The Triple Alliance treaties between Germany, Austria and Italy were concluded on May 20, 1882; they remained in force, with some modifications, until 1914. Austria and Germany undertook to assist Italy with all means in their power in the event of an attack by France; such an attack did not seem improbable at the time, as the Italians considered their interests to be gravely injured by the French occupation of Tunis. Italy undertook to help Germany in the case of an unprovoked attack by France. The existing treaty obligations between Germany and Austria were maintained.

Bismarck's system of alliances as laid down by these treaties was only modified in appearance when, after the Balkan conflicts of 1884 and 1885, it became impossible to renew the alliance of the three emperors on its expiry in 1887. In order to provide a substitute, Bismarck concluded the so-called Reinsurance Treaty with Russia on June 18, 1887. He recognised Bulgaria as falling within the Russian sphere of influence, and even promised diplomatic and moral support if Russia found itself obliged to occupy Constantinople. The text of the other clauses shows that a temporary occupation was all that was intended; permanent frontier changes in the Balkans could not be made without Germany's consent.

This treaty cannot be rightly judged unless it is borne in mind that at the same time an agreement was being concluded between Great Britain, Italy and Austria, with Bismarck's knowledge but without the participation of Germany, the aim of which was the maintenance of the *status* quo in the Near East. Moreover, when the Triple Alliance was renewed in Feb. 1887, Bismarck obtained the inclusion of a new clause under which Austria and Italy undertook to give compensation to the State concerned if they should proceed to the temporary or permanent occupation of territory in the Balkans. The intention of these mutually complementary treaties was to prevent either Russia or Austria from engaging in an unchecked policy of conquest in the Balkans. The affiliation of Rumania to the Triple Alliance was to serve the same object. Bismarck was aware of the strong opposition of interests which existed between Russia and Austria and between Italy and Austria, and he thought that peace could best be ensured if he maintained close relations with all the Powers in question so that he could mediate between them if relations became strained.

It was most important at this time that steps should be taken to keep the peace, for the situation had become exceedingly serious owing to France's increasing desire for *"revanche"* and owing to the growing influence of the Panslavists in Russia. Bismarck felt it necessary to strengthen the defences of Germany. In the autumn of 1886 he laid a bill before the *Reichstag* to increase effectives of the army by 41,000 men and to fix the figure for a further period of seven years. The *Reichstag* threw out the bill because the Centre would only consent to a period of three years; it was therefore dissolved. At the new elections in Feb. 1887 the Conservatives and National Liberals were returned in greatly increased strength; they held respectively 122 and 97 seats, and thus they had between them an absolute majority in the *Reichstag.* They had worked together in the electoral campaign with a view to securing the passing of the Army bill. It seemed clear that if the "cartel" of the two parties could be maintained it would form the basis for a stable parliamentary majority. The Army bill was passed on March 11, 1887. Although Bismarck had repeatedly declared in the *Reichstag* that the increase in the army was intended solely to strengthen the defensive power of Germany, it was regarded in France as a threat. Feeling ran so high that a minor incident, the arrest of the French frontier commissioner Schnabele on German soil, nearly led to war. By another law adopted early in 1888, Bismarck raised the age for compulsory service in the *Landwehr* to 39. This did not involve any increase in the size of the army in peace time, but made it possible to draw on a considerably larger number of trained men in time of war.

Colonial Policy. — Whereas in Europe Bismarck confined his aims to the preservation of Germany's existing frontiers and to the maintenance of peace, he was beginning to contemplate an extension of German territory overseas. Germany was the only one of the great industrial Powers which had no colonies. Since the occupation of Egypt by the British and of Tunisia by the French, the division of territory between the European Powers had begun to progress so rapidly that Bismarck was anxious to obtain a share for Germany before all that was available should have been allotted. He directed his attention only to districts where German traders or colonists had already established themselves firmly. Having first made sure that Great Britain had no rights of sovereignty over the districts in question, he declared on April 24, 1884, that the settlements founded on the south-west coast of Africa by the trader Liideritz of Bremen were under the protection of the German empire. Subsequently the whole of the coast district from the frontier of Cape Colony to that of Portuguese Angola, with the exception of the British settlement of Walfisch Bay, was, with the consent of Great Britain, made a German protectorate. In the summer of 1884 Dr. Nachtigal concluded treaties with the local chieftains in the Cameroons and Togoland, and in the autumn of the same year similar treaties were made by Dr. Karl Peters in the hinterland of Zanzibar; these districts, as well as the north-eastern part of New Guinea ana the neighbouring islands, were also declared German protectorates. Bismarck had no idea of making these districts into provinces of the German empire overseas; their administration and economic development was to be left to special companies, and only if the interests of the German traders there were threatened by the natives or by foreign Powers would Germany intervene to protect them. Later, however, German colonial development was to follow other lines. The German East African Company found itself unable to deal with an important revolt which took place among the natives; the revolt was suppressed by Major von Wissmann, acting as imperial commissioner, and the company had to make over its rights to the empire. The New Guinea Company also made over its rights in 1899, and in 1907 all the colonies were placed under the control of the Colonial Office.

William **II.** and **the** Dismissal **of** Bismarck. — The Emperor William **I.** died on March 9, 1888, at the age of 91. His reserved and impressive personality inspired universal respect, and did much to reconcile the non-Prussian rulers and populations of Germany to the new régime. He was succeeded by his son Frederick III., who had already shown his quality as general in the wars of 1866 and 1870, and was specially popular in South Germany, whose troops he had led to battle against France. For some time, however, he had been suffering from a serious complaint of the throat, and the doctors agreed that he had not long to live. As a matter of fact, his reign only lasted 99 days. In these circumstances, although he was personally much more sympathetic to Liberal ideas than his father or Bismarck, he left Bismarck a free hand in the conduct of business, and only showed by isolated acts that his real views on questions of internal policy were different. On June 15, 1888, he was released by death from his cruel sufferings.

William II., the eldest son of the Emperor Frederick and the English Princess Victoria, came to the throne at the age of 29. He was a man of quick intelligence and great self-confidence, and was determined to take an active part in affairs. Although he took a great interest in modern technical progress, his general outlook was that which prevailed among the Conservative officials and officers. He entertained exceedingly lofty ideas of the position of a monarch, based on religious and mystical assumptions. His father's Liberal tendencies were distasteful to him; but he did not possess his grandfather's tact and stability of character. He was liable to be swayed by the influences of the moment, and he was very susceptible to skilful flattery. His intentions were excellent; but he was firmly convinced that he was the only person who knew what was good for his country. He had in times past

often assured Bismarck of his profound admiration; but this had not prevented occasional minor disagreements. When he came to the throne, he asked Bismarck to remain in office; but it very soon became clear however that Bismarck and the young Emperor would not be able to work together very long.

The immediate cause of the conflict between the emperor and his chancellor was that the former suddenly expressed a desire to have a number of social measures of a far-reaching character introduced, and to announce them in advance by a sort of proclamation. Bismarck had serious objections to such a course, and thought that at the least the probable consequences of the measures should first be carefully considered. Differences of opinion also arose on the question whether the Socialists' Act, which was due to expire in the autumn of 1890, should be re-enacted in an attenuated form. Bismarck tried to persuade his colleagues in the Prussian ministry to declare their solidarity with him, but they, regarding themselves according to the traditional view of Prussian officialdom as being primarily the servants of the monarch, refused to do so. The emperor looked upon Bismarck's action as an attempt to make him subject to the will of his first minister and practically to depose him. Bismarck, on the basis of a cabinet order dating from 1850, forbade any minister to have an audience with the emperor at which he himself was not present. William II. demanded that the order should be withdrawn. Bismarck refused to do so on the ground that the unity of the Government would be endangered if the prime minister's authority were weakened. The emperor thereupon gave him the choice of drawing up a decree reversing the order or handing in his resignation. He chose the latter. In his letter of resignation, dated March 18, 1890, he set forth all his objections to the policy which the emperor had hitherto followed. His resignation was at once accepted

The decisive factor in the conflict between Bismarck and William II. was not the difference of view between the older and the younger generation or between different political tendencies, but the young emperor's unwillingness to yield to any will but his own. Questions of foreign policy played only an incidental part. Bismarck's attempt to come to an understanding with the old Centre leader Windthorst without the emperor's knowledge, after the *Reichstag* elections had destroyed the majority of the Conservatives and National Liberals, was an aggravating feature but not the real cause. On Bismarck's side the desire to keep the power which he had enjoyed for the last 27 years played an important part, as well as his distrust of the Emperor's personality, which he believed to be fraught with the gravest dangers for Germany. How trivial the emperor's immediate motives were is shown by the fact that he completely dropped his schemes for social legislation before more than a small part of them had been realized, and did not even insist on the revocation of the cabinet order of 1850 which had been the principal bone of contention.

Caprivi.—As Bismarck's successor in the chancellorship, the emperor appointed Count Caprivi, who had hitherto occupied exclusively military positions, and had no experience either of administration or of foreign policy. The new foreign secretary was Marschall, formerly public prosecutor in Mannheim, who took over that difficult department of State with equally little experience. The man who, from now on, really dominated the Foreign Office was Holstein, an official trained in the school of Bismarck, who had, however, assisted in bringing about the fall of the former chancellor. He was a man of keen insight and comprehensive experience, but solitary and aloof, avoiding publicity and responsibility, and of a morbidly suspicious temperament. His reports exercised a tangible influence on German foreign policy up to 1905.

The first significant act of the new Government was the decision not to renew the "re-insurance compact" with Russia, which expired in the spring of 1890. Holstein took the view that the compact was inconsistent with obligations to Austria. He instigated Marschall and Caprivi to advise the emperor to put an end to the compact, in spite of the strong desire of Russia for renewal, which the emperor personally favoured. The result of this step was to clear the way for a *rapprochement* between France and Russia. Bismarck had throughout considered it his most urgent task to prevent Germany from being placed in the position of having to wage war simultaneously on both fronts. In August 1891 an alliance was concluded between Russia and France, and a year later the alliance was strengthened by a military convention.

At the same time, the emperor was endeavouring to effect a *rapprochement* with England. By a treaty signed on July 1, 1890 Heligoland was ceded to Germany, and German sovereignty was recognised in East Africa from Lake Tanganyika to the coast, with a slight extension of the boundaries of German South West Africa; Germany resigned in favour of England the claim to a protectorate in Witu and Uganda and renounced possession of the island of Zanzibar. The treaty removed certain causes of friction, but failed to lead to closer relations between Germany and England. The attempts of Germany during the next few years to bring about an understanding failed because of the conviction entertained by the English Government at the time that the policy of "splendid isolation" was in the best interests of the country.

A serious disagreement between the two Powers resulted from the attempt of England to annex from the Congo Free State a strip of land between Lake Tanganyika and Albert Nyanza, contrary to the Congo Act of 1885, which had been signed by all the great Powers. England was forced to renounce the transaction, and there was strong feeling in London over the attitude of Germany in this matter, and also over the close relations maintained between Germany and the Boer States in South Africa. Marschall's efforts to bring about a more sympathetic understanding with France also failed.

In home affairs, attempts were made to carry out the promises contained in the emperor's manifesto of Feb. 4, 1890, on social policy. The Industrial Courts Act of July 29, 1890 gave jurisdiction in labour disputes to a court including representatives of workers and employers. An amendment to the Trade Regulations on June 1, 1891 gave legal sanction to the Sunday rest, limited the right of employers to impose fines and introduced special safety regulations for unhealthy industries. It also provided for the institution of committees of workers entitled to advise on matters connected with the internal working of an undertaking. and regulated the employment of women and children. Provision was made for the appointment of special factory inspectors to see that the law was enforced. In order to promote German trade, important commercial treaties were concluded with Austria, Italy, Bulgaria and Switzerland. Germany extended to these countries a reduction in the protective duties on corn from five marks to 3·50 marks on every two cwt., and received in return a reduction of tariffs in favour of German industrial exports. These treaties were concluded for 12 years, and came into force at the beginning of 1892. Rumania and Serbia subsequently entered into similar agreements. Caprivi aroused the opposition of the conservative element by these treaties, which favoured industry at the expense of agriculture. The foundation of the League of Agriculturists in 1893 marked a strengthening of the influence of the large landowners within the Conservative Party.

The chancellor was obliged to obtain the support of the Centre Party in order to obtain ratification of the commercial treaties by the *Reichstag*, and had to purchase this support with concessions in other directions. Among these concessions was the introduction of a new Prussian Education bill, which gave the Church control of religious instruction and introduced Church schools. The bill aroused keen opposition on the part of the Liberal party, and Miquel, the Prussian minister of finance, who had been a member of the National Liberal Party, threatened to resign if it were passed. The emperor intervened, and at the session of the privy council on March 17, 1892 insisted on thorough revision of the bill. Zedlitz, the minister of education, thereupon resigned, and the bill was withdrawn by his successor. The Centre Party returned to the Opposition, and the Government was not certain of a majority either in the *Reichstag* or in the Prussian *Landtng*. The difficulty of the situation made itself felt during the debate

on the Army bill introduced in the autumn of 1892. It appeared necessary to strengthen the army in view of the change in the position of Germany resulting from the alliance between Russia and France. It was proposed to increase the force by 84,000 men, reducing the period of service from three to two years. The combined opposition of the Radicals, the Social Democrats and the Centre Party resulted in the rejection of the bill on May 6, 1893. Caprivi thereupon dissolved the *Reichstag*. The elections resulted in a temporary division of the Progressive Party, the "Progressive Association" accepting the Army bill, and the "National Progressive Party" rejecting it. The weakening of the Progressive and Centre Parties resulted in the adoption of the bill, with a number of amendments, on July 13, 1893, by a bare majority of 16 votes. But the opposition of the Conservative and Centre parties prevented the establishment of a permanent Government majority.

The Socialists' Act had expired in 1890, and the Social Democratic Party had resumed its agitation in all directions. In the election of 1893, 44 Social Democratic candidates were returned. The emperor, who had anticipated that his social legislation would counteract the movement, was extremely disappointed. He regarded the assassination of Carnot, the French president, in June 1894, as a sign of the growing power of the elements working for the overthrow of the existing order. From that time on, he began, in his public utterances, to declare war against the revolutionary forces, and demanded the introduction of new exceptional legislation. There appeared, however, to be no possibility of the adoption of such legislation by the *Reichstag*, and Caprivi decided merely to increase the severity of the general provisions of the penal code. He proposed that any person who advocated the violent overthrow of the State should be punished with penal servitude, and that any person who incited the population to commit acts of violence against other classes of society should be punished with imprisonment. Violent disagreement ensued between Caprivi and Count Eulenburg, the Prussian prime minister, and in Oct. 1894 the emperor dismissed both ministers.

Hohenlohe.—Caprivi's successor as chancellor was Prince Chlodwig Hohenlohe-Schillingsfiirst, who had been prime minister of Bavaria until 1870 and subsequently served as German ambassador in Paris and Governor of Alsace-Lorraine. He was a man trained in practical diplomacy, and his views on home policy were more inclined to liberalism than those of the Prussian bureaucracy. He was now 75 years of age, however, and not likely to initiate any strong measures. The Revolutionary Activities Act was introduced in the *Reichstag* and rejected in May 1895. A similar fate befell a bill introduced in 1899, at the urgent wish of the emperor, to punish with penal servitude threats or violence to voluntary workers during a strike. Hostility between the Social Democrats and the Government, supported by the other parties, was aggravated by these proceedings, and the Government attempted to consolidate the bourgeois parties in a firm majority. The real leader in matters of home policy, and sponsor of this policy of consolidation, was Miquel, the Prussian minister of finance, who had earned a considerable reputation by achieving the reform of the Prussian system of taxation. The policy failed on account of the exorbitant demands of the Conservatives for concessions in return for their support of the Government. The proposal of Count Canitz for the nationalization of the corn trade, rejected by the *Reichstag* in Jan. 1896, indicates the direction in which Conservative opinion was moving. The Party was not satisfied by the concessions granted, which took the form of the prohibition of speculation in futures of corn on the Stock Exchange, and a number of less important trade protection regulations. The Centre Party also advanced demands for concessions as the price of further support of the Government. These included the removal of the ban on Jesuits, which had already been refused by the *Bundesrat*. The Centre Party also attempted to pass an act providing penalties for artistic and literary works likely to cause prejudice to religious and moral principles, but the bill was whittled down in the *Reichstag* to such an extent as to lose all significance.

Hohenlohe's Government was thus also without a reliable majority in the *Reichstag*. It succeeded with difficulty in securing approval for an increase of the army by 20,000 men (considered indispensable by the military authorities in view of the increasing tension in the international situation), and of the Navy Act drafted by Admiral Tirpitz. This act provided for the building of a high seas fleet, to be completed by 1904 and maintained at the same strength by the replacement of obsolete vessels. The civil code, which had been in course of drafting for many years, was also approved by the *Reichstag* after a long debate, and came into force on Jan. 1, 1900. An Act was also passed providing uniform procedure for courts martial. In order to obtain the support of the Liberals for these measures, Hohenlohe agreed to the repeal of the prohibition of permanent connections between political associations.

Foreign Policy.—In matters of foreign policy, a number of difficult decisions had to be taken during this period. Endeavours to revive an understanding with Russia were facilitated by the death of the Tsar Alexander III. on Nov. 1, 1894. His son, Nicholas II., had for a long time been on terms of personal friendship with William II., and for many years had carried on with him a confidential correspondence, which frequently touched on political questions. The progress of the war between Japan and China aroused fears on the part of Russia that Japan might become too powerful in the Far East, and William II. saw a welcome opportunity to win the gratitude of the Tsar by joining with France in supporting the Russian intervention to prevent Japan from getting a foothold on the continent of Asia. Japan yielded to the united pressure of the three Powers and consented to the modification of the peace terms to be imposed on China. The emperor's hope that this affair would have permanent results in bringing about closer co-operation between Russia, France and Germany was, however, doomed to disappointment. Russia gratefully accepted the proffered services, but immediately raised difficulties when Germany sought to use the murder of certain missionaries by the Chinese as a pretext for demanding the surrender of the port of Kiaochow. The Tsar finally consented, with reluctance, and an agreement relating to Kiaochow was concluded between Germany and China on March 6, 1898.

During the same period, relations between Germany and England took a critical turn. On the occasion of the Jameson raid at the beginning of 1896, the German Government felt inclined to interfere on behalf of the Boers. Since Jameson was defeated and captured by the Boers and the English Government expressly denied having authorized or consented to the raid, there was clearly no excuse for direct intervention. On Jan. 3, 1896, however, the emperor telegraphed to Kruger his best wishes for the successful defence of the independence of the Transvaal. This act aroused keen resentment in England, where it was regarded as an interference in the internal affairs of the British empire. No serious clash occurred, but there remained a strong feeling of suspicion on both sides, which was not diminished by the retirement of Marschall from the Foreign Office in June 1897 and his replacement by Prince Bernhard von Biilow, previously German Ambassador in Rome.

Biilow was an extremely clever and skilful diplomat and knew how to gain the favour of the emperor, but the Foreign Office continued to be dominated intellectually by Holstein, who had for some time been inspired by strong suspicion of England, which showed itself with far-reaching effects in the following years, when attempts at a *rapprochement* were made by England.

The British empire had been placed in a position of hostility to Russia by rivalry in the Far East, which was becoming more and more acute, and to France by constant friction over African and East Indian questions. War with France in the region of the Upper Nile seemed inevitable in the near future, and at the same time war with the Boers on a large scale was imminent in South Africa. In these circumstances, Joseph Chamberlain, the English colonial secretary, considered it impossible for England to maintain the policy of isolation pursued hitherto. He believed that it would be easier for England to arrive at a permanent understanding with Germany than with France and Russia, and made pro-

posals in Berlin for the conclusion of a defensive alliance between Germany and England, which would become effective if either should be attacked by two great Powers. Negotiations went on with long interruptions from March 1898 to the end of 1901, but led to no result in the end. Holstein and Bulow feared that England was only trying to involve Germany in a war with Russia, and would always try to avoid active participation herself. They seized the opportunity, however, to obtain concessions in the colonial field. In Aug. 1898 they succeeded in concluding a treaty between Germany and England for the subsequent partition of the African colonies of Portugal, in case Portugal should be forced by financial difficulties to alienate them. The negotiation of the treaty for the partition of Samoa between England, Germany and the United States, signed on Nov. 14, 1899, was also greatly facilitated by the willingness of England to make concessions at the moment. No complete understanding was obtained as regards the recognition of the Yangtse basin as a neutral zone and the prevention of further partition of China among the European Powers. The treaty on this subject concluded on Oct. 16, 1900 was variously interpreted by the parties and subsequently gave rise to many disagreements. A *rapprochement* seemed to be favoured by the fact that the German Government observed strict neutrality during the Boer War and that the emperor refused to receive Kruger when he sought assistance in Europe (although public opinion in Germany was strongly on the side of the Boers); but the confiscation by the English of a number of German ships, alleged to be carrying contraband of war, in Jan. 1900, aroused resentment which was not entirely removed by the return of the vessels.

In the spring of 1901 the English Government desired a decisive answer as to whether or no Germany was prepared to enter into an alliance, and the decision could no longer be postponed. Holstein and Bulow were now impressed by a new consideration. They reflected that if Austria and Russia went to war as a result of their rivalry in the Near East, Germany would then have to declare war on Russia on account of the alliance with Austria; if France as an ally of Russia then declared war on Germany, England would be able to say that there was no obligation to give assistance because Germany had not been attacked but had declared war on Russia on the ground of an alliance to which England was not a party. The alliance would thus be of no use to Germany in the very event in which it would be most needed. Holstein thought that this possibility of evasion must be eliminated beyond question. He believed that the best method of doing so was to propose that England conclude the alliance not with Germany alone but with the Triple Alliance. This possibility had been suggested in London at an earlier date, but it was now decided to reject the proposal. It was feared that after the death of the Emperor Francis Joseph the Austrian State might fall to pieces, and there was no desire to undertake an obligation to defend Austrian interests in the Balkan Peninsula. The proposal was therefore rejected, and, since the German Government believed it indispensable to insist on the inclusion of Austria, the negotiations broke down. Holstein was of the opinion that the alliance would come about in time, when it became clear that England could not arrive at an understanding with Russia and France on account of the colonial sacrifices which would be demanded. England would then have to consent to an alliance on the terms laid down by Germany. Subsequent developments have shown that this supposition was false. The alliance was definitely abandoned, and England entered into the Entente with France and Russia. These negotiations may be regarded as a turning-point in international relations. With their failure begins the course of events which led to the war.

Bülow.—On Oct. 17, 1900 Prince Hohenlohe retired from the chancellorship, on account of his advanced age, and was succeeded by the foreign secretary, Biilow.

The most important and urgent question of home policy was that of the attitude of the State to labour. In the 1903 election the Social Democrats received over 3,000,000 votes and 81 seats in the *Reichstag;* about one-third of all the votes cast were in their favour. Within the Social Democratic Party there had been a revival of the old opposition between the convinced Marxists, who believed that their objects could be achieved only by the radical overthrow of the existing State, and tht so-called Revisionists, who wished to introduce reforms on the basis of the existing State and with its help. Externally, however, the Party presented a united front, and its influence over the workers was steadily increasing. An attempt on the part of Friedrich Naumann to form a new National Socialist Party failed completely.

Bulow was now confronted with the question of the renewal of the commercial treaties, which expired in 1905. Agriculturists were of the opinion that the maintenance of the existing duty on corn would mean ruin to them, and the position of agriculture had, in fact, become very difficult. The Government consequently decided to increase the duty on corn from 3·50 marks to 5–5·50 marks on every two cwt. After a stormy session, this proposal was adopted by the *Reichstag* on Dec. 14, 1902, in spite of the violent opposition of the Liberal Parties. At the same time, the duties on manufactured goods were considerably reduced, and the States with which the treaties had been concluded were ultimately induced to accept the new tariff. In Feb. 1905 the renewal of the commercial treaties until 1917 was ratified by the *Keichstag.*

This measure was put through by means of the support of the Conservative and Centre Parties. As a result, Bulow was obliged to depend on those Parties for a majority in order to carry on the Government. To meet a growing deficit in the imperial budget, he attempted to bring about a revision of the system of taxation, but the bills introduced in 1904 and 1906 were amended in the *Reichstag* to such an extent that the increase in income was not sufficient to meet the requirements. At the same time, the Centre Party attempted to take an injudicious advantage of the influential position in which it was temporarily placed. Bulow agreed to the removal of the ban on Jesuits and to the establishment of a Catholic theological faculty in the University of Strassburg. The wishes of the Centre Party were also gratified to a considerable extent by the new Prussian Education Act. Pressure from this quarter became, however, more and more irksome to the chancellor, and the attitude of the Centre Party in colonial matters finally led to an open breach.

In the autumn of 1906 the Centre Party proposed considerable reductions in the grants demanded for the suppression of a native revolt in South West Africa, and Dernburg, who had recently been appointed director of the Colonial Office, made a violent attack on the Party. Bulow decided to dissolve the *Reichstag,* hoping to be able to obtain a majority without the aid of the Centre and Social Democratic Parties by consolidating the Conservatives, National Liberals and Progressives. The election took place on Jan. 25, 1907, and resulted in the desired majority. The three Parties obtained altogether 222 seats, as against 185 for all other groups. The Social Democratic representation fell from 81 to 43, from the increase in the proportion of bourgeois voters who went to the polls.

This majority enabled Bulow to pass an Associations Act removing all restrictions on the founding of political associations and the holding of political meetings. He also succeeded in raising the grants for colonial development and in passing an act for the encouragement of German settlement in the Polish parts of Prussia. Conservative opposition prevented, however, the reform of the Prussian franchise in the direction of stronger representation of unpropertied classes. It was soon evident that the differences of opinion between the Conservatives and the more advanced Liberals were so fundamental as to preclude the possibility of lasting co-operation. The breach was precipitated by a renewed attempt on the part of Biilow to increase the budget. He called for an increase of 500,000,000 marks, of which 400,000,000 was to be raised by increasing the taxes on brandy, beer and tobacco, and 100,000,000 by increasing the succession duties. The Conservatives were uncompromising in their opposition to a heavier burden on property, and united with the Centre Party in the *Reichstag* in accepting the other taxes but rejecting those on property. Biilow felt that his home policy was wrecked, and retired from office on June 14, 1909.

His decision to resign was due not only to the fact that he no longer had a majority in the *Reichstag,* but also partly to the consideration that for some time he had ceased to enjoy the personal confidence of the emperor, as a result of disagreement over questions of foreign policy.

Morocco Crisis.—After the negotiations with England broke down, Biilow had also refused the offer of a Russian alliance. The Triple Alliance was weakening. Italy strove more and more openly for better relations with France, and in November 1902 undertook to give assistance if France were compelled by provocation to declare war on Germany. The bonds between England and France were tightened by a treaty concluded on April 8, 1904. Germany's position was becoming more precarious. The outbreak of war between Russia and Japan in Jan. 1904 favoured the maintenance of peace in Europe; the Russian forces were immobilized in the Far East for some time; France was obliged to avoid any complications so long as her most powerful ally was not in a position to give any assistance. If the German Government had intended to bring about war with France, this would have been the most favourable moment But neither the emperor nor Biilow entertained any such notion. The chancellor proposed to take advantage of the situation merely to prevent France from acquiring actual possession of Morocco, which had been recognized as lying within the French sphere of interest by the treaty with England mentioned above. He thought that such an extension of the power of France could not be tolerated unless Germany received some colonial compensation. He induced the emperor, against his will, to seize the opportunity of a Mediterranean cruise to land in Tangier on March **31,** 1905 and inform the sultan's representative that Morocco was regarded as a completely *indepehdent* country. The French Government interpreted this announcement as calculated to elicit an offer of compensation from France, and attempted to ascertain the extent of the German demands by direct negotiations with Berlin.

The emperor had, however, informed the king of Spain shortly before that he sought no territorial expansion but merely wished to ensure the political and economic equality of all nations in Morocco, and Bulow was thus unable to enter into any arrangement. He insisted on the convening of a conference of all Powers which were engaged in trade in Morocco and had been parties to a treaty signed in Madrid in **1880,** guaranteeing equality of treatment for all foreigners in Morocco, for the purpose of reaffirming the principle of equality. France wished to avoid a renewal of such a guarantee, which might be an obstacle to future policy, and consequently opposed the conference altogether. In the face of Biilow's insistence, a group of French politicians led by Delcassé was in favour of refusal, even at the risk of war, believing that they could count on assistance from England if necessary, although there was no definite undertaking on the part of England. In the end, however, pacific opinion preponderated and Delcassé resigned in July 1905. It was arranged that the conference should be held in the following year at Algeciras. (See also MOROCCO; ALGECIRAS CONFERENCE.)

In the meantime, Russia was completely defeated by Japan. The tsar met the Emperor William at Bjorko in Finland in July 1905. By agreement with Biilow, the emperor endeavoured to persuade the tsar to conclude an alliance, to which France was to become a party under pressure from Russia. The tsar was induced to sign a treaty to this effect, but his Ministers decided that such an arrangement was inconsistent with the terms of the alliance with France, and he withdrew from the agreement under various pretexts. In the meantime a serious disagreement had arisen between the emperor and Biilow, because the former had altered the wording of the text of the treaty as approved by Biilow. The chancellor announced that he felt obliged to resign. The emperor formally requested him to remain in office. Biilow gave way, but the emperor cherished a strong feeling of resentment on account of the incident.

The conference held at Algeciras from January to April 1906 did not follow the course desired by Germany. Russia and England were openly on the side of France, and Italy, bent on the annexation of Tripoli, showed more consideration for France than for Germany. Germany could thus count only on Spain and Austria. The majority agreed to recognise the priority of French interests in Morocco, and Germany was forced to consent in order to avoid the complete failure of the Conference which she had herself proposed. The independence of Morocco was formally guaranteed, but in military and economic matters international adjustments were made in which France was specially favoured.

The failure of the German policy in Morocco led to the retirement of Holstein, who had played a leading part in determining it. There was, however, no appreciable change in the direction of German foreign policy as a result of his retirement.

The German interference in Morocco indirectly affected England, since the consent of France to the complete establishment of the English protectorate in Egypt was conditional on the acquisition of Morocco by France. When the possibility of war arose, the English Government agreed that members of the French and English military and naval staffs should collaborate in preparing plans to be carried out in the event of a common war against Germany. Through the mediation of France, England also entered into negotiations with Russia with a view to the adjustment of colonial rivalries. A treaty concluded on Aug. **31,** 1907 defined the English and Russian spheres of interest in Asia, and formed a basis for a closer political understanding between the two Powers. Germany was now faced with the danger of having to meet the combined strength of France, Russia and England if a conflict arose. Bulow frequently expressed a feeling of uneasiness at this isolation, but saw no means of counteracting it except a further attempt to arrive at a sympathetic understanding with England so far as possible—which was rendered difficult by the suspicion aroused in England by the growth of the German navy. As a result of the understanding with France, a redistribution of the English fleet had taken place, involving a reduction in the number of ships in the Mediterranean and the Far East and an increase in the number assigned to the Channel and the North Sea. In 1906 a new type of battleship, the Dreadnought, was constructed, which went far beyond all previous achievements in size, speed and fighting strength. The other Naval Powers felt obliged to build similar warships in order to be able to hold their own in a battle. Largely for this reason, Admiral Tirpitz proposed in 1906 an amendment to the Navy Act, increasing the building plan adopted in 1900 by six large cruisers and providing that all new vessels should be of the Dreadnought type. A further amendment adopted in 1908 provided for more rapid replacement of obsolete vessels. Although the complete realization of these plans would have left the German navy considerably smaller than the English navy, the increase was regarded with apprehension in England. If the English naval superiority was to be maintained to the same extent as before, England would have to undertake a vast programme of naval construction, which the Liberal Government desired to avoid.

At the second Peace Conference in The Hague an unsuccessful attempt was made to bring about a general reduction of naval armaments. The English Government then endeavoured to arrive at a direct understanding with Germany. It was proposed that Germany should retard the rate of construction laid down in the Navy Act, and that England should undertake not to exceed a fixed annual number of new ships. The emperor and Tirpitz were of the opinion, however, that the honour and interest of Germany did not permit the extent of her armaments by land or sea to be determined by any standard other than the requirements of her own safety, and the proposals were rejected. Bulow was in favour of arriving at an agreement, but was overruled. On the occasion of King Edward's visit to Friedrichshof in Aug. 1908, a conversation took place between Lord Hardinge and the emperor but with no effect. The emperor, during his visit to England in the autumn of 1907, had endeavoured by personal conversation with influential persons to dispel the apprehension that Germany's naval construction was designed for purposes of aggression, but without success. One of these individuals, with the emperor's consent, published an account of his interview in the Daily *Telegraph,* and certain remarks contained in it aroused renewed resentment in England.

GERMAN CATHEDRALS AND OTHER CHURCHES

1. The cathedral at Speyer (capital of the Bavarian palatinate), founded in 1030; one of the best examples of Romanesque architecture in Germany. 2. The cathedral at Berlin, in the Italian Renaissance style, built between 1894 and 1905 from designs by Julius and Otto Roschdorff. 3. The cathedral at Worms, province of Rhenish Hesse, an example of the German Romanesque style, dating from the 12th century. 4. The Gothic cathedrai at Frankfurt-on-Main province of Hesse-Nassau, Prussia, in which the emperors of the Holy Roman empire were formerly crowned. The cathedral, founded in 852, was reconstructed in 1235–39 and added to in the 14th and 15th centuries. Following a fire in 1867 the building was restored, and the tower, formerly unfinished, was completed from a 15th century design. 5. The cathedral at Ulm, Wurttemberg, now a Protestant church, was begun in 1377 and completed in the 16th century. It is a distinguished example of the Gothic style in Germany. The modern spire, 528 ft. in height, is the highest in the world. 6. Freiburg im Breisgau, in the Black forest, Baden; a view of the minster, considered one of the finest of German Gothic structures. it was built about 1122–1252, except the choir, which was completed in the 15th century. 7. Hedwig's church, Berlin, notable for its large, low dome. At the left is the Opera house. 8. Cathedral at Aachen (Aix-la-Chapelle), begun under Charlemagne's auspices in 796. After being almost entirely wrecked by Norman raiders, it was rebuilt by the Emperor Otto in 983; the octagonal domed structure shown in the centre of the picture dates from this period. The Gothic choir seen to the left was added in the 14th and early 15th centuries. The spire is modern

MUNICH AND LEIPZIG

1. The Marienplatz and **Rathaus,** Munich, seen from the air
2. The Reichsgericht (supreme tribunal) at **Leipzig,** built in 1888–95
3. The Wittelsbach fountain in Munich, built by Adolf Hildebrand on the **Maximillansplatz** in 1895
4. The "Brown House," headauarters of the nazi party on the **Königsplatz** in Munich. Originally **built** in 1830, **it** was completely remodelled in 1930–31
5. The House of German Art at Munich

In Germany, this public expression of the emperor's views mas regarded as an improper interference on his part in the details of public policy. Before consenting to the publication of the interview, the Emperor had obtained the approval of the Foreign Office in accordance with the usual procedure, but Bulow stated in reply to a question in the *Reichstag* that through inadvertence he had not himself read the article. He offered his resignation, but the emperor declined to accept it in view of the political situation in Germany at the time. On account of the excitement aroused by the discussion in the *Reichstag*, the emperor announced on Oct. 31, 1908 that in future he would take no action of political importance without the advice of the chancellor. He felt humiliated, however, by Bülow's behaviour, and in future placed no personal confidence in him.

England now decided on a considerable increase in her navy. Much ill-feeling had been aroused on both sides, but no one desired a war, and it seemed still possible to co-operate in important matters in the interests of peace. This was clearly shown in the crisis which was precipitated by events in the Near East.

The Bosnian Crisis.—Since Russia had had to renounce its schemes of conquest in Eastern Asia, it once more became the chief object of its policy to gain control over the Balkan peninsula and the Black sea. Austria however was also anxious to secure permanent possession of Bosnia and control of the road to Salonika in case it should come to the partition of Turkey in Europe. Germany was now more closely interested in Near Eastern questions than before. A German company had begun the construction of a railway to Baghdad through Asia Minor in 1898; it was opened as far as Konia in 1904. Although Germany did not aim at using its economic power in Turkey to gain political control of the country, it nevertheless now had a greater interest in the maintenance of Turkey.

When the Young Turk Revolution broke out in July 1908, Austria considered it necessary to annex Bosnia (Oct. 5). Serbia protested, and was strongly supported by Russia. Austria could not draw back, and the danger of an armed conflict between the two Powers became imminent. Biilow and the emperor, who were not informed of Austria's intentions until the last moment, thought Aehrental's action unwise, because they were anxious that the existence of Turkey should not be endangered; but as Austria was the only remaining ally on whom Germany could rely, they thought that the only course open to them was to support Austria's policy unreservedly. Biilow therefore informed Russia that if she did not recognize the annexation she would be held solely responsible for the consequences. After the severe defeat which it had suffered in Asia, and in view of the internal disturbances which had followed, Russia was not prepared to go to war with Austria and Germany, and it was therefore obliged to yield and recognize the annexation. Austria thereupon withdrew its troops from the Sandjak. In Russia the course which events had taken was ascribed mainly to Germany's intervention, and still more effort was made to establish closer relations with England and to arrive at an understanding with Italy.

Bülow fully realized that what had taken place had rendered the situation more acute, and he tried to improve Germany's relations with France by expressly recognizing that the French, as neighbours of Morocco, must enjoy a privileged position there (Feb. 9, 1909). He also made fresh advances to England, which had offered its offices as mediator in the Bosnian crisis. Before, however. he had achieved much success in this attempt, he resigned office.

Morocco: 1911.—The emperor appointed as his successor von Bethmann-Hollweg, who had been secretary of State for home affairs. Bethmann-Hollweg was a conscientious and painstaking official, but he was utterly inexperienced in foreign affairs, and did not possess the strength of will and power of decision which a prime minister needs. He was most anxious to improve relations with Great Britain by an agreement on naval building programmes, but he could not overcome the opposition of the emperor and Admiral von Tirpitz. Feeling that he needed a colleague with a diplomatic training to assist him in the conduct of foreign affairs, he induced the emperor in June 1910 to appoint Herr von Kiderlen-Wachter, who had been German ambassador at Bucharest, as secretary of State for foreign affairs. Although the new secretary of State was a man of intelligence and strong character, his imprudent and uncompromising conduct, in the Morocco crisis of 1911 helped to make the position of Germany still more difficult.

The French were at this time taking further steps to establish their supremacy in Morocco. Kiderlen said that Germany could not let this pass without protest unless it received compensation. At first he demanded that the whole of the French Congo should be ceded to Germany, and persuaded the emperor, in spite of his unwillingness, to send the warship Panther to Agadir to protect the German subjects in Morocco while the fighting continued (July 1911). The threat which this implied embittered feeling in France, but also aroused anxiety in England, and Lloyd George made a strongly worded speech in the House of Commons. Kiderlen would have been ready to go to war to obtain satisfaction for his demands, but could not induce either Bethmann-Hollweg or the emperor to adopt his point of view. He was therefore obliged to moderate his claims, and an agreement was finally reached on Nov. 4, 1911, by which France ceded a part of its colonies in the Congo in return for full freedom of action in Morocco. Germany thus gained a small accession of colonial territory, but the distrust of its policy which had for some time prevailed in other countries was greatly strengthened. Germany was blamed for being willing to endanger the peace of the world for the sake of a slight advantage. In England in particular it was increasingly thought that Germany was meditating an attack on France, and that in that case Great Britain would probably have to go to war in support of France.

As a direct consequence of the French occupation of Morocco, Tripoli was occupied by the Italians. In Germany this new step towards the partition of Turkish territory was looked upon askance, but it was not desired to protest against the action of Italy because that would have meant the complete break-up of the Triple Alliance. Turkey however resisted, and the war in Tripoli dragged on until the autumn of 1912; and the Balkan States, which had formed a coalition under the protectorate of Russia, decided to seize the opportunity in order to put an end to Turkish rule in Europe. They attacked in Oct. 1912, and this opened the first Balkan War.

The Balkan Wars.—At this time when new perils were appearing on the horizon, Germany began to consider the strengthening of its defensive forces. It was only with great reluctance that Bethmann agreed to the introduction of a new Naval bill under which six new battle-ships in addition to those already planned were to be laid down in the coming years. Serious anxiety was felt in Great Britain when this became known, and an oral discussion of the situation was proposed. Haldane, who was secretary of State for war, came to Berlin in Feb. 1912; he seemed ready to conclude a treaty of neutrality and to make certain colonial concessions if an agreement on future programmes of naval shipbuilding could be reached At one time agreement seemed on the point of being attained, but it soon appeared that there had been a misunderstanding The Emperor and Tirpitz believed that England would be satisfied if the new Naval bill, the exact purport of which Haldane only learned when he came to Berlin, were applied, and an agreement were simply reached on future naval programmes. The British on the other hand considered that such an agreement would only be of value if it came into force immediately, and if the provisions of the German Naval bill were modified accordingly. It was also found impossible to agree on the wording of a treaty of neutrality, for Great Britain was anxious to avoid any drafting which might offend its French allies.

Although the desired agreement was not reached the two countries made every effort during the Balkan War of 1912–13 to maintain peace. The complete defeat of the Turks made it appear probable that little would remain of Turkey in Europe. Austria would, however, in no case accept an extension of Serbia to the Adriatic, whereas Russia supported Serbia's demands. France under the leadership of Poincaré endeavoured to stiffen Russia in its attitude, even at the risk of war, while Great Britain used its

influence to preserve peace. Russia finally made up its mind to give way. A conference of ambassadors of the Great Powers which was held in London in Jan. 1913 attempted to bring about an armistice and to negotiate peace. As. however, Serbia found it necessary to give up the northern part of Albania, it demanded a greater extension in the south-east; this could only be at the expense of Bulgaria. This question led to a war between Serbia and Bulgaria, in which Rumania, Greece and Turkey came in on the side of Serbia. After a short period of hostilities, Bulgaria was obliged to conclude the Peace of Bucharest (Sept. 29, 1913). In Vienna the question once again arose whether it would be necessary to go to war to prevent the aggrandizement of Serbia. In view of urgent representations from Germany however, it was decided to raise no objection to the Peace of Bucharest. *(See* BALKAN WARS.)

Relations between Russia and Austria continued to be extremely strained after the Balkan War, and a danger of war was liable to arise at any moment. A difference of opinion also arose between Germany and Russia when the sultan entrusted the German General Liman von Sanders with the reorganization of the Turkish army, and Russia protested. The final solution was that the German general continued to be responsible for the training of the Turkish army, but did not actually hold a military command.

The collaboration of Germany and Great Britain on Eastern questions made Bethmann-Hollweg, who exercised greater influence on foreign policy after the death of Kiderlen on Dec. 30, 1912, hope to bring Great Britain and Germany permanently into closer relations. During the following months two important treaties were negotiated between London and Berlin. The aim of one of them was a new agreement on the future of the Portuguese colonies in Africa, and that of the other an arrangement for the further development of the Baghdad Railway (*q.v.*) with the help of British capital. Both treaties were drafted and only required ratification when the World War broke out.

Home Policy.—Bethmann-Hollweg was equally unsuccessful in home affairs. His attempts to achieve electoral reform in Prussia broke down owing to the resistance of the Centre and the Conservatives. Social legislation was carried a stage further in some respects by the adoption of the imperial insurance code of 1911, but after this it came to a complete standstill. Bethmann-Hollweg was equally unable to solve the question how the inhabitants of Alsace-Lorraine and Poland were to be won over to accept their incorporation in the German empire.

The imperial province of Alsace-Lorraine had had a representative assembly in addition to the *Statthalter* since 1879, and union with Germany had brought with it important economic advantages. Even those Alsace-Lorrainers who had reconciled themselves to the idea of permanent union with Germany however demanded that their province should become a State with the same rights as the other German States. The repeal of the exceptional legislation applying to the imperial province, and in particular the so-called dictatorship clauses, in May 1902 was not enough for them. Bethmann-Hollweg only gave partial satisfaction to these demands. The act of May 30, 1911, gave the imperial province a considerable measure of autonomy in home affairs; in future it was to have three seats in the *Bundesrat;* but a *Statthalter* appointed by the emperor continued to govern the province. These concessions did not satisfy public opinion in Alsace-Lorraine, and the discontent of the population was unmistakably expressed in connection with the Zabern incident in Nov. 1913. *(See* also ALSACE-LORRAINE.)

German policy in the eastern districts had continually wavered between attempts to win over the Poles to Germany by granting them a certain measure of autonomy, and endeavours gradually to Germanize the country by buying out the great Polish landowners and settling German peasants on the land. On March 3, 1908, when Bülow was still in power, an act was passed empowering the Government to undertake the compulsory expropriation of Polish landowners to a maximum of 70,000 hectares. This act aroused so much feeling among the Poles that Bethmann-Hollweg scarcely ventured to enforce it, though it was not repealed.

Generally speaking the home policy of the German empire after the dismissal of Bismarck was extraordinarily sterile. Both in the individual States and in the empire the influence of the Conservatives and the Clericals steadily increased. The ever-growing and ever more strongly organized working class was hostile to the existing political order, and no serious effort was made to draw them into responsible collaboration. The capitalist employers did much to develop commerce and industry, but were entirely absorbed by economic considerations and did not attempt to collaborate in political life or to reconcile their particular interests with those of the community as a whole.

THE WORLD WAR

June 28–August 4.—On June 28, 1914, Francis Ferdinand, heir to the throne of Austria, was assassinated at Serajevo. The assassins came from Belgrade and had received money, passports and arms from Serbian officials. Vienna was therefore convinced that the assassination had been planned in Serbia with the knowledge or at the least the connivance of the Serbian Government. It was therefore decided to send an ultimatum to Serbia demanding the repression of Greater Serbian propaganda, the dismissal of all officials associated with such propaganda, and the collaboration of Austrian authorities in the investigation of the origins of the murder of the Crown Prince. Germany was not consulted in the framing of these demands, and was only informed of them just before they were communicated to Belgrade. Serbia sent a reply within the period of 48 hours which had been fixed; the reply was in general conciliatory, and accepted some of the demands, while others were refused or made subject to conditions. The Austrian ambassador declared that this implied the rejection of Austria's demands, and left Belgrade on the evening of July 25, 1914. Serbia mobilized, and Austria also mobilized its eight southern army corps. Attempts at mediation were made in several quarters; Great Britain in particular proposed arbitration by the four Great Powers not directly involved. The Emperor William was absent on a Northern tour from which he returned only on July 28; but the German Government did not feel it possible to bring the dispute between Austria and Serbia before a tribunal of the European Powers, and took up the attitude that the conflict must be localized which meant in practice that Russia must be prevented from intervening in favour of Serbia. At first public opinion on the whole was not unfavourable to Austria. When however the Serbian reply became known, opinion veered round against Austria. It was thought that Austria could obtain sufficient satisfaction if it moderated its demands in certain respects. Vienna however persisted in the view that nothing less than full compliance on the part of Serbia would be satisfactory; and Russia thereupon began to prepare for war.

Anxiety now began to be felt in Berlin, and Austria was advised to accept the British proposals for mediation or to enter into direct negotiations with Russia on the demands made to Serbia. It was only when Bethmann informed Vienna that Germany would not let itself be involved in a world war lightly, or if its counsels were disregarded, that Vienna made up its mind to adopt the latter course. Now, however, it was too late. In the meantime the tsar, who had received assurances of full support from France, had decided on July 31 to order the mobilization of the entire Russian army. It was believed in Berlin that war was now inevitable, but it was desired not to lose the advantage of more rapid mobilization. An attempt to obtain a declaration of neutrality from England having failed, a demand was sent to the tsar that the mobilization order should be revoked. Consent was not given within the stipulated period of 12 hours, and Germany thereupon declared war on Russia. It was thought certain that France would come to the help of its allies, and it was considered that the French should not be allowed to choose the moment for the attack. The French minister, when asked whether France would undertake to remain neutral, gave an evasive reply, and Germany thereupon declared war on France on Aug. 3.

Germany, by declaring war both on Russia and on France, assumed before the world the odium of being the aggressor. This however is no proof that Germany intended to cause the war. The most serious error of the German Government must be ad-

mitted to be that it did not from the outset declare that it would only support Austria if agreement on every step were reached in advance. The peremptory terms of the ultimatum and Austria's declaration of war on Serbia came as a surprise to Germany, and forced its hand. The counsels of moderation which were subsequently given to Austria came too late. They might perhaps still have achieved something if Russia had not mobilized in the meantime. It was this which really made war inevitable. The fact that Germany did not wait for a formal declaration of war from the other side was due to the obvious military considerations, and to Germany's belief that war could not now be averted.

The British Government was resolved from the outset to stand by France and Russia if war could not be prevented. The only question was whether parliament and public opinion would endorse its views. On this point the Belgian question was decisive. The essence of the German plan of campaign was a swift and decisive blow at France; and as the north-east frontier of France was strongly fortified, this only seemed possible if the German army marched through Belgium. The neutrality of Belgium was however guaranteed by the Powers, and it was therefore thought in London that steps must be taken to prevent such a possibility. France and Germany were therefore asked whether both Powers would undertake to respect Belgian neutrality so long as it was respected by the other side. France agreed, but Germany refused to give any definite undertaking, and informed Belgium on Aug. 2 that it found itself compelled to send its troops into that country because it had reliable information that French troops were on the point of invading Belgium from the south. Although Germany declared itself ready to promise to respect the integrity of Belgium and to evacuate its territory immediately on the conclusion of peace, its action was regarded by Belgium as tantamount to a declaration of war, and the Belgian Government appealed to Great Britain and France for help. Grey, having obtained a majority in Parliament for his policy on Aug. 3, once more sent a demand to Berlin that Germany should undertake to respect Belgian neutrality. Germany could not give such an undertaking, since its troops had already crossed the Belgian frontier. Great Britain declared war on Germany on the night of Aug. 4. (*See* also EUROPE; DIMITRIEVIC.)

The War.—The course of events in the World War will be found described under that heading. The decisive factor was the failure of the attempt at a rapid and decisive defeat of France. The German advance was checked at the Battle of the Marne in Sept. 1914; and the fact that the German army succeeded in occupying nearly the whole of Belgium and warding off the Russian invasion at the battle of Tannenberg could not really make up for this. When Italy came into the war against Germany on May 23, 1915, and Rumania in the summer of 1916, the prospect of obtaining a decisive victory became more remote. Germany's only allies besides Austria were Turkey and Bulgaria, and the military power of these was not very great. The attempt to attack the British position in Egypt and on the Persian gulf through Asia Minor and Mesopotamia was unsuccessful, but the endeavours of the other side to capture Salonika and to break the enemy front in the south-east were for a long time equally fruitless. Germany was completely cut off from the world market by the blockade of its coasts, and had to rely entirely on its own resources for its food supply and for the replenishment of its war material. The shortage of food and munitions became more and more serious every year. As a final attempt to turn the fortunes of war in favour of Germany, it was decided to try ruthless submarine warfare, with the idea of creating a *de facto* blockade of England and cutting off its food supplies. There were however not enough submarines available to make this scheme successful. Its final result was to determine the United States of America to come into the war on the other side in the spring of 1917.

The position of the Central Powers was further weakened by the death of Emperor Francis Joseph on Nov. 21, 1916. His successor, the Emperor Charles. soon attempted to open peace negotiations with England and France, and though these were not successful, they showed the other side that the unity of the Central Powers was shaken. On the other hand, the outbreak of the Russian Revolution in March 1917 seemed likely to ease the position of the Central Powers. The new Russian Government which came into power as a result began peace negotiations in November, but it was not until March 8, 1918 that the Treaty of Brest-Litovsk (*q.v.*) was finally signed. This however was only a temporary success. The attempts which were made to set up independent States in the Ukraine and Poland which would support Germany had no lasting result, and their consequence was that much of Germany's military strength was frittered away in minor operations in South Russia. After the great German offensive in Northern France in March and April 1918 had failed to break the Allied front, the French, British and Americans attacked on the Western front. In September the British and French attacked the Bulgars from Salonika and completely destroyed their army.

In the meantime the position in Germany had greatly changed. At the beginning of the war the greatest enthusiasm prevailed, and the nation was ready for any sacrifice, because it was firmly convinced that war had been forced on it and that it was fighting for existence. This applied to the workers as well as the rest, and the Social Democrat deputies voted for the war credits in the Reichstag. But as the war dragged on, and every department of economic life suffered from the blockade, while the loss of life became greater and greater, that section of the Social Democrats who desired the end of the war at any price increased in strength. In 1918 they formed a separate party, the Independent Social Democrats. Their spokesmen said that it was not in the interest of the working classes that Germany should be victorious in the war, for such a victory would only consolidate the rule of militarism and capitalism. The huge fortunes made by war profiteers helped to embitter public feeling. More and more people began to believe that only the military leaders and those capitalists who were making money by the continuance of the war stood in the way of the conclusion of peace. However mistaken such a view might be, it was impossible to eradicate it from the public mind.

Bethmann-Hollweg felt it necessary to make some concession in view of the increasing popular discontent, and at his suggestion the emperor, in the Easter proclamation of April 7, 1917, promised the reform of the Prussian electoral system so soon as peace should have been concluded. This promise did not however produce much effect, as it was extremely doubtful whether it could be legally carried out against the will of the majority of the Prussian *Landtag*. An increasingly critical attitude began to prevail in the *Reichstag*. It was demanded that parliament should enjoy a greater measure of influence, and a proclamation was drafted declaring that Germany was ready to make peace on the basis of the pre-war territorial position if all the belligerents would renounce any claim to war damages. Bethmann-Hollweg tried in vain to allay the unrest by the issue of an imperial proclamation promising the introduction of equal suffrage in Prussia. His vacillation and indecision had cost him the confidence of all parties. The Emperor therefore made up his mind to dismiss him on June 14, 1917. But Germany could not at the moment produce a personality capable of taking over the real control of affairs at this difficult time. The new chancellor, Michaelis, who had been head of the Imperial Grain Office, soon proved himself quite unfitted for his position, and was replaced on Nov. 2 by the Bavarian premier Count Hertling, who was a man of 75 years of age, but who enjoyed the confidence of the Centre Party.

The peace resolution of the *Reichstag* was adopted on June 19 by a majority composed of the Centre, the Progressive People's Party and the Social Democrats. It could not fail to strengthen the view in the outside world that Germany's power of resistance was breaking down. Whether the various attempts which the German Government made both before and after the autumn of 1917 to bring about the conclusion of peace ever had any prospect of success, and why they failed, cannot yet be determined with any certainty, since the relevant documents have not yet been made public.

The military events of the late autumn of 1918 were not long in producing their effect on the internal situation in Germany.

When, on Sept. 29, the Supreme Command urged that negotiations for an armistice should be opened at once because it was impossible to hold the front any longer, Count Hertling handed in his resignation; for it was generally felt that a Government must be brought in which would possess the confidence of parliament. The various parties united in proposing to the emperor that Prince Max von Baden should be appointed imperial chancellor; this was done on Oct. 3. He had the reputation of being an adherent of the idea of international reconciliation, which was an important feature in President Wilson's programme, and he was therefore thought a specially suitable person to take over the conduct of affairs at the present juncture. The new chancellor at once informed President Wilson that Germany was ready to conclude an armistice and peace on the basis of the Fourteen Points (*q.v.*) which Wilson had laid down as the basis of a new settlement of affairs on Jan. 8, 1918. Wilson, however, said that before he could approach his allies, the occupied districts of France and Belgium must be evacuated, and the German political system must be changed by "the destruction of every arbitrary power anywhere that can separately, secretly, and of its own single choice, disturb the peace of the world." This was taken to mean that the emperor's power must be greatly restricted, and real control placed in the hands of a Government responsible to the *Reichstag*. As this entirely corresponded to the desires of the majority parties, the *Reichstag* resolved on Oct. 26 that the consent of the *Reichstag* was necessary for the declaration of war or the conclusion of peace, and that the imperial chancellor must, in the exercise of his functions, possess the confidence of the *Reichstag* and consequently of the nation. The emperor gave his consent to this decision a few days later.

The Revolution. — It thus appeared as if the German Constitution would be changed by peaceful methods; but in the meantime the Revolution broke out on Nov. 3. It began with a mutiny in the fleet at Kiel, and spread to the workers and the *Landwehr* troops behind the lines. The Socialists demanded that the emperor should abdicate; Prince Max von Baden, seeing no other way out, advised the emperor to accede. Although the emperor had not yet consented, he proclaimed on Nov. 9 that the emperor renounced the throne and the crown prince the succession, and that a Regency would be set up. He hoped by this means to preserve the monarchical form of Government. The Social Democrats, however, replied by proclaiming a republic. Not enough forces were available to fight the revolutionaries with any prospect of success, and Prince Max therefore resigned the office of Chancellor and handed over the conduct of affairs to the Social Democrat deputy Ebert. On hearing of ,what had taken place, the emperor fled to Holland, where he found refuge on neutral soil. The other German rulers also thought resistance useless and renounced their rights.

In the meantime President Wilson had declared in the name of the Allied and Associated Powers that they were ready to take the Fourteen Points as a basis for a treaty of peace on condition that Germany should pay compensation for all damage suffered by the civilian population of the occupied territories during the war. When however the commission which was sent to negotiate an armistice met the Allied commanders, conditions were proposed which amounted to a complete capitulation. The occupied territories in the West and the whole left bank of the Rhine were to be evacuated, all war material surrendered, and all prisoners released without corresponding obligation on the other side. German troops in the East were to withdraw behind the 1914 frontiers. In view of the circumstances prevailing in Germany at the time it was impossible to contemplate continuing the struggle, and the terms were therefore accepted on Nov. 11, 1918. An armistice of 30 days was granted. The German army, under the leadership of Hindenburg, executed the difficult operation of withdrawal in perfect order, but was at once disbanded on arrival in Germany, as the Socialist Party, which was now in power, regarded it as a menace to the new order.

The Socialists, who found themselves so suddenly in possession of power, were not able to set up a social and political order corresponding to their ideals. Sharp divergences of opinion soon made themselves felt in their own ranks. The Council of People's Representatives, which at first took over the direction of affairs, removed all restrictions on freedom of assembly and on the freedom of the press, granted a general amnesty and announced the introduction of an eight hour day for workers; but it did not venture to abolish private ownership of property, as the strict Socialist programme would have required, because it was not felt practicable to take over the entire control of economic affairs. A conference of representatives of the newly formed Governments of the individual States, which met in Berlin on Nov. 25, decided that a National Constituent Assembly should be elected at once to draw up a new Constitution for the whole of Germany; until the Assembly met, the workers' and soldiers' councils which had been formed during the revolution in the various States should continue to control affairs. The left wing of the Social Democrats, who were known as the Spartacists, were dissztisfied with this solution and tried to prevent the elections to the National Assembly by raising fresh revolts. There was street fighting in Berlin, but the disturbances were suppressed by Noske. The elections took place on Jan. 19, 1919; all Germans over the age of 20, irrespective of sex, were entitled to vote. Even during the electoral campaign it became clear that the revolution had not radically altered the relative position of the various parties. They continued to exist under new names, and in most cases their leaders remained unchanged. Those who had been Conservatives were now called the German National People's Party (*Deutschnationale Volkspartei*), the National Liberals became the German People's Party (*Deutsche Volkspartei*), and the former Progressive Party was known as the Democratic Party. A section of the National Liberals went over to the Democrats, but broke away in the years which followed. The Centre was to some extent weakened by the secession of the Bavarian People's Party, while the Social Democrats split into two groups, the Majority Socialists and the Independents. A separate Communist Party was also formed. If the Social Democrats had hoped to obtain a majority in the National Assembly, they were doomed to disappointment. The elections resulted in the return of 163 Majority Socialists and 22 Independents, while the bourgeois parties obtained 236 seats. The composition of the Assembly nevertheless showed a marked shifting to the Left as compared with previous Parliaments.

THE GERMAN REPUBLIC

The National Assembly met at Weimar on Feb. 6, 1919, and elected Friedrich Ebert as president of the Republic. He was to govern through a ministry responsible to the Assembly. The discussion of the Constitution occupied several months. It was finally promulgated on Aug. 11. The new German State, which kept the old traditional name of the *Deutsches Reich*, although it was now transformed from an empire into a republic, was still to be on a federal basis. The proposal of Secretary of State Preuss to make Germany into a single State, abolishing the distinction between the old separate States and dividing the whole country up afresh into provinces, was rejected. The powers of the Reich were extended in some respects; it was given complete control of taxation, and the right to lay down the guiding principles for education and church affairs. The head of the Government was to be a president elected for a period of seven years by the whole nation; he was to be assisted by a federal ministry, the members of which were to be obliged to resign if they ceased to enjoy the confidence of parliament. The *Reichstag* was to continue to consist of a single chamber, and the suffrage was to be the same as that which had been adopted for the elections to the National Assembly. A *Reichsrat* was set up to provide representation for the individual States, but it was not similar to the old *Bundesrat*, since it was only to have an advisory voice. Provision was made for a plebiscite to be taken in certain cases.

In drawing up the Constitution an endeavour was made to embody in a new form those elements which seemed to have worked satisfactorily in the history of other States which had adopted the republican form of government. The Constitution included clauses allowing for the possibility of the formation of new German States or the amalgamation of States which already existed, Up to the year 1933 these clauses were only applied

in three cases. Saxe-Weimar, Saxe-Gotha, Saxe-Aitenburg, the two Principalities of Reuss and the two Principalities of Schwarzburg combined to form the Free State of Thuringia; Saxe-Coburg united with Bavaria, and (in 1929) Waldeck with Prussia. The electoral system was changed: proportional representation and voting by lists were adopted, the object being to ensure that parliament reflected the state of opinion in the nation as accurately as possible. As however no electoral list was admitted unless it was drawn up by a political party, the effect of the system was enormously to increase the influence of the party organizations on the election results, and in practice to limit the freedom of choice of the elector. Another consequence was to favour the formation of a large number of minor parties, since each one could be sure of gaining a few seats under the new electoral system.

Although the new Constitution of Germany had many defects, it represented a great step forward towards more satisfactory conditions in Germany. Since the revolution there had been no generally recógnised political order sanctioned by law, whereas the life of the country could now resume a regular course.

The Peace Treaty.— The National Assembly at Weimar also had the difficult task of concluding peace with the victorious Powers. There cannot be said to have been any real negotiation of the peace terms; the conditions were fixed by the Allies in Paris. They were simply submitted for acceptance to the German delegation, headed by Count Brockdorff-Rantzau, which had arrived in Paris on May 7, 1919, at the request of the Allies. The German objections were not taken into account. The provisions of the treaty—a long document containing 440 articles—which were the most important from the German point of view were the following: Germany had to cede all its colonial possessions to the Allies, Alsace-Lorraine to France, North Schleswig to Denmark, the districts of Prussia, Posen and Upper Silesia in which the majority of the inhabitants were Poles to the newly created country of Poland, Memel to Lithuania and a few small frontier districts in the West to Belgium. Danzig became an independent free city. The precise delimitation of the territory to be ceded to Poland and Denmark was to be settled on the basis of a plebiscite. Germany lost territory in Europe to an extent of about 87,000 square km. with a population of over 7,000,000.

In addition, the left bank of the Rhine was to be occupied-by Allied troops for from j to 15 years, and the Saar Basin to be administered by the League of Nations for 1 j years, after which a plebiscite was to be taken. The amount which Germany was to pay by way of reparations was to be fixed in 1921. A provisional payment of 20 milliard marks in gold was to be made between 1919 and 1921. Germany also undertook to make payments in kind, consisting of ships, cattle, coal and railway rolling stock, which were to be written off against reparation payments at a rate to be fixed by the Reparation Commission. Germany was in future to maintain a standing army consisting of not more than 100,000 soldiers and 15,000 sailors, and was not to reintroduce compulsory military service. It was only to manufacture arms and munitions to the amount required by an army of this size. All fortresses up to a line 50 km. east of the Rhine were to be demolished, and the fleet to be reduced to 6 battleships, 6 small cruisers, 12 destroyers and 12 torpedo boats. If it is remembered that all the Germans in foreign countries who had lost property owing to the war received no compensation, and that Germany had to give the victorious countries most favoured nation treatment in commerce for a period of five years, it will be possible to form an idea of the immense economic burdens which were laid on a country already impoverished by the war. The worst feature of the situation was that the amount to be paid by way of reparations was not fixed, but was to be settled in the future in accordance with Germany's capacity to pay. The reason given for the severity of these conditions was that Germany had deliberately brought about a terrible war in order to increase its own power. This assertion is now recognized by the great majority of those who have studied the history of the events which led up to the war as being quite unfounded.

In the circumstances which prevailed at the time, there seemed nothing else to be done than to accept the conditions which were forced upon Germany, though they were only accepted under protest. If they had been refused, the Allied troops would at once have crossed the Rhine, and now that the old army had been disbanded, Germany would have been entirely defenceless. On June 23 a majority of the National Assembly accepted the Treaty of Peace, and it was signed at Versailles on June 28.

Many people in Germany blamed President Wilson, by whose mediation the armistice had been concluded, because they said that he had not kept his promise to bring about a peace on the basis of his Fourteen Points. They considered that the handing over of a considerable number of Germans to foreign countries was quite contrary to the principle of self-determination, and that the payments required of Germany moreover went far beyond compensation to the civil population of the occupied territories for damage suffered. Practically the only one of Wilson's aims which was realised was the creation of a League of Nations. Since even this consisted at first only of the victorious Powers and some of the smaller neutral States, it was felt in Germany that there could be no guarantee of the impartiality of its decisions. (See VERSAILLES, TREATY OF; and PARIS, CONFERENCE OF.)

Foreign Relations Since 1919.—The new boundaries of Germany had yet to be determined by the taking of plebiscites in certain areas. A plebiscite held in Schleswig in Feb. and March 1920 gave the towns of Hedersleben, Apenrade and Tondern and the island of Alsen to Denmark, Flensburg remaining German. In East and West Prussia, a plebiscite held on July 11, 1920 resulted in a large majority for Germany in the disputed areas, Allenstein and Marienwerder. Nevertheless, in accordance with the terms of the Treaty of Versailles, the majority of West Prussia, though largely inhabited by Germans, was handed over to Poland, to provide communication with the sea. This "Polish corridor" completely cut off East Prussia from the rest of Germany. In Upper Silesia, a plebiscite taken on March 20, 1921 gave 707,000 votes for Germany and 479,000 for Poland. On this showing, the whole territory, being economically indivisible, should have remained German, but the Poles raised a violent protest and organised a revolt in the districts in which the majority of the population was Polish. France supported the Polish claims, and the Supreme Council of the Allies decided to refer the matter to the League of Nations for settlement. The award was published on Oct. 20, 1921. Poland received the districts of Pless, Rybnik, Kattowitz and Konigshutte, and a number of adjacent areas in which the population was principally Polish. Germany had to accept the award, in spite of the serious economic blow sustained by the loss of the coalfields.

At the same time, the French made unsuccessful attempts to induce the population of the Rhineland to set up an independent State under French protection; Bavaria was also incited to secede from Germany. Under the pretext that Germany had not loyally carried out her undertakings as regards disarmament and reparations payments, the French temporarily occupied Frankfurt., Homburg, Hanau and Darmstadt in April 1920; in May 1921 they occupied Dusseldorf, Duisburg, Ruhrort, Miihlheim and Oberhausen, and in Jan. 1923 the whole territory of the Ruhr. Their attempts to separate these districts from Germany failed on account of the resolute attitude of the population.

TOWARDS STABILIZATION

The assessment of reparations presented enormous difficulties. According to the peace terms, the amount was to be fixed definitely in 1921. At a conference in Brussels in Dec. 1920, the Allies demanded 269,000 million gold marks, to be paid in 42 annual instalments. The German representatives rejected this demand as impossible of fulfilment. The Allies did not accept the German counter-proposals, and the question remained completely in suspense; it was merely laid down that Germany should pay certain sums during the next few years. On Oct. 20, 1921, an agreement was concluded at Wiesbaden to the effect that these payments should be made partly in cash and partly in materials for the restoration of the devastated areas. Payments had to be reduced or postponed repeatedly, on account

of the financial situation in Germany, and in July 1922 a moratorium was obtained only by giving the Allied Powers the right of scrutiny over all German financial measures so long as it lasted. It gradually became clear that a final settlement would never be reached in this manner. As a result of the occupation of the Ruhr, serious differences of opinion had arisen between France and England on the subject of future relations with Germany, and the Allies finally decided to convene a conference of experts to estimate Germany's capacity to pay. The chairman of this international committee was Charles Dawes, an American financier. His proposal, known as the "Dawes Plan," was accepted by the Allies and by Germany, after long negotiations, in the summer of 1924. (See REPARATIONS AND DAWES PLAN.) The German State railways were made over to a company, which had to issue 11,000 million gold marks of first mortgage bonds for reparations. A large share of the indirect taxes was also pledged as security for the reparations payments. The payments were to begin with 1,000 million gold marks in the first year, rising to 2,500 million in 1928. No attempt was made to determine the total amount to be paid by Germany. This settlement, though incomplete, provided a definite basis for calculating the German payments during the next few years, and the French were obliged to evacuate the Ruhr in July 1925.

In order to bring about a permanent improvement in the relations between Germany and France, England proposed a guarantee pact in respect of Germany's western frontier. After prolonged negotiations, a conference was held at Locarno (*q.v.*), where the proposed pact was concluded on Oct. 16, 1925. Germany voluntarily re-affirmed the renunciation of Alsace-Lorraine in favour of France, and undertook not to attempt any alteration of the frontiers by violent means. The inviolability of the new frontiers between Germany, France and Belgium was guaranteed by the signatory Powers, which included England and Italy. Special treaties of arbitration were drawn up for the regulation by pacific means of any differences which might arise. The first tangible result of the Pact of Locarno was the evacuation of the northern third of the Rhineland, including Cologne, by the French and British troops in Dec. 1925. According to the Treaty of Versailles, this zone should have been evacuated two years earlier, but the French had hitherto interposed delays. Another result was the entry of Germany into the League of Nations, with a permanent seat on the Council (Sept. 10, 1926).

In the meantime, Germany had also resumed relations with Russia. By the Treaty of Rapallo, signed on April 17, 1922, Germany definitely recognised the Soviet Republic, and agreed to a reciprocal renunciation of all claims to war indemnities. On April 24, 1926, this treaty was supplemented by a Treaty of Friendship and Neutrality, modelled on the Pact of Locarno, providing for the amicable adjustment of future disputes. Germany's economic relations with other nations were restored by commercial treaties with England, Russia, Italy, the Netherlands, Spain and a number of smaller States. She thus gradually regained a position in the European world corresponding to her size and importance. At the Assembly of the League of Nations at Geneva, Sept. 1927, Stresemann demanded that since Germany was already completely disarmed, the other Powers should likewise make a serious effort towards disarmament. The negotiations on this point never reached any satisfactory conclusion. On the other hand, he was successful in obtaining a promise from France that the number of the troops of occupation still in the Rhineland should be reduced by ten thousand men; this was carried out in October. The suggestion made by America, of an international pact for the renunciation of war received a warm welcome in Germany, and Stresemann went to Paris in person in the summer of 1928 to sign the pact for Germany.

Home Policy After 1919.—The Weimar Constitution represented a compromise between the views of the different Parties existing in Germany. Extremists both of the reactionary and of the revolutionary type were dissatisfied, and made several attempts during the next few years to overthrow it. A serious Communist revolt took place in the Ruhr territory in the spring of 1920, but was suppressed by the Government with the help of the newly constituted Defence Corps, after heavy fighting. Another unsuccessful Communist rising took place in Thuringia and the neighbouring regions of Central Germany in March 1921. On the other hand, in March 1920, Kapp, Director of the Agricultural Credit Institute, together with General von Liittwitz, attempted, at the head of a volunteer army, to seize the Government. They succeeded in assuming power in Berlin for a short time, and Ebert, the President, and Bauer, the Chancellor, fled. The new Government failed, however, to receive the support which had been anticipated, either from the Defence Corps or from the public, and Kapp and Luttwitz were obliged to give up the enterprise and flee. In Nov. 1923, Hitler attempted to take over the Government in Munich by a sudden stroke. His intention was to establish himself in power in Bavaria and then to march to Berlin and carry out a complete revolution there. After a brief appearance of success, this attempt also ended in complete failure.

A clear indication of the political excitement and bitterness of the years following the revolution is given by the occurrence of a series of assassinations. Erzberger, the Centre Party Minister of Finance, was murdered on Aug. 29, 1921, and Rathenau, the Democratic Foreign Minister, on June 24, 1922. By emergency legislation passed on June 18, 1922 and the establishment of a special court to deal with political offences, the Government succeeded in restoring order and security.

In financial matters, the crucial event was the stabilization of the mark, which was achieved largely through the instrumentality of Schacht, the president of the national bank. On account of the disturbed condition of the country, the enormous reparations payments and the decline of production, the Government had not been able to discover any means of relieving the acute shortage of specie except by a progressive increase in the issue of notes. As a result of this inflation, the value of the paper money was constantly falling. In the course of time, the depreciation became so rapid that financial calculations were rendered impossible. On Nov. 15, 1923, a dollar was worth 2½ billion marks. It was finally decided to establish a special bank of issue, the notes of which were guaranteed by the leading personalities in the economic life of the country. At the same time, the printing of paper money by the State was entirely suspended. The new notes were temporarily the only currency in use. When they were generally accepted at their face value in international trade, they were replaced by a new State issue at par. The return to a normal currency paved the way for the recovery of German trade, though the depreciation of the old paper money dealt a blow to small and middling incomes which was felt for many years.

Relations between employers and workers, which had been very strained immediately after the war and the Revolution, under the influence of the current of Communism emanating from Russia, gradually became more satisfactory. A noticeable improvement soon resulted from the introduction of workers' representation in the larger undertakings, the establishment of the National Economic Council in June 1920, and the development of arbitration procedure in wage disputes.

In the political sphere, complexity of party divisions continued to be the principal obstacle to progress. The constitution provided that the ministry must possess the confidence of a majority in parliament. It was practically impossible for any single party to obtain a majority, and, whenever a new Government was formed, a coalition of different groups had to be arranged by negotiations between the leaders of the largest parties. Being made up of heterogeneous elements, the coalition was generally short-lived. The Government formed by Bauer as chancellor in June 1919 consisted of six Socialists and four Catholics, and was increased in October by the inclusion of three Democrats. This distribution was maintained in the Government formed by H. Muller in March 1920. In June 1920, Fehrenbach, the leader of the Catholic Party, became chancellor. His ministry consisted of five Catholics, three Democrats and three members of the German People's Party. He was succeeded in May 1921 by another member of the same Party, Wirth. Wirth's Government

was made up at first of four Catholics, four Democrats and three Socialists, and, after Oct. 1921, of four Catholics, three Democrats and four Socialists. In Nov. 1922, Cuno, a member of the People's Party, became Chancellor. His ministry contained three members of the People's Party, three Democrats and two Catholics. In Aug. 1923, the "grand coalition" was temporarily achieved; the Government comprised two members of the People's Party, two Catholics, two Democrats and four Socialists, with Stresemann as chancellor. In Nov. 1924, it was replaced by a ministry formed by Marx, a member of the Centre (Catholic) Party, consisting of four Catholics, three Democrats and one representative of the People's Party.

A Government formed by Luther in Jan. 1925 was the first to contain a Nationalist minister. A comparison of these ministries shows that it was still impossible to obtain a majority without the co-operation of the Centre Party. The influence of that large party consequently increased, and showed itself particularly in the regulation of spiritual matters, including the establishment of a Bavarian Concordat with the Catholic Church. Strenuous efforts for the adoption of a similar Concordat for the whole of Germany were finally successful in July 1933. An Education Act which would allow the widest possible scope for the influence of the Church was brought in by the minister of the interior, Von Keudell, a member of the Conservative Party, in July 1927, but met with very violent opposition and was rejected.

After the death of Ebert (Feb. 28, 1925), Field Marshal von Hindenburg was elected president. Hindenburg reconciled differences between the political parties on various occasions, but took no prominent part in politics. Luther remained for the time at the head of the Government as chancellor, while Stresemann remained in charge of foreign policy. After the conclusion of the Locarno Pact, a violent dispute broke out between the Government parties. Although the German National members of the Government had given their consent in advance, they were forced by their party to leave the Government. The Conservatives looked on the concessions made by the Government as detrimental to German interests, and also attempted to delay Germany's entry into the League of Nations. On Dec. 5, 1925, they succeeded in forcing the resignation of the Government. Attempts to form a new ministry under the Democrat Dr. Koch proved, however, unsuccessful, and in Jan. 1926, Luther was again appointed chancellor. Stresemann remained minister for foreign affairs. Neither the Conservatives nor the Social Democrats were represented in the new Government.

During the next months the question of the compensation of the deposed princely houses became acute. A bill was brought in for giving them suitable compensation. The Parties of the Left, however, looked on this as an unjustifiable imposition on the people and requested a plebiscite on the question whether the ex-ruling houses should not be expropriated without compensation. The plebiscite (June 20, 1926) did not give the majority required by the Constitution for this motion, and the compensation bill was then passed by the *Reichstag*. Shortly before this, however, Luther had enacted an order that the black-white-red commercial ensign should be hoisted on public buildings on certain occasions besides the black-red-gold flag of the *Reichstag*. Thereupon the Democrat ministers, who considered this an improper concession to Conservative circles, resigned. The Democrats and Social Democrats combined. and, on May 12, 1926, carried a vote of nonconfidence which forced Luther to resign. His place was again taken by Marx, one of the leaders of the Centre Party, who had already filled the office of chancellor on two occasions. His cabinet was composed of five Clericals, three members of the German People's Party, three of the Democrats and one of the Bavarian People's Party. In Dec. 1926, the ministry was defeated and resigned; Marx, however, was entrusted with the formation of a new cabinet in which the three members of the Democratic Party were replaced by Conservatives. The *Reichstag* elections of May 20, 1928 brought a considerable change in the relative strength of the parties. The German National Party, with its allied groups, received 86 seats, the German People's Party 45, the Centre Party with the Bavarian People's Party 78, the Democrats 25, the Social Democrats 153, the Communists 54 and the smaller groups 50 together. The different composition of the *Reichstag* necessitated the formation of a new Government. The Social Democrats, as the strongest party, provided the chancellor, in the person of Hermann Miiller, together with three other ministers, while the German People's Party and the Democrats each supplied three ministers, the Centre Party one.

The most serious problem of home policy remained that of the relation between the Federal Government and the various States. The States demanded a greater measure of financial autonomy; on the other hand, a strong section of public opinion was in favour of further development of Federal institutions at the expense of the States. In Germany, as in all Capitalist countries, there was great antagonism between the propertied classes and the workers; but the population was also divided by religious differences, and by the conflict between the partisans of national unity and those who favoured the maintenance of the political individuality of different parts of the German federation, a conflict which was a constant feature of German history. These were problems which Adolf Hitler and his National Socialist Party were to solve by their vigorous and ruthless centralizing methods after Jan. 1933.

(E. BRA.; X.)

GERMANY'S DIFFICULTIES, 1929-33

Under the Dawes Plan, from 1924 to 1929 Germany enjoyed comparative economic prosperity and met promptly her Reparations obligations, but she was able to do so only by borrowing large amounts abroad. She could not pay Reparations in the normal way by a surplus of exports over imports, because foreign countries still felt a war prejudice against German goods and set up high tariffs to protect their own manufactures. During these five years Germany also borrowed abroad large sums in addition to what she needed for Reparations payments. These sums were partly spent by the Socialists in public welfare enterprises which brought in no economic return — reading rooms, public baths, parks and stadiums. They were also partly spent by the big industrialists in what was called "rationalization of industry," that is, the introduction of new and more efficient labour-saving machinery, with the hope of reducing the cost of production in Germany and thus increasing exports to pay Reparations and the interest on the borrowed money. Dr. Hjalmar Schacht, the President of the Reichsbank, had warned his countrymen against the folly of this excessive borrowing. In 1929 the foreign bankers also began to see their mistake and ceased to extend more loans to Germany. The collapse of the New York stock market and the beginning of the general world depression made matters worse.

It soon became evident that Germany, unable to borrow further abroad, would soon seek protection of the "gold clause" in the Dawes Plan which permitted her, under certain conditions, temporarily to suspend Reparations payments. In view of these conditions the Germans, the foreign bankers, and Reparations debtors were all glad to abandon the Dawes Plan and replace it by the Young Plan of 1930. This for the first time fixed definitely the total amount that Germany was to pay. As compared with the two and one-half billion gold mark annuity (plus a sum based on the index of prosperity) of the Dawes Plan, the Young Plan reduced Germany's annual payments to about two billion gold marks a year from 1930 to 1966, followed by annual payments averaging a little over a billion and a half marks for the 22 years from 1967 to 1988. With the adoption of the Young Plan, the French withdrew their army of occupation from the Rhineland in June, 1930, and the Allied financial commissions of control were withdrawn from Berlin, so that the Germans were at last free masters of their whole territory.

Even the Young Plan payments, however, soon proved to be beyond Germany's capacity to pay. Herr Briining, who succeeded Hermann Miiller as Chancellor in March, 1930, made heroic efforts to meet Germany's financial obligations and to save the tottering coalition of moderate parties (Roman Catholic Centre and Social Democrats) against the attack of the extremist anti-Republican parties (Communists and National Socialists). Briining, at that time only forty-five years of age, was one of the finest characters of the post-War period. As a scholar, equally at home with

Aristotle and St. Thomas Aquinas, he had risen to be the leader of the Catholic Centre party, was a skilful parliamentarian, an expert financier, and a man who understood the practical value of moderation and compromise in politics. But he was too optimistic and too disinclined to use force to suppress the internal enemies of the German Republic. He made drastic financial reforms to reduce expenditures in the effort to meet the Young Plan Reparations payments. When the National Socialists made an alarming gain in the Reichstag elections of September, 1930, rising from 12 to 107 deputies out of a total of 577, Bruning sought to strengthen his coalition government in March, 1931, by proposing an economic union between Germany and Austria. This proposal aroused a storm of opposition in France and other states which feared that an economic union might ripen into a political union, and thus accomplish the *Anschluss* (annexation) forbidden by the Peace Treaties of 1919. France withdrew her credits from Austria and Germany, causing the failure of many-banks in both countries. President Hoover proposed and secured a moratorium for a year on Reparation payments and on Allied debt payments to the United States.

At the close of the Hoover Moratorium, in June, 1932, it was clear to financial experts that Germany's economic condition was so bad that she could make no immediate payments. Consequently a new settlement was arranged by Bruning (though finally signed at Lausanne by his successor, Chancellor von Papen) which was to take the place of the Young Plan. The Reparations payment was slashed to three billion marks on easy payments. Ratification by the Allies was made contingent upon their securing a satisfactory arrangement in regard to their war debts owing to the United States; this has never been secured, so that technically the Lausanne Settlement is inoperative and Germany is still liable under the Young Plan; but no one expects that she will be able or willing to pay the Young Plan annuities. As a practical matter, Reparations payments ceased with the Hoover Moratorium of June, 1931.

Chancellor Bruning's coalition majority gradually dwindled away until he could not muster enough votes to pass his financial and other measures through the Reichstag. Owing to the fact that there were some thirty parties and that the system of proportional representation worked against the formation of a stable cabinet, the parliamentary system was breaking down. Bruning therefore resorted to Article 48 of the Constitution, which allowed the President of the Republic, in case of emergency, to govern by presidential decree instead of by Reichstag legislation. Finally, in May, 1932, Bruning proposed to President von Hindenburg an emergency decree for breaking up the great landed estates in East Prussia to make small farms on which some of the unemployed could be settled. It was a wise and desirable measure, but Hindenburg refused to approve it. He himself had a large East Prussian estate, his friends were land-owning aristocrats, and he could not bring himself to agree to Brüning's proposal. So Bruning resigned, and was followed by Col. Franz von Papen.

Chancellor von Papen dissolved the Reichstag and appealed to the country in a new election on July 31, 1932. Hitler's National Socialists secured more than a third of the total number of seats (230 out of 608). No Reichstag majority could be formed without his support. Chancellor von Papen therefore offered Hitler a position in the cabinet as vice-chancellor. Hitler declined. As head of the largest party he demanded the chancellorship for himself—"all or nothing." This was too much for President von Hindenburg who curtly refused to place him at the head of the cabinet. Von Papen called for a new election in November, 1932, in which Hitler's National Socialists lost slightly, but still won a third of the total vote and were strong enough to defeat the coalition cabinet. Von Papen, like Bruning, proposed a presidential emergency decree breaking up the East Prussian estates, but, when von Hindenburg again refused to approve it, resigned in December. In his place von Hindenburg appointed an army officer, Kurt von Schleicher, as Chancellor. But he met with the same difficulties as his two predecessors and resigned on January 28, 1933. He was succeeded as Chancellor by Adolf Hitler, the leader of the National Socialist Party.

NATIONAL SOCIALIST GERMANY AFTER 1933

Hitler formed a cabinet two days later. It contained three National Socialists—Hitler (Chancellor), Frick (Interior), Goering (Aviation)—and eight others, mostly Nationalists, taken over from the Papen and Schleicher cabinets—Papen (Vice-Chancellor), Neurath (Foreign Affairs), Krosigk (Finance), Blomberg (Defence), Hugenberg (Economics), Eltz-Rubenach (Communications), Seldte (Labour), and Giirtner (Justice). The Nationalist majority had expected to dominate Hitler; but the reverse took place. Papen and Hugenberg were later dropped, and new National Socialists were taken in: Darré (Agriculture), Schacht (Economics), Goebbels (Propaganda), Hess (Deputy without portfolio), and Kerrl (Church). Hitler announced a new Reichstag election for March 5. On the evening of February 27 the central part of the Reichstag Building was destroyed by fire. Whether the fire was set by the Communists, as charged by Reichstag President Goering and the National Socialists, or by secret agents of the latter, as generally believed abroad and by many persons in Germany itself, or solely by a half-witted Dutch boy, Van der Lubbe, who was executed for it, was never definitely determined. But the fire was made the pretext by the Nazis, as the National Socialists were popularly called. for the wholesale arrest of Communists and the suppression of their newspapers, so that they could play no part in the Reichstag election. As a result of this and other strong-arm methods the Nazis won 44 per cent of the votes, and, with 8 per cent of their Nationalist coalition allies, had a clear majority of 52 per cent. Though Hitler was opposed in principle to parliamentary government, which he had denounced as a lamentable failure, he was ready to use the ballot and the existing constitutional machinery to secure absolute control: on March 23 the Reichstag majority virtually set aside the Weimar Constitution, leaving virtually dictatorial power in Hitler's hands. The Nazi Revolution had begun.

In reorganizing Germany Hitler proceeded to sweep away to a large degree the old division of Germany into States—Prussia, Bavaria, Saxony, Baden, etc. He set up instead a more centralized government ruled from Berlin. Germany, like France as a result of the French Revolution, became "one and indivisible." Federal government was replaced by unitary government. This gave Germany greatly increased strength, abolished local "states' rights" jealousies, and put an end to expensive and unnecessary duplication of administration. He also abolished or forced the "voluntary" dissolution of all political parties except the National Socialist Party. Germany became a one-party state, the state being controlled by the party. Hitler became the supreme head of both. On the "leadership principle" he appointed his lieutenants who were responsible to him. They in turn appointed their subordinates, and so on down through the hierarchy of state and party. One of the chief duties of the party is to instil Nazi tenets into the party members and also into all German citizens, thus uniting the whole German people into a single "Totalitarian State."

Treatment of Jews.—Hitler aimed to destroy the influence of the Jews in Germany who had secured power and coveted positions under the Weimar Republic. A law of April 7, 1933, for purifying the civil service decreed the dismissal of Jewish officials except those who held the office before 1914, had fought at the front, or had a son, father or brother killed in the World War. Many Jews, and also Liberals, were dismissed from the universities and schools. This and other harsh treatment of the Jews caused a boycott of German goods by many foreigners, but the foreign boycott only fanned the anti-Semitic feeling in Germany. It increased until in November, 1935, a series of laws sought to settle the Jewish problem once and for all. In place of the distinction between "Aryan" and "non-Aryan," the people of the Reich fall into three categories: "Germans and persons of kindred blood," "Jews," and "Mixed Jews."

"Jews" are persons who have at least three racially Jewish grandparents, that is, who are 75% Jewish; also persons who are racially 50% Jewish, if (1) they belonged to a Jewish religious community at the time of the passage of the Nurnberg laws of September 15, 1935, or (2) if at that time they were married to a Jew or married one subsequently, or (3) if they are the offspring

of a marriage with a 75 per cent Jew or full Jew concluded after the passage of the Niirnberg law. "Jews" under this definition may not become full citizens, or hold office. They are condemned to a kind of ghetto existence with a cultural life of their own.

"Mixed Jews" are those who have only 25 per cent Jewish blood, or who have 50 per cent but do not fall under any of the three conditions mentioned above. Such "Mixed Jews" may marry Germans under certain restrictions but not one another. They may also acquire full citizenship and enjoy its privileges.

These provisions, however, were not generously interpreted and the plight of all persons of Jewish blood grew more and more desperate. It seemed to reach a culmination during the night of Nov. 9–10, 1938. Organized bands of National Socialists all over Germany, evidently at the instigation of high Government officials, began about 2 A.M. an anti-Semitic orgy of destruction, looting, and incendiarism. Some 500 synagogues were more or less destroyed or wrecked by bombs and fire. The police offered no interference, and the fire department confined its efforts chiefly to preventing the spread of the fire to neighbouring houses. Meanwhile other National Socialist bands of young men toured the streets, smashing the windows of every Jewish shop and hurling the furniture and goods into the street.

The following afternoon Dr. Goebbels issued a proclamation, saying: "The justified and understandable anger of the German people over the cowardly Jewish murder of a German diplomat in Paris found extensive expression during last night. In numerous cities and towns of the Reich retaliatory action has been undertaken against Jewish buildings and businesses. . . . A final answer to the Jewish assassination in Paris will be given to Jewry by way of legislation and ordinance." This final answer was given a few days later by a decree which made the whole body of Jews in Germany collectively responsible for the crazed act of a young Polish Jew in Paris. It imposed an "atonement" fine of 1,000,000,000 marks on German Jewry. It took the form of a capital levy of 20% of the property of all German Jews possessing more than 5,000 marks. Each Jew must pay at least a quarter of his quota of the fine on or before December 15, and pay the remainder in three more quarterly instalments in Feb., May, and Aug. 1939, or pay it all in a lump sum any time before the final date on Aug. 15, 1939. No Jew might leave Germany until he showed tax receipts proving that he had paid the full 20% of his property.

Another decree ordered all Jewish business men to repair at once at their own expense all the shattered windows and other damage that the National Socialist gangs had wantonly destroyed on the night of November 9–10. Insurance companies were forbidden to pay to Jews any insurance on the wrecked property. Still another decree ordered the complete elimination of Jews from all retail trade before Jan. 1, 1939, and their businesses were "Aryanized." that is, taken over by Aryans at very low figures arranged by the Government. Jews in Berlin were forbidden to appear in any German theatres, movies, cafés, concert halls, and bathing establishments, or to set foot in certain parts of the city unless provided with a pass. Landlords in the better residential districts were encouraged to evict Jews before leases expired. The Jews were thus restricted to a pitiful ghetto-like existence reminiscent of the Middle Ages. In Oct. 1939 Hitler attempted a new "solution" of the Jewish problem. Large numbers of Jews from Vienna and other cities in Eastern Germany were transported to the Lublin district of conquered Poland. This district was to be made a settlement area also for hundreds of thousands of Polish Jews.

The Papacy signed a Concordat with the Nazi State on July 8, 1933, which guaranteed to German Roman Catholics various privileges, including the continuance of religious youth organizations and certain societies. But disputes over the interpretation and observance of the Concordat have caused great friction between the Catholics and the Nazis.

The Protestants have also had serious conflicts with the Nazi government. The twenty-eight Lutheran and Calvinistic churches which were in existence when Hitler came into power hastened to unite in July, 1933, into a single German Evangelical Church. But as the control of this passed into the hands of so-called "German Christians," who were regarded by more devout persons as being more nationalistically German than Christian, many pastors refused to accept its authority. They established their own Confessional Synods, defying all efforts to unite all Lutherans and Calvinists in a single church.

In five years Hitler cut down the number of unemployed in Germany from 6,000,000 in January 1933, to 423,000 in April 1938. In reality he virtually wiped out unemployment altogether, for among these 423,000 some were merely temporarily unemployed owing to changing work or residence, etc. This remarkable reduction of unemployment greatly benefited the labouring class as a whole, but it did not improve the standard of living of the individual worker, because wages have remained fixed while the cost of living has increased.

Foreign Policy.—By a combination of shrewd skill, bluff, and threats of force, Hitler achieved a series of diplomatic victories which enabled him to throw off many of the unwise and irritating restrictions of the Versailles Treaty of 1919. In 1933, since the former Allied Powers had done little or nothing to carry out their implied obligation to reduce their own armaments after Germany was disarmed. Hitler withdrew from the Disarmament Conference and gave notice on October 19 of withdrawal from the League of Nations. On Jan. 26, 1934, he made a ten-year treaty with Poland by which Germany and Poland sought to establish friendship, recognized each other's frontiers, and agreed not to use force against each other; this drew Poland to some extent from dependence on France to dependence on Germany. By a plebiscite in the Saar on Jan. 13, 1935, in which 90% voted for Germany, he reunited 811,000 Germans to the Fatherland.

On March 16, 1935, Hitler suddenly announced the immediate reintroduction of compulsory military service—a unilateral repudiation of the Versailles Treaty limiting Germany's force to a long-service professional army of 100,000. Service in this new army was at first fixed at one year, but in August was extended to two years. An Anglo-German naval agreement, signed on June 18, 1935, authorized Germany's building up to 35% of British tonnage. On March 7, 1936, he ventured successfully in marching troops into the demilitarized zone of the Rhineland, and his action was acclaimed two weeks later by 98·79% of the German voters. A five-year agreement with Japan, signed on Nov. 25, 1936, was adhered to by Italy a few months later and strengthened the so-called "Rome-Berlin Axis."

Greater Germany, 1938–39.—Having thus strengthened Germany's military and diplomatic position. Hitler decided in Jan. 1938, that the time had come to revise what he regarded as some of the "criminal injustices" in the territorial clauses of the Versailles Treaty.

The clauses forbidding the union of Germany and Austria were contrary to the principle of self-determination. and were a political mistake. Both countries had been united for centuries in the Holy Roman Empire. Though at war in the time of Frederick the Great and in 1866, they had become allies against Napoleon I and again in 1879. They had suffered side by side during the World War. Austria as pared down in 1919 was almost purely German in speech. tradition, and sentiment. To forbid them to unite was a psychological factor making them want to unite. Again, in 1931, the thwarting by France and her eastern satellites of the proposed economic, but not political, union was a short-sighted mistake, because such a successful diplomatic achievement might perhaps have enabled Dr. Briining to remain in office and prevent Hitler from becoming chancellor.

After 1933 the sentiment of the Austrians toward Germany rapidly changed. The majority now abhorred union with Germany when they saw beyond the border how Hitler was persecuting Catholics, Protestants, and Jews, and destroying trade unions, political parties, and personal liberty. This abhorrence was increased by the secret incitement and public propaganda by which German National Socialists tried to stir up revolts within Austria against the Austrian Republic, so that Germany might have a pretext to intervene and annex the country. Nazi incitement did succeed in stirring up an abortive rising or "putsch" on July 25, 1934, in which the Austrian Chancellor, Dollfuss, was assassinated. The

ringleaders were executed and Dr. Schuschnigg succeeded Dollfuss as Chancellor.

During the next four years German Nazis kept up their policy of incitement to revolt with Hitler's approval, but publicly Hitler declared: "Germany has neither the wish nor the intention to mix in internal Austrian affairs, or to annex or unite with Austria." Nevertheless, his acts soon belied his words. During 1937 and the early weeks of 1938 he adopted toward Austria the same methods which he was also to use against Czechoslovakia and against Poland. He first encouraged Nazi sympathizers in Austria to acts of violence and disorder against Dr. Schuschnigg's republican government. Then he turned on a violent radio propaganda among his own people depicting the intolerable "atrocities" supposedly perpetrated by Dr. Schuschnigg against the Nazi trouble-makers in Austria. Finally, he threatened to use force, and backed up his threat by massing German troops along the frontier of the country he was determined to invade and annex.

Chancellor Schuschnigg was persuaded to visit Hitler at his Berchtesgaden mountain villa on Feb. 12, 1938, to talk over the situation. Hitler used such strong threats that Schuschnigg felt compelled, in order to prevent greater dangers to Austrian independence, to promise to take some Austrian Nazis into his cabinet, in return for Hitler's promise to respect the independence of Austria. Three weeks later Schuschnigg sought to strengthen his position by announcing that he would hold a plebiscite in Austria on March 13 to endorse his policies. On March 11 Hitler sent ultimatums to Vienna demanding that the plebiscite must be postponed and that Schuschnigg must resign. He emphasized his demands by massing German troops and Black Shirts along the Austrian frontier. Armed resistance by Austria would have been hopeless. To avert bloodshed Schuschnigg resigned. Before dawn next morning German troops and police had poured over the frontier at many points and made straight for Vienna. On March 13 Hitler proclaimed the annexation of Austria to Germany and made a triumphal entry into the Austrian capital the next day. This aggrandizement of the Third Reich by 32,300 sq.mi. and by 6,760,000 subjects was his first step in the creation of a "Greater Germany."

Munich Accord, 1938.—About 3,500,000 Sudeten Germans lived in Czechoslovakia in a fringe of territory just beyond the German frontier. Before World War I these Germans in Bohemia had been Austrian subjects. They were given to Czechoslovakia by the peace treaties because of historical and strategic considerations. Bohemia is surrounded by high mountains which make an excellent strategic frontier. When the Czechs of Bohemia were given independence as part of the new State of Czechoslovakia, the frontier was quite properly drawn along the ridge of the mountains, even though it left the Sudeten Germans under Czech rule. The Sudeten Germans naturally disliked this. But no serious troubles occurred until their economic condition grew worse as a result of the general world economic depression and until the advent of Hitler to power in Germany in 1933. Then a Sudeten "Little Hitler," Konrad Henlein, began to agitate for the annexation of the Sudetenland to Germany. His hopes were greatly encouraged by Hitler's successful annexation of Austria. The Czechs were alarmed. In May 1938, fearing that Hitler might intervene during the municipal elections in the Sudetenland, the Czechs mobilized part of their army. Hitler publicly disclaimed any intention of intervening, but realized that the Czechs might fight sooner than give up the Sudetens and the good strategic frontier. Therefore Hitler immediately gave orders for the building of a great line of fortifications in the west against France. This German "Westwall" opposite the French Maginot Line would, he hoped, protect his western frontier in case he had to fight the Czechs and the French should try to come to the assistance of their Czech allies.

During the summer of 1938, while the Westwall was being rapidly brought to completion, Konrad Henlein increased his agitation for the annexation of the Sudetenland to Germany. He made several visits to Hitler. Serious disorders broke out. Finally, on September 12, Hitler announced that the Sudetens must be allowed to join the Reich. This brought on a European crisis: the Czechs would resist by force; they would probably be assisted by the French, and the French by the English and perhaps by the Russians, while Germany would perhaps be joined by Italy. To avert such a general European war, the British Prime Minister, Sir Neville Chamberlain, made an attempt at "appeasement" by three flights to Berchtesgaden, Godesberg, and Munich for personal conversations with Hitler. He got the strong impression that Hitler was "prepared to risk a world war" rather than abandon his demand for immediate annexation of the Sudetenland. In this critical situation, the British and French Prime Ministers. Chamberlain. and Daladier, and Hitler and Mussolini, met and signed on September 30 the Munich Accord. By this the German armies were allowed to occupy the Sudetenland within the next two weeks. Greater Germany was thereby further aggrandized by 29,000 sq.mi. and 3,000,000 new subjects.

Hitler had declared to Mr. Chamberlain personally and in a public speech that the Sudetenland represented "his last territorial ambitions in Europe." Nevertheless, in less than six months he resorted to the same methods of inciting internal disorders, violent propaganda, and threats of force against Czechoslovakia. This unhappy country, already partly dismembered at Munich and deprived of its strategic frontier and strong fortifications, felt that armed resistance would be hopeless. At Hitler's demand President Benes resigned and his successor, Dr. Hacha, was "invited" to a conference with Hitler at Berlin. He arrived on March 15, 1939, at 1:10 A.M., and soon after 5 A.M., according to a German communiqué, "trustfully laid the fate of the Czech people and the country in the hands of the Fuehrer of the German Reich." Already German troops had invaded Czechoslovakia, and by 9:15 A.M. their vanguard had entered Prague, the former capital of the now extinct Czechoslovakian Republic. Hitler quickly followed them and announced that henceforth the "Protectorate of Bohemia-Moravia" belonged to the German Reich, and would be allowed to enjoy a certain amount of self-government.

In this final dismemberment of Czechoslovakia Hitler encouraged the Slovaks to revolt from Czech rule and to set up a tiny little Slovak Republic. He promised to guarantee its existence for 25 years, but at the same time secured the right to move German troops through it and to build German fortifications in it against Poland. On March 22, he also annexed Memelland, which before the World War had been part of East Prussia.

Encouraged by these successes Hitler next turned to Poland. Already on Oct. 24, 1938, less than a month after the Munich Accord, it was suggested privately to Poland that there ought to be a German-Polish "settlement." The city of Danzig, which was mainly German in population, ought to be returned to the Reich, and Germany ought to be given a strip of territory across the Polish Corridor to connect East Prussia with the rest of the Reich. This suggestion, or rather demand, was renewed the following January and discussed at Berchtesgaden where Colonel Beck, the Polish foreign minister visited Hitler. Colonel Beck apparently neither accepted nor flatly rejected the demand. But on March 21, less than a week after Hitler's annexation of Bohemia, the demand was again renewed, the Poles rejected it on March 26. but were willing to listen to other proposals. They naturally feared that the cession to Germany of Danzig and a strip of territory across the Polish Corridor would simply be a first step in the dismemberment of Poland.

Meanwhile, Prime Minister Chamberlain's attitude had been completely altered by Hitler's acts since the Munich Accord. In annexing 6,000,000 Czechs in Bohemia-Moravia Hitler could no longer pretend that he merely wanted to annex territories of German population; he seemed to be aiming at the domination of Eastern Europe. Moreover, Mr. Chamberlain felt that Hitler had flagrantly broken the promise personally given to him at Munich that the Sudetenland represented his last territorial ambitions in Europe; the limit had been reached in allowing Hitler to remake the map of Europe in disregard of promises and international agreements by force and threats of force. The British Prime Minister therefore announced on March 31 that in the event of any German action which clearly threatened Polish independence and which the Polish Government accordingly considered vital to re-

sist with force, Great Britain would lend the Polish government all the support in its power.

In a public speech on April 28 Hitler denounced the German-Polish treaty of friendship of 1934 and the Anglo-German naval agreement of 1935. He also renewed his demand on Poland for Danzig and a pathway across the Polish Corridor. The Poles, encouraged by Chamberlain's promise of support, refused to yield. This caused a new European diplomatic crisis which grew in intensity during the summer. On Aug. 23 Hitler's minister of foreign affairs, Herr von Ribbentrop, signed at Moscow a Russian-German pact, declaring that the two powers would stand together in bringing about order in Poland and central Europe. This news for a moment caused consternation in Britain and France, which had been negotiating for weeks at Moscow with the aim of bringing Russia into a "stop Hitler" front; Britain, however, not intimidated by Ribbentrop's diplomatic success in Moscow, continued to try to find a peaceful solution of the German-Polish problem, but without success. At dawn on Sept. 1, 1939, German troops began to pour into Poland. Britain and France, after vainly trying to secure a promise that the invasion of Poland would be countermanded, announced on Sept. 3 that they would aid Poland and were therefore at war with Germany.

GERMANY DURING WORLD WAR II

Hitler's first aims in World War II were to destroy the British empire, with its sea power and colonies, and give the Germans more "living room" *(Lebensraum)* by extending German domination eastwards. During the progress of the war, in order to crush Britain. he found himself involved in ever-widening fields of battle. He conquered nearly all Europe, and then aimed to establish a "New Order" which would give the German "master race" (*Herrenvolk*) political and economic domination of Europe, western Asia, northern Africa and perhaps ultimately of South America.

One of his first war measures was the creation of a Ministerial Council for the Defense of the Reich. It was composed of six of the most powerful members of the nazi party. Field Marshal Hermann Goering, president of the reichstag and head of the basically important four-year plan, was made its presiding officer and designated as Germany's future leader if Hitler himself should die. Rudolf Hess, Hitler's personal aid, was designated as next in succession to Goering. The other four members of the Ministerial council were: Wilhelm Frick, minister of interior; Walther Funk, head of the reichsbank and minister of economics; General Wilhelm Keitel, Hitler's deputy as supreme commander of all the reich's armed forces — military, naval and air; and Heinrich Lammers, chief of Hitler's reich chancellery. The council resembled somewhat the "war council" or "inner cabinet" of other countries in time of war. Its purpose was to provide a small body with full powers which could break through all bureaucratic red tape and act quickly and efficiently. It was co-ordinate in power with the reichstag and even with the fuehrer himself. It had authority to issue decrees having the force of law, without their being approved by Hitler or the reichstag, unless Hitler should order otherwise.

The Ministerial council at once forbade Germans to listen to any foreign broadcasts, "because in modern war the enemy fights not only with military weapons, but also with means which are intended to influence and break down the morale of the people. One of these means is the radio. Every word which the enemy sends over is, it goes without saying, a lie, and is calculated to bring damage to the German people." Germans were expected as a matter of honour and duty to refrain from listening to any foreign broadcasts. For Germans lacking in this sense of duty, severe penalties were imposed, amounting to death if one listened and reported to his neighbours what he heard. In the following months receiving sets capable of picking up foreign broadcasts were widely confiscated, leaving to the Germans only the weak receiving sets intended to hear official nazi broadcasts from within Germany. In 1933 Germany had only 4,307,000 radio receiving sets.

Dr. Goebbels, in co-operation with the producing companies, made great efforts to increase this channel by which the nazis could carry their propaganda to the people more effectively. As a result the number of German radio sets was increased to 12,591,000 at the outbreak of the war.

Rationing cards for food and a number of household necessities were put into operation on Aug. 27, even before the war began, in order to forestall any panicky rush to buy up and hoard goods. It would also prevent a repetition of the mistake of 1914, when no timely measures were taken to conserve necessities for a long war and blockade. They were not adopted until 1916. As a result. Germany consumed with prodigality during the first two years of the war, and then suffered very great privation during the last two years.

The National Socialists, wiser by experience and foresight, would not allow this to happen again.

The Ministerial council on Sept. 4 issued a series of regulations to prevent any rise in prices or wages during the war. To provide more war revenue the tax on tobacco, beer and similar "luxuries" was increased 20% and the already heavy personal income tax by 50%. Metal coins were largely withdrawn from circulation and replaced with paper notes in small denominations. The army high command was authorized to issue large promissory notes to pay for its supplies. In Poland and later in the other conquered lands the army also issued "reich credit notes" with which officers and men could buy up whatever they wanted. As the war progressed the list of rationed articles was steadily extended and the burden of taxation was increased. The cost of the war to Germans was about equally divided between money raised by taxation and money borrowed. The admitted public debt rose during the first 28 months of the war from 37,200,000,000 marks in Sept. 1939 to 128,500,000,000 marks (about $51,000,000,000) at the end of 1941. Much of the cost of the war, however, was covered by all sorts of payments exacted from the conquered countries.

German Expansion Eastward, 1939.—The transition from peace to war was relatively easy for Germany. For several years Hitler had been organizing the country for war. By his policy of "guns instead of butter" the people had been hardened to economic sacrifices. Hitler had built up the mightiest war machine the world had ever seen, at a cost, according to his own statement, of 90,000,000,000 marks (about $36,000,000,000).

Among the German people, however, the war evoked no enthusiasm during the first days of Sept. 1939. They had been repeatedly assured by German propaganda that Hitler would always know how to get what he wanted without actually going to war, as in the case of the annexations of the Saar, Austria and the Sudetenland. Now that Germans found themselves at war with Britain and France, the two great democracies which had helped defeat them in 1918, as well as with Poland, they were disillusioned. They feared that they would have to fight a war on two fronts. But the amazingly quick and complete victory over Poland rapidly developed a real war enthusiasm and renewed their confidence in their fuehrer.

The "lightning war" (blitzkrieg) against Poland, which became the model for Hitler's later conquests, opened with the lightning-like destruction of Polish aeroplanes and means of communication —telephone and telegraph, railaays and bridges—by the greatly superior number of German bombing planes and parachute troops. German armoured cars and mechanized units poured over the frontier, cut between and surrounded or annihilated Polish armies before they were fully concentrated and ready to fight. Warsaw, the Polish capital, made a heroic resistance until Sept. 27. Its fall virtually sealed the fate of Poland. Hitler arrived in person on Oct. 5 to take possession. Next day he flew to Berlin to announce that the campaign had been completed within a month, and that German casualties had been remarkably small: 10,572 dead; 30,322 wounded; and 3,404 missing.

While Poland was fighting a life-and-death struggle on the west against the Germans, she was suddenly invaded on the east by the Russians. Stalin wished to recover the "White Russian" part of Poland which had once been part of the tsarist empire, and also to prevent Hitler from establishing the borders of the reich too close to the heart of Russia.

On Sept. 28 the two spoliators signed an agreement for the partition of Poland. Stalin took most of the eastern half and eventually joined it to Russia as the soviet republics of White Russia and the Ukraine.

Hitler took the remaining richer and more populous half of Poland west of the Bug and San rivers, and divided it into two parts. The whole Polish Corridor, Danzig and a wide strip of territory east of Silesia were annexed directly to the German reich. It included the great industrial city of Lodz and valuable coal, iron and other mineral deposits, as well as heavy industries important for the manufacture of war materials. The Adolf Hitler canal, a waterway connecting the Upper Silesian coal and iron fields at Gleiwitz with Germany's great inland canal system at Kosel on the Oder river, was one of the important economic results of the German conquest of western Poland. At the end of 1939 direct railroad traffic between Germany and Russia was opened at nine points in former Polish territory. But owing to the deterioration and shortage of rolling stock in both Russia and Germany the traffic between the two countries was not large. It was also impeded by Stalin's unwillingness to make deliveries of large supplies which would increase Hitler's military strength, and by the necessity of reloading all shipments at the junction points between the European standard-gauge rail lines (4 ft. 8½ in.) and the Russian broad-gauge (5 ft.) lines.

In this territory annexed directly to the reich, Poles and Jews were systematically uprooted and expelled upon an hour's notice, and deprived of all their lands and possessions without any compensation. The Poles mere shipped into the reich to work virtually as slaves in the German fields and factories. The Jews were deported in locked box cars without food or heat in the cold of winter on a journey of several days to a ghetto in Warsaw or to other places in the new German "Government General of Poland."

The farms. stores and houses of the deported Poles and Jews were handed over to new German settlers. These included some 17,000 Baltic Germans who were uprooted from homes in Latvia and Estonia where their ancestors had lived for centuries. They included also some 130,000 Germans from the part of Poland seized by Russia. To these "repatriated" Germans Hitler planned to add 185,000 Germans from the Italian Tirol, 30,000 from Lithuania and several thousands from overcrowded areas in Germany. This former Polish territory was to be thoroughly Germanized, as Robert Ley, leader of the German Labour Front, indicated in a speech at Lodz in Jan. 1940. After emphasizing the rights of the German "master race" and their natural superiority over the Poles, he told his German hearers: "You must remain hard. Then the wish of the fuehrer will be fulfilled, that millions of young Germans will grow up here; that in fifty years this will be a flourishing German farmland in which there will not be a single Pole or Jew. We shall keep this land for all time."

The rest of German-conquered Poland Hitler intended to set up, he declared on Oct. 6, 1939, as "a Polish state so constituted and governed as to prevent its becoming once again a hotbed of anti-German activity or a centre of intrigue against Germany or Russia." But having failed to find any Poles of distinction willing to become officials in a nazi-controlled puppet state, he finally organized it as the "Government General of Poland" under the rule of a nazi leader, Hans Frank. No great effort was made to rebuild Warsaw. A large part of it was walled off as a ghetto for Jews. It ceased to be the capital. This was transferred to Cracow. This city, which was much closer to the German and Austrian frontier. became the residence of Governor General Frank. The Lublin district east of Warsaw would be set aside, Hitler said, as a "solution" of the Jewish problem; here Jews from Germany as well as from Poland were herded together in a crowded pitiful existence and died in great numbers of hunger and cold.

On Jan. 28, 1940, the pope made public a report by Cardinal Hlond, primate of Poland. It gave a terrible picture of the cold-blooded brutality, plundering and systematic persecution and extermination of Poles by Germans in the region blasted by Hitler's first blitzkrieg.

German Expansion Westward, 1940.—While conquering and organizing Poland in the east, Hitler stood on the defensive against Britain and France in the west. He was well protected against French invasion by his recently constructed Westwall. The French likewise felt well protected by their Maginot line. Neither side wished to risk the great slaughter of troops which would inevitably result from any frontal attack on either of these powerful defensive fortifications. For seven months therefore the war in the west was strangely quiet. Newspaper men called it a "phony war." Germans called it a "sitzkrieg," because the soldiers spent most of their time sitting in the shellproof shelters of the Westwall and the Maginot line.

Hitler took advantage of this breathing spell to build up greater stocks of gasoline, lubricants and other war supplies for an eventual blitzkrieg in the west which would crush France and Britain. He also reorganized the administration of war production at home. In place of the Ministerial Council for the Defense of the Reich created at the beginning of the war, he announced on Jan. 4, 1940, the establishment of a new "General council." This was a kind of economic general staff. It was a planning, co-ordinating and initiating board, again directed by Goering as president and inspired by his driving energy. It was composed mainly of state secretaries representing the ministries most essential for war needs: Paul Koerner and Reich Neumann, state secretaries in Goering's four-year plan; Major General Georg Thomas, chief of the armaments office of the supreme command; Friedrich Landfried and Hans Posse (economics ministry); Herbert Backe (food); Johannes Krohn (labour); Wilhelm Kleinmann (transportation); Hans Pfundtner (interior); Friedrich Alpers (forestry); Josef Wagner, reich price commissar; and a representative of Rudolf Hess as Hitler's deputy for party affairs. These state secretaries, who ranged in age from 38 to 64, were trained technical experts rather than politicians like the heads of the respective ministries to which they belonged. Many of them had been civil servants before the nazis came into power. Like Goering himself, they were somewhat more conservative and orthodox in their views as compared with the more radical nazis.

One of the most important raw materials for war which Germany had to import was iron ore from Sweden. In the years before the mar about 3,000,000 tons annually were sent down by rail from the Iron mountains in northern Sweden to Lulea at the head of the Gulf of Bothnia and then transported by ship down the Baltic to Germany. But this route was closed by ice for several months during the winter. Another 6,000,000 tons came from the Iron mountains by electric railway westward to the Norwegian port of Narvik, where it was dumped into ships for cheap transport to Germany. This route was free from ice the year round, but the British were interfering with it more and more. They threatened to cut it off completely by placing mines and firing on German ore ships even behind the islands within the three-mile limit of Norwegian territorial waters where the ore ships took refuge. By seizing Norway Hitler believed he could protect securely his imports of Swedish iron ore from Narvik. He would also acquire air bases from which to control the North sea and attack British shipping along the coasts of eastern England and Scotland.

On April 9, 1940, therefore, he suddenly opened a blitzkrieg against Norway and Denmark. The king of Denmark, seeing overwhelming numbers of German troops rush across his unfortified frontier, realized that any resistance was hopeless. He therefore bowed before the inevitable and accepted Hitler's "protection." He was accordingly permitted to remain in his castle at Copenhagen as the nominal ruler of his country. Real political power, however, was taken over by the German army and the hated secret police (gestapo). The Germans seized Denmark's gold and forced the country to supply the reich with butter, eggs, milk, bacon and other products, much of which the Danes had been in the habit of selling in England. Since this food was now going to Germany, the British stopped supplying Denmark with cattle fodder, so that the Danes had to slaughter half their poultry and cattle or see them starve to death.

Norway made a determined resistance for a month and was aided by an Anglo-French expeditionary force. But the Germans

had made such a sudden and unexpected attack and had such overwhelming numbers of aeroplanes and mechanized troops that it was impossible for the little nation of 3,000,000 population to prevent the German conquest. King Haakon and his cabinet barely escaped capture in their capital at Oslo, and managed to escape to England where they established the government in exile of "Free Norway." Hitler then placed Norway under the rule of a nazi commissar, Josef Terboven. He was assisted by a few subservient Norwegians who selfishly preferred self-advancement under nazi domination to the independence of their country. The name of one of these, Major Vidkun Quisling, became a new synonym for traitor. He organized a tiny pro-nazi party, called *Nasjonal Samling,* and was rewarded for his treachery by being made political leader of the nazi administration under Josef Terboven. In Feb. 1942 Quisling was made prime minister, but he had no parliament and little power among the great mass of the Norwegian people. They despised him, sullenly submitted to nazi domination or secretly opposed it, and waited for the day when Norway would again be free and independent.

A month later, on May 10, 1940, encouraged by these successes and anxious to deal a knockout blow at France and Britain, Hitler suddenly launched his great blitzkrieg in the west. The Netherlands were overrun before the Dutch had time to open their dikes and flood the country. German bombers and parachute troops attacked the cities at the rear of the Dutch troops. Queen Wilhelmina and her ministers escaped a nazi plot to arrest them and fled to England. The campaign was over in five days and the Netherlands army had to lay down its arms. The commissioner whom Hitler then appointed to rule the country was Dr. Arthur Seyss-Inquart, the Austrian nazi, who had helped him overthrow Dr. Schuschnigg and seize Austria in 1938.

The Netherlands Indies, however, with its vast wealth and population of 70,000,000, remained loyal to Queen Wilhelmina; so also did the Dutch navy and all Dutch merchantmen upon the high seas and in foreign ports. They provided a valuable addition to British naval and merchant shipping.

Attacking Belgium at the same moment that they invaded the Netherlands, German motorized troops were able to seize strategic bridges and cross the Albert canal which the Belgians had relied on as their first line of defense. The Belgian armies therefore had to fall back toward the west and count upon support from the British and French, who promptly sent considerable forces. But the German tank divisions, aided by the murderous fire of innumerable bombing planes, swept around the southern flank of the Allied armies, cut them off from France and drove them back toward the English channel at Dunkirk. On May 25 King Leopold of the Belgians, believing that the military situation was hopeless and that further resistance would mean useless shedding of blood, decided to surrender. He was at first left nominally as king. But he refused to collaborate with the Germans at their dictation and retired to a castle, virtually a prisoner in his own land. His ministers escaped to France and thence to London, where they formed a government in exile of "Free Belgium." In Belgium itself the administration was exercised by Belgian local authorities under the rigid control of a nazi military governor, Lieutenant General Alexander von Falkenhausen.

German troops meanwhile had poured into France along the valley of the Meuse north of the Maginot line. They quickly completed the military and political collapse of France. The old French leaders resigned, fled or were captured. The 84-year-old Marshal Henri Pétain, hero of World War I, became head of the French government. On June 22, in spite of Winston Churchill's efforts to hold France firm in her alliance with Britain, Marshal Pétain felt compelled to accept an armistice with Germany, hoping that Hitler would honourably live up to its terms

The armistice gave Germany virtually political and economic control of all of continental France, but not of the French navy nor of North Africa snd the other parts of the French colonial empire. In the northern and western three-fifths of France, north of a line running roughly from Switzerland westward to the Luire river and then southwestward to the Pyrenees, German troops mere to remain in occupation until a final peace should be signed. This region of "occupied France" included Paris, Orleans, Dijon and most of the great industrial cities. As it included the whole coast along the English channel and the Atlantic seaboard beyond Bordeaux to the Pyrenees, it gave Germany invaluable naval bases and ports from which her submarines and sea raiders could prey upon British commerce and threaten British naval power. For the alleged support of the German army of occupation France had to pay 400,000,000 francs a day.

The southern two-fifths of the country, known as "unoccupied France," was to remain under the rule of Marshal Pétain's government which established itself at Vichy. The French had to deliver up all stocks of war material or store them at German direction, except the French navy, which was to be demobilized in designated French ports. About 1,500,000 French prisoners remained in German hands and were transported to the reich where some four-fifths of them were put to work in the fields or factories to aid Germany's war production.

Alsace and Lorraine, which had been under German rule from 1871 to 1918, lay in "occupied France." Germany soon began to expel all Frenchmen without any compensation from these two provinces and to settle Germans in their places, in spite of protests from the Vichy government. Alsace was later annexed directly to the reich, and administered by Robert Wagner, *Gauleiter* of Baden. Lorraine was united in Jan. 1941, with the Saar-Palatinate territory of Germany to form a new region known as the "Westmark" under *Gauleiter* Josef Buerckel.

German casualties in killed, wounded and missing during the blitzkrieg in the west were: 5.296 in the Norwegian campaign; and 156.492 on the western front from May 10 to June 25, 1940. These official figures of the German high command may be an understatement. In any case, they do not include civilians killed and wounded in enemy air raids; nor casualties on the western front from Sept. 3, 1939, to May 10, 1940; nor the complete air and naval losses.

German Expansion Eastward, 1941.—Hitler failed to invade Britain at the moment that he had the best chance to do so—in June 1940, after the British defeat in Belgium and the evacuation from Dunkirk. Though German propagandists had repeatedly declared that he would invade England, his general staff had apparently made no plans to do so. Probably he thought that the collapse of France would quickly bring about the collapse of Britain. But the British, after the evacuation of Dunkirk, were more determined than ever to fight on for eventual victory. They quickly organized the defenses of the island, so that Hitler let his best opportunity slip by. Instead of trying an invasion across the channel, he tried to crush Britain during the summer and autumn of 1940 by a terrific aerial bombardment of London, Coventry, Liverpool, Plymouth and other important industrial cities and seaports. He also tried to starve her into submission by an intensification of attacks on British commerce by explosive mines, submarines, surface raiders and bombing from the air. British merchant shipping losses rose dangerously during the winter and spring of 1941, but the flow of food and munitions across the Atlantic from the United States, the British' dominions and neutral states not only prevented Britain from starving but actually built up her strength. In Britain itself war production was also steadily increasing.

Unable to invade Britain or crush her by cutting off supplies, Hitler turned again eventually toward the east. He might be able to break up the British empire by striking at Egypt, the Suez canal and the middle east with its rich supplies of oil which he so much needed for his own war machine. Meanwhile he spent the autumn and winter of 1940 in organizing the conquered countries to produce food and war supplies and in building new stocks of munitions. Men were temporarily transferred from his fighting forces to labour in the war industries.

By threats, false promises and military pressure Hitler gradually brought Hungary, Rumania and Bulgaria under his domination. Turkey, however, encouraged by Britain and Russia, and relying on her own strength, refused to be bullied. She adhered to a precarious neutrality. When Hitler's armies had done the hard fighting against France and were about to crush her, Mussolini

had hurriedly joined him as an active ally. He declared war on France hoping to share in the spoils. He did not get much. He was ambitious, however, to drive the British from the Mediterranean and acquire more of North Africa. On Oct. 4, 1940, Hitler and Mussolini had a meeting on the Brenner pass, after their respective foreign ministers, Ribbentrop and Ciano, had visited one another and held long diplomatic conversations. Shortly afterwards German troops moved into Rumania, and Italian troops made a sudden invasion of Greece from Albanian territory.

It looked as if the axis powers were going to strike at Britain's life line in the eastern Mediterranean. Nazi forces based on Rumanian Black sea ports would be in a position to overawe Turkey, strike at the invaluable British pipe line bringing oil from Iraq to Palestine, and then drive across the narrow desert at Suez from the east. Meanwhile Italian troops would push forward again towards Egypt from Libya and the west. Thus the axis pincers would close in upon the Nile valley region from two sides, and cut Britain's vital short route to India and Singapore. Britain's empire would be disrupted by the annihilation of sea power in the coveted Mediterranean. Germany and Italy could then divide the lion's skin by each taking appropriate parts of Africa.

Mussolini's proud ambitions met with ignominious failure. When his armies invaded Greece on Oct. 28, 1940, he expected an easy victory as a result of his surprise attack. But he had made no proper preparations. His soldiers, insufficiently protected with winter clothing, suffered terribly from the cold as well as from the heroic Greek counteroffensive By March 1941 his defeated frostbitten troops had not only been thrown out of Greece but seemed likely to be driven out of Albania also. The Greeks were aided by a small British force. In Libya Mussolini's troops under General Graziani had pushed slowly eastward to the desert frontier of Egypt. But early in 1940 General Wavell's forces from Egypt suddenly attacked Graziani's army which was waiting for more supplies and drove it headlong 300 mi. to the west, capturing a great many prisoners and large supplies of war material. Far to the south in Abyssinia South African and other British imperial troops were gradually chasing Italian soldiers into the western mountains, and opening the way for Emperor Haile Selassie to return to his capital at Addis Ababa.

Hitler, to save his Italian ally from further disasters, to restore the prestige of the axis and to strike at the British who were aiding the Greeks in Albania, opened a blitzkrieg against Yugoslavia on April 6, 1941, and a little later against Greece. Within six weeks he had crushed both of the small Balkan states and forced their armies to surrender. But a great many Serbs from the Yugoslav armies managed to escape with their guns to the mountains. In the autumn they began to wage a fierce and very troublesome guerrilla war against the German and Italian armies of occupation. Organized and led by the young General Mikhailovich, these Serb guerrillas had an army of 80,000 men. They destroyed railways and bridges, attacked isolated German detachments and controlled at least a fifth of Serbia. Hitler had to send three new German divisions to try to put them down, but without success.

The Greeks were more thoroughly crushed and so completely robbed of all their food that thousands died of starvation in the winter of 1941–42. Of the 60,000 British who had come to aid the Greeks, about a quarter were killed or taken prisoner in Greece. The other three-quarters were embarked either to Crete or back to Egypt. Those in Crete were soon assailed by German parachute troops and planes in great numbers, as well as by German troops ferried over in small boats from Greece. After an unequal struggle the British had to evacuate Crete also, but with heavy losses in men killed and captured and in British boats sent to the bottom.

Hitler's losses in this Balkan campaign, not including the Cretan fighting, were again remarkably small according to German official figures of June 12, 1941: 2,559 killed, 5,820 wounded and 3,169 missing, a total of only 11,548 casualties. The Germans claimed to have captured over 500,000 prisoners: 344,000 Serbians, 218,000 Greeks and 11,224 British.

While coming to Mussolini's rescue in the Balkans, Hitler sent strong German reinforcements under General Erwin Rommel to aid Graziani's army in Libya. Taking command of this German-Italian army, while British troops were dispersed in Greece, Palestine, Abyssinia and elsewhere in the near and middle east, Rommel reconquered Libya in April as rapidly as Graziani had lost it a short time before. But he could get little farther than the desert frontier of Egypt at Halfaya ("Hellfire") pass and was unable seriously to threaten Britain's hold on the Suez canal.

Hitler also tried to stir up anti-British revolts in Iraq and Iran (Persia) and thus cut off Britain's oil supply to Palestine and shake British influence in the whole middle east. General Wavell, however, effectively thwarted these nazi plans. With the aid of General de Gaulle's "Free French" troops, his British forces occupied Syria in June and compelled the pro-nazi troops of the Vichy government to surrender. He thus prevented Hitler from acquiring territory which would have placed Turkey in a nazi vise, and which might have afforded the nazis a stepping-stone to the middle east and ultimately to Egypt. British troops were also rushed to Mesopotamia. The Iraqi chiefs whom Hitler had worked upon were overawed, and in August British and Russian detachments joined hands in putting successful pressure on Iraq and Iran to expel nazi agents, thus making the oil regions safe for the Allies.

Meanwhile, on June 22, 1941, Hitler took the world by surprise by his sudden blitzkrieg against soviet Russia. His reasons, as he told the German people, were that he had never trusted Stalin in spite of the German-Russo pact of Aug. 23, 1939; that he had only signed it with a heavy heart and could no longer put up with Stalin's repeated aggressions; and that he had decided to strike first before Stalin should strike him. Unable to invade England or to crush the British empire at Suez, he could not continue the war against Britain as long as Stalin was in a position to deal a treacherous blow upon Germany's flank and rear. Therefore he had to destroy the soviet army once and for all, and the rest of Europe ought to join with Germany in the crusade to end the communist menace to western civilization.

In six months Hitler's war machine swept 400 mi. eastward over the plains of Russia up to the outskirts of Leningrad and Moscow and even crossed the Don river at Rostov. All of the Crimea was occupied except the Russian naval base at Sevastopol. Hitler had seized the rich grain fields of the Ukraine and seemed about to push on to the coveted oil wells of the Caucasus. But this great expansion eastward brought Germany little economic advantage. Stalin adopted a "scorched earth" policy. Russian villages and grain fields were set on fire before the advancing German armies. Factories, power plants and bridges were blown up. Industrial machinery was moved farther east. As far as possible everything of military value to the Germans was either destroyed or transported deeper into Russia toward the Ural mountains.

Though Hitler claimed to have taken 5,000,000 Russian prisoners, he did not succeed in his fundamental purpose of annihilating quickly the red armies. Even when Russian divisions were cut off by German pincer movements and were supposed to surrender, thousands of Russians managed to escape with their arms. They remained behind the German front lines and carried on a very effective guerrilla warfare, shooting at Germans from hiding places in forest and field, and blowing up German lines of communication. Hitler had not prepared for a long winter campaign, and his troops began to suffer terribly from cold and from transport difficulties caused by snow.

The deeper the Germans advanced into Russia, the stiffer became the Russian resistance. Stalin brought up reinforcements from Siberia. Hitler had to admit publicly to the German people that he had seriously miscalculated the great amount of armaments that Stalin had been secretly preparing. Finally, about Nov. 22, after five months of war, the nazi blitzkrieg slowed down to a standstill. Hitler seemed unable to capture Moscow. The Russians then began a vigorous counteroffensive all along the 1.000-mi. front from the Baltic to the Black sea. Aided by winter cold to which they were accustomed and often using ski troops, they began to push the frostbitten Germans slowly back. After

nearly three months, by the middle of Feb. 1942, they had freed Leningrad and Moscow from danger of capture and driven the Germans out of a broad strip of territory varying from 50 to 300 mi. in width and extending from the Gulf of Finland to the Crimean peninsula. Stalin had recovered about a quarter of the land which the Germans had conquered and was still driving them slowly but steadily backward toward Germany. Hitler had lost the offensive and been placed on the defensive.

Hitler gained little and lost much by his invasion of Russia, judging by the situation in Feb. 1942. The myth of his invincibility was destroyed. The blitzkrieg had failed in its fundamental aim of annihilating the Russian armies so that he could devote all his attention to crushing Britain. While he was losing tanks and planes on the steppes of Russia, Britain had been increasing her own production of war material and had been receiving growing supplies from the "arsenal of democracy" across the Atlantic. Hitler had promised his people he would take Moscow before Christmas, but instead his armies were in retreat. All this had a somewhat depressing effect on the morale of the army and on the German people at home. It gave corresponding encouragement to the nazi-dominated peoples everywhere and led to renewed acts of sabotage and the shooting of German officials. General Walther von Brauchitsch, commander in chief of the German army, was relieved of command "for reasons of health," as were several other high German officers. General von Reichenau died of heart failure. Hitler announced that he himself would henceforth take direct command of all military operations and be guided by his "intuitions."

Hitler's most serious loss was his loss of man power. In contrast to his earlier campaigns, the casualties in the Russian campaign had been heavy. He admitted in his reichstag speech of Dec. 11, 1941, that "German losses in the eastern campaign from June 22 to Dec. 1 are as follows: 162,414 dead, 477,767 mounded and 33,334 missing," a total of 673.515 casualties. By the middle of Feb. 1942 they probably amounted to at least twice that figure, for the destructive effect of the Russian counter-offensive had been very severe. Moreover, his figures apparently did not include the heavy losses from frostbite, typhus and other sickness. This loss in soldiers and military equipment not only weakened Hitler's fighting strength, it made it necessary for him to withdraw German troops to some extent from the armies of occupation in western Europe and in the Balkans. He had to call for more but less reliable troops from Italy, Rumania. Hungary and Bulgaria. It also made more serious the shortage of man power in Germany for the production of planes, tanks and other military supplies to replace what had been lost or spent in Russia.

GERMERSHEIM, town in the Bavarian Palatinate, at the confluence of the Queich and the Rhine, 8 mi. S.W. of Speyer. Pop. (1933) 3,727. From 1644 to 1815 it was sometimes in the possession of France and sometlmes in that of the Palatinate. In 1835 the new town was built.

GERMINAL, "the month of buds," the first spring month of the French Republican calendar, substituted for the Gregorian calendar on Oct. 5, 1793. *See* FRENCH REPUBLICAN CALENDAR.

GERMINATION, of seeds: *see* ANGIOSPERMS: *Germination* of *Seed.*

GERMISTON, in Transvaal, 9 mi. E. of Johannesburg. Altitude 5,478 ft. Pop. (1936) 32,564 whites, 46,876 coloured. It is an important railway junction, where lines meet from Natal and Cape Colony ports, Laurenço Marques, Pretoria and Johannesburg. Germiston is situated in the heart of the Witwatersrand gold mining area, and has a large gold refinery. Much land has been taken up since 1917 for industrial sites.

GERM PLASM, a term used in biology to denote the reproductive elements and their forerunners in the embryo, in contradistinction to the soma, or body cells. The term is due to A. Weismann. (*See* HEREDITY; EVOLUTION, ORGANIC; EMBRYOLOGY.)

GERO (c. 900–965), margrave of the Saxon east mark, mas entrusted in 937 by the German king Otto, afterwards the emperor Otto the Great, with the defence of the eastern frontier of Saxony against the Wends and other Slavonic tribes. In a few years he extended the Saxon frontier almost to the Oder, and suppressed a rising of the conquered peoples in a great victory on Oct. 16, 955. In 963 he defeated the Lusatians and compelled the king of the Poles to recognize the supremacy of the German king.

GEROLSTEIN, a village and climatic health resort of Germany, in the Prussian Rhine province, situated on the Kyll, in the Eifel range, 1,240 ft. above the sea, 28 m. north of Trier. The castle of Gerolstein was built in 1115 and is now in ruins. Gerolstein is celebrated for its lithia waters which are largely exported. Pop. (1933) 3,052.

GÉRÔME, JEAN LÉON (1824–1904), French painter, was born on May 11, 1824, at Vesoul (Haute-Saône). He went to Paris in 1841 and worked under Paul Delaroche, whom he accompanied to Italy (1844–1845). On his return he exhibited "The Cock-fight," which gained him a third-class medal in the Salon of 1847. In 1854 Gérôme made a journey to Turkey and the shores of the Danube, and in 1857 visited Egypt. To the exhibition of 1859 he contributed a large historical canvas, "The Age of Augustus and the Birth of Christ," which was purchased by the State. Gérôme was a good draughtsman in the style of Ingres and an inventive illustrator in the style of Delaroche; he was also a sculptor. Gérôme was elected member of the Institut in 1865. He died on Jan. 12, 1904.

GERONA, a maritime frontier province in the extreme north-east of Spain, formed in 1833 of districts taken from Catalonia and bounded on the north by France, east and south-east by the Mediterranean sea, south-west and west by Barcelona, and north-west by Lerida. In the north-west a small section of the province, with the town of Llivía, is entirely isolated and surrounded by French territory, otherwise Gerona is separated from France by the Pyrenees. The population (1920) was 325,619, (1939) 325,515. Area 2,264 sq. miles. The region has numerous historical associations (see CATALONIA), and it acted as the guardian of the passes through the Pyrenees at the eastern end, performing the same service as Roncesvalles in the west. The three main rivers, the Ter, Muga and Fluvia, rise in the Pyrenees and flow in a south-easterly direction to the sea. Along their banks there is much good arable land, while the lower slopes of the Pyrenees are well wooded with oak, pine and chestnut. Cape Creus is a marked feature of the coastline and is the most easterly point of the Iberian peninsula. It is formed by the dying down seawards of the Pyrenees. The climate varies locally. The Cerdãne district and other mountainous tracts are cold during eight months while Gerona, La Bisbal and Santa Coloma have typical Mediterranean features. The coastal fisheries are important especially at Llansá, Rosas, Palamos and Blanes. The cork industry flourishes at San Feliu de Guixols (with fisheries), Palafrugell and Cassa. There is also a little metalliferous mining. Much use is made of water-power and the linen, cotton and general textile manufactures are important. Gerona (*q.v.*) is the capital while Figueras (*q.v.*) was long a most important frontier fortress. Gerona was held by government troops during the civil war of 1936–39 until after the capture of Barcelona Jan. 26, 1939.

GERONA, the capital of the province of Gerona in north-eastern Spain, on the railway from Barcelona to Perpignan in France and on the right bank of the river Ter, at its confluence with the Oiia, a small right-hand tributary. Pop. (1940) 23,179. Gerona is the ancient Gerunda, a city of the Auscetani. It claims to be the place in which St. Paul and St. James first rested when they came to Spain and it became the see of a bishop about 247. It was for a long time in the hands of the Moors whose emir, Suleiman, was in alliance with Pippin the Short, king of the Franks about 759. It was taken by Charlemagne in 785, but the Moors regained and sacked it in 795 and it was not until 1015 that they were finally expelled. It gave the title of count to the king of Aragon's eldest son. It has been besieged no fewer than twenty-five times in all, and only four of the sieges have resulted in its capture. Its noblest resistance was in 1809 when it was besieged in May by the French with 35,000 troops under Verdier, Augereau and Gonvion St. Cyr; forty batteries were erected against it and a heavy bombardment maintained; but under the leadership of Mariano Alvarez de Castro it held out till famine and fever compelled a capitulation on December 12. The French, it is said, had spent 20,000 bombs and 60,000 cannon balls, and their loss was estimated at 15,000 men.

The older part of the town occupies the steep slope of the Montjuich or Hill of the Capuchins; the newer portion stretches down into the plain and beyond the Oiia. There are still remains of the city walls, and the hill is crowned by what were at one time very strong fortifications, now put to other uses. The cathedral is a fine specimen of Gothic architecture; the nave measures 73 ft. from side to side. The old cathedral on the same site was used as a mosque by the Moors, and on their expulsion in 1015 it appears to have been greatly modified if not entirely rebuilt. New works were carried out during the 14th century, but it was not till the beginning of the 15th that the work on the present structure was really begun. The collegiate church of San Feliu (St. Felix) is mainly of the 14th century, but was modified in the 16th and its façade dates from the 18th. The spire is conspicuous. The Benedictine church of San Pedro de Galligans (or de los Gallos) is an interesting Romanesque building of early date. It is named from the small river Galligans, an affluent of the Oiia, which flows through the city. In the same neighbourhood is a small church with a rare Spanish example of a transverse triapsal plan. Gerona is still the seat of a bishop. There is a public library. Paper, cotton and woollen goods are extensively manufactured.

GERONIMO (*c.* 1829–1909), a chief of the Chiricahua band of the Apache tribe of North American Indians, was, according to his own story, born in No-do-yohn canyon, Ariz., in June 1829. From 1875 to 1885 as leader of a band of "hostiles" he terrorized the territories of New Mexico and Arizona. An expedition commanded by Gen. George Crook succeeded in bringing Geronimo to a meeting in March 1886, wherein the chief agreed to surrender if he and his men would be taken to Florida, where their families were being held. The terms were agreed to, but on the way the Indians escaped. Gen. Crook was succeeded by Gen. Nelson A. Miles, who followed the Indians for months, finally capturing them in August in Skeleton canyon, Ariz. Geronimo and 14 companions were taken to Ft. Pickens, Fla., and in 1888 were removed to Alabama, but the climate proving unhealthy, they were in 1894 finally transferred to Ft. Sill, Okla., where the chief lived until his death, on Feb. 17, 1909. He dictated the story of his life to S. M. Barrett, who published it under the title Geronimo's Story of *His* Life (1906).

See also Arizona Historical Review, vol. i. (1928), and Britton Davis, The Truth *About* Geronimo (New Haven, 1929).

GERONTOCRACY, a system of government by old men. Almost everywhere in primitive society, old age commands respect and gives authority and prestige. The older members of the community may take a less active part in the ordinary daily occupations of the people, but as the great depositories of tradition they exercise an influence referable to their experience and knowledge of precedent, and their leadership in ceremonial and political matters is often pronounced. In some communities their authority is so great that they even constitute a dominant ruling class, able to control and guide the conduct of the community in all departments of its activity. The distinctive feature of this gerontocracy (from Greek words meaning rule of the old men), is that political authority is not invested in any persons as individuals, but in the elders as a class. This form of government develops chiefly where the political unit is a small local group, and where the absence of any strong central authority tends to accentuate the influence of age and experience. It occurs most frequently in Australia and Melanesia, and is also found in parts of Africa and America.

The nature and functioning of gerontocracy varies. As a rule the government lies in the hands of the older men only, women being more or less rigidly excluded from political activity, while the younger men are regarded as of little importance. But the elders do not always form a body formally constituted or marked off from the rest of the community by any sharply defined line. In many parts of Melanesia, *e.g.*, there is no organized form of government, the regulation of social affairs being in the hands of the older men generally. In particular there are a few old men to whose decisions the people consent, and whose influence is based largely on the knowledge of magic and tradition which they possess. Their authority, however, is by no means absolute,

and they are not necessarily obeyed. They exercise their power not by command but by advice, and they have no regular means of imposing their will upon the members of the community. In certain aspects of ceremonial life old women may also have considerable authority, but otherwise their influence is slight. (*See* R. Thurnwald, "Politische Gebilde bei den Natür volkern," *Zeitschrift* f. *Vergl. Rechtswiss.*, 37, 379 *seq.*, 1919.)

In Australia, on the other hand, the dominance of the aged men is the salient feature of public life. Among the Dieri, *e.g.*, all the men who have passed through the initiation ceremony officially conferring the status of maturity, constitute an assembly which meets from time to time in council. Its deliberations are kept secret, and anybody revealing them to an outsider may be punished by death. This council decides upon all questions of importance, and is implicitly obeyed by the rest of the community. It administers justice according to a well-understood code, punishes breaches of tribal law, and regulates the ceremonies and movements of the group. At the same time old men who are distinguished in war, magic or debate, will stand out in the council, and their influence over its other members is marked. (A. . Howitt, *Native Tribes of South-east Australia*, 295 *seq.*; 320 *seq.*, 1905.) Similarly in northern Queensland the camp council is a secret assembly including all the older men of some consequence, and its authority in social affairs is supreme. Here also, however, there are gradations of power dependent upon personal factors, and a man who has passed through the various stages leading to an elder's status, or who is renowned as a warrior or magician, or has a large following acquired by plural marriage, is likely to exercise more than usual influence. (W. E. Roth, *North Queensland Ethnography*, Bulletin *8*, 5 *seq.*, 1906.)

Elsewhere membership of the elders' council is more restricted. In certain parts of Melanesia, *e.g.*, in the Banks islands, it is dependent upon a man's position in the secret societies which play so important a part in the life of the community. These societies comprise a hierarchically graded series of divisions, in which each grade is entered by initiation and payment. The process of initiation becomes more complex and expensive the higher the rank attained, and as the government of the community rests entirely in the hands of the men of high rank, the rulers are necessarily old and wealthy men. Owing both to their position in these societies and to the belief in their magical powers, they wield great authority in the tribe. (*W.* H. R. Rivers, *History of Melanesian Society.*) A system somewhat similar in nature is found in parts of east Africa, where a man passes successively through the various age-grades into which the population is divided (*see* AGE-GRADES), until he reaches the grade of elders, election into which enables him to take part in the government of the community. (*See* C. *W*. Hobley, *Bantu Beliefs and Magic*, 209 *seq.*, 1922.)

Age in itself is therefore not always a sufficient claim for supreme political prestige. Other qualifications are usually desirable as well, and the nature of these varies with the type of society. Sometimes it is knowledge of magic and tradition, sometimes wealth, sometimes ability in war or debate which adds to the authority of the old men. Frequently they will retain their prestige only as long as they are in possession of their full mental and physical powers. But that age alone may count for a great deal is seen, *e.g.*, in the case of the Yaurorka headman cited by Howitt, who was almost childish from old age and had to be carried about, but whose power and prestige remained unshaken.

Similarly the power of the old men will vary according to the activities of the group. Where the respect for tradition is enhanced by complicated religious and magical ceremonies, as in Australia, the absolute dominance of the elders is the most conspicuous social phenomenon. Where, again, as among some of the Plains Indians of North America and in parts of East Africa, military activities predominate, the fighting men may dispute leadership with the aged; while, as in Melanesia, the men's secret societies will often supplant the control of the council of elders. There is thus no uniform pattern of gerontocracy, but rather a general tendency the direction of which is determined by local circumstances.

Wheeler, *The Tribe and Intertribal Relations in Australia* (1910); *A.* Knabenhans, *Die Politische Organization bei den australischen Eingeborenen* (1919); *R.* Thurnwald, *Die Gemeinde der Bánaro* (1921). *(I. S.)*

GEROUSIA, the council of elders at Sparta, corresponding in some of its functions to the Athenian Boulē. In historical times it numbered 28 members, to whom were added *ex officio* the two kings and, later, the five ephors. Candidates must have passed their 60th year; *i.e.*, they must no longer be liable to military service. Vacancies were filled by the Apella; once elected, the *gerontes* held office for life and were irresponsible. The council prepared the business which was to be submitted to the Apella and was empowered to set aside, in conjunction with the kings, any "crooked" decision of the people. Together with the kings and ephors it formed the supreme executive committee of the state, and it exercised also a considerable criminal and political jurisdiction, including the trial of kings; its competence extended to the infliction of a sentence of exile or even of death (*see* APELLA).

Greenidge, *Greek Constitutional History* (1896); L. Whibley, *Companion to Greek Studies* (1916). For ancient authorities *see* Aristotle, *Politics* II., Plutarch, *Lycurgus.*

GERRHA, ancient port on the Arabian coast of the Persian gulf inhabited by Chaldean exiles from Babylon (Strabo, Bk. xvi., and Pliny, *Hist. Nat.* vi. 32). Various identifications of the site have been suggested (Qatif, Kuwait, Salwa), but the ancient name is unquestionably preserved in that of modern 'Uqair (pronounced Ujair, Ojer) as suggested by Philby. Cheesman in 1923 discovered ruins here which tend to confirm this conjecture though the matter still requires further examination. The classical story that the houses here were built of rock-salt is difficult to understand. 'Uqair is now one of the chief ports of Hasa with a growing trade. It has an excellent deep-water harbour with a very difficult approach from Bahrein, where goods are trans-shipped from ocean steamers to sailing-boats.

GERRY, ELBRIDGE (1744–1814), American statesman, was born in Marblehead (Mass.), July 17, 1744, the son of Thomas Gerry, a prosperous Marblehead merchant. He graduated at Harvard in 1762 and entered his father's business. In 1772 and 1773 he was a member of the Massachusetts general court, and in 1773 he served on the committee of correspondence which became one of the great instruments of intercolonial resistance. In 1774–75 he was a member of the Massachusetts Provincial Congress. The passage of a bill proposed by him to arm and equip ships to prey upon British commerce (Nov. 1775) was, according to his biographer, Austin, "the first actual avowal of offensive hostility against the mother country which is to be found in the annals of the Revolution." From 1776 to 1781 Gerry was a member of the Continental Congress, where he early advocated independence, and was one of those who signed the Declaration after its formal signing on Aug. 2, 1776, at which time he was absent.

Gerry was again a member of Congress in 1783–85 and in 1787 was a delegate to the Constitutional Convention. He served as an Anti-Federalist in the National House of Representatives in 1789–93. In 1797 he was sent by President John Adams, with John Marshall and Charles Cotesworth Pinckney, on a mission to France to obtain from the government of the Directory a treaty embodying a settlement of several long-standing disputes. The discourteous and underhand treatment of this embassy by Talleyrand and his agents resulted in the speedy retirement of Marshall and Pinckney. The episode is known in American history as the "X Y Z Affair." Gerry remained in Paris for some time in the vain hope that Talleyrand might offer to a known friend of France terms that had been refused to envoys whose anti-French views were more than suspected. This action of Gerry's brought down upon him from Federalist partisans a storm of abuse and censure, from which he never wholly cleared himself.

In 1810–12 he was governor of Massachusetts. His administration was especially notable for the enactment of a law by which the State was divided into new senatorial districts in such a manner as to consolidate the Federalist vote in a few districts,

thus giving the Democratic-Republicans an undue advantage. The outline of one of these districts, which was thought to resemble a salamander, gave rise in 1812, through a popular application of the governor's name, to the term "Gerrymander" (*q.v.*). In 1812 Gerry, who was an ardent advocate of the war with Great Britain, was elected vice president of the United States, on the ticket with James Madison. He died in office at Washington, Nov. 23, 1814.

See J. T. Austin, Life of *Elbridge* Gerry, with *Contemporary* Letters (Boston, 1828–29); Edward Channing, History vol. iv.; Yale, *Chronicles* of *America;* Henry Adams, History.

GERRYMANDER (usually pronounced "jerrymander," but the g was originally pronounced hard), an American expression which has taken root in the English language, meaning to arrange election districts so as to give an unfair advantage to the party in power by means of a redistribution act, or to manipulate constituencies generally. The word is derived from the name of the American politician Elbridge Gerry (*q.v.*). It was, however, only a new name for an old practice. In the American colonial period political advantage was often obtained by changing county lines.

See John Fiske, Civil Government in the United States (1890); E. C. Griffith, The Rise and Development of the Gerrymander (1907); J. W. Dean, "History of the Gerrymander," in New England *Historical* and Genealogical Register, vol. xlvi. (1892).

GERS, a department of south-western France, composed of the whole or parts of certain districts of Gascony, viz. Armagnac, Astarac, Fezensac, Pardiac, Pays de Gaure, Lomagne, Comminges, Condomois and of a small part of Agenais. It is bounded N. by the department of Lot-et-Garonne, N.E. by Tarn-et-Garonne, E. and S.E. by Haute-Garonne, S. by Hautes-Pyrénées, S.W. by Basses-Pyrénées and W. by Landes. Pop. (1936) 192,451. Area, 2,429 sq.mi. The department consists of a plateau sloping from a height of 1,100 ft. at the base of the Pyrenees to the Garonne beyond the northern boundary. It is drained by the Save, Gimonne, Arrats, Gers and Baise diverging fanwise to the Garonne, and by the Arros, Midouze and Douze feeding the Adour in the west. The climate is temperate, but subject to an unwholesome south-east wind and destructive spring hail-storms. There is seldom any snow or frost. The annual rainfall varies between 28 and 32 in. Gers is primarily agricultural. The valleys are fertile especially in the south-west and the grain produced is more than enough for local needs. Wheat, maize and oats are the chief cereals. Two-thirds of the wine produced is made into brandy, known by the name of Armagnac, second only to Cognac in reputation. The natural pastures are supplemented chiefly by crops of sainfoin and clover; horses, cattle, sheep and swine are reared in large numbers; turkeys, geese and other poultry are abundant. There are mineral springs at Aurenson, Barbotan and several other places in the department. There are flour mills and tanneries; faïence and cream of tartar are made, and feathers cleaned and prepared.

Gers is divided into the arrondissements of Auch, Mirande and Condom, uith 29 cantons and 466 communes. The chief town is Auch, the seat of an archbishopric.

GERSCHOM BEN JUDAH (960–1040), French rabbi, was born at Metz. Settling in Mainz in early life, he became the originator of Talmudic studies in France and Germany. About 1000 he called a synod which prohibited polygamy and discussed the problems of divorce and of apostasy under compulsion. Gerschom died in Mainz in 1040. Besides his revision of the text of the Mishnah and Talmud, he produced works on Biblical exegesis, the Masorah and lexicography.

GERSHWIN, GEORGE (1898–1937), American composer, prominently identified with music of the jazz type, was born in Brooklyn, New York city, on Sept. 26, 1898. Though he had already written the music for eight musical comedies, and various other works, it was his Rhapsody in Blue, an elaborate composition for piano and orchestra in the jazz style, that first drew serious attention. Later compositions are *Concerto in F* (1925); a suite of preludes for the piano, 1926; Porgy and Bess (opera), 1935.

GERSON, JOHN (1363–1429), otherwise JEAN CHARLIER DE GERSON, French divine, chancellor of the University of Paris, and the ruling spirit in the oecumenical councils of Pisa and Constance, was born at Gerson on Dec. 14, 1363, the son of pious peasants. He was educated at the famous ccilege of Navarre in Paris, studying theology under Pierre d'Ailly, who remained his life-long friend. At the university, he was elected procurator for the French "nation" in 1383, and in 1387 was sent with the chancellor and others to Clement VII. to procure the condemnation of John of Montson, a Dominican, who had rejected the Immaculate Conception. When Pierre d'Ailly was made bishop of Puy in 1395, Gerson was elected chancellor of the university, and made a canon of Notre Dame. The university was then at the height of its fame, and its chancellor was necessarily a man prominent in Europe, sworn to maintain the rights of his university against both king and pope, and entrusted with the studies of its students attracted from almost every country. Gerson's work has three periods, in which he was engaged in reforming the university studies, maturing plans for overcoming the schism, and in the evening of his life writing books of devotion.

Gerson wished to banish scholastic subtleties and make theology plain and simple by founding it on the philosophical principles of nominalism; but like the great nominalist William of Occam, he saved himself from rationalism by laying hold on the mysticism of the Victorines. The study of the Bible and of the fathers was to supersede the idle questions of the schools, and in his Tract. contra romantiam de rosa (iii. 297) he warns young men against the evil consequences of romance-reading.

Gerson's chief work was concerned with the great schism. In the new elections after the death of Clement VII., both Rome and Avignon felt the displeasure of the University of Paris so much that each of the new popes swore to "cede" if his rival would do so also. Meanwhile in 1395 the national assembly of France and the French clergy adopted the programme of the university—cession or a general council. In 1398 most of the cardinals and crowned heads in Europe had given their adhesion to the plan, which was supported by Gerson's multitude of pamphlets. Finally in 1409, a general council assembled, deposed both anti-popes, and elected Alexander V. Gerson was chosen to address the new pope on the duties of his office. He did so in his Sermo coram Alexandro *Papa* in die *ascensionis* in *concilio Pisano.* When, however, Alexander, who had been a Franciscan, issued a bull which laid the parish clergy and the universities at the mercy of the mendicants, the university rose in revolt, headed by her chancellor, who wrote a fierce pamphlet—*Censura professorum* in *theologia* circa *bullam Alexandri V.* The pope died soon after, and was succeeded by John XXIII.

The council of Pisa had not brought peace; it had only added a third pope. Gerson now maintained in a series of tracts that a general council could depose a pope; he drew up indictments against the reigning pontiffs, and reiterated the charges against Jean Petit, a theologian who had justified the treacherous murder of the duke of Orleans by the followers of the duke of Burgundy. His efforts were seconded by the emperor Sigismund, and the result was the council of Constance in 1415 (*see* CONSTANCE, COUNCIL OF). Gerson's influence at the council was supreme up to the election of a new pope. He dictated the form of submission and cession made by John XXIII., and directed the process against Huss. But the council became in the end the cause of his downfall. He was the prosecutor in the case of Jean Petit, and the council, overawed by the duke of Burgundy, would not affirm the censure of the university and archbishop of Paris. Petit's justification of murder was declared to be only a moral and philosophical opinion, not of faith. The council would only condemn one proposition, and even this censure was annulled by the new pope, Martin V., on a formal pretext. Not daring to return to France, because the duke of Burgundy was in Power, Gerson retired to Rattenberg in Tirol, where he wrote his famous *De consolatione theologiae.* On the death of the duke, he proceeded to Lyons, where his brother was prior of the Celestines. His last years were spent in writing books of mystical devotion and hymns. He died at Lyons on July 12, 1429.

The best editions of his works are those of Paris (3 vols., 1606) and Antwerp (5 vols., 1706), to which is prefixed Dupin's *Gersoniana,* including Vita *Gersoni.* See C. Schmidt, Essai *sur* Jean *Gerson* (Strasbourg, 1839); J. B. Schwab, *Johannes Gerson* (Würzburg, 1859); H. Jadart, Jean Gerson (Reims, 1882); Thomassey, *Jean Gerson* (2nd ed.

1872); Masson, *Jean Gerson* (Lyons, 1894); Lafontaine, *Jehan Gerson* (1906); P. Tschackert, *Peter von Ailli* (Gotha, 1877); Herm. v. der Hardt, *Con. Constantiensis libri iv.* (1695–99); L. Salembier, *Le grande schisme* (1900). *See* also Chevalier, *Repertoire des sources hist. Bio-bibliographie* (1905), and Überweg, *Gesch. der Philosophie*, Bd. 2 (1928).

GERSONIDES or **BEN-GERSON (GERSHON), LEVI,** known also as RALBAG (1288–1344), Jewish philosopher and commentator, was born at Bagnols in Languedoc, probably in 1288. His family had been distinguished for piety and exegetical skill, but though he was known in the Jewish community by commentaries on certain books of the Bible, he never seems to have accepted any rabbinical post. Possibly the freedom of his opinions may have put obstacles in the way of his preferment. He was at Avignon and Orange during his life, and is believed to have died in 1344, though Zacuto asserts that he died at Perpignan in 1370. Part of his writings are commentaries on Aristotle, or rather of commentaries on the commentaries of Averroes. Some of these are printed in the early Latin editions of Aristotle's works. His most important treatise, that by which he has a place in the history of philosophy, is entitled *Milhamoth 'Adonai* (The Wars of God), and occupied 12 years in composition (1317–29). A portion of it, containing an elaborate survey of astronomy as known to the Arabs, was translated into Latin in 1342 at the request of Clement VI.

The *Milhamoth* is throughout modelled after the great work of Jewish philosophy, the *Moreh Nebuhim* of Moses Maimonides, and may be regarded as an elaborate criticism from the more philosophical point of view (mainly Averroistic) of the syncretism of Aristotelianism and Jewish orthodoxy as presented in that work. Gersonides was also the author of a commentary on the Pentateuch and other exegetical and scientific works.

A careful analysis of the *Milhamoth* is given in Rabbi Isidore Weil's *Philosophie religieuse de Lévi-Ben-Gerson* (1868). *See* also Munk, *Milanges de phil. juive et arabe;* and Joel, *Religionsphilosophie d. L. Ben-Gerson* (1862). The *Mzlhamoth* was published in 1560 at Riva di Trento, and has been published at Leipzig, 1866. (I A.)

GERSOPPA, FALLS OF, a cataract on the Sharavati river, in North Kanara district of Bombay. The river descends in four cascades called the Raja or Horseshoe, the Roarer, the Rocket and the Dame Blanche. The cliff over which the river plunges is 830 ft. high, and the pool at the base of the Raja Fall is 132 ft. deep. Near the village are extensive ruins (the finest of which is a cruciform temple) of Nagarbastikere, the capital of the Jain chiefs of Gersoppa. Their family was established in power in 1409 by the Vijayanagar kings, but subsequently became practically independent. The chieftaincy was several times held by women, and on the death of the last queen (1608) it collapsed, having been attacked by the chief of Bednur. Among the Portuguese the district was celebrated for its pepper, and they called its queen "Regina da pimenta" (queen of pepper).

GERSTENBERG, HEINRICH WILHELM VON (1737–1823), German poet and critic, was born at Tondern, Schleswig, on Jan. 3, 1737. After studying law at Jena he entered the Danish military service and took part in the Russian campaign of 1762. He spent the next 12 years in Copenhagen, where he was intimate with Klopstock. From 1775 to 1783 he represented Denmark's interests as "Danish Resident" at Lubeck, and in 1786 received a judicial appointment at Altona, where he died on Nov. 1, 1823. His *Ariadne auf Naxos* (1767) is the best cantata of the 18th century; he translated Beaumont and Fletcher's *Maid's Tragedy* (1767), and himself wrote a gruesome but powerful tragedy, *Ugolino* (1768). His chief service to the new literary movement was his *Briefe über Merkwürdigkeiten der Literatur* (1766–70), in which the critical principles of the *Sturm und Drang*—and especially its enthusiasm for Shakespeare—were first definitely formulated.

His *Vermischte Schriften* appeared in 3 vols. (1815). The *Briefe uber Merkwürdigkeiten der Literatur* were republished by 4. von Weilen (1888), and a selection of his poetry, including *Ugolino*, by R. Hamel, will be found in Kürschner's *Deutsche Nationalliteratur*, vol. xlviii. (1884). *See* also *A. M.* Wagner, H. *W. von Gerstenberg und der Sturm und Drang* (1920, etc.).

GERUNIUM. A town in Apulia which was the scene of the one important engagement between the Romans and Carthaginians during the first period of "Fabian" strategy which intervened between Trasimenus (*q.v.*) and Cannae (*q.v.*). It is described under CALICULA. (*See* also PUNIC WARS and HANNIBAL.)

GERVASE OF CANTERBURY (d. *c.* 1210), English monk and chronicler, entered the house of Christchurch, Canterbury, at an early age. He made his profession and received holy orders in 1163, and seems to have resided almost continuously at Canterbury from the time of his admission. The only office which we know him to have held is that of sacrist, which he received after 1190 and laid down before 1197. About 1188 he began the compilation of his *Chronica.* Beginning with the accession of Stephen he continued his narrative to the death of Richard I. Up to 1188 he relies almost entirely upon extant sources; but from that date onwards is usually an independent authority. A second history, the *Gesta Regum,* is planned on a smaller scale and traces the fortunes of Britain from the days of Brutus to the year 1209. The latter part of this work, covering the years 1199–1209, is the only part of the *Gesta* which deserves much attention.

See the introductions and notes in W. Stubbs's edition of the *Historical Works of Gervase of Canterbury* (Rolls Ser., No. 73, 2 vols., 1879–1880).

GERVASE OF TILBURY (*fl.* 1211), Anglo-Latin writer of the late 12th and early 13th centuries, was a kinsman and schoolfellow of Patrick, earl of Salisbury, but lived the life of a scholarly adventurer, wandering from land to land in search of patrons. Before 1177 he was a student and teacher of law at Bologna; his first employer of royal rank was Henry fitz Henry, the young king of England (d. 1183), for whom Gervase wrote a jest-book which is no longer extant. Subsequently Gervase was a clerk in the household of William of Champagne, cardinal archbishop of Reims (d. 1202), and before 1189 he entered the service of William II. of Sicily, who had married Joanna, the sister of Henry fitz Henry. Some time after 1198, he found employment under the emperor Otto IV. Though a clerk in orders Gervase became marshal of the kingdom of Arles, and married an heiress of good family. For the delectation of the emperor he wrote, about 1211, his *Otia Imperialia* in three parts. It is a farrago of history, geography, folklore and political theory—one of those books of table-talk in which the literature of the age abounded. The most interesting of his dissertations are contained in the second part of the *Otia,* where he discusses, among other topics, the geography and history of England.

See the *Otia Imperialia* in *G.* Leibnitz's *Scriptores rerum Brunsvicensium,* vols. i. and ii. (Hanover, 1707); extracts in J. Stevenson's edition of *Coggeshall* (Rolls series, No. 66, 1875). Of modern accounts the best are those by W. Stubbs in his edition of *Gervase of Canterbury;* vol. i. introd. (Rolls series, 2 vols., No. 73, 1879), and by R. Pauli in *Nachrichten der Gesellschaft der Wissenschaften zu Göttingen* (1882). In the older biographies the *Dialogus de scaccario* of Richard Fitz Neal (*q.v.*) is wrongly attributed to Gervase.

GERVEX, HENRI (1852–1929), French painter, was born in Paris on Dec. 19, 1852, and studied painting under Cabanel, Brisset and Fromentin. His early work belonged almost exclusively to the mythological genre which served as an excuse for the painting of the nude—not always in the best of taste; indeed, his "Rolla" of 1878 was rejected by the jury of the Salon *pour immoralité.* He afterwards devoted himself to representations of modern life and achieved signal success with his "Dr. Péan at the Salpétrière," a modernized paraphrase of Rembrandt's "Anatomy Lesson." He was entrusted with several important official paintings and the decoration of public buildings.

GERVINUS, GEORG GOTTFRIED (1805–1871), German historian and Shakespearian commentator, was born on May 20, 1805 at Darmstadt. He studied at Giessen and at Heidelberg, where he attended the lectures of Schlosser. In 1830 he became *Privatdozent* at Heidelberg, and in 1835 professor of history at Göttingen. His *Geschichte der poëtischen Nationallitteratur der Deutschen* (1835–42, 5 vols., subsequently entitled *Geschichte der deutschen Dichtung;* 5th edition, by K. Bartsch, 1871–74) is the first comprehensive and scholarly history of German literature. In 1837 he was one of the seven Gottingen professors dismissed for their protest against the violation of the constitution by the king of Hanover. After spending some years in Heidel-

berg, Darmstadt and Rome, Gervinus settled permanently in Heidelberg, where, in 1844, he was appointed honorary professor.

Between 1849 and 1852 Gervinus published his important work on *Shakespeare* (4 vols., 4th ed., 2 vols., 1872; Eng. trans. by F. E. Bunnett, 1863, new ed. 1877). He also revised his *History of German Literature,* for a fourth edition (1853), and sketched out his *Geschichte des neunzehnten Jahrhunderts* (8 vols., 1854–60), which was preceded by an *Einleitung in die Geschichte des neunzehnten Jahrhunderts* (1853). He died on March 18, 1871.

Gervinus's autobiography *(G. G. Gervinus' Leben, von ihm selbst)* was published by his widow in 1893. It does not, however, go beyond the year 1836. *See* E. Lehmann, *Gervinus, Versuch einer Charakteristik* (1871); *R.* Gosche, *Gervinus* (1871); J. Dorfel, *Gervinus als historischer Denker* (1904); *M.* Rychner, *G. Gervinus* (Berne, 1922).

GERYON (GERYONES, GERYONEUS), in Greek mythology, the son of Chrysaor and Callirrhoë, daughter of Oceanus, who lived in the island of Erytheia, *i.e.,* "red," situated in the far west, the land of the red sunset, later identified with Spain. He is represented as a monster with three heads or three bodies, sometimes with wings, and as the owner of herds of red cattle, which were tended by the giant shepherd Eurytion and the two-headed dog Orthrus. He seems to be a figure of the underworld, and Heracles' exploit a kind of "Harrowing of Hell." To carry off these cattle to Greece was one of the twelve "labours" imposed by Eurystheus upon Heracles. The hero travelled through Europe and Libya, set up the two pillars in the Strait of Gibraltar to show the extent of his journey, and reached the great river Oceanus. Having reached the island, Heracles slew Orthrus, Eurytion and Geryon and drove off the cattle. After various adventures he succeeded in getting them safe to Greece, where they were offered in sacrifice to Hera by Eurystheus. In some accounts Heracles crosses Oceanus in the golden cup or boat of the sun-god Helios. The euhemeristic explanation of the struggle with the triple monster was that Heracles fought three brothers.

See Hesiod, *Theogony,* 287; Herodotus iv. 8; Apollodoros, II. 106; Diod. Sic. iv. 17; Preller-Robert, II. p. 465 ff.; and the classical dictionaries.

GESENIUS, HEINRICH FRIEDRICH WILHELM (1786–1842), German orientalist and biblical critic, was born at Nordhausen, Hanover, on Feb. 3, 1786, and was educated at Helmstadt and at Gottingen. In 1811 he became professor of theology at Halle, where he remained until his death on Oct. 23, 1842. To Gesenius, who was an exceptionally popular teacher, belongs in a large measure the credit of having freed Semitic philology from theological and religious prepossession, and of inaugurating the strictly scientific (and comparative) method.

His chief work, the *Hebraisches* u. *Chaldäisches Handwörterbuch* (1810–12), has passed through several editions (15th ed. 1910, Eng. trans. 1892).

See H. Gesenius, *Wilhelm Gesenius* (1886), and the article in the *Allgemeine deutsche Biographie.*

GESNER, JOHANN MATTHIAS (1691–1761), German classical scholar and schoolmaster, was born at Roth, near Ansbach, and died at Gottingen, where he had become professor of rhetoric. His special merit lies in the attention he devoted to the explanation and illustration of the subject matter of the classical authors.

His principal works are editions of the *Scriptores rei rusticae,* of Quintilian, Claudian, Pliny the Younger, Horace, and the Orphic poems (published after his death); *Primae lineae isagoges in eruditionem universalem* (1756); an edition of B. Faber's *Thesaurus eruditionis scholasticae* (1726), afterwards continued under title *Novus linguae et eruditionis Romanae thesaurus* (1749); *Opuscula minora varii argumenti* (1743–45); *Thesaurus epistolicus Gesnerianus* (ed. Klotz, 1768–70); *Index etymologicus latinitatis* (1749). *See* C. H. Pohnert, J. M. *Gesner und sein Verhaltnis zum Philanthropinismus und Neuhumanismus* (1898);,and Sandys, *Hist. of Class. Schol.,* iii. 5–9 (1908).

GESNER, KONRAD VON (1516–1565), German-Swiss writer and naturalist, called by Cuvier "the German Pliny," was born at Zurich. He took his M.D. at Basle in 1541, and then practised at Zurich, where he became lecturer in physics at the Carolinum. He died of plague on Dec. 13, 1565.

To his contemporaries he was best known as a botanist, though his botanical mss. were not published till long after his death at Nuremberg, 1751–71, he himself issuing only the *Enchiridion historiae plantarum* (1541) and the *Catalogus plantarum* (1542) in four tongues. In 1545 he published his remarkable *Bibliotheca universalis* (ed. J. Simler, 1574), a catalogue (in Latin, Greek and Hebrew) of all past writers with the titles of their works, etc. A second part, *Pandeclarium sive partitionum universalium Conradi Gesneri Ligurini libri xxi.,* with the exception of Bk. 20, appeared in 1548–49. His great zoological work, *Historia animalium,* 4 vols. folio (Ziirich, 1551–58), is the starting-point of modern zoology. Gesner also published in 1555 his *Mithridates de differentiis linguis,* an account of about 130 known languages with the Lord's Prayer in 22 tongues, and his narrative (*Descriptio Montis Fracti sive Montis Pilati*) of his excursion to the Gnepfstein, and in 1556 his edition of the works of Aelian.

See Lives by *J.* Hanhart (Winterthur, 1824) and J. Simler (Ziirich, 1566); *see* also Lebert's *Gesner als Arzt* (Ziirich, 1854). *A* part of his unpublished writing, ed. by Schmiedel, was published at Nuremberg in 1753.

GESSLER, OTTO KARL (1875–), German statesman, was born at Ludwigsburg on Feb. 6, 1875, and entered the legal department in Bavaria in 1905. He was burgomaster of Regensburg in 1911, and of Nuremberg in 1914–19. He was a member of the German Democratic Party and was minister of reconstruction in the Reich from 1919–20, and from 1920–28 minister of defence. After the entry of German troops into the demilitarized zone in 1920, and the consequent occupation by French troops of Frankfurt, Darinstadt and Hamburg, General Noske resigned. and Gessler, following him, began his tenure of office as minister of war, faced with the necessity of allaying the suspicion of the Allies. He had as his colleague General von Seeckt and in spite of difficulties succeeded in reorganizing the *Reichswehr.* Gessler became increasingly unpopular with the parties of the Left, and the social democrats asserted that relations were maintained between the patriotic unions and the *Reichswehr.* He resigned on Jan. 12, 1928.

GESSNER, SALOMON (1730–1788), Swiss poet, painter and etcher, was born at Zurich on April 1, 1730, and died there on March 2, 1788. The first of his writings to attract attention was his *Lied eines Schweizers an sein bewafnetes Mädchen* (1751); but most of his other work consisted of "Pastoral Idylls" in a rhythmical prose. *Der Tod Abels* (1758) was translated into most European languages, including Welsh. The English version ran through about a score of editions, was appreciated by Scott, Byron and Wordsworth, and is mentioned by Hood in his "Dream of Eugene Aram." This extraordinary popularity, not very intelligible now, was apparently due to the fact that he was one of the earliest poets to combine keen observation and love of nature, profound religious feeling and strong patriotism. He translated some of Pope's *Pastorals.* His etchings are better than his somewhat conventional landscapes.

The final collected edition of his works was published at Ziirich in 1841. Lives of him were written by J. J. *Hottinger* (1796) and *H. Wölfflen* (1884). *See* also his *Briefwechsel mit seinem Sohn* (1861) and Bertha Reed, *The Influence of Salomon Gessner on English Literature* (Philadelphia, 1905).

GESSO, an Italian word (Lat. *gypsum*) for "plaster of Paris," especially when used as a ground for painting, or for modelling or sculpture. *(See* **SCULPTURE**: *Technique.)*

GESTALT ("figure," "form," "shape"), an expression introduced into psychology by Christian Ehrenfels in 1890, to indicate the character of a perception as a unity. Thus the seeing of a square does not consist in seeing four equal straight lines enclosing four right angles, but is the perception of the square as a whole. In the same way a melody is the totality of a series of tones, not the sum of the separate tones. Bertrand Russell defines *Gestaltpsychologie* as the psychology of form, dealing with the apprehension of wholes. He says that "reading is a case in point. Whether we read black letters on white paper or white letters on a blackboard is a matter which we hardly notice; it is the forms of the letters that affect us, not their colour or their size." And again, "as we have already seen in connection with *Gestaltpsychologie* and with sentences, the causal unit is often a configuration which

cannot be broken up without losing its distinctive causal properties." He adds a personal illustration: "In writing a book, my own experience—which I know is fairly common, though by no means universal—is that for a time I fumble and hesitate, and then suddenly I see the book as a whole, and have only to write it down as if I were copying a completed manuscript" *(Philosophy,* 1927).

See W. Kohler, *Die physischen Gestalten in Ruhe und im stationaren Zustand* (1920); G. E. Muller, *Komplextheorie und Gestalttheorie* (1923).

GESTA ROMANORUM, a Latin collection of anecdotes and tales, probably compiled about the end of the 13th century or the beginning of the 14th; one of the most popular books of the time, and the source, directly or indirectly, of later literature, in Chaucer, Gower, Shakespeare and others. Of its authorship nothing certain is known; but it was evidently intended as a manual for preachers. The name, *Deeds of the Romans,* is only partially appropriate to the collection, since it comprises fragments of very various origin, oriental and European. The style is barbarous, and the narrative ability of the compiler seems to vary with his source; but he has managed to bring together a considerable variety of excellent material. He gives us, for example, the germ of the romance of "Guy of Warwick"; the story of "Darius and His Three Sons," versified by Occleve; part of Chaucer's "Man of Lawe's Tale"; and a tale of the emperor Theodosius, the same in its main features as that of Shakespeare's *Lear.* Owing to the loose structure of the book, it was easy for a transcriber to insert any additional story into his own copy, and consequently the mss. of the *Gesta Romanorum* exhibit considerable variety. The earliest editions are supposed to be those of Ketelaer and de Lecompt at Utrecht, of Arnold Ter Hoenen at Cologne, and of Ulrich Zell at Cologne—all of uncertain date.

An English translation, probably based directly on the ms. Harl. 5,369, was published by Wynkyn de Worde about 1510–15, the only copy of which now known is preserved in the library of St. John's college, Cambridge. In 1577 Richard Robinson published a revised edition of Wynkyn de Worde, and the book proved highly popular. Between 1648 and 1703 at least eight impressions were issued. In 1703 appeared the first volume of a translation by B. P., probably Bartholomew Pratt, "from the latin edition of 1514." A translation by the Rev. C. Swan forms part of Bohn's antiquarian library and was re-edited by Wynnard Hooper in 1877. Critical editions of the Latin text have been produced by A. Keller (Stuttgart, 1842) and Oesterley (Berlin, 1872). *See* also Warton, "On the Gesta Romanorum," dissertation iii., prefixed to the *History of English Poetry;* Douce, *Illustrations of Shakespeare,* vol. ii.; F. Madden, Introduction to the Roxburghe Club edition of *The Old English Versions of the Gesta Romanorum* (1838); *Gesta Romanorum,* trans. by C. Swan (1924); *Tales of the Monks from the Gesta Romanorum,* ed. *M.* Komroff (1928).

GESUALDO, DON CARLOS, PRINCE OF VENOSA (c. 1560–1613), Italian composer, was born in Naples about the year 1560. He was a nephew of Alfonso Gesualdo, archbishop of Naples, and probably a pupil of Pomponio Nenna of Bari. His fame as a lutenist in his own day was great and spread over all Italy; his madrigals have a peculiar interest to-day in view of their extreme modernness. A dramatic incident in his life was the murder, in 1590, of his wife with her lover by his orders. He afterwards went to the court of Alfonso d'Este at Ferrara, and in 1594 married Donna Eleonore d'Este. In the same year he published his first two books of five-part madrigals. These were followed at intervals by the third, fourth, fifth, and sixth books, and in 1613 there appeared the complete edition: *Partitura delli sei libri de Madrigali a cinque Voci.* The first four books were masterly in style, but the fifth and sixth showed an extraordinary advance in the direction of modern harmony and close affinity between music and words. Gesualdo seems to have been a law unto himself, and to have written down such progressions and modulations as pleased him. His instinct for harmonic effect was marvellous; not less wonderful was his grasp of the emotional possibilities in his texts. The union of words and music was complete. Short, exclamatory phrases and compressed harmony in the dramatic portions contrasted vividly with the smooth contrapuntal writing of quieter moments. One of his most characteristic madrigals, *Moro lasso al mio duolo,* is printed in Dr. Burney's *General History of Music.* A volume of *Sacrae Cantiones* for five, six, and seven voices appeared in 1603.

See Hawkins, *Hist. of Music* (1776); Kroyer, *Anfange der Chromatik im italienischen Madrigal des XVI. Jahrhunderts* (1902); Gray and Hesseltine, *Carlo Gesualdo* (1926); and Grove's *Dictionary of Music and Musicians,* edit. "Gesualdo," by Scott Goddard (on which the present article is based).

Modern reprints of the madrigals will be found in *Raccolta nazionale* (Riccordi, Milan), vols. lix.–lxii.; Barclay Squire, *Ausgewahlte Madrigale* (Breitkopf, Leipzig); L. Torchi, *L'Arte musicale in Italia,* vol. iv.; Pr. de la Moskova, *Recueil des morceaux de musique ancienne.*

GETA, PUBLIUS SEPTIMIUS (189–212), younger son of the Roman emperor Septimius Severus, was born at Mediolanum (Milan). In 198 he received the title of Caesar, and in 209 those of Imperator and Augustus. Between him and his brother Caracalla there existed from their early years a keen rivalry. On the death of their father in 211 they were proclaimed joint emperors; and after the failure of a proposed arrangement for the division of the empire, Caracalla pretended a desire for reconciliation. He arranged a meeting with his brother in his mother's apartments, and had him murdered in her arms by some centurions.

GETAE (gĕt'ī), an ancient people of Thracian origin, closely akin to the Daci *(see* DACIA). Their original home seems to have been the district on the right bank of the Danube between the rivers Oescus (Iskr) and Iatrus (Yantra). The view that the Getae were identical with the Goths is not generally accepted. Their name first occurs in connexion with the expedition of Darius Hystaspes (515 B.C.) against the Scythians *(see* SCYTHIA), in the course of which they were brought under his sway, but they regained their freedom on his return to the East. During the 5th century, they appear as furnishing a contingent of cavalry to Sitalces, king of the Odrysae, in his attack on Perdiccas II., king of Macedon, but the decay of the Odrysian kingdom again left them independent. When Philip II. of Macedon in 342 B.C. reduced the Odrysae to the condition of tributaries, the Getae made overtures to the conqueror. Their king Cothelas undertook to supply Philip with soldiers, and his daughter became the wife of the Macedonian. About this time, perhaps being hard pressed by the Triballi (q.v.) and other tribes, the Getae crossed the Danube. Alexander the Great, before transporting his forces into Asia, decided to make his power felt by the Macedonian dependencies. His operations against the Triballi not having met with complete success, he resolved to cross the Danube and attack the Getae. The latter, unable to withstand the phalanx, abandoned their chief town, and fled to the steppes, whither Alexander was unwilling to follow them. About 326, an expedition conducted by Zopyrion, a Macedonian governor of Thrace, against the Getae, failed disastrously. In 292, Lysimachus declared war against them, alleging as an excuse that they had rendered assistance to certain barbarous Macedonian tribes. He penetrated to the plains of Bessarabia, where his retreat was cut off and he was forced to surrender. Although the people clamoured for his execution, Drornichaetes, king of the Getae, allowed him to depart unharmed, probably on payment of a ransom. When the Gauls made their way into eastern Europe, they came into collision with the Getae, whom they defeated and sold in large numbers to the Athenians as slaves. From this time the Getae seem to have been usually called Daci; for their further history *see* DACIA.

The Getae are described by Herodotus (iv. 93–6) as the most valiant and upright of the Thracian tribes; but what chiefly struck Greek inquirers was their belief in the immortality of the soul and their worship of Salmoxis whom the euhemerists of the colonies on the Euxine made a pupil of Pythagoras. They were experts in the use of the bow and arrow while on horseback.

GETHSEMANE (*i.e.,* "oil-press"), the place to which Jesus withdrew with his disciples on the eve of the Crucifixion. The

Greek terms used of it in the Gospels suggest that it was an enclosed piece of ground. There was probably a house on it and presumably an oil-press. It lay east of Kidron and was a part of the Mount of Olives. The traditional site was secured by the Franciscans (1681), enclosed by them (1848), and laid out as an European flower garden. The "garden" of Christ's time was an orchard. The "Grotto of the Agony" was marked from the 4th century by a sanctuary which was later destroyed. Another church was erected on the site in the 12th century. In 1920 when the church was being rebuilt on the site of the 12th century building, the floor of the 4th century basilica was laid bare, disclosing a different orientation. Plans were altered and re-erection proceeded on the site and along the lines of the primitive church. The Greeks have a garden called Gethsemane distinct from the Latins.

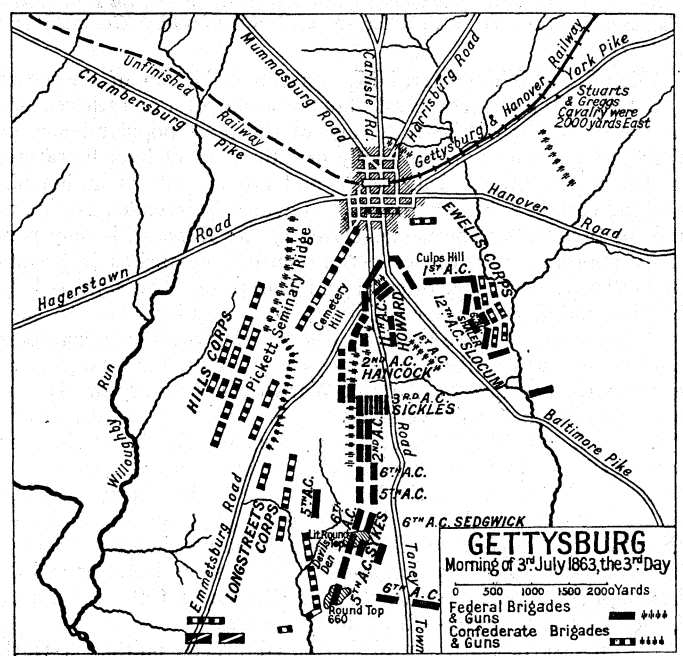
(E. Ro.)

GETTYSBURG, a borough of southern Pennsylvania, U.S.A., 35m. S W. of Harrisburg; the county-seat of Adams county. It is on Federal highways 15, 30 (the Lincoln) and 140; and is served by the Reading and the Western Maryland railways. The population in 1930 was 5,584; in 1940, 5,916. It lies in a valley 1½ mi. wide, at an altitude of 520 ft., surrounded by beautiful rolling country and fertile farm lands. In the national cemetery, which was laid out soon after the battle of Gettysburg, are the graves of 3,814 U.S. soldiers; and the spot where Lincoln, at the dedication in Nov. 1863, delivered his memorable "Gettysburg Address" is marked by a monument. The battlefield (25,000 ac.) was made a national military park in 1895 and was transferred to the jurisdiction of the National park service in 1933. The lines of the battle have been laid out and details of the battle are commemorated by monuments, markers and tablets. Five steel observatories provide views of the entire area. Gettysburg was settled about 1780, became the county seat in 1800, and was incorporated as a borough in 1806.

Battle **of Gettysburg.**—The battle of July 1, 2 and 3, 1863, is often regarded by reliable historians as the turning-point of the American Civil War (*q.v.*). It arose from a chance encounter. Lee, the commander of the Confederate army of Northern Virginia, had intended to concentrate his scattered forces at Cashtown while Meade, the Federal commander, although he had a cavalry division in Gettysburg, had no idea of holding the town prior to the battle on July 1. This cavalry division, supported by two weak army corps, was screening the concentration of his army of the Potomac in a selected position on Pipe Creek to the south-eastward. On June 30, however, one of A. P. Hill's Confederate brigades, sent to Gettysburg to obtain fresh stocks of shoes, had found it occupied by Federal cavalry. This led Hill, on his own initiative, to advance thither on July 1 to explore the situation. At the same moment Ewell's corps was moving down towards Gettysburg from the north. Lee's remaining corps, commanded by Longstreet, was in rear of Hill's corps. Hill's leading brigades met a strenuous resistance from the Federal cavalry division of Gen. John Buford, which was promptly supported by the infantry of the 1st Corps under Gen. J. F. Reynolds. The Federals so far held their own that Hill had to deploy two-thirds of his corps for action, and the western approaches of Gettysburg were still held when Ewell appeared to the northward. Reynolds had already fallen, and the command of the Federals, after being held for a time by Gen. Abner Doubleday, was taken over by Gen. O. O. Howard, the commander of the 11th Corps, which took post to bar the way to Ewell on the north side. But Ewell's attack, of which the decisive thrust at 3.30 P.M. was led by the fiery Jubal Early, swiftly drove back the 11th Corps to Gettysburg; the 1st Corps, with its flank thus laid open, fell back also, and the remnants of both Federal corps retreated through Gettysburg to the Cemetery Hill position. They had lost severely in the struggle against superior numbers, and there had been some disorder in the retreat. Still a formidable line of defence was taken up on Cemetery Hill and both Ewell and Lee refrained from further attacks, for the Confederates had also lost heavily during the day and their concentration was not complete. In the meanwhile Meade had sent forward Gen. W. S. Hancock, the commander of the Federal 2nd Corps, to examine the state of affairs, and on Hancock's report he decided to fight on the Cemetery Hill position. Two corps of his army were still distant, but the 12th arrived before night, the 3rd was near, and Hancock



PLAN OF THE BATTLE OF GETTYSBURG MORNING OF THE THIRD DAY. JULY 3, 1863. SHOWING DISPOSITION OF UNION AND CONFEDERATE TROOPS

moved the 2nd Corps on his own initiative. Headquarters and the artillery reserve started for Gettysburg on the night of July 1. On the other side, the last divisions of Hill's and Ewell's corps formed up opposite the new Federal position, and Longstreet's corps prepared to attack its left.

Owing, however, to misunderstandings between Lee and Longstreet (*q.v.*), the Confederates did not attack early on the morning of the 2nd, so that Meade's army had plenty of time to make its dispositions. The Federal line at this time occupied the horseshoe ridge, the right of which was formed by Culp's Hill, and the centre by Cemetery Hill, from which point the left wing stretched southward, the 3rd Corps on the extreme left, however, being thrown forward considerably. The 12th held Culp's, the remnant of the 1st and 11th Cemetery Hill. On the left was the and, and in its advanced position—the famous "salient"—which was occupied contrary to Meade's orders, the 3rd, soon to be supported by the 5th; the 6th, with the reserve artillery, formed the general reserve. It was late in the day when the Confederate attack was made, and valuable time had been lost, but Longstreet's troops advanced with great spirit. The 3rd Corps salient was the scene of desperate fighting; and the "Peach Orchard" and the "Devil's Den" became as famous as the "Bloody Angle" of Spottsylvania or the "Hornets' Nest" of Shiloh. While the Confederate attack was developing, the important positions of Round Top were unoccupied by the defenders—owing to the 3rd Corps having taken up its unduly advanced position. This omission was repaired only in the nick of time. The danger was perceived by the commanding engineer of the army, General Gouverneur K. Warren, who at once notified General George Sykes, commanding the 5th army corps. General Warren asked for troops with which to hold Little Round Top, and Vincent's and Weed's brigades were sent there. The attack on Little Round Top was, after a hard struggle, repulsed. The 3rd corps, in the meantime attacked by troops of Hill's and Longstreet's corps, was pressed back, and the Confederates actually penetrated the main line of the defenders, though for want of support Wright's brigade (Hill's corps) which

achieved this was quickly driven out. Ewell on the Confederate left waited for the sound of Longstreet's guns, and thus no attack was made by him until late in the day. Here Culp's Hill was carried with ease by one of Ewell's divisions, most of the Federal 12th Corps having been withdrawn to aid in the fight on the other wing; but Early's division was repulsed in its efforts to storm Cemetery hill. Two of Hill's divisions, Pender and Heth, and Rode's division of Ewell's corps, remained inactive

That no decisive success had been obtained by Lee was clear to all, but Ewell's men on Culp's Hill, and Longstreet's corps below Round Top, threatened to turn both flanks of the Federal position, which was no longer a compact horseshoe but had been considerably prolonged, to the left; and many of the units in the federal army had been severely handled in the fighting. General Meade did not discuss a plan of retreat on July 2, but during a council of war that night did discuss plans of battle for July 3. General Lee decided to alter his tactics. The broken ground near Round Top offered so many obstacles that he decided not to press Longstreet's attack further. Ewell was to resume his attack on Meade's extreme right, while the decisive blow was to be given in the centre (between Cemetery Hill and Trostle's) by an assault delivered in a pseudo-Napoleonic manner — Napoleon would scarcely have launched his characteristic decisive thrust with one fresh division against an "unstretched" line and strong front — by the fresh troops of Pickett's division, which belonged to the corps of Longstreet, who was put in charge of the central attack. Meade, however, was not disposed to resign Culp's Hill, and with it the command of the Federal line of retreat to Ewell, and at early dawn on the 3rd a division of the 12th Corps, well supported by artillery, opened the Federal counter-attack; the Confederates made a strenuous resistance. but after four hours' hard fighting the other division of the 12th Corps and a brigade of the 6th, intervened with decisive effect, and the Confederates were driven off the hill. The defeat of Ewell did not, however, cause Lee to alter his plans. Pickett's division was to lead in the great assault, supported by the part of Hill's corps that had not already been engaged. Col. E. P. Alexander, Longstreet's chief of artillery, formed up one long line of 75 guns, and 6j guns of Hill's corps came into action on his left. To the converging fire of these 140 guns the Federals, cramped for space, could oppose only seventy-seven. The attacking troops formed up before 9 A.M., yet it was long before Longstreet could bring himself to order the advance, upon which so much depended, and it was not till about 1 P.M. that the guns at last opened fire to prepare the grand attack. The Federal artillery replied, but after nearly two hours' cannonade its commander, Gen. H. J. Hunt, ordered his batteries to cease fire in order to reserve their ammunition to meet the infantry attack. Ten minutes later, in response to an appeal from Alexander, Pickett asked and received permission to advance, and the infantry moved forward to cross the 1,200–1,400yds. which separated them from the Federal line. Their own artillery was short of ammunition — hence Alexander's appeal; the projectiles of that day were not sufficiently effective to cover the advance at long ranges, and thus the Confederates, as they came closer to the enemy, met a tremendous fire of unshaken infantry and artillery.

The charge of Pickett's division is one of the most famous episodes of military history. In the teeth of an appalling fire from the rifles of the defending infantry, who were well sheltered, and from the guns which Hunt had reserved for the crisis, the Virginian regiments pressed on and finally broke Meade's first line. But the strain was too great for the supporting brigades, Heth's division and parts of Pender's and Anderson's divisions. Hancock made a counterstroke, and the remnant of the Confederates retreated. Of Pickett's own division over three-quarters, 3,393 officers and men out of 4,800, were left on the field, two of his three brigadiers were killed and the third wounded, and of 15 regimental commanders ten were killed and five wounded. One regiment lost 90% of its numbers. The failure of this assault practically ended the battle; but Lee's line was so formidable that Meade did not in his turn send forward the army of the Potomac — a reluctance for which he has been severely criticized. By the morning of July 5, Lee's army was in full retreat for Virginia. He had lost about 30,000 men in killed, wounded and missing out of a total force of perhaps 75,000. Meade's losses were over 23,000 out of about 82,000 on the field. The main body of the cavalry on both sides was absent from the field, but a determined cavalry action was fought on July 3 between the Confederate cavalry under J. E. B. Stuart and that of the Federals under D. McM. Gregg some miles east of the battlefield, and other Federal cavalry made a dashing charge in the broken ground south-west of Round Top on the third day, inflicting thereby, though at great loss to themselves, a temporary check on the right wing of Longstreet's infantry.

GEULINCX, ARNOLD (1624–1669), Belgian philosopher, was born at Antwerp on Jan. 31, 1624. After studying and lecturing at Louvain, he became a Protestant, and in 1663, was made lecturer at the university of Leiden where he died in Nov. 1669.

His philosophical works, edired by J. P. N. Land (1891–93), include the more important *Metaphysica vera* (1691), the *Γνῶθι σεαυτόν, sive Ethica* (under the pseudonym "Philaretus," 167j), *Physica vera* (1688), *Logica restituta* (1662) and *Annotata* in *Principia philosophiae R. Cartesii* (1691).

Geulincx' Erkenntnisstheorie und Occasionalismus* **(1875)**; *E.* Pfleiderer, *A. G. als Hauptvertreter der okkasionalistischen Metaphysik und Ethik* **(1882)**; *G.* Samtleben, *Geulincx, ein Vorganger Spinozas* **(188;)**; G. Monchamp, *Hist. du Cartésianisme en Belgique* (Brussels, **1886)**.

GEUM, a genus of hardy perennial herbs (family Rosaceae), containing about 40 species, widely distributed in temperate and arctic regions; commonly called *avens*. The erect flowering shoots spring from a cluster of radical leaves, which are deeply cut or lobed, the largest division being at the top of the leaf. The flowers are borne singly or in clusters on long stalks at the end of the stem or its branches. They are white, yellow or red in colour, and shallowy cup-shaped. The fruit consists of a number of dry achenes, each bearing a hook formed from the persistent lower portion of the style, and admirably adapted for ensuring distribution. Two species occur in Great Britain; G. *urbanum* is a common hedge-bank plant with small yellow flowers. G. *rivale* (water avens) is a rarer plant, found in England and in the U.S. About 15 other species are natives of North America. Several are easy to cultivate and well adapted for borders or the rock-garden, especially the showy G. *chiloense*, which is known in several horticultural forms with bright scarlet flowers.

GEVELSBERG, a town of Germany, in the Prussian province of Westphalia, 6 m. S.W. from Hagen, on the railway to Düsseldorf. It has hardware factories. Pop. (1939) 22,465.

GEWANDHAUS CONCERTS, famous concerts given at Leipzig, probably those of the oldest standing in existence, since they date back to the time when Bach was cantor of the Thomasschule. They acquired special fame under Mendelssohn (1835–43), while other conductors have included Niels Gade (1844–48), K. Reinecke (1860–95), Arthur Nikisch (1895–1922) and W. Furtwangler (1922–28).

GEX, a town of eastern France, chief town of the arrondissement of Gex, in the department of Ain; formerly it was the chief town of the canton of Gex when it was included in the arrondissement of Nantua; 10 mi. N N.W. of Geneva and 3 mi. from the Swiss frontier. Pop. (1936) 1,342 town; commune, 1,966. It gives its name to the old Pays de Gex, between Alps and Jura, at various times under Swiss, Genevese and counts of Savoy, until in 1601 it came into the possession of France, retaining, however, until the Revolution its old independent jurisdiction, with Gex as its chief town. The Pays de Gex is isolated by the Jura from the rest of French territory, and until 1926 came within the circumscription of the Swiss customs, certain restrictions being imposed on its products by the French customs. The town is situated 2,000 ft. above sea-level at the base of the most east-

erly chain of the Jura. The cutting of diamonds is carried on.

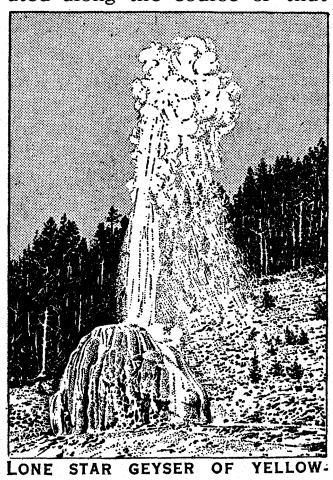
GEYSER, a natural spring or fountain which discharges into the air, at more or less regular intervals of time, a column of heated water and steam; it may consequently be regarded as an intermittent hot spring. The word is the Icelandic *geysir,* gusher or rager, but in native usage it is the proper name of the Great Geyser—the general term ***hver,*** a hot spring, making the nearest approach to the more general sense of the word. Geysers exist in many volcanic regions, as in the Malay Archipelago, Japan and South America; but the three localities where they attain their highest development are Iceland, New Zealand and the Yellowstone Park, U.S.A. The very name by which we call them indicates the historical priority of the Iceland group.

The Iceland geysers are situated about 30m. N.W. of Hekla, in a broad valley at the foot of a range of hills from 300 to 400ft. in height. Within a circuit of about 2m., upwards of one hundred hot springs may be counted, varying greatly both in character and dimensions. The Great Geyser in its calm periods appears as a circular pool about 60ft. in diameter and 4ft. in depth, occupying a basin on the summit of a mound of siliceous sinter; and in the centre of the basin is a shaft, about 10ft. in diameter and 70ft. in depth, lined with the same siliceous material. The clear sea-green water flows over the eastern rim of the basin in little runnels. On the surface it has a temperature of from 76° to 89° C, or from 168° to 188° F. Within the shaft there is a continual shifting both of the average temperature of the column and of the relative temperatures of the several strata. The results of the observations of Bunsen and A. L. O. Descloizeaux in 1847 showed that the temperature of the column diminishes from the bottom upwards; that, leaving out of view small irregularities, the temperature in all parts of the column is found to be steadily on the increase in proportion to the time that has elapsed since the previous eruption; that even a few minutes before the great eruption the temperature at no point of the water column reached the boiling point corresponding to the atmospheric pressure at that part; and finally, that the temperature about half-way up the shaft made the nearest approach to the appropriate boiling point, and that this approach was closer in proportion as an eruption was at hand. The Great Geyser has varied very much in the nature and frequency of its eruptions since it began to be observed. In 1809 and 1810, according to Sir W. J. Hooker and Sir George S. Mackenzie, its columns were 100 or 90ft. high, and rose at intervals of 30 hours, while, according to Henderson, in 1815 the intervals were 6 hours and the altitude from 80 to 150ft.

About 100 paces from the Great Geyser is the ***Strokkr*** or churn, which was first described by Stanlay in 1789. The shaft in this case is about 44ft. deep, and, instead of being cylindrical, is funnel-shaped, having a width of about 8ft. at the mouth, but contracting to about 10in. near the centre. By casting stones or turf into the shaft so as to plug the narrow neck, eruptions can be accelerated, and they often exceed in magnitude those of the Great Geyser itself. During quiescence the column of water fills only the lower part of the shaft, its surface usually lying from 9 to 12ft. below the level of the soil. Unlike that of the Great Geyser, it is always in ebullition, and its temperature is subject to comparatively slight differences.

The great geyser district of New Zealand is situated in the south of the province of Auckland in or near the upper basin of the Waikato river, to the north-east of Lake Taupo. The scene presented in various parts of the districts is far more striking and beautiful than anything of the same kind to be found in Iceland, but this is due not so much to the grandeur of the geysers proper as to the bewildering profusion of boiling springs, steam-jets and mud-volcanoes, and to the fantastic effects produced on the rocks by the siliceous deposits and by the action of the boiling water. In about 1880 the geysers were no longer active, and this condition prevailed until the Tarawera eruption of 1886, when seven gigantic geysers came into existence; water, steam, mud and stones were discharged to a height of 600 to 800ft. for a period of about four hours, when quieter conditions set in. Waikite near Lake Rotorua throws a column to a height of 30 or 35ft.

In the Yellowstone National Park, in the north-west corner of Wyoming, the various phenomena of the geysers can be observed on a large scale. The geysers proper are about one hundred in number; the non-eruptive hot springs are much more numerous, there being more than 3000. The dimensions and activity of several of the geysers render those of Iceland and New Zealand almost insignificant in comparison. The principal groups are situated along the course of that tributary of the Upper Madison which bears the name of Fire Hole River. Many of the individual geysers have very distinctive characteristics in the form and colour of the mound, in the style of the eruption and in the shape of the column. The "Giantess" lifts the main column to a height of only 50 or 60ft., but shoots a thin spire to no less than 250ft. The "Castle" varies in height from 10 or 15 to 250ft.; and on the occasion of greatest effort the noise is appalling, and shakes the ground like an earthquake. "Old Faithful" owes its name to the regularity of its action. Its eruptions, which raise the water to a height of 100 or 150ft., last for about five minutes, and recur every hour or thereabouts. The "Beehive" sometimes attains a height of 219ft., and the water, instead of falling back into the basin, is dissipated in spray.



LONE STAR GEYSER OF YELLOWSTONE PARK. SOMETIMES CALLED THE "BEE-HIVE– BECAUSE OF ITS SHAPE

The eruptive action of geysers can be explained as follows: far down the pipe the water is at a temperature much above its boiling point in the open air, owing to the pressure of the column of water above it, and its temperature is constantly increasing owing to volcanic heat below. The vapour pressure of the steam also increases, till eventually a point is reached when it exceeds the pressure due to the water above. The water at this point passes suddenly into steam, which by expanding raises the column of water above, causing an overflow at the surface. The consequent diminution of pressure allows more water to flash into steam, which blows out the whole column of water and causes the eruption.

GEZELLE, GUIDO (1830–1899), Flemish poet, was born at Bruges, on May 1, 1830, and died at Bruges on Nov. 27, 1899. He was one of the earliest and greatest leaders for the revival of Flemish as a literary language. He wrote in the dialect of west Flanders patriotic and religious poems inspired by deep feeling snd a philosophic spirit. His first volumes of poetry appeared in 1862.

His works were collected ***(Volledige Gedichten)*** in 6 vols. in 1900. ***See*** C. van Herwarden, *Guido Gezelle, leven en werken* (1911).

GEZER, a royal Canaanite city described in the Old Testament as on the boundary of Ephraim, in the maritime plain, and near the Philistine border. According to Jerome, Gezer was four Roman miles north of Nicopolio (ʿAmwās). At this point, near the village of Abu Shūsheh, stands Tell Jezar, whose identification with Gezer was suggested by Clermont Ganneau in 1871 and subsequently confirmed by the discovery of boundary inscriptions with the name Gezer inscribed on rock-outcrops around the site.

History.—In the time of Papi I. (*c.* 2500 B.C.) Gezer marked the high tide of Egyptian invasion of Palestine, and was an objective in the time of Sesostris I. (1980–1935 B.C.). It is the Kazir of Thutmose III.'s lists (*c.* 1500 B.C.) and three of the Tel el Amarna tablets came from Gezer (Gazri). Merneptah, in quelling the revolt of the Palestinian cities, evidently looked upon Gezer as formidable, for he proclaims himself "Binder of Gezer," and "Seized upon is Gezer" is a triumphal cry in his hymn of victory. Throughout the Maccabean wars Gazera, as it was known, was an important frontier post.

Archaeology.—The site was excavated systematically and thoroughly by Macalister for the Palestine Exploration Fund

BY COURTESY OF (2, 8) THE NEW ZEALAND HIGH COMMISSIONER, (7) MAGNUS OLAFSSON; PHOTOSRAPHS, (1, 3, 4, 6) EWING GALLOWAY, (5) ELMENDORF FROM EWING GALLOWAY

GEYSERS IN ICELAND, NEW ZEALAND AND AMERICA

1. The Giant Geyser, upper geyser basin, Yellowstone National Park, U.S. This geyser lifts its main column of hot water to a height of 50 to 60 ft. and sends a thinner column of water to a height of 250 ft.
2. Waikite Geyser, New Zealand. This eruptive spring, situated close to Lake Rotorua, throws a column of water over 30 ft. high. Volcanic formations around the geyser are due to siliceous deposits from geyser in eruption
3. Old Faithful Geyser, Yellowstone National Park. Its eruptions last for five minutes and occur at regular intervals of about an hour
4. View of the crater of Waimauku Geyser, New Zealand, measuring 280x 400 ft., showing encrustations and erosions on surrounding walls
5. Geyserite formation at Mammoth Hot Springs, Yellowstone National Park. The hill of geyser encrustation resembling volcanic cone
6. Castle Geyser, Yellowstone National Park, showing mound of "castle"
7. Gyrla (Bogey) Geyser in Iceland, where these phenomena were first observed and named by white men, about 25m. from Reykjavik
8. Pohutu Geyser, Rotorua, New Zealand, beginning its eruptive action

from 1902–05 and 1907–09. The excavations revealed a whole series of strata covering all periods from the Neolithic age to the time of the Maccabees, together with a long series of structures and objects illustrative of a corresponding variety of cultures and cults. Amongst the discoveries of special interest are two cuneiform tablets of the 7th century B.C., an alignment of monoliths (mazzēbōth), many instances of presumed infant sacrifice, a water tunnel cut to a vertical depth of 94 ft., an agricultural calendar for the year written on a limestone plaque, and a variety of cult objects. Part of the site, including the acropolis, was unfortunately not available for excavation. Fresh excavations were begun on the site in 1923–24, at the instigation of a private individual. Tombs and diverse epochs with furniture intact have been disclosed.

See R. A. S. Macalister, *Bible Sidelights from the Mound of Gezer* (1906), and *The Excavations of Gezer*, 3 vols. (1912); W. N. Stearns, "The Story of Gezer," *Bibliotheca Saera* 75 (1918) 104 *seq.*

(E. Ro.)

GFRÖRER, AUGUST FRIEDRICH (1803–1861), German historian, was born at Calw, Wdrttemberg, on March 5, 1803. He was librarian at Stuttgart (1830–46), and professor of history at Gottingen (1846–61). In his Kritisclte Geschicltte des *Urchristenthums* (3 vols., Stuttgart, 1838) Gfrorer developed opinions unfavourable to Protestantism, which were plainly avowed in his Church history (Allgemeine *Kirchengeschichte bis Beginn* des *14ten* Jahrhunderts, Stuttgart, 1841–46). In 1848 he sat as a representative in the Frankfurt parliament, where he supported the "High German" party, and in 1853 he publicly went over to the Church of Rome. He was a bitter opponent of Prussia and an ardent controversialist. He died at Carlsbad on July 6, 1861.

Among his later historical works the most important is the *Geschichte der ost-* u. *westfränkischen Karolinger* (Freiburg, 1848); but others, notably that on Hildebrand (*Papst Gregorius VII.* u. *sein Zeitalter*, 7 vols., 1859–61), are also of real value.

GHADAMES, GADAMES or **RHADAMES** (anc. Κιδάμη, Lat. Cidamus or Cydamus), a town in an oasis of the same name, in that part of the Sahara which forms part of the Italian colony of Tripoli-Tamia. It is about 300 m. S.W. of the city of Tripoli and some 10 m. E. of the Algerian frontier, which closely follows the caravan route from Ghadames to Ghat. The oasis, which stands on the cretaceous Tinghert plateau 1,200 ft. above the sea, is enclosed by a circular rampart over 3 m. in circumference, the town being at the S.W. corner. The mean temperature is 73°, the rainfall about 8 in., and the number of rainy days six. The streets of the town are narrow and vaulted and have been likened to the bewildering galleries of a coalpit. The roofs are laid out as gardens and preserved for the exclusive use of the women. The Ghadamsi merchants have been known for centuries as keen and adventurous traders. Ghadames itself is the centre of a large number of caravan routes, and in the early part of the 19th century about 30,000 laden camels entered its markets every year. Its prosperity was affected by the competition of the Tripolitan merchants about 1873 and by the invasion of Bornu by Rabah in 1893. The chief articles brought by the caravans are ostrich feathers, skins and ivory and one of the principal imports is tea. In 1845 the population was estimated at 3,000, of whom about 500 were slaves and strangers, and upwards of 1,200 children; in 1905 it amounted in round numbers to 7,000. The inhabitants are chiefly Berbers and Arabs, while many Tuaregs (*q.v.*) live outside.

Before the Christian era Ghadames was a stronghold of the Garamantes, who took their name from Garama (see FEZZAN). There are remains of the old settlement of the Garamantes on the plateau near the town. In the 7th century Ghadames was conquered by the Arabs. It appears afterwards to have fallen under the power of the rulers of Tunisia, then to a native dynasty which reigned at Tripoli, and in the 16th century it became part of the Turkish vilayet of Tripoli. It has since then shared the political fortunes of that country.

GHALCHA, GHARCHA, a name applied by the Turki-speaking population to the group of tribes about the sources of the Oxus and the mountainous regions near them. These fall into three parts: (1) Yüdghāh, held by the Yidakh tribes, south of the Dorlh Pass over the Hindu Kūsh, in the British sphere of influence, (2) Wakhān, the Wakhi tribe's seat on the upper Panj, Sanglich and Minjān, on the valleys of the Warōj, in Afghanistan, and (3) Shignān, Roshān, about the confluence of the Panj and Oxus, Sarikōl on the eastern slope of the Pamir, and Yaghnōb, on an upper affluent of the Zar-afshln — all in the Russian sphere.

Doubtless Iranian by origin, the Ghalchas are classed as an outlier of the shortheaded Alpine race, and the form Gharcha suggests that they may be akin to the Gharjis of Gharjistān. They differ from the Tljiks of Badakhshān in type. They are tall, with hair black, chestnut or red, eyes brown to bluish grey, oval faces and nose slightly aquiline. Converted at an early date to the Shi'a creed of Islam they still profess it, which fact separates them from their orthodox neighbours. Wakhān used to export musk, gold, silver and slaves, and Minjān, lapis lazuli, from mines still worked, but little else is known of them, excepting their dialects which differ in each of the regions mentioned. Of the languages four distinct forms are known: Wakhi, spoken in Wakhan, Shigni or Khigni in Shignan and Roshan, Ish Kashmi and Murjani or Munji. These tongues possess sonic forms in common with the Dardic languages (*q.v.*), to the south, thus linking the latter with the Iranian tongues. Persian is the second language of these bilingual people.

The Encyclopaedia of Islam, II, 1914, and the *Linguistic Survey of India*, vol. x. (1921) pp. 455 *sqq.* and vol. i. (1927), give full bibliographies.

GHARIAL (*Gavialis* gangeticus), also called the gavial, a relative of the crocodile (*q.v.*), inhabiting northern India. The snout is very long and slender and the reptile feeds on fishes. The false gharial (Tomistoma) of Borneo and Sumatra is very similar, but has fewer teeth (20 or 21, instead of 27 to 29, on each side of the upper jaw). (See CROCODILE.)

GHATS, EASTERN AND WESTERN, ranges of mountains along the eastern and western shores of the Indian peninsula. The word properly applies to the passes through the mountains, but from an early date was transferred by Europeans to the mountains themselves.

The Eastern Ghats run in fragmentary spurs and ranges parallel with the Madras coast. They begin in the Orissa district of Balasore, pass southwards through Cuttack and Puri, enter the Madras presidency in Ganjam, and sweep southwards. They run at a distance of 50 to 1jo m. from the coast, except in Ganjam and Vizagapatam, where in places they almost abut on the Bay of Bengal. The rocks are granite, gneiss and mica slate, with clay slate, hornblende and primitive limestone overlying. The average elevation is about 1,500 ft., but several hills in Ganjam reach 4,000 to 5,000 ft. Their line is pierced by the Godavari, Kistna, Cauvery and other rivers.

The Western Ghats (Sahyadri in Sanskrit) start from the south of the Tapti valley and run south, meeting the Eastern Ghats at an angle near Cape Comorin. The range is uninterrupted except by a valley 25 m. across, known as the Palghat gap, through which runs the principal railway of the south of India. The length of the range is 800 m. from the Tapti to the Palghat gap, and south of this about 200 m. to the extreme south of the peninsula. In many parts there is only a narrow strip of coast between the hills and the sea. The average elevation is 3,000 ft., precipitous on the western side facing the sea, but more gradual on the east down to the plateaux. The highest peaks in the northern section are Kalsubai, 5,427 ft.; Harischandragarh, 4,691 ft.; and Mahabaleshwar, where is the summer capital of the government of Bombay, 4,700 ft. South of Mahabaleshwar the elevation diminishes, but again increases, and attains its maximum towards Coorg, where the highest peaks vary from 5,500 to 7,000 ft., and where the main range joins the interior Nilgiri hills. South of the Palghat gap, the peaks of the Western Ghats rise as high as 8,000 ft. The rocks are mainly trap in the northern and gneiss in the southern section.

GHAZALI or **ALGAZEL** [Mohammed ibn Mohammed Abu Ḥamid al-Ghazali] (1058–1111), Arabian philosopher and theologian, was born at Tus, and was educated in his native town,

in Jorjan and in Nishapur. In 1091 the celebrated vizier Nizam ul-Mulk appointed him professor in his college at Baghdad. Here he was engaged in writing against the Isma'ilites (Assassins), but after four years he suddenly gave up his chair, left his family and devoted himself to an ascetic life. This was due to a growing scepticism, which gradually gave way to mysticism, and to his attack on philosophers. Some of their problems which he declared insoluble were the eternity of the world, the reality of the Divine attributes, God's knowledge of things outside of Himself and the independence and immortality of the soul. Ghazali wandered through Damascus, Jerusalem, Hebron, Mecca, Medina and Alexandria until, at the wish of the sultan Malik Shah, he became professor in the college of Nizam ul-Mulk at Nishapur. He returned soon after to Tūs, where he died in Dec. 1111.

Of the 69 works ascribed to Ghazali (cf. C. Brockelmann's Gesch. d. *arabischen* Litteratur, i., Weimar, 1898), the chief are: a treatise on eschatology called Ad-durra *ul-fākhira* ed. L. Gautier (Geneva, 1878); the great work, Ihyd *ul-'Ulūm* ("Revival of the sciences") (Bulaq, 1872; Cairo, 1889); a commentary by al-Murtada called the *Ithāf*, published in 13 vols. at Fez, 1885–87, and in 10 vols. at Cairo, 1893; the Bidayat ul-Hiddya (Bulaq, 1870, and often at Cairo); a compendium of ethics, *Mizān ul-'Amal*, Heb. trans., ed. J. Goldenthal (Paris, 1839); a popular treatise on ethics, the *Kimīya us-Sa'āda*, ed. H. A. Homes as *The* Alchemy of Happiness (Albany, N.Y., 1873); the ethical work *O* Child, ed. by Hammer-Purgstall in Arabic and German (Vienna, 1838); the Destruction of Philosophers (*Tahafūt ul-Falāsifa*) (Cairo, 1885, and Bombay, 1887); the *Maqāsid ul-Falāsifa*, of which the Latin trans. by Gundisalvi was pubd. at Venice, 1506, later ed. by G. Beer (Leiden, 1888); the *Kitāb ul-Munqid*, describing the changes in his philosophy, ed. by F. A. Schmolders in his Essai *sur* les *écoles* philosophiques *chez* les Arabes (1842), also at Constantinople, 1876, and translated into French by Meynard (1877); answers to questions ed. in Arabic and Hebrew, with German trans. by H. Malter (Frankfort, 1896); Eng. trans., Confessions of *al*-Ghazzali, by Claud Field (1909).

For Ghazālī's life see McG. de Slane's translation of Ibn Khallikān, ii. ff.; R. Gosche's Uber *Ghazālī's* Leben und Werke (1859); D. B. Macdonald's "Life of al-Ghazāli," in Journal of American Oriental Society (1899), Carra de Vaux's Gazali (1902) and bibliography in Überweg's Gesch. der Philosophie (Bd. 2, 1928); see ARABIAN PHILOSOPHY.

GHĀZĪ (Arabic "warrior"). A Mohammedan who has vowed to exterminate unbelievers by the sword. It is also used by the Turks as a title of honour, generally translated "the Victorious," for military officers of high rank, who have distinguished themselves in the field against non-Muslim enemies; thus it was assumed by Mustafa Kemal Pasha, President of the Turkish Republic.

GHAZIABAD, a town of British India in the Meerut district of the Gnited Provinces. Pop. (1931) 18,831. The town was founded in 1740 by Ghazi-ud-din, son of Azaf Jah, first nizam of the Deccan, and takes its name from its founder. It has considerably risen in importance as an important railway junction and does some trade in grain and hides.

GHAZIPUR, a town and district of British India, in the Benares division of the United Provinces. The town stands on the left bank of the Ganges, 44 m. E. of Benares. It is the headquarters of the dwindling opium department, where all the opium grown under licence from Government used to be collected and manufactured. There are also scent distilleries, using the produce of the rose-gardens in the vicinity. Pop. (1931) 27,498.

The district of Ghazipur has an area of 1,302 sq.m. It forms part of the great alluvial plain of the Ganges, which divides it into two unequal portions. The northern tract lies between the Gumti and the Gogra, whose confluences with the main stream mark its eastern and western limits respectively. The southern tract is a much smaller strip of country, enclosed between the Karamnasa and the great river itself. In 1931 the population was 824,971. Sugar refining is the chief industry, and provides the principal article of export.

GHAZNI, a famous city in Afghanistan, the seat of an extensive empire under two mediaeval dynasties, and interesting in the modern history of British India. Ghazni stands on the high tableland of central Afghanistan, in 68° 18' E. 33° 44' N., at a height of 7,280 ft., and on the direct road between Kandahar and Kabul, 221 m. by road N.E. from the former, and 92 m. S.W. from the latter. A very considerable trade in fruit, wool, skins, etc., is carried on between Ghazni and India by the *povindah* merchants. Ghazni, long in decay, is reviving since the opening of the Kabul road for motors. It stands at the base of the terminal spur of a ridge of hills, an offshoot from the Gul-Koh, which forms the watershed between the Arghandáb, and Tarnak rivers. The castle stands at the northern angle of the town next the hills, and is about 150 ft. above the plain. The town walls are on an elevation, partly artificial, and form an irregular square, partly of stone or brick laid in mud, and partly of clay built in courses, flanked by numerous towers with three gates. The plain in the direction of Kandahar is bare except near the river, where villages and gardens are tolerably numerous. Abundant crops of wheat and barley are grown, as well as of madder, besides minor products. Snow lies 2 or 3 ft. deep for about three months, and tradition speaks of the city as having been more than once overwhelmed by snowdrift. Fuel consists chiefly of prickly shrubs. In summer the heat is not like that of Kandahar or Kabul, but the radiation from the bare heights renders the nights oppressive, and constant dust-storms occur. Probably the existing site formed the citadel only of the city of Mahmud. The remarks of Ibn Batuta (c. 1332) already suggest the present state of things, viz., a small town occupied, a large space of ruin; for a considerable area to the north-east is covered with ruins, or rather with a vast extent of mounds, spoken of as Old Ghazni. The only remains retaining architectural character are two remarkable towers rising to the height of about 140 ft., and some 400 yd. apart belonging, on a smaller scale, to the same class as the Kutb Minar at Delhi (*q.v.*). Arabic inscriptions in Cufic characters show the most northerly to have been the work of Mahmud himself, the other that of his son Masa'ud. On the Kabul road, a mile beyond the Minaret of Mahmud, is a village called Rauzah. Here, in a poor garden, stands the tomb of the famous conqueror. The village stands among luxuriant gardens and orchards, watered by a copious aqueduct.

History.— The city is not positively mentioned by any ancient author but it is possibly the Gazaca which Ptolemy places among the *Paropamisadae*, and this may not be inconsistent with Sir H. Rawlinson's identification of it with *Gazos*, an Indian city spoken of by two obscure Greek poets as an impregnable place of war. We seem to have definite evidence of the existence of the city before Mohammedan times (644) in the travels of the Chinese pilgrim, Hsüan Tsang, who speaks of *Ho-si-na* (*i.e.*, probably Ghazni) as one of the capitals of *Tsaukuta* or Arachosia, a place of great strength. In early Mohammedan times the country adjoining Ghazni was called *Zābul*. When the Mohammedans first invaded that region Ghazni was a wealthy entrepôt of the Indian trade. Of the extent of this trade some idea is given by Ibn Haukal, who states that at Kabul, then a mart of the same trade, there was sold yearly indigo to the value of two million dinars (£1,000,000). The provinces on the Helmund and about Ghazni were invaded as early as the caliphate of Moawiya (662–680). The arms of Yaqub b. Laith swept over Kabul and Arachosia (Al-Rukhaj) about 871, and the people of the latter country were forcibly converted. Though the Hindu dynasty of Kabul held a part of the valley of Kabul river till the time of Mahmud, it is probably to the period just mentioned that we must refer the permanent Mohammedan occupation of Ghazni. In the latter part of the 9th century the family of the Samanid, sprung from Samarkand, reigned in splendour at Bokhara. Alptagin, originally a Turkish slave, and high in the service of the dynasty, about the middle of the 10th century, losing the favour of the court, wrested Ghazni from its chief (who is styled Abu Bakr Lawik, wali of Ghazni), and established himself there. His government was recognized from Bokhara and held till his death. In 977 another Turk slave, Sabuktagin, who had married the daughter of his master Alptagin, obtained rule in Ghazni. He made himself lord of nearly all the present territory of Afghanistan and of the Punjab. In 997 Mahmud, son of Sabuktagin, succeeded to the government, and with his name Ghazni and the Ghaznevid dynasty have become perpetually associated. Issuing forth year after year from that capital, Mahmud (*q.v.*) carried fully 17 expeditions

of devastation through northern India and Gujarat, as well as others to the north and west. The wealth brought back to Ghazni was enormous, and contemporary historians give glowing descriptions of the magnificence of the capital as well as of the conqueror's munificent support of literature. Mahmud died in 1030, and some 14 kings of his house came after him; but though there was some revival of importance under Ibrahim (1059–99), the empire never reached anything like the same splendour and power. It was overshadowed by the Seljuks of Persia and by the rising rivalry of Ghor (*q.v.*), the hostility of which it had repeatedly provoked. Bahram Shah (1118–52) put to death Kutbuddin, one of the princes of Ghor, called king of the Jibal or hill country, who had withdrawn to Ghazni. This prince's brother, Saifuddin Suri, came to take vengeance and drove out Bahram. But the latter, recapturing the place (1149), paraded Saifuddin and his vizier ignominiously about the city and then hanged them on the bridge. Ala-uddin of Ghor, younger brother of the two slain princes, then gathered a great host and came against Bahram, who met him on the Helmund. The Ghori prince. after repeated victories, stormed Ghazni and gave it over to fire and sword. The dead kings of the house of Mahmud, except the conqueror himself and two others, were torn from their graves and burnt, whilst the bodies of the princes of Ghor were solemnly disinterred and carried to the distant tombs of their ancestors. It seems certain that Ghazni never recovered the splendour that perished then (1152). Ala-uddin, who from this deed became known in history as *Jahān-soz* (Burn-all), returned to Ghor, and Bahram reoccupied Ghazni; he died in 1157. In the time of his son Khusru Shah, Ghazni was taken by the Turkish tribes called Ghuzz (generally believed to have been what are now called Turkomans). The king fled to Lahore, and the dynasty ended with his son. In 1173 the Ghuzz were expelled by Ghiyasuddin, sultan of Ghor (nephew of Ala-uddin Jahansoz), who made Ghazni over to his brother Muiz-uddin. This famous prince, whom the later historians call Mohammed Ghori, shortly afterwards (1174–75) invaded India, taking Multan and Uchh. This was the first of many successive inroads on western and northern India, in one of which Lahore was wrested from Khusru Malik, the last of Mahmud's house, who died a captive in the hills of Ghor. In 1192, the king of Ajmere being defeated and slain near Thanewar, the whole country from the Himalayas to Ajmere became subject to the Ghori king of Ghazni. On the death of his brother Ghiyasuddin, with whose power he had been constantly associated and of whose conquests he had been the chief instrument, Muizuddin became sole sovereign over Ghor and Ghazni, and the latter place was then again for a brief period the seat of an empire nearly as extensive as that of Mahmud the son of Sabuktagin. Muizuddin crossed the Indus once more to put down a rebellion of the Khokhars in the Punjab, and on his way back was murdered by a band of them, or, as some say, by one of the *Mulāhidah* or Assassins. The slave lieutenants of Muizuddin carried on the conquest of India, and as the rapidly succeeding events relieved their dependence on any master they established at Delhi that monarchy of which the shadow was still surviving in 1857. The death of Muizuddin was followed by struggle and anarchy, ending for a time in the annexation of Ghazni to the empire of Khwarizm by Mohammed Shah, who conferred it on his famous son, Jelaluddin, and Ghazni became the headquarters of the latter. After Jenghiz Khan had extinguished the power of his family in Turkestan, Jelaluddin defeated the army sent against him by the Mongol at Parwan, north of Kabul. Jenghiz then advanced and drove Jelaluddin across the Indus, after which he sent Ogdai, his son, to besiege Ghazni. Henceforward Ghazni is much less prominent in Asiatic history. It continued subject to the Mongols, sometimes to the house of Hulagu in Persia, and sometimes to that of Jagatai in Turkestan.

Ibn Batuta (*c.* 1332) says the greater part of the city was in ruins, and only a small part continued to be a town. Timur seems never to have visited Ghazni, but we find him in 1401 bestowing the government of Kabul, Kandahar, and Ghazni on Pir Mohammed, the son of his son Jahangir. At the end of the century it was still in the hands of a descendant of Timur, Ulugh Beg Mirza, who was king of Kabul and Ghazni. The illustrious nephew of this prince, Baber, got peaceful possession of both cities in 1504, and has left notes on both in his own inimitable Memoirs. "It is," he says, "but a poor mean place, and I have always wondered how its princes, who possessed also Hindustan and Khorasan, could have chosen such a wretched country for the seat of their government, in preference to Khorasan." He commends the fruit of its gardens, which still contribute largely to the markets of Kabul. Ghazni remained in the hands of Baber's descendants, reigning at Delhi and Agra, till the invasion of Nadir Shah (1738), and became after Nadir's death a part of the new kingdom of the Afghans under Ahmad Shah Durani. The historical name of Ghazni was brought back from the dead, as it were, by the news of its capture by the British army under Sir John Keane, July 23, 1839, at the cost of 182 killed and wounded. Two years and a half later the Afghan outbreak against the British occupation found Ghazni garrisoned by a Bengal regiment of sepoys, but neither repaired nor provisioned. They held out under great hardships from Dec. 16, 1841, to Mar. 6, 1842, when they surrendered. In the autumn of the same year General Nott, advancing from Kandahar upon Kabul, reoccupied Ghazni, destroyed the defences of the castle and part of the town, and carried away the famous gates of Somnath (*q.v.*).

GHEE, clarified butter used in India (Hindu, *ghi*). The best is prepared from butter of the milk of cows, the less esteemed from that of buffaloes. The butter is melted over a slow fire and set aside to cool; the thick, opaque, whitish, and more fluid portion, or ghee, representing the greater bulk of the butter, is then removed. The less liquid residue, mixed with ground-nut oil, is sold as an inferior kind of ghee. It may be obtained also by boiling butter over a clear fire, skimming it the while, and, when all the water has evaporated, straining it through a cloth. Ghee which is rancid or tainted, as is often that of the Indian bazaars, is said to be rendered sweet by boiling with leaves of the *Moringa pterygosperma* or horse-radish tree.

In India, ghee is one of the commonest articles of diet, and indeed enters into the composition of everything eaten by the Brahmans. It is also extensively used in Indian religious ceremonies, being offered as a sacrifice to idols, which are at times bathed in it. Sanskrit treatises on therapeutics describe ghee as cooling, emollient, and stomachic, as capable of increasing the mental powers, and of improving the voice and personal appearance, and as useful in eye-diseases, tympanitis, painful dyspepsia, wounds, ulcers, and other affections. Old ghee is in special repute among the Hindus as a medicinal agent, and its efficacy as an external application is believed by them to increase with its age. Ghee more than ten years old, the *purāna ghrita* of Sanskrit *materia medicas,* has a strong odour and the colour of lac. Some specimens which have been much longer preserved—and "clarified butter roo years old is often heard of"—have an earthy look, and are quite dry and hard, and nearly inodorous. Medicated ghee is made by warming ordinary ghee to remove contained water, melting, after the addition of a little turmeric juice, in a metal pan at a gentle heat, boiling with the prepared drugs till all moisture is expelled and straining through a cloth.

GHEEL or **GEEL,** a town of Belgium, about 30 m. E. of Antwerp and in the same province. Pop. (1930) 18,638. It is remarkable on account of its colony of insane persons. The legend reads that in the year 600 Dymphna, an Irish princess, was executed here by her father; in consequence of certain miracles she was canonized and made patron saint of the insane. The old Gothic church is dedicated to her, and in the choir is her shrine, with fine panel paintings-by, probably, a contemporary of Memling. The colony of the insane is in farms and houses round the little place within a circumference of 30 m. and is said to have existed since the 13th century. This area is divided into four sections, each having a doctor and a superintendent attached to it. The Gheel system is regarded as the most humane method of dealing with the insane.

GHENT, the capital of East Flanders, Belgium, at the junction of the Scheldt and the Lys (Leie). Pop. (1938) 162,858. The city is divided by the rivers (including the small streams Lieve and Moere) and by canals, some navigable, into numerous

islands connected by over 200 bridges of various sorts; there are fine quays and docks. The cathedral of St. Bavo has a rich interior, its crypt dates from 941, the choir from 1274–1300, the Late Gothic choir chapels from the 15th century, and the nave and transept from 1533–54. Among the treasures of the church is the famous "Worship of the Lamb" by Hubert and Jan van Eyck. The original 12 panels, dispersed since 1816, were brought together again in 1920 under the provisions of the Treaty of Versailles. Among the other 55 churches may be mentioned that of St.

THE OUDEBURG OR GRAVENSTEEN. DATING FROM 1180

This mediaeval fortress, the stronghold of the early counts of Flanders, was restored by the city after serving for nearly 100 years as a factory

Nicholas, an Early Gothic building, the oldest church in date of foundation in Ghent, and that of St. Michael, completed in 1480, with an unfinished tower. In the centre of the city stands the unfinished Belfry (Belfort), a square tower some 300 ft. high, built 1183–1339. It has a cast-iron steeple (restored in 1854), on the top of which is a gold dragon which, according to tradition, was brought from Constantinople either by the Varangians or by the emperor Baldwin after the Latin conquest. Close to it is the former Cloth hall, a Gothic building of 1325. The town hall consists of two distinct parts. The northern façade, a magnificent example of Flamboyant Gothic, was erected between 1518 and 1533, restored in 1829 and again some 50 years later. The eastern façade overlooking the market place was built in 1595–1628, in the Renaissance style, with three tiers of columns. It contains a valuable collection of archives, from the 13th century onwards. On the left bank of the Lys is the Oudeburg, the former castle of the first counts of Flanders, dating from 1180 and now restored.

To the north of the Oudeburg, on the other side of the Lys, is the Vrÿdagmarkt, the principal square of the city. This was the centre of the life of the mediaeval city, the scene of all great public functions, such as the homage of the burghers to the counts, and of the auto-da-fés under the Spanish regime. On the Scheldt, near the Place Laurent, is the Geerard-duivelsteen (château of Gerard the Devil), a 13th-century tower formerly belonging to a patrician family, now restored and used as the office of provincial records. In the park on the site of the citadel erected by Charles V are some ruins of the ancient abbey of St. Bavo and of a 12th-century octagonal chapel dedicated to St. Macharius. In the park is also situated the Museum of Fine Arts, completed in 1902. One of the most interesting institutions of Ghent is the great Begynhof (Béguinage) which, originally established in 1234 by the Bruges gate, was transferred in 1874 to the suburb of St. Amandsberg. It constitutes a little town of itself, surrounded by walls and a moat, and contains numerous small houses, 18 convents and a church. It is occupied by some 700 Béguines, women devoted to good works (see BÉGUINES). Near the station is a second Béguinage with goo inmates.

The main industries are cotton-spinning, flax-spinning, cotton-printing, tanning and sugar refining; in addition to which there are iron and copper foundries, machine-building works, breweries and factories of soap, paper, tobacco, etc. As a trading centre the city is even more important. It has direct communication with the sea by a ship-canal, greatly enlarged and deepened since 1895, which connects the Grand Basin, stretching along the north side of the city, with a spacious harbour excavated at Terneuzen on the Scheldt, 21½ m. to the north, thus making Ghent practically a sea-port; while a second canal, from the Lys, connects the city via Bruges with Ostende. A new lock at Terneuzen enables vessels up to 26 ft. draught to pass at any tide into or out of the canal between that port and Ghent.

Among the many educational establishments is the State university founded by King William I. of the Netherlands in 1816, actually a Flemish university. With it are connected a school of engineering, a school of arts and industries and the famous library (about 300,000 printed volumes and 2,000 mss.) formerly belonging to the city. The art academy has a fine collection of pictures taken from religious houses on their suppression in 1795. Ghent has more than 700 horticultural establishments. Every five years her great flower shows, *"Floralies"* attract visitors from all parts of the world.

Ghent was in the hands of the Germans from Oct. 1914 till Armistice day, Nov. 11, 1918. The west part of the town suffered some damage in the final operations. German troops again occupied Ghent in May 1940.

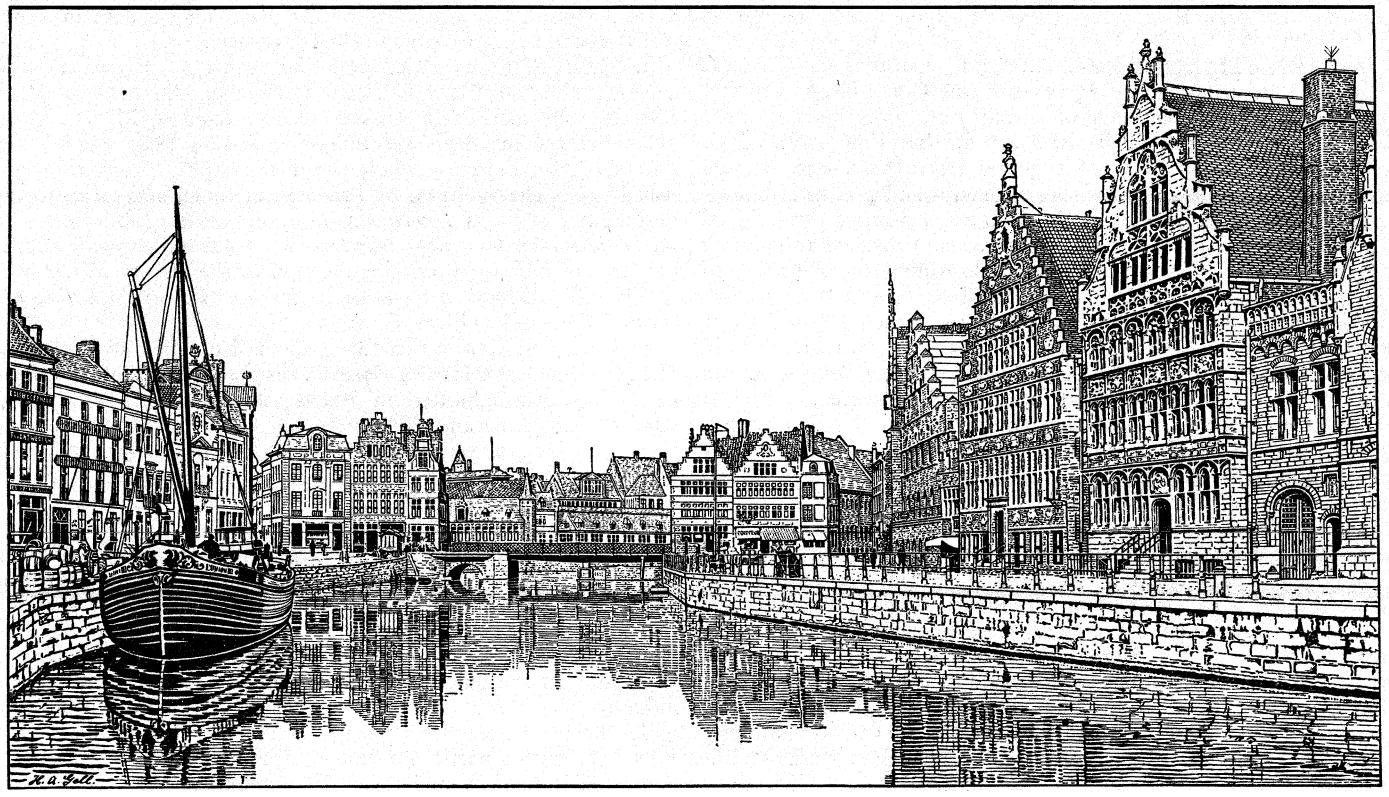
History. — The history of the city is closely associated with that of the countship of Flanders (*q.v.*), of which it was the seat. It is mentioned as early as the 7th century, and in 868 Baldwin of the Iron Arm, first count of Flanders, who had been entrusted by Charles the Bald with the defence of the northern marches, built a castle here against the Normans raiding up the Scheldt. This was captured in 949 by the emperor Otto I. and was occupied by an imperial burgrave for some 50 years, after which it was retaken by the counts of Flanders. Under their protection, and favoured by its site, the city rapidly grew in wealth and population, the zenith of its power and prosperity being reached between the 13th and 15th centuries, when it was the emporium of the trade of Germany and the Low Countries, the centre of a great cloth industry, and could put some 20.000 armed citizens into the field. The wealth of the burghers during this period was equalled by their turbulent spirit of independence; feuds were frequent — against the rival city of Bruges, against the counts, or, within the city itself, between the plebeian crafts and the patrician governing class. Of these risings the most notable was that in the earlier half of the 14th century, against Louis de Crécy, count of Flanders, under the leadership of Jacob van Artevelde (*q.v.*).

The earliest charter to the citizens of Ghent was that granted by Count Philip of Flanders between 1169 and 1191. It did little more than arrange for the administration of justice by nominated jurats (scabini) under the count's *bailli*. Far more comprehensive was the second charter, granted by Philip's widow Mathilda, after his death on crusade in 1191. The magistrates of the city were still nominated scabini (fixed at 13), but their duties and rights were strictly defined and the liberties of the citizens safeguarded; the city, moreover, received the right to fortify itself and even individuals within it to fortify their houses. This charter was confirmed and extended by Count Baldwin VIII., and the burghers attained to a very considerable measure of self-government. A charter of 1212 of Count Ferdinand (of Portugal) and his wife Johanna introduced a modified system of election for the scabini.

By the 14th century the democratic craft guilds, notably that of the weavers, had asserted themselves; the citizens were divided for civic and military purposes into three classes — the rich (*i.e.*, those living on capital), the weavers, and the members of the 52 other guilds. In the civic executive, as it existed to the time of Charles V., the deans of the two lower classes sat with the scabini and councillors.

In the long struggle of the Netherlands against Spain, Ghent took a conspicuous part, and it was here that, on Nov. 8, 1576, was signed the instrument known as the Pacification of Ghent, which established the league against Spanish tyranny.

War, persecution and the emigration or expulsion of its people



BY COURTESY OF THE BELGIAN NATIONAL RAILWAYS

THE OLD PORT AT GHENT. THE CAPITAL OF EAST FLANDERS IS AN IMPORTANT TRADING CENTRE AND HAS DIRECT SEA COMMUNICATION BY TWO SHIP CANALS. THE MAIN CANAL. 21½ MILES LONG. ENLARGED AND DEEPENED SINCE 1895. RUNS TO TERNEUZEN, ON THE SCHELDT, WHERE A SPACIOUS HARBOUR HAS BEEN EXCAVATED. THE OTHER RUNS TO OSTEND VIA BRUGES

wrecked the prosperity of Ghent, the recovery of which was made impossible by the closing of the Scheldt. After 1714 it formed part of the Austrian Netherlands, and in 1794 became the capital of the French department of the Scheldt. In 1814 it was incorporated in the kingdom of the United Netherlands, and after 1830 became part of Belgium.

For a comprehensive bibliography, *see* Ulysse Chevalier, *Rtpertoire des sources hist. topo bibliogr., s.v.* "Gand."

GHERARDESCA, UGOLINO DELLA (c. 1220–1289), count of Donoratico, was the head of the powerful family of Gherardesca, the chief Ghibelline house of Pisa. He allied himself by marriage with the Visconti, leaders of the Guelph faction in the city. For his share in the defeat of the Pisans by the Genoese at the battle of Meloria (1284) *see* MELORIA and PISA: *History.* He was accused of treachery, and increased his own unpopularity by ceding castles to Florence and Lucca, and by his hesitation to make peace with Genoa, lest the return of the Pisan prisoners, including the leading Ghibellines, should diminish his power. Civil war broke out in Pisa in 1288, stirred up by Gherardesca's rival the archbishop Ruggieri, who captured the count, his two sons, Gaddo and Uguccione, and his grandsons, and starved them to death in the Muda, a tower belonging to the Gualandi family. Dante, in a terrible but magnificent passage, placed Ugolino and Ruggieri in the second ring of the lowest circle of the *Inferno.*

See P. Tronci, *Annali Pisani* (2 vols., Pisa, 1868–71); S. de Sismondi, *Histoire des républiques italiennes* (Brussels, 1838); also the various annotated editions of Dante, especially W. W. Vernon's *Readings from the Inferno,* vol. ii. (2nd ed., 1905).

GHETTO, formerly the street or quarter of a city in which the Jews were compelled to live. The term is now used loosely of any locality where they congregate.

The mediaeval *Jewry* (*Juiverie, Juderia,* etc.) was the inevitable social expression of Jewish solidarity and Gectile aversion, and did not necessarily have any legal implication. The third Lateran Council (1179), which prohibited true believers even from lodging amongst the infidels, laid the foundations of a stricter control, which was sporadically enforced. It was not, however, reduced to a system until the counter-Reformation, when the bull *cum nimis absurdum* of Paul IV. (1555) enjoined for the first time the consistent enforcement of the mediaeval principles of segregation, the Ghetto of Rome being established in the following year. The Papal example ultimately prevailed in almost every city of Italy; and the name *Ghetto,* originally found in Venice, was generally applied to the new quarter thus created. In Germany, where a similar system obtained, the names *Judengasse,* etc., were used instead. In the Papal territories in France the term *Carrière (des Juifs)* was employed. In the rest of Europe the formal institution never generally prevailed. Among the most important examples of it in the north were Frankfort and Prague; in the south, Avignon, Rome and Venice, where the old buildings may still be seen.

Within their Ghettos the Jews enjoyed a considerable degree of autonomy under their own authorities, who were responsible for the collection of the oppressive communal taxation. The Jewish quarter thus formed to some extent an independent corporation, with its own officials, purveyors, guilds, amusements, and courts. Economic activity was however restricted by law to money-lending and a few more of the meanest occupations. The houses tended to be of unusual height, being compelled to extend vertically since there was no room for them to do so laterally. In order to prevent exploitation by Gentile landlords (the Jew was forbidden to hold real estate), security of tenure was guarded by an extension of the old Jewish principle of *Hazakah,* or prescriptive right. In Italy this ultimately acquired full legal status as the *jus gazaga.* The Ghettos were enclosed with walls and gates, which were kept locked at night and on certain church festivals; *e.g.,* from Thursday to Saturday in Holy Week. Outside, and sometimes inside as well, a badge or hat of distinctive colour had to be worn. The French Revolution temporarily swept away the infamous system, though it was widely restored in the reaction that followed. It was abolished however for good by the liberal movements of the 19th century, the last vestige disappearing with the capture of Rome in 1870.

See D. Philipson, *Old European Jewries* (1894); Israel Abrahams,

Jewish Life in the Middle Ages (1896); *S.* Kahn, article "Ghetto" in the *Jewish Encyclopedia.*

GHIBERTI, LORENZO (1378–1455), Italian sculptor, was born at Florence in 1378. His father was Cione di Ser Buonaccorso. He learned the trade of a goldsmith under his stepfather Bartoluccio; but the goldsmith's art at that time included all varieties of plastic arts, and required from those who devoted themselves to its higher branches a general and profound knowledge of design and colouring. In 1400 when Florence was visited by the plague, he left for the Romagna and assisted in painting frescoes in Pesaro in the castle of Carlo Malatesta. He returned to Florence on the urgent entreaties of his stepfather, who informed him that a competition was to be opened for designs of a second bronze gate in the baptistery, and that he would do wisely to take part in this artistic contest. The subject for the artists was the sacrifice of Isaac; and the competitors were required to observe in their work a certain conformity to the first bronze gate of the baptistery, executed by Andrea Pisano about 100 years previously. Of the six designs presented by different Italian artists, those of Donatello, Brunelleschi and Ghiberti were pronounced the best, and Ghiberti received the commission. This great work occupied him for fully twenty years. The unbounded admiration called forth by Ghiberti's first bronze gate led to his receiving from the chiefs of the Florentine gilds the order for the second, of which the subjects were likewise taken from the Old Testament. The Florentines gazed with especial pride on these magnificent creations, which must still have shone with all the brightness of their original gilding when, a century later, Michelangelo pronounced them' worthy to be the gates of paradise. Next to the gates of the baptistery Ghiberti's chief works still in existence are his three statues of St. John the Baptist, St. Matthew and St. Stephen, executed for the church of Or San Michele, two reliefs for the baptistery in Siena and the bas-relief of the coffin of St. Zenobius, in the Florence cathedral. As an architect he was employed on the Florence cathedral. As a painter he furnished designs for the painted glass windows of the same building. He died at Florence on Dec. 1, 1455.

Ghiberti's writings known by the name of "Commentarii" are invaluable for the study of art history. The first section gives an account of ancient art founded on Pliny; the second is devoted to mediaeval art and contains biographies of artists, mainly Tuscans of the 14th century; the third deals with optics and proportions.

See Vasari-Milanesi II.; C. Frey, *Sammlung ausgewählter Biographien Vasaris III.* (1886); Ch. Perkins, *History of Tuscan Sculpture* (1864); Lord Balcarres, *The Evolutzon of Italian Sculpture* (1909); Ghiberti's writings were published in 1912 by Julius von Schlosser.

GHICA, GHIKA or **GHYKA,** a family which played a great part in the modern development of Rumania, many of its members being princes of Moldavia and Walachia. According to Rumanian historians the Ghicas were of humble origin, and came from Kiupru in Albania.

1. GEORGE (c. 1600–1664), the founder of the family, is said to have been a playmate of Kiipruli Aga, the famous vizier, who recognized George while he was selling melons in the streets of Constantinople, and helped him on to high positions. George became prince of Moldavia in 1658 and prince of Walachia in 1659–60. He moved the capital from Tirgovishtea to Bucharest. From him are derived branches of the family which became so conspicuous in the history of Moldavia and Walachia.

2. The Walachian branch starts afresh from the great ban DEMETRIUS or DUMITRU GHICA (1718–1803), who was twice married and had 14 children. *(See* RUMANIA: *History.)* One of these, Gregory, prince of Walachia 1822–28, starts a new era of civilization, by breaking with the traditions of the Phanariot (Greek) period and assisting in the development of a truly national Rumanian literature. His brother, Prince Alexander Ghica, appointed jointly by Turkey and Russia (1834–42) as hospodar of Walachia, died in 1862. Under him the so-called *rkglement organique* had been promulgated; an attempt was made to codify the laws in conformity with the institutions of the country and to secure better administration of justice. Prince Demetrius Ghica, who died as president of the Rumanian senate in 1897, was the son of the Walachian prince Gregory.

3. MICHAEL (1794–1850) was the father of ELENA (1827–1888), a well-known novelist, who wrote under the name of Dora d'Istria. She married a Russian prince, Koltsov Mazalskiy, in 1849, but the marriage was unhappy, and in 1855 she left St Petersburg for Florence, where she died in 1888. There she published works characterized by lightness of touch and brilliance of description, such as *Pèlerinage au tombeau de Dante, La Vie monastique dans les églises orientales* (1844), *La Suisse allemande,* etc. One of her last works was devoted to the history of her own family, *Gli Albanesi in Roumenia: Storia dei Principi Ghika nei secoli XVII.–XIV.* (Florence, 1873).

4. SCARLAT GHICA (1750–1802) was twice prince of Walachia. His grandson JOHN (IOAN) GHICA (1817–1897), a lifelong friend of Turkey, was educated in Bucharest and in the West, and studied engineering and mathematics in Paris (1837–40); returning to Moldavia he was involved in the conspiracy of 1841, which was intended to bring about the union of Walachia and Moldavia under one native prince (Michael Sturdza). The conspiracy failed and John Ghica became a lecturer on mathematics at the university which was founded by Prince Sturdza in Jassy. In 1848 he joined the party of revolution and in the name of a provisional government then established in Bucharest went to Constantinople to approach the Turkish government. Whilst there he was appointed Bey of Samos (1853–59), where he extirpated piracy. In 1859 after the union of Moldavia and Walachia, Prince Cuza induced John Ghica to return. He was the first prime minister under Prince (afterwards King) Charles of Hohenzollern. He joined the anti-dynastic movement of 1870–71. In 1881 he was appointed Rumanian minister in London and retained office until 1889. He died on May 7, 1897 in Gherghani.

GHILZAI, a large and widespread Afghan tribe, who extend from Kalat-i-Ghilzai on the S. to the Kabul river on the N., and from the Gul Koh range on the W. to the Indian border on the E., in many places overflowing these boundaries. They are of the same stock as the Isa' Khel and Lodi Pathans. The Ghilzai clans now rank collectively as second to none in strength of military and commercial enterprise. They are a fine, manly race of people, and it is from some of their most influential clans (Suliman Khel, Nasir Khel, Kharotis, etc.) that the main body of *povindah* merchants is derived.

See *Tribes and Castes of the Punjab and North-west Frontier Province,* vol. ii. (1911).

GHIRLANDAJO, DOMENICO (1449–1494), Florentine painter. His father, Tommaso Bigordi, was a goldsmith, and Domenico was at first apprenticed in that craft, and afterwards placed with Alesso Bigordi to study painting and mosaic. Unfortunately his early works in Florence were destroyed, his earliest extant paintings being at San Gimignano, where he was commissioned to decorate the chapel of S. Fina in the Collegiata in the year 1475. The frescoes representing the death of the local saints already display the characteristics for which his art was to become famous: balanced composition, well-ordered spatial arrangements, fine grouping, characteristic portraiture and clear and powerful draughtsmanship. Here, as in all his larger works, he employed assistants of whom the most distinguished were his two brothers Daniele and Benedetto and his brother-in-law Bastiano Mainardi. Domenico was essentially a fresco painter; being a consummate master of design, and an insatiate worker, he is said to have expressed a wish to have the entire circuit of the walls of Florence to paint upon. In 1480 he painted the fresco of "St. Jerome" in the church of Ognissanti at Florence. His "Last Supper" in its refectory is notable for individual action and expression. In 1481 he was called to Rome by Pope Sixtus IV., and asked to co-operate in a series of frescoes in the Sistine chapel with his compatriots Cosimo Roselli and Sandro Botticelli. Ghirlandajo undertook two of the series but only one has survived: the "Christ calling the first Apostles." The figures are set against a landscape background of lake and mountain scenery, extending into the far distance; on both sides are groups of onlookers—statuesquely conceived figures portraying contemporary person-

ages. From 1482 to 1485 he and his assistants were employed on frescoes in the Sala dell' Orologio of the Palazzo Vecchio. The expansive wall surfaces are covered with representations of Roman heroes and with the "Apotheosis of St. Zenobius." The architectural settings, which successfully sustain the composition, prove that Ghirlandajo, like so many Florentine artists, had profited during his sojourn in Rome by studying the ancient architecture of that city. In 1485 followed the commission to decorate the chapel of the Sassetti family in the church of S. Trinita with scenes from the life of St. Francis. Three of the principal incidents are "St. Francis obtaining from Pope Honorius the approval of the Rules of his Order," his "Death and Obsequies" and the "Resuscitation of a child of the Spini family." A number of contemporary portraits are introduced. Some of the backgrounds display views of Florence. Ghirlandajo also painted an altarpiece for the chapel representing the "Adoration of the Shepherds." In the same year he was asked by Giov. Tornabuoni to renew the frescoes in the choir of S. Maria Novella, a work which has set the seal on his celebrity. The frescoes, in the execution of which many assistants were employed, are arranged in four courses on the three walls, the leading subjects being the lives of the Virgin and of the Baptist. It is suggested that the lower course was undoubtedly painted by the master himself, the "Birth of the Virgin" being one of the finest of the series. These grand and dignified compositions show us the stately life of Florence at the glorious time of Lorenzo the Magnificent and contain portraits of many distinguished men, including members of the Tornabuoni family, the artist and his brothers. The altarpiece of S. Maria Novella, representing the "Virgin in Glory," was also painted by Ghirlandajo, and is now in Munich. Other pictures by the master are the "Virgin and Saints" (1484) in the Uffizi gallery, Florence; the "Adoration of the Magi" (1488) in the Innocenti, Florence; the "Visitation" (1491) in the Louvre, Paris, and "Christ in Glory" (1492) in the Badia of Volterra bearing the latest date. Domenico died of fever on Jan. 11, 1494, and was buried in Santa Maria Novella. Although fine portraits abound in his frescoes, there are but few single portraits by him extant; one is the fine profile of Giovanna Tornabuoni in the Morgan collection; another, the "Old man with his grandson," in the Louvre. The Uffizi gallery contains fine drawings and sketches by the master. Domenico Ghirlandajo contributed greatly to the development of his art. His great fresco compositions prepared the way for the classic art of the cinquecento; he may be regarded as an innovator in more than one respect, his art leading towards realism when compared with that of his predecessors; the plastic conception of his figures, the individualistic tendency in his portraits, his rendering of folds in drapery, his representation of three dimensional space, and his treatment of backgrounds and interiors all point in that direction. Being one of the most popular masters of his time, his influence was widespread, and he was surrounded by pupils and assistants. Michelangelo is said to have studied under him.

Egger, *Codex Escurialensis, Ein Skizzenbuch aus der Werkstatt Domenico Ghirlandaios* (1906); G. S. Davies, *Ghirlandajo* (1908). (I. A. R.)

GHIRLANDAJO, RIDOLFO (1483–1561), son of Domenico Ghirlandajo, Florentine painter, was born on Jan. 4, 1483, and was brought up by his uncle David. But he owed more in the way of professional training to Granacci, Piero di Cosimo and perhaps Cosimo Rosselli. Vasari says that Ridolfo studied under Fra Bartolommeo. He was one of the earliest students of the famous cartoons of Leonardo da Vinci and Michelangelo. His works between the dates 1504 and 1508 show a marked influence from Fra Bartolommeo and Raphael, with the latter of whom he was on terms of familiar friendship. He was prominent in the execution of vast scenic canvases for various public occasions, such as the wedding of Giuliano de' Medici, and the entry of Leo X. into Florence in 1515. In his prime he was honest and conscientious as an artist; but from about 1527 he declined and his style became mannered. He died in Florence on Jan. 6, 1561.

The following are some of his leading works: An "Annunciation" in the Abbey of Montoliveto near Florence, Leonardesque in style; in 1504, the "Coronation of the Virgin," now in the Louvre, Paris; a "Nativity," very carefully executed, now in the Hermitage, Leningrad; a "Predella," in the Bigallo, Florence, five panels, of the Nativity and other subjects, charmingly finished; in 1514, on the ceiling of the chapel of St. Bernard in the Palazzo Vecchio, Florence, a fresco of the "Trinity," with heads of the 12 apostles and other accessories, and the "Annunciation"; also the "Assumption of the Virgin, who bestows her girdle on St. Thomas," in the choir loft of Prato cathedral; in 1517 two pictures, which display his highest skill, replete with expression, vigorous life and firm accomplished pictorial method, now in the gallery of the Uffizi, Florence: "St. Zenobius resuscitating a child"; also the translation of the remains of the same Saint. In the National Gallery, London, is "The Procession to Calvary," painted 1506 for the Antinovi family.

GHOR or **GHUR,** an ancient kingdom in the southern portion of that great peninsula of strong mountain country which forms the western part of modern Afghanistan.

Ghor is mentioned in the Shahnama of Firdousi (A.D. 1010), and in the Arab geographies of that time, but the people and princes of Ghor first became known to us in connection with the Ghaznevid dynasty, and the early mediaeval histories of Ghor and Ghazni are so intertwined that nothing need be added to what will be found under GHAZNI (*q.v.*).

About A.D. 1100 one of the princely families of Ghor, deriving the appellation of Shansabi, or Shansabaniah, from a certain ancestor Shansab, of local fame, acquired predominance in all the country, and Malik 'Izzuddin al Hosain of this family was known afterwards as "the Father of Kings," from the honour to which several of his seven sons rose. Three of these were—(1) Amir Kutbuddin Mahommed, called the lord of the Jibal or mountains; (2) Sultan Saifuddin Suri, for a brief period master of Ghazni, both of whom were put to death by Bahram the Ghaznevid; and (3) Sultan Alauddin Jahansoz, who wreaked vengeance upon Ghazni and began the conquests which were afterwards immensely extended both in India and in the West by his nephews Ghiyasuddin Mahommed b. Sam and Mahommed Ghori. For a brief period during their rule it was boasted, with no great exaggeration, that the public prayer was read in the name of the Ghori from the extremity of India to the borders of Babylonia, and from the Oxus to the Straits of Ormus. After the death of Mahommed Ghori the Indian dominion became independent, and the whole kingdom fell to pieces before the power of Mahommed Shah of Khwarizm and his son Jelaluddin (*c.* 1214–15), a power in its turn speedily shattered by the Mongol flood.

The princes of Ghor experienced, about the middle of the 13th century, a revival of power, which endured for 140 years. This later dynasty bore the name of Kurt or Kărt. The first of historical prominence was Malik Shamsuddin Kurt, who in 1245 held the lordship of Ghor in some kind of alliance with, or subordination to, the Mongols, and in 1248 received from the Great Khan Mangu an investiture of all the provinces from Merv to the Indus, including by name Seistan, Kabul, Tirah (adjoining the Khyber pass), and Afghanistan, which he ruled from Herat. He stood well with Hulagu, and for a long time with his son Abaka, but at last incurred the latter's jealousy, and was poisoned when on a visit to the court at Tabriz (1376). His son Ruknuddin Kurt was, however, invested with the government of Khorasan (1278), but after some years, mistrusting his Tatar suzerains, he withdrew into Ghor, and abode in his strong fortress of Kaissar till his death there in 1305. The family held on through a succession of eight kings in all, sometimes submissive to the Mongol. sometimes aiming at independence. But in 1380 Timur came against Herat, and carried away the king and the treasures of his dynasty. A revolt and massacre of his garrison provoked Timur's vengeance; he put the captive king to death, came against the city a second time, and showed it no mercy (1383). Ghor has since been obscure in history.

The valleys of the Taimani tribes though narrow are fertile and well cultivated, and there are many walled villages and forts about

Parjuman and Zarni in the south-eastern districts. The peak of "Chalap Dalan" (described by Ferrier as "one of the highest in the world") is the Koh-i-Kaisar, which is a trifle over 13,000ft. in height. All the country now known as Ghor was mapped during the progress of the Russo-Afghan boundary delimitation.

See the "Tabakát-i-Násiri," in the *Bibl. Indica*, transl. by Raverty; *Journal asiatique*, ser. v. tom. xvii.; "Ibn Haukal," in *J. As. Soc. Beng.*, vol. xxii.; Ferrier's *Caravan Journeys;* Hammer's *Ilkhans.*

GHOSE, LALMOHUN (1849–1909), lawyer, statesman, orator and scholar, was born at Krishnagur, Bengal, on Dec. 17, 1849. He was the second son of Rai Ram Lochun Ghose Bahadur, Principal Sadar Amin of the district. Ghose was called to the bar in England in 1873, and on his return to India began to practise in the Calcutta High Court. Ghose was honorary secretary and principal speaker of a deputation on Indian administration to the Marquess of Hartington. The result was repeal of the Vernacular Press Act and the establishment of a Statutory Indian Civil Service.

Early in 1880, he returned to India, but two months later the Indian Association again sent him to England to continue their opposition to Lord Lytton's policy. Returning in November the same year, he resumed practice at the Bar, and devoted the next two years to various political measures, such as the Vernacular Press Act, Criminal Procedure Code Amendment Bill, etc.

In 1883, he again proceeded to England in order to assist in an appeal of Surendranath Banerjea before the Privy Council. From August 1883 to August 1884, he addressed meetings in London and elsewhere in support of Ripon's policy in the Ilbert Bill and the representation of Indian interests in Parliament. He was the first Indian to seek election to Parliament; in 1885 and again in 1886 the Liberals of Deptford invited him to become their candidate, but on both occasions he was defeated—the second time owing to his support of the Irish Home Rule Bill. He returned to India in 1887.

In 1892, he was elected a member of the Bengal Legislative Council from which he retired in 1895. In 1903, he was elected president of the Indian National Congress at Madras and for some years took an important part in its deliberations. Ghose's last political speech was delivered as chairman of a public meeting called in 1906 at Calcutta to protest against Lord Curzon's partition of Bengal. Ill-health prevented him from taking any further active part in political work, and he died at Calcutta on Sept. 18, 1909.

Ghose was a thorough Constitutionalist and the whole spirit of his utterances was loyal to the British Government. He was the greatest orator of his time in India. As a member of the Bar he was rather an advocate than a lawyer, and commanded the fullest respect of Bench and Bar alike.

BIBLIOGRAPHY.—*Speeches of Lalmohun Ghose,* Parts I.–II., edited by A. Banerjea, 1883–84. (H. DA.)

GHOST, the spirit of a dead person considered as appearing in some visible or sensible form to the living (O.E. goest) (see APPARITIONS; PSYCHICAL RESEARCH; SPIRITUALISM). The language of the Authorized Version of the Bible has preserved the phrase "to give up the ghost," still sometimes used of dying. The Spirit of God, the third person of the Trinity, is still called the Holy Ghost.

GHOST DANCE. In 1870 there started among the Paiute (Paviotso) of Western Nevada a new faith—the Ghost Dance religion—which in most cases spread rapidly because of the wide feeling, founded on solid fact, that the westward movement of white culture was destined to destroy the native culture. In some cases "the new cult was encouraged by the chiefs as a check to the rival powers of the Shamans" (Spier, see bibliography). The Modoc war of 1873 saw the immediate disappearance of the cult, but it may still survive, or more probably there may survive separate cult-elements which, if re-stimulated and recombined, would present a very close resemblance to the complex of ideas, beliefs and rites which constitute the Ghost Dance religion.

In 1890 changes in the administration with the appointment of inexperienced men in charge of the reserves, led to discontent, notably among the Sioux of Pine Ridge. Pledges had been broken. Messianic ideas of a deliverer who shall restore the world to the godly and punish the transgressors of his ordinances are found in Indian thought, and there is a continuity of idea, inspired by, and probably based on, political conditions, between the ideals of Pontiac; the' Paiute dreamer of 1870 named Ta'vibo; Smohalla, the dreamer of the Columbia region whose oratory, activities and personality made him a man of wide influence; the Shaker teachers of Puget Sound; and the doctrines of Wovoka the Messiah, the Paiute who is known as Jack Wilson. The new teaching—in reality the old teaching—reached the Sioux in 1889 and took the form of a prophecy of a new world. Even progressive and intelligent Indians held the belief in the close advent of a liberator who should restore the Indian race, living and dead, to a regenerated earth where the pristine conditions of life should prevail. Administration of Indian reserves had been adequate, intelligent, sympathetic and satisfactory in many cases. The prophecy sometimes allowed the white man to share the predicted felicity. The movement took hostile expression among the discontented Sioux, whose leaders, Sitting Bull and Red Cloud, were irreconcilable enemies of the whites. Sitting Bull, a medicine man rather than a secular chief, was killed on Dec. 15, 1890. By Jan. 16, 1891, the outbreak ended, as a result of the military and political operations conducted by Gen. Miles, who put the agencies in charge of military officers known to and respected by the Indians.

The Ghost Dance' begins in the middle of the afternoon or later. No musical instrument is used except by individual dancers. The Sioux wore a "ghost shirt," almost always made of white cloth, tailored in Indian fashion. No metal was allowed to be worn. The ghost stick carried by the leader was a staff about 6 ft. long, with red cloth and red feathers. Other articles used were arrows with bone heads, a bow, a gaming wheel and sticks. The ground was consecrated. The priests were ordained by the conferment of a consecrated feather, either of a crow, the sacred bird of the Ghost Dance, or of the eagle, sacred in Indian lore, given to the candidates by the apostle. The feathers were painted. The dancers were ceremonially painted on the face with elaborate designs, in red, yellow, green and blue, suggested in trances, and were thus strengthened in spiritual vision and physical health. All went to bathe—to wash away all evil, spiritual and material. Attendance was compulsory, as those who stayed away would be turned to stone or punished. Songs, adapted to the simple dance step, were carefully rehearsed. Participants fell into trances and on regaining consciousness narrated their visions. The general psychology of the dance as an element in religious and social life, and as it functions in the lives of primitive people, forms a topic of importance as, in general, sexual display takes place and selection is encouraged—a feature sternly and successfully repressed in the Ghost Dance, in which the whole attention of the performers, the whole community, was successfully concentrated upon the purpose of the dance and upon the message of salvation which it conveyed.

Kroeber, "A Ghost Dance in California" (*Journal of American Folklore*, 1904, 17, p. 32–35), and *Handbook of the Indians of California* (Bulletin 78, Bureau of American Ethnology, 1925); Leslie Spier, *The Ghost Dance of 1870 among the Klamath of Oregon* (University of Washington publications in Anthropology, vol. ii. No. 2, 1927).

GIACOMETTI, PAOLO (1816–1882), Italian dramatist, born at Novi Ligure, was educated in law at Genoa, but at the age of twenty had some success with his play *Rosilda* and then devoted himself to the stage. Among the best of his plays, most of which were written for various touring companies to which he was attached, were La Donna (1850), La Donna in seconde *nozze* (1851), Giuditta (1857), Sofocle (1860), La *Morte civile* (1880). A collection of his works was published at Milan in eight volumes (1859 *et seq.*).

GIAMBELLI or **GIANIBELEI, FEDERIGO** (*fl.* 16th century), Italian military engineer, a native of Mantua, who, during the siege of Antwerp by the duke of Parma in 1584, put himself in communication with Queen Elizabeth, who engaged him as an adviser in the defence. The senate agreed to a modification of his scheme for destroying the bridge which closed the

entrance to the town from the side of the sea, by the conversion of two ships of 60 and 70 tons into infernal machines. One of these exploded, killed more than 1,000 soldiers, effected a breach more than 200ft. wide, by which, but for the hesitation of Admiral Jacobzoon, the town might at once have been relieved. After the surrender of Antwerp Giambelli went to England, where he fortified the river Thames; and when the Spanish Armada was attacked by fireships in the Calais roads, the Spaniards were persuaded that the fireships were infernal machines constructed by Giambelli. He is said to have died in London.

GIAMBONO (MICHELE DI TADDEO BONO) (*fl.* 1420–1462), Italian painter and mosaicist, active in Venice from 1420–62. His grandfather was a painter of Treviso called Giam Bono (also Zambono) and he himself is generally called by this name. He was the most distinguished niember of a large family of artists working chiefly in Venice for nearly a century and a half, from 1396 to 1546. The decorations of the Cà Doro and of the celebrated Porta della Carta leading into the court of the doge's palace, most accomplished examples of the highly ornate Late Gothic architecture in Venice, were executed by members of the family at the time when Michele was painting his altar pieces which embody the same taste in another medium and are enclosed in elaborate Gothic architectural framework. Giambono belonged to the generation preceding that of Giovanni and Gentile Bellini. It is not known in whose studio he was trained.

There are but few fully authenticated works by this master extant. The Venice academy has a large polyptych representing the Saviour and four Saints, signed "Michel Cambono pinxit," and a "Coronation of the Virgin" which, according to documentary evidence, was copied by the artist from a work by Giovanni d'Alemagna and Antonio Vivarini. There is an exquisite "Virgin and Child," signed by the artist, in Rome (Hertz bequest). Among the works attributed to him are the "St. Mark" in the National Gallery (Mond bequest), London, the St. Michael in Eerenson's collection, and a "Pietà" in the Metropolitan Museum of Art, New York. After the death of Jacobello del Fiore in 1423, Giambono was made director of the mosaic works in the church of St. Mark's, and he there composed the mosaics on the left side of the vault in the Capella dei Mascoli, representing the Nativity and the Presentation in the Temple. The figures are set against a background of Gothic architecture, and there is a first attempt to introduce three-dimensional representation in a technique, where up till that time the monumental two-dimensional design of the Byzantine tradition had reigned supreme.

See Paoletti di Osmaldo, *Raccolte di Documenti inediti* (Padua, 1895); J. **R.** Richter, *Mond Collection* (1910); *L.* Testi, *La Storia della Pittura Veneziana* (Bergamo, 1915).

GIANNONE, PIETRO (1676–1748), Italian historian, was born at Ischitella, in Capitanata, on hlay 7, 1676. He spent 20 years on his great work, the Storia civile del *regno di Napoli* (1723). In this work he espoused the side of the civil power in its conflicts with the Roman Catholic hierarchy. Hooted by the mob of Naples, and excommunicated by the archbishop's court, he left Naples and went to Vienna. Meanwhile his history was put on the Index. At Vienna he received a pension and facilities for the prosecution of his historical studies. Of these the most important result was *Il Triregno, ossia* del *regno* del *cielo,* della terra, e del papa. On the transfer of the Neapolitan crown to Charles of Bourbon, Giannone lost his Austrian pension and was compelled to remove to Venice. Unhappily there arose a suspicion that his views on maritime law were not favourable to the pretensions of Venice, and this suspicion, together with clerical intrigues, led to his expulsion from the State. On Sept. 23, 1735, he was seized and conveyed to Ferrara. After wandering under an assumed name for three months through Modena, Milan and Turin, he at last reached Geneva. But while on a visit to a Catholic village within Sardinian territory in order to hear mass on Easter day, he was kidnapped by the agents of the Sardinian Government, conveyed to the castle of Miolans and thence successively transferred to Ceva and Turin. In the fortress of Turin he spent the remaining 12 years of his life, although part of his time was spent in composing a defence of the Sardinian interests as opposed to those of the papal court, and he was led to sign a retractation of the statements in his history most obnoxious to the Vatican (1738). He died on March 7, 1748. in his 72nd year.

See the notice by L. Panzini, based on Giannone's unpublished *Autobiografia,* in the Milan edition of the historian's works (1823); and *Opere inedite* (Turin, 1859), containing the works written by him in his Turin prison, and edited by P. S. Mancini. G. Bonacci, *Saggio sulla Storia civile del Giannone* (Florence, 1903) is a bitter attack on Giannone, and although the writer's remarks on the plagiarisms in the *Storia civile* are justified, the charge of servility is greatly exaggerated.

GIANT. In classic inythology the word meant beings more or less manlike, but monstrous in size and strength, like the Titans and the Giants sung by Hesiod in the Theogony, who can heap up mountains to scale the sky and war beside or against the gods. (O.E. geant through Fr. *géant* by assimilation from *gigantem,* acc. of Lat. *gigas.*) But there also appear in the legends of giants some with historic significance. The idea that the giants were earth-born or indigenous races was familiar to the ancient Greeks (see Welcker, *Griechische Götterlehre,* i. 787). The Bible records the traditions oi the Israelites of fighting in Palestine with tall races of the land such as the Anakim (Numb. xiii. 33; Deut. ii. 10, iii.; I Sam. xvii. 4). In Homer "the Cyclops and the wild tribes of the Giants" seem dim traditions of pre-Hellenic barbarians, godless, cannibal, skin-clothed, hurling huge stones in their rude warfare. Giant-legends of this class are common in Europe and Asia. In early times it was usual for cities to have their legends of giants. Thus London had Gog and Magog, whose effigies (14ft. high) still stand in the Guildhall (see Gog); Antwerp had her Antigonus, 40ft. high; Douai had Gayant, 22ft. high, and so on.

It was a common opinion that the human race had itself degenerated, the men of primeval ages having been of far greater stature and strength, in fact gigantic. Yet so far as can be judged from actual remains, it does not appear that giants, in the proper sense, ever existed, or that the men of ancient time were on the whole taller than those now living. It is now usual to apply the word giant merely to unusually tall men and women. In every race of mankind the great mass of individuals do not depart far from a certain mean or average height, while the very tall or very short men become less and less numerous as they depart from the mean standard, till the utmost divergence is reached in a very few giants on the one hand, and a very few dwarfs on the other.

See P. Lohmann, Archäologisches vcn en-nebi Samwil: *Zeitschr.* (1904); *E.* **J.** Wood, *Giants and Dwarfs* (1860).

GIANT ORDER or **COLOSSAL ORDER,** in architecture, an order used decoratively on the face of a building whose columns or pilasters extend through two or more storeys in height.

GIANT'S CAUSEWAY, a promontory of columnar basalt, on the north coast of Co. Antrim, Ireland. It is divided by whindykes into the Little Causeway, the Middle Causeway and the Larger or Grand Causeway. The pillars composing it are for the most part irregular hexagons. In diameter they vary from 1 j to 20 in., and some are 20 ft. in height. The Great Causeway is in some places nearly 40 ft. in breadth and is highest at its narrowest part. It extends outwards into a platform and for nearly 100 yd. is above water. The neighbouring cliffs, particularly in the bay to the east, exhibit in many places similar columns. The most remarkable of the cliffs is the Pleaskin, the upper pillars of which are 60 ft. in height; beneath these is a mass of coarse black amygdaloid, of the same thickness, underlain by a second range of basaltic pillars, from 40 to 50 ft. in height. Near the Giant's Causeway are the ruins of the castles of Dunseverick and Dunluce, situated on isolated crags. In 1883 an electric railway, the first in the United Kingdom, was opened, connecting the Causeway with Portrush and Bushmills.

GIANT'S KETTLE, GIANT'S CAULDRON, a glacial pot-hole, *i.e.,* a deep cylindrical hole in solid rock drilled out by eddying currents of water of sub-glacial streams, bearing stones, gravel and other detrital matter. The size varies from a few inches to several feet in depth and diameter and upon the retreat of the ice, the whole frequently contains the sand, gravel or

boulders which have assisted in its formation. Good examples occur in the Alps (Lucerne), Germany, Norway and U.S.A. These must not be confused with true pot-holes which occur in river beds and at the base of sea cliffs.

GIAOUR, a word used by the Turks to describe all who are not Mohammedans, especially Christians. The word, first employed as a term of contempt, has become so general that in most cases no insult is intended in its use. It is a Turkish adaptation of the Persian gaur.

GIARDINO, GAETANO (1864–1935), Italian soldier, was born at Montemagno, Italy, on Jan. 24, 1864. He joined the army in 1882 and saw service in Eritréa (1889–94) and in Tripoli (1911–12). On Italy's intervention in the World War he was appointed chief of staff to the II. Army and was promoted brigadier-general in Aug., 1915. In June, 1916, he was given command of the 48th Brigade and played an important part in the attack on Gorizia. In June, 1917, he was promoted lieutenant-general, but a few days later was chosen minister of war and made a senator. He held office until after Caporetto, when he was appointed assistant chief of staff to the new commander-in-chief, Gen. Diaz. In April, 1918, he was given the command of the IV. Army in the Grappa sector. At the battle of Vittorio Veneto (Oct. 24–Nov. 3, 1918) he delivered a general attack on the Austrian lines and after a hard struggle forced the enemy to retreat. In 1919 he was promoted general *d'esercito*. In Sept., 1923, as the Government of Fiume was unable to carry on, Giardino was sent to take charge of the town, where he remained until its annexation by Italy under the terms of the treaty between Italy and Yugoslavia in Jan., 1924. He died in Turin, Nov. 21, 1935.

GIB, ADAM (1714–88), Scottish divine and leader of the Antiburgher section of the Scottish Secession Church, was born on April 14, 1714 in the parish of Muckhart, Perthshire, and, on the completion of his literary and theological studies at Edinburgh and Perth, was licensed as a preacher in 1740. In 1741 he was ordained minister of the large Secession congregation of Bristo street, Edinburgh. In 1745 he was almost the only minister of Edinburgh who continued to preach against rebellion while the troops of Charles Edward were in occupation of the town. When in 1747 "the Associate Synod," by a narrow majority, decided not to give full immediate effect to a judgment which had been passed in the previous year against the lawfulness of the "Burgess Oath," Gib led the protesting minority, who separated from their brethren and formed the Antiburgher Synod (April 10) in his own house in Edinburgh. It was chiefly under his influence that it was agreed by this ecclesiastical body at subsequent meetings to summon to the bar their "Burgher" brethren, and finally to depose and excommunicate them for contumacy. Gib's action in forming the Antiburgher Synod led, after prolonged litigation, to his exclusion from the church in Bristo street. From 1753 till within a short period of his death, which took place on June 18, 1788, he preached in Nicolson street church, to an audience of 2,000 persons. He was nicknamed "Pope Gib."

GIBARA or **JIBARA** (once *Punta del Yarey* and Yarey de Gibara), a north-coast city of Oriente province, Cuba, 80 m. N.W. of Santiago de Cuba. Pop. (1931) 30,705. It is served by railway to the south-south-west, to Holguin and Cacocum (where it connects with the main line between Santiago and Havana), and is a port of call for the American Munson line. It lies on a circular harbour, about 1 m. in diameter, which, though open to the north, affords fair shelter. At the entrance to the harbour is San Fernando, an old fort (1817), and the city is very quaint in appearance. At the back of the city are three stone-topped hills, Silla, Pan and Tabla, reputed to be those referred to by Columbus in his journal of his first voyage. Enclosing the town is a stone wall, built by the Spaniards as a defence against attack during the rebellion of 1868–78. Gibara is the port of Holguin. It exports cedar, mahogany, tobacco, sugar, tortoise-shell, Indian corn, cattle products, coco-nuts and bananas; and is the centre of the banana trade with the United States. Gibara is an old settlement, but its importance dates from the opening of the port to commerce in 1827.

GIBBET, a primitive form of gallows. It was a custom at one time—though not part of the legal sentence—to hang the body in chains, this being known as gibbeting. See HANGING and GALLOWS.

GIBBON, EDWARD (1737–1794), English historian, was born at Putney on April 27 (O.S.), 1737. His father, who was also named Edward Gibbon, was M.P. for Petersfield and Southampton until 1747; he married Judith, daughter of James Porten, by whom he was the father of seven children. Edward was the only one to survive childhood, and he was so delicate as a child that his life was often despaired of. He first attended a day-school in Putney, and studied Latin with John Kirkby, author of *Authomates* (1745). He went in 1746 to a school at Kingston-on-Thames, where "at the expense of many tears and some blood, I purchased the knowledge of the Latin syntax." Meanwhile he was reading Pope's Homer and Dryden's Virgil. His mother died in 1747, and his father moved into Hampshire, but Gibbon lived under the care of his aunt, chiefly at his grandfather's house at Putney. Here he developed his great love of reading, and had the run of his grandfather's library. His 12th year, 1748, he records as "the most propitious to the growth of my intellectual stature." At the end of that year, his aunt, Catherine Porten, opened a boarding-house for Westminster school. Gibbon went with her, and entered the school in Jan. 1749. His health broke down again, and he was taken in 1750 to Bath and Winchester, without much effect. He made one more attempt at Westminster, but it was evident that his health would never stand it, and after this he studied under various tutors. Meanwhile his appetite for history was developing, and he read widely, ranging over every period. On a visit to his father he first discovered later Roman history.

Oxford and Lausanne.—About his 16th year his health rapidly improved, and on April 3, 1752, he went to Magdalen college, Oxford, as a gentleman commoner, "with a stock of erudition which might have puzzled a doctor, and a degree of ignorance of which a schoolboy might have been ashamed." He disliked the university and his tutors, and they disliked him. "I spent 14 months at Magdalen college," he says; "they proved the 14 months the most idle and unprofitable of my whole life." While at Oxford he was influenced by Middleton's Free Inquiry (1749) to join the church of Rome, and his conversion was completed by Bossuet's Variations of Protestantism and Exposition of Catholic Doctrine. Gibbon was received into the church on June 8, 1753. He announced his decision in a letter to his father, who became exceedingly annoyed and removed him from Oxford. Soon afterwards he was sent to live at Lausanne, with M. Pavilliard, a Calvinist minister. Here he learned French of necessity, and after five years "spontaneously thought" in that language, which influenced his style to the last. He studied the logic of Crousaz, and "the articles of the Romish creed disappeared like a dream." In less than two years he had returned to Protestantism. He studied widely, classics, philosophy and mathematics, which last he soon abandoned. In 1755 he travelled in Switzerland, studying the Swiss political institutions. In 1757 he met Voltaire. In the same year he fell in love with Susan Curchod, daughter of the pastor of Crassier, who afterwards became Madame Necker. On his return to England his father objected to the marriage, and Gibbon "sighed as a lover," but "obeyed as a son." He found that his father had married again. At this time he met Mallet, who introduced him to Lady Hervey's circle, where his French accomplishments made him welcome. Mallet advised him to counteract the influence of French on his style by reading Addison and Swift. In 1761 Gibbon published his *Essai* sur *l'étude* de la *littérature,* begun in Lausanne in 1758. His father urged its publication, hoping that it might introduce him to public notice, but it was more successful abroad than in England. It was translated into English in 1764.

His Later Life.—He was already contemplating a history, but had not chosen his period. In 1763 he left for a tour on the continent. He went first to Paris, where he found the circle of d'Alembert and Diderot congenial, and was tempted to stay there permanently; then to Switzerland, staying a year at Lau-

sanne, and in April 1764 to Italy. Rome was the main object of his visit, and it was in Rome he records "on the fifteenth of October 1764, as I sat musing amidst the ruins of the Capitol . . . that the idea of writing the decline and fall of the city first started to my mind." He returned from the tour in June 1765, visiting Naples, Venice, and Verona on the return journey. The next five years were uneventful. Gibbon lived chiefly at Buriton. He projected and abandoned a history of the Swiss revolution, and in 1770 successfully exposed Warburton's Virgilian theories in *Critical Observations on the Sixth Book of the Aeneid.* But he had by now formed the plan of his history, and settled down to the vast researches it involved. His studies were interrupted in 1770 by his father's death, and his own consequent move to London, but by Oct. 1772 he was fairly started. At first he moved slowly and with hesitation; after the first few chapters, swiftly and without corrections or alterations. In Feb. 1776 the first volume was published, and met with an unprecedented success, passing rapidly through three editions. He was allowed by his publishers two-thirds of the profits on the first edition, which amounted to £490. Hume, in the midst of his congratulations, warned him that he was provoking a controversy in the chapters on the growth of Christianity, and the controversy was not slow in following. His only reply was the *Vindication* (1779), a complete and crushing reply to Davies and others who had attacked him (for a full account see *Bibliographers' Manual*, 1858, pp. 885–886).

In 1774 he became M.P. for Liskeard, which did not interrupt his work, except for an interval in 1779 when he was employed to write a *Mémoire justificatif* in answer to a French manifesto. For this service he was rewarded with a seat at the Board of Trade and plantations worth £800 a year. Gibbon lost his seat in Sept. 1780, but was returned for Lymington in a by-election in June 1781. In April 1781 the second and third volumes of his history appeared, which caused no excitement, but sold fast. Then followed a critical event in his life; Lord North's ministry fell, and Burke abolished the Board of Trade. Gibbon gave up his parliamentary career, which had been mute and inglorious indeed, but had acted as "a school of civil prudence, the first and most essential virtue of an historian," sold everything but his library, and moved to Lausanne in Sept. 1783, where he joined his friend Deyverdun. Here, in a house with a charming garden and a wonderful view, the history was quickly finished; the fourth volume was finished in 1784, the fifth two years later; and, he says, "it was on the day, or rather night, of the 27th of June 1787, between the hours of 11 and 12, that I wrote the last line of the last page in a summer-house in my garden. After laying down my pen, I took several turns in a *berceau*, or covered walk of acacias, which commands a prospect of the country, the lake and the mountains. The air was temperate, the sky was serene, the silver orb of the moon was reflected from the waters, and all nature was silent. I will not dissemble the first emotions of joy on the recovery of my freedom, and, perhaps, the establishment of my fame. But my pride was soon humbled, and a sober melancholy was spread over my mind by the idea that I had taken an everlasting leave of an old and agreeable companion, and that whatsoever might be the future fate of my history, the life of the historian must be short and precarious."

He took the manuscript to London in 1787, and in April 1788 the last three volumes were published, with as great success as before. He returned to Lausanne, where he suffered greatly from the loss of his friend Deyverdun, who died on July 4, 1789. The provisions of Deyverdun's will enabled Gibbon to remain in the same house, and there he wrote his *Memoirs of my Life and Writings* in 1789. In 1793 he came back to England and later in the year was obliged to undergo several operations. He never recovered his strength, and died on Jan. 16, 1794. He was buried at Flitching, Sussex. (J. S. B.; X.)

The Value of His Work. — Gibbon's literary art, the sustained excellence of his style, his piquant epigrams and his brilliant irony, would perhaps not secure for his work the immortality which it seems likely to enjoy, if it were not also marked by ecumenical grasp, extraordinary accuracy and striking acuteness of judgment. It is needless to say that in many points his statements and conclusions must now be corrected. He was never content with second hand accounts when the-primary sources were accessible; "I have always endeavoured," he says, "to draw from the fountain-head; my curiosity, as well as a sense of duty, has always urged me to study the originals; and if they have sometimes eluded my search, I have carefully marked the secondary evidence on whose faith a passage or a fact were reduced to depend." Since he wrote, new authorities have been discovered or rendered accessible; works in Greek, Latin, Slavonic, Armenian, Syriac, Arabic and other languages, which he was unable to consult, have been published. Again, many of the authorities which he used have been edited in superior texts. The relative weights of the sources have been more nicely determined by critical investigation. Archaeology has become a science. In the immense region which Gibbon surveyed there is hardly a section which has not been submitted to the microscopic examination of specialists.

But apart from the inevitable advances made in the course of a century during which historical research entered upon a new phase, the reader of Gibbon must be warned against one capital defect. In fudging the *Decline and Fall* it should carefully he observed that it falls into two parts which are heterogeneous in the method of treatment. The first part, a little more than five-eighths of the work, supplies a very *full* history of 460 years (A.D. 180–641); the second and smaller part is a summary history of about 800 years (A.D. 641–1453) in which certain episodes are selected for fuller treatment and so made prominent. To the first part unstinted praise must be accorded; it may be said that, with the materials at the author's disposal, it hardly admitted of improvement, except in trifling details. But the second, notwithstanding the brilliancy of the narrative and the masterly art in the grouping of events, suffers from a radical defect which renders it a misleading guide. The author designates the story of the later empire at Constantinople (after Heraclius) as "a uniform tale of weakness and misery," a judgment which is entirely false; and in accordance with this doctrine, he makes the empire, which is his proper subject, merely a string for connecting great movements which affected it, such as the Saracen conquests, the crusades, the Mongol invasions, the Turkish conquests. He failed to bring out the momentous fact that up to the 12th century the empire was the bulwark of Europe against the East. nor did he appreciate its importance in preserving the heritage of Greek civilization. He compressed into a single chapter the domestic history and policy of the emperors from the son of Heraclius to Isaac Angelus; and did no justice to the remarkable ability and the indefatigable industry shown in the service of the State by most of the sovereigns from Leo III. to Basil II. He did not penetrate into the deeper causes underlying the revolutions and palace intrigues. His eye rested only on superficial characteristics which have served to associate the name "Byzantine" with treachery, cruelty, bigotry and decadence. It was reserved for Finlay to depict, with greater knowledge and a juster perception, the lights and shades of Byzantine history. Thus the later part of the *Decline and Fall*, while the narrative of certain episodes will always be read with profit, does not convey a true idea of the history of the empire or of its significance in the history of Europe. It must be added that the pages on the Slavonic peoples and their relations to the empire are conspicuously insufficient; but it must be taken into account that it was not till many years after Gibbon's death that Slavonic history began to receive due attention, in consequence of the rise of competent scholars among the Slavs themselves.

His Attack on Christianity. — The most famous chapters of the *Decline and Fall* are the 15th and 16th, in which the historian traces the early progress of Christianity and the policy of the Roman Government towards it. The flavour of these chapters is due to the irony which Gibbon has employed with consummate art and felicity. There was a practical motive for using this weapon. An attack on Christianity laid a writer open to prosecution and penalties under the statutes of the realm (9 and 10 William III. c. 22, still unrepealed). Gibbon's stylistic artifice both averted the peril of prosecution and rendered the attack

more telling. In his *Autobiography* he alleges that he learned from the *Provincial Letters* of Pascal "to manage the weapon of grave and temperate irony, even on subjects of ecclesiastical solemnity." It is not easy, however, to perceive much resemblance between the method of Pascal and that of Gibbon, though in particular passages we may discover the influence which Gibbon acknowledges. For instance, the well-known description (in chap. xlvii) of the preposition "in" occurring in a theological dogma as a "momentous particle which the memory rather than the understanding must retain" is taken directly from the first Provincial Letter. The main points in the general conclusions of these chapters have been borne out by subsequent research. The account of the causes of the expansion of Christianity is chiefly to be criticized for its omissions. There were a number of important contributory conditions (enumerated in Harnack's *Mission und Ausbreitung des Christentums*) which Gibbon did not take into account. He rightly insisted on the facilities of communication created by the Roman empire, but did not emphasize the diffusion of Judaism. And he did not realize the importance of the kinship between Christian doctrine and Hellenistic syncretism, which helped to promote the reception of Christianity. He was ignorant of another fact of great importance (which has only in recent years been fully appreciated through the researches of F. Cumont), the wide diffusion of the Mithraic religion and the close analogies between its doctrines and those of Christianity. In regard to the attitude of the Roman Government towards the Christian religion, there are questions still *sub judice;* but Gibbon had the merit of reducing the number of martyrs within probable limits.

Gibbon's verdict on the history of the middle ages is contained in the famous sentence, "I have described the triumph of barbarism and religion." It is important to understand clearly the criterion which he applied; it is frequently misapprehended. He was a son of the 18th century; he had studied with sympathy Locke and Montesquieu; no one appreciated more keenly than he did political liberty and the freedom of an Englishman. This is illustrated by his love of Switzerland, his intense interest in the fortunes of that country, his design of writing "The History of the Liberty of the Swiss"—a theme, he says "from which the dullest stranger would catch fire." Such views and sentiments are incompatible with the idealization of a benevolent despotism. Yet in this matter Gibbon has been grossly misapprehended and misrepresented. For instance, Mirabeau wrote thus to Sir Samuel Romilly: "I have never been able to read the work of Mr. Gibbon without being astounded that it should ever have been written in English; or without being tempted to turn to the author and say, 'You an Englishman? No, indeed.' That admiration for an empire of more than two hundred millions of men, where not one had the right to call himself free; that effeminate philosophy which has more praise for luxury and pleasures than for all the virtues; that style always elegant and never energetic, reveal at the most the elector of Hanover's slave." This criticism is based on a perverse misreading of the historian's observations on the age of Trajan, Hadrian and the Antonines. He enlarges, as it was his business to do, on the tranquillity and prosperity of the empire in that period, but he does not fail to place his finger on the want of political liberty as a fatal defect. He points out that under this benevolent despotism, though men might be happy, their happiness was unstable, because it depended on the character of a single man; and the highest praise he can give to those virtuous princes is that they "deserved the honour of restoring the republic, had the Romans of their days been capable of a rational freedom." The criterion by which Gibbon judged civilization and progress was the measure in which the happiness of men is secured, and of that happiness he considered political freedom an essential condition. He was essentially humane; and it is worthy of notice that he was in favour of the abolition of slavery, while humane men like his friend Lord Sheffield. Dr. Johnson and Boswell were opposed to the anti-slavery movement.

BIBLIOGRAPHY.—Of the original quarto edition of *The Decline and Fall,* vol. i. appeared, as has already been stated, in 1776, vols. ii. and iii. in 1781 and vols. iv.–vi. (inscribed to Lord North) in 1788. In later editions vol. i. was considerably altered by the author; the others hardly at all. The number of modern reprints has been very considerable. For many years the most important and valuable English edition was that of Milman (1839 and 1845), which was reissued with many critical additions by Dr. W. Smith (8 vols. 8vo, 1854 and 1872). This has now been superseded by the edition, with copious notes, by J. B. Bury (7 vols. 8vo, 1896–1900; netv ed. 1909–13). The edition in Bohn's British Classics (7 vols., 1853) deserves mention. *See* also the essay on Gibbon in Sir Spencer Walpole's *Essays and Biographies* (1907). There are in addition, translations in nearly every European language. Gibbon's *Miscellaneous Works, with Memoirs of his Life and Writings, composed by himself; illustrated from his Letters, with occasional Notes and Narrative,* published by Lord Sheffield in two vols. in 1796, has been often reprinted. The new edition in five vols. (1814) contained some previously unpublished matter, and in particular the fragment on the revolutions of Switzerland. A French translation of the *Miscellaneous Works* by Marigné appeared at Paris in 1798. There is also a German translation (Leipzig, 1801).

(J. B. B.)

GIBBON, the collective title of the smaller man-like apes of the Indo-Malay countries, all belonging to the genus *Hylobates* (*see* PRIMATES), which constitutes the family *Hylobatidae.* One of the distinctive features of this family is the presence of small naked callosities on the buttocks. The extreme length of the limbs and the absence of a tail are other features of these small apes, which are arboreal in their habits, and make the woods resound with their unearthly cries at night; in agility they are unsurpassed. When they descend to the ground—which they do to obtain water—they walk in the upright posture, either with the hands crossed behind the neck, or with the knuckles resting on the ground., Their food consists of leaves and fruits. Gibbons may be divided into two groups, the one represented by the siamang, *Hylobates* (*Symphalangus*) *syndactylus,* of Sumatra and the Malay Peninsula, and the other by a number of closely allied species. The union of the index and middle fingers by means of a web extending as far as the terminal joints is the distinctive feature of the siamang, which is the largest of the group and black in colour with a white frontal band. Black or puce-grey is the prevailing colour in the second group, of which the hulock *(H. hulock)* of Assam, *H. lar* of Arakan and Pegu, H. *entelloides* of Tenasserim, and H. *agilis* of Sumatra are representatives. The range of the genus extends from the southern bank of the Brahmaputra in Assam to southern China, the Malay Peninsula, Java. Sumatra and Borneo.

SILVERY GIBBON (HYLOBATES LEUCISCUS), THE MAN-LIKE SMALL APE OF INDO-MALAY COUNTRIES

GIBBONS, GRINLING (1648–1721), English wood-carver, was born in 1648, according to some authorities of Dutch parents at Rotterdam, and according to others of English parents at London. By the former he is said to have come to London after the great fire in 1666. He died in London on Aug. 3, 1721. Gibbons early displayed great talent in his art, and was recommended by Evelyn to Charles II., who employed him in the execution of statuary and of ornamental carving in wood. He also worked for Sir Christopher Wren. One of his principal works is a life-size bronze statue representing James II. in the dress of a Romsn emperor, and he also designed the base of the statue of Charles I. at Charing Cross. He is, however, chiefly famous as a sculptor in wood. He executed the ornamental carving for the chapel at Windsor, the foliage and festoons in the choir of St. Paul's, the baptismal fonts in St. James's, and an immense quantity of ornamental work at Burleigh, Chatsworth and other great houses. The finest of all his productions is a ceiling at Petworth. His subjects are chiefly birds, flowers, foliage, fruit and lace, characterized by delicacy and elaboration of details, and truthfulness of imitation. In 1714 Gibbons was appointed master carver in wood to George I. Sometimes, he would waste his time on trifling subjects. Many flowers he carved shook when shaken by *a* breeze.

See A. E. Bullock, *Grinling Gibbons & his Compeers,* H. A. Tipping, *Grinling Gibbons & the Woodwork of his Age* (1914).

GIBBONS, JAMES (1834–1921), American Roman Cachoiic Cardinal and Archbishop, was born in Baltimore, Md., July 23, 1834. He was educated at St. Charles college, Ellicott City, Md., and St. Mary's Seminary, Baltimore, where he studied theology and was ordained priest on June 30, 1861. After four years as curate in parishes and as volunteer chaplain to Northern troops he became secretary to Archbishop Martin J. Spalding. In 1868 he was consecrated bishop and appointed to organize the new Vicariate Apostolic of North Carolina. At the Vatican Council, 1870, he was the youngest bishop in the Catholic Church. The four years as missionary bishop in North Carolina, a great deal of which time was spent travelling about and meeting all classes of people, were the formative years of his career. During this time he wrote *The Faith of Our Fathers,* a presentation of the doctrines of the Roman Catholic Church, intended for orthodox Protestants; it passed through more than 40 editions in America and about 70 in England. Gibbons was transferred to the See of Richmond, Va., in 1872 and in 1877 was made coadjutor with the right of succession to Archbishop James R. Bayley of Baltimore. In October of the same year he succeeded to the archbishopric. Pope Leo XIII. in 1883 selected him to preside over the Third Plenary Council of Baltimore (1884) and on June 30, 1886, created him a cardinal priest with the title of Santa Maria in Trastevere. His address on taking over his titular church was in praise of the practical workings of the American system of separation of Church and State. This admiration of things American characterized his whole career. The Knights of Labor were condemned by a Canadian cardinal and their cause was taken up successfully by Cardinal Gibbons. Various efforts made to maintain control of immigrant groups under European leadership were opposed and defeated by him. His foresight and prudence in the conduct of church affairs and of the relations of the Church with the American people marked him as a great leader. He contributed frequently to periodicals, but as an author is known principally by his works on religious subjects, including *Our Christian Heritage* (1889), *The Ambassador of Christ* (1896) and *A Retrospect of Fifty Years* (1916). For many years an ardent advocate of the establishment of a Catholic university, at the Third Plenary Council of Baltimore, 1884, he saw the realization of his desires in the foundation of the Catholic University of America at Washington, of which he became first chancellor and president of the board of trustees. In 1911, on the occasion of his Silver Jubilee as cardinal and his Golden Jubilee as priest, the most distinguished men in the country, without regard to religious belief, gathered in Washington to voice his praises. Similar testimony was rendered at his death on March 24, 1921.

(F. P. D.)

GIBBONS, ORLANDO (1583–1625), English composer, was the most illustrious of a family of musicians all more or less able. His father, William Gibbons (d. 1595) was one of the "waits" of Cambridge, and his three sons, and, at least, one of his grandsons, were all good musicians. The eldest son, Edward *(c.* 1570–*c.* 1650), was priest-vicar and succentor at Exeter cathedral, and some of his music is extant in various libraries. Ellis (1573–1603) contributed two madrigals to Morley's *Triumphs of Oriana.* Orlando, the youngest and most famous of the brothers, was born at Cambridge, Dec. 25, 1583. At 12 years of age he became a chorister of King's college, Cambridge, and in due course a sizar of the college, taking his degree of Mus.D. in 1606. At the age of 21, he became organist of the Chapel Royal. Gibbons received many marks of royal favour, and in 1619 was appointed one of the king's musicians for the virginals. In 1622 he received the honorary degree of Mus. Doc. at Oxford, for which occasion he composed the anthem "O, clap your hands." Next year he was appointed organist of Westminster Abbey, but only lived to hold the post for two years. In 1625 he went to Canterbury to produce a composition written in honour of the marriage of Charles to Henrietta Maria, and there died of apoplexy on June 5, 1625. He was buried in Canterbury cathedral.

The works published by Gibbons during his lifetime were *Fantastes in Three Parts, composed for viols (c.* 1610), said to have been the first piece of music in England printed from engraved copper plates; six pieces for the virginals printed in the collection called *Parthenia* (1611); *Madrigals and Motets of 5 parts, Apt for Viols and Voices* (1612), which rank among the most exquisite of his works; and two anthems printed in Leighton's *Teares or Lamentaciones* (1614). His fame was kept alive as a composer of church music by the selections from his services and anthems printed by Barnard in his First Book of Selected Church Music (1641), and by Boyce in his Cathedral Music (1760–78). Some 40 anthems by Gibbons are in existence. Some of these are in the polyphonic style of which he was a consummate master; others show him as a pioneer in the new form developed by Blow, Purcell and others of a later generation, for they have solos, often with instrumental accompaniment, and chorus. He wrote church services in both the old and the new style, and left 17 hymn tunes marked with his own peculiar dignity of expression.

A collection of Gibbons's church music was edited by Sir F. Ouseley, in 1873; a complete edition is in the Carnegie edition of Tudor Church Music (vol. iv., 1925). His pieces for keyboard instruments were edited by Margaret Glyn (5 vols., 1925), and some of his music for strings by Fellowes (1924). *See* Margaret H. Glyn, *About Elizabeth and Virginal Music and its Composers* (1924), and E H Fellowes, *Orlando Gibbons* (Oxford, 1925).

GIBBS, JOSIAH WILLARD (1839–1903), American mathematical physicist, was born at New Haven, Conn., on Feb. 11, 1839. Entering Yale in 1854 he graduated 1858, and in 1863 went to Europe, studying in Paris in 1866–67, in Berlin in 1867 and in Heidelberg in 1868. Returning to New Haven in 1869, he was appointed professor of mathematical physics at Yale in 1871 and held that position till his death on April 28, 1903. His first contributions to mathematical physics were two papers published in 1873 on "Graphical Methods in the Thermodynamics of Fluids," and "Method of Geometrical Representation of the Thermodynamic Properties of Substances by means of Surfaces." His next and most important publication was his famous paper "On the Equilibrium of Heterogeneous Substances" (1876–78), which, it has been said, founded a new department of chemical science. This was translated into German by W. Ostwald (who styled its author the "founder of chemical energetics") in 1891 and into French by H. le Chatelier in 1899. In 1881 and 1884 he printed some notes on the elements of vector analysis for the use of his students; these were never formally published, but they formed the basis of a text-book on *Vector Analysis* which was published by his pupil, E. B. Wilson, in 1901. Between 1882 and 1889 a series of papers on certain points in the electromagnetic theory of light and its relation to the various elastic solid theories appeared in the *American Journal of Science,* and his last work, *Elementary Principles in Statistical Mechanics,* was issued in 1902. The name of Willard Gibbs, who was the most distinguished American mathematical physicist of his day, is especially associated with the "Phase Rule." In 1901 the Copley medal of the Royal Society of London was awarded him as being "the first to apply the second law of thermodynamics to the exhaustive discussion of the relation between chemical, electrical and thermal energy and capacity for external work."

For biographical sketch *see* his *Scientific Papers* (1906).

See W. *L.* Miller, *The Method of Willard Gibbs in Thermodynamics* (1925); *E.* Cohen, "Semi-century of Willard Gibbs's Phase Law, 1876–1926," in *Science,* n.s. vol. lxiv., p. 621 (1926); and John Johnson "Josiah Gibbs: An Appreciation," in *Scientific Monthly,* Feb., 1928, pp. 129–139.

GIBBS, OLIVER WOLCOTT (1822–1908), American chemist, was born in New York city on Feb. 21, 1822. He graduated at Columbia college in 1841, and at the College of Physicians and Surgeons in 1845. Leaving America he studied in Germany with von Liebig and others, and in Paris with A. Laurent, J. B. Dumas and H. V. Regnault, returning in 1848. In that year he became professor of chemistry at the Free Academy, now the College of the City of New York, and in 1863 he obtained the Rumford professorship in Harvard university, a post retained until his retirement in 1887. He died on Dec. g, 1908. Gibbs' researches were mainly in analytical and inorganic chemistry, the cobaltammines, platinum metals and complex acids being especially investigated. He was an excellent teacher, and contributed many articles to scientific journals.

GIBEON, an ancient city of Palestine, whose inhabitants successfully tricked Joshua into a truce (Josh. ix.). David's select warriors fought with the chosen of Ishbosheth at the "Pool of Gibeon" (2 Sam. ii.), and here Joab treacherously slew Amasa (2 Sam. xx.). But Gibeon was more renowned for its "high place" which the youthful King Solomon made it one of his first cares to visit, and where for a time the tabernacle was deposited. Gibeon is most probably represented to-day by El-Jib, where we seem to have an echo, if faint and uncertain, of the ancient name. El-Jib is a small village on an isolated hill, 5m. N.W. of Jerusalem, and is surrounded by olive groves. Here are to be found springs and the remains of a reservoir.

Alt would identify Gibeon with Tell en-Nasbeh.

Dalman, Nochmals Gibeon: *Palastina Jahrbuch,* 22 (1926) 140 *seq.;* A. Alt, Gibeon und Beeroth: *Palästina Jahrbuch,* 22 (1926) 11 *seq.* (E. Ro.)

GIBEONITES, the inhabitants of Gibeon (*q.v.*).

GIBRALTAR. A British fortress and crown colony at the western entrance to the Mediterranean. Area 0.9 sq.mi. Described by Ramsay and Geikie *(Quart. Journ. Geol. Soc.,* London, 1878, p. 505):—"The Rock . . . forms a well marked promontory that trends in a direction south by west into the Mediterranean. The extreme length of the Rock from the base of the cliff at the north front to Europa Point is only a little over 2½ m., and the promontory tapers somewhat gradually away from a breadth of 1,550 yds. between Gibraltar and Catalan Bay to a width of 550 yds. at Europa. The Rock shoots abruptly upwards from the low flat ground at the north front in a fine mural precipice, the basal portion of which is partly concealed by a sloping curtain of débris and breccia. This precipitous wall culminates . . . at the Rock Gun (1,349 ft.) from which point the dividing ridge or backbone of the promontory extends southward in a sharp jagged arch, the dominant points of which are Middle hill (1,195 ft.), Signal station (1,294 ft.), heights above Monkey's Alameda (1,396 ft.) and O'Hara's tower (1,370 ft.). At the latter the ridge is sharply truncated, and succeeded to the south by the well-marked plateau of Windmill hill and Europa. From the Rock Gun to O'Hara's tower the dividing ridge presents to the east a bold escarpment, which is for the most part inaccessible, and in places almost vertical, the cliffs where they are lowest having a drop of not less than 300 or 400 ft., and of more than 1,000 ft. where they approach the sea on the north. From their base the ground falls rapidly away to the coastline at angles that vary from 30° to 40°. The opposite slopes of the dividing ridge are not so abrupt, the only really precipitous portion that faces the west being the line of cliff that overlooks Gardiner's road and Engineer's road between the Moorish wall and the Mount. A low sandy plain, that does not average more than 10 ft. in height above the sea, connects the Rock with the mainland."

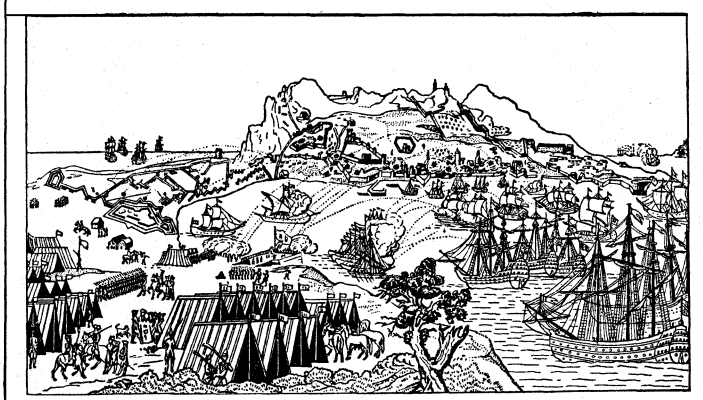
The top of Windmill hill slopes from 400 to 300 ft. above sea, and so is separated by a great cliff from O'Hara's tower on the north, it ends southward in a 200 ft. cliff, below which are Europa flats that themselves end in a 50 ft. cliff plunging steeply into fairly deep water. Europa Point is 11½ nautical miles from the African coast, and its lighthouse is in 5° 21' W. and 36° 6' 30" N. The rock is built of limestone, covered on the west by shales, both of Lower Jurassic age. The limestone has many caves with accumulations of bone-breccia and there are several apparently Pleistocene or still more recent deposits.

According to M. Déperet (*Comptes Rendus Acad. Sci.,* Paris, *T.* 166, 1918), "it was formerly supposed that Gibraltar was connected with the African shore during or after the Pleistocene Ice age but the trend of opinion is now towards the view that the connection must be Pliocene at the latest. Reference used to be made to the occurrence of Barbary apes on the Rock, but it is now thought that these were introduced by Romans or Moors; no fossil remains of them have been found in any caves or breccias. Neither the surviving nor the fossil-Pleistocene fauna suggests an African connection. The presence of the great auk in Pleistocene times at the Rock is not held to imply any great difference of climate, as its remains have been found in south Italy, Brittany, etc., though it became restricted in course of time to the far north. Several caves have been examined towards the south end, but special attention has been given to one at the north end overlooking the isthmus near the Devil's tower (see *Journ. Roy. Anthr. Inst., op. cit.*), which has yielded evidence of the former presence of 25 species of mammals, including the elephant and rhinoceros; for the rest the mammalian remains are essentially European." When tunnelling operations were in progress during World War II a cave 40 ft. high was found. Believed to have been sealed 20,000 years ago, the cave, in area the size of a cathedral, contained a fresh-water lake 40 yd. in length.

The flora of the Rock is not over rich, because of the isolation and of the character of much of its surface. The stone pine and the wild olive appear to be old established. The fauna, apart from the barbary apes, is not of great interest. A Mousterian flint industry was described for Gibraltar (especially the Devil's tower site) by Miss Garrod, who also found two skulls of Mousterian type. (H. J. F.; X.)

Climate.— June, July and August are practically rainless and May and September nearly so. The rest of the year is delightful, with occasional storms. The thermometer in summer does not often reach 90° F. in the shade; from 83° to 85° may be taken to be the average maximum for July and August, and the mean annual temperature is 64" 4″. The average yearly rainfall is 35⅓ in., and the highest recorded rainfall in Gibraltar occurred in the winter of 1855–56 when it was 77.14 in., the lowest recorded rainfall being in 1800–01 when it was 15.12 in. The water-supply for drinking and cooking purposes is almost wholly derived from rain water, stored chiefly in underground tanks; there are only two fresh-water wells. Rain reservoirs with a capacity of 12,000,000 gal. are filled with water from specially prepared collecting areas high up the Rock, these areas covering some 50 acres.

The Town.—The modern town of Gibraltar is of comparatively recent date, nearly all the older buildings having been destroyed during the great siege (1779–83). The town lies, with most of its buildings crowded together, at the northwestern corner of the Rock, and covers an area of only ¾ by ¼ mile. A good deal of land has been reclaimed from the sea. Much of the town, in fact the entire business quarter, is on level ground, and the narrow streets and ramps that go up the Rock only communicate with various private houses, barracks, etc. To the south of the town are the barracks for the military garrison and the majority of the biggest official residences, together with sports grounds and many other interesting parts of Gibraltar. The Gibraltar museum, which was opened in 1930, contains casts of the celebrated Gibraltar skulls, a collection of the flora of the Rock, and pictures, coins and stamps.



FROM THE "EUROPEAN MAGAZINE." OCT. 1, 1792

THE SIEGE OF GIBRALTAR. 1779–1783, SHOWING ARRIVAL OF BRITISH RELIEVING SQUADRON UNDER ADMIRAL DARBY, APRIL 12, 1781

Population.— After the capture of the town by the British, the former Spanish population emigrated and founded, 6 mi. away, the little town of San Roque. Most of the native inhabitants are of Italian or Genoese descent; there are also a number of Maltese and between two and three thousand Jews.

The Jews form a distinct society of their own. The language of the people is Spanish, not very correctly spoken. English is learned as a foreign language and is rarely, if ever, spoken by the people in their own homes. Thousands of workers cross "the Lines" daily from the neighbouring Spanish town of La Linea de la Concepción, itself a mere suburb of Gibraltar whose population is 35,371. Though the gates are kept open, the frontier barrier closes at 10 P.M. save for those who have a pass. Aliens are not allowed to reside in Gibraltar without a special permit, which must be renewed at short intervals. After 1900 like disabilities were extended to British subjects not previously resident. In 1938 the estimated population, that resident between sunset and sunrise, amounted to 20,000.

Government. — Power of legislation is vested in the governor, who is also the commander-in-chief. He is assisted by an executive council (established in 1922) of four official and three nominated unofficial members. A board of sanitary commissioners was succeeded in 1921 by a city council of four elected members. The council is responsible for buildings and streets, and for managing the water supply and other matters dealt with by local authorities in England. An appeal from its decisions, so far as they affect individuals, lies to the supreme court.

Religion and Education. — Apart from the garrison and civil officials, there are comparatively few members of the Anglican Church. The great majority of the people belong to the Church of Rome, and in 1910 Gibraltar became a Roman Catholic bishopric, independent of the Spanish hierarchy and subject directly to the Vatican. There are, besides an Anglican cathedral, four Roman Catholic churches, Nonconformist churches and four Jewish synagogues.

Education is compulsory for all children between the ages of 5 and 14. The 13 elementary schools (of which 11 are Roman Catholic) are subsidized by the government, as are, also, 4 secondary schools; there are, in addition, several private schools. In 1938 there was an average attendance in government-aided schools of 2,313 scholars.

Commerce. — With few exceptions, Gibraltar has been a free port since 1705—a distinction due, it is said, to the refusal of a sultan of Morocco to allow much-needed exports from Morocco to Gibraltar if full liberty of trade were not granted to his subjects.

During the great wars of the beginning of the 19th century trade was most active in Gibraltar, and some large fortunes were made; but trade on a large scale later almost disappeared. Before 1898, wine, beer and spirits were the only goods which paid duty. In that year a duty was placed upon tobacco for the first time, and all these imports enjoy the preferential rates accorded to products of the British empire. There is also a duty on motor spirit.

The chief business of Gibraltar was the coaling of passing steamers, but this entered a period of decline after World War I. With installation of modern coaling machinery in 1932 and exemption from the payment of port dues by vessels calling solely for bunkers, the coaling business enjoyed a modest revival. The increased use of oil fuel by ships, however, made unlikely restoration of the earlier prosperity in the coaling business. Another source of trade is the export of goods landed for re-export to Morocco, but much of this business which formerly went to Gibraltar was transferred to lines of steamers operating directly between Morocco and British, German and French ports. Nearly all the fresh meat consumed in Gibraltar ordinarily comes from Morocco, and also large quantities of poultry and eggs. The main sources of revenue comprise (1) duties upon wine, spirits, malt liquors, tobacco and motor spirit; (2) port and harbour dues; (3) tavern and other licences; (4) posts and telegraphs; (5) rent of the crown estate in the town; (6) stamps and miscellaneous.

The money, weights and measures in legal use are British. Before 1898 Spanish money only was in use. The great depreciation of the Spanish currency during the war with the United States led in 1898 to the reintroduction of British currency as the legal tender of Gibraltar. Notwithstanding this change the Spanish dollar remains in current use, because much of the retail business of the town is done with persons resident in Spain. After 1927 the currency included notes issued by the government of Gibraltar of the value of £5, £1 and 10s. There are branches of Barclays bank (Dominion, Colonial and Overseas), the Credit Foncier d'Algérie et de Tunisie and several private bankers. A government savings bank was founded in 1882 and had at the end of 1938 £313,000 deposited by 5,470 depositors.

Harbour and Fortifications. — Early in the 20th century the defenses of Gibraltar were modernized. Old pieces of artillery at or near the sea level were replaced by new weapons placed high up, many of them on the crestline of the Rock, and new dockyard works were undertaken. Gibraltar became an important naval base where ships could lie at anchor secure against attack by surface vessels and be given extensive repair.

The land space available for the purposes of dockyard extension being very limited, a space of about 64 ac. was reclaimed from the sea in front of the Alameda and the road to Rosia; some of the land reclaimed was as much as 40 ft. under water. The large quantity of material required for this purpose was obtained by tunnelling the Rock from west to east and from quarries above Catalan Bay village, to which access was gained through the tunnel. The graving docks occupy the dugout site of the former New Mole Parade. There are three of these docks, 850, 550 and 450 ft. in length respectively, and a small dock which is available for merchant vessels of light draught. The largest dock is divisible by a central caisson so that four ships can be docked at one time. The docks are all 95 ft. wide at the entrance, with 353 ft. of water over the sills at low-water spring tides. The enclosed harbour covers 440 ac., 250 having a minimum depth of 30 ft. at low water. It is closed on the south and southwest by the South (or New) Mole and the South Mole extension, together 3,660 ft.; on the west by the Detached Mole, 2,717 ft.; and on the north by the North (or Commercial) Mole. The last runs westward from Devil's Tongue for about 2,900 ft., and then southward, giving a total length of over a mile.

The South Mole is said to have been begun by the Spaniards in 1620. It was successfully assaulted by landing parties from the British fleet under Sir George Rooke at the capture of Gibraltar by the British in 1704. It is formed of rubble stone floated into position in barges. The mole has a width at top of 102 ft., and it has a continuous wharf wall on the harbour side, 3,500 ft. long, with water alongside 30–35 ft. deep.

The Detached Mole is a vertical wall formed of concrete blocks, each block weighing 28 tons. These blocks were built together on the sloping block system upon a rubble foundation of stone deposited by barges and levelled by divers for the reception of the concrete blocks.

The North Mole is chiefly used by the navy as a convenient wharf for destroyers and other smaller craft. At the end nearest the town are large stores. Parallel with and inside the western arm of the mole, which is built of rubble, are five jetties faced with a concrete wharf wall and having 20 to 30 ft. of water alongside. The Devil's Tongue was constructed during the great siege of 1779–83 in order to bring a flanking fire to bear upon part of the Spanish lines.

The old wharf at Waterport was extended and improved by the addition of a new mole, which was provided with sheds for transit cargo, electrical cranes and other equipment to facilitate the handling of cargo.

With the development of air warfare the defense of Gibraltar became a problem of particular difficulty because of the lack of space upon which to construct adequate airfields. During World War II there was available only one small landing-place with a length of merely 200 yds.

History. — Gibraltar was known to the Greek and Roman geographers as Calpe or Alybe, the two names being probably corruptions of the same local (perhaps Phoenician) word. The eminence on the African coast near Ceuta which bears the modern English name of Apes' hill was then designated Abyla; and Calpe and Abyla, at least according to an ancient and widely current interpretation, formed the renowned Pillars of Hercules

(*Herculis* columnae, Ἡρακλέους στῆλαι), which for centuries were the limits of enterprise to the seafaring peoples of the Mediterranean world. Gibraltar is called after Tariq (or Tarik) ben Zaid, its name being a corruption of Jebel Tariq (Mount Tariq). Tariq invaded Andalusia in A.D. 711 with an army of 12,000 Arabs and Berbers, and in the last days of July of that year destroyed the Gothic power in a three days' fight on the banks of the river Guadalete near where Jerez de la Frontera now stands. In order to secure his communications with Africa he ordered the building of a strong castle upon the Rock, known to the Romans as Mons Calpe. This work, begun in the year of the great battle, was completed in 742. It covered a wide area, reaching from the shores of the bay to a point half-way up the north-western slope of the Rock; here the keep, a massive square tower, still stands and is known as the Moorish castle. In 1309 it was taken by Spain, and in 1333 retaken by the Moors, from whom it passed in 1411 to the Moorish ruler of Granada. In 1462 it became Spanish once more, passing in 1469 into the family of the duke of Medina Sidonia. In 1502 Gibraltar was formally incorporated with the domains of the Spanish crown. The Spanish made great efforts to strengthen the place, and they succeeded so well that throughout Europe Gibraltar was regarded as impregnable, the engineer, Daniel Speckle (1536–1589), being chiefly responsible for the design of the fortifications.

Gibraltar was taken by the allied British and Dutch forces, after a three days' siege, on July 24, 1704. (See SPANISH SUCCESSION, WAR OF THE.) The capture was made, as the war was being fought, in the interests of Charles, archduke of Austria, but Sir George Rooke, the British admiral, on his own responsibility caused the British flag to be hoisted, and took possession in the name of Queen Anne, whose government ratified the occupation. The Spaniards quickly assembled an army to recapture the place, and a new siege opened in Oct. 1704 by troops of France and Spain under the marquess of Villadarias. The activity of the British admiral, Sir John Leake, and of the military governor, Prince George of Hesse-Darmstadt (who had commanded the land forces in July), rendered the efforts of the besiegers useless. During the next 20 years there were endless negotiations for the peaceful surrender of the fortress, varied in 1720 by an abortive attempt at a coup de *main*, which was thwarted by the resourcefulness of the governor of Minorca (Col. Kane), who threw reinforcements and supplies into Gibraltar at the critical moment. Gibraltar was unsuccessfully besieged by the Spaniards in 1726.

The Great Siege **of** 1779–1783.—Neither in the War of the Austrian Succession nor in that of 1762 did Spain endeavour to besiege the Rock, but during the War of American Independence the siege of 1779–83 is justly regarded as one of the most memorable sieges of history. The governor, Gen. Sir George Augustus Elliot (afterwards Lord Heathfield), was informed from England on July 6, 1779, that hostilities had begun. A short naval engagement in the straits took place on the 11th, and Gen. Elliot made every preparation for resistance. It was not, however, until the month of August that the Spaniards became threatening. The method of the besiegers appeared to be starvation, but the interval between strained relations and war had been well employed by the ships, and supplies were, for the time at any rate, sufficient. While the Spanish siege batteries were being constructed the fortress fired, and many useful artillery experiments were carried out by the garrison at this time and subsequently throughout the siege. On Nov. 14, there took place a spirited naval action in which the privateer "Buck," Captain Fagg, forced her way into harbour. This was one of many such incidents, which usually arose from the attempts made from time to time by vessels to introduce supplies from Tangier and elsewhere. Dec. 1779, indeed, was a month of privation for the garrison, though of little actual fighting. In Jan. 1780, on the rumour of an approaching convoy, the price of foods "fell more than two-thirds," and Admiral Sir George Rodney won a great victory over De Langara and entered the harbour. Prince William Henry (afterwards King William IV.) served on board the British fleet as a midshipman during this expedition. Supplies and reinforcements were thrown into the fortress by Rodney, and the whole affair was managed with the greatest address both by the Home Government and the royal navy. "The garrison," in spite of the scurvy, "might now be considered in a perfect state of defence," says Drinkwater.

On June 7 took place an attack by Spanish fireships, which were successfully dealt with by the naval force in the bay under Captain Lesley of H.M. frigate "Enterprise." Up to October the state of things within the fortress was much what it had been after Rodney's success. "The enemy's operations on the land side had been for many months so unimportant as scarcely to merit our attention" (Drinkwater). Scurvy was, however, prevalent (see Drinkwater, p. 121), and the supply question had again become acute. Though the enemy's batteries did not open fire, the siege works steadily progressed, in spite of the fire from the fortress, and there were frequent small engagements at sea in which the English were not always successful. Further, the expulsion, with great harshness, of the English residents of Barbary territory put an end to a service of supply and information which had been of the greatest value to Elliot (Jan. 1781). Three more months passed in forced inaction. Then, on April 12, 1781, on the arrival of a British relieving squadron under Admiral Darby, the whole of the Spanish batteries opened fire. Stores were landed in the midst of a heavy bombardment, and much damage was done both to the fortifications and military buildings and to the town. At this time there was a good deal of indiscipline in the garrison, with which Gen. Elliot dealt severely. This was in the last degree necessary, for the bombardment continued up to June 1, after which the rate of the enemy's fire decreased to 500 rounds per day. By July 12 it had almost ceased. In September the firing again became intense and the casualties increased, the working parties suffering somewhat heavily. In October there was less expenditure of ammunition, as both sides were now well covered, and in November the governor secretly prepared a great counterstroke. The sortie made on the night of Nov. 26–27 was brilliantly successful, and the Spanish siege works were mostly destroyed. At the close of the year the garrison was thus again in an excellent position.

Hot-Shot Experiment.—Early in 1782 a gun-carriage wheel, allowing of a large angle of depression, was invented by an officer of the Royal Artillery, and indeed throughout the siege many experiments (such as would nowadays be carried out at a school of gunnery) were made with guns, mountings, ammunition, methods of fire, etc., both in Gibraltar and in the Spanish camp. The gun-carriage referred to enabled 93% of hits to be obtained at 1,400 yds. range. In April grates for heating shot were constructed by order of the governor; these were destined to be famous. At the same time it was reported that the duc de Crillon was now to command the besiegers (French and Spaniards) with D'Arçon as his chief engineer. The grand attack was now imminent, and preparations were made to repel it (July 1782). The chief feature of the attack was to be, as reported on July 26, ten ships "fortified 6 or 7 ft. thick . . . with green timber bolted with iron, cork and raw hides; which were to carry guns of heavy metal and be bombproof on the top with a descent for the shells to slide off; that these vessels . . . were to be moored within half gunshot of the walls," etc. On the other side many of the now existing rock galleries were made about this time. The count of Artois and another French prince arrived in the French lines in August to witness the culminating effort of the besiegers, and some polite correspondence passed between Crillon and the governor (reprinted in Drinkwater, p. 267). The garrison made a preliminary trial of the red-hot shot on Sept. 8, and the success of the experiment not only elated the garrison but was partly instrumental in causing Crillon to hasten the main attack.

After a preliminary bombardment the famous battering ships took up their positions in broad daylight on the 13th and opened fire. The British solid shot seem to have failed absolutely to penetrate the massive wooden armour on the sides and the roofs of the battering ships, and about noon the ships had settled down to their work and were shooting coolly and accurately. But between 1 and 2 P.M. the British artillerymen began to use red-hot shot freely. All day the artillery duel went on, the shore guns,

though inferior in number, steadily gaining the upper hand, and the battering ships were in great distress by nightfall. The struggle continued in the dark, the garrison now shooting rapidly and well, and one by one the ten ships were set on fire. Before noon on the 14th the attack had come to an end by the annihilation of the battering fleet, every ship having been blown up or burned to the water's edge. Upwards of 8,300 rounds were expended by the garrison, though less than a hundred pieces were in action. The enemy's bombardment was, however, resumed and partial engagements continued up to the third naval relief of the fortress by Lord Howe, who won a great victory at sea over the Spaniards. The long siege came to an end on Feb. 6, 1783, when the duc de Crillon informed Elliot that the preliminaries of peace had been signed. On March 31 the duke visited the fortress, and many courtesies passed between the late enemies. Captain (afterwards Colonel) John Drinkwater (1762–1844), the historian of the siege, first published his work in 1785. A new edition of *A History of the Siege of Gibraltar* was published in 1905. The history of the four eventful years' siege is fully detailed also in the Memoir, attached to Green's *Siege of Gibraltar* (1784), of its gallant defender Sir George Augustus Elliot, afterwards Lord Heathfield, whose military skill and moral courage place him among the best soldiers and noblest men of his time.

After 1783 the history of Gibraltar was comparatively uneventful. Rumours in 1801 of a Spanish and French attack ended after Admiral Soumarez defeated the Spanish ships off Algeciras in June. During World War I the Rock was of great value as a base for Allied navies, the most important being that of the United States. Thousands of Spanish refugees sought shelter in the fortress during the civil war of 1936–39. After Italy entered World War II in 1940 all women and children were removed from Gibraltar, as well as all male civilians except some 3,000 engaged in essential work. Defenses were constructed on the land side of the Rock to guard against attack through Spain, and military engineers expanded the interior defenses of Gibraltar fivefold, the length of tunnelling being increased from 2 to 10 mi.

GIBSON, CHARLES DANA (1867–), American artist and illustrator, was born at Roxbury (Mass.), on Sept. 14, 1867. After a year's study at the schools of the Art Students' League, he began with some modest little drawings for the humorous weekly *Life*. These he followed up with more serious work, and soon made a place for himself as the delineator of the American girl, at various occupations, particularly those out of doors. These obtained an enormous vogue, being afterwards published in book form, running through many editions. Some book illustrations followed, notably for *The Prisoner of Zenda*.

He was imitated by many of the younger draughtsmen, copied by amateurs, and his popularity was shown in his engagement by *Collier's Weekly* to furnish weekly for a year a double page, receiving for the 52 drawings the sum of $50,000, said to have been the largest amount ever paid to an illustrator for such a commission. These drawings covered various local themes and were highly successful, being drawn with pen and ink with masterly facility and great directness and economy of line. So popular was one series, "The Adventures of Mr. Pipp," that a successful play was modelled on it. In 1905, although besieged with commissions, Gibson withdrew from illustrative work, determining to devote himself to portraiture in oil, in which direction he had already made some successful experiments; but in a few years he again returned to illustration. He has published a number of books of sketches. In 1932 he became a member of the National Academy of Design.

GIBSON, EDMUND (1669–1748), English divine and jurist, was born at Bampton in Westmorland. In 1686 he entered Queen's College, Oxford, where in 1692 he published a valuable edition of the *Saxon Chronicle* with a Latin translation, indices and notes. This was followed in 1693 by an annotated edition of the De *institutione oratoria* of Quintilian, and in 1695 by a translation (2 vols., fol.) of Camden's *Britannia*, "with additions and improvements," with the assistance of William Lloyd, John Smith and other English antiquaries. Gibson was appointed chaplain and librarian to the archbishop of Canterbury, when he began to catalogue the library, and in 1703 and 1710 respectively he became rector of Lambeth and archdeacon of Surrey. During the reigns of William and Anne the controversy over the rights and privileges of Convocation suggested to him the researches which resulted in the famous *Codex iuris ecclesiastici Anglicani* (2 vols., 1713; 2nd enl. ed. 1761). This work is a learned and comprehensive discussion of the legal rights and duties of the English clergy, and the constitution, canons and articles of the English Church. In 1716 Gibson was presented to the see of Lincoln, whence he was in 1720 translated to that of London, where for twenty-five years he exercised great influence, being regularly consulted by Sir Robert Walpole on ecclesiastical affairs. He broke with Walpole on the Quakers' Relief Bill of 1736. He died on Sept. 6, 1748.

Gibson's other works include: *Vita Thomae Bodleii* with the *Historia Bibliofhecae Bodleianae* in the *Catalogi librorum manuscriptorum* (Oxford, 1697), and the *Reliquiae Spelmannianae* (Oxford, 1698).

GIBSON, JOHN (1790–1866), English sculptor, was born near Conway in 1790, his father being a market gardener. He went to Rome in Oct. 1817, where Canova introduced him into the Academy supported by Austria. Gibson, who had had no technical training, was at first depressed by the sense of his deficiencies in common matters of practice. But his first work in marble—a "Sleeping Shepherd" modelled from a beautiful Italian boy—has qualities of the highest order. Gibson was soon launched, and distinguished patrons, first sent by Canova, made their way to his studio in the Via Fontanella. He very seldom declined into the prettiness of Canova, and if he did not usually approach the masculine strength which redeems the faults of Thorwaldsen, he more than once surpassed him even in that quality. We allude specially to his "Hunter and Dog," and to the promise of his "Theseus and Robber," which take rank as the highest productions of the sculpture of his time.

The group of Queen Victoria supported by Justice and Clemency, in the Houses of Parliament—was his finest work in the round. Another famous work by Gibson is the statue of Huskisson (Royal Exchange, London). But great as he was in the round, Gibson's chief excellence lay in basso rilievo, and in this less-disputed sphere he obtained his greatest triumphs. His thorough knowledge of the horse, and his constant study of the Elgin marbles resulted in the two matchless bassi rilievi, the size of life, which belong to Lord Fitzwilliam—the "Hours leading the Horses of the Sun," and "Phaethon driving the Chariot of the Sun." Gibson was the first Englishman to introduce colour on his statues—first, as a mere border to the drapery of a portrait statue of the queen, and by degrees extended to the entire flesh, as in his so-called "tinted" Venus, and in the "Cupid tormenting the Soul," once in the Holford collection, now dispersed. He justified his use of colours by reference to Greek practice. Gibson was elected R.A. in 1836, and bequeathed all his property and the contents of his studio to the Royal Academy, where his marbles and casts are open to the public. An important collection of his works made by Mrs. Sandbach, the granddaughter of W. Roscoe, is at Hafod in Denbighshire. He died at Rome on Jan. 27, 1866.

See Lady Eastlake, *Life of John Gibson, R.A.* (1870) which contains his autobiography; also T. Matthews, *The Biography of John Gibson* (1911); *T.* M. Rees, *Welsh painters, engravers and sculptors* (1912).

GIBSON, THOMAS MILNER (1806–84), English politician, was born in Trinidad, where his father, an officer in the army, was serving. As one of Cobden's chief allies, he was

elected for Manchester in 1841, and from 1846 to 1848 he was vice-president of the board of trade in Lord John Russell's ministry; he sat in the cabinets from 1859 to 1866 as president of the board of trade. He was the leading spirit in the movement for the repeal of "taxes on knowledge," and his successful efforts on behalf of journalism and advertising were recognized by a public testimonial in 1862. He retired from political life in 1868, but he and his wife, whose salon was a great Liberal centre, were for many years very influential in society.

GIBSON, WILLIAM HAMILTON (1850–1896), American illustrator, author and naturalist, was born in Sandy Hook (Conn.), on Oct. 5, 1850. The failure and (in 1868) death of his father, a New York broker, put an end to his studies in the Brooklyn Polytechnic institute and made it necessary for him to earn his own living. From the life insurance business, in Brooklyn, he soon turned to the study of natural history and illustration. He had sketched flowers and insects when he was only eight years old, had long been interested in botany and entomology, and had acquired great skill in making wax flowers. His first drawings, of a technical character, were published in 1870. He rapidly became an expert illustrator and a remarkably able wood-engraver, while he also drew on stone with great success. He drew for many periodicals. He died of apoplexy brought on by overwork, on July 16, 1896, at Washington (Conn.). He was an expert photographer, and his drawings had a nearly photographic and almost microscopic accuracy of detail which slightly lessened their artistic value, as a poetic and sometimes humorous quality somewhat detracted from their scientific worth. Gibson was perfectly at home in black-and-white, but rarely (and feebly) used colours. He was a popular writer and lecturer on natural history; in his lecture on "Cross-Fertilization," he used ingenious charts and models.

GICHTEL, JOHANN GEORG (1638–1710), German mystic, was born at Ratisbon on March 14, 1638. He was admitted an advocate, first at Spires, and then at Ratisbon, but a meeting with the baron Justinianus von Weltz (1621–1668), a Hungarian nobleman who cherished schemes for the reunion of Christendom and the conversion of the world, and a natural leaning towards mysticism changed his career. He promoted a society known as the *"Christerbauliche Jesusgesellschaft."* The movement in its beginning provoked no active hostility; but when Gichtel began to attack the teaching of the Lutheran clergy and church, especially upon the fundamental doctrine of justification by faith, he was prosecuted and banished (1665). He settled at Zwolle, Holland, where he co-operated with Friedrich Breckling (1629–1711), who shared his views and aspirations. In 1668 he removed to Amsterdam, where he made the acquaintance of Antoinette Bourignon (1616–1680), and became an ardent disciple of Jakob Boehme, whose works he published in 1682 (Amsterdam, 2 vols.). He had attracted to himself a small band of followers known as Gichtelians or Brethren of the Angels, who held views at which he had arrived independently of Boehme. But, unlike Boehme, who "desired to remain a faithful son of the Church," the Gichtelians became Separatists *(cf.* J. A. Dorner, *History of Protestant Theology,* ii. p. 185).

Gichtel's correspondence was published without his knowledge by Gottfried Arnold, a disciple, in 1701 (2 vols.), and again in 1708 (3 vols.). It has been frequently reprinted under the title *Theosophia practica.* The seventh volume of the Berlin edition (1768) contains a notice of Gichtel's life. See also G. C. A. von Harless, *Jakob Bohme und die Alchimisten* (1870, 2nd ed., 1882).

GIDDINGS, JOSHUA REED (1795–1864), American statesman, prominent in the anti-slavery conflict, was born at Tioga Point, now Athens, Pa., on Oct. 6, 1795. In 1806 his parents removed to Ashtabula county, Ohio. For several years after 1814 he was a school teacher, but in Feb. 1821 he was admitted to the Ohio bar and soon obtained a large practice. He served in the lower house of the state legislature in 1826–28, and from 1838 until 1859 was a member of the national house of representatives, first as a whig, then as a free-soiler, and finally as a republican. Recognizing that slavery was a state institution, with which the Federal government had no authority to interfere, he contended that slavery could only exist by a specific state enactment, that therefore slavery in the District of Columbia and in the territories was unlawful and should be abolished, that the coastwise slave-trade in vessels flying the national flag, like the international slave-trade, should be rigidly suppressed, and that Congress had no power to pass any act which in any way could be construed as a recognition of slavery as a national institution. His attitude in the so-called "Creole case" attracted particular attention. In 1841 some slaves who were being carried in the brig "Creole" from Hampton Roads, Va., to New Orleans, revolted, killed the captain, gained possession of the vessel, and soon afterwards entered the British port of Nassau. Thereupon, according to British law, they became free. The minority who had taken an active part in the revolt were arrested on a charge of murder, and the others were liberated. Efforts were made by the U.S. government to recover the slaves, Daniel Webster, then secretary of State, asserting that on an American ship they were under the jurisdiction of the United States and that they were legally property. On March 21, 1842, before the case was settled, Giddings introduced in the house of representatives a series of resolutions, in which he asserted that "in resuming their natural rights of personal liberty" the slaves "violated no law of the United States." For offering these resolutions Giddings was formally censured by the house. Thereupon he resigned, appealed to his constituents, and was immediately re-elected by a large majority. From 1861 until his death, at Montreal, on May 27, 1864, he was U.S. consul-general in Canada.

Giddings published a series of political essays signed "Pacificus" (1843); *Speeches in Congress* (1853); *The Exiles of Florida* (1858); and a *History of the Rebellion: Its Authors and Causes* (1864).

See *The Life of Joshua R. Giddings* (Chicago, 1892), by his son-in-law, George Washington Julian (1817–1899), a Free-soil leader and a representative in Congress in 1849–1851, a Republican representative in Congress in 1861–1871, a Liberal Republican in the campaign of 1872, and afterwards a Democrat.

GIDE, ANDRE (1869–), French novelist and essayist, was born in Paris on Nov. 21, 1869, and educated at the *Ecole Alsacienne* and the *Lycée Henri IV.* He made his début in literature with a half-psychological, half-lyrical confession, *les Cahiers d' Andre' Walter* (1891). This was followed by the ironical *Le Voyage d'Urien* (1893), *Paludes* (1895) depicting the mediocrity of man's life, and by *Les Nourritures Terrestres* (1897) a work in which his anti-intellectualism is carried to the extreme of advocating a pure voluptuousness for the enrichment of life. In 1902 Gide published his first novel, *l'Immoraliste,* a masterpiece, following the purest classical tradition with clear-cut psychological design and sureness of touch. *La Porte étroite* (1909, Eng. trs. 1924), *Isabella* (1911), *La Symphonie Pastorale* (1919), are comparatively short analytical novels, distinguished by the same merits. In the *Caves du Vatican* (1914) he attempts less successfully the fantastic and humorous novel. This "sotie" is interesting as illustrating the idea of the *acte gratuit,* that is, void of all ethical or social finality. Among Gide's more recent works are *Les Faux Monnayeurs* (1925), an unequal work, encumbered with detail, but of acute analysis; and *Si le Grain ne Meurt* (1924), an autobiographical account in which sincerity sometimes gives way to cynicism. Gide is also the author of several critical essays and translations.

See the bibliography of his works compiled by R. Simonson (Paris 1924), and S. Braak: *A. Gide et l'Ame moderne* (1923).

GIDE, CHARLES (1847–1932), French economist, was born on June 29, 1847, at Uzès (Gard). Educated at the Collège d'Uzès, he entered the faculty of law of the University of Paris. He early became professor of political economy, first at Bordeaux, then at Montpellier, and from 1898 to 1920 at the University of Paris. He is the author of one of the best introductory treatises on political economy, *Principes d'Economie Politique,* first published in 1884 and since translated into English and other languages, and is joint author with Prof. Rist of an excellent work on the history of economic theory, *Histoire des Doctrines Economiques* (3rd ed. 1920). Gide devoted a great deal of time and energy to the encouragement and furtherance of the co-operative movement in France, and wrote largely on this question. He made unremitting endeavours to maintain and promote har-

monious international relations and especially to preserve co-operation among intellectual workers in different countries.

GIDEON, a liberator, reformer and "judge" of Israel who delivered Israel from hordes of desert raiders—Midianites and others (Jud. vi.–viii.). He is called Jerubbaal also in the narrative, and it is possible that the exploits of two heroes have been combined in the passage. There are, as a matter of fact, at least two narratives combined in the relevant chapters of Judges. According to one account Gideon is visited by the Angel of Yahweh as he is threshing corn in a wine-press, to hide it from the Midianites, and is greeted as the future saviour of Israel. A portion of this narrative has been lost, but it must have told of a raid on Tabor by the Midianites, in the course of which Gideon's brothers were killed. Gathering 300 of his clansmen, Gideon first attacked the raiders by night and drove them away in flight, and then, pursuing them beyond Jordan, captured and slew their two chiefs, Zebah and Zalmunnah. He was then offered the throne, but refused it, and made an image from the Midianite spoil, thus leading Israel into idolatry. In the other narrative Gideon is summoned at night by Yahweh to overthrow the altar of Baal and to establish an altar to Yahweh in its place. This is discovered in the morning, and Gideon is only saved from the anger of his felloivs by the pleading of his father, who argues that since Baal has been insulted, Baal must take vengeance—if he can. Gideon then gathers all Israel, his force is reduced to 300 in number, and with these, encouraged by a dream which he hears told in the camp of Midian, he assaults the enemy by night. They flee in panic, but find that the fords of Jordan are held against them by Ephraimites, who capture and kill the two chiefs Oreb and Zeeb. The Ephraimites then complain that Gideon, a Manassite, had not summoned them to follow him, and he appeases their anger by pointing to the honour they have won in killing Oreb and Zeeb. The story is important as illustrating the danger of raids from the desert to which Palestine was subject, and it prepared the way for Abimelech, Gideon's son, who made the first effort to establish an Israelite monarchy. (S. A. C.; T. H. R.)

GIDEOMS, THE. The Gideons, the Christian Commercial Men's Association of America, International, was organized by three travelling men at Janesville, Wisconsin on July 1, 1899. In Nov., 1908, the organization began to place copies of the Bible in hotel guest rooms, a work which made it famous the world over. On that date, Bibles were placed in the Superior Hotel, Iron Mountain (now Superior), Montana. Later the work was extended to include hospitals and penal institutions and schools. In 1941, the Gideons began to supply the U.S.A. armed forces with service testaments. The Bible work of the Gideons is supported through free-will offerings. By 1941, nearly 2,000,000 Bibles had been placed in many countries by the organization.

The emblem of The Gideons is a two-handled pitcher and torch, in memory of the Bible account of Gideon's victory over the Midianites in Judges vii. The association is managed by an international cabinet consisting of a president, vice president, treasurer, chaplain and six trustees.

GIEBEL, CHRISTOPH GOTTFRIED ANDREAS (1820–1881), German zoologist and palaeontologist, was born on Sept. 13, 1820 at Quedlinburg in Saxony, and educated at the University of Halle, where he became professor of zoology and director of the museum in 1858. He died Nov. 14, 1881.

His chief publications were *Palaozoologie* (1846); *Fauna der Vorwelt* (1847–56); *Deutschlands Petrefacten* (1852); *Odontographie* (1855); *Lehrbuch der Zoologie* (1857); *Thesaurus ornithologiae* (1872–77).

GIEN, a town of central France in the arrondissement of Montargis, within the department of Loiret on the Loire, 39 mi. E.S.E. of Orléans by rail. Pop. (1936) 7,329. Gien has many old houses and a stone bridge built by Anne de Beaujeu, daughter of Louis XI, about the end of the 15th century. The old castle. used as a law court, was built in 1494 by Anne de Beaujeu, of brick and stone arranged in geometrical patterns. The church of St. Pierre possesses a late 15th century square tower. Gien is important for opaque porcelain.

GIERS, NICHOLAS KARLOVICH DE (1820–1895), Russian statesman of Swedish extraction, was born on May 21, 1820. He was educated at the lyceum of Tsarskoye Selo, near St. Petersburg (Leningrad). At 18 he entered the service of the Eastern department of the Ministry of Foreign Affairs, and spent more than 20 years in subordinate posts, chiefly in south-eastern Europe, until he became minister plenipotentiary in Persia in 1863. Here he remained for six years, and, after serving as a minister in Switzerland and Sweden, he was appointed in 1875 director of the Eastern department and assistant minister for foreign affairs under Prince Gorchakov, whose niece he had married. The Herzegovinian insurrection had broken out, and he could perceive from secret official papers that the incident had far-reaching ramifications. While the Austrian officials in Dalmatia were almost openly assisting the insurgents, Russian volunteers were flocking to Serbia with the connivance of the Russian and Austrian Governments, and General Ignatiev, as ambassador in Constantinople, was urging his Government to take advantage of Turkey's weakness and bring about a radical solution of the Eastern question, Gorchakov did not want a radical solution involving a great European war, but he did nothing to stem the current of popular excitement. Alexander II., personally averse to war, was not insensible to the patriotic enthusiasm, and remained undecided. Giers gauged the situation accurately. As an official and a man of non-Russian extraction he had to be reticent, but in private he condemned severely the ignorance and recklessness of those around him. The event justified his sombre previsions. The so-called patriots wished to defy Europe in order to maintain intact the Treaty of San Stefano, and again Giers found himself in an unpopular minority. His influence was thrown into the scale of peace. His views, supported by Count Shuvalov, finally prevailed, and the European congress assembled at Berlin. He was not present at the congress, and escaped the blame for the concessions which Russia made to Great Britain and Austria. From that time he was practically minister of foreign affairs, for Prince Gorchakov was in weak health, and lived mostly abroad.

On the death of Alexander II. in 1881 it was generally expected that Giers would be dismissed, as deficient in Russian nationalist feeling, for Alexander III. had strong anti-German Slavophil tendencies. In reality the young tsar was fully determined not to let his hand be forced by men less cautious than himself. He wanted a minister of foreign affairs who would allow him to control the main lines, and occasionally the details, of the national policy. Giers was, therefore, appointed minister of foreign affairs on the retirement of Prince Gorchakov in 1882; he held office until 1894. In accordance with Alexander III.'s wish, M. de Giers followed systematically a pacific policy. Accepting the Triple Alliance as a *fait accompli,* he sought to establish more friendly relations with the cabinets of Berlin, Vienna and Rome. To the advances of the French Government he at first turned a deaf ear, but when the *rapprochement* between the two countries was effected with little or no co-operation on his part, he utilized it for restraining France and promoting Russian interests. He died on Jan. 26, 1895, soon after the accession of Nicholas II.

GIESEBRECHT, WILHELM VON (1814–1889), German historian, born in Berlin on March 5, 1814, studied under Leopold von Ranke, and his first important work, *Geschichte Ottos II.,* was contributed to Ranke's *Jahrbiicher des deutschen Reichs unter dem sächsischen Hause* (1837–40). His *Geschichte der deutschen Kaiserzeit* (6 vols. 1855–95), the work of a lifetime, was the first general history of the period (up to 1190) based on modern scientific methods. He died at Munich on Dec. 17, 1889.

His other works include *Jahrbiicher des Klosters Attaich* (1841); a translation of Gregory of Tours's *Historia Francorum* (1851); *Deutsche Reden* (Munich 1871), and *Arnold von Brescia* (1873). *See* also Lord Acton in the *English Historical Review* vol. v. (1890).

GIESELER, JOHANN KARL LUDWIG (1792–1854), German writer on church history, mas born on March 3, 1792 at Petershagen, near Minden. He was professor at Bonn (1819), and Gottingen (1831). He died July 8, 1854. His *Lehrbuch der Kirchengeschichte* (6 vols., 1824–57) has copious references to original authorities.

GIESSEN, a town of Germany, capital of the province of Upper Hesse in the *Land* of Hesse. It is situated at the conflu-

ence of the Wieseck with the Lahn, 41 m. N.N.W. of Frankfort-on-Maib on the railway to Cassel. Pop. (1939) 47,680. Giessen was formed in the 12th century out of the villages Selters, Aster and Kroppach, for whose protection Count William of Gleiberg built the castle of Giessen. The town came, in 1203, into the possession of the count palatine, who sold it in 126j to the landgrave Henry of Hesse. It was fortified in 1530 but in 1805 the walls were demolished. In the old part of the town the streets are narrow and irregular. The principal buildings are the Stadtkirche, the provincial government offices, comprising a portion of the old castle dating from the 12th century, and the town-hall (containing an historical collection). The university, founded in 1607 by the landgrave of Hesse, has a library, a botanic garden, an observatory, medical schools, a museum of natural history, a chemical laboratory and an agricultural college. The industries include metal founding and the manufacture of rubber articles, machines, leather, tobacco and beer.

GIFFARD, GODFREY (*c.* 1235–1302), chancellor of England and bishop of Worcester, brother of Walter Giffard (*q.v.*), succeeded his brother as chancellor in 1266, and held that office until 1270. He was bishop of Worcester from 1268 until his death on Jan. 26, 1302. He was a benefactor of his cathedral.

See W. Thomas, *Survey of Worcester Cathedral; Episcopal Registers; Register of Bishop Godfrey Giffard,* edited by J. W. Willis-Bund (Oxford, 1898–1899); and the Annals of Worcester in the *Annales monastici,* vol. iv., edited by H. R. Luard (London, 1869).

GIFFARD, WALTER (d. 1279), chancellor of England and archbishop of York, was a son of Hugh Giffard of Boyton, Wiltshire, and after serving as canon and archdeacon of Wells, was chosen bishop of Bath and Wells in May 1264. In August 1265 Henry III. appointed him chancellor of England, and he was one of the arbitrators who drew up the *dictum de Kenilworth* in 1266. Later in this year Pope Clement IV. named him archbishop of York. He was the chief of the three regents of the kingdom from the death of Henry III. in 1272 until the return of Edward I. in August 1274, and again in 1275. Giffard died in April 1279.

See *Fasti Bboracenses,* edited *by J.* Raine (London, 1863). Giffard's *Register* from 1266 to 1279 has been edited for the Surtees Society by W. Brown.

GIFFARD, WILLIAM (d. 1129), bishop of Winchester, was chancellor of William II. and received his see, in succession to Bishop Walkelin, from Henry I. (1100). He was one of the bishops elect whom Anselm refused to consecrate (1101) as having been nominated and invested by the lay power. During the investitures dispute Giffard was on friendly terms with Anselm, and drew upon himself a sentence of banishment through declining to accept consecration from the archbishop of York (1103). He was, however, one of the bishops who pressed Anselm, in 1106, to give way to the king. He was consecrated after the settlement of 1107. He became a close friend of Anselm, founded at Waverley, Surrey, the first English Cistercian house (1128) and restored Winchester cathedral with great magnificence.

See Eadmer, *Historia novorum,* ed. *M.* Rule (1884); S. H. Cass, *Bishops of Winchester* (1827).

GIFFEN, SIR ROBERT (1837–1910), K.C.B., 1895, British statistician and economist, was born at Strathaven, Lanarkshire. He entered a solicitor's office in Glasgow, attending courses at the university. He drifted into journalism, and after working for the *Stirling Journal,* he joined the staff of the *Globe* in 1862. He assisted John Morley on the *Forfnightly Review.* In 1868 he became Walter Bagehot's assistant-editor on the *Economist;* and in 1873 city-editor of the *Daily News,* and later of *The Times.* In 1876 he was appointed head of the statistical department in the Board of Trade, and subsequently he became assistant secretary (1882) and finally controller-general (1892), retiring in 1897. As chief statistical adviser to the Government, he was constantly employed in drawing up reports, giving evidence before commissions of inquiry, and acting as a government auditor. In 1892 he was elected F.R.S. He died in Scotland on April 12, 1910.

His principal publications were *Essays on Finance* (1879 and 1884), *The Progress of the Working Classes* (1884), *The Growth of Capital* (1890), *The Case against Bimetallism* (1892), and *Economic Inquiries and Studies* (1904).

GPFFORD, ROBERT SWAIN (1840–1905), American marine and landscape painter, was born on Naushon island (Mass.), on Dec. 23, 1840. He studied art with the Dutch marine painter Albert van Beest, who had a studio in New Bedford, and in 1864 he opened a studio for himself in Boston, subsequently settling in New York. He was a charter member of the American Water Color Society and the Society of American Artists. From 1878 until 1896 he was teacher of painting and chief master of the Woman's Art School of Cooper Union, New York, and from 1896 until his death he was director. Gifford painted longshore views, sand dunes, and landscapes generally, with charm and poetry. He was an etcher of considerable reputation. He died in New York on Jan. 13, 1905.

GIFFORD, WILLIAM (1756–1826), English publicist and man of letters, was born at Ashburton, Devon, in April 1756, the son of a glazier. Before he was 13 William had lost both parents, and after being sent to sea and then apprenticed to a shoemaker, he was able to return to school through the kindness of an Ashburton surgeon, William Cooksley. In 1779 he proceeded to Oxford, where he was appointed a Bible clerk in Exeter college. On graduating, he found a patron in the first Earl Grosvenor, who sent him on two prolonged Continental tours in the capacity of tutor to his son, Lord Belgrave. Settling in London, Gifford published in 1794 his clever satirical piece, after Persius, entitled the *Baviad,* aimed at *a* coterie of writers at Florence, then popularly known as the Della Cruscans, of which Mrs. Piozzi was the leader. A second satire of a similar description, the *Maeviad,* directed against the corruptions of the drama, appeared in 1795. About this time Gifford became acquainted with Canning, with whose help he originated the weekly newspaper of Conservative politics entitled the *Anti-Jacobin,* which began to appear in 1799. In 1809, when the *Quarterly Review* was projected, he was made editor. The success which attended the *Quarterly* from the outset was due in no small degree to Gifford, but Southey, one of his regular contributors, said that Gifford looked on authors as Izaak Walton did on worms. His bitter opposition to Radicals and his onslaughts on new writers, conspicuous among which was the article on Keats's *Endymion,* called forth Hazlitt's *Letter to* W. *Gifford* in 1819. His connection with the *Review* continued until within about two years of his death in London on Dec. 31, 1826. Giiford also published an English version of Juvenal (1802), an annotated edition of Massinger's *Plays* (1804), a metrical translation of Persius (1821) and an edition of the dramas of Ben Jonson (1816). His edition of Ford and a short autobiography appeared posthumously in 1827.

GIFT, a general English term for a present or thing bestowed, *i.e.,* an alienation of property otherwise than for a legal consideration. Formerly in English law property in land could be conveyed by one person to another by a verbal gift of the estate accompanied by delivery of possession. The Statute of Frauds required all such conveyances to be in writing, and a later statute (8 & 9 Vict. c. 106) requires them to be by deed (*q.v.*).

Chattels may be effectually transferred from one person to another by a simple verbal gift accompanied by delivery. But unless the actual thing is bodily handed over to the donee, the mere verbal expression of the donor's desire or intention has no legal effect whatever. The persons are in the position of parties to an agreement which is void as being without consideration. But a declaration of trust, while retaining possession, is good *(see* Williams, *Personal Property).* When the nature of the thing is such that it cannot be bodily handed over, it will be sufficient to put the donee in such a position as to enable him to deal with it as the owner. For example, when goods are in a warehouse, the delivery of the key will make a verbal gift of them effectual; but it seems that part delivery of goods which are capable of actual delivery will not validate a verbal gift of the part undelivered. The gift of such personal property as is not chattels or transferable to bearer requires a written transfer in proper form. But *see* CONVEYANCE.

GIFT EXCHANGE: *see* TRADE, PRIMITIVE.

GIFU, a city of Japan, capital of the *ken* (government) of Central Japan, which comprises the two provinces of Mino and

Hida. Pop. (1940) 172,340. It lies E. by N. of Lake Biwa, on the Central railway, on a tributary of the river Kiso, which flows to the Bay of Miya Uro. The *ken* has an area of about 4,000 sq.mi., and is thickly peopled, the population exceeding 1,000,000. The chief industries are silk and paper goods.

GIG, an onomatopoeic word for any light whirling object; *e.g.,* a top, or a revolving lure made of feathers for snaring birds; but now chiefly used of a light two-wheeled cart or carriage for one horse; of a narrow, light, ship's boat for oars or sails; and of a clinker-built rowing-boat used on the Thames. A "gig" in mining, is a wooden chamber or box divided in the centre and used to draw up and lower down miners in a pit or shaft, and the "gig-mill" or "gigging machine," is a textile machine which raises the nap on cloth by means of teazels. A "gig" or "fish-gig" (properly "fiz-gig," possibly an adaptation of Span. *fisga,* harpoon) is an instrument for spearing fish.

GIGANTISM, a condition in which the stature is unusually great (see MONSTER).

GIGLIO, an island of Italy (anc. *Igilium*), off the southwest coast of Italy, in the province of Grosseto, 11 m. to the west of Monte Argeniario. it measures about 5 m. by 3 and its highest point is 1,634 ft. above sea level. Pop. (1936) of Giglio Castello, the village at the highest point, 1,089; of Giglio Porto (at the harbour), 1,054. Granite was quarried here by the Romans and is still used; the island is fertile, and produces wine and fruit, the cultivation of which has taken the place of the forests of which Rutilius spoke when it served as a place of refuge from the barbarian invaders. Chzrlemagne gave it to the abbey of Tre Fontane at Rome, with a considerable part of the Maremma. From 1264 to 1406 it belonged to Pisa, then to Florence, then, after being seized by the Spanish fleet, it was ceded to Antonio Piccolomini, nephew of Pius II. In 1558 it was sold to Eleonora, wife of Cosimo I. of Florence.

See Archduke Ludwig Salvator, *Die Insel Giglio* (Prague, 1900).

GIGTHI, a Roman city of north Africa, near the west coast of the Little Syrtis (Gulf of Gabès). It lies about 20 m. N.E. of the modern Medenine. The ruins are considerable, especially those of the forum, surrounded on three sides by Corinthian porticos; here were the Capitolium, Curia and basilica, and various temples. The thermae and a market have also been cleared. To the north-west is the island of Djerba, identified with the land of the lotus eaters. In Roman times it was joined to the mainland by a causeway, the remains of which are still visible. Mount Souk, the chief village, on the north coast of the island (pop. 7,500) is a centre of the sponge fishery. The Spaniards intervened in Djerba in 1510 and after 1535, and made it their base of operations against Tripoli in 1560. They were defeated and the Spanish garrison on the island was exterminated.

See Mondricourt, *L'expédition espagnole* de *1560 contre l'ile de* Djerba (Paris, 1914).

GIGUE: see JIG.

GIJON, a seaport of northern Spain, province of Oviedo; on the Bay of Biscay, and the terminus of railways from Avilés, Oviedo and Langreo. Pop. (1930), 78,239. The older parts of Gijón occupy the slopes of a rocky peninsula, Santa Catalina point, while its more modern suburbs extend east and west along the shore. The town contains few buildings of architectural interest beyond the 15th century parish church of San Pedro, with its triple rows of aisles and the Jovellanos Nautical and Technical institute, which contains a fine collection of drawings. This institute was founded in 1797 by Gaspar Melchor de Jovellanos (1744–1811), the poet and statesman, a native of Gijón, who is buried in San Pedro church.

A stretch of sandy beach east of the peninsula has made this the bathing quarter of the town. Westward, to Cape Torres extends the Bay of Gijón, the most important roadstead on the Spanish coast between Ferrol and Santander. The construction of a commercial port at Gijón was begun with a royal grant in 1480. An arsenal was added in the reign of Philip II. (1556–98), and to this the remnant of the Invincible Armada returned for repairs in 1588. In 1778 the port was equipped for trade with the West Indies. Its modern prosperity, however, dates from 1884, when railway communication was established with Langreo and other Asturian mining districts. In 1892 the harbour of Musel, at the western end of the bay, was constructed. At the eastern end, protected by Santa Catalina and two moles, lie the outer and two inner harbours of Gijón proper.

Gijón is usually identified with the Roman *Gigia,* captured by the Moors early in the 8th century; it was one of the first cities to be retaken by King Petayo (720–737). In 844 Gijón successfully resisted a Norman raid; in 1395 it was burned down, and in the 16th and 17th centuries it suffered many attacks by corsairs. In the civil war of 1936–39, the capture of Gijón by Nationalist forces in Oct. 1937 marked the end of fighting in the region.

Coasting, as well as foreign trade, is considerable. Gijón is also an important industrial centre, with iron, copper and bronze foundries, petroleum refineries, large tobacco, glass, sugar and porcelain factories, and chemical, preserved food, paper, candle and cloth-making works. Coal is the main export, others being iron, zinc and copper ores, apples, nuts, butter, cider and fish. The chief imports are timber, machinery, petroleum, superphosphate and foodstuffs.

GILA CLIFF DWELLINGS, a national monument (reservation) situated about 35 m. north of Silver City in the south-eastern part of Catron county, New Mexico, U.S.A. The reservation (160 ac. in area) was established on Nov. 16, 1907 to protect a group of four cliff dwellings still in good preservation in the canyon of the West fork of the Gila river.

GILA MONSTER (Heloderma *suspectum*), the only lizard known to be poisonous. It inhabits deserts in the south-western United States, chiefly in the valley of the Gila river in Arizona and New Mexico. The Gila monster is usually about 2 ft. in length and has a thick body covered with small bead-like tubercles. In colour it is blackish or purplish, with large, somewhat transverse, pinkish or yellowish blotches. The poison fangs are in the lower jaw, and its bite has been known to cause death in man. This lizard is usually sluggish but, especially in the wild state, is vicious when aroused, snapping its powerful jaws from side to side with an unexpected agility, all the while emitting sharp hisses. Its grip is very tenacious and cannot be broken by man without some prying instrument. In movement the Gila Monster is slow and methodical, but not clumsy, dragging rather than lifting its body over the ground. It is oviparous, depositing its soft-shelled eggs in the sand. (See LIZARD, REPTILES.)

GILAN, the westernmost of the three Caspian provinces of Persia, lying between 37" and 38" N. with a breadth varying from 15 to 60 m. Separated on the north from Russia by the little river of Astara, it is bounded on the west by the province of Azerbaijan, on the south by Kazvin and on the east by Mazandaran. Like all the Caspian provinces of Persia, Gilan consists geographically of two zones; the coastal plain, backed by a well nigh impenetrable jungle; and the forestclad spurs running out northward from the massif of the Elburz range. These zones present an astonishing contrast in climate, landscape and race. Though the Safid Rud (called Kizil Uzun in its upper reaches) is the only river of any volume, the province is abundantly watered by a great number of smaller streams.

The climate of the plains in the neighbourhood of Resht, the capital, is exceedingly damp and relaxing, with a very high rainfall—56 inches having been recorded; yet, over a great part of the area the fall is not sufficiently sure and regular in summer to provide for cultivation without resort to irrigation. The mild and wet winter is broken by the bad-i-garm, or warm wind. The soil is very fertile, consisting mainly of a rich loam lying over sandstone and shingle. The vegetation resembles that of southern Europe, but owing to the warm humidity which prevails, it is more tropically luxuriant, and in the lower valleys of the Elburz, up to 5,000 ft., there are forest tracts as dense as any Indian jungle.

The prevailing forest trees are box, oak, ash, beech, elm and hornbeam; the first named comes to rare perfection but unfortunately indiscriminate cutting for export has tended to make it scarce. Many kinds of fruit-bearing trees are to be met with but the quality of the fruit they yield is on the whole disappoint-

ing. Two varieties of wild grape occur but the cultivated vine does not thrive; the medlar and the fig flourish, as do the wild pomegranate and the water-melon, the latter attaining huge proportions. Oranges and lemons thrive in the gardens, and in the hilly district of Rudbar there is considerable cultivation of olives, but the process of oil extraction in vogue is crude and wasteful. The specialities of Gilan in the direction of fruit are a peculiar variety of pear, in great demand for grafting, and the "Gilan plum" which is well known all over northern Persia.

The fauna is well represented, but tigers, once not uncommon, are now very scarce; panther, hyaena, jackal, wild boar, are to be found, and two species of deer, the fine Maral stag *(Cervus elephus maral)* and the Ahu or roedeer *(Capreolus pyargus)*. Among the birds, pheasant, woodcock, duck, teal, geese and various other waterfowl abound.

The fishing industry on the Caspian from this province is very important, but during the World War and onwards the business was practically at a standstill owing to the unacceptable claims advanced by the Soviet Government in regard thereto. Early in 1928, however, the parties came to terms, since when the fisheries have been working satisfactorily.

Of crops, rice, the cultivation of which only became general in comparatively recent years, when it gradually replaced a then moribund silk industry, holds its own as the fundamental produce of Gilan, and about 1911 reached an average yield of 180,000 tons, or five-sixths of the total exported from the country.

Sericulture which was formerly a very important and practically the sole industry of Gilan was almost reduced to nothing about 1865 by a mysterious epidemic disease which broke out among silkworms alike in Persia and in France; but thanks to the researches of the famous bacteriologist, Pasteur, who was deputed by Napoleon III. to study the disease, it was gradually got under control and from 1890 onwards the trade regained some of its former prosperity, so that just before the World War the output of raw silk had risen to 1,200,000 lb., 88% of which was produced in Gilan. Another notable product of the Caspian provinces, though not specially of Gilan, is sugar-cane, for the growth of which the climate seems eminently suited. Tea-planting was introduced into the Lahijan district in 1901 and production has considerably increased in the last few years, so that Lahijan tea is now procurable in most Persian towns; but more capital is needed to put the industry on a prosperous and progressive footing. The other crop of importance produced in the province is tobacco, to the cultivation of which considerable impetus has been given by the increase in cigarette smoking throughout Persia. Gilan is said to supply the wants of all northern Persia in this direction. Various indications of the existence of petroleum have been found in the provinces but no action has yet been taken in the direction of its exploitation.

Estimates of the population of Gilan differ enormously. Lorini, in 1911, put the figure at 340,000, which was considered high at the time, but a later rough census made for official purposes in 1915, suggested that from 5 to 6 million would be nearer the mark.

The capital of the province, and the most active commercial centre is Resht (*q.v.*), through which the Tehran-Kazvin-Pahlavi motor road runs, one of the best in the country. The latter place (formerly known as Enzeli) enjoys by far the most lively trade of all the Caspian ports of Persia. The revenue of the province in 1926–27 amounted to nearly 24½ million krans.

After remaining long independent, Gilan was conquered by Hulagu Khan, who razed the fortifications of Shamiran to the ground in 1227 and formed it into two small principalities, separated by the river Safid Rud and with their capitals at Lahijan and Resht respectively. This remained the position until 1567 when the province was finally incorporated in Persia by the Safavid monarch. It was however occupied by a Russian force in the early part of 1723 and Tahmasp III., the tenth Safavid Shah, being then without a throne, and his country occupied by the Afghans, ceded it, together with Mazandaran and Astarabad, to Peter the Great by treaty. Russian troops remained in occupation until 1734 when they were obliged to evacuate it.

The derivation of the name Gilan from the modern Persian word *gil* meaning mud (hence "land of mud") is incorrect. It probably means "land of the Gil," an ancient tribe which classical writers mention as the Gelae.

See H. L. Rabino, *Les provinces caspiennes de la Perse. Le Guilan* (1917); J. B. L. Noel, "A reconnaissance in the Caspian provinces of Persia," *Geogr. J.*, 1921, lvii.; L. S. Fortescue, "The Western Elburz and Persian Azerbaijan," *Geogr. J.*, 1924, lxiii., and "Les provinces caspiennes de la Perse," *La Geographie*, 1925, xliii.

GILBART, JAMES WILLIAM (1794–1863), English writer on banking, was born in London on March 21, 1794. He worked first as a bank clerk in London, and then became a branch manager of the Provincial Bank of Ireland. In 1834 he became manager of the London and Westminster Bank, and did much to develop the system of joint-stock banking. On the renewal of the bank charter in 1844, he procured the insertion of a clause granting to joint-stock banks the power of suing by their public officer, and also the right of accepting bills at less than six months' date. In 1846 he was elected F.R.S. He died in London on Aug. 8, 1863. The Gilbart lectures on banking at King's college are called after him. The following are his principal works on banking, most of which have passed through more than one edition: *Practical Treatise on Banking* (1827); *The History and Principles of Banking* (1834); *The History of Banking in America* (1837); *Lectures on the History and Principles of Ancient Commerce* (1847); *Logic for the Million* (1851); and *Logic of Banking* (1857).

GILBERT, SIR ALFRED (1854–1934), British sculptor and goldsmith, born in London, was the son of Alfred Gilbert, musician. He received his education mainly in Paris (École des Beaux-Arts, under Cavelier), and studied in Rome and Florence where the significance of the Renaissance made a lasting impression upon him and his art. He also worked in the studio of Sir J. Edgar Boehm, R.A. His first work of importance was the charming group of the "Mother and Child," then "The Kiss of Victory," followed by "Perseus Arming" (1883), produced directly under the influence of the Florentine masterpieces he had studied. Its success was great, and Lord Leighton forthwith commissioned "Icarus," which was exhibited at the Royal Academy in 1884, along with a remarkable "Study of a Head," and was received with general applause. Then followed "The Enchanted Chair," which along with many other works, deemed by the artist incomplete or unworthy of his powers, was ultimately broken by the sculptor's own hand. The next year Gilbert was occupied with the Shaftesbury Memorial Fountain, known as "Eros," in Piccadilly, London, a beautiful and original work, shorn of some of the intended effect through restrictions put upon the artist. In 1888 was produced the statue of H. M. Queen Victoria, set up at Winchester, in its main design and in the details of its ornamentation the most remarkable work of its kind produced in Great Britain, and perhaps, it may be added, in any other country in modern times. Other statues of great beauty, at once novel in treatment and fine in design, are those set up to Lord Reay in Bombay, and John Howard at Bedford (1898), the highly original pedestal of which did much to direct into a better channel what are apt to be the eccentricities of what is called the "New Art" school. The sculptor rose to the full height of his powers in his "Memorial to the Duke of Clarence," at Windsor, proving his fast development of fancy. His sense of decoration was paramount in all he did and although in addition to the work already cited he produced busts of extraordinary excellence of Cyril Flower, John R. Clayton (since broken up by the artist—the fate of much of his admirable work), G. F. Watts, Sir Henry Tate, Sir George Birdwood, Sir Richard Owen, Sir George Grove and various others, it is on his goldsmithery that the reputation of the artist will rest; on his mayoral chain for Preston, the epergne for Queen Victoria, the figurines of "Victory" (a statuette designed for the orb in the hand of the Winchester statue), "St. Michael" and "St. George," as well as smaller objects such as seals, keys and the like. Gilbert was elected associate of the Royal Academy in 1887, full member in 1892 (resigned 1909; resumed 1932), and professor of sculpture in 1900 (resigned 1909). In 1889 he won the *Grand Prix* at the Paris International Exhibition. He received the M.V.O. in

1897, and was knighted in 1932. His last triumph was the Queen Alexandra Memorial opposite St. James Palace, not wholly completed, as regards design, in 1934.

See Joseph Hatton, *The Life and Work of Albert Gilbert, R.A., M.V.O., LL.D.,* (*Art Journal* Office, 1903), and Isabel McAllister, *Alfred Gilbert (A.* & C. Black, 1929). (M. H. S.)

GILBERT, CASS (1859–1934), American architect, was born at Zanesville (O.), on Nov. 24, 1859. He studied at the Massachusetts institute of technology and in 1883 began his career as an architect in St. Paul, but later moved to New York. He became perhaps most widely known as the architect of the Woolworth building in New York, which has 57 storeys and is 792ft. in height, and, with the exception of the Eiffel Tower in Paris, was, at the time, the tallest structure in the world. He designed the Minnesota State Capitol, St. Paul; the Endicott building, the Dayton avenue church and St. Clement's Episcopal church in St. Paul; the U.S. custom house and the Union club, New York; the Brazer building and the Suffolk Savings Bank, Boston; Art building and Festival Hall (for the Louisiana Purchase Exposition), and the Central Public Library, St. Louis; Ives Memorial Library, New Haven (Conn.); Public Library, Detroit. He drew the plans for the University of Minnesota and for the University of Texas. He was appointed by President Roosevelt a member of the Council of the Fine Arts; and by President Taft a member of the National Commission of Fine Arts; being reappointed by President Wilson. In 1926 he was appointed design architect for the proposed bridge over the Hudson river at New York city, and in the same year was elected president of the National Academy of Design.

GILBERT, GROVE KARL (1843–1918), American geologist, was born at Rochester, N.Y., on May 6, 1843, and graduated at the University of Rochester in 1862. He began the study of geology and in 1869 went as a volunteer assistant on the second Ohio State survey. In 1871 he was assigned to the Wheeler survey and during his three years service took a remarkable trip by boat up the lower canyons of the Colorado river, by pack train through central Arizona and down the valley of the Gila, and again by boat down the Colorado to the Gulf of California. As a result of this trip he published two papers characterizing the basin range and plateau provinces and naming and describing ancient Lake Bonneville. He was transferred to the Powell survey in 1875 which took him to Utah, and with the formation of the U.S. geological survey in 1879, he was made one of the six senior geologists. In 1884 he was placed in charge of the Appalachian division of geology, and in 1889, upon the creation of the division of geologic correlation, he was placed at its head. After 1892 he relinquished most of his administrative duties and his position as chief geologist in order to return to the fuller study of some of his earlier problems. During this period his studies included the geology of Colorado, Mexico and Alaska, and he visited the latter with the Harriman expedition. The *Bonneville Monograph,* which he himself regarded as his *magnum opus,* was published in 1890. His report on the *Geology of the Henry Mountains,* in which the volcanic structure known as laccolite was first described, and his *History of the Niagara River* (1890) were of particular importance. He had much to do with planning the Federal Survey's bibliographic work and the adoption of principles of nomenclature and cartography, which form the basis of the survey's geologic map work.

He died at Jackson, Mich. on May 1, 1918

See Bulletin of the Geological Society of America, vol. xxxi., pp. 26–64, which includes a complete bibliography of his publications; and N. M. Davis, *American Journal of Science,* 4th ser., vol. xlvi., pp. 669–681.

GILBERT, SIR HUMPHREY (*c.* 1539–1583), English soldier, navigator and pioneer colonist in America, was the second son of Otho Gilbert. of Compton, near Dartmouth, Devon, and half-brother of Sir Walter Raleigh. He mas educated at Eton and Oxford; intended for the law; appointed (July 1566) captain in the army of Ireland under Sir Henry Sidney. In April 1566 he had already joined with Antony Jenkinson in a petition to Elizabeth for the discovery of the North-east Passage; in November following he presented an independent petition for the "discovering of a passage by the north to go to Cataia." In Oct. 1569 he became governor of Munster; on Jan. 1, 1570 he was knighted; in 1571 he was returned M.P. for Plymouth; in 1572 he campaigned in the Netherlands against Spain without much success; from 1573 to 1578 he lived in retirement at Limehouse, devoting himself especially to the advocacy of a North-west Passage (his famous *Discourse* on this subject was published in 1576). Gilbert's arguments, widely circulated even before 1575, were apparently of weight in promoting the Frobisher enterprises of 1576–78. On June 11, 1578, Sir Humphrey obtained his long-coveted charter for North-western discovery and colonization, authorizing him, his heirs and assigns, to discover, occupy and possess such remote "heathen lands not actually possessed of any Christian prince or people, as should seem good to him or them." Disposing not only of his patrimony but also of the estates in Kent which he had through his wife, daughter of John Aucher of Ollerden. he fitted out an expedition which !eft Dartmouth on Sept. 23, 1578, and returned in May 1579, unsuccessful.

In 1579 Gilbert aided the Government in Ireland; and in 1583, after many struggles—illustrated by his appeal io Walsingham on July 11, 1582, for the payment of an amount due to him from government, and by his agreement with the Southampton venturers—he succeeded in equipping another fleet for "Western Planting." On June 11, 1583, he sailed from Plymouth with five ships and the queen's blessing; on July 30 he was off the north coast of Newfoundland; on Aug. 3 he arrived off the present St John's, and selected this site as the centre of his operations; on Aug. 5 he began the plantation of the first English colony in North America. Proceeding southwards with three vessels, exploring and prospecting, he lost the largest near Cape Breton (Aug. 29); immediately after (Aug. 31) he started to return to England with the "Golden Hind" and the "Squirrel," of forty and ten tons respectively. Obstinately refusing to leave the "frigate" and sail in his "great ship," he shared the "Squirrel's" fate in a tempest off the Azores. "Monday, Sept. 9," reports Hayes, the captain of the "Hind," "the frigate was near cast away . . . yet at that time recovered; and, giving forth signs of joy, the general, sitting abaft with a book in his hand, cried out unto us in the 'Hind,' 'We are as near to heaven by sea as by land.' . . . The same Monday night, about twelve, the frigate being ahead of us in the 'Golden Hind,' suddenly her lights were out. . . . in that moment the frigate was devoured and swallowed up of the sea."

See Hakluyt, *Principal Navigations,* vol. iii. (1600), pp. 135–181; Gilbert's *Discourse of a Discoverie for a New Passage to Cataia,* published by George Gascoigne in 1576, with additions, probably without Gilbert's authority; Hooker's *Supplement* to Holinshed's *Irish Chronicle,* Roger Williams, *The Actions of the Lowe Countries* (1618); *State Papers, Domestic* (1577-83); Wood's *Athenae Oxonienses; North British Review,* No. 45; Fox Bourne's *English Seamen under the Tudors;* D. B Quinn, *The Voyages and Colonising Enterprises of Sir Humphrey Gilbert* (1940). Gilbert's interesting writings on the need of a university for London, anticipating in many ways not only the modern London University but also the British Museum library and its compulsory sustenance through the provisions of the Copyright Act, have been printed by Furnivall *(Queene Elizabethe's Achademy)* in the Early English Text Society Publications, extra series, No. viii. *See* also the lives by W G Gosling (1911) and D. B. Chidsey (1932).

GILBERT, SIR JOHN (1817–1897), English painter and illustrator, was born at Blackheath, London, on July 21, 1817. He had had little formal instruction when he began to exhibit at the Gallery of British Art watercolours on historical and romantic subjects. Gilbert began to exhibit at the Royal Academy in 1838, was elected A.R.A. in 1872 and R.A. on June 29, 1876. Many of his most ambitious works are at the Academy. But it is not in these large works in oils that Gilbert was seen at his best. At the gallery of the Old Water Colour society, to which from 1852, when he was elected an associate exhibitor, till he died (Oct. 5, 1897), he contributed 270 drawings, most of them admirable because of the largeness of their style, massive colouration, broad chiaroscuro and vigorous design. "The Trumpeter," "The Standard-Bearer," "Richard II. resigning his Crown" (now at Liverpool), "The Drug Bazaar at Constantinople," "The Mer-

chant of Venice" and "The Turkish Water-Carrier" are examples Gilbert was elected a full member in 1855, and president of the society in 1871, shortly after which he was knighted.

GILBERT, SIR JOHN THOMAS (1829–1898), Irish Celtic scholar and historian, was born in Dublin on Jan. 23, 1829. As a young man he studied the records of his native city, and his first important work was a *History of the City of Dublin* (3 vols., 1854–59). He was secretary of the Public Record office (1867–75). Gilbert was, from 1855 onwards, secretary of the Irish Celtic and Archaeological society, and published many original documents relative to Irish history, notably those of the convents of St. Mary and St. Thomas in Dublin. He died in Dublin on May 23, 1898.

See *Life of Sir John T. Gilbert* (2 vols., 1905) by his wife, Lady Gilbert.

GILBERT, SIR JOSEPH HENRY (1817–1901), English chemist, was born at Hull on Aug. 1, 1817. He studied chemistry first at Glasgow; then at University College, London; and finally at Giessen under Liebig. He was for 58 years director of the chemical laboratory at the experimental station established by Sir J. B. Lawes at Rothamsted, near St. Albans, for the systematic study of agriculture. He died on Dec. 23, 1901. The work which he carried out in collaboration with Lawes involved the application of many branches of science, such as chemistry, meteorology, botany, animal and vegetable physiology and geology; its influence in improving the methods of practical agriculture extended all over the civilized world. His name is perhaps best associated with the development of the "nitrogen" theory of fertilizers as opposed to the "mineral" theory of Liebig (*q.v.*). Gilbert was elected a fellow of the Royal Society in 1860, and in 1867 was awarded a Royal medal jointly with Lawes. In 1882 he was president of the London Chemical Society, and for six years from 1884 he filled the Sibthorpian chair of rural economy at Oxford. He was knighted in 1893.

GILBERT, MARIE DOLORES ELIZA ROSANNA ["LOLA MONTEZ"] (1818–1861), dancer and adventuress, the daughter of a British army officer, was born at Limerick, Ireland, in 1818. Her father dying in India when she was seven years old, and her mother marrying again, the child was sent to Europe to be educated, subsequently joining her mother at Bath. In 1837 she made a runaway match with a Captain James of the Indian army, and accompanied him to India. In 1842 she returned to England, and shortly afterwards her husband obtained a decree *nisi* for divorce. She studied dancing, making an unsuccessful first appearance at Her Majesty's theatre, London, in 1843, billed as "Lola Montez, Spanish dancer." Subsequently she appeared with considerable success in Germany, Poland and Russia. Thence she went to Paris, and in 1847 appeared at Munich, where she became the mistress of the old king of Bavaria, Ludwig I. She was naturalized, created comtesse de Landsfeld, and given an income of £2,000 a year. She soon proved herself the real ruler of Bavaria, adopting a liberal and anti-Jesuit policy. Her political opponents proved, however, too strong for her, and in 1848 she was banished. In 1849 she came to England, and in the same year was married to George Heald, a young officer in the Guards. In 1851 she appeared in America, and in 1853 Heald was drowned at Lisbon. Subsequently she appeared in Australia, but returned in 1857 to America, where she died on Jan. 17, 1861.

See E. B. D'Auvergne, *Lola Montez* (New York, 1909).

GILBERT, NICOLAS JOSEPH LAURENT (1751–1780), French poet, was born at Fontenay-le-Château in Lorraine. In 1774 he came to Paris, where he became known as an opponent of the Encyclopaedists and a panegyrist of Louis XV. The satiric force of one or two of his pieces, as *Mon Apologie* (1778) and *Le Dix-huitième Siècle* (1775), justify his reputation, which has been further increased by writers, who, like Alfred de Vigny in his *Stello* (chaps. 7–13), considered him a victim to the spite of his philosophic opponents. His best-known verses are the *Ode imitée de plusieurs psaumes*, usually entitled *Adieux à la vie.*

Gilbert's *Oeuvres complètes* were first published in 1788, and they have since been edited by Mastrella (1823), by Charles Nodier (1817 or 1825) and by M. de Lescure (1882).

GILBERT, SEYMOUR PARKER (1892–1938), American lawyer and financial expert, was born in Bloomfield, N.J., on Oct. 13, 1892. He graduated from Rutgers college in 1912, and from Harvard law school in 1915. After admission to the New York bar, he practised with the firm of Cravath and Henderson in New York city from 1915 to 1918. In the latter year, on the initiative of R. C. Leffingwood. a former associate secretary of the Treasury, he joined the War Loan staff as counsel. In June 1920 he became assistant secretary (later under-secretary) of the Treasury in charge of fiscal affairs. He resigned on Nov. 17, 1923, and was appointed permanent agent general for reparation payments from Germany under the Dawes Plan on Oct. 31, 1924, succeeding Owen D. Young. At the end of his first year, Nov. 30, 1925, Gilbert reported that the initial annuity of a billion gold marks due on reparation payments had been received in full. On Sept. 2, 1926, he turned over to the U.S. Treasury the first cash payment, $5,900,000, received by the United States from Germany under the operation of the Dawes Plan. At this time, by agreement with the German finance minister, Gilbert modified the amount of immediate cash payments and fixed the total annuities to be paid during the ensuing three years.

Gilbert relinquished his reparations post in 1930 and returned to the United States to become a partner in J. P. Morgan and Company. After his return to private business, he made few public utterances. He died in New York city, Feb. 23, 1938.

GILBERT (or GYLBERDE), **WILLIAM** (1544–1603), the most distinguished man of science in England during the reign of Queen Elizabeth, was a member 6f an ancient Suffolk family, long resident in Clare, and was born on May 24, 1544, at Colchester, where his father, Hierome Gilbert, became recorder. Educated at Colchester school, he entered St. John's college, Cambridge, in 1558, and after taking the degrees of B.A. and M.A. in due course, graduated M.D. in 1569, in which year he was elected a senior fellow of his college. He travelled in Europe, and in 1573 settled in London, where he practised as a physician. He was admitted to the College of Physicians probably about 1576, and he held several important offices. In 1589 he was one of the committee appointed to superintend the preparation of the *Pharmacopoeia Londinensis* which the college in that year decided to issue, but which did not actually appear till 1618. In 1601 Gilbert was appointed physician to Queen Elizabeth, with the usual emolument of £100 a year. On the death of the queen in 1603 he was reappointed by her successor; but he did not long enjoy the honour, for he died on Nov. 30 (Dec. 10, N.S.), 1603, either in London or in Colchester. He was buried in the latter town, in the chancel of Holy Trinity church, where a monument was erected to his memory. To the College of Physicians he left his books, globes, instruments and minerals, but they were destroyed in the great fire of London.

Gilbert's principal work is his treatise on magnetism (*q.v.; see* also ELECTRICITY), entitled *De magnete, magneticisque corporibus, et de magno magnete tellure* (London, 1600; later editions—Stettin, 1628, 1633; Frankfort, 1629, 1638). This work, which embodied the results of many years' research, was distinguished by its strict adherence to the scientific method of investigation by experiment, and by the originality of its matter. It contains an account of the author's experiments on magnets and magnetic bodies and on electrical attractions, and also his great conception that the earth is nothing but a large magnet, and that it is this which explains, not only the direction of the magnetic needle north and south, but also the dipping or inclination of the needle. A posthumous work of Gilbert's was edited by his brother from two mss.; its title is *De mundo nostro sublunari philosophia nova* (Amsterdam, 1651). He was also the first advocate of Copernican views in England. and he concluded that the fixed stars are not all at the same distance from the earth.

An English translation of the *De magnete* was published by P. F. Mottelay in 1893, and another, with notes by S. P. Thompson, was issued by the Gilbert club of London in 1900.

GILBERT, SIR WILLIAM SCHWENK (1836–1911), English playwright and humorist, son of William Gilbert (a descendant of Sir Humphrey Gilbert), was born in London on Nov.

18, 1836. His father wrote novels, the best-known of which were *Shirley Hall Asylum* (1863) and *Dr. Austin's Guests* (1866). Several of these novels were illustrated by his son, who developed a talent for whimsical draughtsmanship. W. S. Gilbert was educated at Boulogne, at Ealing and at King's college, London. He became a clerk in the education department of the privy council office in 1857. Disliking the routine work, he left the Civil Service in 1861, entered the Inner Temple, was called to the bar in Nov. 1864, and joined the northern circuit. His practice was inconsiderable, and his military and legal ambitions were eventually satisfied by a captaincy in the volunteers and appointment as a magistrate for Middlesex (June 1891). In 1861 he began to contribute excellent comic verse to *Fun,* with humorous illustrations, the work of his own pen, over the signature of "Bab." These were collected in 1869 under the title of *Bab Ballads,* followed by *More Bab Ballads.* The two collections and *Songs of a Savoyard* were united in a volume issued in 1898, with many new illustrations. The best of the old cuts, such as those depicting the "Bishop of Rum-ti-Foo" and the "Discontented Sugar Broker," were preserved intact.

While remaining a staunch supporter of *Fun,* Gilbert became dramatic critic to the *Illustrated Times.* Early in Dec. 1866 T. W. Robertson was asked by Miss Herbert, lessee of the St. James's theatre, to find some one who could turn out a bright Christmas piece in a fortnight, and suggested Gilbert; the latter promptly produced *Dulcamara,* a burlesque of *L'Elisire d'amore,* written in ten days, rehearsed in a week, and duly performed at Christmas. He sold the piece outright for £30, a piece of rashness which he had cause to regret, for it turned out a commercial success. In 1870 he was commissioned by Buckstone to write a blank verse fairy comedy, based upon *Le Palais de la vérité,* the novel by Madame de Genlis. The result was *The Palace of Truth,* a fairy drama, poor in structure but clever in workmanship, produced by Mr. and Mrs. Kendal in 1870 at the Haymarket. This was followed in 1871 by *Pygmalion and Galatea,* another three-act "mythological comedy"; *The Wicked World,* written for Buckstone and the Kendals; and in collaboration with Gilbert & Beckett, *The Happy Land* (1873). Gilbert's next dramatic ventures inclined more to the conventional pattern, combining sentiment and a cynical humour in a manner strongly reminiscent of his father's style. These were: *Sweethearts* (Prince of Wales's theatre, Nov. 7, 1874); *Tom Cobb* (St. James's, April 24, 1875); *Broken Hearts* (Court, Dec. 9, 1875); *Dan'l Druce* (Haymarket, Sept. 11, 1876); and *Engaged* (Haymarket, Oct. 3, 1877). The first and last of these proved decidedly popular. *Gretchen,* a verse drama in four acts, appeared in 1879. A one-act piece, called *Comedy and Tragedy,* was produced at the Lyceum on Jan. 26, 1884. Two dramatic trifles of later date were *Foggerty's Fairy* and *Rozenkrantz and Guildenstern,* a travesty of *Hamlet,* performed at the Vaudeville in June 1891. Several of these dramas were based upon short stories by Gilbert, a number of which had appeared from time to time in the Christmas numbers of various periodicals. The best of them have been collected in the volume entitled *Foggerty's Fairy, and other Stories.*

In the autumn of 1871 Gilbert commenced his memorable collaboration (which lasted over 20 years) with Sir Arthur Sullivan. The first two comic operas, *Thespis; or The Gods grown Old* (Sept. 26, 1871) and *Trial by Jury* (Royalty, March 25, 1875), were merely essays. Like one or two of their successors, they were, as regards plot, little more than extended "Bab Ballads." Later (especially in the *Yeomen of the Guard),* much more elaboration was attempted. The next piece was produced at the Opera Comique (Nov. 17, 1877) as *The Sorcerer.* At the same theatre were successfully given *H.M.S. Pinafore* (May 25, 1878), *The Pirates of Penzance; or The Slave of Duty* (April 3, 1880), and *Patience; or Bunthorne's Bride* (April 23, 1881). In Oct. 1881 *Patience* was removed to a new theatre, the Savoy, specially built for the Gilbert and Sullivan operas by Richard D'Oyly Carte (*q.v.*). *Patience* was followed on Nov. 25, 1882, by *Zolanthe; or The Peer and the Peri;* and then came, on Jan 5, 1884, *Princess Ida; or Castle Adamant,* a re-cast of a charming and witty fantasia which Gilbert had written some years previously, and had then described as a "respectful perversion of Mr. Tennyson's exquisite poem." The impulse reached its fullest development in the operas that followed next in order—The *Mikado; or The Town of Titipu* (March 14, 1885); *Ruddigore* (Jan. 22, 1887); *The Yeomen of the Guard* (Oct. 3, 1888); and *The Gondoliers* (Dec. 7, 1889). After the appearance of *The Gortdoliers* a coolness occurred between the composer and librettist; Gilbert thought that Sullivan had not supported him in a business disagreement with D'Oyly Carte. But the estrangement was only temporary. Gilbert wrote several more librettos, and of these *Utopia Limited* (1893) and the exceptionally witty *Grand Duke* (1896) were written in conjunction with Sullivan.

As a master of metre Gilbert had shown himself consummate, as a dealer in quips and paradoxes and ludicrous dilemmas, unrivalled. Even for the music of the operas he deserves some credit, for the rhythms were frequently his own (as in "I have a Song to Sing, O"), and the metres were in many cases invented by himself. One or two of his librettos, such as that of *Patience,* are virtually flawless. Enthusiasts are divided only as to the comparative merit of the operas. *Princess Ida* and *Patience* are in some respects the daintiest. There is a genuine vein of poetry in *The Yeoman of the Guard.* Some of the drollest songs are in *Pinafore* and *Ruddigore. The Gondoliers* shows the most charming lightness of touch, while with the general public *The Mikado* proved the favourite. The enduring popularity of the Gilbert and Sullivan operas was abundantly proved by later revivals. Among the birthday honours in June 1907 Gilbert was given a knighthood. In 1909 his *Fallen Fairies* (music by Edward German) was produced at the Savoy. Gilbert was drowned at Harrow Weald, Middlesex, on May 29, 1911. (T. S.)

GILBERT AND ELLICE ISLANDS, British colony in the mid-Pacific, consisting of two archipelagoes. The islands of the Gilbert archipelago lie north and south of the equator, between 174° and 178° E., while the Ellice (Lagoon) islands lie between 5° and 11° S. and about 178° E. The total area of the colony is 180 sq.mi. and the population (1938) 32,838. The islands were taken over as a British protectorate in 1892 and annexed as a colony at the request of the native governments in 1915. Most of the islands were seized by the Japanese soon after the outbreak of the war with the United States and Great Britain. In 1942 Funafuti in the Ellice group was recaptured by U.S. forces.

Of the two groups, the Gilberts are much the more populous, with 28,000 inhabitants in 1938. The islands are located on the borderline between Polynesia and Melanesia, and the natives show a mixture of these two racial strains with a larger negroid element in the Ellice group. Despite health measures adopted by the colonial authorities, the natives of the Gilberts apparently declined in numbers after the coming of the whites. Syphilis, introduced by whalers, and tuberculosis took an especially heavy toll. The natives show little inclination for steady work.

The principal islands of the Gilbert group are Butaritary, Makin, Tarawa, Abaiang, Marakei, Maiana, Abemama, Kuria, Aranuka, Nonouti, Tabetauea, Beru, Nukunau, Onotoa, Tamana and Arorae. The Ellice group, located farther to the south, about midway between the Gilberts and Fiji, contains a large number of tiny coral islands or atolls, grouped in nine clusters, extending over a distance of about 400 mi. from northwest to southeast. The total area is 14 sq.mi., the population a little over 4,000. The chief groups are Funafuti or Ellice, Nukulailai or Mitchell, Nurakita or Sophia, Nukufetau, Nui or Egg, Hudson and Niutao or Lynx. Nearly all the natives are Christians, with Protestant missions established in the islands.

The islanders of the Nui group speak the language of the Gilbert~,while the others are Samoan in their speech. Research supports the tradition that they came originally from Samoa. The islands are hot, and enjoy plentiful rainfall. Borings and soundings taken at Funafuti indicate almost beyond doubt that the whole of this Polynesian region is an area of comparatively recent

subsidence. *(See* also PACIFIC ISLANDS).

(W. H. CH.)

GILBERT DE LA PORREE *(c.* 1075–1154), scholastic logician and theologian, was born at Poitiers. After teaching for some 12 years in Chartres, he lectured in Paris (from 1137), and in 1142 became bishop of Poitiers. Gilbert's association with Abelard, and his heterodox opinions regarding the Trinity, led to his being attacked by Bernard of Clairvaux at the Synod of Reims in 1148, but he escaped formal condemnation. He returned to his diocese where he died on Sept. 4, 1154. His celebrated *De sex principiis,* often quoted by his successors, seeks to complete Aristotle's study of the categories, *substance, quantity, quality* and *relation* by an account of the remaining six, *when, where, action, passion, position* and *habit,* called *formas assistentes* His tendency towards extreme realism led him in his commentary on the *De Trinitate* of Boethius to come near to the theological heresy of tritheism. For him, the pure form of existence, that by which God is God, must be distinguished from the three persons who are God by participation in this form, which is to say, *Deitas* or *Divinitas* must be distinguished from *Deus.*

BIBLIOGRAPHY.—*De sex principiis* and commentary on the *De Trinitate* in Migne, *Patrol. GILBERT FOLIOT (d. 1187), bishop of Hereford, and of London, is first mentioned as a monk of Cluny, whence he was called in 1136 to plead the cause of the empress Matilda against Stephen at the Roman court. Shortly afterwards he became prior of Cluny; then prior of Abbéville, a house dependent upon Cluny. In 1139 he was elected abbot of Gloucester. The appointment was confirmed by Stephen, and from the ecclesiastical point of view was unexceptionable. But the new abbot proved himself a valuable ally of the empress, and her ablest controversialist. Gilbert's reputation grew rapidly. He was respected at Rome and in 1148 was nominated by the pope to the see of Hereford. He was an Angevin at heart, and after 1154 was treated by Henry II with every mark of consideration. He was Becket's rival for the primacy, and the only bishop who protested against the king's choice. Becket endeavoured to win his friendship by procuring for him the see of London (1163). But Gilbert evaded the profession of obedience to the primate, and apparently aspired to make his see independent of Canterbury. On the questions raised by the Constitutions of Clarendon he sided with the king, whose confessor he had now become. He urged Becket to yield, and, when this advice was rejected, encouraged his fellow bishops to repudiate the authority of the archbishop. Gilbert was twice excommunicated by Becket, but both on these and on other occasions he showed great dexterity in detaching the pope from the cause of the exile. To him it was chiefly due that Henry avoided an open conflict with Rome of the kind which John afterwards provoked. Gilbert was one of the bishops whose excommunication in 1170 provoked the king's knights to murder Becket; but he cannot be reproached with any share in the crime. His later years were uneventful, though he enjoyed great influence with the king and among his fellow bishops.

(H. W. C. D.)

GILBERT OF SEMPRINGHAM, ST., founder of the Gilbertines, the only religious order of English origin, was born at Sempringham in Lincolnshire, *c.* 1083–89. He was educated in France, and ordained in 1123, being presented by his father to the living of Sempringham. About 1135 he established there a convent for nuns; and to perform the heavy work and cultivate the fields he formed a number of labourers into a society of lay brothers attached to the convent. Similar establishments were founded elsewhere, and in 1147 Gilbert tried to get them incorporated in the Cistercian order. Failing in this, he formed communities of priests and clerics to perform the spiritual ministrations needed by the nuns. The women lived according to the Benedictine rule as interpreted by the Cistercians; the men according to the rule of St. Augustine, and were canons regular. The special constitutions of the order were largely taken from those of the Premonstratensian canons and of the Cistercians. Like Fontevrault (*q.v.*) it was a double order, both communities living side by side; but, though the property belonged to the nuns, the superior of the canons was the head of the whole establishment, and the general superior was a canon, called "Master of Sempringham." The general chapter was a mixed assembly composed of two canons and two nuns from each house. The order received papal approbation in 1148. By Gilbert's death (1189) there were nine double monasteries and four of canons only, containing about 700 canons and 1,000 nuns in all. At the dissolution there were some 25 monasteries. The order never spread beyond England.

GILDAS or **GILDUS** (516?–570), the earliest of British historians *(see* CELTIC LITERATURE, "Welsh"), surnamed by some Sapiens, and by others Badonicus. Two short treatises exist, purporting to be lives of Gildas, and ascribed respectively to the 11th and 12th centuries; but they seem to confuse two, if not more, persons who had borne the name. Gildas was almost certainly an ecclesiastic. He went abroad, probably to France, in his 34th year, where after 10 years of hesitation and preparation, he composed the work bearing his name. His materials, he tells us, were collected from foreign rather than native sources. The *Cambrian Annals* give 570 as the year of his death.

The writings of Gildas have come down to us under the title of *Gildae Sapientis de excidio et conquestu Britanniae.* The work is now usually divided into three portions,—a preface, the history proper, and an epistle,—the last, largely made up of Scriptural passages brought together for the purpose of condemning the vices of his countrymen and their rulers, being the longest but least important. In the second he passes in brief review the history of Britain from its invasion by the Romans till his own times. Among other matters he refers to the persecution under Diocletian, the election of Maximus as emperor by the legions in Britain, the final abandonment of the island by the Romans and the corning of the Saxons under Vortigern. Unfortunately his statements are vague and obscure. With one exception (the date of the battle of Mount Badon referred to in connection with the date of his own birth, *see* ARTHUR) no dates are given, and events are not always taken up in the order of their occurrence. These faults become serious when, as is the case from nearly the beginning of the 5th century to the date of his death, Gildas's brief narrative is our only authority for most of what passes current as the history of England. Thus it is on his sole, though in this instance perhaps trustworthy, testimony that the famous letter rests, said to have been sent to Rome in 446 by the despairing Britons, commencing:—"To Agitius (Aetius), consul for the third time, the groans of the Britons."

Gildas's treatise was first published in 152 j by Polydore Vergil, but with many avowed alterations and omissions. In 1568 John Josseline, secretary to Archbishop Parker, issued a more accurate edition; and in 1691 a still better edition appeared at Oxford by Thomas Gale. The next English edition described by Potthast as *editio pessima* was published by the English Historical Society in 1838, and edited by the Rev. J. Stevenson. The text of Gildas founded on Gale's edition collated with two other mss., with elaborate introductions, is included in the *Monumenta Historica Britannic*~edited by Petrie and Sharpe (1848). Another edition is in A. W. Haddan and W. Stubbs, *Councils and Eccles. Documents* relating to Great Britain (Oxford, 1869); *see* also Theodor Mommsen's edition in *Monum. Germ. hist. auct. antiq.* xiii., *Chronica minora saeculorum iv.-vii.* vol. iii. (1898). For useful bibliographical notes *see* C. Gross, *Sources of English History* (1915), and *E.* K. Chambers, *Arthur of Britain* (1927).

GILDER, RICHARD WATSON (1844–1909), American editor and poet, was born in Bordentown, New Jersey, Feb. 8, 1844. Although in later life apropos of his honorary doctor's degrees from several institutions, he spoke of his "total freedom from collegiate training" and "general ignorance," Gilder early manifested a taste for letters, which his father, a minister and teacher, encouraged. As a boy he edited a paper of his own and had some poetry and even a youthful formless novel published in the newspapers; and although his father's death and brother's absence in the Civil War, in which he himself had a brief experience as a soldier, threw a heavy domestic burden on his youthful shoulders, forcing him to take the most lucrative position obtainable, he soon drifted into newspaper work. After several years with the Newark (New Jersey) *Daily Advertiser,* he founded, with R. Newton Crane, the *Newark Morning Register.* Because of the paper's financial weakness and final failure, Gilder for a year (1869–70) held a second editorial position on *Hours at Home,* and in 1870 accepted the assistant editorship of *Scribner's Monthly* (later the *Century Magazine),* of which he became editor in 1881. Throughout this time he was contributing verse to the magazines and reviews, and descriptive pieces to the newspapers, but the great development of his lyric impulse came after his introduction by Helen Hunt, later Mrs. Jackson, to his future wife, Helena de Kay. Miss de Kay, a granddaughter of Joseph Rodman Drake, was at that time a student of art at Cooper Union. Her knowledge of art and music widened Gilder's appreciation; and after their marriage June 3, 1874, their studio home became a social centre for some of the most distinguished men and women of the day. The immediate fruit of this new relationship was *The New Day* (1875), tender and beautiful love sonnets, which were followed by *The Celestial Passion* (1878), a sequel and companion volume. Gilder's later verse, although dominantly lyric, shows to some extent the factors so prominent in his life—patriotism, enthusiastic participation in the best artistic movements of the day and burning indignation at abuses. Not only is he credited with a revolution in magazine management, but his days were filled with public addresses, committee meetings, and disinterested labours of all sorts. Perhaps most memorable were his efforts on behalf of international copyright and as chairman of the New York Tenement House Commission in 1894. Mrs. Gilder not only continued her painting but translated Sensier's biography of Millet, assisted in founding the Society of American Artists, and throughout 35 years of companionship proved an ideal wife and mother. Gilder, who had several breakdowns because of overwork, died on Nov. 18, 1909.

Gilder published ten books of verse, *Lyrics and dther Poems* (1885) and *Five Books* of *Song* (1894), being collective editions of his work until those years. His complete poems appeared in 1908. His full and upright life is best brought out in his *Letters,* edited by his daughter Rosamond Gilder (1916). Brander Matthews gives an admirable estimate, "Richard Watson Gilder," in the *North American Review* (Jan. 1910).

GILDERSLEEVE, BASIL LANNEAU (1831–1924), American classical scholar, born in Charleston (S.C.) on Oct. 23, 1831, graduated at Princeton in 1849, and studied at Berlin, Bonn and Gottingen. From 1856 to 1876 he was professor of Greek in the University of Virginia, holding the chair of Latin also in 1861–66, and in 1876 he became professor of Greek in the newly-founded Johns Hopkins university, a position from which he retired in 1915. In 1880 *The American Journal of Philology* was established under his editorial charge.

He published a *Latin Grammar* (1867; revised, with the co-operation of Gonzalez B. Lodge, 1894 and 1899) and a Latin series for use in secondary schools (1875), both marked by lucidity of order and mastery of grammatical theory and methods. His edition of *Persius* (1875) is of great value. But his bent was rather toward Greek than Latin. His special interest in Christian Greek was partly the cause of his editing in 1877 *The Apologies of Justin Martyr,* "which"—to use his own words—"I used unblushingly as a repository for my syntactical formulae." His *Syntax of Classical Greek* from Homer to Demosthenes with C. W. E. Miller (Part I., 1900; Part II., 1911) collects these formulae. Gildersleeve edited in 1885 *The Olympian and Pythian Odes of Pindar,* with a brilliant and valuable introduction. His views on the function of grammar were summarized in a paper on *The Spiritual Rights of Minute Research* delivered at Bryn Mawr in 1895, and his collected contributions to literary periodicals appeared in 1890 under the title *Essays and Studies Educational and Literary.* He was also the author of *Hellas and Hesperia* (1909) and of *Creed of the Old South* (1915). He died in Baltimore on Jan. 9, 1924.

GILDING, the art of spreading gold, either by mechanical or chemical means, over the surface of a body for the purposes of protection or ornament. The art of gilding was known to the ancients. According to Herodotus, the Egyptians were accustomed to gild wood and metals; and gilding by means of gold plates is frequently mentioned in the Old Testament. Pliny informs us that the first gilding seen at Rome was after the destruction of Carthage, under the censorship of Lucius Mummius, when the Romans began to gild the ceilings of their temples and palaces, the capitol being the first place on which this enrichment was bestowed. Owing to the comparative thickness of the gold-leaf used in ancient gilding, the traces of it which yet remain are remarkably brilliant and solid. Gilding has in all times occupied an important place in the ornamental arts of Oriental countries; and the native processes pursued in India at the present day may be taken as typical of the arts as practised from the earliest periods.

Modern gilding is applied to numerous surfaces and by various processes, making the art an important part of widely different ornamental and useful arts. It forms an important and essential part of picture framemaking *(see* FRAME), is largely employed in connection with cabinet-work, decorative painting and house ornamentation, and is of great importance in bookbinding and ornamental leather work. Further, gilding is much employed in electro-gilt reproductions and in electro-plating, and is also a characteristic feature in the decoration of pottery, porcelain and glass. Any of these various processes may, however, fall under one of two heads—mechanical gilding and chemical gilding.

MECHANICAL GILDING

This embraces all the operations by which gold-leaf is prepared *(see* GOLDBEATING), and the several processes by which it is mechanically attached to the surfaces it is intended to cover. It thus embraces the burnish or water-gilding and the oil-gilding of the carver and gilder, and the gilding operations of the house decorator, the sign-painter, the bookbinder, the paper-stainer and several others. Polished iron, steel and other metals are gilded mechanically by applying gold-leaf to the metallic surface at a temperature just under red-heat, pressing the leaf on with a burnisher and reheating, when additional leaf may be laid on. The process is completed by cold burnishing. Copper and wood are perhaps the most widely used bodies for the application of gilding.

Copper Gilding.—For the gilding of copper, employed in the decoration of temple domes and other large works, the following is an outline of the process employed: The metal surface is thoroughly scraped, cleaned and polished, and then sufficiently heated in a fire to remove any traces of grease or other impurity which may remain from the operation of polishing. It is then dipped in an acid solution prepared from dried unripe apricots, and rubbed with pumice or brick powder. Next, the surface is rubbed over with mercury, which forms a superficial amalgam with the copper, after which it is left some hours in clean water, again washed with the acid solution and dried. It is now ready for receiving the gold, which is laid on in leaf, and, on adhering, assumes a grey appearance from combining with the mercury, but on the application of heat, the latter metal volatilizes, leaving the gold a dull, greyish hue. The colour is brought up by means of rubbing with agate burnishers. The weight of mercury used in this process is double that of the gold laid on, and the thickness of the gilding is regulated by the circumstances or necessities of the case. For the gilding of iron or steel, the surface is first scratched over with chequered lines, then washed in a hot solution of green apricots, dried and heated just short of red-heat. The gold-leaf is then laid on, and rubbed in with agate burnishers, when it adheres by catching into the prepared scratched

surface.

Wood Gilding.—In applying gilding to wood, after the surface has been sand-papered in order to remove all sharp edges, followed by a very careful dusting, the glue priming size stage is of first importance.

Priming.—Glue size is made by mixing an ounce of glue to a gill and one-half of water, and allowing it to soak at least two hours, after which the mixture is placed in a double boiler and heated until it has become all liquid; then it is removed to set. The combination, which is of jelly-like appearance, can then be cut into blocks or squares, and is generally known as the stock glue size. It is the supply base for all following sizes where glue is used as an ingredient.

Sizing, a term used mostly by painters, is primarily applied to the act of glazing the surface of the material to be gilded. For this preparation, the stock glue size is thinned by mixing a two-thirds proportion of water and dissolving the combination by heat in a double boiler, being careful not to place the vessel near an open fire.

It is necessary for this size to be painted on the raw wood when the combination is still warm. It is well also to have the surface moderately warm so that the size will not form a film on the surface of the wood, but will soak into the grain and act as a filler. It is also necessary to remove any superfluous liquid and blank spaces that may appear just after the glue size is applied. From two to five hours are required for the wood to dry. The glue priming size is followed by the whiting size. This size is made by adding another one-third portion of water to the stock glue size and then heating.

The First Coat of Whiting.—After this mixture has reached the proper temperature, which is somewhat under boiling, sprinkle in the best quality of bolted whiting until the mixture becomes a thick cream.

The first coat of whiting should be applied in a stipple-like fashion, which enables the second coat to have a gripping surface on which to take a better hold. This stippling should be given at least two hours to dry. After the first coat has been applied and allowed sufficient time to dry, the surface should be carefully examined for imperfections such as miscuts, openings at joints, or nail holes. These imperfections require considerable care in filling with putty, made in the following manner:—

Putty Filler.—Make a depression in the stock dry whiting, and pour in a small amount of stock size glue, which should be heated. Take a putty stick and work it around until it becomes a doughy mass of whiting and glue. When it has finally been kneaded sufficiently to allow handling, work it in the palm of the hand until it becomes as pliable as common painter's putty. In placing this prepared putty into the blemishes on the wood, moisten each particle immediately before putting it into place. It is also advisable to use a Bttle moisture in smoothing over the surface and removing any superfluous putty.

The second coat of whiting or filling coat is also called the smooth coat. It is applied as evenly and smoothly as possible, with the exception of the parts that are desired to retain a stippled effect, in which case, the stipple is repeated and applied on the parts as in the previous coat. Do the stippling before finally smoothing the other surfaces with a brush.

The third coat, if necessary, is next applied. This all depends on the surface to be gilded and the amount of ornamentation, and is mainly intended to produce a pleasing effect. When the desired body of whiting has been applied and has dried for at least two hours, the parts which are to remain smooth are rubbed down with a damp cloth. If necessary, especially in deep ornamentation, a brush will answer this purpose better. After the moist smoothing of the surface has been accomplished, it is gone over with a fine piece of sandpaper (o or oo) in order to remove the burr which is caused by the damp smoothing. After removing all dust after sand-papering, it is ready for its first coat of gold size.

Gold Size is applied in much the same manner as paint would be applied, which means working it out smoothly so as to prevent any surplus remaining in corners or causing puddles. Where ornamentation is deep, puddles or floods in hollows are causes of crackling and endless trouble, and one of the most common warnings to an apprentice is, "Don't let the depths fill up."

A Second Coat, and sometimes a third, is applied in like manner, being careful again to allow the surface to dry well after each application and sandpaper to remove any surface burrs. After this, the wood is again dusted off carefully and a coat of very weak size is applied, by heating a piece of stock glue until it is completely dissolved. This weak size must not be applied in a hot state and must be of an even, cool temperature before applying; in fact, less warm than luke-warm. The weak size must be applied by a long soft-haired brush, avoiding puddles in the depths and with such a gentle touch that you do not disturb the gold size. **A** weak size solution is made as follows: A piece of stock size glue the size of a lima bean dissolved in one gill of hot water, allowed to cool, add a few drops of denatured alcohol.

Burnished gold size is made as follows: Take a desired amount of the basic (red clay, blue clay or any one of many more colours as it comes in the jar) place it in the vessel and add cold water. Stir until it has reached such a consistency that the brush will stand upright in it, then place it in the heater to remain only long enough to take off the chill. The stock glue, having previously been placed in a heater to bring to a very high temperature, is poured, a little at a time, into the clay, stirring the mixture in a rapid, agitative manner, adding glue until it reaches the consistency of just wanting to drip from the brush in a heavy, creamy form; the jar containing the burnished gold size is covered and allowed to set over night to ascertain its strength, which should be of a jelly consistency.

A test of gold size for immediate use is made as follows: Apply very thinly, a coat of the size on the thumb nail or two other finger nails, so that it may dry through the heat of the finger and fanning in the air. When this has dried, take the opposite thumb nail and begin to burnish the nail that holds the gold size. If it comes off, it lacks glue; if it is dull and slaty looking, it lacks body clay; but if it burnishes by the finger nail action and has a mellow lustre, the test is successful and the size is ready for use.

Hints on Application.—Gold size must never be cold, nor can it be warm when it is applied. In laying gold-leaf with the hair tip, a solution of a few drops of alcohol in water should be added to the gold sizing before the leaf is flipped on. Also, if possible, keep the wood tilted so that the liquid will run down and not remain in puddles in any one spot. Burnishing must be done within 48 hours, the sooner the better, after the liquid and gold size have dried; but the minimum should be four hours for drying. After burnishing the surface, it may be necessary to apply small patches of gold in spots where it did not adhere in the first laying.

Fazlting, or patching, is done in the same manner as gilding with the exception that the solution in this case should contain a greater percentage of alcohol, which quickens the drying. Small patches dry in about 30 minutes. After the patching has been completed, then, with a soft brush, preferably goat hair or badger, dust off all surplus particles of gold, so that they will not mix with the lacquer which follows. When the burnishing has been done, take some weak size and with a camel's hair brush, apply very lightly a coat all over, not with a heavy brush motion, but just laying it on. When dry, which takes about one hour, the wood is ready for lacquering.

Lacquering is the process in which pure white shellac, diluted with denatured alcohol until it flows in a watery state, is applied with a camel's hair brush in a light manner. The lacquer must dry for about ten hours, after which the wood is ready for toning.

Any desired effect may be obtained by dissolving a pigment with turpentine and adding a few drops of painters' dryer, which acts as a binder. It should have the consistency of thin, transparent white raw umber or zinc white. This medium is freely applied, allowing it to settle into the depths, removing the surplus from all high light with cheese cloth or soft, absorbent cloth. After a few moments, the final effect can be obtained by

an additional light wiping with the cloth, although the best results are often obtained by using the fingers instead of a rag. It is advisable not to tone, at any one time, a greater surface than can be kept under control, because within ten minutes, this tone so strongly adheres to the lacquer that erasure is difficult.

(A. E.)

CHEMICAL GILDING

This embraces those processes in which the gold used is at some stage in a state of chemical combination. Of these the following are the principal:—

Cold Gilding.—In this process the gold is obtained in a state of extremely fine division, and applied by mechanical means. Cold gilding on silver is performed by a solution of gold in aqua-regia applied by dipping a linen rag into the solution, burning it, and rubbing the black and heavy ashes on the silver with the finger or a piece of leather or cork.

Wet Gilding is effected by means of a dilute solution of chloride of gold with twice its quantity of ether. The liquids are agitated and allowed to rest, when the ether separates and floats on the surface of the acid. The whole mixture is then poured into a funnel with a small aperture, and allowed to rest for some time, when the acid is run off and the ether separated. The ether will be found to have taken up all the gold from the acid, and may be used for gilding iron or steel, for which purpose the metal is polished with the finest emery and spirits of wine. The ether is then applied with a small brush, and as it evaporates it deposits the gold, which can now be heated and polished. For small delicate figures a pen or a fine brush may be used for laying on the ether solution.

Fire-gilding or Wash-gilding is a process by which an amalgam of gold is applied to metallic surfaces, the mercury being subsequently volatilized, leaving a film of gold or an amalgam containing from 13 to 16% of mercury. In the preparation of the amalgam the gold must first be reduced to thin plates or grains, which are heated red hot, and thrown into mercury, previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally six or eight to one. When the amalgam is cold it is squeezed through chamois leather for the purpose of separating the superfluous mercury; the gold, with about twice its weight of mercury, remains behind, forming a yellowish, silvery mass of the consistency of butter. When the metal to be gilded is wrought or chased, it ought to be covered with mercury before the amalgam is applied, that this may be more easily spread; but when the surface of the metal is plain, the amalgam may be directly applied to it. When no such preparation is applied, the surface to be gilded is simply bitten and cleaned with nitric acid. A deposit of mercury is obtained on a metallic surface by means of "quick-silver water," a solution of nitrate of mercury, the nitric acid attacking the metal to which it is applied, and thus leaving a film of free metallic mercury. The amalgam being evenly spread over the prepared surface of the metal, the mercury is then sublimed by a heat just sufficient for that purpose; for, if it is too great, part of the gold may be driven off, or it may run together and leave some of the surface of the metal bare. When the mercury has evaporated, which is known by the surface having entirely become of a dull, yellow colour, the metal must undergo other operations, by which the fine gold colour is given to it.

First, the gilded surface is rubbed with a scratch brush of brass wire, until its surface is smooth; then it is covered with a preparation called "gilding wax" and again exposed to the fire until the wax is burnt off. This wax is composed of bees-wax mixed with some of the following substances: viz., red ochre, verdigris, copper scales, alum, vitriol, borax. By this operation the colour of the gilding is heightened; and the effect seems to be produced by a perfect dissipation of some mercury remaining after the former operation. The dissipation is well effected by this equable application of heat. The gilt surface is then covered over with nitre, alum or other salts ground together, and mixed up into a paste with water or weak ammonia. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved and brought nearer to that of gold, probably by removing any particles of copper that may have been on the gilt surface. This process, when skilfully carried out, produces gilding of great solidity and beauty; but owing to the exposure of the workmen to mercurial fumes, it is very dangerous, and besides there is much loss of mercury.

Gilding of Pottery and Porcelain.—The quality of gold consumed for these purposes is very large. The gold used is dissolved in aqua-regia, and the acid is driven off by heat, or the gold may be precipitated by means of sulphate of iron. In this pulverulent state the gold is mixed with one-twelfth of its weight of oxide of bismuth, together with a small quantity of borax and gum water. The mixture is applied to the article with a camel's-hair pencil, and after passing through the fire is of a dingy colour, but the lustre is brought out by burnishing with agate and bloodstone, and afterwards cleaning with vinegar or white lead (*see* POTTERY AND PORCELAIN).

GILDS: *see* GUILDS.

GILEAD, a name used to denote the whole of the territory occupied by the Israelites between the plateaus of Moab and the Hauran, and sometimes in a wider and more general sense to denote the region extending from the river Arnon, to the base of Hermon. It is a country of high forest ridges (average height, 2,500 ft.) lying between the Jordan and the desert plateau. The base slopes are of sandstone partly covered by white marls and the upper of limestone scored and riven by numerous *wadis*. Whilst the gentle declivities towards the eastern plateau have tended to be bare of trees, the western slopes, prior to the World War, were well clothed with oak, terebinth and pine. Gilead is in the main a fertile and beautiful land. "The pastures are everywhere luxuriant, and the wooded heights and winding glens, in which the tangled shrubbery is here and there broken up by open glades and flat meadows of green turf, exhibit a beauty of vegetation such as is hardly to be seen in any other district of Palestine."

History.—The name Gilead first appears in the narrative of the reconciliation of Jacob and Laban (Gen. xxxi.), where the composite nature of the narrative renders identification of locality difficult, and was in use in the time of Josephus, and even later, but with no precise geographical definition. In the Israelitic conquest of the territory east of the Jordan Sihon was crushed at Jahaz, south of Heshbon (Num. xxi., 23) and Og, king of Bashan, smitten at Edrei (Deut. i., 5). In the division of the land the southern half of Gilead fell to Reuben and Gad (according to one account) and the northern half to Manasseh. Gideon on the soil of Gilead swept back the routed hosts of Midian (Judges viii.); Jephthah the Gileadite smote the Ammonites from Aroer to Minnith (Judges xi.) and dealt faithfully with the treacherous men of Ephraim when their tongues betrayed them at the fords of Jordan (Judges xii.). Gilead was the scene of the fierce battle between David and Absalom. Round Ramoth-Gilead many bitter struggles were waged and Ahab perished before its walls. The land, too, played a prominent part in the Maccabean revolt.

It was the fate of the Gileadites to meet the first shock of the Syrian onslaughts and the rolling tide of Assyrian invasion. The Gilead hill country appears to have bred a bold, independent people, but kindly and hospitable. Its intricate country formed a refuge for royalty expectant or in eclipse. Saul's son, Ishbosheth, was here made king by Abner. To its friendly shelter Absalom fled before the anger of his father and abode three years, and David, too, when Absalom's rebellion was at its height, found harbourage and a kindly welcome. It was men of Jabesh-Gilead who risked their lives to recover the bodies of Saul and his sons from the walls, or market-place of Beth-Shan (Beisān). From his home amongst the Gilead hills Elijah emerged to become one of the world's great spiritual leaders, and twice at least did Jesus visit the region—the land beyond Jordan. To Josephus it was Peraea, a land of small provinces whose names re-echoed the centres in which Greek colonists had established themselves during the reign of the Seleucidae. Gilead had as chief cities in Old Testament times, Mahanaim, Succoth, Penuel, Mizpeh, Jazer, Ramoth-Gilead, Jabesh-Gilead, and in later times Pella (Fihl), Gerasa (Jerāsh) and others. Ramoth and Mahanaim were stations

of two out of three of Solomon's commissariat officers. The country was later extensively and intensively Romanized, as architectural monuments witness, and it is difficult, apart from excavations still to be undertaken, to determine where the Old Testament cities of Gilead lie under their Roman covering. Ramoth-Gilead especially has been sought in a variety of places.

The balm associated with Gilead is probably to be identified with mastic, the resin furnished by the *Pistachia Lentiscus.* Gilead is now part of the new territory of Trans-Jordan under British mandate.

GILES, ST., who flourished in the 6th or 7th century, is said to have been an Athenian of royal descent. After the death of his parents he distributed his possessions among the poor, and went to Arles. Two years later, he retired to a neighbouring desert, where he was discovered by Flavius, the king of the Goths, who built a monastery and made Giles the first abbot. St. Giles was buried probably in the hermitage which he had founded in a spot which was afterwards the town of St.-Gilles (diocese of Nimes, department of Gard). In 808 Charlemagne took the abbey of St.-Gilles under his protection, and it is mentioned among the monasteries from which only prayers for the prince and the State were due. St. Giles is the special patron of lepers, beggars and cripples, and his feast is celebrated on Sept. 1.

GILGAL (*i.e.,* "circle" of sacred stones), the name of several places in western Palestine mentioned in the Old Testament. The most important is that situated near Jericho (*Josh.* iv. 19: xv. 7). Josephus has recorded that it was 10 stadia, and Jerome that it was 2 Roman miles, from Jericho, but neither was explicit in its location. The latter speaks of it as a deserted place held in deep veneration by the natives. The sacredness of the spot may have been due to the erection there of the 12 memorial stones (Josh. iv. 20). Zschokke (1865), Conder (1874) and Dalman (1911), identify it with sites at or near Khirbet el-Ethilek between Jericho and Jordan, and about 1½ m. from Jericho. Another Gilgal, mentioned in Josh. xii. 23, appears to have been situated in the maritime plain. This has been identified with Jiljuliyeh, 4 m. N. of Antipatris. A third Gilgal (2 Ki. iv. 38) was in the mountains near Bethel, evidently the modern Jiljuliyeh, about 7 m. N. of Bethel (Beitin). **A** fourth Gilgal (Deut. xi. 30) would seem to be suggested in the neighbourhood of Mt. Gerizim. A place called Juleijil 1 m. E. of the foot of Mt. Gerizim is a likely identification.

GILGAMESH, EPIC OF, the title given to one of the most important literary products of Babylonia, from the name of the chief personage in the series of tales of which it is composed.

Though the Gilgamesh Epic is known to us chiefly from the fragments found in the royal collection of tablets made by Assur-bani-pal, the king of Assyria (668–626 B.C.) for his palace at Nineveh, internal evidence points to the high antiquity of at least some portions of it, and the discovery of tablets two and three and of a fragment of the epic in the older form of the Babylonian script, which can be dated *c.* 2000 B.C., confirms this view. Equally certain is a second observation of a general character that the epic originating, as the greater portion of the literature in Assur-bani-pal's collection, in Babylonia is a composite product, that is to say, it consists of a number of independent stories or myths originating at different times and united to form a continuous narrative with Gilgamesh as the central figure. This view naturally raises the question whether the independent stories were all told of Gilgamesh or, as almost always happens in the case of ancient tales, were transferred to Gilgamesh as a favourite popular hero. Internal evidence again comes to our aid to lend its weight to the latter theory.

Gilgamesh is said to have been a king in the first dynasty of Erech, and to have reigned 126 years, but he belongs to an age that could only have preserved a dim recollection of his achievements and adventures through oral traditions. The name[1] is Sumerian and fragments of an early Sumerian poem concerning him have been found at Nippur. Why and how he came to be a popular hero in Babylonia cannot with our present material be determined, but the epic indicates that he came as a conqueror and established himself at Erech. In so far we have embodied in the first part of the epic dim recollections of actual events, but we soon leave the solid ground of fact and find ourselves soaring to the heights of genuine myth. Gilgamesh becomes a god, and in certain portions of the epic clearly plays the part of the sun-god of the spring-time, taking the place apparently of Tammuz or Adonis, the youthful sun-god, though the story shows traits that differentiate it from the ordinary Tammuz myths. **A** separate stratum in the Gilgamesh epic is formed by the story of Enkidu — introduced as the friend of Gilgamesh, who joins him in his adventures. There can be no doubt that Enkidu, who symbolizes primeval man, was a figure originally entirely independent of Gilgamesh, but his story was incorporated into the epic by that natural process to be observed in the national epics of other peoples, which tends to connect the favourite hero with all kinds of tales that for one reason or the other become embedded in the popular mind. Another stratum is represented by the story of a favourite of the gods known as Ut-Napishtim, or in Sumerian Zi-B-sud-ra, the Xisuthros of Berossos, who is saved from a destructive storm and flood that destroys his fellow-citizens of Shuruppak. Gilgamesh is artificially brought into contact with Ut-Napishtim, to whom he pays a visit for the purpose of learning the secret of immortal life and perpetual youth which he enjoys. During the visit Ut-Napishtim tells Gilgamesh the story of the flood and of his miraculous escape. Nature myths have been entwined with other episodes in the epic and finally the theologians took up the combined stories and made them the medium for illustrating the truth and force of certain doctrines of the Babylonian religion. In its final form, the outcome of an extended and complicated literary process, the Gilgamesh Epic covered 12 tablets, each tablet devoted to one adventure in which the hero plays a direct or indirect part, and the whole covering according to the most plausible estimate about 3,000 lines. Of all 12 tablets portions have been found among the remains of Assur-bani-pal's library, but some of the tablets are so incomplete as to leave even their general contents in some doubt. The fragments do not all belong to one copy. Of some tablets portions of two, and of some tablets portions of as many as four, copies have turned up, pointing, therefore, to the great popularity of the production. The best preserved are tablets VI. and XI., and of the total about 1,500 lines are now known, wholly or in part, while of those partially preserved quite a number can be restored. A brief summary of the contents of the 12 may be indicated as follows:

In the 1st tablet, after a general survey of the adventures of Gilgamesh, his rule at Erech is described, where he enlists the services of all the young able-bodied men in the building of the great wall of the city. The people sigh under the burden imposed, and call upon the goddess Aruru to create a being who might act as rival to Gilgamesh, curb his strength, and dispute his tyrannous control. The goddess consents, and creates Enkidu, who is described as a wild man, living with the gazelles and the beasts of the field. Enkidu, whose name points to the tradition which made Ea (*q.v.*) the creator of humanity, symbolizes primeval man. Through a hunter, Enkidu and Gilgamesh are brought together, but instead of becoming rivals, they are joined in friendship. Enkidu is induced by the snares of a maiden to abandon his life with the animals and to proceed to Erech, where Gilgamesh,

[1] The name of the hero, written always ideographically, was for a long time provisionally read *Izdubar;* but a tablet discovered by T. G. Pinches gave the equivalent *Gilgamesh* (*see* Jastrow, *Religion of Babylonia and Assyria,* p. 468).

who has been told in several dreams of the coming of Enkidu, awaits him. Together they proceed upon several adventures, which are related in the following four tablets. At first, indeed, Enkidu curses the fate which led him away from his former life, and Gilgamesh is represented as bewailing Enkidu's dissatisfaction. The sun-god Shamash calls upon Enkidu to remain with Gilgamesh, who pays him all honours in his palace at Erech. With the decision of the two friends to proceed to the forest of cedars in which the goddess Irnina—a form of Ishtar—dwells, and which is guarded by Khumbaba, the and tablet ends. In the 3rd tablet, very imperfectly preserved, Gilgamesh appeals through the goddess Ninsun, mother of Gilgamesh, to the sun-god Shamash for his aid in the proposed undertaking. The 4th tablet contains a description of the formidable Khumbaba, the guardian of the cedar forest. In the 5th tablet Gilgamesh and Enkidu reach the forest. Encouraged by dreams, they proceed against Khumbaba, and despatch him near a specially high cedar over which he held guard. In the 6th tablet Gilgamesh is wooed by the goddess of love, Ishtar. Gilgamesh, recalling to the goddess the sad fate of those who fall victims to her charms, rejects the offer. In the course of his recital snatches of other myths are referred to, including the famous Tammuz-Adonis tale, in which Tammuz, the youthful bridegroom, is slain by his consort Ishtar. The goddess, enraged at the insult, asks her father Anu to avenge her. A divine bull is sent to wage a contest against Gilgamesh, who is assisted by his friend Enkidu. This scene of the fight with the bull is often depicted on seal cylinders. The two friends by their united force succeed in killing the bull, and then after performing certain votive and purification rites return to Erech, where they are hailed with joy. In the 7th tablet Enkidu is smitten with sore disease, but the fragmentary condition of this and the succeeding tablet is such as to envelop in doubt the accompanying circumstances, including the cause and nature of his disease. The 8th tablet records the death of Enkidu. The 9th and 10th tablets, exclusively devoted to Gilgamesh, describe his wanderings in quest of Ut-Napishtim, from whom he hopes to learn how he may escape the fate that has overtaken his friend. He goes through mountain passes and encounters lions. At the entrance to the mountain Mashu, scorpionmen stand guard, from one of whom he receives advice as to how to pass through the Mashu district. He succeeds in doing so, and finds himself in a wonderful park, which lies along the sea coast. In the 10th tablet the goddess Sabitu, who, as guardian of the sea, first bolts her gate against Gilgamesh, after learning of his quest, helps him to pass in a ship across the sea to the "waters of death." The ferryman of Ut-Napishtim brings him safely through these waters, despite the difficulties and dangers of the voyage, and at last the hero finds himself face to face with Ut-Napishtim. In the 11th tablet, Ut-Napishtim tells the famous story of the Babylonian Aood. Ut-Napishtim and his wife are anxious to help Gilgamesh to new life. He is sent to a place where he washes himself clean from impurity. He is told of a weed which restores youth to the one grown old. Scarcely has he obtained the weed when it is snatched away from him by a serpent, and the tablet closes somewhat obscurely with the prediction of the destruction of Erech. In the 12th tablet Gilgamesh succeeds in obtaining a view of Enkidu's shade, and learns through him of the sad fate endured by the dead. With this description, in which care of the dead is inculcated as the only means of making their existence in Aralu, where the dead are gathered, bearable, the epic, so far as we have it, closes.

The reason why the flood episode and the interview with the dead Enkidu are introduced is quite clear. Both are intended as illustrations of doctrines taught in the schools of Babylonia; the former to explain that only the favourites of the gods can hope under exceptional circumstances to enjoy life everlasting; the latter to emphasize the impossibility for ordinary mortals to escape from the inactive shadowy existence led by the dead, and to inculcate the duty of proper care for the dead. That the astro-theological system is also introduced into the epic is clear from the division into 12 tablets, which correspond to the yearly course of the sun, while throughout there are indications that all the adventures of Gilgamesh and Enkidu, including those which have an historical background, have been submitted to the influence of this system and projected on to the heavens. This interpretation of the popular tales, according to which the career of the hero can be followed in its entirety and in detail in the movements in the heavens, in time, with the growing predominance of the astral-mythological system, overshadowed the other factors involved, and it is in this form, as an astral myth, that it passes through the ancient world and leaves its traces in the folk-tales and myths of Hebrews, Phoenicians, Syrians, Greeks and Romans throughout Asia Minor and even in India.

GILGIT, an outlying province in the extreme north-west of India, over which Kashmir has reasserted her sovereignty Only a part of the basin of the river Gilgit is included within its political boundaries. There is an intervening width of mountainous country, represented chiefly by glaciers and ice-fields, and intersected by narrow sterile valleys, measuring some 100 to 150 m. in width, to the north and north-east, which separates the province of Gilgit from the Chinese frontier beyond the Muztagh and Karakoram. This part of the Kashmir borderland includes Kanjut (or Hunza) and Ladakh. To the north-west, beyond the sources of the Yasin and Ghazar in the Shandur range (the two most westerly tributaries of the Gilgit river) is the deep valley of the Yarkhun or Chitral. Gilgit proper now forms a *waearat* of the Kashmir states administered by a *wazir*. Gilgit is the headquarters of a British political agent, directly responsible to the government of India for the administration of the outlying districts or petty states of Hunza, Nagar, Ashkuman, Yasin and Ghizar, the little republic of Chilas, etc. These states acknowledge the suzerainty of Kashmir, paying an annual tribute in gold or grain, but they form no part of its territory.

Within the wider limits of the former Gilgit agency are many mixed races, speaking different languages, which have all been usually classed together under the name Dard. The Dard, however, is unknown beyond the limits of the Kohistan district of the Indus valley to the south of the Hindu Koh, the rest of the inhabitants of the Indus valley belonging to Shin republics, or Chilas. The great mass of the Chitral population are Kho (speaking Khowar), and they may be accepted as representing the aboriginal population of the Chitral valley. (See HINDU KUSH.) Between Chitral and the Indus the "Dards" of Dardistan are chiefly Yeshkuns and Shins, and it would appear from the proportions in which these people occupy the country that they must have primarily moved up from the valley of the Indus in successive waves of conquest, first the Yeshkuns, and then the Shins. The Shins are of Hindu origin and spread themselves northwards and eastwards as far as Baltistan, where they collided with the aboriginal Tatar of the Asiatic highlands. The *waearat* of Gilgit contains a population (1901) of 60,885, all Mohammedans, mostly of the Shiah sect, but not fanatical. The dominant race is that of the Shins, whose language is universally spoken. This is one of the so-called Pisacha languages, an archaic Aryan group intermediate between the Iranian and the Sanskritic.

In general appearance and dress all the mountain-bred peoples extending through these northern districts are very similar. Thick felt coats reaching below the knee, loose "pyjamas" with cloth "putties" and boots (often of English make) are almost universal, the distinguishing feature in their costume being the felt cap worn close to the head and rolled up round the edges. Their temperament varies much with their habitat—those who live on the shadowed sides of mountains being distinctly more morose and more serious in disposition than the dwellers in valleys which catch the winter sunlight. They are, at the same time, bloodthirsty and treacherous to a degree which would

appear incredible to a casual observer of their happy and genial manners, exhibiting a strange combination of "the monkey and the tiger." Addicted to sport of every kind, they are excellent agriculturists, and show great ingenuity in their local irrigation works.

Routes in the Gilgit Agency.--One of the oldest recorded routes through this country is that which connects Mastuj in the Chitral valley with Gilgit, passing across the Shandur range (12,250). It now forms the high-road between Gilgit and Chitral, and has been engineered into a passable route. From the north three great glacier-bred affluents make their way to the river of Gilgit, joining it at almost equal intervals, and each of them affords opportunity for a rough passage northwards. (1) The Yasin river, which follows a fairly straight course from north to south for about 40 m. from the foot of the Darkôt pass across the Shandur range (15,000) to its junction with the river Gilgit, close to the little fort of Gupis, on the Gilgit-Mastuj road. Much of this valley is cultivated and extremely picturesque. At the head of it is a grand group of glaciers, one of which leads up to the well-known pass of Darkôt. (2) 25 m. (by map measurement) below Gupis the Gilgit receives the Ashkuman affluent from the north. The little Lake of Karumbar is held to be its source, as it lies at the head of the river. The same lake is sometimes called the source of the river Yarkhun or Chitral; and it seems possible that a part of its waters may be deflected in each direction. The Rarumbar, or Ashkuman, is nearly twice the length of the Yasin, and the upper half of the valley is encompassed by glaciers, rendering the route along it uncertain and difficult. (3) 40 m. or so below the Ashkuman junction, and nearly opposite the little station of Gilgit, the river receives certain further contributions from the north which are collected in the Hunza and Nagar basins. These basins include a system of glaciers of such gigantic proportions that they are probably unrivalled in any part of the world. The glacial head of the Hunza is not far from that of the Karumbar, and, like the Karumbar, the river commences with a wide sweep eastwards, following a course roughly parallel to the crest of the Hindu Kush (under whose southern slopes it lies close) for about 40 m. Then striking south for another 40 m., it twists amidst the barren feet of gigantic rock-bound spurs which reach upwards to the Muztagh peaks on the east and to a mass of glaciers and snow-fields on the west, hidden amidst the upper folds of mountains towering to an average of 25,000 ft. The next great bend is again to the west for 30 m., before a final change of direction to the south at the historical position of Chalt and a comparatively straight run of 25 m. to a junction with the Gilgit. The valley of Hunza lies some 10 m from the point of this westerly bend, and 20 (as the crow flies) from Chalt.

Glaciers and Mountains.—Conway and Godwin Austen have described the glaciers of Nagar which, enclosed between the Muztagh spurs on the north-east and the frontier peaks of Kashmir (terminating with Rakapushi) on the south-west, and massing themselves in an almost uninterrupted series from the Hunza valley to the base of those gigantic peaks which stand about Mount Godwin Austen, seem to be set like an ice-sea to define the farthest bounds of the Himalaya. From its uttermost head to the foot of the Hispar, overhanging the valley above Nagar, the length of the glacial ice-bed known under the name of Biafo is said to measure about 90 m. Throughout the mountain region of Kanjut (or Hunza) and Nagar the valleys are deeply sunk between mountain ranges, which are nowhere less than 15,000 ft. in altitude, and which must average above 20,000 ft. As a rule, these valleys are bare of vegetation. Where the summits of the loftier ranges are not buried beneath snow and ice they are bare, bleak and splintered, and the nakedness of the rock scenery extends down their rugged spurs to the very base of them. Sun-baked in summer and frost-riven in winter, the mountain sides are but immense ramps of loose rock débris, only awaiting the yearly melting of the upper snow-fields, or the advent of a casual rainstorm, to be swept downwards in an avalanche of mud and stones into the gorges below. Here it becomes piled and massed together, till the pressure of accumulation forces it out into the main valleys, where it spreads in alluvial fans and silts up the plains. This formation is especially marked throughout the high level valleys of the Gilgit basin.

Passes.—Each of these northern affluents of the main stream is headed by a pass, or a group of passes, leading either to the Pamir region direct, or into the upper Yarkhun valley from which a Pamir route diverges. The Yasin valley is headed by the Darkôt pass (15,000 ft.), which drops into the Yarkhun not far from the foot of the Baroghil group over the main Hindu Kush watershed. The Ashkuman is headed by the Gazar and Kora Bohrt passes, leading to the valley of the Ab-i-Punja; and the Hunza by the Kilik and Mintaka, the connecting links between the Taghdumbash Pamir and the Gilgit basin. They are all about the same height—15,000 ft. All are passable at certain times of the year to small parties, and all are uncertain. In no case do they present insuperable difficulties in themselves; but the gorges and precipices which distinguish the approaches to them from the south, the slippery sides of shelving spurs whose feet are washed by raging torrents, the perpetual weary monotony of ascent and descent over successive ridges multiplying the gradient indefinitely—these form the real obstacles blocking the way to these northern passes.

Gilgit Station.—The pretty little station of Gilgit (4.890 ft. above sea) spreads itself in terraces above the right bank of the river nearly opposite the opening leading to Hunza, almost nestling under the cliffs of the Hindu Roh, which separates it on the south from the savage mountain wilderness of Darel and Kohistan. It includes a residency for the British political officer, with about half a dozen homes for the accommodation of officials, barracks suitable for a battalion of Kashmir troops, and a hospital. Evidences of Buddhist occupation are not wanting in Gilgit, though they are few and unimportant. Such as they are, they appear to prove that Gilgit was once a Buddhist centre, and that the old Buddhist route between Gilgit and the Peshawar plain passed through the gorges and clefts of the unexplored Darel valley to Thakot under the northern spurs of the Black mountain.

Connection with India.—The Gilgit river joins the Indus a few miles above the little post of Bunji, where an excellent suspension bridge spans the river. A little below Bunji the Astor river joins the Indus from the south-east, and this deep pine-clad valley indicates the continuation of the highroad from Gilgit to Kashmir via the Tragbal and Burzil passes. Another well-known route connecting Gilgit with the Abbottabad frontier of the Punjab lies across the Babusar pass (13,000 ft.), linking the lovely Hazara valley of Kaghan to Chilas; Chilas (4,150 ft) being on the Indus, some 50 m. below Bunji. This is a more direct connection between Gilgit and the plains of the Punjab than that afforded by the Kashmir route via Gurais and Astor, which latter route involves two considerable passes—the Tragbal (11,400) and the Burzil (13,500); but the intervening strip of absolutely independent territory (independent alike of Kashmir and the Punjab) which includes the hills bordering the road from the Babusar pass to Chilas, renders it a risky route for travellers unprotected by a military escort. Like the Kashmir route, it is now defined by a good military road.

History.—The Dards (Daradae) are located by Ptolemy with surprising accuracy on the west of the Upper Indus, beyond the head-waters of the Swat river (*Soastus*), and north of the *Gandarae*, *i.e.*; the Gandharis, who occupied Peshawar and the country north of it. This region was traversed by two of the Chinese pilgrims of the early centuries of our era, who have left records of their journeys, viz., Fahien, coming from the north, c. 400, and Hsüan Tsang, ascending from Swat, c. 631. The latter says: "Perilous were the roads, and dark the gorges, Sometimes the pilgrim had to pass by loose cords, sometimes by light stretched iron chains. Here there were ledges hanging in mid-air; there flying bridges across abysses; elsewhere paths cut with the chisel, or footings to climb by." Yet even in these inaccessible regions were found great convents and miraculous images of Buddha. How old the name of **Gilgit** is we do not know, but it occurs in the writings of the great Mohammedan savant al-Biruni, in his

notices of Indian geography. Speaking of Kashmir, he says: "Leaving the ravine by which you enter Kashmir and entering the plateau, then you have for a march of two more days on your left the mountains of Bolor and Shamilan, Turkish tribes who are called *Bhattavaryan*. Their king has the title Bhatta-Shah. Their towns are Gilgit, Aswira and Shiltash, and their language is the Turkish. Kashmir suffers much from their inroads" (Trs. Sachau, i. 207). It is impossible to say what ground the writer had for calling the people Turks. But it is curious that the Shins say they are all of the same race as the Moguls of India, whatever they may mean by that. Gilgit, as far back as tradition goes, was ruled by rajahs of a family called Trakane. When this family became extinct the valley was desolated by successive invasions of neighbouring rajahs, and in the 20 or 30 years ending with 1842 there had been five dynastic revolutions. The most prominent character in the history was a certain Gaur Rahman or Gauhar Aman, chief of Yasin, a cruel savage and man-seller, of whom many evil deeds are told. Being remonstrated with for selling a mullah, he said, "Why not? The Koran, the word of God, is sold; why not sell the expounder thereof?" The Sikhs entered Gilgit about 1842 and kept a garrison there. When Kashmir was made over to Maharajah Gulab Singh of Jammu, in 1846, by Lord Hardinge, the Gilgit claims were transferred with it. And when a commission was sent to lay down boundaries of the tracts made over, Mr. Vans Agnew (afterwards murdered at Multan) and Lieut. Ralph Young of the Engineers visited Gilgit, the first Englishmen who did so. The Dogras (Gulab Singh's race) had much ado to hold their ground, and in 1852 a catastrophe occurred, parallel on a smaller scale to that of the English troops at Kabul. Nearly 2,000 men of theirs were exterminated by Gaur Rahman and a combination of the Dards; only one person, a soldier's wife, escaped, and the Dogras were driven away for eight years. Gulab Singh would not again cross the Indus, but after his death (in 1857) Maharajah Ranbir Singh longed to recover lost prestige. In 1860 he sent a force into Gilgit. Gaur Rahman just then died, and there was little resistance. The Dogras took Yasin twice, but did not hold it. They also, in 1866, invaded Darel, one of the most secluded Dard states, to the south of the Gilgit basin, but withdrew again. In 1889, in order to guard against the advance of Russia, the British Government, acting as the suzerain Power of Kashmir, established the Gilgit agency; in 1901, on the formation of the North-West Frontier province, the rearrangement was made as stated above.

GILKIN, IWAN (1858–1924), *Belgian poet, was born at Brussels on Jan. 7, 1858. He was a member of the group of poets known as La jeune Belgique, and his earlier work shows strongly the influence of Baudelaire. He wrote Damnation de l'artiste* (1890), *Ténèbres* (1892), *and other poems collected under the title of La Nuit (1897). Other volumes of verse followed. His most individual work is to be found in his dramatic poem, Prométhée* (1899), *and the blank verse drama, Le Roi Cophétua. Gilkin died at Brussels on Sept. 30,* 1924.

GILL, ERIC ROWLAND (1882–1940), *English stone carver, wood engraver and draughtsman, was born on Feb. 22, 1882, at Brighton, where his father was curate of the church of "The Countess of Huntingdon's Connexion." In 1897 the family moved to Chichester and the boy was sent to the art school in that city. His father decided to make him an architect, and in 1899 he apprenticed him to a London office. Gill did not, however, adopt this profession but took his career into his own hands. Becoming fascinated with the art of lettering, he began to carve letters and shields for tombstones, and for some years made a living by this work. In* 1910 *he produced his first sculpture, a Madonna and Child, which received much favourable criticism. Through the influence of* Augustus *John he was enabled to give an exhibition of his work at the* Chenil *gallery, London, in* 1911. *About this time he went through a phase of profound spiritual struggle. Religion and art were to him inseparable, and after vain attempts to find or create a religion consistent with his special creed of absolute values, he entered the Roman Catholic Church in* 1913. *In the same year he was commissioned to carve the Stations of the Cross in Westminster cathedral. These were carved in Hoptonwood stone and form flat, low reliefs on the brick pillars of the church. Much discussion was aroused by them at the time, objection being raised to their so-called archaism; in fact they have the beauty of sincerity and conviction, and, although unequal, they contain examples of Gill's finest work. His principal sculptures before this date included the statue "Mother and Child"* (1910); *a Crucifix in Hoptonwood stone* (1910), *now in the Tate Gallery, London; his "Cupid" (Portland stone,* 1910); *the "Tumbler" (1912); the "Madonna and Child" (in Portland stone, coloured and gilt, 1912); "Torso" in Bath stone* (Manchester *art gallery, 1912); and in 1913: "Dancer," "Mother and Child," "Boxers," and "Torso and Head." After 1918 he produced "St. Sebastian," "Torso," "Adam and Eve,"* 1920 *(headless —an* unusual *concession to* the *modern tendency),* "Anadiómené," *"Splits" (two postures) and the black marble torso "Deposition"* (1924). *In* 1922–23 *he executed the relief of "Christ driving the moneylenders out of the Temple" as war memorial for Leeds university and in 1922 the Stations of the Cross for St. Cuthbert's, Bradford. He also did a very large number of woodcuts. In* 1933 *he executed the sculptures on Broadcasting House, London.*

His ideals were clearly set forth in his writings: Christianity and Art (1927); *Sculpture, an Essay on Stone Cutting — with a Preface about God* (1917); *Id quod visum placet, A Practical Test of the Beautiful* (1926); *Beauty Looks After Herself* (1933). *It was his creed that craftsman and designer should be, not two persons, but one, and he fiercely denounced the practice of modelling in clay and having the model translated into marble by other hands. Gill's later published works included Money and Morals* (1934); *Work aizd Leisure* (1935); *The Necessity of Belief (1936); Work and Property* (1937).

See Albert Rutherston, Eric Gill in Contemporary British Artists Series (London, 1927); Kineton *Parkes, Sculpture of To-day (Universal Art Series,* 1921).

GILL *or* **BRANCHIA,** *the name given to any structure specially adapted for aquatic respiration. Gills are found in some Annelida; most* Mollusca; *Crustacea; the aquatic* Arachnida, *such as the king-crab; the larvae of many aquatic insects; and in protochordates, fishes and most larval and a few adult Amphibia. In the Lamellibranchia (q.v.) among the molluscs and in Amphioxus and the* Tunicata *(qq.v.), the gills are modified for feeding purposes, and in one group of lamellibranchs, the Septibranchia, they have entirely lost their respiratory function. (See MOLLUSCA, ANNELIDA,* CRUSTACEA, *ARACHNIDA, FISHES.)*

The word is also applied to structures resembling the branchiae of fishes, such as the wattles of a fowl or the radiating films on the under side of fungi. In liquid measure a gill is one-fourth of a pint.

GILLES DE ROYE *or* **EGIDIUS DE ROYA** (d. 1478), *Flemish Cistercian chronicler, was born probably at Montdidier, and became professor of theology in Paris and abbot of the monastery of Royaumont at* Asnières-sur-Oise, *retiring about 1458 to the convent of* Notre *Dame des Dunes, near Furnes. Gilles wrote the Chronicon Dunense or Annales Belgici, a* résumé *and continuation of the work of another monk, Jean Brandon (d. 1428), which deals with the history of Flanders, and also with events in Germany, Italy and England from 792 to 1478.*

The Chronicle was published by F. R. Sweert in *the Rerum Belgicarum annales (Frankfort, 1620); and the earlier part of it by C. B. Kervyn de Lettenhove in the Chroniques relatives à l'histoire de la Belgique (1870).*

GILLES LI MUISIS *or* **LE MUISET** (*c.* 1272–1352), *French chronicler, was born probably at Tournai, and in* 1289 *entered the Benedictine abbey of St. Martin in his native city, becoming prior of this house in* 1327, *and abbot four years later. Gilles wrote two Latin chronicles, Chronicon majus and Chronicon*

minus, dealing with the history of the world from the creation until 1349. This work, ed. J. J. de Senet, in *Corpus chronicorum Flandriae,* tome ii. (Brussels, 1841), continued by another writer to 1352, is valuable for the history of northern France and Flanders during the first half of the 14th century. Gilles also wrote some French poems, and these *Poesies de Gilles li Muisis* have been published by Baron Kervyn de Lettenhove (Louvain, 1882).

See A. Molinier, *Les Sources de l'histoire de France,* tome iii. **(1903).**

GILLESPIE, GEORGE (1613–1648), Scottish divine, was born at Kirkcaldy, where his father, John Gillespie, was parish minister, on Jan. 21, 1613, and was educated at the University of St. Andrews. He was acting as private chaplain to the earl of Cassillis when he wrote his first work, *A Dispute against the English Popish Ceremonies obtruded upon the Church of Scotland* (1637), which was burnt by order of the privy council. In April 1638 Gillespie was ordained minister of Wemyss (Fife), and in the same year was a member of the Glasgow Assembly, before which he preached (Nov. 21) a sermon against royal interference in matters ecclesiastical. In 1642 Gillespie was translated to Edinburgh. In 1640 he had accompanied the commissioners of the peace to England as one of their chaplains; and in 1643 he was appointed one of the four Scottish commissioners to the Westminster Assembly, where he displayed great power as a controversialist. In 1645 he returned to Scotland, and is said to have drawn the Act of Assembly sanctioning the directory of public worship. On his return to London he had a hand in drafting the Westminster confession of faith, especially chap. i. Gillespie was elected moderator of the Assembly in 1648. The hard work entailed by this office hastened his death, which took place at Kirkcaldy on Dec. 17, 1648.

His principal publications were controversial and chiefly against Erastianism.

See *Works,* with memoir, published by Hetherington (1843–46).

GILLESBIE, THOMAS (1708–74), Scottish divine, was born at Clearburn, Duddingston, Midlothian, in 1708. He received ordination at Northampton in January 1741. In September of the same year he was admitted minister of the parish of Carnock, Fife, the presbytery of Dunfermline admitting as valid the ordination he had received in England, and allowing a qualification of his subscription to the church's doctrinal symbol, so far as it had reference to the sphere of the civil magistrate in matters of religion. Having absented himself from the meetings of presbytery held for the purpose of ordaining one Andrew Richardson, an unacceptable presentee, as minister of Inverkeithing, he was deposed by the Assembly of 1752 for maintaining that the refusal of the local presbytery to act in this case was justified. He continued, however, to preach, first at Carnock, and afterwards in Dunfermline, where a large congregation gathered round him. In 1761, in conjunction with Thomas Boston of Jedburgh and Collier of Colinsburgh, he formed a distinct communion under the name of "The Presbytery of Relief,"—relief, that is to say, "from the yoke of patronage and the tyranny of the church courts." The Relief Church eventually became one of the communions combining to form the United Presbyterian Church. He died on Jan. 19, 1774.

See Lindsay, *Life and Tinzes of the Rev. Thomas Gillespie;* Smithers, *History of the Relief Church;* for the Relief Church *see* UNITED PRESBYTERIAN CHURCH.

GILLESPIE, a city of Macoupin county, Ill., U.S.A., 45 mi. N.E. of Saint Louis, in a rich agricultural and coal-mining district. It is served by the Big Four and the Illinois Terminal (electric) railways. Population was 5,111 in 1930; 4,440 in 1940.

GILLETTE, WILLIAM HOOKER, (1855–1937) American playwright and actor, was born in Hartford, Conn., on July 24, 1855, the son of former United States Senator Francis G. Gillette and of Elizabeth Daggett (Hooker) Gillette, a descendant of one of the town's founders. As a boy he displayed histrionic talent, planning and building scenery and miniature stages, and giving marionette shows. He graduated at the Hartford high school, but soon afterwards defied parental objection to a theatrical career by becoming utility man in a stock company in New Orleans. Mark Twain (Samuel L. Clemens), a neighbour and close friend of the family, intervened for him, and he became a member of John T. Raymond's company. His first appearance was on Sept. 29, 1875, in *Faint Heart Ne'er Won Fair Lady,* at the Globe theatre in Boston. While in Boston Gillette studied at the Massachusetts Institute of Technology, at Boston university, and at Harvard, and later, when working in New York, he studied at New York university. After experience in stock companies in Cincinnati, O., and St. Louis, Mo., he appeared in the title rôle of his own play, *The Professor,* at the Madison Square Garden theatre, on Oct. 29, 1881. After that, except for his heralded appearance in *Samson, Diplomacy, The Admirable Crichton, A Successful Calamity,* and *Dear Brutus,* he has acted exclusively in plays of his own making. *Held by the Enemy,* the first successful play about the Civil War, was produced in Brooklyn on Feb. 22, 1886. It was followed by *A Legal Wreck,* a play of a New England coast town (Aug. 14, 1888). *All the Comforts of Home* (March 3, 1890), *Mr. Wilkinson's Widows* (March 3, 1891), and *Too Much Johnson* (Oct. 25, 1894), were all amusing comedies; as were *Because She Loved Him So, Clarice,* and others of less importance. But Gillette's most successful character is that of a "cool resourceful man of action," and it is the plays in which this character appears portrayed by him that have been most successful; for instance, *Held by the Enemy; Sherlock Holmes,* first put on in New York on Nov. 6, 1899, and in London on Sept. 9, 1901; and *Secret Service,* first played in Philadelphia, May 13, 1895, staged in London and Paris in 1897, and revived in New York in 1915–16.

See J. B. Clapp and E. F. Edgett, *Plays of the Present* (1902); Norman Hapgood, *The Stage in America,* chap. iii. (1901) and A. H. Quinn's *Representative American Plays* (1917, 1923).

GILLIE, an attendant on a Gaelic chieftain (from Irish *gille* or *giolla,* a servant or boy). The name is now applied in the Highlands of Scotland to the man-servant who attends a sportsman in shooting or fishing. A *gillie-wetfoot,* a term now obsolete, was the gillie whose duty it was to carry his master over streams.

GILLIES, JOHN (1747–1836), Scottish historian and classical scholar, was born at Brechin, in Forfarshire. In 1784 he completed his *History of Ancient Greece, its Colonies and Conquests* (published 1786). On the death of William Robertson (1721–93), Gillies was appointed historiographer-royal for Scotland. In his old age he retired to Clapham, where he died on Feb. 15, 1836.

Of his other works, none of which is much read, the principal are: *View of the Reign of Frederic II. of Prussia, with a Parallel between that Prince and Philip II. of Macedon* (1789), rather a panegyric than a critical history; translations of Aristotle's *Rhetoric* **(1823)** and *Ethics and Politics* (1786–97); of the *Orations* of Lysias and Isocrates (1778); and *History of the World from Alexander to Augustus* (1807), which, although deficient in style, was commended for its learning and research.

GILLINGHAM, a market town of Dorsetshire, England, on the river Stour, 105 mi. W.S.W. from London by the S.R. Pop. (1931), 3,274. The church of St. Mary the Virgin has a Decorated chancel. The rich surrounding district was a forest preserved by King John and his successors. There is a large agricultural trade and bacon-curing, also small manufactures of bricks, etc.

GILLINGHAM, a municipal borough of Kent, England, on the Medway. Pop. (1938) 70,600. Area 10.7 sq.mi. It comprises the Gillingham division of the Rochester parliamentary borough. Its population is largely industrial, employed in the Chatham dockyards. The church of St. Mary Magdalene ranges in date from Early English to Perpendicular, retaining also traces of Norman work and some early brasses. A battle between Edmund Ironside and Canute, *c.* 1016, is placed here; and there was formerly a palace of the archbishops of Canterbury. Gillingham was incorporated in 1903 and in 1929 the boundaries were extended to include Rainham parish (5.4 sq.mi.).

GILLOT, CLAUDE (1673–1722), French painter and engraver, best known as the master of Watteau and Lancret, was born at Langres on April 27, 1673. His sportive mythological landscape pieces, with such titles as "Feast of Pan" and "Feast of Bacchus," opened the Academy of Painting at Paris to him in 1715; and he then adapted his art to the fashionable tastes of the day. He was connected with the opera and theatre as a designer of scenery and costumes. He died in Paris on May 4, 1722.

GILLOTT, JOSEPH (1799–1873), English pen-maker. was born at Sheffield on Oct. 11, 1799. He set up in business in Birmingham, and about 1830 he turned his attention to the manufacture of steel pens by machinery; in 1831 he patented a process for placing elongated points on the nibs of pens. Subsequently he invented other improvements, getting rid of the hardness and lack of flexibility, which had been a serious defect in nibs, by cutting, in addition to the centre slit, side slits, and cross grinding the points. Gillott was a liberal art-patron and one of the first to recognize the merits of J. M. W. Turner. He died at Birmingham Jan. 5, 1873.

GILLOW, ROBERT (d. 1773), the founder at Lancaster of a distinguished firm of English cabinet-makers and furniture designers whose books begin in 1731. He was succeeded by his eldest son Richard (1734–1811), who was taken into partnership about 1757, when the firm became Gillow and Barton, and his younger sons Robert and Thomas, and the business was continued by his grandson Richard (1778–1866). The firm were architects as well as cabinet-makers, and the first Richard Gillow designed the classical custom house at Lancaster. About 1761 premises were opened in Oxford street, London. For a iong period the Gillows were the best known makers of English furniture; Sheraton, Hepplewhite and Robert Adam designed for them. Between 1760 and 1770 they invented the original form of the billiard-table; they were the patentees (about 1800) of the telescopic dining-table; for a Captain Davenport they made, if they did not invent, the first writing-table of that name.

See *Gillow's, a Record of a Furnishing Firm during Two Centuries* (1901).

GILLRAY, JAMES (1757–1815), English caricaturist, was born at Chelsea in 1757. Gillray commenced life by learning letter-engraving, in which he soon became an adept. This employment, however, proving irksome, he wandered about for a time with a company of strolling players. After a checkered experience he returned to London and was admitted a student in the Royal Academy, supporting himself by engraving, and probably issuing a considerable number of caricatures under fictitious names. Hogarth's works were the delight and study of his early years. "Paddy on Horseback," which appeared in 1779, is the first caricature which is certainly his. Two caricatures on Rodney's naval victory, issued in 1782, were among the first of the memorable series of his political sketches. The name of Gillray's publisher and printseller, Miss Humphrey, is inextricably associated with that of the caricaturist. Gillray lived in Miss Humphrey's house during all the period of his fame. His plates were exposed in Humphrey's shop window. A number of his most trenchant satires are directed against "Farmer George" and his court. George's comment, on being shown a set of Gillray's sketches, was: "I don't understand these caricatures." Gillray revenged himself for this utterance by his "A Connoisseur Examining a Cooper," which he is doing by means of a candle on a "save-all"; the sketch satirizes at once the king's pretensions to knowledge of art and his miserly habits.

The French Revolution made Gillray conservative; and he issued caricature after caricature, ridiculing the French and Napoleon and glorifying John Bull. His last work, from a design by Bunbury, is entitled, "Interior of a Barber's Shop in Assize Time" and is dated 1811. While he was engaged on it he became mad, although he had occasional intervals of sanity, which he employed on his last work. The approach of madness must have been hastened by his intemperate habits. Gillray died on June 1, 1815, and was buried in St. James's churchyard, Piccadilly.

Gillray's caricatures are divided into two classes, the political series and the social. The political caricatures form a historical record of the latter part of the reign of George III. They were circulated not only over Britain but throughout Europe and exerted a powerful influence. In this series George III, the queen. the prince of Wales, Fox, Pitt, Burke and Napoleon are the most prominent figures. In 1788 appeared two fine caricatures by Gillray. "Blood on Thunder Fording the Red Sea" represents Lord Thurlow carrying Warren Hastings through a sea of gore: Hastings looks very comfortable and is carrying two large bags of money. "Market-Day" pictures the ministerialists of the time as horned cattle for sale. Among Gillray's best satires on the king are: "Farmer George and His Wife," two companion plates, in one of which the king is toasting muffins for breakfast, and in the other the queen is frying sprats; "The Anti-Saccharites," where the royal pair propose to dispense with sugar, to the great horror of the family; "A Connoisseur Examining a Cooper"; "Temperance Enjoying a Frugal Meal"; "Royal Affability"; "A Lesson in Apple Dumplings"; and "The Pigs Possessed." Among his other political caricatures may be mentioned: "Britannia between Scylla and Charybdis," a picture in which Pitt, so often Gillray's butt, figures in a favourable light; "The Bridal Night"; "The Apotheosis of Hoche," which concentrates the excesses of the French Revolution in one view; "The Nursery with Britannia Reposing in Peace"; and "The First Kiss These Ten Years" (1803), another satire on the peace, which is said to have greatly amused Napoleon.

BIBLIOGRAPHY.—The principal editions of Gillray's caricatures are those by Thomas M'Lean (1830); by H. G. Bohn (1851), with a commentary by T. Wright and R. H. Evans; by T. Wright (1874). *See* T. Wright's *Hist. of Caricature and Grotesque* in Literature and Art (1865); aiso the article CARICATURE.

GILLYFLOWER, a name applied to various flowers, but most commonly to the clove pink, *Dianthus Caryophyllus,* of which the carnation is a cultivated variety, and to the stock, *Mathiola incana,* a well-known garden favourite. The word is sometimes written gilliflower or gilloflower, and is reputedly a corruption of July-flower, "so called from the month they blow in." The name was originally given in Italy to plants of the pink tribe, especially the carnation, but has in England been transferred to several cruciferous plants. The gillyflower of Chaucer and Spenser and Shakespeare was, as in Italy, *Dianthus Caryophyllus;* that of later writers and of gardeners, *Mathiola.* The principal other plants which bear the name are the wallflower, Cheiranthus *Cheiri,* called wall-gillyflower in old books; the dame's violet, *Hesperis matronalis,* called variously the queen's, the rogue's and the winter gillyflower; the ragged-robin, *Lychnis* Flos-cuculi, called marsh-gillyflower and cuckoo-gillyflower; the water-violet, Hottonia *palustris,* called water-gillyflowei-; and the thrift, *Statice armeria,* called sea-gillyflower. As a separate designation it is nowadays usually applied to the wallflower.

GILMAN, DANIEL COIT (1831–1908), American educator, was born in Norwich, Conn., on July 6, 1831. After his graduation at Yale in 1852 he engaged in teaching and miscellaneous literary work, went to St. Petersburg with his life-long friend, Andrew D. White, as attaché, and studied at Berlin (1854–55). On his return to America he was at Yale for 17 years as assistant librarian, professor of physical and political geography in the Sheffield scientific school and as secretary of the governing board of that institution. All these positions as well as his general educational activities fitted him well for his important posts as head of the University of California (1872–75) and first president of Johns Hopkins university. He entered upon his duties in the latter institution in May 1875 and was formally inaugurated on Feb. 22, 1876. This post he filled until 1901. From 1901 to 1904 he was the first president of the Carnegie institution at Washington, D.C. He died at Norwich, Conn., on Oct. 13, 1908, the recipient of many honourary degrees and other marks of scholastic distinction. His influence upon higher education in America was great, especially at Johns Hopkins. To the organization of the Johns Hopkins hospital, of which he was made director in 1889, he contributed greatly. He was a singularly good judge of men and an able administrator, and under him Johns Hopkins had an immense influence, especially in the promotion of original and productive research. As a trustee of the John F. Slater fund, of the Peabody Educational fund and of the Russell Sage Foundation for Social Betterment, as an original member of the General Education board, and as successor to Carl Schurz as president of the National Civil Service Reform league, he further aided in educational and social betterment in the United States. In 1896–97 he served on the Venezuela Boundary commission appointed by President Cleveland.

Some of his papers and addresses are collected in a volume entitled *University Problems in the United States* (1898). He wrote, besides,

James Monroe (1883), in the American Statesmen Series; a *Life of James D. Dana,* the geologist (1899); *Science and Letters at Yale* (1901) and *The Launching of a University* (1906), an account of the early years of Johns Hopkins.

See Fabian Franklin, *Life of Daniel Coit Gilman* (1910) and John Thomas Faris, *Men Who Conquered* (Chicago, 1922).

GILMAN, LAWRENCE (1878–), music critic and author, was born at Flushing (N.Y.), July 5, 1878. He was educated in the New York public schools and the Collins street classical school, Hartford (Conn.), and studied painting under William M. Chase. In 1901 he was appointed music critic of Harper's *Weekly,* acting also as assistant editor, 1903–11, and managing editor, 1911–13. Following two years on the staff of Harper's Magazine, he became critic of the North American Review in 1915, leaving to go to the New York Herald-Tribune as music critic in 1923. He was programme annotator for the New York Philharmonic Society and the Philadelphia Orchestra from 1921.

His works include *Phases of Modern Music, Edward MacDowell* (in the series *Living Masters of Music,* first published 1905; revised and enlarged, 1909); *The Music of Tomorrow, A Guide to Strauss' "Salomé"; Stories of Symphonic Music; Debussy's "Pelléas et Mélisande"; Aspects of Modern Opera; Nature in Music,* and *A Christmas Meditation.* He is the composer of settings for voice and piano of three poems by W. B. Yeats: *A Dream of Death, The Heart of the Woman,* and *The Curlew.*

GILMORE, PATRICK SARSFIELD (1829–1892), American bandmaster, was born in Ireland, and settled in America about 1850. He organized the best wood-wind and brass players of Europe and America, playing in the remoter areas and introducing Wagner, Liszt and other great composers where they had been unknown. He was responsible also for many great orchestras, including one at the World's Peace Jubilee, Philadelphia, 1872, when the orchestra numbered 2,000 and the chorus 20,000. He died at St. Louis Sept. 24, 1892.

GILPIN, BERNARD (1517–1583), the "Apostle of the North," was born at Kentmere in 1517, and educated at Queen's College, Oxford, where he was elected fellow in 1542; in the same year he was ordained. Gilpin was one of the first scholars elected to Wolsey's new foundation at Christ Church. At Oxford he defended the doctrine of the church against Hooper, but his confidence in his own cause was somewhat shaken by a public disputation in which he supported Hooper against Peter Martyr. In 1552 he preached before Edward VI. a sermon on sacrilege, in which he denounced the expropriation of church property. About this time he became vicar of Norton in the Durham diocese, and obtained a licence, through William Cecil, as a general preacher throughout the kingdom during the king's lifetime. On Mary's accession he went abroad to study at Louvain, Antwerp and Paris, returning to England in 1556 as rector of Easington and archdeacon of Durham. His outspokenness excited hostility, and he was brought before Tunstall, bishop of Durham, on a charge of heresy. Tunstall dismissed the case, and presented Gilpin with the rich living of Houghton-le-Spring, and when the accusation was renewed, he again protected him. Gilpin's enemies, however, obtained a royal warrant for his apprehension from Bonner, bishop of London, but his arrival in London was fortunately delayed by an accident in which he broke his leg, and he was freed from danger by the news of Queen Mary's death. He died at Houghton on May 4, 1583.

Gilpin steadily refused promotion. He held a great position in the North, and displayed a magnificent hospitality at Houghton to all classes of his parishioners, and treated them with great generosity in critical times. He built and endowed a grammar school, maintained a large number of poor children at his own charge, and helped the more promising pupils to enter the universities.

See Chr. Wordsworth, *Ecclesiastical Biography* (vol. iii., 4th ed.), which contains a contemporary sketch by G. Carleton, originally printed in Bates's *Vitae selectorum aliquot virorum.*

GIL POLO, GASPAR (?1530–1591), Spanish novelist and poet, was born at Valencia. He finds a place in the history of the novel as the author of La Diana enamorada, a continuation of Montemayor's Diana, and perhaps the most successful continuation ever written by another hand. One of the most agreeable of Spanish pastorals, it was imitated by Cervantes in the Canto de Caliope, and was translated into English, French, German and Latin. The English version of Bartholomew Young, published in 1598 but current in manuscript 1j years earlier, is said to have suggested the Felismena episode in the Two Gentlemen of Verona; the Latin version of Caspar Barth, entitled *Erotodidascalus* (Hanover, 1625), is a performance of uncommon merit as well as a bibliographical curiosity.

GILSONITE, an asphaltite found in eastern Utah and western Colorado mainly in the Uinta Basin (whence its alternative names, Uintahite or Uintaite), where it occurs in vertical veins up to 18ft. in thickness which can be traced for several miles. It is black in colour with conchoidal fracture and lustrous surface, and was so named after S. H. Gilson of Salt Lake City. On heating it softens and then fuses completely; it dissolves freely in carbon disulphide, and is largely used in the manufacture of paints and varnishes. The output from the Uinta Basin region is about 20,000 tons annually.

GILYAKS, a Palaeo-Asiatic people originally widespread throughout the Lower Amur and the north of Sakhalin. The clan forms a society based on common rights and marital duties. The men in one class, A, had to take wives from another class, B. The women in class A had to marry men—not from B but from a third class, C. Thus brother and sister mated into different clans. The classificatory system of relationship is developed on these lines: Common fire, community in the bear rites, common enemies, community in bloodmoney and common tabus bind the clans together. Shamanism and bear-worship existed. Death was due to evil spirits and the corpse was cremated, except in certain special cases.

See M. Czplicka, *Aboriginal Siberia* (1914).

GIMA'A: see ARABS.

GIMBAL, a mechanical device for hanging some object so that it should keep a horizontal and constant position, while the body from which it is suspended is in free motion, so that the motion of the supporting body is not communicated to it. It is thus used particularly for the suspension of compasses or chronometers and lamps at sea, and usually consists of a ring freely moving on an axis, within which the object swings on an axis at right angles to the ring.

The word is derived from the 0. Fr. *gemel,* a term for a ring formed of two hoops linked together and capable of separation, used in the 16th and 17th centuries as betrothal and keepsake rings. They sometimes were made of three or more hoops linked together.

GIMLET, a tool used for boring small holes. It is made of steel, with a shaft having a hollow side, and a screw at the end for boring the wood; the handle of wood is fixed transversely to the shaft. A gimlet is always a small tool. **A** similar tool of large size is called an "auger" (see TOOL).

GIMLI, in Scandinavian mythology, the great hall of heaven whither the righteous will go to spend eternity.

GIMP or **GYMP.** (1) Probably a nasal form of the Fr. guipure, from *guiper,* to cover or "whip" a cord over with silk, a stiff trimming made of silk or cotton woven around a firm cord, often further ornamented by a metal cord running through it. It is also sometimes covered with bugles, beads or other glistening ornaments. The trimming employed by upholsterers to edge curtains, draperies, the seats of chairs, etc., is also called gimp; and in lace work it is the firmer or coarser thread which outlines the pattern and strengthens the material. (2) **A** shortened form of gimple (the O.E. wimple), the kerchief worn by a nun around her throat, sometimes also applied to a nun's stomacher.

GIN. A potable spirituous liquor which derives its characteristic flavour principally from the juniper berry. The term is an abbreviation of "genevan—a corruption of "genièvre" or "junever," the French and Dutch equivalents respectively for juniper. For many centuries juniper has been used in the preparation of alcoholic beverages and in all probability the practice at first arose from a desire to mask, by means of this or some other flavouring material, the nauseous taste of the crude spirit obtained by the earlier methods of distillation. The principal varieties

are the English and American, to which the term "gin" or "dry gin" is usually applied, and the Dutch, which, in addition to being known as "geneva," is sometimes referred to as "Schnapps" or "Hollands."

British gin is prepared from a spirit obtained by distilling a fermented mash consisting usually of 75% of maize, 15% of malt and 10% of rye. In order to deprive it of the characteristic flavour of grain, the spirit is redistilled in the presence of the flavouring matter—chiefly juniper and coriander—this process being repeated several times, thus producing the "dry gin" of commerce.

In the United States spirits are prepared from a mash consisting of about 85% corn or maize, 12% malt and 3% rye. There are two general methods of distillation of spirits from this mash, which may be classified as continuous and batch type. In the continuous method, the mash is fed into the beer column and run through a series of rectifying columns in such a manner that all the higher and lower boiling point alcohols are removed, and completely refined spirits. free from any odours or taste of grain, are continuously withdrawn from the final rectification column. These refined spirits are then distilled in the presence of juniper berries, coriander seeds and other ingredients without the necessity of redistillation at this point in the process. In the batch method distillation, the process is discontinuous and several redistillations are usually necessary in order to produce a final highly refined neutral spirit. From this point on the production of gin is the same as the preceding method. In either case it should be noted that in the United States the spirits are first thoroughly refined before adding the flavouring ingredients, whereas in the British method this is not usually done until after their addition.

Many British distilleries, however, operate according to the American method.

Sweetened gin, usually consumed as a cordial, is obtained by adding sugar syrup to the "dry" variety. In the preparation of the syrup refined sugar is dissolved in its own weight of water, and the solution is added in the proportion of about 6gal. of syrup to 100gal. of gin. Compound gin is a product obtained by mixing neutral spirits with distilled gin or gin essence, or other flavouring materials customarily used in the production of gin. In this case there is no redistillation of the flavouring ingredients with neutral spirits but only a mixing operation. This type of gin is practically negligible in the United States.

In preparing the Dutch product one measure of malted barley is mixed with two measures of ground rye. Each hundredweight of the mixed meal is then mashed with about 24gal of water at a moderately high temperature Cold water is then added in sufficient quantity to reduce the specific gravity of the wort to about 1·035, yeast being then added to ferment it. After two or three days the fermented wort is distilled and juniper berries and other flavouring materials added to the resultant distillate—known as low wines—the mixture being again distilled To obtain a product of high quality the spirit is sometimes redistilled more than once. Some manufacturers of geneva purchase pot-still spirit, specially prepared for the purpose at Schiedain and known as "moutwyn" or "maltwine." The spirit is then treated in a manner similar to that adopted in the manufacture of British gin.

In general, in the Dutch product the distiller endeavours to retain a certain portion of the taste and odour of the grain, and also some of the higher and lower boiling point alcohols, sometimes known as heads and tails. The American and British distillers on the other hand try to eliminate these as far as possible, the best gin being considered that in which the spirits are the most refined. (F.G.H.T.; J.W.L.)

GINDELY, ANTON (1829–1892), Austrian historian, was born at Prague on Sept. 3, 1829. He studied at Prague and at Olmütz, and became professor of history at the university of Prague and archivist for Bohemia in 1862. He died at Prague on Oct. 24, 1892. Gindely's chief work is his *Geschichte des dreissigjährigen Krieges* (Prague, 1869–80; Eng. trans. New York, 1884); and his historical work is mainly concerned with the period of the Thirty Years' War. Among his numerous works are: *Geschichte der böhmischen Brüder* (Prague, 1857–58); *Rudolf II. und seine Zeit* (1862–68), and a criticism of Wallenstein, *Waldstein während seines ersten Generalats* (2 vols. 1886). He wrote a history of Bethlen Gabor in Hungarian, and edited the *Monumenta historiae Bohemica.* Gindely's posthumous work, *Geschichte der Gegenrefornzation in Bohmen,* was edited by T. Tupetz (1894).

GINER DE LOS RIOS, FRANCISCO (1840–1915), Spanish philosopher and jurist. was born in Ronda (Andalusia) on Oct. 10, 1840. He graduated in Granada, and in 1867 went to the University of Madrid as a professor of jurisprudence and there came under the influence of Professor Sanz del Rio, Krause's famous disciple. In accordance with his belief that philosophy should have a concrete influence on practical life, he devoted himself to the educational question. Twice Giner resigned his chair, together with several of his colleagues, in a stand for liberty of thought in the university against a reactionary Government, and was twice reinstated He helped to found the Institucion Libre de Enseñanza, an educational institution which did much to improve teaching methods in Spain, by the application of philosophical thought to the problems of ediication. His greatest influence was personal and direct, for he was a born teacher, a man of refined sensibility, pure in his life as in his ideals

Giner published several volumes of essays—literary, educational, philosophical and religious—as well as *Lecciones Sumarias de Psicologia (1871)*; *Psicologia; Idea del Derecho,* with Alfredo Calderon, trans. from the German of Röder (1885); *Resumen de Filosofia del Derecho,* with Alfredo Calderon *(1898)*; and other works. A complete edition of his numerous works was undertaken a vear after his death.

See S. de Madariaga, *The Genius of Spain* (1923).

GINGEE, a rock fortress of southern India, in the South Arcot district of Madras. It consists of three hills, connected by walls enclosing an area of 7 sq m. The origin of the fortress is shrouded in legend. When occupied by the Mahrattas at the end of the 17th century, it withstood a siege of eight years against the armies of Aurangzeb. In 1750 it was captured by the French. who held it with a strong force for eleven years It surrendered to the English in 1761.

GINGER, the rhizome or underground stem of *Zingiber officinale* (family Zingiberaceae), a perennial reed-like plant growing from 3 to 4ft. high. The flowers and leaves are borne on separate stems, those of the former being shorter than those of the latter and averaging from 6 to 12in. The flowers themselves are borne at the apex of the stems in dense ovate-oblong cone-like spikes from 2 to 3in. long, composed of obtuse strongly-imbricated bracts with membranous margins, each bract enclosing a single small sessile flower. The leaves are alternate and arranged in two rows, bright green, smooth, tapering at both ends, with very short stalks and long sheaths which stand away from the stem and end in two small rounded auricles. The plant rarely flowers and the fruit is unknown. Though not found wild, it is considered with good reason to be a native of the warmer parts of Asia, over which it has been cultivated from an early period and the rhizome imported into England. From Asia the plant has spread into the West Indies, South America, western tropical Africa, and Australia.

GINGER, THE UNDERGROUND STEM OF THE PLANT ZINGIBER OFFICINALE, WHICH HAS BEEN USED AS A SPICE FROM EARLY TIMES

The use of ginger as a spice has been known from very early times; it was supposed by the Greeks and Romans to be a product of southern Arabia, and was received by them by way of the Red Sea; in India it has also been known from a very remote period.

Ginger is known in commerce in two distinct forms, coated and uncoated ginger, *i.e.*, having or wanting the epidermis. For the first, the pieces, called "races" or "hands," from their irregular palmate form, are washed and simply dried in the sun. In this form ginger presents a brown, more or less irregularly wrinkled or striated surface, and when broken shows a dark brownish fracture, hard, and sometimes horny and resinous. To produce uncoated ginger the rhizomes are washed, scraped and sun-dried, and are often subjected to bleaching, either from the fumes of burning sulphur or by immersion for a short time in a solution of chlorinated lime. The whitewashed appearance that much of the ginger has, as seen in the shops, is due to the fact of its being washed in whiting and water, or even coated with sulphate of lime. Uncoated ginger, as seen in trade, varies from single joints an inch or less in length to flattish irregularly branched pieces of several joints, the "races" or "hands," and from 3 to 4in. long; each branch has a depression at its summit showing the former attachment of a leafy stem. The colour, when not whitewashed, is a pale buff; it is somewhat rough or fibrous, breaking with a short mealy fracture, and presenting on the surfaces of the broken parts numerous short bristly fibres.

The principal constituents of ginger are starch, volatile oil (to which the characteristic odour of the spice is due) and resin (to which is attributed its pungency). Its chief use is as a condiment or spice, but as an aromatic and stomachic medicine it is also used internally. The rhizomes, collected in a young green state, washed, scraped and preserved in syrup, form a delicious preserve, which is largely exported both from the West Indies and from China. Cut up into pieces like lozenges and preserved in sugar, ginger also forms an agreeable sweetmeat.

GINGER ALE. A sweetened, carbonated, non-excisable beverage, the predominating flavour and pleasant warmth of which are derived mainly from the rhizome *Zingiber officinale*. The aeration of the beverage may be due to fermentation or to artificial saturation with carbon dioxide gas. The Jamaican variety of ginger rhizome yields the finest-flavoured beverages, the flavour and pungency of the rhizome being dependent upon the essential oil and oleo-resin, which are its active principles. Other flavouring materials frequently enter into the composition of ginger ale, for example cloves, cinnamon, lemon essence, malt, etc.; also, additions are occasionally made of a foam-producing substance and pungent materials, such as capsicum, to increase the sharpness and pungency of the beverage. In 1922 the joint committee of definitions and standards of the United States department of agriculture defined ginger ale as the carbonated beverage prepared from ginger ale flavour, sugar, syrup, harmless organic acid, potable water and caramel colour. Ginger ale flavour, or ginger ale concentrate, was defined as the flavouring product in which ginger is the essential constituent, with or without the addition of other aromatic and pungent ingredients, citrus oils and fruit juices.

In preparing an artificially carbonated ginger ale, a syrup is first made, this being compounded from water, sugar, ginger ale flavour or extract, citric or tartaric acid, caramel colour and foam essence. Such a syrup is employed in making the carbonated beverage in the manner which is described under AERATED WATERS.

GINGER BEER. A fermented, non-excisable beverage brewed from a mixture of ginger, other spices and bitter vegetable substances. Sometimes, however, the name ginger beer is applied to artificially carbonated liquor which is flavoured with compounded ginger beer flavour or extract. The principal differences between ginger ale and ginger beer lie in the rather higher gravity and greater proportion of extractive matter of ginger beer and also in the fact that it is more usual to employ bitters of the nature of hops or gentian in preparing ginger beer than in ginger ale. Capsicum extract, or the oleoresin capsicine, is frequently employed in the compounding of ginger beverages of this type to increase the sharpness of the beverage without greatly increasing the cloudiness of the finished product. Also, a foam-producing extract is frequently added to the syrup when the liquor is prepared by artificial carbonation.

The production of ginger beer by fermentation is carried out by first making an aqueous infusion of a mixture of vegetable products among which ginger predominates. The following is a suitable mixture: Bruised Jamaica ginger 6 parts, liquorice extract 2 parts, hops 3 parts, cloves 3 parts, gentian $\frac{1}{4}$ part. Five parts of such a mixture are boiled in 200 parts of water for about 20 to 30 min.; the extract is strained and sweetened with 6 to 7 parts of sugar. Caramel colour is added as desired, the extract cooled to about 70° and, after adding 1 fl. oz. of brewer's yeast, allowed to ferment for 24 hours. Citric acid is then added to the liquor according to the taste of the manufacturer and the beverage bottled after standing for a few days to permit the mucilaginous matter to settle out. In some instances the beverage is given a fuller tone of flavour by the addition of malt essence. Ginger beverages are exceedingly popular in countries possessing temperate climates, a tremendous increase in consumption having followed the introduction of prohibition in the United States, while in Great Britain the sale of ginger drinks is one of the principal sections of the trade in non-excisable beverages *(see* AERATED WATERS).

GINGHAM, cotton or linen cloth, woven of dyed or white yarns either in a single colour or different colours, and in stripes, checks or plaids. It is made in Lancashire and in Glasgow, and also to a large extent in the United States. Imitations of it are obtained by calico-printing. It is used for dresses, etc.

GINGUENE, PIERRE LOUIS (1748–1815), French author, was born at Rennes, in Brittany. He was educated at a Jesuit college in his native town, and came to Paris in 1772. He wrote criticisms for the *Mercure de France,* and composed a comic opera, *Pomponin* (1777). The *Satire des satires* (1778) and the *Confession de Zulmé* (1779) followed. His defence of Piccinni against the partisans of Gluck made him still more widely known. He welcomed the Revolution, and joined Giuseppe Cerutri, the author of the *Mémoire pour le peuple français* (1788), and others in producing the *Feuille villageoise,* a weekly paper addressed to the villages of France. Imprisoned during the Terror, he escaped death by the downfall of Robespierre. He assisted, as director-general of the "commission exécutive de l'instruction publique," in reorganizing the system of public instruction, and was an original member of the Institute of France. In 1797 he was for a few months minister plenipotentiary to the king of Sardinia. He was appointed a member of the tribunate, but Napoleon had him expelled at the first "purge," and Ginguené returned to his literary pursuits. He was one of the coinmission charged to continue the *Histoire litte'raire de la France.* Ginguené's most important work is the *Histoire litte'raire d'Italie* (14 vols., 1811–35), unfinished at the time of his death. The last five volumes were written by Francesco Salfi and revised by Pierre Daunou.

See D. J. Garat, *Notice sur la vie et les ouvrages de P. L. Ginguené,* prefixed to *a* catalogue of his library (1817).

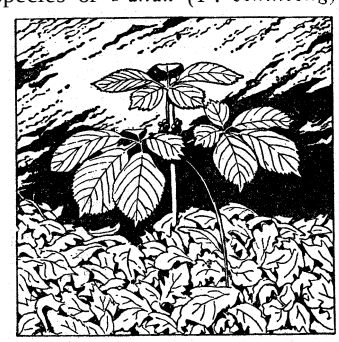
GINKEL, GODART VAN (1630–1703), 1st earl of Athlone, Dutch general in the service of England, was born at Utrecht in 1630, followed William, prince of Orange to England in 1688, and entered the English service. He distinguished himself in the suppression of a mutiny of a Scottish regiment, and in 1691 was entrusted with the sole command of the forces in Ireland. On June 30 he carried Athlone by storm, and on July 12 he defeated, near Aughrim, with terrible slaughter, a great number of the Irish, who were disorganized by the death of their commander, the French general, Saint-Ruth. Galway next capitulated, and Ginkel followed up this victory by a series of bold and successful manoeuvres by which he captured Limerick, the Irish cavalry camp, and the fort on Thomond bridge. The signing (Oct. 3, 1691) of a capitulation at Limerick completed his conquest or pacification of Ireland. For his services he received the formal thanks of the House of Commons, the earldom of Athlone, and the baronetcy of Aughrim. He continued in the English service and in 1702 commanded the Dutch contingent under Marlborough. He died at Utrecht on Feb. 11, 1703, and was succeeded by his son, the 2nd earl (1668–1719). On the death of the 9th earl without issue in 1844, the title became extinct.

GINKGO or **MAIDENHAIR TREE** *(Ginkgo biloba)*, a remarkable tree grown since ancient times about temples in China where it is considered a sacred plant. Although reported as native in western China, it is not positively known to occur in a truly wild state. It is a smooth, sparingly branched tree, sometimes 120 ft. high, with deciduous fan shaped leaves, 2–4 in. broad and nearly as long, which in form, veining and aspect resemble those of the maidenhair fern. Botanically, the closest allies of the ginkgo are the cycads. Like them, it is dioecious. As the sole survivor of a numerous group of plants with a very long geological ancestry the ginkgo may be legitimately regarded as a "living fossil." It has existed essentially unchanged for millions of years, or probably for a longer period than any other living tree, tracing back directly to the fossil Cordaitales of the Palaeozoic. Fossil species occur in the Triassic, Jurassic and Tertiary formations in the British Isles, and forms with leaves very similar to those of the living ginkgo are abundant in Triassic and Jurassic rocks of the Pacific coast of North America, especially in Oregon and Alaska. The ginkgo is cultivated as an ornamental tree in temperate countries, growing without protection in many parts of Europe and also in North America as far north as the Great Lakes. (For its structural peculiarities *see* GYMNOSPERMS: *Ginkgoales, Cycadales.)*

GINNING: *see* COTTON AND *THE* COTTON INDUSTRY.

GINSBURG, CHRISTIAN DAVID (1831–1914), Hebrew scholar, was born on Dec. 25, 1831, at Warsaw. Shortly after conversion in 1846, he came to England, where he published a translation of the Song of Songs, with a commentary (1857), a translation of Ecclesiastes (1861) and treatises on the Karaites (1862), on the Essenes (1864) and on the Kabbala (1865). From the appearance in 1867 of Jacob ben Chajim's Introduction to the Rabbinic Bible, Hebrew and English, with notices, and the Massoreth Ha-Massoreth of Elias Levita, in Hebrew, with translation and commentary, Dr. Ginsburg ranked as an eminent Hebrew scholar. In 1870 he was appointed to the committee for the revision of the English version of the Old Testament. His lifework culminated in the publication of the Massorah (1880–86), and the Masoretico-critical edition of the Hebrew Bible (1894) and the elaborate introduction (1897). His later works include: *Facsimiles of Manuscripts of the Hebrew Bible* (1897–98) and *The Text of the Hebrew Bible in Abbreviations* (1903), in addition to a critical treatise "on the relationship of the so-called Codex Babylonicus of A.D. 916 to the Eastern Recension of the Hebrew Text" (1899). Ginsburg died on March 7, 1914.

GINSENG, the root of a species of *Panax (P. schinseng,* formerly known as *P. ginseng),* native of Manchuria and Korea, of the family Araliaceae, used in China as a medicine. Other roots are substituted for it, notably that of *Panax quinquefolium,* distinguished as American ginseng, and imported from the U.S. At one time the ginseng obtained from Manchuria was considered to be the finest quality, and in consequence became so scarce that an imperial edict was issued prohibiting its collection. That prepared in Korea is now the most esteemed variety. The root of the wild plant is preferred to that of cultivated ginseng, and the older the plant the better is the quality of the root considered to be. Great care is required in the preparation of the drug.



AMERICAN GINSENG. EXPORTED FROM THE UNITED STATES TO CHINA. WHERE THE ROOT IS USED AS MEDICINE

Ginseng of good quality generally occurs in hard, rather brittle, translucent pieces, about the size of the little finger, and varying in length from 2in. to 4in. The taste is mucilaginous, sweetish, and slightly bitter and aromatic. The root is frequently forked, and it is probably owing to this circumstance that medicinal properties were in the first place attributed to it, its resemblance to the body of a man being supposed to indicate that it could restore virile power to the aged and impotent. In price it varies from $6 to $12 to the enormous sum of $300 or $400 an ounce.

The action of the drug appears to be entirely psychic, and comparable to that of the mandrake of the Hebrews. There is no evidence that it possesses any pharmacological or therapeutic properties.

GIOBERTI, VINCENZO (1801–1852), Italian philosopher and politician, was born at Turin where he was educated. He was ordained priest in 1825. Partly under the influence of Mazzini, the freedom of Italy became his ruling motive in life,—its emancipation, not only from foreign masters, but from modes of thought alien to its genius, being linked in his mind with papal supremacy, though in an intellectual rather than political way. On the accession of Charles Albert he received a court chaplaincy, but he resigned this office in 1833. and shortly afterwards was arrested on suspicion of political intrigue. Imprisoned and banished without a trial, Gioberti went to Paris, and a year later, to Brussels, where he remained till 1845, teaching philosophy, and writing philosophical works. An amnesty having been declared by Charles Albert in 1846, Gioberti returned to Italy in 1847 and was enthusiastically received. He was soon elected president of the Chamber of Deputies. At the close of the same year a new ministry was formed, headed by Gioberti; but with the accession of Victor Emmanuel in March 1849, his active life came to an end. For a short time he held a seat in the cabinet, though without a portfolio; but an irreconcilable disagreement soon followed, and he was sent on a mission to Paris where he remained until his death on Oct. 26, 1852.

Gioberti's writings are more important than his political career. Writing against the speculations of Rosmini-Serbati, he reconstructs, as he declares, ontology, and begins with the assertion that the *Ens* creates *ex nihilo* the existent, which is the universal idea in God become finite and individual. God is the only being *(Ens);* all other things are merely existences. God is also the origin of all human knowledge, and we apprehend Him by intuition. A knowledge of both being and existences, and of their mutual relations, is necessary as the beginning of philosophy. Gioberti is in some respects a Platonist. He identifies religion with civilization, and in his *Del primato morale e civile degli Italiani* (1843) concludes that the church is the axis on which the well-being of human life revolves. In it he pictures the supremacy of Italy, brought about by the restoration of the papacy as a moral dominion, founded on religion and public opinion. In his later works, the *Rinnovamento* and the *Protologia,* he is thought by some to have shifted his ground under the influence of events. In his first publication La *Teorica del sovran-naturale* (1838) he supported the reality of revelation and the future life. In the *Introduzione allo studio della filosofia* (3 vols., 1839–40) he states his reasons for requiring a new method and new terminology, and brings out the doctrine that religion is the direct expression of the *idea* in this life, and is one with true civilization in history. Civilization is a conditioned mediate tendency to perfection, to which religion is the final completion; it is the end of the second cycle expressed by the second formula, the *Ens* redeems existences, the many return to the one. In 1846 appeared his essays on the more popular subjects, *Del bello* and *Del buono. Del primato morale e civile degli Italiani* and its *Prolegomeni* and his attack on the Jesuits, *Il Gesuita moderno* (1847), no doubt hastened the transfer of rule from clerical to civil hands. The hope that the loss of the papal temporal power would lead to a revival of religion expressed in the *Rinnovantento civile d'Italia* (1851), together with the pantheistic ontologism of his philosophy led to Gioberti's writings being placed on the *Index.* They were edited by G. Massari (Turin, 1856–61).

GIOCONDO, FRA GIOVANNI (*c.* 1433–1515), Italian antiquary and architect, was born at Verona, and died on July 1, 1515, at Rome. On becoming a Franciscan he went to study in Rome, where he collected over 2,000 inscriptions, which he presented to Lorenzo de' Medici. In 1499 Louis XII. commissioned him to build the bridge of Notre Dame in Paris; in 1509 he fortified Treviso, and in 1514 assisted Raphael at St. Peter's. The design of the Palazzo del Consiglio at Verona is generally attributed to him.

GIOIOSA-IONICA, a town of Calabria, Italy, province of Reggio di Calabria. It is 65 mi. northeast by rail from the town of Reggio, and 38 mi. direct, 492 ft. above sea level. Pop. (1936) town, 4,796; commune, 14,518. Near the station, which is on the east coast of Calabria 3 mi. below the town to the southeast, are the remains of a small theatre belonging to the Roman period but the name of the city to which it belonged is unknown. Remains of baths and other buildings have also been found.

GIOJA, MELCHIORRE (1767–1829), Italian writer on philosophy and political economy, was born at Piacenza, on Sept. 20, 1767. Renouncing his orders in 1796, he went to Milan, and on the arrival of Napoleon in Italy, advocated a republic under the dominion of the French in a pamphlet I *Tedeschi*, i *Francesi, ed i Russi in Lombardia*. Under the Cisalpine Republic he became historiographer and director of statistics. He was several times imprisoned, in 1820 on a charge of being implicated in a conspiracy with the Carbonari. After the fall of Napoleon he retired into private life, and died at Milan on Jan. 2, 1829.

Besides the *Nuovo Prospetto delle scienze economiche* (1815–17), a summary of what had already been written on economics, administration and finance, Gioja's more important productions which reflect his passion for statistics and his inclination towards the English economists, are *Del merito e delle ricompense* (1818), *Filosofia della statistica* (2 vols., 1826) and contributions to the *Annali Universali di Statistica* founded by him in 1824. His complete works appeared at Lugano (1832–49).

See monographs by G. D. Romagnosi (1829) and F. Falco (1866), and G. Pecchio, *Storia dell' economia pubblica in Italia* (1829).

GIOLITTI, GIOVANNI (1842–1928), Italian statesman, was born at Mondovi, Province of Cuneo, on Oct. 27, 1842, and educated at the Lycée and at Turin University, where he graduated in law in 1861. After working in an advocate's office for some years, he was appointed king's procurator in Turin, and then held appointments in the ministry of justice and the ministry of finance. In 1882 he was appointed councillor of State and elected deputy for Cuneo. As deputy he took part in the attack on Magliani, minister of finance, which led to the fall of the Depretis cabinet. On March 9, 1889 Giolitti was appointed finance minister in the Crispi cabinet, but resigned at the end of 1890. On the fall of the Rudini cabinet in May 1892, Giolitti succeeded to the premiership, but his ministry fell after 18 months in disastrous circumstances. The building crisis and the commercial rupture with France had impaired the situation of the state banks, and one, the Banca Romana, had been further undermined by maladministration. A bank law, passed by Giolitti failed to effect an improvement. The senate refused to confirm Giolitti's conferment of senatorial rank on Tanlongo, director general of the Banca Romana, and an interpellation in parliament on the position of the bank led to Tanlongo's arrest and prosecution. A parliamentary commission of enquiry, appointed to investigate the condition of the state banks acquitted Giolitti of personal dishonesty.

Giolitti left the country for a short time and kept in the background for several years. He gradually regained much of his former influence, however, since he outlined a series of reforms in the social and agrarian field. He became minister for the interior in the Zanardelli cabinet, succeeding Zanardelli, who resigned on account of ill-health, in November 1903. During his tenure of office, he lost the support of the Socialists by the strong measures he was forced to take to quell serious disorders in various parts of the country. In March 1905, feeling himself no longer secure, he resigned, indicating Fortis as his successor.

When Sonnino became premier in Feb. 1906, Giolitti did not openly oppose him, but his followers did, and Sonnino was defeated in May, Giolitti becoming prime minister again. For three years he remained in power, and by clever management of the elections, was returned by a strong majority in 1909. Opposition against him in parliament grew rapidly, however, led by Sonnino, and his cabinet fell in Dec. 1909, the chamber rejecting a bill of fiscal reforms which included a graduated income-tax. He played a leading part in Opposition during the succeeding ministries of Sonnino and Luzzatti, and became premier for the fourth time in March 1911. During this period in office, he introduced a new franchise law (Oct. 26–Nov. 2, 1913) which practically amounted to universal suffrage, raising the electorate from 3,000,000 to 8,000,000. The chief event of Giolitti's fourth cabinet was the Libyan war; adversary as he had always been of colonial adventures, he decided that the conquest of Libya was necessary in order to preserve Italy's prestige in a Europe where Austria-Hungary had annexed Bosnia-Herzegovina two years before and where France was slowly conquering Morocco. When the Turks, defeated, asked for peace, which was concluded at Ouchy, Switzerland, Giolitti extended the electorate, saying that Italians who die at war must have a right to vote. In 1913 the elections took place and gave him a great majority, but with an increase of Socialists. The opposition changed from the extreme Right to the extreme Left. Giolitti, discouraged by dissension among his supporters, and feeling opposition to his rule increasing not only in parliament, but in the country as a whole, seized the opportunity of a hostile vote by the Radical group to resign on March 10, 1914. He was succeeded by Salandra.

When World War I broke out his attitude was in favour of absolute neutrality, and on the eve of Italian intervention he attempted to upset the Salandra cabinet by his personal influence over the parliamentary majority. He was frustrated by formidable popular demonstrations in favour of participation on the side of the Entente; he expressed. however, his views in a famous letter to C. Peano, later on minister of the treasury with him in 1920–21, in which he declared that even without going to war Italy might gain considerably. Giolitti believed that Italian resources were unequal to war, and that her unpreparedness would have serious consequences. But in the dark hour after Caporetto he appeared again in the chamber, and made an eloquent appeal to Italians to stand firm and united in face of disaster. After the war the disappointment over the peace settlement. the heavy burden of suffering and loss caused by the war, and the extreme socialistic policy of the Nitti cabinet brought about the return of Giolitti. On Oct. 12, 1919 he made the well-known election speech, the "Discorso di Dronero" outlining his future policy, and explaining his previous attitude, and on June 15, 1920 the fifth Giolitti cabinet was formed. He succeeded in forming a cabinet which comprised a number of non-Giolittians of all parties, but only a few of his own "old guard," so that he won the support of a considerable part of the chamber, although the Socialists and the Popolari (Catholics) rendered his hold somewhat precarious. His policy of inactivity during the occupation of the factories by the workmen organized by Socialist leaders in Sept. 1920 provoked the irritation not only of the manufacturers but among many of the middle classes. He appears greatly to have over-estimated the strength of the Socialists, and therefore gave them a free hand with the object of avoiding bloodshed, and also perhaps to prove to the workmen that they could not run industry without the capitalists and the technical experts. When he realized the strength of the national reaction, he allowed the fascists free rein to re-establish order and exercise many of the functions pertaining to the government, while he assumed an attitude of Olympic calm and posed as being *au-dessus de la mêlée*, so as to avoid cornpromising himself with any party.

In foreign affairs Giolitti succeeded in achieving a solution of the Adriatic problem, and with Count Sforza carried through the Treaty of Rapallo (q *v.).* He dissolved the chamber on April 7, 1921, and was confirmed in power by the elections on May 15. But he resigned with his cabinet at the end of June, being succeeded as premier by his war minister Bonomi whom he designated to the crown as his successor. Giolitti took no part in the subsequent events; on the eve of Mussolini's so-called "march on Rome" he thought that his duty was to go at once to the capital and oppose the adventure; but Prime Minister Facta persuaded him to remain in his lonely distant country place and went as far as to make him believe the falsehood that floods had destroyed the railways. When Mussolini made his first "elections" in 1924, Giolitti presented a list of his own in Piedmont, independent from the government, which, in the language of the time, meant opposition; but Giolitti's opposition became extreme only after Matteotti's murder; although he was 82 he spoke in the chamber with great firmness against the fascist regime. Giolitti's influence, in spite of his age, remained very strong in Piedmont until his last moments. He died in his country place in Piedmont on July 17, 1928. Before his death he had published *Memorie della mia vita* which have been translated in English under the title *Memoirs of My Life* (London).

For a synthetic judgment of Giolitti as a statesman, see Croce, *History of Contemporary Italy;* and for Giolitti's action in his last cabinet. *see* Sforza, *Makers* of *Modern Europe* (the chapter on Giolitti).

GIORDANI, PIETRO (1774–1848), Italian writer, was born on Jan. 1, 1774, at Piacenza, and died on Sept. 11, 1848, at Parma. He studied philosophy and law at his native town, and after an unsuccessful attempt to become a Benedictine, was made professor of literature at Bologna. He was secretary of the Academy at Bologna from 1808 to 1815, when his *Panegirico à Napoleon* resulted in the loss of his position. He afterwards travelled in various parts of Italy, became friendly with Manzoni and Canova, and wrote, in excellent Italian prose, numerous works on aesthetics and politics. These were edited by Gussali in 14 vols., 1S54–62.

See D. Giovanni, *P. Giordani* (Milan, 1882), and S. Fermi, *Bibliografia delle Lettere a stampa di P. Giordani* (Florence, 1923).

GIORDANO, LUCA (1632–1705), Italian painter, was born in Naples, son of the painter Antonio, who imparted to him the first rudiments of drawing. He was a pupil of Giuseppe Ribera. He acquired the nickname of Luca Fa-presto (Luke Work-fast), derived from the almost miraculous celerity with which from an early age he handled the brush. He copied nearly 20 times the "Battle of Constantine" by Giulio Romano, and with proportionate frequency several great works of Raphael and Michelangelo. His rapidity, which belonged as much to invention as to mere handiwork, and his versatility, which enabled him to imitate other painters deceptively, earned for him two other epithets, "Fulmine" (the Thunderbolt) and "The Proteus," of Painting. He visited all the main seats of the Italian school of art, and formed for himself a style combining in a certain measure the ornamental pomp of Paul Veronese and the contrasting compositions and large schemes of Pietro da Cortona. Returning to Naples, he practised his art with so much applause that Charles II. of Spain in 1692 invited him over to Madrid, where he remained eight years. Soon after the death of Charles in 1700 Giordano, gorged with wealth, returned to Naples. He spent large sums in acts of munificence, and was particularly liberal to his poorer brethren of the art. He again visited various parts of Italy, and died in Naples on Jan. 12, 1705, his last words being "O Napoli, sospiro mio" (O Naples, my heart's love!). One of his maxims was that the good painter is the one whom the public like, and that the public are attracted more by colour than by design.

Giordano left numerous oil pictures besides extensive fresco paintings. One of the most renowned works is "Christ expelling the Traders from the Temple," in the church of the Padri Girolamini, a colossal work, full of expressive lazzaroni; also the frescoes of S. Martino, and those in the Tesoro della Certosa, including the subject of "Moses and the Brazen Serpent"; and the cupola-paintings in the Church of S. Brigida, which contains the artist's own tomb. In Spain he executed a surprising number of works — continuing in the Escorial the series commenced by Cambiasi, and painting frescoes of the "Triumphs of the Church," the "Genealogy and Life of the Madonna," the stories of Moses, Gideon, David and Solomon, and the "Celebrated Women of Scripture," all works of large dimensions. His pupils, Aniello Rossi and Matteo Pacelli, assisted him in Spain. In Florence, near the end of his life, he painted the Cappella Corsini, the impressive ceiling decoration in the Palazzo Medici and other works. In youth he etched with considerable skill some of his own paintings, such as the "Slaughter of the Priests of Baal." He also painted much on the crystal borderings of looking-glasses, cabinets, etc., seen in many Italian palaces, and was, in this form of art, the master of Pietro Garofolo. His best pupil, in painting, was Paolo de Matteis. His influence on Spanish art was detrimental to the local traditions.

Bellori, in his *Vite de' pittori moderni,* is a leading authority regarding Luca Giordano. *See* also W. Rolfs, *Geschichte der Malerei Neapels* (1910).

GIORGIO, FRANCESCO (1439–1502), Italian engineer, architect, painter and sculptor, was born on Nov. 14, 1439, at Siena, and died there in 1502. He was engaged on constructive and decorative work in his native town from 1463 to 1478 when he was employed by the duke of Urbino as architect and military engineer. In 1490 he constructed the model for the dome of Milan cathedral, and five years later invented the mines used at the siege of Naples. Some of his pictures, which show the influence of Fra Filippo Lippi, are now in the Siena gallery.

His *Trattato di architettura eivile e militare* was edited by C. Saluzzo in 1841.

GIORGIONE (c. 1478–1510), Italian painter, was born at Castelfranco. In contemporary documents he is always called (according to the Venetian manner of pronunciation and spelling) Zorzi, Zorzo or Zorzon of Castelfranco. A tradition, having its origin in the 17th century, represented him as the natural son of some member of the great local family of the Barbarelli, by a peasant girl of the neighbouring village of Vedelago; consequently he is commonly referred to in histories and catalogues under the name of Giorgio Barbarelli or Barbarella. This tradition has, however, on close examination been proved baseless. On the other hand mention has been found in a contemporary document of an earlier Zorzon, a native of Vedelago, living in Castelfranco in 1460. Vasari, who wrote before the Barbarella legend had sprung up, says that Giorgione was of very humble origin. It seems probable that he was simply the son or grandson of the afore-mentioned Zorzon the elder and that the after-claim of the Barbarelli to kindred with him was a mere piece of family vanity.

Of the facts of his life we are almost as meagrely informed as of the circumstances of his birth. The little city, or large fortified village, for it is scarcely more, of Castelfranco in the Trevisan stands in the midst of a rich and broken plain at some distance from the last spurs of the Venetian Alps. From the natural surroundings of Giorgione's childhood was no doubt derived his ideal of pastoral scenery, the country of pleasant copses, glades, brooks and hills amid which his personages love to wander or recline with lute and pipe. How early in boyhood he went to Venice we do not know, but internal evidence supports the statement of Ridolfi that he served his apprenticeship there under Giovanni Bellini; and there he made his fame and had his home. That his gifts were early recognized we know from the facts, recorded in contemporary documents, that in 1500, he was chosen to paint portraits of the Doge Agostino Barberigo and the condottiere Consalvo Ferrante; that in 1504 he was commissioned to paint an altarpiece in memory of Matteo Costanzo in the cathedral of his native town, Castelfranco; that in 1507 he received at the order of the Council of Ten part payment for a picture (subject not mentioned) on which he was engaged for the hall of the audience in the ducal palace; and that in 1507–1508 he was employed, with other artists of his own generation, to decorate with frescoes the exterior of the newly rebuilt Fondaco dei Tedeschi or German merchants' hall at Venice, having already done similar work on the exterior of the Casa Soranzo, the Casa Grimani alli Servi and other Venetian palaces. In September or October 1510 he died of the plague then raging in the city. and within a few days, of his death we find the great art-patroness and amateur, Isabella d'Este, writing from Mantua and trying in

vain to secure for her collection a night-piece by his hand of which the fame had reached her.

All accounts agree in representing Giorgione as a personage of distinguished and romantic charm, a great lover, a great musician, made to enjoy in life and to express in art to the uttermost the delight, the splendour, the sensuous and imaginative grace and fulness, not untinged with poetic melancholy, of the Venetian existence of his time. They represent him further as having made in Venetian painting an advance analogous to that made in Tuscan painting by Leonardo more than 20 years before; that is as having released the art from the last shackles of archaic rigidity and placed it in possession of full freedom and the full mastery of its means. He also introduced a new range of subjects. His name and work have exercised, and continue to exercise, a spell on posterity. But to identify and define, among the relics of his age and school, precisely what that work is, and to distinguish it from the kindred work of other men whom his influence inspired, is a very difficult matter. There are inclusive critics who still claim for Giorgione nearly every painting of the time that at all resembles his manner, and there are exclusive critics who pare down to some ten or a dozen the list of extant pictures which they will admit to be actually his.

To name first those which are either certain or command the most general acceptance, placing them in something like an approximate and probable order of date. In the Uffizi at Florence are two companion pieces of the "Trial of Moses" and the "Judgment of Solomon," the latter the finer and better preserved of the two, which pass, no doubt justly, as typical works of Giorgione's youth, and exhibit, though not yet ripely, his special qualities of colour-richness and landscape romance, the peculiar facial types of his predilection, with the pure form of forehead, fine oval of cheek, and somewhat close-set eyes and eyebrows, and the intensity of that still and brooding sentiment with which, rather than with dramatic life and movement, he instinctively invests his figures. Probably the earliest of the portraits by common consent called his is the beautiful one of a young man at Berlin. His earliest devotional picture would seem to be the highly finished "Christ bearing his Cross" (the head and shoulders only, with a peculiarly serene cast of features) formerly at Vicenza and later removed to Boston. The composition of a lost early picture of the birth of Paris is preserved in an engraving of the "Teniers Gallery" series, and an old copy of part of the same picture is at Budapest. In the Giovanelli Palace at Venice is that fascinating and enigmatical mythology or allegory, known to the Anonimo Morelliano, who saw it in 1530 in the house of Gabriel Vendramin, simply as "the small landscape with the storm, the gypsy woman and the soldier"; the picture is conjecturally interpreted by modern authorities as illustrating a passage in Statius which describes the meeting of Adrastus with Hypsipyle when she was serving as nurse with the king of Nemea. The Castelfranco altarpiece, still, despite restorations, one of the most classically pure and radiantly impressive works of Renaissance painting, may be taken as closing the earlier phase of the young master's work (1504). It shows the Virgin loftily enthroned on a plain, sparely draped stone structure with St. Francis and a warrior saint (St. Liberale) standing in attitudes of great simplicity on either side of the foot of the throne, a high parapet behind them, and a beautiful landscape of the master's usual type seen above it. Nearly akin to this masterpiece, not in shape or composition but by the type of the Virgin and the very Bellinesque St. Francis, is the altarpiece of the Madonna with St. Francis and St. Roch at Madrid. Of the master's fully ripened time is the fine and again enigmatical picture at Vienna, described by contemporary witnesses as the "Three Philosophers," and now, on slender enough grounds, supposed to represent Evander showing Aeneas the site of Troy as narrated in the eighth Aeneid. The portrait of a knight of Malta in the Uffizi at Florence has more power and authority, if less sentiment, than the earlier portrait at Berlin, and may be taken to be of the master's middle time. Most enrirely central and typical of all Giorgione's extant works is the "Sleeping Venus" at Dresden, first recognized by Morelli, and now universally accepted, as being the same as the picture seen by the Anonimo and later by Ridolfi in the Casa Marcello at Venice. An exquisitely pure and severe rhythm of line and contour chastens the sensuous richness of the presentment: the sweep of white drapery on which the goddess lies, and of glowing landscape that fills the space behind her, most harmoniously frame her divinity. It is recorded that the master left this piece unfinished and that the landscape, with a Cupid which subsequent restoration has removed, were completed after his death by Titian. The picture is the prototype of Titian's own Venus at the Uffizi and of many more by other painters of the school; but none of them attained the quality of the first exemplar. The portrait of Antonio Brocardo at Budapest represents his fullest and most penetrating power in that branch of art. In his last years the purity and relative slenderness of form which mark his earlier female nudes, including the Dresden Venus, gave way to ideals of ampler mould, more nearly approaching those of Titian and his successors in Venetian art; as is proved by those last remaining fragments of the frescoes on the Grand Canal front of the Fondaco dei Tedeschi which were seen and engraved by Zanetti in 1760, but have now totally disappeared. Such change of ideal is apparent enough in the famous "Concert" or "Pastoral Symphony" of the Louvre, probably the latest, and certainly one of the most characteristic and harmoniously splendid, of Giorgione's creations that has come down to us, and has caused some critics too hastily to doubt its authenticity.

We pass now to pictures for which some affirm and others deny the right to bear Giorgione's name. A beautiful, virginally pensive Judith at St. Petersburg, passed as a work of Giorgione until it was recently given to Catena. Also in dispute are the two fine pictures commonly given to the master at the Pitti gallery in Florence, namely the "Three Ages" and the "Concert." Both are very Giorgionesque, the "Three Ages" leaning rather towards the early manner of Lorenzo Lotto, to whom by some critics it is actually given. The "Concert" is held on technical grounds by some of the best judges rather to bear the character of Titian at the moment when the inspiration of Giorgione was strongest on him, at least so far as concerns the extremely beautiful and expressive central figure of the monk playing on the clavichord with reverted head, a very incarnation of musical rapture and yearning—the other figures are too much injured to judge. A picture in the church of San Rocco at Venice representing "Christ bearing the Cross" is quoted by Ridolfi and copied with the name of Giorgione appended, by Van Dyck in that master's Chatsworth sketch-book; while Vasari gives it to Giorgione in his first and to Titian in his second edition. The jovial and splendid half-length portrait of Catherine Cornaro (or a stout lady much resembling her) with a bas-relief, in the collection of Sir Herbert Cook at Richmond, to the mind of the present writer at least, is more nearly akin to such undoubted early Titians as the "Man with the Glove" at the Louvre than to any authenticated work of Giorgione. At the same time it should be remembered that Giorgione is known to have actually enjoyed the patronage of Catherine Cornaro and to have painted her portrait. A very striking portrait of a young man at Temple Newsam stands nearer than any other extant example to the Brocardo portrait at Budapest. The full-face portrait of a woman in the Borghese gallery at Rome has the marks of the master's design and inspiration, but in its present sadly damaged condition can hardly be claimed for his handiwork. The head of a boy with a pipe at Hampton Court, a little over life size, has been enthusiastically claimed as Giorgione's workmanship, but is surely too slack and soft in handling to be anything more than an early copy of a lost work, analogous to, though better than, the similar copy at Vienna of a young man with an arrow, a subject he is known to have painted. The early records prove indeed that not a few such copies of Giorgione's more admired works were produced in his own time or shortly afterwards. Of important subject pictures belonging to the debatable borderland between Giorgione and his imitators are the large and interesting unfinished "Judgment of Solomon" at Kingston Lacy, which must certainly be the same that Ridolfi saw and attributed to him in the Casa Grimani at Venice, but has weaknesses of design and drawing sufficiently

baffling to criticism; and the "Woman taken in Adultery" in the public gallery at Glasgow, a picture truly Giorgionesque in richness of colour, but betraying in its awkward composition, the relative coarseness of its types and the insincere, mechanical animation of its movements, the hand of some lesser master of the school, almost certainly (by comparison with his existing engravings and woodcuts) that of Domenico Campagnola. It seems unnecessary to refer, in the present notice, to any of the numerous other and inferior works which have been claimed for Giorgione by a criticism unable to distinguish between a living voice and its echoes.

GIOTTINO or **GIOTTO DI MAESTRO DI STEFANO,** an early Florentine painter, whose name occurs in 1368 in the records of the guild. In 1369 he was called to Rome to assist in paintings in the Vatican. His father is sometimes identified with a pupil of Giotto, who attained some fame. To Giottino's early period are ascribed the frescoes in the lower church of Assisi representing the "Coronation of the Virgin" and two scenes of the legend of St. Nicholas. They differ somewhat in style from his later work—the frescoes in the chapel of the Bardi family in S. Croce in Florence representing the miracles of Pope S. Silvestro. These works are animated and firm in drawing, luminous in colour, with naturalism carried further than by Giotto. They are among the most important paintings of Giotto's school. From the evidence of style the fine Pietà from San Remigio, now in the Uffizi at Florence, has been ascribed to Giottino. Some confusion has arisen because Vasari identified Giottino with the painter Maso, who was active between 1320 and 1350, and to whom Ghiberti ascribed the frescoes of the S. Silvestro legend. The Giottino problem has been the subject of recent art critical research.

Crowe and Caralcaselle, *History of Painting in Ztaly,* edit. Douglas (1903); O. Siren, *Giottino* (1908), and *Giotto and some of his Followers* (1917); Guida, "Maso und Giotto di Maestro Stefano," *Monatsschrift fur Kunstwissenschaft,* vol. xii. (1914).

GIOTTO (GIOTTO DI BONDONE) (1267?–1337), Italian painter (not to be confused with Giotto di Buondone, a contemporary citizen and politician of Siena), was born at Vespignano in the Mugello, a few miles north of Florence, according to one account in 1276, and according to another, which from the few known circumstances of his life seems more likely to be correct, in 1266 or 1267. His father was a landowner at Colle in the commune of Vespignano, described in a contemporary document as *vir praeclarus,* but by biographers both early and late as a poor peasant; probably therefore a peasant proprietor of no large possessions but of reputable stock and descent. It is impossible to tell whether there is any truth in the legend of Giotto's boyhood which relates how he first showed his disposition for art, and attracted the attention of Cimabue, by being found drawing one of his father's sheep with a sharp stone on the face of a smooth stone or slate. With his father's consent, the story goes on, Cimabue carried off the boy to be his apprentice, and it was under Cimabue's tuition that Giotto took his first steps in the art of which he was afterwards to be the great emancipator and renovator. The place where these early steps can, according to tradition, be traced, is in the courses of frescoes which adorn the walls of the nave in the Upper Church of St. Francis at Assisi. These frescoes represent subjects of the Old and New Testament, and great labour, too probably futile, has been spent in trying to pick out those in which the youthful handiwork of Giotto can be discerned, as it is imagined, among that of Cimabue and his other pupils. But the truth is that the figure of Cimabue himself, in spite of Dante's testimony to his having been the foremost painter of Italy until Giotto arose, has under the search-light of modern criticism melted into almost mythical vagueness. His accepted position as Giotto's instructor and the pioneer of reform in his art has been attacked from several sides as a mere invention of Florentine writers for the glorification of their own city. One group of critics maintain that the real advance in Tuscan painting before Giotto was the work of the Sienese school and not of the Florentine. Another group contend that the best painting done in Italy down to the last decade of the 13th century was not done by Tuscan hands at all, but by Roman craftsmen trained in the inherited principles of Italo-Byzantine decoration in mosaic and fresco, and that from such Roman craftsmen alone could Giotto have learnt anything worth his learning. The debate thus opened is far from closed, and considering how scanty, ambiguous and often defaced are the materials existing for discussion, it is perhaps never likely to be closed. But there is no debate as to the general nature of the reform effected by the genius of Giotto himself. He was the great humanizer of painting; it is his glory to have been the first among his countrymen to breathe life into wall-pictures and altar-pieces, and to quicken the dead conventionalism of inherited practice with the fire of natural action and naturai feeling. Upon yet another point there is no question; and that is that the reform thus effected by Giotto in painting had been anticipated in the sister art of sculpture by nearly a whole generation. About the middle of the 13th century Nicola Pisano had renewed that art, first by strict imitation of classical models, and later by infusing into his work a fresh spirit of nature and humanity, perhaps partly caught from the Gothic schools of France. His son Giovanni had carried the same re-vitalising of sculpture a great deal further; and hence to some critics it would seem that the real inspirer and precursor of Giotto was Giovanni Pisano the sculptor, and not any painter or wall-decorator, whether of Florence, Siena or Rome.

In this division of opinion it is safer to regard the revival of painting in Giotto's hands simply as part of the general awakening of the time, and to remember that, as of all Italian communities, Florence was the keenest in every form of activity both intellectual and practical, so it was natural that a son of Florence should be the chief agent in such an awakening. And in considering his career the question of his possible participation in frescoes of the Upper Church at Assisi is best left out of account. Giotto's undisputed works at Assisi are the four celebrated allegorical compositions in honour of St. Francis in the vaulting of the Lower Church,—the "Marriage of St. Francis to Poverty," the "Allegory of Chastity," the "Allegory of Obedience" and the "Vision of St. Francis in Glory." These works are scarcely at all retouched, and relatively little dimmed by time; they are of a singular beauty, at once severe and tender, both in colour and design; the compositions, especially the first three, fitted with admirable art into the cramped spaces of the vaulting, the subjects, no doubt in the main dictated to the artist by his Franciscan employers, treated in no cold or mechanical spirit but with a full measure of vital humanity and original feeling. Had the career and influence of St. Francis had no other of their vast and far-reaching effects in the world than that of inspiring these noble works of art, they would still have been entitled to no small gratitude from mankind. Other works at Assisi which most modern critics, but not all, attribute to Giotto himself are three miracles of St. Francis and portions of a group of frescoes illustrating the history of Mary Magdalene, both in the Lower church; and again, in one of the transepts of the same Lower church, a series of ten frescoes of the Life of the Virgin and Christ, concluding with the Crucifixion. It is to be remarked as to this transept series that several of the frescoes present not only the same subjects, but with a certain degree of variation, the same compositions as are found in the master's great series executed in the Arena chapel at Padua and that the Assisi versions show a greater degree of technical accomplishment than the Paduan versions, with a more attractive charm and more abundance of accessory ornament.

In 1298 Giotto completed for Cardinal Stefaneschi for 2,200 gold ducats a mosaic of Christ saving St. Peter from the waves (the celebrated "Navicella"); this is still to be seen, but in a completely restored and transformed state, in the vestibule of

St. Peter's in Rome. For the same patron he executed an elaborate ciborium or altar-piece for the high altar of St. Peter's, for which he received 800 ducats. It represents on the principal face a colossal Christ enthroned with adoring angels beside him and a kneeling donor at his feet, and the martyrdoms of St. Peter and St. Paul on separate panels to right and left; on the reverse is St. Peter attended by St. George and other saints, receiving from the donor a model of his gift, with stately full-length figures of two apostles to right and t o to left, besides various accessory scenes and figures in the predellas and the margins.

Yet a third work by the master at Rome is a repainted fragment at the Lateran of a fresco of Pope Boniface VIII. proclaiming the jubilee of 1300. To about 1302 or 1303 would belong, if there is truth in it, the familiar story of Giotto's "O." Pope Benedict XI., the successor of Boniface VIII., sent, as the tale runs, a messenger to bring him proofs of the painter's powers. Giotto would give no other sample of his talent than an O drawn with a free sweep of the brush from the elbow; but the pope was satisfied and engaged him at a great salary to go and adorn with frescoes the papal residence at Avignon. Benedict. however, dying at this time (1305), nothing came of this commission.

At this point in Giotto's life we come to the greatest by far of his undestroyed and undisputed enterprises, and one which can with some certainty be dated. This is the series of frescoes with which he decorated the entire internal walls of the chapel built at Padua in honour of the Virgin of the Annunciation by a rich citizen of the town, Enrico Scrovegni, perhaps in order to atone for the sins of his father. a notorious usurer whom Dante places in the seventh circle of hell. The building is on the site of an ancient amphitheatre, and is therefore generally called the chapel of the Arena. Since it is recorded that Dante was Giotto's guest at Padua, and since we know that it was in 1306 that the poet came from Bologna to that city, we may conclude that to the same year, 1306, belongs the beginning of Giotto's great undertaking in the Arena chapel. The scheme includes a Saviour in Glory over the altar, a Last Judgment, full of various and impressive incident, occupying the whole of the entrance wall, with a series of subjects from the Old and New Testament and the apocryphal Life of Christ painted in three tiers on either side wall, and lowest of all a fourth tier with emblematic Virtues and Vices in monochrome; the Virtues being on the side of the chapel next the incidents of redemption in the entrance fresco of the Last Judgment, the Vices on the side next the incidents of perdition.

When the middle ages came to a close Giotto was laying the foundation upon which the progress of the Renaissance was afterwards securely based. In his day the knowledge possessed by painters of the human frame and its structure rested only upon general observation and not upon detailed or scientific study; while to facts other than those of humanity their observation had never been closely directed. Of linear perspective they possessed but elementary and empirical ideas, and their endeavours to express aerial perspective and deal with the problems of light and shade were rare and partial. As far as painting could possibly be carried under these conditions, it was carried by Giotto. In its choice of subjects, his art is entirely subservient to the religious spirit of the age in which he lived. Many of those truths of nature to which the painters of succeeding generations learned to give accurate and complete expression, Giotto was only able to express by way of imperfect symbol and suggestion. But among the elements of art over which he has control he maintains so just a balance that his work produces in the spectator less sense of imperfection than that of many later and more accomplished masters. In some particulars his painting has never been surpassed in mastery of expressive line and of harmonious decorative tint, in the massing and scattering of groups, and in the direct and vital gestures of the figures.

Of many other works said to have been executed by Giotto at Padua, all that remains consists of some scarce recognizable traces in the chapter-house of the great Franciscan church of St. Antonio. Besides Padua, he is said to have resided and left great works at Ferrara, Ravenna, Urbino, Rimini, Faenza, Lucca and other cities; in some of them paintings of his school are still shown, but nothing which can fairly be claimed to be by his hand. It is recorded also that he was much employed in Florence; but the vandalism of later generations has effaced nearly all that he did there. Among works whitewashed over by posterity were the frescoes with which he covered no less than five chapels in the church of Santa Croce. Two of these, the chapels of the Bardi and the Peruzzi families, were scraped in the early part of the 19th century, and very important remains were uncovered and immediately subjected to a process of restoration which robbed them in part of their authenticity. The frescoes of the Bardi chapel tell again the story of St. Francis, to which so much of his best power had already been devoted; those of the Peruzzi chapel deal with the lives of St. John the Baptist and St. John the Evangelist. Such scenes as the Funeral of St. Francis, the Dance of Herodias's Daughter, and the Resurrection of St. John the Evangelist, which have to some extent escaped the disfigurements of the restorer, are among acknowledged classics of the world's art. The only clues to the dates of any of these works are to be found in the facts that among the figures in the Bardi chapel occurs that of St. Louis of Toulouse, who was not canonized till 1317, therefore the painting must be subsequent to that year, and that the "Dance of Salome" must have been painted before 1331, when it was copied by the Lorenzetti at Siena. The only other extant works of Giotto at Florence are a fine "Crucifix," not undisputed, at San Marco, and the majestic altar-piece of the Madonna, in the Uffizi.

It appears that Giotto towards the end of his life had come under the notice of Duke Charles of Calabria, son of King Robert of Naples, during the visits of the duke to Florence which took place between 1326 and 1328, in which year he died. Soon afterwards Giotto must have gone to King Robert's court at Naples, where he was enrolled as an honoured guest and member of the household by a royal decree dated Jan. 20, 1330. Another document shows him to have been still at Naples two years later. Tradition says much about the friendship of the king for the painter and the freedom of speech and jest allowed him; much also of the works he carried out at Naples in the Castel Nuovo, the Castel dell' Uovo, and the church and convent of Sta. Chiara. Not a trace of these works remains. According to Vasari he illustrated by order of King Robert St. John's Apocalypse, of which various copies are still extant in churches in southern Italy. The original version was discovered in the panels in possession of Count Erbach of Fiirstenau.

Meantime Giotto had been advancing, not only in years and worldly fame, but in prosperity. He was married young, and had, so far as is recorded, three sons, Francesco, Niccola and Donato, and three daughters, Bice, Caterina and Lucia. He had added by successive purchases to the plot of land inherited from his father at Vespignano. His fellow-citizens of all occupations and degrees delighted to honour him. And now, in his 68th year (if we accept 1266/7 as the correct date of birth), on his return from Naples, he received the final and official testimony to the esteem in which he was held at Florence. By a solemn decree of the *Priori* on April 12, 1334, he was appointed master of the works of the cathedral of Sta. Reparata (later and better known as Sta. Maria del Fiore) and official architect of the city walls and the towns within her territory. What training as a practical architect his earlier career had afforded him we do not know, but his interest in the art from the beginning is made clear by the carefully studied architectural backgrounds of many of his frescoes. Dying on Jan. 8, 1337 (old style 1336), Giotto only enjoyed his new dignities for two years. But in the course of them he had found time not only to make an excursion to Milan, on the invitation of Azzo Visconti and with the sanction of his own government, but to plan two great architectural works at Florence and superintend the beginning of their execution, namely the west front of the cathedral and its detached campanile or bell-tower. The unfinished enrichments of the cathedral front were stripped away in a later age. The foundation-stone of the Campanile was laid with solemn ceremony on July 18, 1334. Its lower courses seem to have been completed from Giotto's design, and the first course of its sculptured ornaments (the famous series of primitive Arts and Industries) actually by his own hand, before his death. It

is not clear what modifications of his design were made by Andrea Pisano, who was appointed to succeed him, or again by Francesco Talenti, to whom the work was next entrusted; but the incomparable structure as we now see it stands as a fitting monument to the genius who first conceived it.

The art of painting, as re-created by Giotto, was carried on throughout Italy by his pupils and successors for nearly a hundred years, until a new impulse was given to art by the combined influences of naturalism and classicism in the hands of men like Donatello and Masaccio Most of the anecdotes related of the master are probably inaccurate in detail, but the general character which tradition has agreed in giving him can never be assailed. He was from the first a kind of popular hero. He is celebrated by the poet Petrarch and by the historian Villani. He is made the subject of tales and anecdotes by Boccaccio and by Franco Sacchetti. From these notices, as well as from Vasari, we gain a distinct picture of the man, as a master craftsman, to whose strong combining and inventing powers nothing came amiss; conscious of his own deserts, never at a loss either in the things of art or in the things of life, and equally ready and efficient whether he has to design the scheme of some great spiritual allegory in colour or imperishable monument in stone, or whether he has to show his wit in the encounter of practical jest and repartee

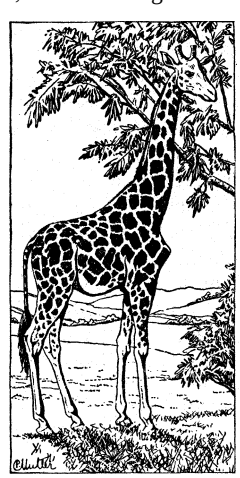
GIPPSLAND: *see* VICTORIA.

GIRAFFE, the tallest of all mammals, reaching 18ft. 7in. in height, the type of the family *Giraffidae*. The classic term "camelopard" has fallen into disuse

Skin-covered horns are present in both sexes, and there is often an unpaired one in advance of the pair on the forehead. Among other characteristics may be noticed the length of the neck and limbs, the absence of lateral toes, and the long tufted tail The tongue is remarkable for its length (up to 18in.) and elasticity. It is covered with numerous large papillae, and forms an organ for the prehension of food. Giraftes inhabit open country and browse on tall trees. To drink or graze they are obliged to straddle the fore-legs apart; but they are capable of going long without water They can gallop at over 30 miles an hour. When standing among mimosas they are difficult of detection. They are almost entirely voiceless. One fawn is produced at a birth Formerly giraffes were found in large herds, but persecution led to their extermination in many districts. Although in Tertiary times spread over southern Europe and India, giraffes are now confined to Africa south of the Sahara.



BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE NUBIAN GIRAFFE
Found only in Africa, south of the Sahara desert, the giraffe is the tallest mammal

Apart from the Somali giraffe (*Giraffa reticulate),* characterized by its deep liver-red colour, there are numerous local subspecies of the ordinary giraffe (*G. camelopardalis*).

GIRALDI, GIGLIO GREGORIO (LILIUS GREGORIUS GYRALDUS) (1479–1552), Italian scholar and poet was born at Ferrara. Later he removed to Naples, where he lived on familiar terms with Jovianus Pontanus and Sannazaro; and subsequently to Lombardy, where he enjoyed the favour of the Mirandola family. At Milan in 1507 he studied Greek under Chalcondylas; and shortly afterwards, at Modena, he became tutor to Ercole (afterwards Cardinal) Rangone About the year 1514 he removed to Rome where, under Clement VII., he held the office of apostolic protonotary; but after the sack of Rome (1527) he returned in poverty once more to Mirandola, whence he was driven by the troubles that followed the assassination of the reigning prince in 1533. The rest of his life was one long struggle with ill-health, poverty and neglect. He died at Ferrara, and his epitaph makes touching and graceful allusion to the sadness of his end. Giraldi was a man of great learning; his *Historia de diis gentium* marked an advdnce in the study of classical mythology; and his treatises, *De annis et mensibus* and on the *Calendarium Romanum et Graecum,* helped to bring about the reform of the calendar. Among his other works are *Progymnasrna adversus literas et literatos; Historiae poëtarum Graecorum ac Latinorum; De poëtis suorum temporum;* and *De sepultura ac vario sepeliendi ritu.* Giraldi was also an elegant Latin poet.

His *Opera omnia* were published at Leyden in 1696.

GIRALDI, GIOVANNI BATTISTA (1504–1573), surnamed CYNTHIUS, CINTHIO or CINTIO, Italian novelist and poet, born at Ferrara in Nov. 1504, was educated at the university of his native town, where in 152j he became professor of natural philosophy, and, 12 years afterwards, succeeded Celio Calcagnini in the chair of belles-lettres. Between 1542 and 1560 he acted as private secretary, first to Ercole II and afterwards to Alphonso II. of Este; but having, in connection with a literary quarrel in which he had got involved, lost the favour of his patron in the latter year, he removed to Mondovi, where he remained as a teacher of literature till 1568. He occupied the chair of rhetoric at Pavia till 1573, when he returned to his native town, where on Dec. 30 he died. Besides an epic entitled *Ercole* (1557), in 26 cantos, Giraldi wrote nine tragedies, the best known of which is *Orbecche* (1541; vol iv. of the *Teatro antico,* 1809). The sanguinary and disgusting character of the plot of this play, and the general poverty of its style are, in the opinion of many of its critics, almost fully redeemed by occasional bursts of genuine and impassioned poetry. Giraldi won a European reputation by his *Hecatommithi* or *Ecatomiti* (modern ed. Turin, 3 vols., 1853–54), a collection of tales closely resembling the novels of Giraldi's contemporary Bandello, though inferior in vigour, liveliness and local colour. Originally published at Monteregale, Sicily, in 1565, they were frequently reprinted in Italy; a French translation by Chappuys appeared in 1j83 and one in Spanish in 1590. The *Hecatommithi* furnished, whether directly or indirectly, the plots of Shakespeare's *Measure for Measure* and *Othello* and of Beaumont and Fletcher's *Custom of the Country.*

GIRALDUS CAMBRENSIS (GERALD DE BARRI) (*c.* 1146–1220), mediaeval historian, was born at Manorbier Castle, Pembrokeshire, the son of William de Barri. He studied at Paris until 1172 when he was appointed to collect tithe in Wales. In 1175 he became archdeacon of Brecon, and on the death of his uncle in the following year, an attempt was made to elect him bishop of St. David's, but Henry II. was unwilling to see anyone with powerful native connections a bishop in Wales. After three more years of study at Paris, Giraldus in 1180 was made commissary to the bishop of St. David's, and in 1184 one of the king's chaplains. While accompanying Prince John to Ireland he wrote his interesting *Topographia Hibernica,* and his *Expurgatio Hibernica,* a strongly prejudiced history of the conquest. In 1188 he went with the primate, Baldwin, to Wales to preach the third crusade, and while there acquired material for his famous *Itinerarium Cambrense.* He then set out for the Holy Land, but in 1189 was sent back to Wales by the king to keep order. Having successively refused the sees of Bangor and Llandaff, he retired to Lincoln from 1192–98 and wrote his *Gemma ecclesiastica* and *Vita S. Remigii.* In 1198 he was elected bishop of St. David's, but Archbishop Hubert's objection necessitated three visits to Rome and a violent indication of the independence of St. David's from Canterbury. In the end, the pope ordered a new election, the prior of Llanthony being elected in 1202. Giraldus spent the rest of his life in retirement, and produced the *Descriptio Cambriae, De rebus a se gestis,* his autobiography, *De Instructione principis,* and the *Vita Galfridi Archiepiscopi Eborecensis.*

Giraldus was an excellent Latinist, well versed in the social and intellectual life of his day. His eloquence, his humour and naïve vanity, his keen, though impressionistic, observation of cus-

toms, traditions, scenery, etc., and his friendships with his great contemporaries, such as Innocent III., Richard Coeur-de-Lion, King John, Stephen Langton, St. Hugh of Lincoln and Grosseteste, all contribute to making him one of the most vivid and enterprising of writers. As historical material, however, his works must be estimated both in the light of his violent party spirit and of his intense patriotism.

His writings mere edited by J. S. Brewer, J. F. Dimock and G. F. Warner in the Rolls series (1861–91) 8 vols. with valuable introductions. The *De Invectionibus* has recently been edited by W. S. Davies in *Cymmrodor,* vol. xxx. (1920). The *Topographia,* the *Expugnatio,* the *Itinerarium* and the *Descriptio* were translated in Bohn's Library series (1863) and the last two again in Everyman's Library (1908) with a good introduction by W. Llewelyn Williams.

GIRANDOLE [from the Ital. *girandola*], an ornamental and luxurious candle-holder that came into use about the second half of the 17th century, and was commonly made and used in pairs. In the great 18th-century period of French house decoration the famous *ciseleurs* designed some exceedingly beautiful examples. Various metals have been used for the purpose and some have been made in hard woods. Gilded bronze has been a very frequent medium, but for table purposes silver is still the favourite material.

AN 18TH CENTURY GIRANDOLE MADE BY ADAM AND

GIRARD, JEAN BAPTISTE (known as "Le Père Girard" or "Le Père Gregoire") (1765–1850), French-Swiss educationalist was born at Fribourg and educated for the priesthood at Lucerne. In 1804 he began his career as a public teacher, first in the elementary school at Fribourg (1805–23), then (being driven away by Jesuit hostility) in the gymnasium at Lucerne till 1834, when he retired to Fribourg and devoted himself with the production of his books on education, *De l'enseignement re'gulier de la langue maternelle* (1834, 9th ed. 1894, Eng. trans. by Lord Ebrington, *The Mother Tongue,* 1847); and *Cours éducatif* (1844–46). Father Girard was hailed, in Switzerland, as a second Pestalozzi, and his books influenced educational methods elsewhere. He abandoned the system of cramming children's minds with rules and facts, seeking instead to stimulate their intelligence.

GIRARD, STEPHEN (1750–1831), American financier and philanthropist, founder of Girard college in Philadelphia, was born in a suburb of Bordeaux, France, on May 20, 1750. His father was a sea captain, and the son cruised to the West Indies and back, 1764–73. In May 1776 he settled in Philadelphia as a merchant. In June of the next year he married Mary (Polly) Lum, daughter of a shipbuilder, who, two years later, after Girard became a citizen of Pennsylvania (1778), built for him the "Water Witch," the first of a fleet trading with New Orleans and the West Indies. Most of Girard's ships were named after his favourite French authors, such as "Rousseau," "Voltaire," "Helvétius," and "Montesquieu." His beautiful young wife became insane, and spent the years from 1790 until her death in 1811 in the Pennsylvania hospital. In 1810 Girard used about $1,000,000 deposited by him with the Barings of London for the purchase of shares of the much depreciated stock of the Bank of the United States—a purchase of great assistance to the United States Government. In May 1812 he established the Bank of Stephen Girard. He subscribed in 1814 for about 95% of the Government's war loans of $5,000,000, of which only $20,000 besides had been taken. In 1793, during the plague of yellow fever in Philadelphia, he volunteered to act as manager of the hospital at Bush hill; again during the yellow fever epidemic of 1797–98 he took the lead in relieving the poor and caring for the sick. He died in Philadelphia on Dec. 26, 1831. His philanthropy was shown in his disposition by will of his estate, the bulk of which went to Philadelphia to be used in founding a school or college, in providing a better police system, and in making municipal improvements and lessening taxation. Girard's heirs-at-law contested the will in 1836. In 1844 Daniel Webster, appearing for the heirs, made a famous plea for the Christian religion, but Justice Joseph Story handed down an opinion adverse to the heirs (Vidals v. Girard's Executors). Work upon the buildings was begun in 1833, and the college was opened in Jan. 1848. The principal building, planned by Thomas Ustick Walter (1804–87), has been called "the most perfect Greek temple in existence." To a sarcophagus in this main building the remains of Stephen Girard were removed in 1851. The course of training is partly industrial—for a long time graduates were indentured till they came of age—but it is also preparatory to college entrance.

See H. A. Ingram, *The Life and Character of Stephen Girard* (1884); George P. Rupp, "Stephen Girard—Merchant and Mariner," in *1848–1849: Semi-Centennial of Girard College* (1898).

GIRARD, a former city of Russell county, Alabama, U.S.A. It was consolidated with Phenix City (*q.v.*) in 1923.

GIRARD, a city of Trumbull county, O., U.S.A., 5 mi. N.W. of Youngstown, on the Mahoning river. It is served by the Erie and (for freight) the Baltimore and Ohio and the Youngstown and Northern railways. The population was 6,556 in 1920 (23% foreign-born white) and was 9,859 in 1930 and 9,805 in 1940 by the federal census. Steel is the principal industry, and in 1940 there were more than 350 industrial plants in the vicinity. Girard was settled about 1800; it was incorporated as a village in 1892 and became a city in 1924.

GIRARDIN, DELPHINE DE (1804–1855), French author, was born at Aix-la-Chapelle, the daughter of Sophie Gay. She published two volumes of miscellaneous pieces, *Essais poétiques* (1824) and *Nouveaux Essais poe'tiques* (1825). A visit to Italy in 1827, during which she was enthusiastically welcomed by the literati of Rome and even crowned in the capitol, was productive of various poems, of which the most ambitious was *Napoline* (1833). Her marriage in 1831 to Émile de Girardin (*see* below) opened up a new literary career. The contemporary sketches which she contributed from 1836 to 1839 to the feuilleton of La *Presse,* under the *nom de plume* of Charles de Launay, were collected under the title of *Lettres parisiennes* (1843), and obtained a brilliant success. *Contes d'une vieille fille à ses neveux* (1832), *La Canne de Monsieur de Balsac* (1836) and *Il ne faut pas jouer avec la douleur* (1853) are among the best-known of her romances; and her dramatic pieces in prose and verse include one-act comedies, *C'est la faute du mari* (1851), *La Joie fait peur* (1854), *Le Chapeau d'un horloger* (1854) and *Une Femme qui déteste son mari,* which did not appear till after the author's death. Among the frequenters of her salon were Théophile Gautier and Balzac, Alfred de Musset and Victor Hugo. She died on June 29, 1855. Her collected works were published in six volumes (1860–61).

Lamartine* (1862); G. d'Heilly, *Madame de Girardin, sa vie et ses oeuvres* (1868); Imbert de Saint Amand, *Mme de Girardin* (1875); H. Malo, *Une Muse et sa mire, Delphine Gay* (1925).

GIRARDIN, EMILE DE (1802–1881), French publicist, was born in Paris, the son of General Alexandre de Girardin and of Madame Dupuy, wife of a Parisian advocate. He became inspector of fine arts under the hfartignac ministry just before the revolution of 1830, and was an energetic and passionate journalist. In 1836 he inaugurated cheap journalism in a popular Conservative organ, La *Presse,* the subscription to which was only forty francs a year. This undertaking involved him in a duel with Armand Carrel, the fatal result of which made him refuse satisfaction to later opponents. In 1839 he was excluded from the Chamber of Deputies, to which he had been four times elected, on the plea of his supposed foreign birth (he was wrongly alleged to have been born in Switzerland), but was admitted in 1842. He resigned early in February 1847, and on Feb. 14, 1848, sent a note to Louis Philippe demanding his resignation and the

regency of the duchess of Orleans. In the Legislative Assembly he voted with the Mountain. He pressed eagerly in his paper for the election of Prince Louis Napoleon, of whom he afterwards became one of the most violent opponents. In 1856 he sold *La Presse,* only to resume it in 1862, but its vogue was over, and Girardin started a new journal, *La Libertd,* the sale of which was forbidden in the public streets. He supported Émile Ollivier and the Liberal Empire, but plunged into vehement journalism again to advocate war against Prussia. His most successful *coup* was the purchase of *Le Petit Journal.* Girardin married in 1831 Delphine Gay *(see* above), and after her death in 1855 Guillemette Joséphine Brunold, countess von Tieffenbach, widow of Prince Frederick of Nassau. He was divorced from his second wife in 1872.

His writings include: *De* la *presse pe'riodique au XIXe siècle* (1837); *De l'instruction publique* (1838); *Etudes politiques* (1838); *De la liberté de la presse et du journalisme* (1842); *Le Droit au travail au Luxembourg et à l'Assemblée Nationale* (2 vols., 1848); *Les Cinquante-deux* (1849, etc.), a series of articles on current parliamentary questions; *La Politique universelle, décrets de l'avenir* (Brussels, 1852); *Le Condamné du 6 mars* (1867), an account of his own differences with the government in 1867 when he was fined 5000 fr. for an article in *La Liberté; Le Dossier de lo guerre* (1877), a collection of official documents; *Questions de mon temps, 1836 à 1856,* articles extracted from the daily and weekly press (12 vols., 1858).

GIRARDON, FRANÇOIS (1628–1715), French sculptor, was born at Troyes on March 17, 1628. As a boy he had for master a joiner and wood-carver, named Baudesson, under whom he is said to have worked at the château of Liébault, where he attracted the notice of Chancellor Séguier. By the chancellor's influence Girardon was sent to Paris and placed in the studio of François Anguier, and afterwards sent to Rome. In 1652 he was back in France; in Paris he found it necessary to conciliate Le Brun, the court painter. Girardon is reported to have declared himself incapable of composing a group, whether with truth or from motives of policy it is impossible to say. This much is certain, that a very large proportion of his work was carried out from designs by Le Brun, and shows the merits and defects of Le Brun's manner. An immense quantity of work at Versailles was entrusted to him, and in recognition of the successful execution of four figures for the Bains d'Appolon, Le Brun induced the king to present his protégé personally with a purse of 300 louis. In 1650 Girardon was made member of the academy, in 1659 professor, in 1674 *adjoint au recteur,* and finally in 1695 chancellor. Five years before (1690), on the death of Le Brun, he had also been appointed *inspecteur général des ouvrages de sculpture.* In 1699 he completed the bronze equestrian statue of Louis XIV., erected by the town of Paris on the Place Louis le Grand. This statue was melted down during the Revolution, and is known to us only by a small bronze model (Louvre) finished by Girsrdon himself. His Tomb of Richelieu (church of the Sorbonne) was saved from destruction by Alexandre Lenoir, who received a bayonet thrust in protecting the head of the cardinal from mutilation. It is a capital example of Girardon's work, and the theatrical pomp of its style is typical of the funeral sculpture of the reigns of Louis XIV. and Louis XV.; but amongst other important specimens yet remaining may also be cited the Tomb of Louvois (St. Eustache), that of Bignon, the king's librarian, executed in 1656 (St. Nicolas du Chardonneret), and decorative sculptures in the Galerie d'Apollon and Chambre du roi in the Louvre. He died in Paris in 1715.

See Corrard de Breban, *Notice sur la vie et les oeuvres de Girardon* (1850).

GIRART DE ROUSSILLON, an epic figure of the Carolingian cycle of romance. In the genealogy of romance he is a son of Doon de Mayence. His legend is contained in a *Vita Girardi de Roussillon,* dating from the early 12th century and written probably by a monk of the abbey of Pothières or of Vezelai, both of which were founded in 860 by Girart; in *Girart de Roussillon,* a *chanson de geste* of similar date, apparently based on an earlier Burgundian poem; in a 14th century romance in alexandrines; and in a prose romance by Jehan Wauquelin in 1447. The historical Girard, son of Leuthard and Grimildis, was count of Paris in 837, and embraced the cause of Lothair against Charles the Bald. In 855 he became governor of Provence for Lothair's son Charles, king of Provence (d. 863). His wife Bertha defended Vienne unsuccessfully against Charles the Bald in 870, and Girard retired with his wife to Avignon, where he died. But the historical facts are so distorted in *Girart de Roussillon* that the *trouvkre* makes him the opponent of Charles Martel, to whom he stands in the relation of brother-in-law. He is nowhere described in authentic historic sources as of Roussillon, a title derived from his castle on Mt. Lassois, near Chbtillon-sur-Seine. Southern traditions concerning Count Girart, in which he is made the son of Garin de Monglane, are embodied in *Girart de Viane* (13th century) by Bertrand de Bar-sur-l'Aube, and in the *Aspramonte* of Andrea da Barberino, where he figures as Girart de Frete or de Fratte. *Girart de Viane* is the recital of a siege of Vienne by Charlemagne, and in *Aspramonte* Girart de Fratte leads an army of infidels against Charlemagne.

See F. Michel, *Gerard de Rossillon . . . publié en français et en provençal d'après les mss. de Paris et de Londres* (1856); *P.* Meyer, *Girart de Roussillon* (1884), a translation in modern French with a comprehensive introduction. For *Girart de Viane* (ed. *P.* Tarbé, Reims, 1850) *see* L. Gautier, *Les Épopées françaises,* vol. iv. (1878–94); F. *A.* Wulff, *Notice sur les sagas de Magus et de Geirard* (Lund, 1874).

GIRAUD, GIOVANNI, COUNT (1776–1834), Italian dramatist, of French origin, a native of Rome, produced his first play, *L'Onestà non si vince,* in 1798. In 1809 he became director-general of the Italian theatres. His comedies, the best of which are *Gelosie per equivoco* (1807) and *L'Ajo nell' imbarazzo* (1824), were bright and amusing on the stage, but of no particular literary quality.

His collected comedies were published in 1823 and his *Teatro domestico* in 1825.

GIRAUDOUX, HIPPOLYTE JEAN (1882–), French author and diplomatist, was born on Oct. 29, 1882 at Bellac (Haute Vienne) and educated at the *Ecole Normale* in Paris. He became head of the press service in the French foreign office, and afterwards secured an appointment in the diplomatic service. He wrote a series of novels in which he showed extraordinary originality and wit. Although the influence of André Gide is apparent, the style is unmistakably Giraudoux's own, and has undoubtedly influenced contemporary writers. René Lalou has described his method as being in literature what impressionism is in painting. The most important of his works are, *Simon le Pathétique* (1918), partly autobiographical in character; *L'Admirable Clio* (1920) one of the lightest and yet the most profound of war studies; *Suzanne et le Pacifique* (1921); *Siegfried et le Limousin* (1922), in which the hero, a French poet, becomes a prisoner of war in Germany, loses his memory, rises to a high political position, and then has to decide whether he shall return to France and learn to be a Frenchman once more; *Bella* (1926) in which the principal personages (and, it may be said, the two great conflicting tendencies) in Paris political life are described; and *Juliette aux pays des hommes* (1924). His collection of short stories, *Provinciales* provides a good example of his impressionist methods. *Siegfried et le Limousin* was dramatized by Jouvet, and produced at the Champs Elysées, Paris, in June 1928.

GIRDER, a main beam of wood employed to support the joisting of a floor, or a latticed frame ork of steel forming the span of a bridge. *See* BRIDGES and STRUCTURAL ENGINEERING.

GIRDLE, a band of leather or other material worn round the waist, either to confine the loose and flowing outer robes so as to allow freedom of movement, or to fasten and support the garments of the wearer. Among the Romans it was used to confine the *tunica,* and it formed part of the dress of the soldier; when a man quitted military service he was said, *cingulum deponere,* to lay aside the girdle. Money being carried in the girdle, *zonam perdere* signified to lose one's purse, and, among the Greeks, to cut the girdle was to rob a man of his money.

Girdles and girdle-buckles are not often found in Gallo-Roman graves, but in the graves of Franks and Burgundians they are constantly present, often ornamented with bosses of silver or bronze, chased or inlaid.

In the Anglo-Saxon dress the girdle makes an unimportant

figure, and the Norman knights, as a rule, wore their belts under their hauberks. After the Conquest, however, the artificers gave more attention to a piece whose buckle and tongue invited the work of the goldsmith. That of Queen Berengaria lets the long pendant hang below the knee, following a fashion which frequently reappears.

In the latter part of the 13th century, the knight's surcoat is girdled with a narrow cord at the waist, while the great belt, which had become the pride of the cavalier, loops across the hips carrying the heavy sword aslant over the thighs or somewhat to the left of the wearer.

But it is in the second half of the following century that the knightly belt takes its most splendid form. Under the year 1356 the continuator of the chronicle of Nangis notes that the increase of jewelled belts had mightily enhanced the price of pearls. The belt is then worn, as a rule, girdling the hips at some distance below the waist, being probably supported by hooks as is the belt of a modern infantry soldier. The end of the belt, after being drawn through the buckle, is knotted or caught up after the fashion of the tang of the Garter. The waist girdle either disappears or as a narrow strap is worn diagonally to help in the support of the belt. Ornament covers the whole belt, commonly seen as an unbroken line of bosses enriched with curiously worked roundels or lozenges which, when the loose strap-end is abandoned, meet in a splendid clasp. About 1420 this fashion tends to disappear, the loose tabards worn over armour in the jousting-yard hindering its display. The belt never regains its importance as an ornament, and, at the beginning of the 16th century, sword and dagger are sometimes seen hanging at the knight's sides without visible support.

In civil dress the belt of the 14th century is worn by men of rank over the hips of the tight short-skirted coat, and in that century and in the 15th and 16th there are sumptuary laws to check the extravagance of rich girdles worn by men and women whose station made them unseemly. Even priests must be rebuked for their silver girdles with baselards. Purses, daggers, keys, penners and inkhorns, beads and even books, dangled from girdles in the 15th and early 16th centuries. Afterwards the girdle goes on as a mere strap for holding up the clothing or as a sword-belt. At the Restoration men contrasted the fashion of the court, a light rapier hung from a broad shoulder-belt, with the fashion of the countryside, where a heavy weapon was supported by a narrow waistbelt. Soon afterwards both fashions disappeared. Sword-hangers were concealed by the skirt, and the belt, save in certain military and sporting costumes, has no more been in sight in England. Even as a support for breeches or trousers, the use of braces has supplanted the girdle.

In most of those parts of the Continent — Brittany, for example — where the peasantry maintains old fashions in clothing, the belt or girdle is still an important part of the clothing. Italian non-commissioned officers find that the Sicilian recruit's main objection to the first bath of his lifetime lies in the fact that he must lay down the cherished belt. With the Circassian the belt still buckles on an arsenal of pistols and knives.

Folklore and ancient custom are much concerned with the girdle. Bankrupts at one time put it off in open court; French law refused courtesans the right to wear it; St. Guthlac casts out devils by buckling his girdle round a possessed man; an earl is "a belted earl" since the days when the putting on of a girdle was part of the ceremony of his creation; and fairy tales of half the nations deal with girdles which give invisibility to the wearer.

(O. B.)

GIRGA or GIRGEH, a town of Upper Egypt on the west bank of the Nile, 313 m. S S E. of Cairo by rail and about 10 m. N N.E. of the ruins of Abydos. Pop. 19,893, of whom about one-third are Copts. The town stands on a sharp bend of the Nile. Many of the houses are of brick decorated with glazed tiles. The town is noted for the excellence of its pottery. Girga is the seat of a Coptic bishop. It also possesses a Roman Catholic monastery, considered the most ancient in the country. As late as the middle of the 18th century the town stood a quarter of a mile from the river, but is now on the bank,

GIRGENTI, a town in Sicily (see AGRIGENTUM).

GIRISHK, a village and fort in Afghanistan, on the right bank of the Helmund 78 m. W. of Kandahar on the road to Herat; 3,641 ft. above the sea. The fort is the residence of the governor of the district (Pusht-i-Rud). It commands the fords of the Helmund and the road to Seistan, from which it is about 190 m. distant; and it is the centre of a rich agricultural district. Girishk was occupied by the British during the first Afghan War; and a small garrison under a native officer, successfully withstood a siege of nine months. The Dasht-i-Bakwa, a level plain of considerable width, stretches beyond Girishk towards Farah.

GIRL GUIDES. The object of the Girl Guide movement is to promote among girls the elements of good citizenship, and the sense of service to others. These are inculcated through means which appeal to the girl and lead her to train herself. Membership is extended to all girls, irrespective of class, creed or country. It has no political or sectarian aims.

The Girl Guides movement was originally a spontaneous effort, promoted by the girls themselves in imitation of their brothers, the Boy Scouts. In order to give this movement some sort of organization, Sir Robert (later Lord) Baden-Powell, with his sister, Miss Agnes Baden-Powell, devised in 1910 the Girl Guide scheme. After her marriage to the Chief Scout in 1915 Lady Baden-Powell became commissioner for the county of Sussex and organized that county on the lines of the Boy Scout organization, with commissioners to direct the work in the different districts and to form a link with headquarters; local committees were formed in each town or village to give the required local impetus, encouragement, and financial support to the young officers who were carrying on the work. In 1917 Lady Baden-Powell was appointed chief commissioner, and from that time onwards the organization of the movement went ahead by leaps and bounds. Commissioners were appointed in every county in Great Britain and in the British dominions and provinces overseas. By the end of 1918 every county was complete with its network of organization.

At a big gathering of commissioners that year (1918) Lady Baden-Powell was unanimously elected permanent Chief Guide. Two years later Princess Mary became president, and in 1923 the movement was granted a royal charter of incorporation.

Organization. — Decentralization is the keyword in the Guide organization. The governing body is a council which meets annually and elects an executive of nine members. Under the executive come the county commissioners, who are nominated by the chief commissioner, appointed by the executive, and in their turn these select division and district commissioners.

Training. — The Girl Guide movement is identical with that of the Boy Scouts in principle, differing only in the details of training. A Girl Guide makes a threefold promise: to do her best to do her duty to God and the king; to help other people at all times; to obey the Guide Law. There are ten guide laws, namely: a Guide's honour is to be trusted; a Guide is loyal; a Guide's duty is to be useful and to help others; a Guide is a friend to all and a sister to every other Guide; a Guide is courteous; a Guide is a friend to animals; a Guide obeys orders; a Guide smiles and sings under all difficulties; a Guide is thrifty; a Guide is pure in thought, word and deed.

The Guides are organized in patrols of six or eight under a leader, two or more patrols forming a company under a captain. The affairs of the company are managed by a court of honour consisting of the patrol leaders who meet periodically under the chairmanship of their captain.

The movement is broadly subdivided into three sections, to meet the needs of the children at the various stages of their development: Brownies, from 8 to 11 years of age; Guides, from 11 to 16 years of age; Rangers, over 16. Under the term Guides is included Guides in ordinary companies, and also "Lone Guides," *i.e.*, girls who wish to be members of the movement but are out of reach of a company or who for some reason have been obliged to give up active company work; and also "Post Guides," *i.e.*, those who, on account of some physical defect, are unable to join ordinary companies, and carry out their Guiding by post.

Under the term Rangers are included Rangers, Cadet Rangers and Sea Rangers. Cadet Rangers are those girls in schools and colleges who take up Guiding with the special object in view of becoming "Guiders" later on; and Sea Rangers, as the name implies, are those girls of 16 and over who might not have been attracted by the ordinary Guide and Ranger activities, but to whom the "call of the sea" has appealed.

Through a system of badges the girls are encouraged to educate themselves to proficiency in some 60 different subjects. The badges particularly encouraged are those which promote among the girls efficiency as home-keepers, wives and mothers. Camping and outdoor pursuits are encouraged; swimming and life-saving are taught. The officers, whether commissioners, secretaries or captains, are grouped under one name "Guiders." At Foxlease park, in the New Forest, presented by Mrs. Anne Archbold and endowed by Princess Mary, Guiders are trained in the different aspects of their work; a similar training school for the north of England has been opened at Waddow, near Clitheroe.

An international conference is held biennially when questions affecting the movement throughout the world are brought forward for discussion. Visits of Guides to all countries are encouraged. The first world camp was held at Foxlease in 1924, and was attended by representatives of every nation. (E. K. W.; X.)

GIRLS, CAMP FIRE, an organization for girls 7 to 18 years of age, offering a program of recreational activities, designed to help girls develop their skills and to become happy, usefui citizens. In response to the growing demand for some kind of organization for girls that would guide them in the constructive use of their leisure time, the program was formulated in 1910–11 by a group of educators headed by Dr. and Mrs. Luther Halsey Gulick.

From 6 to 20 girls, 10 years of age and older form a Camp Fire group under the leadership of a woman volunteer. Dues, paid to the headquarters of the National Council at 88 Lexington avenue, New York city, are $1 a year. The Book of *the Camp Fire Girls* outlines the program with its more than 1,000 suggested activities grouped under home, hand and health craft, camping, nature lore, business and citizenship. Indian symbolism adds colour to the program. Each girl chooses for herself an Indian name indicative of her ambitions and ideals. She creates a design to symbolize this thought and uses it as her personal monogram, weaving it into a headband which she wears at ceremonial meetings. She earns "honours" (coloured wooden beads) for her achievements and may advance in rank from Trail Seeker to Wood Gatherer to Fire Maker, finally achieving the highest rank, Torch Bearer, which signifies that she has developed her abilities in a chosen field and is willing to share her skill with others.

The guardian—which is the name for the leader of each Camp Fire group—does not necessarily have previous experience in group leadership, though that is an asset. She is usually a woman who likes young people, has some hobbies or skills she can share with the girls and is willing to learn with them. She has the opportunity to attend either national or local training courses, or to take a correspondence course especially planned for guardians where no other courses are available. *The Guardian,* a periodical of program suggestions and leadership guidance published by national headquarters, is sent to her upon payment of her dues. *The Handbook for Leaders* and other Camp Fire publications are designed to aid her in her group leadership. Most groups have assistant guardians and all are required to have three or more sponsors, interested parents or friends, who give the guardian their backing and help her in many ways.

In more than 100 cities where there are a large number of Camp Fire groups, local councils of prominent citizens have been formed who promote the Camp Fire work. They engage an executive to train leaders and direct the Camp Fire work and they operate a camp which Camp Fire Girls can attend at minimum expense. Usually the funds of the local council are raised through the community chest or other welfare association. Executives are trained in a school conducted by the national council. National field workers visit the local councils and the nine field districts into which the U.S. is divided to help with Camp Fire extension and leadership training.

Soon after the Camp Fire Girls organization was started for teen-age girls, there was a demand for a program for younger girls, which resulted in the organizing of the Blue Birds for girls 7 to 9 years old. They have a program of creative activities outlined in the *Blue Bird Program Book.* Dues for Blue Birds are fifty cents a year. Later, girls who had belonged to Camp Fire for a number of years asked for a program in keeping with their maturing interests, so in 1941 the Horizon club for senior high school girls was launched.

More than 2,000,000 girls have belonged to Camp Fire since its organization in 1911. Before World War II there were groups in 21 countries. In Great Britain, Camp Fire Girls is organized on a national scale with headquarters in London. (C. F. Lo.)

GIRL SCOUTS, INC. is an organization which provides for girls of the United States of America leisure-time opportunities to gain wider interests and become better citizens. Membership is open to all girls from seven to eighteen and the program is planned for girls of three age groups: Brownies from seven to ten; Girl Scouts from ten to fourteen; and Senior Girl Scouts from fourteen to eighteen. The Girl Scouts of the United States are part of the world-wide Scout movement founded by Lord Baden-Powell of Gilwell; the organization is a member of the World Association of Girl Guides and Girl Scouts. Mrs. Juliette Low of Savannah, Georgia, friend of Lord Baden-Powell, formed the first Girl Scout troop in the U. S. after the pattern set up for Girl Guides, sister organization of the Boy Scouts of England.

The Girl Scout promises: "On my honour, I will try to do my duty to God and my country, to help other people at all times and to obey the Girl Scout Law." The Law is a simple code setting up standards of honesty, loyalty, kindliness, courtesy, cleanliness, helpfulness. It is substantially the same in ail countries in which Scouting is organized and has been recognized as a standard of conduct and an expression of brotherhood which crosses barriers of race, nationality, and religion.

The things that Girl Scouts do are classified under ten headings: homemaking, arts and crafts, community life, sports and games, nature, the out-of-doors, music and dancing, literature and dramatics, health and safety, international friendship and an eleventh, vocational exploration, for Senior Girl Scouts. Girls who are interested in any particular field may learn more by completing the requirements for one or more proficiency badges which deal with the subject.

Girl Scout troop activities help girls to learn how to get along with other people and to handle the techniques of democratic procedure. The twenty-four girls of a troop elect their own officers, and, with an older leader and her assistant, plan and carry out the things the girls themselves want to do. The leader's job is to guide and counsel the girls rather than command them. In each community where there are one or more Girl Scout troops there is either a Girl Scout local council or a troop committee made up of men and women who foster the movement.

In order to become a Girl Scout a girl must take part in four or more troop meetings, know the Girl Scout Promise and Laws and pay her annual membership dues. She will have opportunities to share in activities drawn from each of the ten program fields.

She may learn to sketch a map or use a compass, to alter and clean clothing, to cook a meal with two or three other girls, to find out more about her neighbours in foreign lands, make a drawing or model in clay, learn about the contributions which distinguished immigrants have made to American life, swim fifty yards, care for a pet, make a plan for safety in crossing streets, write a review of her favourite book, and learn an American folk dance. By doing such things she progresses through Scouting, becoming interested in special projects such as serving in a well baby clinic, furnishing her Girl Scout meeting place, giving a play to raise money for troop expenses, making layettes for the children of needy mothers, finding out what jobs are open to women in her community, collecting and mending books for the community library, making a troop garden, and many other constructive undertakings.

All year round Scout troops go on hikes and camp a few miles from town for a night or a week-end. In the summer, Girl Scouts who must stay in town go to day camps in city parks. As many girls as possible go for a week or more to camps outside of town where they can enjoy swimming, boating, folk dancing, singing, arts and crafts, and simple outdoor living away from the distractions of hurried modern living. In camp the girls are all citizens of a miniature democracy.

In discussion groups they plan what they want to do and how they shall do it. As in all Girl Scouting they learn self-reliance and responsibility in a world where problems are suited to their age and abilities. (*See* GIRL GUIDES.)

GIRLS' FRIENDLY SOCIETY, THE. An organization for all girls sponsored by the Protestant Episcopal Church. Founded in England in 1875, it spread to the United States with the establishment of the first branch at St. Anne's Church, Lowell, Massachusetts, in 1877.

Today it has an international membership with branches in forty-four countries. The program of the society, based on the present-day interests and needs of girls, includes worship, study, recreation, and service to the Church and the community. An

understanding of the issues of the world today as they affect young people is emphasized. A junior department provides a program for girls under 12 years of age.

Branches may be organized in any parish, mission, or institution of the Episcopal Church, headed by leaders who are communicants of the Church; the membership of the society, however, is inter-denominational.

GIRNAR, a sacred hill in western India, in the peninsula of Kathiawar, 10 m. E. of Junagarh. Five peaks rise about 3,500 ft. above the sea; on them are numerous Jain temples, frequented by pilgrims. At the foot of the hill is a rock, with an inscription of Asoka (2nd century B.C.), and also two other inscriptions (dated 4 D. 1 jo and 455).

GIRODET DE ROUSSY, ANNE LOUIS (1767–1824), French painter, better known as Girodet-Trioson, was born at Montargis on Jan. 29, 1767. He lost his parents in early youth, and the care of his education fell to his guardian, M. Trioson. Girodet entered the school of David, and at the 'age of 22 he successfully competed for the Prix de Rome. At Rome he executed his "Hippocrate refusant les présents d'Artaxerxès" and "Endymion dormant" (Louvre), exhibited at the Salon of 1792.

The firm-set forms, the grey cold colour, the hardness of the execution proper to one trained in the school of David, harmonize ill with the literary, sentimental and picturesque suggestions which the painter has sought to render. The same incongruity marks Girodet's "Danaë" and his "Quatre Saisons," executed for the king of Spain (repeated for Compiègne), and shows itself to a ludicrous extent in his "Fingal" (Leningrad, Leuchtenberg collection), executed for Napoleon I. in 1802. In 1806 he exhibited "Scène de Déluge" (Louvre), to which (in competition with the "Sabines" of David) was awarded the decennial prize. This success was followed up in 1808 by the production of the "Reddition de Vienne" and "Atala au Tombeau." He executed a quantity of illustrations, amongst which may be cited those to the Didot, *Virgil* (1798) and to the Louvre, *Racine* (1801–05). His designs for *Anacreon* were engraved by M. Chatillon. He died on Dec. g, 1824.

Girodet's poem *Le Peintre* and essays on *Le Gdnie* and *La Grâce,* were published after his death (1829), with a biographical notice by his friend M. Coupin de la Couperie; and M. Delécluze, in his *Louis David et son temps,* has also a brief life of Girodet. (1855).

GIRONDE, a maritime department of south-western France, formed from parts of the old province of Guyenne, viz., Bordelais, Bazadais, and parts of Périgord and Agenais. Area. 4,141 sq.mi. Pop. (1936) 850,567. It is bounded north by the department of Charente-Inférieure, east by those of Dordogne and Lot-et-Garonne, south by that of Landes, and west by the Bay of Biscay. The department lies on the east and the west sides of the Gironde estuary formed by union of Garonne and Dordogne. On the west, the *Landes* consist chiefly of morass or sandy plain, divided from the sea by dunes planted with pines which bind the sand together and prevent it from drifting inland. On the east the dunes are fringed for some distance by large lakes, Hourtin, Carcans and Lacanau, communicating with each other. The Bay of Arcachon forms a vast shallow lagoon, a large part of which has been converted into arable land. The estuary of the Gironde, about 45 m. in length, widens northwards from 2 to 6 miles. Islands and mud banks divide it into east and west channels and make navigation difficult. It is, however, well buoyed and lighted, and has a mean depth of 21 feet. There are wide marshes on the right bank north of Blaye, and on the left low-lying polders protected by dikes and composed of fertile salt marshes. At the mouth of the Gironde stands one of the finest French lighthouses, the tower of Cordouan built 1585–1611, and extended in the late 18th century.

The climate is humid and mild and very hot in summer. Wheat, rye, maize, oats and tobacco are largely grown, but the culture of the vine is by far the most important industry carried on *(see* WINE), the six vine-growing districts occuping about one-seventh of the surface of the department. The Médoc is a region 50 m. long by about 6 m. broad, along the left banks of the Garonne and Gironde. The Graves country is a zone 30 m. long, along the left bank of the Garonne from near Bordeaux to Barsac. The Sauternes country lies south-east of the Graves. The Côtes lie on the right bank of Dordogne and Gironde between Dordogne and Garonne, and on the left bank of the Garonne. The produce of the Palus, the alluvial land of the valleys, and of the Entre-deux-Mers, on the left bank of the Dordogne, is inferior. Fruits and vegetables are largely grown, peaches and pears being especially fine. The Médoc breed of horses, the Bazadais breed of oxen and the Bordelais breed of milch cows are well known. Oyster-breeding is on a large scale in the Bay of Arcachon. Resin, pitch and turpentine are obtained from the pine woods, which also supply vine-props, and there are well-known quarries of limestone. Manufactures and trade are chiefly carried on at Bordeaux (*q.v.*), the chief town, and the third port of France. Pauillac, Blaye, Libourne and Arcachon are minor ports.

Gironde is divided into the arrondissements of Bordeaux, Blaye, Langon and Libourne, and has 50 cantons and jj4 communes. The department is served chiefly by the Orléans and Southern companies. It forms part of the circumscription of the archbishopric, the appeal-court and the *académie* (educational division) of Bordeaux, and of the region of the XVIII. army corps (Bordeaux). Besides Bordeaux, Libourne, La Réole, Bazas, Blaye, Arcachon, St. Emilion and St, Macaire are the most noteworthy towns. Among other places of interest the chief are Cadillac, on the right bank of the Garonne, where there is a 16th century castle, surrounded by fortifications of the 14th century; Labrède, with a feudal château in which Montesquieu was born and lived; Villandraut, where there is a ruined castle of the 11th century; Uzeste, which has a church begun in 1310 by Pope Clement V.; Mazères with an imposing 14th century castle; La Sauve, which has a church (13th cent.) and other remains of a Benedictine abbey; and Ste. Foy-la-Grande, a bastide created in 1255 and afterwards a centre of Protestantism, which is still strong there. La Teste, pop. (1936) 6,829, was the capital, in the middle ages, of the famous lords of Buch.

GIRONDISTS, the name given to a political party in the Legislative Assembly and National Convention during the French Revolution (1791–93) (Fr. *Girondins).* The name was first given them because the most brilliant exponents of their point of view—Vergniaud, Gensonné, Guadet—were deputies from the Gironde In the Legislative Assembly these represented a compact body of opinion which, though not as yet definitely republican, was considerably more advanced than the moderate royalism of the majority of the Parisian deputies. Associated with these views was a group of deputies from other parts of France, of whom the most notable were Condorcet, Jacques Pierre Brissot, Roland and Pétion. On the policy of the Girondists Madame Roland, whose *salon* became their gathering-place, exercised a powerful influence *(see* ROLAND); but such party cohesion as they possessed they owed to the energy of Brissot (*q.v.*) who came to be regarded as their mouthpiece. Hence the name *Brissotins,* coined by Camille Desmoulins. As strictly party designations these first came into use after the assembling of the National Convention (Sept. 20, 1792), to which a large proportion of the deputies from the Gironde who had sat in the Legislative Assembly were returned. For the struggle of the Girondists with the *Montagnards* and their ultimate downfall, *see* FRANCE: *History.*

BIBLIOGRAPHY.—Of the special works on the Girondists, Lamartine's *Histoire des Girondins* (1847, new ed. 1902) is rhetoric rather than history, and is untrustworthy; the *Histoire des Girondins,* by A. Gramier de Cassignac (1860) led to the publication of a *Protestation* by J. Guadet, a nephew of the Girondist orator, which was followed by his *Les Girondins, leur vie privée, leur vie publique, leur proscription et leur mort* (1861, new ed. 1890); with which *cf* Alary, *Les Girondins par Guadet* (Bordeaux, 1863); also Charles Vatel, *Charlotte de Corday et les Girondins; pièces classées et annotées* (1864–72); *Recherches historiques sur les Girondins* (1873); Ducos, *Les Trois Girondines* (Madame Roland, Charlotte Corday, Madame Bouquey) *et les Girondins* (1896); Edmond Biré, *La Légende des Girondins* (1881, new ed. 1896). Memoirs or fragments of memoirs by particular Girondists also exist; *e.g.,* Barbaroux, Pétion, Louvet, Madame Roland.

GIRTIN, THOMAS (1775–1802), English painter and etcher, born on Feb. 18, 1775. He was apprenticed to Edward Dayes, the mezzotint engraver, and soon made J. M. W. Turner's

acquaintance. His architectural and topographical sketches and drawings soon established his reputation, his use of water-colour for landscapes being such as to give him the credit of having created modern water-colour painting, as opposed to mere "tinting." His etchings also were characteristic of his artistic genius. His early death from consumption on Nov. 9, 1802 led indeed to Turner saying that "had Tom Girtin lived I should have starved." From 1794 to his death he was an exhibitor at the Royal Academy; and some fine examples of his work have been bequeathed by private owners to the British Museum and the Victoria and Albert Museum.

See L. Binyon, *Thomas Girtin—His Life and Works* (1900).

GIRVAN, police burgh, parish and fishing town, Ayrshire, Scotland, at the mouth of the Girvan, 21 m. S.W. of Ayr, and 63 m. S.W. of Glasgow by the L.M.S.R. Pop. (1938) 5,343. The principal industry was formerly weaving, but is now fishing, cod and oysters forming the most important catches; there is export of grain and coal. The harbour has been enlarged and protected by piers and a breakwater, Moreover, the town is in repute for sea-bathing. and golf, its situation being very fine. The vale of Girvan is one of the most fertile tracts in the shire. Girvan is the point of communication with Ailsa Craig.

GIRY (JEAN MARIE JOSEPH), **ARTHUR** (1848–1899), French historian, was born at Trévoux (Ain). He studied at the Ecole des Chartes under J. Quicherat, and at the newly established Ecole des Hautes Etudes, where he became assistant lecturer and afterwards full lecturer. His first important work was *Histoire de la ville de Saint-Omer et de ses institutions jusqu'au XIV^e siècle* (1877). His lectures led to a great revival of interest in the origins and significance of the urban communities in France. Giry himself published *Les Etablissements de Rouen* (1883–85), a study, based on very minute researches, of the charter granted to the capital of Normandy by Henry II., king of England, and of similar charters throughout the French dominions of the Plantagenets; a collection of *Documents sur les relations de la royauté avec les villes de France de 1180 à 1314* (1885); and *Etude sur les origines de la commune de Saint-Quentin* (1887).

As assistant (1883) and successor (1885) to Louis de Mas Latrie, Giry restored the study of diplomatic, which had been founded in France by Dom Jean Mabillon, to its legitimate importance. In 1894 he published his *Manuel de diplomatique,* which contained the fruits of his long experience of archives, original documents and textual criticism. With the collaboration of his pupils he undertook the preparation of an inventory and, subsequently, of a critical edition of the Carolingian diplomas for the *Monumenta Germaniae historica.* Simultaneously with this work he carried on the publication of the annals of the Carolingian epoch on the model of the German *Jahrbücher,* reserving for himself the reign of Charles the Bald. The preliminary work on the Carolingian diplomas involved such lengthy and costly researches that the Académie des Inscriptions et Belles-Lettres took over the expenses after Giry's death.

For details of Giry's life and works *see* the funeral orations published in the *Bibliothèque de l'Ecole des Chartes,* and afterwards in a pamphlet (1899). *See* also the biography by Ferdinand Lot in the *Annuaire de l'École des Hautes Etudes* for 1901; and the bibliography of his works by Henry Maistre in the *Correspondance historique et archéologique* (1899 and 1900).

GISBORNE, a seaport of New Zealand, in Cook county, provincial district of Hawke's bay, on Poverty bay of the east coast of North island. Pop. (1941) 16,200. Wool, frozen mutton and agricultural produce are exported from the surrounding district. Petroleum has been discovered in the neighbourhood. Near the site of Gisborne Captain Cook landed in 1769, and gave Poverty bay its name from his inability to obtain supplies owing to the hostility of the natives.

GISLEBERT or **GILBERT OF MONS** (*c.* 1150–1225), Flemish chronicler, was provost of the churches of St. Germanus at Mons and St. Alban at Namur. In official documents he is described as chaplain, chancellor or notary, of Baldwin V., count of Hainaut (d. 1195), who employed him on important business. After 1200 Gislebert wrote the *Chronicon Hanoniense,* a history of Hainaut and the neighbouring lands from about 1050 to 1195, which is specially valuable for the latter part of the 12th century, and for the life and times of Baldwin V.

The chronicle is published in Band xxi. of the *Monumenta Germaniae historica* (Hanover, 1826); and separately with introduction by W. Arndt (Hanover, 1869), and by L. Vanderkindere in the *Recueil de textes pour servir à l'étude de l'histoire de Belgique* (1904).

See W. Meyer, *Das Werk des Kanzlers Gislebert von Mons als verfassungsgeschichtliche Quelle* (Königsberg, 1888); K. Huygens, *Sur la valeur historique de la chronique Gislebert de Mons* (Ghent, 1889); and W. Wattenbach, *Deutschlands Geschichtsquellen,* Band ii. (1894).

GISORS, a town of France, in the department of Eure, in the pleasant valley of the Epte, 44 m. N.W. of Paris on the railway to Dieppe. Pop. (1936) 5,470. In the middle ages Gisors was capital of the Vexin. Its position on the frontier of Normandy caused its possession to be hotly contested by the kings of England and France during the 12th century, when with the fortresses of Neaufles and Dangu it was ceded by Richard Coeur de Lion to Philip Augustus. During the wars of religion of the 16th century it was occupied by the duke of Mayenne on behalf of the League, and in the 17th century, during the Fronde, by the duke of Longueville. Gisors was made a duchy in 1742 and afterwards came into the possession of the count of Eu and the duke of Penthièvre.

Gisors is dominated by an 11th and 12th cent. stronghold of the kings of England. The central tower, the choir and parts of the aisles of the church of St. Gervais dates from the middle of the 13th century, and the rest from the Renaissance. Gothic and Renaissance styles mingle in the west facade, adorned with a profusion of sculptures; the fine carving on the wooden doors of the north and west portals is particularly noticeable. Among the industries of Gisors are felt manufacture, bleaching, dyeing and leather-dressing.

GISSING, GEORGE ROBERT (1857–1903), English novelist, was born at Wakefield on Nov. 22, 1857. He was educated at the Quaker boarding-school of Alderley Edge and at Owens College, Manchester. His life, especially its earlier period, was spent in great poverty, mainly in London, though he was for a time also in the United States, supporting himself chiefly by private teaching. He published his first novel, *Workers in the Dawn,* in 1880. *The Unclassed* (1884) and *Isabel Clarendon* (1886) followed. *Demos* (1886), a novel dealing with socialistic ideas, was, however, the first to attract attention. Gissing's own experiences had preoccupied him with poverty and its brutalizing effects on character. He made no attempt at popular writing, and for a long time the sincerity of his work was appreciated only by the few. But his unflinching realism, and the minute care of his descriptions of the sordid milieu of shabby London streets left their mark on the English novel. Among his more characteristic novels are: *Thyrza* (1887), *A Life's Morning* (1888), *The Nether World* (1889), *New Grub Street* (1891), *Born in Exile* (1892), *The Odd Women* (1893), *In the Year of Jubilee* (1894), *The Whirlpool* (1897). Others, *e.g., The Town Traveller* (1901), indicate a humorous faculty, but his novels are mainly concerned with the life of the poorer middle classes, with lonely men and women engaged in a generally hopeless struggle with fate and with the conflict between education and circumstances. The quasi-autobiographical *Private Papers of Henry Ryecrojt* (1903) reflects Gissing's studious and retiring tastes. He was a good classical scholar and had a minute acquaintance with the late Latin historians, and with Italian antiquities; his posthumous *Veranilda* (1904), a historical romance of Italy in the time of Theodoric the Goth, was the outcome of his favourite studies. He died at St. Jean de Luz in the Pyrenees on Dec. 28, 1903.

Cazamian, *Roman et idtes en Angleterre* (1923); *Letters of George Gissing to Members of his Family,* collected & arr. by A. & E. Gissing (1927); *see* also introductory essay by T. Seccombe to *The House of Cobwebs* (1906), a posthumous volume of Gissing's short stories.

GITSCHIN: *see* JIČIN.

GIUDICI, PAOLO EMILIANO (1812–1872), Italian writer, was born at Mussomeli, Sicily, on June 13, 1812. For a short time in 1848 he was professor of Italian literature at Pisa, but was deprived on account of his liberal views. Later he became

professor of aesthetics (resigning 1862) and secretary of the Academy of Fine Arts at Florence, and in 1867 was elected to the chamber of deputies. His works include *Storia della litteratura italiana* (1844), *Storia del teatro* (1860), and *Storia dei comuni italiani* (1861). He died at Tonbridge, England, on Sept. 8, 1872.

GIULIANI, GIAMBATTISTA (1818–1884), an Italian Dante scholar, was born at Canelli, near Asti, on June 4, 1818. He was originally a professor of mathematics, but from 1843 onwards devoted himself exclusively to the study of Dante. In 1860 he became professor of literature at Florence, where he gave a famous series of lectures on Dante. He completed a critical text of the Convito (2 vols., 1875), and of the Latin works (2 vols., 1878–82) of Dante, but his great commentary was left incomplete. He died at Florence on Jan. 11, 1884.

GIULIO ROMANO or **GIULIO PIPPI** (1499–1546), the head of the Roman school of painting in succession to Raphael. This prolific painter, modeller, architect and engineer receives his common appellation from the place of his birth—Rome. His name in full was Giulio di Pietro di Filippo de' Giannuzzi.

Giulio was quite youthful when he first became the pupil of Raphael, who loved him as a son, and employed him in some leading works, especially in the Loggie of the Vatican, in the saloon of the "Incendio del Borgo" and probably also in the Villa Farnesina. It would appear that in subjects of this kind Raphael simply furnished the design, and committed the execution of it to some assistant, such as Giulio—taking heed, however, to bring it up, by final retouching, to his own standard of style and type. Amid the multitude of Raphael's pupils, Giulio showed universal aptitude; he did, among other things, a large amount of architectural planning for his chief. Raphael died when Giulio was 21 years old and bequeathed to him, and to his fellow-pupil Gianfrancesco Penni, his implements and works of art; and upon them it devolved to bring to completion the vast fresco-work of the "Hall of Constantine" in the Vatican—consisting, along with much minor matter, of the four large subjects, the "Battle of Constantine," the "Apparition of the Cross," the "Baptism of Constantine" and the "Donation of Rome to the Pope." The whole of this onerous undertaking was completed within a period of only three years. By this time Giulio was regarded as one of the first artists in Rome. Among his architectural works is the Villa Madama, with a fresco of Polyphemus, and boys and satyrs; the Ionic facade of this building may have been sketched out by Raphael; and the Villa Lante, where he painted frescoes which are now in the Palazzo Buccari.

Towards the end of 1524 his friend the celebrated writer Baldassar Castiglione seconded with success the urgent request of the duke of Mantua, Federigo Gonzaga, that Giulio should migrate to that city, and enter the duke's service for the purpose of carrying out his projects in architecture and pictorial decoration. The duke treated his painter munificently. In Giulio's multifarious work in Mantua three principal undertakings should be noted. (1) In the Castello he painted the "History of Troy," along with other subjects. (2) In the suburban ducal residence named the Palazzo del Te he rapidly carried out a rebuilding on a vastly enlarged scale in the Doric order—the materials being brick and terra-cotta, as there is no local stone—and decorated the rooms with his most celebrated works in oil and fresco painting—the story of Psyche, Icarus, the fall of the Titans, and the portraits of the ducal horses and hounds. The foreground figures of Titans are from 12 to 14ft. high; the room, even in its structural details, is made to subserve the general artistic purpose. The whole of the work on the Palazzo del Te occupied about five years. (3) Giulio recast and almost rebuilt Mantua cathedral; erected his own mansion, reconstructed the street architecture to a considerable extent, and made the city, sapped as it is by the shallows of the Mincio, comparatively healthy; and at Marmirolo, some 5m. distant from Mantua, he worked out other important buildings and paintings. He was in fact, for nearly a quarter of a century, a sort of Demiurgus of the arts of design in the Mantuan territory Giulio's activity was interrupted but not terminated by the death of Duke Federigo The duke's brother, a cardinal who became regent, retained him in full employment. He was afterwards invited to succeed Antonio Sangallo as architect of St. Peter's in Rome—a splendid appointment, which he had almost resolved to accept, when a fever overtook him and caused his death on Nov. 1, 1546. He was buried in the church of St. Barnaba in Mantua.

Wide and solid knowledge of design, combined with a promptitude of composition that was never at fault, formed the chief motive power and merit of Giulio Romano's art. It would be difficult to name any other artist who, working as an architect, and as the plastic and pictorial embellisher of his architecture, produced a total of work so fully and homogeneously his own; hence he has been named "the prince of decorators." He had great knowledge of the human frame, and represented it with force and truth; he was also learned in other matters, especially in medals, and in the plans of ancient buildings. As a general rule, his drawings are finer and freer than his paintings; his colouring is marked by an excess of blackish and heavy tints. Giulio Romano established at Mantua a school of art. Very many engravings were made contemporaneously from his works, not only in Italy, but in France and Flanders as well. Like Raphael he entrusted principally to assistants the pictorial execution of his cartoons. Primaticcio was one of the leading coadjutors. Among the oil pictures of Giulio Romano are the "Martyrdom of Stephen," in the church of that saint in Genoa, a "Holy Family" in the Dresden Gallery and a "St. Margaret" in the Vienna gallery.

Vasari gives a pleasing impression of the character of Giulio. He was very loving to his friends, genial, affable, liking fine apparel and a handsome scale of living. His portrait, painted by himself, is in the Uffizi, Florence.

Besides Vasari, Lanzi and other historians of art, the following works may be consulted: C. D. Arco, *Vita di G. Pippi* (1842); G. C. von Murr, *Notice sur les estampes gravies après dessins de Jules Romain (1865)*; J. P. Richter, *La collezione Heviz e gli affreschi di Giulio Romano al palazzo Zuciari* (1928).

GIUNTA PISANO, Italian painter of the 13th century, a native of Pisa. He died between 1255 and 1267. It is said that he painted in the upper church of Assisi, notably a "Crucifixion" dated 1236, with a figure of Father Elias, the general of the Franciscans, embracing the cross. This painting no longer exists. Three large Crucifixions are ascribed to the same master, whose signature can be traced on them. One is in S.S. Raineri e Leonardo in Pisa and was formerly in the convent of St. Anna; the other, which has been moved from the Ospedale of S. Chiara to the Museo Civico at Pisa, is completely overpainted; the third is in S. Maria degli Angeli at Assisi. In these paintings Christ is represented with his head leaning on one side with an expression of pain, and his body bending forward in agony—a conception differing from "the triumphant Christ" of the preceding age. Some recent art critics see in Giunta Pisano a pioneer who, coming from Tuscany to Assisi, influenced the development of Umbrian art.

GIURGIU, the capital of the department of Vlashca, Rumania; situated amid mud-flats and marshes on the left bank of the Danube. Pop. (1930) 30,348. Three small islands face the town, and a larger one shelters its port, Smarda 2½ m. east. A railway runs north to Bucharest and north-west to Blejesci and steamers ply to Ruschuk, 2½ m. south-west on the Bulgarian shore, whence railways run to Varna, Sofia and South Bulgaria. Thus Giurgiu, besides having a considerable trade with the home ports lower down the Danube, is the headquarters of commerce between Bulgaria and Rumania. It exports timber, grain, salt and petroleum; importing coal, iron and textiles. There are also large sawmills, and pipe-lines for oil run to Baicoi-Bucharest.

Giurgiu occupies the site of Theodorapolis, a city built by the Roman emperor Justinian (A.D. 483–565). It was founded in the 14th century by Genoese merchants who called the town, after the patron saint of Genoa, San Giorgio (St. George). As a fortified town, Giurgiu figured often in the wars for the conquest of the lower Danube; especi lly in the struggle of Michael the Brave (1593–1601) against the Turks, and in the later Russo-Turkish Wars. It was burned in 1659. Th 1829, its fortifications were finally razed, the only defence left being a castle on the island of Slobosia, united to the shore by a bridge.

GIUSTI, GIUSEPPE (1809–1850), Tuscan satirical poet, was born at Monsummano, a small village of the Valdinievole, on May 12, 1809. In 1826 he went to study law at Pisa; he spent eight years in the course, instead of the customary four. He lived gaily, and learned to know the world, its vices and follies. The experience thus gained he turned to account in his satires.

With the poem called La *Ghigliottina* a vapore (1833) Giusti revealed his genius. From this time he showed himself the Italian Béranger. In 1834 Giusti began nominally to practice as an advocate in Florence. To this period belong the Dies Irae (1835) on the death of the emperor Francis I. and many of his finest verses which for some years passed from hand to hand. His poems were published clandestinely at Lugano, at some risk, as the work was destined to undermine the Austrian rule in Italy. Giusti thoroughly established his fame by his Gingillino, exposing the vileness of the treasury officials, and the base means they used to conceal the necessities of the state. The Gingillino has all the characteristics of a classic satire. His Delenda *Carthago* (1846), Alli *spettri del 4 Settembre* (1847), La *Republica* (1848), furthered the revolution. Giusti entered heart and soul into the political movements of 1847 and 1848, served in the national guard, sat in the parliament for Tuscany; but finding that there was more talk than action, that to the tyranny of princes had succeeded the tyranny of demagogues, he expressed his opinions freely and in 1848 was regarded as a reactionary. His friendship for the marquis Gino Capponi, who had taken him into his house during the last years of his life, was enough to compromise him in the eyes of Guerrazzi, Montanelli and Niccolini. On May 31, 1850 he died at Florence in the palace of his friend, the marquis Gino Capponi.

The best of the many editions of Giusti's poems are those of Carducci (1859; 3rd ed., 1879), G. Fioretti-Donati (1913 and 1926), and F. Martini (1914). For translations see W. D. Howells, Modern Italian Poets (1887). *See* his letters, *Epistolario,* ed. G. Frassi (1859), and F. Martini (3 vols., Florence, 1904); and *Memoire inédite 1845–49,* ed. F. Martini (3 vols., Milan, 1890, 1904).

GIUSTINIANI, the name of a prominent Italian family which originally belonged to Venice, but established itself subsequently in Genoa also, and at various times had representatives in Naples, Corsica and several of the islands of the Archipelago.

In the Venetian line the following are most worthy of mention:—

1. LORENZO (1380–1456), the Laurentius Justinianus of the Roman calendar, entered the congregation of the canons of St. George in Alga, and in 1433 became general of that order. About the same time he was made by Eugenius IV. bishop of Venice; and on the removal of the patriarchate from Grado to Venice by Nicholas V. in 1451, he was promoted to that dignity, which he held for fourteen years. He died on Jan. 8, 1456, and was canonized by Alexander VIII., his festival being kept on Sept. 5. The best edition of his works is that of the Benedictine, P. N. A. Giustiniani (Venice, 2 vols., 1751).

2. LEONARDO (1388–1446), brother of the preceding, was for years a senator of Venice, and in 1443 was chosen procurator of St. Mark. He translated into Italian Plutarch's Lives of *Cinna* and Lucullus, and was the author of some poetical pieces, amatory and religious—strambotti and cartzonetti—as well as of rhetorical prose compositions. The popular songs set to music by him became known as Giustiniani. (See *Poésie inédite* di *Leonardo* Giustiniani, ed. Wiese [Bologna, 1883].)

3. BERNARDO (1408–1489), son of Leonardo, entered the Venetian senate, and served on diplomatic missions to France and Rome, and about 1485 became one of the Council of Ten. He wrote a history of Venice, De origine *urbis* Venetarum *rebusque* ab ipsa gestis *historia* (1492; Ital. trans. 1545). It is to be found in vol. i. of the Thesaurus of Graevius.

4. PIETRO, also a senator, lived in the 16th century, and wrote a *Historia rerum* Venetarum in continuation of Bernardo. He also wrote chronicles *De* gestis Petri *Mocenigi* and De bello *Venetorum* cum Carolo VIII. (Script, rer. Ital. vol. xxi.).

Of the Genoese branch of the family the most prominent members were the following:—

5. AGOSTINO (1470–1536) was born at Genoa, and after joining the Dominicans in 1487, studied Greek, Hebrew, Chaldee and Arabic, and in 1514 began the preparation of a polyglot edition of the Bible. As bishop of Nebbio, Corsica, he took part in the earlier sittings of the Lateran council (1516–17), but, in consequence of party complications, withdrew to his diocese, and ultimately to France, where he became a pensioner of Francis I., and was the first to occupy a chair of Hebrew and Arabic in the University of Paris. He became acquainted with Erasmus and More and returned to Nebbio, about 1522. He bequeathed his fine library to the republic of Genoa. Of his projected polyglot only the Psalter was published (*Psalterium* Hebraeurn, Graecum, Arabicum, et *Chaldaicum,* Genoa, 1616). Besides the Hebrew ext, the LXX. translation, the Chaldee paraphrase and an Arabic version, it contains the Vulgate translation, a new Latin translation by the editor, a Latin translation of the Chaldee and a collection of scholia. Giustiniani printed 2,000 copies at his own expense, including 50 in vellum for presentation to the sovereigns of Europe and Asia. Besides an edition of Job, containing the original text, the Vulgate and a new translation, he published a Latin version of the Moreh *Nevochim* of Maimonides (Director *dubitantium aut perplexorum,* 1520), and also edited in Latin the *Aureus libellus* of Aeneas Fiatonicus, and the *Timaeus* of Chalcidius. His annals of Genoa (*Castigatissimi annali di* Genova) were published posthumously in 1537.

6. POMPEIO (1569–1616), a native of Corsica, who served under Alessandro Farnese and the marquis of Spinola in the Low Countries, where he lost an arm, and was known by the sobriquet Bras de Fer. He defended Crete against the Turks, and subsequently was killed at Friuli. He left in Italian a personal narrative of the war in Flanders, repeatedly published in Latin (*Bellum* Belgicum, Antwerp, 1609).

7. GIOVANNI (1513–1556), born in Candia, was the translator of Terence's *Andria* and *Eunuchus,* of Cicero's *In* Verrern, and of Virgil's Aeneid, viii.

8. ORSATTO (1538–1603), Venetian senator, translator of the Oedipus Tyrannus of Sophocles and author of a collection of Rime, in imitation of Petrarch, was one of the latest representatives of the classic Italian school.

g. GERONIMO, a Genoese (16th century), translated the *Alcestis* of Euripides and three of the plays of Sophocles, and wrote two original tragedies, Jephte and Christo in Passione.

10. VINCENZO, who in the beginning of the 17th century built the Roman palace, made the art collection associated with his name. The collection was removed in 1807 to Paris, and in 1815 all that remained of it, about 170 pictures, was purchased by the king of Prussia and removed to the Berlin royal museum.

GIVET, town of northern France, in the department of Ardennes, 40 mi. N. by E. of Mézières on the Eastern railway between the town and Namur. Pop. (1936) 6,583; commune, 6,923. Givet lies on the Meuse near the Belgian frontier, and was formerly an important fortress. It is divided into three portions—the citadel called Charlemont and Grand Givet on the left bank of the river, and on the opposite bank Petit Givet. The fortress, the only survival of the fortifications, at the top of a precipitous rock 705 ft. high, was founded by the emperor Charles V. in the 16th century, and further fortified by Vauban at the end of the 17th century; it is the only survival of the fortifications of the town, the rest of which were destroyed in 1892. In Grand Givet there are a church and a town-hall built by Vauban, and a statue of the composer, Étienne Méhul, stands in the fine square named after him. Petit Givet, the industrial quarter, is traversed by tanneries and glue factories. Pencils and tobacco-pipes are also manufactured. The town has considerable river traffic, consisting chiefly of coal, copper and stone. There is a chamber of arts and manufactures.

GIVORS, manufacturing town, south-eastern France, department of Rhône, on the railway between Lyons and St. Étienne, 14 m. S. of Lyons. Pop. (1936) 12,867. It stands on the bank of the Rhône, here crossed by a suspension bridge, at its confluence with the Gier and the canal of Givors. The chief industries are metal-working, engineering-construction, glass-working, brick-making, rope-making, and the manufacture of glue and earthenware. There are coal mines near. On the hill above the town are

the ruins of the chbteau of St. Gérald and of the convent of St. Ferréol, remains of the old town destroyed in 1594.

GJALLAR, in Scandinavian mythology, the horn which, when a stranger approached, had to be blown by Heimdal.

GJELLERUP, KARL (1857–1919), Danish poet and novelist, was born on July 2, 1857, at Roholte, Zealand. His early works, written under the influence of Georg Brandes, were strongly optiniistic in character; the best of these is *The Disciple* of *the Teutons* (1882). But a prolonged journey in southern and eastern Europe brought out other aspects of his many-sided genius, and he wrote dramas and novels showing a deeper comprehension of the spiritual and ethical problems of life. In his later years he took up classical, Gothic and Eastern subjects as the basis of his work. Of a series of these—Die *Opferfeuer* (1903), *Das Weib der Vollendeten* (1907), *Der Pilger Kamanota* (1906), *Die Weltwanderer* (1910)—the scene is laid in India. Gjellerup wrote many of his later works in German. From 1892 onwards he lived at Klotzsche, near Dresden, where he died on Oct. 11, 1919. He had received the Nobel prize for literature in 1917.

GLABRIO. 1. MANIUS ACILIUS GLABRIO, Roman statesman and general, member of a plebeian family. When consul in 191 B.C. he defeated Antiochus the Great of Syria at Thermopylae, and compelled him to leave Greece. Flamininus interceded to save the Aetolians. In 189 Glabrio was a candidate for the censorship, but was opposed by the nobles.

See Censorinus, *De die natali,* xx.; Macrobius, *Saturnalia,* i. 13; index to Livy; Appian, *Syr.* 17–21.

2. MANIUS ACILIUS GLABRIO, Roman statesman and general, grandson of the famous jurist P. Mucius Scaevola. When praetor urbanus (70 B.C.) he presided at the trial of Verres. When consul with L. Calpurnius Piso in 67 he brought forward a law (Lex Acilia Calpurnia) against illegal canvassing at elections. In the same year he was appointed to supersede L. Lucullus in the government of Cilicia and the command of the war against Mithridates, but he did nothing, and was in turn superseded by Pompey.

See Dio Cassius xxxvi. 14, 16. 24; Cicero, *Pro. lege Manilia,* a. *g;* Appian, *Mithrid.* 90.

GLACE BAY, a town and port of entry of Cape Breton county, Nova Scotia, Canada, on the Atlantic ocean, 14 mi. E. of Sydney, with which it is connected by railway. It is the centre of a coal-producing district. Though it has a fair harbour, most of the shipping is done from Sydney in summer and from Louisburg in winter. Pop. (1941) 25,147. It is a transatlantic wireless station.

GLACIAL PERIOD or **PLEISTOCENE ICE AGE,** in geology, is the name given to a geological period, probably within the duration of man's occupancy of Europe, characterized, according to the now universal interpretation, by cold conditions approaching arctic severity, the evidence of which is contained in superficial deposits extending over 8,000,000 sq.m. of Europe and North America, and great areas of Asia, and the southern Hemisphere.

The attention of geologists of the 18th and early 19th centuries was directed to the existence of a series of deposits—clays, gravels, brickearths, sands and the like—that seemed to be an exception to the general orderly arrangement of the geological strata, associated as they were with strangely scored blocks of stone foreign to the districts in which they were found, and with scorings and "dressings" of rock surfaces, and seemed to indicate the operation of agencies different from those to which ordinary geological phenomena were attributed. It thus came about that the ideas involved in the Mosaic cosmogony and the Noachian deluge were readily seized upon and an explanation seemingly adequate was found ready to hand. The deposits were styled *Diluvium,* a term long since abandoned by British and American geologists, but still used by some writers on the Continent.

The earliest notes of dissent were sounded by Schimper, Venetz and Charpentier, who recognized in the action of Alpine glaciers forces productive of effects generally comparable with those attributed to a universal deluge, allowance being made for differences of physiographic conditions. Though many workers on the Continent adopted and developed this hypothesis, circumstances conspired to delay its acceptance in Britain, the chief, perhaps, being that British geologists were less familiar with the action of glaciers. Another reason is to be found in the fact that, as the general direction of transport seemed to be from north to south and many unfamiliar types of crystalline rocks had apparently been transported by a hill-and-valley ignoring agency, a great "wave of translation" seemed to be the only agency adequate to explain the facts. This view found its last advocate in the late Sir Henry Howorth. This hypothesis was followed by one admitting the agency of ice but with the corollary, to which the facts seemed to point, of a great ice-sheet extending in all directions from the North Pole. This in turn was modified when it was discovered that in certain parts of Britain marine shells were contained in the deposits. This fact was brought to the knowledge of geologists in 1831 by Joshua Trimmer who found shell fragments, not only on the low grounds in many places, but also at altitudes up to 1,350 ft. above the sea at Moel Tryfaen near Snowdon. Smith of Jordanhill about the same time recognized that shells found in Till (boulder-clay) of Scotland included species whose present habitat is in the Arctic seas.

Speculation now took the form of a marine submergence sufficient to cover all the country up to 1,400–1,500 ft. with a sea cumbered with icebergs and floe-ice, and from the melting of these their burden of rock-materials, the boulder-clays, etc., were produced. In 1838 Buckland, who had only a few years before published his *Reliquiae Diluvianae* (1823), while on a tour in Switzerland made the acquaintance of Louis Agassiz who, though at first sceptical, had been converted to the views of Charpentier and Venetz that the boulders found across the plain of Switzerland and on the flanks of the Jura had been transported by glacier-ice, of which the existing glaciers of the Alps were the dwindled representatives. Buckland was at first no less sceptical, but with characteristic open-mindedness he fully accepted Agassiz's conclusions and induced the great Swiss to visit Britain. The product of a joint tour was to confirm Buckland in the belief that the diluvial phenomena were attributable to the action of land-ice. All the phenomena of glacier-action were recognized—terminal and lateral moraines, ice-worn surfaces (one of which in the Blackford hills has been preserved and its significance recorded on a tablet), *roches moutonnées,* striated and far carried blocks. Agassiz described the famous parallel roads of Glen Roy as the strand-lines of a temporary glacier-dammed lake of the type of the Marjelen See, though its full story was not deciphered until Jamieson's demonstration in 1863.

Buckland's paper marked a new departure in glacial geology in Britain. It was followed by Lyell's memoirs on the Drift of Norfolk, and on the geological evidences of glaciers in Forfarshire. It has already been remarked that the older views still found advocates, and even in the 20th century, the marine origin of baulder-clay has found some support. It may, however, be safely asserted that the postulate of a great ice-sheet having its radiant-point near the head of the Gulf of Bothnia is the starting point for all modern work on the glaciation of northern Europe.

Geological Evidences.—The geological evidences of ice-action in low latitudes cover, in fact, substantially all the phenomena observed in or about modern glaciers and ice-sheets. Of the direct effects of ice upon the subjacent rocks, the most conspicuous must always be the production by the action of the stone-laden basal layers of scratched and abraded rock-surfaces, striated surfaces and *roches moutonnkes.* The form and direction of the *striae* are often valuable indications of the direction of the last movement of the ice, though, as has been remarked, "the last stroke of the joiner's plane removes the evidence of all the previous movements." *Roches moutonnées,* the smoothed and rounded hammocks of rock compared by de Saussure to the curls on a wig, have commonly acquired a curved outline which is highly characteristic especially taken in conjunction with the hard and unweathered condition in which they occur. Their surfaces are usually well striated and, when freshly exposed, are polished. In many instances they exhibit a tendency to stream-line forms, though this may be modified by "plucking" or the rending away of blocks from the lee-side (downstream) by the dragging of the

ice. "Plucking" may also operate by snatching out crescentic or semicircular flakes from the surfaces both of striated floors and of *roches moutonnées*.

Rocky hills or abrupt declivities in the path of a glacier may be *moutonnées,* and the effect of "plucking" on the lee-side will cause a retreat of the face upstream at the same time that the blocks detached will contribute to the burden of stones carried by the base of the glacier. Where a boss of rock of exceptional hardness stands in the path of an ice-stream the lower layers of the ice cleave round it and it is usual to find a gully eroded across the front and along the two sides becoming evanescent towards the rear. The lowland valley of Scotland is replete with examples, such as the Castle rock at Edinburgh, and North Berwick Law. In the former case the long slope of the High street has been found to consist of a protected mass of soft coal measure rock forming a characteristic illustration of "crag and tail," but the "tail" in many instances is formed by accumulation of sand, gravel or the like in the "slack-water" in the rear of the crag.

The erosion-effects of ice-streams exhibit themselves in other forms and a great controversy without at present a decisive issue has arisen as to the limit of the scaie of magnitude of these effects. Whether, for example, it being admitted that grooves and shallow hollows can be produced, the production of lake-basins and the characteristics of valley contours on a large scale can be ascribed to glacial erosion. Ramsay, James Geikie, Alfred Russel Wallace, Penck, Prof. W. M. Davis and others have held the opinion that they can. Prof. Collet in 1922 remarked "of all the Swiss geographers and geologists, Heim is the only one who will not admit that the great lakes at the foot of the Alps were formed by the action of glaciers." On the other side can be quoted also Bonney, Garwood and Gregory.

The Glacial Deposits.—Two principal types of deposits are recognizable—those which have been directly released from the ice upon its melting, without any sorting by the agency of the water, and those which, though transported in part by ice, have been finally sorted and distributed by water. To the first category will belong many moraines, the long ridges of materials cast down along the margins of glaciers, generally from the superficial, "rock-trains," of valley glaciers in mountainous regions, and the terminal ridges which may be produced either from the superficial burden or from *englacial* rock-débris carried in the lower layers of the ice. Terminal moraines in the case of valley glaciers commonly form crescentic ramparts across the valleys or horseshoe shaped mounds where a valley debouches in the plain. The magnitude of these ridges may vary between small mounds of a foot or two in height and colossal ramparts, like La Serra at the mouth of the Val d'Aosta, 2,000 ft. in height. Some terminal moraines, like the one just mentioned, may be a single even-crested ridge, but in the case of the moraines of the great ice-sheets they may take the form of a congeries of lumps and hollows.

Moraines, as regards their structure, commonly show a confused intermingling of rock-materials of every grade from the minutest of mud-particles up through sand-grains and stones to giant rock-masses of such dimensions that it is difficult to realize that they are not part of the solid fabric of the country; these will be further mentioned later. Where the clayey element is very abundant a moraine may be said to consist of true boulder-clay (the Scottish "Till"). Boulder-clay occurs, however, in other forms than as moraines. Its most common aspect is as sheets of greater or less extent spread over the land, sometimes in undulating relief, but, more commonly, forming extensive plateaux like, for example, that expanse between Manchester and Liverpool or much of Suffolk and north Essex, or the north German plain. This type of boulder-clay is usually tough and hard, indeed in some of the excavations it is necessary to blast it with explosives; but the texture will naturally depend primarily on the nature of the constituents, and in a secondary degree as Sorby showed, upon the pressure to which it has been exposed.

The stones in boulder-clay assume in many cases characteristic attitudes—in one known as the "forced arrangement," the forward end of the boulder is uptilted (Hinde). The orientation of a stone of large size will often serve to indicate the direction of travel, the longer axis being in line of movement and if there is a sharp and a blunt end, the sharp end will be foremost. It is hardly an exaggeration to say that there is no limit to the size of boulders: at Birkenwald near Berlin there is a transported mass of chalk of an estimated volume of 2,000,000 cu. metres, which is believed to have travelled 15 km., and an erratic of chalk at Great Catworth, Huntingdon, though not quite equalling it in magnitude, must have been carried not less than 70 miles. Composite erratics of a succession of secondary rocks such as the Roswell erratic near Ely—long used as a quarry—may perhaps have been originally outliers from an escarpment which have been pushed off their bases. Boulder-clay occasionally assumes the form of semi-ovoid mounds to which the name of "drumlins" has been given. These may have been built up near the melting end of an ice-stream by the accretions of englacial materials, but they may owe their form to the erosion of a belt of boulder-clay transverse to the front of an over-riding ice-sheet or glacier: they may be compared with *roches moutonnées,* and, like them, have taken on a form stable, at least temporarily, under moving ice.

Water-borne or **Fluvio-glacial** Deposits.—Every glacier at its termination, whether on land or in water, discharges its melt-water not merely by tricklets coursing down its sloping front but at some points by the emergence of a subglacial stream of turbid water charged with sand and stones. When the glacier is of steep gradient the stream will have the force of a torrent and will carry its load forward to be deposited in order of magnitude of materials—first the coarse, then finer, and last of all the impalpable mud, as the velocity of the stream diminishes, hence in Alpine valleys the river channels may come to be mere stony wildernesses like the floor of the Rhone valley near its debouchure into the Lake of Geneva at Villeneuve. Where, as in that instance, the stream discharges into a lake, or, as in Greenland, into a sea or fjord, the turbid water deposits its load as a species of cone or delta, the finest materials forming in deeper water a deposit of stratified or laminated mud, each pair of layers, finer or coarser, representing a period of melting, alternating with one of diminished flow. In a glacier of small dimensions the cycle will be diurnal and when the feeder comes from one of larger size the cycle may be an annual one, which is probably the case with the great ice-lobes descending into the Greenlandic fjords. There is thus a criterion by which the laminated muds deposited from a glacier-fed stream can be distinguished from those derived from an ice-sheet. These will demand further discussions when considering the date of the Ice age.

Intimately connected with outwash plains are the Kames or Eskers (Scandinavian Asar). These two terms were in their original significance applied in Ireland and Scotland respectively to phenomena of the same type, but American geologists employ them to designate structures different in form and geological relations. Fairchild defines them in the following terms: "The term 'kame' is here used . . . as designating deposits, chiefly sand and gravel, having a general knob and basin topography and formed at the margin or periphery of an ice-sheet. The term 'esker' . . . is employed to denote distinct ridges, chiefly gravel, believed to have been deposited in the beds of subglacial streams, being phenomena of radial drainage." The distinction is fundamental—a kame, to an American geologist, is an accumulation parallel to the ice-front; an esker is radial to it. As understood by British geologists, "eskers are winding ridges or strings of mounds composed of water-worn sand and gravel. . . . They frequently show in their course across country a distinct disregard for the present surface gradient, thus proving that the streams which deposited them could not have flowed entirely on the surface, or else must have been under sufficient hydrostatic pressure to flow uphill" (Wright). Sollas favours the idea that they were formed in the channels of subglacial streams; but Gregory attributes a morainic origin to them, in which opinion Charlesworth concurs, and he applies the term *åsar* to those disposed radially to the ice-front.

The surface beneath the glacial deposits has in general the characteristics of a land-surface: H. B. Woodward has described examples of "piping" of chalk in such situations which he

regarded as evidence of sub-aerial erosion. The evidence outside the glaciated areas of the existence of ice-sheets and glaciers or of cold conditions are no less significant than those direct proofs of ice-action, and they have in recent years received a large amount of attention. When a glacier or ice-sheet obstructs the natural drainage of the ice-free country a lake will be formed, but will usually drain away on the removal of the ice barrier, leaving, however, certain signs by which its former existence may be recognized and which may furnish valuable corroboration, not otherwise obtainable, of the position and fluctuations of the ice-front. The criteria relied on for their identification are mainly four: (1) strand lines; (2) floor deposits; (3) deltas, and (4) drainage channels cutting spurs or watersheds. The earliest example to be recognized in Britain was the famous parallel roads of Glen Roy. The channels cut by water overflowing from such lakes furnish some of the most picturesque features of a glaciated country — many thousands have been recognized in the British Isles.

Biological Evidence. — The biological evidences of a cold episode in recent geological history are no less patent than the physical. Reference has already been made to Smith of Jordanhill's recognition in the Drift deposits of shells whose modern equivalents now live in boreal or even arctic seas. Mammals such as the musk ox and reindeer, whose modern representatives are restricted to high latitudes, had already been identified.

It is necessary to amplify a little the allusion to the occurrence of marine shells — a few whole and many more fragments — in the glacial deposits, which retarded for more than half a century the recognition of the true explanation of our glacial phenomena. The shelly Drift can, with few exceptions, be shown to occupy positions shown by independent evidence to have been invaded by ice that had crossed the sea-bed in its progress and thus had an opportunity of incorporating in its lower layers such relics of marine life. It was objected by advocates of the submergence hypothesis that even if the ice could pick up such shells it would inevitably grind them to powder. This objection has been met by Garwood and Gregory's discovery of perfect shells on the surface of the Ivory glacier in Spitzbergen at a higher elevation than the raised beach from which the glacier had rifled them. Later, Lamplugh and others have described the moraine of the Sefstrom glacier, also in Spitzbergen, in which vast numbers of marine shells in perfect condition have been thrust out of the fjord entangled in boulder-clay. Another way in which marine organisms can be uplifted has been described by Debenham. He found on the surface of two of the antarctic glaciers which are partially afloat marine muds with delicate organisms. He attributed their occurrence to the freezing of the glacier on to the sea floor, and melting at its upper surface causing the gradual emergence of the entangled mud

Glacial Epochs in Older Geological Periods. — It was once the general opinion (shared by the present writer) that the Pleistocene Ice age was a unique episode in the history of the earth, but so long ago as 1848 Cumming, in his *Geology of the Isle of Man*, surmised on very insufficient evidence that the Basement Conglomerate of the Carboniferous might be of glacial origin. A few years later Ramsay (1855) made a similar suggestion regarding conglomerates of Permian age in the midlands. It was probably as hazardous a speculation as Cumming's, but, by a strange coincidence, within four years, a true glacial Till of nearly equivalent geological age was discovered by the Blandfords in India. Shortly after this Sutherland (1870) described an ancient boulder-clay in Natal of Permo-Carboniferous age, and Stow followed in the same year with a fuller account. Thus on two continents deposits of approximately the same geological date were found to bear evidence of glacial origin; not only this, but in both countries the beds were associated with others containing a new and strange flora of ferns *(Glossopteris)* of types not recognized in European rocks of the same age. The glacial deposits of South Africa have now been traced over an area of many thousands of square miles and in places may be seen to rest on true *roches moutonnées,* as for example at the junction of the Vaal and Orange rivers. Similar deposits have been recognized in Australia, with some doubt in New Zealand, Tasmania, the Falkland Islands, Brazil, Bolivia and the Argentine, in most cases accompanied by *Glossopteris.*

Some doubt attaches to the geological age of Tillites (the name given to the ancient indurated boulder-clays) in localities in North America, *e.g.,* Alaska, Nova Scotia and Prince Edward's island. At Squantum near Boston (U.S.A.), however, though some doubt exists as to geological age, the deposit is avouched by Coleman to be a typical ancient boulder-clay. After eliminating all doubtful records there remains a body of unchallengeable evidence of glaciation in Permo-Carboniferous times on a scale even vaster than that of the Pleistocene period, extending over enormous areas, and approaching in Africa, India, Australia and Brazil so near to the present position of the Equator as to constitute a most baffling problem and which finds at present only partial solution in the speculations of Wegener.

Glacial deposits have now been recognized in rocks of many geological ages from the indubitable Tillites of the pre-Cambrian rocks of Canada and India to the great glacial series of Cambrian age in South Australia and the Silurian Tillites of Alaska. No authentic signs of glacial conditions can be recognized in the Devonian rocks; the Permo-Carboniferous have been mentioned above. Sporadic signs of glacial conditions have been recognized in rocks of Mesozoic and Cainozoic age, but nothing that could bear comparison with the earlier or with Pleistocene Ice ages.

The Quaternary Ice Age. — The traces of a great ice-sheet in Europe having its radiant point, not, as might be expected a *priori,* on the mountains of the Jotunheim but in the low grounds at the head of the Gulf of Bothnia, are to be found over an area of about two million square miles. It spread across northern Russia as far as the Urals and a sinuous margin passes across to the Carpathians, with two great lobes descending the valleys of the Don and the Dnieper. In its further course it abutted against the opposing slopes of the Riesengebirge, Thüringer Wald and Harz and covered the north German plain. The edge in Holland is marked by a low moraine ridge charged with erratics. Its extension in the southern part of the North sea is largely conjectural, but it must have coalesced with native British streams that invaded the eastern and midland counties at one time, leaving deposits spread over part of the London area and traceable thence into Buckinghamshire, Oxfordshire' and Warwickshire. Along its western margin it influenced the flow of ice-streams pouring off the mountain and hill centres of the British Isles, though it is doubtful if it actually invaded Britain, saving perhaps parts of Lincolnshire and East Anglia.

A second great ice-sheet was constituted by the glaciers of the Alps, which spread in all directions, filling the great valleys and debouching on the plains. The whole area between the Alps and the Jura was filled with ice which left its deposits and erratics at high levels upon the confronting slope, in a few instances thrusting lobes through the passes. To the south it invaded the plains of Lombardy, excavated, as some would say, the great Italian lake-basins, and cast down the colossal moraines of the Dora Baltea and Dora Riparia. The lesser mountain chains of Europe had their own glacier systems, and great extensions of the glaciers of the Himalayas and probably every other mountain chain of Asia have been recognized. It is of interest to note that the famous cedars of Lebanon are growing on morainic material.

In North America three ice-sheets have been identified. The Labradorean on the north-east had its centre, or radiant point, in northern Quebec, whence it spread in every direction. Its southerly flow covered most of eastern Canada and reached as far as New York and Cincinnati. The Keewatin sheet, radiating from relatively low ground to the west of Hudson bay, expanded in all directions so as to come on the one hand into confluence with the Labradorean sheet and on the other to meet the third sheet. The Cordilleran diverges from an axis west of the Rocky mountains, and when it was at its full development lobes were thrust through some of the passes and may have come in contact with the Keewatin ice. In a south-westerly direction it reached Vancouver island and Queen Charlotte's islands and the Pacific ocean. Three hundred miles within the lobate front of the

Keewatin-Labradorean sheet lies the Driftless area of Wisconsin —an area several hundred miles in extent left untouched between the two sheets. These three ice-sheets are computed to have covered an area of 4,000,000 sq. miles. Besides extensions of glaciers from some of the other mountainous centres of North America, Greenland was at some stage of the glacial period covered with ice to a greater extent than at present, and contributed with other areas of arctic America to a total of ice-covered land in the Old and New World of the Northern Hemisphere of about 8,000,000 sq. miles.

In the Southern Hemisphere evidence exists of a greater development of glaciers than at the present time. Thus in Australia, New Zealand and Tasmania, glaciers extended much below existing limits, in some cases, and in others to areas where no glaciers are now found. In British East Africa Gregory found moraines 5,400 ft. below the present limits. In South America the same facts of greater glacier extension are disclosed. It must be observed, however, that no proof has yet been adduced that the glaciers of the Southern Hemisphere were at a maximum simultaneously with those of the Northern Hemisphere, and it would be in agreement with some speculations regarding the cause of Ice ages if the northern and southern glaciations were alternate. Nor does it follow that temperature is the only factor governing the growth of glaciers; on the contrary the pole of greatest cold in the Northern Hemisphere, near Verkojansk, has no perennial snow though the subsoil is frozen probably to a depth exceeding 700 ft. as at Irkutsk.

CLASSIFICATION

Correlation **of** the Glacial Deposits.—The question of succession of glacial deposits in such a country as Great Britain has presented a problem of great complexity: not only is there great lithological diversity, but the deposition has been governed so largely by local conditions of relief and drainage that, even now, after the deposits over the greater part of the country have been carefully mapped by the official surveyors, correlation between, *e.g.,* Lancashirc and Norfolk has hardly been attempted. One contributory cause has been the fact that the ice-streams have, in the cases chosen for illustration, come from widely separated sources and nowhere come into unmistakable contact. The presence of organic remains can be used only after careful elimination of such as are *remaniés* (*i.e.,* mere erratics) and when this is done their testimony is still equivocal. For some purposes the provenance of the erratics characterizing the respective deposits may be utilized.

James Geikie in the 2nd edition of his Great Ice Age (1877) was probably the first geologist to attempt a general classification of British deposits and their correlation with those of the Continent, but his views were largely coloured by Croll's splendid exposition of an astronomical theory of the Ice age with its necessary implication of glacial alternating with interglacial periods, and, further, by the doctrine of the great submergence which then dominated British geology, and to which he appeared to have adhered with some modification to the end. Geikie was content, in the work cited, to specify one composite "Great succession of Glacial and Interglacial periods," a "Last Interglacial period," and "Last Glacial period," but in his last publication he differentiated the following:

6th Glacial epoch, Upper Turbarian, indicated by the deposits of peat which underlie the lower raised beaches.

5th Interglacial epoch, Upper *Forestian.*

5th Glacial epoch, Lower Turbarian, indicated by peat deposits overlying the lower forest-bed, by the raised beaches and carse-clays of Scotland, and in part by the Littorim-clays of Scandinavia.

4th *Interglacial* epoch, Lower *Forestian,* the lower forests under peat beds, the Ancylus-beds of the great freshwater Baltic lake and the *Littorina*-clays of Scandinavia.

4th Glacial epoch, Mecklenburgian, represented by the moraines of the last great Baltic glacier, which reach their southern limit in Mecklenburg; the 100 ft. terrace of Scotland and the *Yoldia*-beds of Scandinavia.

3rd Interglacial epoch, *Neudeckian,* intercalations of marine and freshwater deposits in the boulder-clays of the southern Baltic coasts.

3rd Glacial epoch, Polandian, glacial and fluvio-glacial formations of the minor Scandinavian ice-sheet; and the "upper boulder-clay" of northern and western Europe.

2nd Interglacial epoch, Helvetian, interglacial beds of Britain and lignites of Switzerland.

2nd Glacial epoch, Saxonian, deposits of the period of maximum glaciation when the northern ice-sheet reached the low ground of Saxony, and the Alpine glaciers formed the outermost moraines.

1st *Interglacial epoch,* Norfolkian, the forest-bed series of Norfolk.

1st Glacial epoch, Scanian, represented only in the south of Sweden, which was overridden by a large Baltic glacier. The Chillesford clay and Weybourne crag of Norfolk and the oldest moraines and fluvio-glacial gravels of the Arctic lands may belong to this epoch.

This classification was subjected to a searching criticism by Lamplugh in 1906. He pointed out that by the method adopted, except as regards the uppermost members, the sequence involved a continual change of locus—thus, for relics of the 1st Giaciai epoch it was necessary to go to Sweden, where no trace of the Norfolkian 1st Interglacial epoch, is found, and so on through the series. Lamplugh could further quote geologists of each country in turn who disclaimed belief in the order or position in the sequence of each member. He ascribed the assumed sequences to the temporary oscillations of an ice-sheet, but disputed the suggestion of complete, or even of considerable, deglaciation. It may also be remarked that differences of alimentation of different portions of an ice-sheet having an area of 2,000,000 sq.m. must have caused large fluctuations in the extension of the ice. Charlesworth has shown in a recent discussion of the glaciation of the northwest of Ireland how variations of pressure brought first one then another of contending ice-streams over the same spot. Geikie's 4th Interglacial, 5th Glacial, 5th Interglacial and 6th Glacial stages are all based on variations in the plant constituents of the peat beds of Scotland and the north of England, and whatever may be the value of this evidence it would seem quite inadequate to sustain the burden of two glacial and two interglacial epochs, which, if Croll's astronomical theory of the Ice age were accepted, would comprise in all four periods of 10,500 years each. The beautiful methods of de Geer, to be mentioned later, give an approximation to an actual chronology of the time, in years, that has elapsed since the Yoldia beds of Scandinavia were laid down. It is 12,500 years and into that brief space must be crowded Geikie's four climatic phases, as well as the first 18 centuries of the present era, which can hardly be regarded as part of the 6th Glacial epoch, and will therefore constitute a "6th Interglacial epoch."

Benck and **Brückner's** Classification.—A classification which, unlike Geikie's, has the merit of a more limited range of locality, and of being based on the observations of a pair of geologists working in concert, is that of Penck and Bruckner (*Die Alpen* im *Eiszeitalter*). To accord with the stratigraphical succession their table is inverted—the oldest at the bottom:

Daun Stadium, snowline 300 metres lower than at present.

Geschnitz Stadium, snowline 600m. lower than at present.

Buhl Stadium, snowline 900m. lower than at present.

4th Würm Glaciation (divided by Achen interstadial), snowline 1,200m. lower than at present.

Riss-Würm Interglacial, brief period warmer than at present.

3rd Riss Glaciation, maximum glaciation of France, Switzerland, Po and Rhine valley, snowline about 1,300m. below present.

Mindel-Riss Interglacial, period of uplift, very long duration.

2nd Mindel Glaciation, maximum glaciation of eastern, north-eastern and south-eastern Alps, snowline 1,300m. below present.

Günz-Mindel Interglacial, doubtful.

1st Günz Glaciation, not well represented—snowline probably 1,200 m. lower than at present.

There are here four recognized glacial periods, and, with some doubt, three, or with the Achen interstadial dividing the Wünz period, four interglacial. This classification, though designed only for the Alpine region, has been applied by many geologists to

other districts, or even continents, and with some degree of probability has been adopted as a standard to which other classifications are made to conform.

British Glacial Deposits.—These have not been reduced to a general scheme of classification and the reason for the failure is clear: instead of the comparatively simple advances and retreats of a single ice-front, the British glaciation was effected by a number of ice-streams of moderate magnitude originating, some in one hill or mountain centre, and some in another, and influenced by reason of their relatively small size and mutual interference and by minor features of relief. Added to their internecine conflicts there was at all times the influence of the Scandinavian ice-sheet to obstruct free access to the coasts of the North sea, and to shift the lines of ice-flow to more westerly courses.

In the basin of the Irish sea only two boulder-clays separated by "Middle sands" are commonly observed, except where an oscillating ice-margin abutted on the hills, when the boulder-clays may interdigitate with many repetitions of sands and gravels due probably to the sorting action of water near the melting edge, or to the intercalation of hill-wash.

In Yorkshire, while inland there are an older and newer boulder-clay, never seen either in superposition, or even in the same district, on the coast three, or possibly four, boulder-clays can be identified, not only by the test of superposition, but by characteristics of colour and the assemblages of the far transported erratics which they contain. In ascending or chronological order they are: (1) Basement clay; (2) Purple clay, sometimes in two divisions separated by sands and gravels; (3) Hessle clay. The first of these is a leaden-coloured clay with occasional included patches of sea-bottom. It contains a few Scandinavian rocks, and rocks from the Lake District and the Pennine chain. The Purple clay is characterized by a redder colour and by the presence of numerous large blocks of Shap granite and Carboniferous limestones. The Hessle clay is by far the best characterized, as it contains in great profusion rocks from the Tweed valley and the Cheviots. Between the Purple clay and the Hessle clay, that normally succeeds it, there is found at one locality in Lincolnshire at an elevation of about 80ft. above sea-level a bed of estuarine silt with marsh plants and brackish-water shells. This is the only "interglacial" bed in Britain that is beyond challenge.

The ice of the Hessle-clay phase at its maximum failed to cross the Cleveland hills, but the comparative obstruction of its movements in the North sea, by the opposition of the Scandinavian ice-sheet, deflected much of its flow into the Vale of York and a great moraine at Escrick, 5m. S. of the city of York, seems to mark its utmost extension. Beyond that line scattered shreds of a much older, greatly denuded, boulder-clay are found. The contrast between the two glaciations is very striking and the difference between the sharp and well-preserved topography of the later (Hessle) and the almost complete obliteration of that produced by the earlier glaciation gives a measure of their relative ages. The same contrast will be seen in America.

American Glacial Deposits.—The glacial deposits of North America, like those of Europe, increase in complexity as the distance from the ice-radiants increases. This might be attributed, either to the fact that though the ice front retreated it never wholly disappeared; or that, though it might entirely disappear, any traces of interglacial conditions would be less likely to be preserved beneath a new ice-sheet. Both opinions are held by American geologists.

The most complete succession of deposits is naturally to be found in the peripheral areas and the classification of deposits in the Mississippi valley is as follows:

	Illinoian Till Sheet.
Wisconsin Till Sheet.	Sangamon Interglacial.
Peorian Interglacial.	
	Kansan Till Sheet.
Iowan Till Sheet.	Aftonian Interglacial.
Yarmouth Interglacial.	
	Nebraskan Till Sheet.

The Nebraskan Till and Aftonian Interglacial are not admitted by all American geologists. Each Till sheet overlaps its predecessor from north to south, but the Kansan is considered to have been laid down by the Keewatin ice, which was confined to the states on the western side of the Driftless area of Wisconsin, viz., Nebraska, Iowa, Kansas and Missouri, and to have retreated in a northerly direction, before the advance of the Labradorean ice, which in parts of Illinois and Wisconsin overrode the Kansan drift. Between these two sheets of Till, beds of peat and other subaerial deposits are traceable over an area indicating an advance of the Labradorean ice for not less than 150 years over the country laid bare by the Kansan retreat. The Iowan marks a re-advance of the Keewatin ice but its relations to the Labrador ice is not definitely settled. The so-called Iowan Till is in some places separated from the Illinoian by a terrestrial surface upon the weathered Illinoian Till, of which the Iowan is by some considered to be an upper division. The Wisconsin Till, whether a single sheet or in two stages is still uncertain, is underlain by a weathered terrestrial surface in many sections.

It is evident that many and extensive fluctuations of the ice-margins must have taken place but there is no means of deciding whether this amounted to a complete deglaciation or only a partial shrinkage. Coleman has described sections near Toronto, discovered by Hinde, which give support to the supposition of complete disappearance of the ice, or at least its withdrawal from the area of the Great Lakes and subsequent re-advance in great force. At the Scarboro Heights sections show three beds of boulder-clay separated by sedimentary beds. Fossiliferous silts intervening between the older boulder-clay and the next have yielded a large suite of freshwater shells, and an abundant flora comprising many timber-trees such as oaks, elms and maples, some of which are now extinct, while others are limited to latitudes four or five degrees south of Toronto. It is unfortunate that the associated boulder-clays cannot be referred to equivalents south of the Great Lakes. Coleman is of the opinion that these deposits are unmistakable evidence of, at the least, one complete removal of the ice from the Labradorean centre.

Methods of Correlation.—The question may now be approached: In what way may the glacial succession in discontinuous areas be correlated, *e.g.*, can the glacial deposits of Britain be equated with those studies in the Alpine field by Penck and Brückner, on the one hand, and those of America on the other? The answer of most geologists would, probably, be yes; and Sollas, Wright, Brooks and Osborne, to name a few authors, have made the attempt, though not always on exactly the same bases. The method most generally adopted has been to take the Alpine succession of Penck and Brückner with its several stages of glaciation and deglaciation and to place in parallelism the sequence observed in other areas. This process receives support from the consideration that if these large scale advances and recessions are due to other than merely local causes, other areas must have been similarly affected. There are, however, defects arising from the fact that each advance of the ice may not extend as far as its immediate, or any predecessor, and consequently in a peripheral region, such for example as the east of England, though it may show a corresponding number of fluctuations, they may not record the same episodes as those recognizable in areas nearer to the source of the ice. When the comparison is between Europe and America the meteorological arguments advanced by Harmer to show that these two continents could not have been simultaneously glaciated must also be considered.

The use of biological and anthropological data stands on a different footing from these and is, in fact, the application of the geological test of "characteristic fossils." It is in many ways more trustworthy, though it too has its limitations, for latitude and the distribution of land and sea no less than the character of the vegetation and conditions of the terrain, have had their influence upon the distribution of the Pleistocene mammalia which are adopted as criteria of age. Some of the same factors must also have operated to control the dispersal of early man. To cite but a single instance—Magdalenian man who hunted the reindeer in southern Europe during the closing stages of the Ice age is represented to-day by the Eskimo.

Using the two classes of evidence separately, or conjointly where possible, a sequence of human culture and in some cases of race, can be correlated with the contemporary mammalian fauna and these in turn with the more or less direct products of the ice, or of the deglaciated land, and with deposits of rivers outside the glaciated areas.

Culture Stages.—The culture stages that are of most value for this purpose are—the oldest being at the bottom of the table:

(Mayet, 1919)	Neolithic Azilian
(Glaciation, neo Würmian)	Magdalenian (late)
Postglacial	Magdalenian
(Fourth period of regression of glaciers)	Magdalenian (early) Solutrian Aurignacian (late)
IV. Glaciation of Würm	Aurignacian
(Fourth period of extension of glaciers)	Aurignacian (early) Mousterian (late)
Third Interglaciation Riss-Würm	Mousterian
(Third period of regression of glaciers)	Mousterian (early) Close of Acheulian
III. Glaciation of Riss	Acheulian
(Third period of extension of glaciers)	Close of Chellean
Second Interglaciation Mindel Kiss	Chellean
(Second period of regression of glaciers)	pre-Chellean?
II. Glaciation of Mindel	
(First Interglaciation Gunz Mindel)	
I. Glaciation of Günz	

Minor modifications have been proposed by Obermaier, Boule and others. It will be seen from the table that Mayet would refer relics of Chellean man to a warm period anterior to the Riss glaciation. The Acheulian he includes in the Riss glacial stage but with an overlap into the milder Riss-Wiirm interglacial when it linked on to the Mousterian, which in its turn extended in its latest stages into the Würm glacial stage, and that embracing the greater part of the Aurignacian, though the latest Aurignacian overlapped into a fourth period of glacial retreat which covered the Solutrian, and a part of the Magdalenian. The main Magdalenian period, however, was marked by a recrudescence of glaciation that Mayet styles the Neo Wiirmian.

A mere enumeration of the mammalia associated with these stages of culture would furnish an imperfect basis for classification of the deposits apart from the implements and weapons of man, but one decisive contrast is afforded between the Chellean and later faunas, viz., the presence in Chellean deposits of the straight-tusked elephant (*Elephas antiquus)* which does not occur in Acheulian or later deposits being replaced by the mammoth *(E. primigenius*) which survived in Europe till the close of the Magdalenian period. Similarly the soft-nosed rhinoceros *(R. leptorhinus*) gives place to the woolly rhinoceros *(R. tichorhinus).* A hippopotamus closely related to the existing Nilotic species is characteristic of Chellean deposits in this country. The Chellean fauna has a distinctly warm aspect and it furnishes perhaps the best indication of geological age of any of the Pleistocene faunas.

It is fortunate that where the cultural criteria are lacking, the mammalian evidence may fix the age of deposits and vice versa: thus the mammalian remains are the sole evidences in the north of England, while in the south many river-terraces, though lacking the mammalia, rarely fail to reward prolonged search for implements. The terraces of rivers in the country beyond the glaciated area can be brought into relation with the phases of the Ice age by these means.

Evidence of Laminated Muds.—These criteria, valuable as they are in Europe, are entirely without application to the problem of correlating European and North American deposits, but there is a sanguine hope entertained by some geologists that a part at least of the difficulty may be removed by using an entirely different class of evidence. Allusion has been made to deposits of laminated mud thrown down from the turbid melt-waters of glaciers and ice-sheets, and to the rhythmical succession of layers corresponding to the diurnal or annual melting. These muds or "varves" have proved a means—thanks to de Geer—of establishing a chronology in terms of years for the closing stages of the Ice age when the great Scandinavian ice-sheet was shrinking back to its source in the mountains. The melting-edge retreated stage by stage across southern Sweden, which was then covered by sea, with occasional halts marked by terminal moraines. De Geer argued that each pair of laminae—a dark and a light—would represent a season of melting and of cessation. By careful measurement of the layers and their representation as a graph it was possible to recognize sequences many miles apart. When a moraine intervened between the sections the duration of the halt could be discovered by noting the number of layers which were lacking on the inner side of the moraine. De Geer with the assistance of a willing corps of helpers traversed the whole country from the extreme south of Scania to the place where the ice-sheet broke up into a detail of smaller glaciers. The drainage of Lake Ragunda exposed a series of muds that completed the series down to the year 1796. This beautiful demonstration, which has been endorsed by all who have examined the evidence gives a definite chronology for the retreat of the ice from the first uncovering of the site of Stockholm, viz., 9,000 years. De Geer and his followers believe they can recognize the same sequence of layers not only in Iceland, but also in North America. If this is established it will dispose finally of the idea of alternate glaciations on opposite sides of the Atlantic, and the close general agreement between this measurement and the calculations based upon the recession of the Falls of Niagara seems to show that there is no grave error.

CAUSE OF THE ICE AGE

The special instance of the cause of the Ice age is but a special aspect of the general question of climates in geological time—genial conditions as well as frigid—and it is possible that the explanation, whatever it may be, has not yet been formulated though speculation has engaged the minds of astronomers, geologists and meteorologists for more than a century. W. B. Wright has discussed with great perspicuity a number of proposals and his work (*The Quaternary Ice Age)* and *C. E.* P. Brooks' *Evolution of Climate* must be consulted by all interested in the question.

The causes suggested by various authors arranged themselves roughly in the two categories of Astronomical and Telluric. Disregarding the chronological order of their enunciation there is convenience in considering, if only to dismiss, one or two of the first. One cause suggested was the variation of solar radiation. The sun has been considered to be a variable star, and the 11-year Sun-spot period gives some countenance to this as a possible cause of variation of the intensity of solar radiation of longer period, but as it is unsupported by definite evidence it cannot be fruitfully discussed. Another explanation is based on the supposition that there are cold regions in space; this cause, however, is manifestly insufficient; the amount of radiant heat received from star-shine is entirely inadequate to produce an appreciable change in the climate of the earth. A third is based on changes in the position of the earth's axis of rotation. Sir G. H. Darwin has examined this question and on the hypothesis of an absolutely rigid earth he concluded that the maximum displacement possible was 3°, but on the assumption of some degree of plasticity it was possible for the pole to wander 10° to 15°, an amount disproportionate to the observed climatic effects.

The Astronomical Theory.—The theory that now holds the field owed its inception to Herschel's *Outlines* of *Astroitomy* and is based upon the fact that the form of the earth's orbit varies in the degree of its departure from a circle. When the eccentricity is at a maximum, the effect of the precession of the equinoxes will be to give each hemisphere in turn for a period of 10,500 years a short hot summer and a long cold winter; and this will be followed by another equal period of long mild summers and short winters of moderate intensity. Sir Robert

Ball puts the contrasts in this way: the year will be unequally divided into seasons of 166 days and 199 days respectively, but the solar radiation will be in the ratios 63:37. He puts the results as follows:

Glacial	229	heat measures spread over 166 days.
	136	heat measures spread over 199 days.
Interglacial	229	heat measures spread over 199 days.
	136	heat measures spread over 166 days.

E. P. Culverwell exposes the fallacy of taking an entire hemisphere as a unit, and presents the maximum effects of winter in Aphelion at maximum eccentricity by comparing latitudes which at present receive a corresponding amount of sun-heat. A single illustration will suffice: Oxford, under the extremest conditions, would receive the same amount of sun-heat as Edinburgh receives now. A further objection to the astronomical theory consists in the fact that for each glacial and each interglacial period it provides only 10,500 years, which is certainly inadequate for the growth of an ice-sheet which shall extend from the Gulf of Bothnia to Norfolk—a distance of about 1,400 miles. Croll, who first elaborated Herschel's proposition, admitted the insufficiency of the hypothesis which would not diminish the total amount of sun-heat received annually by the hemisphere having its winter in Aphelion, and proposed several ways in which the effects of winter cold could be accentuated by fogs generated in summer over the snowfields by the chilling of moisture-laden winds. It is true that fogs do occur in the Arctic regions but, as has been pointed out by Wright, the heat thereby liberated raises the temperature of the snow and thus tends to neutralize the argument. Wallace, however, made the valuable suggestion that heat cannot be stored in the same way that cold in the form of snow can be stored, and that a snow field or ice-sheet tends to perpetuate itself and so to carry over the effects from one precessional period to another though with fluctuations of the margins.

Croll and others have attempted to explain the Ice age or to supplement Croll's argument by modification of ocean currents, especially by the severance of the Isthmus of Panama, whereby the Gulf Stream would be deflected into the Pacific. To this hypothesis many objections can be urged, one of them quite fundamental, viz., that while it is true that the lowest part of the ridge dividing the two oceans is only 154ft. high, there is no evidence that it has ever been submerged since the Miocene period; on the contrary, the existing marine faunas of the two shores are so different as to indicate that there can have been no communication since about the middle of the Tertiary period. J. W. Gregory concludes that there is "no evidence, afforded either by stratigraphy or zoology, to show that the Atlantic and Pacific oceans have been united across Central America in post-Miocene times." Even if a free communication had existed during the Glacial period it could have affected only that part of the Gulf Stream which emerges through the Straits of Florida, and not the equally important part which sweeps outside the Antilles.

Another agency invoked to reinforce Croll's argument was that the chilling of high latitudes in the Northern Hemisphere would increase the strength of the northern trade winds and cause a general displacement to the south of the equatorial current which feeds the Gulf Stream, whereby less warm water would pass into the north Atlantic circulation. This and other expedients seem necessary to supplement the astronomical theory, and when all is said, there remain strong grounds for doubting its sufficiency.

Telluric Causes.—Turning now to telluric causes—geographical and other—the first and simplest is the suggestion of Arrhenius that a decrease in the amount of carbonic dioxide in the atmosphere would cause a fall of temperature sufficient to produce a glacial period. Chamberlin has with a wealth of geological detail elaborated this hypothesis, but Angstrom has shown that the quantity of CO_2 now present in the atmosphere absorbs all the radiations the gas is capable of intercepting.

Two hypotheses have been advanced having this in common that both would invoke elevation of the land as the primary cause of the Ice age, but they differ in that one would require epeirogenic uplift, *i.e.*, uplift on a continental scale, while the other would find more local elevation sufficient. It is generally admitted that the chilling effect of altitude, other things being equal, will induce the formation of snow fields and glaciers so that no question of adequacy need be raised, and discussion is confined to that of evidence. Both explanations derive some support from the existence of submarine prolongations of fjords or river valleys extending to great depths across the continental shelf. They have been recognized on many coasts not only in high latitudes, as off the coast of Norway, but at the mouth of the Adour, and at the entrance to the Straits of Gibraltar. Similar features characterize the west coast of Africa where a submerged groove of great depth prolongs the course of the Congo. The Lightning channel, between the Faeroes and Iceland, furnishes another example and the whole Atlantic coast of North America from Labrador to the Gulf of Mexico, typically illustrated by the submerged troughs of the Delaware and Hudson traceable to a depth of 3,500ft., have been cited as evidence of an uplift to nearly that amount in glacial times. No proof has been produced connecting this uplift, if it ever occurred, with the date of the Ice age, and Dana and other geologists have referred the erosion of these valleys to the Mesozoic period. The occurrence of dead shells of shallow water Mollusca over wide areas of sea-floor off the west coast of Norway down to 2,600 metres has been regarded by Nansen as proving an uplift of, at the least 8,000ft., but the facts would bear a quite different construction and may be interpreted as evidence of transport by floating ice.

Pre-glacial Land Levels.—It is useful in this connection to examine the evidence of preglacial land levels, and the records of events preceding the first indications of ice-action in the British Islands. Wright remarks that throughout the southern half of the British isles and the north of France the level of the sea in pre-glacial times was practically the same as at the present day. The shallow North sea, the English Channel, the Irish sea and many of the minor indentations, such as the Clyde and the Moray firth, existed then, much as they are to-day. A pre-glacial cliff with, in some instances, a beach at the foot, can be traced at intervals from Flamborough head southward to both sides of the Straits of Dover and along the south coast of England far up the coast of Wales, and along the south of Ireland. The Flamborough section is of particular importance, for on the beach which lies at its foot, a few erratics have been found, showing that some transport, perhaps by floating ice, was already taking place. An extensive denuded plain of marine erosion, having about the same slope as the existing sea floor, fronts the beach, and is traceable almost to the Wash. The sea, however, withdrew from the beach, which then became covered with landwash and blown sand, containing mammalian remains including hippopotamus, and *Elephas antiquus,* animals very characteristic, as already remarked, of the Chellean stage. After an interval, so brief that little or no erosion of the cliff took place, the whole was buried beneath the oldest of the three or four boulder-clays of the Yorkshire coast region. At the other side of the headland, a deposit with estuarine shells underlies the boulder-clay.

Before its full significance can be discussed, however, it is necessary to make a cast back to the immediately preceding geological period, the Pliocene. Of this period the geological record in the southern part of the North sea is singularly complete. It opens with the Coralline crag a rather shallow water accumulation containing a fauna bearing a strong resemblance to that found at present on the coast of Spain and in the Mediterranean, but with a large infusion of elements at present found in the British sea and a very few forms now restricted to higher latitudes. Indications of floating ice are not wholly wanting. A slight upheaval brought this deposit above the sea, but it was again depressed to receive the Red crag, a series of beach or inshore deposits forming a succession of beaches of a sea that retreated from south to north. The oldest of these deposits is at Walton-on-the-Naze where it occupies a position about 40ft. above sea-level. The newest is near Aldeburgh. In this series can be readily recognized the gradual substitution of a fauna very near to that of the Coralline crag, with its marked southern affinities, by one in which, along with many of the shells now found in the British seas, there is a large infusion of shells of high northern and some

even of Arctic range. During all this period the delta of the Rhine on the opposite coast in Holland and Belgium was steadily sinking. Harmer has argued that the profusion of shells found in the beaches of the Red crag and the comparative scarcity on the east was the result of prevalent on shore easterly winds, and as an indication "that the climate of regions to the north of Great Britain had . . . by that time become considerably colder than now, and therefore frequently anticyclonic in winter, an ice-sheet having permanently established itself on the Scandinavian highlands."

The further Pliocene history of the North sea is a story of steadily accentuating cold, subject to the qualification that a freshwater bed, the Forest bed proper, brings an anomalous warm flora and fauna into the midst of a series in which plants and animals alike bespeak a climate of great severity.

The next member of the sequence on the coast of Norfolk is the Cromer Till,—a mass of boulder-clay of pronounced type, containing, *inter alia,* erratics from the Oslo district of Norway. This Pliocene and Early Pleistocene record of progressive and apparently uninterrupted refrigeration is a fact which seems to refute decisively the hypothesis that the glaciation was caused by continental uplift, and equally opposes the view that it was the effect of those astronomical causes invoked by Croll. The duration of Pliocene time must have greatly exceeded the possible duration of any progressive change of climate postulated by the theory.

Continental Uplift.—The hypothesis of continental uplift has received a new impulse in recent years by the recognition by La Mothe and Depéret of four successive raised beaches and river terraces at altitudes ranging from 300ft. down to about 60ft. above the respective present levels of the Mediterranean, and the rivers discharging into it. The lower three of these have been considered to correspond with the last three interglacial episodes, but geological opinion is sharply divided as to the connection.

It is to be deprecated that in allusion to the events of the Ice-age or to discoveries connected with the successive stages of primitive cultures free use is made of time scales for which little justification exists. The only definite measure at present available is that of de Geer and the various estimates of the age of the Falls of Niagara which give measures so far accordant as to make it fairly safe to assume that the glaciation of North America and Northern Europe was simultaneous. The hypothesis that would explain the great extensions of glaciers in almost every mountain centre in the world in recent geological time by supposing them to have been uplifted so as to produce a lowering of the snow line involves a series of coincidences not easy of acceptance, especially when synchronized in their advances and retreats.

The final disappearance of the ice-sheets of northern Europe and North America was attended by a rise of the centres whence they respectively emanated. The Scandinavian region, as is shown by raised beaches which on all the coasts show a steady increase of elevation as they are traced up the fjords, has risen since the departure of the ice to a maximum of over 800ft. which is attained, as according to the doctrine of isostasy it should be, not at the mountainous axis of the Scandinavian peninsula, but just where by other evidence it was proved that the maximum weight of ice rested. Near the outer margin of the ice sheet Scotland had been pressed down to an extent proportional to the weight imposed, and the recovery recorded in raised beaches is correspondingly less, whereas Scandinavia has not yet completed its recovery.

In North America, the shrinking Labrador sheet gradually withdrew behind the watershed between the Mississippi and the St. Lawrence drainage basins, and great lakes came into existence between the watershed and the retreating ice front. The strand-lines or beaches rise towards the site of the ice-radiant in a manner analogous to the rise of the Scandinavian beaches. When the ice reached in its retreat to the north of Niagara the lake drainage fell over the steep escarpment and the famous Falls thus came into existence The gorge of Niagara, 7m. in length, was produced by the cutting back of the Falls and estimates of the lengths of time occupied in the operation have furnished a measure of the date of this stage of retreat, but many complications are introduced into the problem by the fact that at one stage an alternative route for much of the drainage was opened by way of the Mattawa, a tributary of the Ottawa river. There is a general agreement between the results obtained and those given by de Geer's measurements of the seasonal clays in Sweden. (P. F. K.)

GLACIER, a mass of compacted ice originating in a snow-field (French, *glace,* ice, Lat. *glacies).* Glaciers occur in those portions of the globe where the rate of precipitation is greater than the rate of melting of the snow. These conditions are fulfilled in high mountain tracts and in the Polar regions. The lower limit of a snow-field, above which the snow lies throughout the whole of the year, is known as the *snow-line.* The altitude of the snow-line, changes locally as well as at different latitudes, varying from 15,000 to 18,000 ft. in the tropics to sea level in the Polar regions. The main features of the type of glaciation of a region depend upon the topography, the geographical position and the elevation above sea level. Apart from the Polar ice-sheets, four distinct types of glaciation have been recognized:—the Alpine, Piedmont, Spitzbergen and Greenland types, but as many of the fundamental facts were first studied in regions where the Alpine type occurs, this will be described first.

Alpine Types.—In mountain regions snow accumulates on gentle slopes, in high mountain valleys, in hollows and depressions and on the summits of dome-like peaks. Owing to the weight of accumulated snow, the lower layers become compacted together into dense clear ice with a granular structure throughout. This is known as *névé* or *firn.* The ice thus formed is more or less stratified as the result of successive falls of snow and of melting between falls, and by the accumulation, between successive falls, of films of dust from the air or from the snow which has melted. Wind causes the drifting of the snow, produces a rippled surface on the névé and carries loose snow to lower altitudes. The névé is comparatively easy to cross on foot; very little debris cumbers its surface but concealed *crevasses* (cracks in the ice) are a source of danger. The most important crevasse in this part is the *bergschrund* which has the form of a great symmetrical arc at the head of the névé. It lies but a short distance from the exposed rock surface and the rock wall is exposed to disintegration by frost action, and the debris thus formed drops to the bottom of the crevasse. Frost action also affects all exposed rocks in these high mountain tracts, producing sharp pointed pinnacles (aiguilles), arêtes and precipitous crags, snow capped peaks being protected from frost action. The disintegrated rock falls downward and much of it finally comes to rest upon the edge of the névé where it forms a *moraine.*

Glaciers creep down the mountain side. The greatest movement naturally takes place in the summer when the average temperature is above freezing point. The rate of movement also depends upon the mass of snow and ice, the slope and smoothness of the valley floor and the slope of the upper surface of the ice. The rate and direction of movement can be determined by driving stakes into the ice which it is found does not move as one block but yields under the pressure of its own weight by cracking and regelation and moves slowly. The movement can be compared to that of a river, the greatest rates being in the centre, the upper layers and in restricted parts of its channel. Because of its higher rigidity, however, shearing of one mass upon another takes place producing foliation within the mass.

The character of the ice changes as it passes down to lower altitudes and at a point where in summer the melting is in excess of the precipitation, the granular ice appears beneath the snow. This point is taken as the lower limit of the névé and below it the valley glacier commences. It is known as the *firn-line* but it does not necessarily coincide in altitude with the snow-line on adjoining mountains. Below the *firn-line,* boulders and other debris occur on the surface of the ice. Some of the boulders sink to the bottom but flat varieties do not sink, they protect the ice beneath them from the rays of the sun, so that they remain perched (as *ice-tables)* on a column of ice as the surrounding ice is melted. Dust and small particles of rock absorb heat from the sun's rays quicker than does ice and therefore they melt

the ice beneath them and sink into shallow pits known as *dust-wells*, the action ceasing when the rays can no longer reach them. The moraines increase in size by the addition of material as they pass to lower altitudes. At the confluence of the main glacier with a tributary glacier, the two adjacent lateral moraines meet and pass into the middle of the lower combined glacier producing a *median moraine*. The lower reaches of a valley glacier may contain several median moraines. *Ground moraines* are formed by attrition along the bed of a glacier and they are augmented by debris falling down crevasses. At the lower end of a glacier the melting ice dumps a large portion of its rock burden in the form of mounds, generally crescent-shaped, across the valley producing a *terminal moraine*. (*See* MORAINE.)

Crevasses are more obvious in the valley glacier than in the névé. They are due to strain set up in the glacier by movement over an uneven surface, or round sharp bends or by differential movement due to other causes. They may be transverse or longitudinal and may be covered by fresh snow thus producing ice-bridges across them. When a glacier passes over a very steep slope the crevasses open wide and produce wedges and pinnacles of ice known as *seracs*. Frequently the slope may be so steep that the glacier breaks completely along the crevasses and the masses of ice fall to lower levels, where they are moulded again into a solid mass as a reconstructed or recemented glacier. Glaciers in hanging valleys and on cliff faces, which end in ice-falls are known as *glacierefs, hanging glaciers* or *cliff glaciers*. These names are also applied to accumulations of névé which are not large enough to produce a valley glacier. Water from surface melting and water which flows on to the glacier from the surrounding rocks forms lakes or surface streams on the glacier. Such lakes are not of a permanent character, the colour of the water in them is clear blue and they may lie partly upon the ice and partly upon the solid rock. Lakes frequently occur at the confluence of two surface streams. In the majority of cases surface water ultimately finds its way down a crevasse and so are initiated *en-glacial* and *sub-glacial streams*. These streams are laden with sediment. Some surface streams disappear down a *moulin*, which is a cylindrical hole through the ice, the position of which is often fairly permanent and in which the stream sets up a swirling motion so that it bores out a deep pot-hole, known as a *giant's kettle* (*q.v.*) in the rock beneath.

The lower end of a valley glacier may advance or retreat. This is regulated by a variety of factors, such as the amount of snow which falls in the catchment area, the rate of movement, and the rate of melting. Observations have been carried out for a number of years on various Alpine and other glaciers in order to obtain accurate information relative to the movement and attempts have been made to ascertain the relation that it bears to variations in meteorological conditions. It appears that in a period of between 35 and 40 years many glaciers pass through a cycle of advancing and retreating.

Glaciers which extend well down below the snow-line may affect to a considerable extent the drainage of the surrounding country. In such cases tributary streams may be dammed back to form lakes, *e.g.*, Lake Marjelen, and the level of the water may be high enough to cause the effluent to escape over a low lateral col, thus forming an *overflow channel*, the level of which may ultimately be lowered to permit the draining of the lake and so divert the stream. There is clear evidence of the existence of such lakes during and at the close of the Great Ice Age, and the effects of them are seen in the occurrence of overflow channels, lake terraces, permanently modified drainage and in hills of sands and gravels representing lacustrine deltas.

A large part of the morainic material carried by a glacier is dumped at its lower end, forming a terminal moraine. The streams which emerge are heavily laden with sediment, much of which is quickly unloaded forming debris strewn valleys and *outwash plains* or *frontal aprons*. Such deposits are rudely stratified and among them large depressions known as *kettles* sometimes occur and these probably mark the sites of large blocks of ice enclosed for a time in the debris. Sands and gravels from the effluent streams are deposited in the rear of the terminal moraines and form rounded mounds, elongated parallel to the direction of the valley. They are known as *drumlins*. Similar ridges transverse to the valley are termed *kames*. Drumlins and kames are more frequently associated with ice-sheets than valley glaciers, as also are *eskers, osars* and *serpentine kames*, which are long narrow ridges supposed to have been formed by deposition directly from en-glacial and sub-glacial streams. The water of effluent streams is dirty grey in colour, due to a large amount of clayey matter suspended in the water in a colloidal state.

Piedmont Type, etc.—The Piedmont type of glaciation is characteristic of Alaska and consists of great valley glaciers meeting to form a large sheet of nearly stagnant ice. The Malaspina glacier, 1,500 sq.m. in extent, is the best example of this type. It has an almost level surface covered with a great amount of debris, sufficient to support dense forests. There is approximate equilibrium between the supply of ice and the loss by melting. *The glaciation of Greenland* is very different. Here the greater part of the country is covered by an ice-sheet which slopes toward the coast at a very low angle. Valley glaciers occur only in the coastal regions where also rocky peaks, *nunataks*, project through the ice-sheet. Nunataks vary much in size, are sometimes covered by Arctic vegetation and are frequently fringed by crescent-shaped moraines, formed by the driving upward of the ground moraine. The latter is not so large as in the Alpine type of glaciation, for the greater part consists of material torn off from the rock surface beneath the ice-sheet. For long stretches along the coast the ice forms vertical or overhanging cliffs, known as *Chinese Wall fronts*, their steepness being due to the fact that the lower layers contain more debris and in consequence melt more quickly. The Greenland ice-cap, as well as the great Polar ice-caps, sends into the sea a large number of *icebergs* during the summer. These drift to lower latitudes and gradually disappear by melting. In *Spitzbergen* there is a central ice-cap on a high plateau, the sides of which are deeply trenched by radial valleys containing valley glaciers. Some of the latter have Chinese Wall fronts when they reach the sea, but others have normal "Alpine" fronts. In the former case the movement of the glacier is comparatively rapid. In some parts of the Himalayas, the glaciers are retreating as they are in North America.

Evidences of Past Glaciation.— As already pointed out, the topography and drainage of a region may be considerably modified by glaciation. Glaciers, assisted by frost action upon exposed rock surfaces, are important eroding agents, but authorities are not agreed upon the extent of such erosion. Cirques, with their steep walls and backward-graded floors, arêtes and pyramid-shaped mountain peaks can all be traced to the eroding action of frost: hanging valleys, U-shaped valleys, truncated spurs and steps in a valley floor to the deepening action of valley glaciers: roche moutonnées, rounded, striated, grooved and polished rock surfaces, and striated and polished erratics to the smoothing action of moving ice: and the scratching power of rocks frozen into the glacier: the occurrence of erratics and perched blocks to the transporting power of moving ice. Giant's kettles, overflow channels and old lake terraces (*e.g.*, the Parallel Roads of Glenroy) are evidences of water action associated with glaciers Boulder clay is the deposit left behind by a retreating ice sheet. Lateral and terminal moraines, with associated "kettles" are formed by the melting of a valley glacier: drumlins, kames and outwash plains by fluvio-glacial action: eskers, osars and serpentine kames by deposition by en-glacial and sub-glacial streams. Icebergs breaking away from the Polar ice-sheets transport material for a considerable distance. A large number of the lakes in higher latitudes are of glacial origin. (*See* LAKE.)

BIBLIOGRAPHY.—Among the older works the following must be mentioned: J. Tyndall, *The Glaciers of the Alps* (1896); T. G. Bonney, *Ice-Work, Past and Present* (1896); H. Hess, *Die Gletscher* (1904); in addition there are: W. H. Hobbs, *Characteristics of existing Glaciers* (1911); W. M. Davis, *The Sculpture of Mountains by Glaciers* (Scot. Geog. Mag. 1906); A. Penck and E. Bruckner, *Die Alpen im Eiszeitalter* (1909); W. B. Wright, *The Quarternary Ice Age* (1914); A. P. Coleman, *Ice Ages* (1926); the two latter books contain good bibliographies. In addition mention must be made of the descriptions of the expeditions to the Arctic and Antarctic regions within recent years

VARIOUS TYPES OF GLACIERS

1. Hailett **Glacier,** Rocky Mountain National Park, Colorado. Glacier of the Alpine type, showing lake
2. Monte Rosa Glacier from Gornergrat, Switzerland. The dark rock on the right is hundreds of feet in height
3. Crest of **Mount** Hood from the Eliot Glacier, Oregon. Below and to the left a portion of the glacier is visible
4. Mendenhall Glacier near Juneau, Alaska. This glacier is of the piedmont **type,** a large nearly stagnant ice sheet
5. La **Romanche** Glacier, Beagle Channel, Tierra del **Fuego,** at the southern extremity of South America
6. Upper **Rhône** Glacier near **Gletsch,** Switzerland. A valley glacier of the Alpine type with crevasses
7. Svartisen Glacier, Norway
8. Taku Glacier, south-eastern Alaska. Piedmont type
9. **Balmaceda** Glacier, Last Hope Sound, **Chile, South America.** Huge blocks of ice stand above the glacier's surface
10. **Tschierva** Glacier. View from **Alp** Ota, near **Pontresina,** Switzerland. Alpine type, showing valley formation
11. Franz Josef Glacier and Castle Rock. **Westland, South Island,** New **Zealand.** Crevasses and jagged ice formations show on the surface

GLACIER BAY NATIONAL MONUMENT, a reservation (1,820 sq m. in area) in south-eastern Alaska, extends inland from Glacier bay to include Muir and Brady glaciers and ice-covered peaks of the first rank, among which are Mts. Fairweather, Lituya, La Perouse and several others. Besides containing tidewater glaciers of first rank, the region is also valuable as a field of scientific study of glacier behaviour, of resulting movements and the development of flora and fauna after glacial retreat.

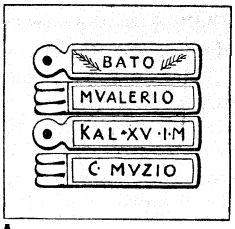
GLADBACH, the name of two towns in Germany distinguished as Bergisch-Gladbach and Munchen-Gladbach.

1. BERGISCH-GLADBACH is in Rhenish Prussia, 8 mi. N.E. of Cologne by rail. Pop. (1939) 22,132. It possesses four large paper-mills and among its other industries are percussion caps, nets, machinery, iron founding, and fire-clay. Ironstone, peat and lime are found in the vicinity. Near Gladbach is Altenberg, with a remarkably fine church, built for the Cistercian abbey at this place.

2. MÜNCHEN-GLADBACH, also in Rhenish Prussia, 16 mi. W.S.W. of Dusseldorf on the main line of railway to Aachen. Pop. (1885) 44,230; (1939) 127,115. Its industries are the spinning and weaving of cotton, the manufacture of silks, veivet, ribbon and damasks, and dyeing and bleaching. There are also tanneries, machine works and foundries. The beautiful minster has a Gothic choir (1250), a nave (early 13th cent.) and a crypt of the 8th century. The town is the headquarters of important insurance societies. A Benedictine monastery was founded near Gladbach in 793, and so it was called Munchen-Gladbach (Monks' Gladbach). The monastery was suppressed in 1802. It became a town in 1336 and came into the possession of Prussia in 1815. Its oil tanks, railway yards and airfield were frequent targets for British bombers in World War II.

GLADIATORS (from Lat. *gladius,* sword), professional combatants who fought to the death in Roman public shows. That this form of spectacle, which is almost peculiar to Rome and the Roman provinces, was originally borrowed from Etruria is shown by various indications. On an Etruscan tomb discovered at Tarquinii there is a representation of gladiatorial games; the slaves employed to carry off the dead bodies from the arena wore masks representing the Etruscan Charon; and we learn from Isidore of Seville (*Origines,* x.) that the name for a trainer of gladiators (*lanista*) is an Etruscan word meaning butcher or executioner. The older Roman name for the fighters was bustuarii.

The first gladiators are said, on the authority of Valerius Maximus (ii. 4. 7.), to have been exhibited at Rome in the Forum Boarium in 264 B.C. by Marcus and Decimus Brutus at the funeral of their father. On this occasion only three pairs fought, but the taste for these games spread rapidly, and the number of combatants grew apace. In 174 B.C. Titus Flamininus celebrated his father's obsequies by a three-days' fight, in which 74 gladiators took part. Julius Caesar engaged such extravagant numbers for his aedileship that his political opponents took fright and carried a decree of the senate imposing a certain limit of numbers, but notwithstanding this restriction he was able to exhibit no iess than 300 pairs. During the later days of the republic the gladiators were a constant element of danger to the public peace. The more turbulent spirits among the nobility had each his band of gladiators to act as a bodyguard, and the armed troops of Clodius, Milo and Catiline played the same part in Roman history as the armed retainers of the feudal barons or the condottieri of the Italian republics. Under the empire, notwithstanding sumptuary enactments, the passion for the arena steadily increased. Augustus, indeed, limited the shows to two a year, and forbade a praetor to exhibit more than 120 gladiators, yet allusions in Horace (Sat. ii. 3. 85) and Persius (vi. 48) show that 100 pairs was the fashionable number for private entertainments; and in the Marmor Ancyranum the emperor states that more than 10,000 men had fought during his reign. Claudius was devoted to this pastime, and would sit from morning till night in his chair of state, descending now and then to the arena to coax or force the reluctant gladiators to resume their bloody work. Under Nero senators and even well-born women appeared as combatants. Even the emperor Titus ordered a show which lasted 100 days; and Trajan, in celebration of his triumph over Decebalus, exhibited 5,000 pairs of gladiators. Domitian at the Saturnalia of A.D. 90 arranged a battle between dwarfs and women. Even women of high birth fought in the arena, and it was not till AD. zoo that the practice was forbidden by edict. How widely the taste for these sanguinary spectacles extended throughout the Roman provinces is attested by monuments, inscriptions and the remains of vast amphitheatres. From Britain to Syria there was not a town of any size that could not boast its arena and annual games. After Italy, Gaul, North Africa and Spain were most famous for their amphitheatres; and Greece was the only Roman province where the institution never thoroughly took root.



A GLADIATOR'S TESSERA
Tesserae were used as emblems, tokens, etc., and consisted of four inscribed ivory or stone slabs fastened into a quadrangular tablet

Gladiators were commonly drawn either from prisoners of war, or slaves or criminals condemned to death. Thus in the first class we read of tattooed Britons in their war chariots, Thracians with their peculiar bucklers and scimitars, Moors from the villages round Atlas and negroes from central Africa, exhibited in the Colosseum. Down to the time of the empire only greater malefactors, such as brigands and incendiaries, were condemned to the arena; but by Caligula, Claudius and Nero this punishment was extended to minor offences, such as fraud and peculation, in order to supply the growing demand for victims. For the first century of the empire it was lawful for masters to sell their slaves as gladiators, but this was forbidden by Hadrian and Marcus Aurelius. Besides these three regular classes, the ranks were recruited by a considerable number of freedmen and Roman citizens who had squandered their estates and voluntarily took the *auctoramentum gladiatorium,* by which for a stated time they bound themselves to the *lanista.* Even men of birth and fortune not seldom entered the lists, either for the pure love of fighting or to gratify the whim of some dissolute emperor; and one emperor, Commodus, actually appeared in person in the arena.

Gladiators were trained in schools (ludi) owned either by the state or by private citizens, and though the trade of a *lanista* was considered disgraceful, to own gladiators and let them out for hire was reckoned a legitimate branch of commerce. Thus Cicero, in his letters to Atticus, congratulates his friend on the good bargain he has made in purchasing a band, and urges that he might easily recoup himself by consenting to let them out twice. Men recruited mainly from slaves and criminals, whose lives hung on a thread, must have been more dangerous characters than modern galley slaves or convicts; and, though highly fed and carefully tended, they were of necessity subject to an iron discipline. In the school of gladiators discovered at Pompeii, of the 63 skeletons buried in the cells many were in irons. But hard as was the gladiators' lot (so hard that special precautions had to be taken to prevent suicide) it had its consolations. A successful gladiator enjoyed far greater fame than any modern prize-fighter or athlete. He was presented with broad pieces, chains and jewelled helmets, such as may be seen in the museum at Naples; poets like Martial sang his prowess; his portrait was multiplied on vases, lamps and gems; and high-born ladies contended for his favours.

There were various classes of gladiators, distinguished by their arms or modes of fighting. The Samnites fought with the national weapons—a large oblong shield, a vizor, a plumed helmet and a short sword. The Thraces had a small round buckler and a dagger curved like a scythe; they were generally pitted against the Mirmillones, who were armed in, Gallic fashion with helmet, sword and shield, and were so called from the fish (μορμύλος or μορμύρος) which served as the crest of their helmet. In like manner the Retiarius was matched with the Secutor; the former had nothing on but a short tunic or apron, and sought to entangle his pursuer, who was fully armed, with the cast-net (iaculum) that he carried in his right hand; and if successful, he despatched him with the trident (tridens, *fuscina*) that he carried in his left. We may also mention the Andabatae who are believed to have fought on horse-

back and wore helmets with closed vizors; the Dimachaeri of the later empire, who carried a short sword in each hand; the Essedarii, who fought from chariots like the ancient Britons; the Hoplomachi, who wore a complete suit of armour; and the Laquearii, who tried to lasso their antagonists.

The shows were announced some days before they took place by bills affixed to the walls of houses and public buildings, copies of which were also sold in the streets. These bills gave the names of the chief pairs of competitors, the date of the show, the name of the giver and the different kinds of combats. The spectacle began with a procession of the gladiators through the arena, after which their swords were examined by the giver of the show. The proceedings opened with a sham fight (*praelusio, prolusio*) with wooden swords and javelins. The signal for real fighting was given by the sound of the trumpet, those who showed fear being driven on to the arena with whips and red-hot irons. When a gladiator was wounded, the spectators shouted *"habet"* (he is wounded); if he was at the mercy of his adversary, he lifted up his forefinger to implore the clemency of the people, with whom (in the later times of the republic) the giver left the decision as to his life or death. If the spectators were in favour of mercy, they waved their handkerchiefs; if they desired the death of the conquered gladiator, they turned their thumbs downwards. (A different account is given by Mayor on Juvenal iii. 36, who says: "Those who wished the death of the conquered gladiator turned their thumbs towards their breasts, as a signal to his opponents to stab him; those who wished him to be spared turned their thumbs downwards as a signal for dropping the sword.") The reward of victory consisted of branches of palm, sometimes of money. Gladiators who had exercised their calling for a long time, or such as displayed special skill and bravery, were presented with a wooden sword (*rudis*), and discharged from service. The first Christian emperor was persuaded to issue an edict abolishing gladiatorial games (325), yet in 404 we read of an exhibition of gladiators to celebrate the triumph of Honorius over the Goths, and it is said that they were not totally extinct in the West till the time of Theodoric.

The attention of archaeologists has been recently directed to the tesserae of gladiators. These tesserae, of which about 60 exist in various museums, are small oblong tablets of ivory or bone, with an inscription on each of the four sides. The first line contains a name in the nominative case, presumably that of the gladiator; the second line a name in the genitive, that of the *patronus* or *dominus;* the third line begins with the letters SP (for *spectatus*=approved), which shows that the gladiator had passed his preliminary trials; this is followed by a day of a Roman month; and in the fourth line are the names of the consuls of a particular year.

GLADIOLUS, a numerous genus of showy herbs belonging to the iris family (Iridaceae). They grow from a solid fibrous-coated corm, and have long narrow plaited leaves and a terminal one-sided spike of generally bright-coloured irregular flowers. The segments of the limb of the perianth are very unequal, the perianth tube is curved, funnel-shaped and widening upwards, the segments equalling or exceeding the tube in length. There are about 200 known species, a large number of which are South African, but the genus extends into tropical Africa, forming a characteristic feature of the mountain vegetation, and as far north as central Europe and western Asia. One species G. *illyricus*, though very rare, is found wild in England, in the New Forest and the Isle of Wight. Some of the species have long been cultivated in flower gardens, where both the introduced species and the modern varieties bred from them are very ornamental and popular.

The modern varieties of gladioli have almost completely driven the natural species out of gardens, except in botanical collections. The most gorgeous groups—in addition to the gandavensis type—are those of hybrid origin, most of which have been derived from G. *blandus*, G. cardinalis, G. *dracocephalus*, G. *psittacinus*, G. *oppositiflorus* and G. *primulinus*. The flowers of the best varieties of the Childsi type are of great size and substance, often measuring 7 to 9 in. across, while the range of colour is marvellous, with shades of grey, purple, scarlet, salmon, crimson, rose, white, pink, yellow, etc., often beautifully mottled and blotched in the throat. The plants are vigorous in growth, often reaching a height of 4 to 5 ft.

A deep and rather stiff sandy loam is the best soil for the gladiolus, and this should be trenched up in October and enriched with well-decomposed manure, consisting partly of cow dung, the manure being disposed altogether below the corms, a layer at the bottom of the upper trench, say 9 in. from the surface, and another layer at double that depth. The corms should be planted in succession at intervals of two or three weeks through the months of April, May and June, about 3 to 5 in. deep and at least 1 ft. apart.

The gladiolus is easily raised from seeds, which should be sown in March or April in pots of rich soil placed in slight heat, the pots being kept near the glass after they begin to grow, and the plants being gradually hardened to permit their being placed out-of-doors in a sheltered spot for the summer. The time occupied from the sowing of the seed until the plant attains its full strength is from three to four years. The approved sorts are multiplied by secondary corms or offsets or "spawn," which form around the principal corm; but in this they vary greatly, some kinds furnishing abundant increase, while others persistently refuse to yield offsets. The stately habit and rich glowing colours of the modern gladioli render them exceedingly valuable as decorative plants during the late summer months. They are, moreover, very desirable and useful flowers for room decoration, for while the blossoms themselves last fresh for some days if cut either early in the morning or late in the evening, the undeveloped buds open in succession, if the stalks are kept in water, so that a cut spike will go on blooming for some time.

GLADSHEIM, in Scandinavian mythology, the region of joy, home of Odin and Valhalla (*q.v.*).

GLADSTONE, HERBERT JOHN GLADSTONE, 1ST VISCOUNT (G.C.M.G., cr. 1910) (1854–1930), English statesman, son of W. E. Gladstone (*q.v.*), was born in London on Jan. 7, 1854, and educated at Eton and at University college, Oxford. He lectured on history at Keble college for three years (1877–80) and then entered on a parliamentary career, representing Leeds from 1880–1910. From 1880 to 1881 he acted as private secretary to his father, and in 1881 became a lord of the treasury. His other political offices were financial secretary to the War Office (1886); under-secretary at the Home Office (1892–94); first commissioner of works (1894–95); chief whip to the Liberal party (1899–1906) and secretary of State for home affairs (1905–10). In 1910 he was created a viscount, was appointed the first governor-general and high commissioner for South Africa, a post which he held until July, 1914. He was made G.C.B. in 1914. He wrote *W.* E. Gladstone (1918) and After Thirty Years (1928). Lord Gladstone died at Dane End, near Ware, Herts., on March 6, 1930.

GLADSTONE, JOHN HALL (1827–1902), English chemist, was born at Hackney, London, on March 7, 1827. He studied under Thomas Graham at University College, London, and Liebig at Giessen, where he graduated as Ph.D. in 1847. In 1850 he became chemical lecturer at St. Thomas's hospital, and in 1853 was elected F.R.S. From 1874 to 1877 he was Fullerian professor of chemistry at the Royal Institution, in 1874 he was first president of the Physical Society, and in 1877–1879 president of the Chemical Society. In 1897 the Royal Society recognized his 50 years of scientific work by awarding him the Davy medal. Gladstone is particularly known for his work on optical refractivity (partly in conjunction with Dale), for his investigations into the chemistry of the lead-accumulator (with A. Tribe and W. Hibbert) and for his use (with Tribe) of the "zinc-copper couple" in the preparation of organic compounds. As early as 1876 he showed the

importance of the spectroscope in chemical research, and he was one of the first to notice that the Fraunhofer spectrum at sunrise and sunset differs from that at midday. Gladstone always took a great interest in educational questions, and from **1873** to **1894** he was a member of the London School Board. He died in London on Oct. **6,** 1902.

GLADSTONE, WILLIAM EWART (1809–1898), British statesman, was born in Liverpool on Dec. **29,** 1809. The Gledstanes were an ancient Border stock who held lands in the Douglas country. William Gledstanes, of the branch from whom Gladstone descended, was laird of Arthurshiel in Lanarkshire in 1551; but the lands were lost and the 18th century found the Gledstanes maltsters in the town of Biggar. One of them, Thomas, became a corn-merchant at Leith. His son, John Gladstone, became a merchant-prince at Liverpool, a member of parliament, a friend of Canning, a baronet and a Scottish landlord: and Sir John's second wife drew Highland blood from the Robertsons of Inshes and the Mackenzies of Coul Their famous son recalled his mother as "a beautiful and admirable woman," and bore witness to his father's large, strong nature and deep sense of duty. William was sent tit Eton in 1821, and spoke later of his own slow development there. But under Hawtrey and Keate he learned to work well. His contemporaries recalled his good looks, his growing scholarship, his contributions to the *Eton* Miscellany, his early and remarkable contributions to debate and, above all, the fine influence of his character: Arthur Hallam was not the only friend who noted that.

In **1828** Gladstone went up to Christ Church, Oxford, serious-minded, deeply interested in religion and in politics, an unbending Tory in his fear of revolution, but always generous in his feeling for the poor. He read classics, philosophy and mathematics. He was offered a Christ Church studentship. But he tried for the Ireland and the Newdigate in vain. He took long and vigorous walks. He talked, no doubt, as vigorously. He brooded upon poetry and religion. Neither Pusey nor Newman had as yet much influence on his mind. He attended sermons and taught in Sunday school. He founded a college debating society, called after him the "W.E.G." He shone with splendour at the Union, where Manning' and the Wilberforces were already famous, and where other friends were making names. He became secretary and president of that young, renowned society, and in May **1831,** in a debate on Lord Grey's Government and parliamentary reform, he delivered a speech regarded by competent judges as the most eloquent and impressive ever heard within its walls. Before the end of that year he had secured a double first at Oxford. Before another year was over, the duke of Newcastle, who had heard from his son, Lord Lincoln, of young Gladstone's achievements as an opponent of reform, invited him to stand for Newark, and in January **1833** he took his seat in the assembly which he was to charm, to move, to dominate for **60** memorable years.

It was his father's counsel which made him a statesman. His own choice would have been the Church. But he soon began to justify his father's wisdom, and it was in defence of the system of slave labour as administered on his father's estate in Demerara that he made, in June **1833,** his maiden speech. He was soon speaking again, on the Irish Church and on university questions, always with notable success. He became a lord of the Treasury in Peel's Government of **1834,** under-secretary for the colonies a year later, and he at once concentrated on his task. He was already keenly interested in colonial questions, and no politician was ever readier to learn. Before long he was recognized as one of the few members of parliament who understood colonial interests. He gradually convinced himself that it was in local autonomy that the real solution of the imperial problem would be found. But Peel's Government could not stand. Gladstone was soon released from his labours, free to devote himself to every kind of reading, and free also to prepare his famous book on The State in its Relations *with* the *Church* **(1838).** Old friends, among whom James Hope and Henry Manning were conspicuous, linked him in sympathy with the Oxford movement. He could not follow them or Newman to the goal they found, but he could believe still in the duty of the State to give active and exclusive support to one religion, and plead for the political supremacy and spiritual independence of the Church. "Oxford had not taught me," he said later, "nor had any other place or person, the value of liberty as an essential condition of excellence in human things." Macaulay reviewed the treatise. Many praised it. But Peel expressed neither sympathy nor respect. In **1840** its author followed it up by a volume on Church Principles, which made less mark. A year previously the young controversialist had married Miss Catherine Glynne of Hawarden, a marriage which brought him long-enduring happiness as well as a historic and delightful home. A year later he was drawn back into the full current of politics by the Tory triumph of 1841.

Gladstone returned to office with Peel as vice-president of the Board of Trade. It was not the office which he wished for. He was called to new and unfamiliar problems. But again his readiness to learn and his rare power of concentration prepared the way for great administrative success. He had the chief share in drawing up the revised tariff of **1842.** with its masterly rearrangement and reduction of duties—a long step towards free trade. His industry in that laborious task, his incessant speeches, his gifts of exposition, his intimate knowledge of a complicated subject impressed and delighted the house. Next year, at the age of **33,** he joined the cabinet as president of his department, and soon carried his reform of the tariff further. He still supported duties on corn: but his daily study of business had begun to "beat like a battering ram" on his protectionist armour. Meanwhile he carried through parliament the great Railway Bill of **1844.** When he resigned in **1845** on the question of Maynooth, the unbending Oxford churchman, "Oxford on the surface but Liverpool below," was renowned already as a commercial minister, if thought a little fastidious in his scruples. And the four hours' speech on the sugar question, with which he soon after came to the defence of the Government, proved him again a master of detail. At **36** Gladstone was one of the most striking figures in the House of Commons. His superb health, his astonishing powers of work—he could do in four hours, said Graham, what took any other man **16,** and he worked **16** hours a day—his never-failing intrepidity of spirit, his combination of impetuosity and ardour with easy self-command, his rich imagination tamed and disciplined by study, and the sense that he breathed something of "an ampler ether, a diviner air," profoundly impressed all who knew him. His contemporaries noted his fine appearance and fine manners. The pale, expressive, intellectual face, the deep-set, flashing eyes, the strongly-marked features, the erect and dignified bearing, the free and graceful gestures, the voice of incomparable flexibility and strength, gave him a natural equipment such as few orators have possessed. And to this he added a rare mastery of the subjects which he spoke on and a rare capacity for moving, persuading and inspiring men.

In Dec. **1845,** when Peel re-formed his Government to repeal the Corn Laws, Gladstone became colonial secretary and thereby vacated his seat at Newark. The duke of Newcastle, a protectionist, could not support his re-election, and he remained a cabinet minister outside parliament all through the memorable session of **1846.** At the general election of **1847** he became member for the University of Oxford, an honour which Peel and he both regarded as one of the dearest prizes of their lives. Years followed of steady, if unconscious, development on Liberal lines, years, too, of great parliamentary achievements, notably his opposition to Palmerston in the Don Pacifico debate, and his tribute in July **1850** to the chief whom he always regarded, as on the whole, the greatest man that he had ever known. In **1851,** after wintering in Italy, he startled Europe by his famous letters to Lord Aberdeen, impeaching the tyranny of the Government of Naples, the first occasion on which he appeared as the spokesman of oppressed and suffering nations. In the political crises of that year the Peelites received overtures from both sides. But when Lord Derby formed an unstable Government in **1852** it was not possible for Gladstone to join it. He remained outside and tore Disraeli's budget to pieces in one of the greatest unpremeditated speeches of his life. The coalition under Lord Aberdeen came into power, and Gladstone took the place at the Exchequer which

he was to make, for the first time, one of the greatest offices of State, and to illumine with a genius such as no finance minister, not even Peel or Pitt, had shown before.

Lord Aberdeen's administration, though overshadowed by the Crimean War, gave Gladstone the opportunity of proposing a memorable budget and of carrying through parliament a great scheme of university reform. The budget of 1853, introduced in a five hours' speech which he perhaps never surpassed, reviewed and examined the whole system of the income-tax, and arranged for its gradual reduction and its extinction in seven years' time. It established a succession duty on real estate, reduced the tea duty, abolished the duty on soap, and, continuing Peel's policy of enfranchising business and lowering the price of food, it swept away nearly 140 duties and diminished nearly 150 more. The Crimean War broke in upon these projects, and in 1854 the income-tax had to be increased. Gladstone insisted on meeting war expenditure, as far as possible, out of income. For the war he shared responsibility, but he shared also the misgivings of his chief. And he turned with relief to university reform. A typical Oxford man, brought reluctantly to realize the necessity of change, he had special qualifications for this task. And his conduct of the Bill of 1854 revealed again his mastery of his subject and his ascendancy in the house. But in Jan. 1855 the widespread dissatisfaction with the conduct of the war destroyed Lord Aberdeen's administration, and Gladstone and other Peelites, after some hesitation, withdrew from the Government, of which Lord Palmerston became the head. Then for a time he reserved himself for criticism — criticism of Cornewall Lewis's finance, criticism of Palmerston's high-handed policy in China, criticism of the act which established the divorce court, criticism of Palmerston's Conspiracy Bill after the Orsini plot. On Palmerston's fall Gladstone was pressed to take office under Lord Derby. But he preferred to stand apart, devoting himself to Homeric studies — the three volumes of 1858 showed characteristic enthusiasm and industry — visiting Corfu on a mission which resulted in the ultimate union of the Ionian islands with Greece, and finally returning to criticize with detachment Disraeli's first Reform Bill in the House of Commons. The general election of 1859 brought Palmerston back to office, and Gladstone, who had voted with the Tories in the division which turned Lord Derby out, caused some surprise by joining Palmerston as chancellor of the Exchequer. But he believed the country needed his services. He had proved himself no office-seeker, and he may scarcely have realized that his action meant his permanent enlistment in the Liberal party.

The 15 years which followed were years of brilliant effort and almost uninterrupted power. A succession of great budgets, introduced in wonderful speeches and reflecting a period of great prosperity, made Gladstone the most conspicuous figure in the Government from 1859–65. The budget of 1860, combined with Cobden's commercial treaty with France, carried the policy of free trade still further, and brought the number of dutiable articles down to 48. The proposal to repeal the paper duty, a proposal which created the cheap press, was defeated by the House of Lords, and Gladstone frankly warned the peers that he would not flinch from asserting the rights of the Commons over taxation. In 1861 he made good his warning by including all his financial proposals, including the repeal of the paper duty, in a single Money Bill, which the peers could only accept or reject as a whole. In 1863 he had a substantial surplus and was able to reduce the income-tax to sevenpence again. He reduced it further to sixpence in 1864 and to fourpence in 1865. He would not abandon the hope of getting rid of it altogether. Sugar and tea duties came down too. The country saw with delight the minister taking off tax after tax, and yet announcing a larger surplus every year. And these financial triumphs were accompanied by votes and speeches which showed his ever-widening Liberal outlook, his ever-growing dissatisfaction with the military expenditure and other characteristic actions of his chief. Against increasing armaments he fought to his last day.

One famous utterance of these days, when, in 1862, he described Jefferson Davis as having made a nation, Gladstone himself afterwards condemned as a mistake "of incredible grossness." Another, in 1864, asserting the moral right of every Englishman "to come within the pale of the constitution," frankly delighted Liberal opinion. Lord Palmerston was not alone in understanding the phrase to assert the moral right of every man to a vote. The dissolution, however, in July 1865, found Gladstone rejected at Oxford, "unmuzzled" as he told his friends in Lancashire, where he was immediately provided with a seat. Palmerston died in October, and Gladstone, who had strong claims on the first place, readily agreed to serve under Lord Russell. As leader of the Commons he introduced the modest Reform Bill of 1866, and defended it undauntedly in a series of speeches which proved too strong for Lowe and a Palmerstonian House of Commons. When the Government were defeated a great crowd of Londoners marched to cheer Gladstone in his home. Lord Derby and Disraeli came into power, and promptly introduced a wider Reform Bill: and Gladstone, in spite of the factious groups around him, remodelled it as it passed through the house. At Christmas, Lord Russell's retirement left him undisputed leader of the Liberal party, and in 1868 he carried, over the heads of the Government, his famous resolutions for the disestablishment of the Irish Church. The general election of that autumn ended in his return to power, as prime minister — unseated indeed in Lancashire, but elected for Greenwich — at the head of the strongest and most strenuous Government of those times.

The great measures of Gladstone's first administration have long since passed into history. The disestablishment of the Irish Church was carried by an admirable mixture of firmness and conciliation through the House of Lords. The Irish Land Act of 1870 did much to give security to Irish tenants. The same year saw the passing of Forster's Education Act, the establishment of competitive examinations for the civil service, the outbreak of the Franco-Prussian War, and a new pact to protect the neutrality of Belgium. Army reform followed and the abolition of the purchase of commissions, which Gladstone enforced by royal warrant when the House of Lords refused assent. University tests were swept away; it had taken years to bring the old member for Oxford to agree to this. The ballot was adopted after some resistance from the peers. The settlement of the Alabama claims afforded a striking and significant example of the value of international arbitration as a method of avoiding war; and Gladstone's own power over popular feeling was illustrated afresh by an astonishing meeting at Blackheath, where he spoke for two hours in the open air to many thousands of people and completely conquered an audience disposed to be unsympathetic and disorderly at first.

But the Government's difficulties increased. Their proposals for a university in Ireland were defeated. They were weakened by resuming office when Disraeli refused to come in. Tiresome points of judicial and ecclesiastical patronage led to decisions in which the prime minister was accused of evading the law. On Lowe's removal to the Home Office, Gladstone reluctantly took over the Exchequer, and the question arose whether he had not thereby vacated his seat. In Jan. 1874 he suddenly dissolved parliament and held out hopes of abolishing the income-tax, now reduced to threepence, which he had always regarded as a possibility to be kept in view. The election resulted in a Tory majority. The prime minister travelled down to Windsor, taking The *Merchant of Venice* and *Thomas à Kempis* with him. Disraeli returned both to office and to power. Gladstone, now aged 64, with a long record of service and activity behind him, reserved the right to withdraw from parliament, though he took a prominent part in opposing Archbishop Tait's Bill for regulating public worship. Early in 1875 he laid down the leadership of the Liberal party and Lord Hartington was elected leader in his place.

Sunshine, men said, had gone out of politics. But the eyes of the country were on Gladstone still. His health was unimpaired: his doctor laughed at misgivings on the subject. His public interests, his powers of work, his zest for life, for literature, far politics, were as inexhaustible as ever, and he had hardly made up his mind to retire before the Eastern Question (*q.v.*) called him back. When the iniquities of Turkish misrule began to stir the heart of Europe, Gladstone inevitably became the spokesman of

the indignation aroused. Parliamentary colleagues might hang back; Lord Beaconsfield might profess himself indifferent to "coffee-house babble"; fears of Russian influence might obscure the issue and enable rash politicians to beat up a "jingo" spirit and to bring the country within sight of war. But as the public realized the growing danger of the Government's adventurous policies in Europe, in South Africa and in Afghanistan, British opinion turned the more readily to a statesman whose ripe experience and formidable arguments gave his warnings an unusual weight. In 1879 Gladstone entered on an electoral campaign which became a rallying-point for Liberals all over the country: and the series of speeches in which he unfolded to vast Scottish audiences which hung upon his words, the principles which, as he conceived, should govern the policy of this country, seemed to many to sound a new note of equity in the conduct of international affairs. Students of his career have regarded these speeches, the maxims of foreign policy laid down in Midlothian and reiterated elsewhere, as Gladstone's greatest contributian to the public life of Europe. Friends of peace and arbitration have found in him the first statesman of high rank to plead, in a world still ruled by obsolete traditions of diplomacy, for a finer and truer conception of national duty, dignity and greatness.

Gladstone had roused the country aknost single-handed. When the battle was won and Lord Beaconsfield swept from office, all attempts to form a Liberal Government under any other leader vanished like mists before the sun, Queen Victoria, over whom Lord Beaconsfield had acquired an unrivalled personal ascendancy, had, unhappily, learned to regard Lord Beaconsfield's great opponent as a "violent, mischievous and dangerous" politician. Her letters leave no doubt of the lasting prejudice excited against a statesman who had enjoyed her high regard until Lord Beaconsfield's influence became supreme. And her attitude towards her prime minister from 1880 onwards, though eased at times by her fine manners, unquestionably added to the difficulties of his task. On this subject it is characteristic that Gladstone never allowed a word of complaint to escape him. But he felt keenly the growing alienation of a sovereign whom he served through life with a tender and considerate loyalty not often surpassed. At 70 he took up again with undiminished vigour the burden of the State, and the years of his second administration, from 1880 to 1885, were some of the most strenuous and eventful of his life. The troubles bequeathed by Lord Beaconsfield were dealt with, though not without leaving seeds of further trouble in the future. But the call of Ireland was, from the first, insistent, and even Gladstone found it difficult to watch at each step the widespread negotiations of his colleagues. When the hope of federation in South Africa failed and the Boers protested against annexation, delays and mistakes at the Colonial Office undoubtedly aggravated a difficult situation. The Boers rose in arms. Military mistakes then followed; and the chapter of accidents ended in a grave setback at Majuba Hill. Ministers refused, with unusual moral courage. to treat that setback as sufficient reason for abandoning their policy of conciliation or for stopping negotiations already begun. But to some their action gave the impression of weakness, and party critics not unnaturally accused them of surrendering to defeat.

Even greater difficulties arose in Egypt, when Arabi Pasha's outbreak and the refusal of France and Turkey to co-operate, forced an unwelcome responsibility upon Britain. The difficulties were never adequately grasped, the consequences of the action taken never perhaps sufficiently examined. The determination of Gladstone and his cabinet to avoid, as far as possible, any policy of annexation did not prevent very serious commitments. In much that followed Gladstone's share was less than that of some of his colleagues. He declared strongly in 1882 against the policy of restoring order in the Sudan. He was the only member of the cabinet who objected to despatching troops to Suakin in 1883. He was absent from London when the decision to send out Gordon was taken. He would have been the last indeed to deny his responsibility for that or for any other episode in the unhappy series of miscalculations which ended in the tragedy at Khartoum. But the critics who, after the disaster, voiced the deeply-stirred emotions of the nation did not'always remember that the abandonment of the Sudan was recommended by Sir Evelyn Baring and by Gordon himself, and that Gordon went there with explicit instructions not to hold, but to evacuate the country.

Events abroad, however, were only a part of the difficulties of Gladstone's second administration. He spoke of it afterwards as "a wild romance of politics," a succession of accidents and hairbreadth escapes. There was a grave crisis over the Franchise Bill of 1884. But the fine temper shown by the prime minister, helped by the queen's influence, brought it safely into port. There was, all through, a rising tide of troubles in Ireland, an alarming increase of disorder, a demand for new and exceptional legislation to settle the land question and to put down crime. The great Land Act of 1881, with its obvious benefits for Irish tenants, virtually broke the Land League agitation. But the Coercion Act which accompanied it roused a storm of defiance in the country, and was followed hy a startling increase in serious crime. Forster's methods failed, and their failure deeply impressed his chief. Parnell's arrest was followed by the Kilmainham Treaty, by the "black act" in Phoenix Park~by angry reproaches from the Government's critics. But Gladstone's conviction of the impossibility of governing Ireland without the support of Irish representatives grew. When in June 1885 a sudden combination between Conservatives and Parnellites threw him out of office, he was already contemplating new departures. A brief Conservative administration was followed by a general election which returned 333 Liberals, 251 Conservatives and 86 Parnellites to the House of Commons. Gladstone came back to power for the third time at the age of 76, and entered with unquenchable ardour on the most astonishing period of his career.

Of all the many interests which engrossed him from the days of his earliest speeches in parliament, Irish questions, the Irish Church, Irish land, Irish university education, the whole difficult problem of Irish government, had again and again occupied his mind. To those who knew him best and watched his utterances closely, his declaration for Home Rule was scarcely a surprise. Months before, a critic so acute as Healy had pointed out in public the movement of Gladstone's mind. But a new departure so momentous startled many of his followers, and not even the skill with which the great measure was drafted, and the consummate gifts employed to recommend it to the House of Commons, could avert the defeat of the Home Rule Bill of 1886. Six years of vigorous opposition followed, marked by a Liberal recovery in the country, by the Parnell triumph before the special commission, by the Parnell tragedy which stemmed "the flowing tide." Gladstone's fourth premiership was chiefly remarkable for a fresh attempt to carry a Home Rule Bill in 1893. The Liberal majority was too small for success. But the power, the vitality, the astonishing resources of argument and eloquence, dexterity and understanding with which the prime minister of 83 fought every detail of his bill fascinated opponents hardly less than friends. The opposition of the House of Lords to the measures of the Liberal Government provoked a warning of the coming issue between the peers and the democracy, which proved to be Gladstone's last speech in parliament, his last appearance in the House of Commons. But the refusal of some trusted colleagues to support him in his life-long determination to keep down expenditure on armaments was the immediate cause of a resignation for which age and failing sight and hearing supplied unanswerable pleas. His chief political opponent declared that the country lost by his withdrawal the most brilliant intellect ever devoted to the public service since parliamentary government began.

CLOSING YEARS

Such men cannot retire, can rarely rest. Yet, if there could be no complete relief from activities, there was a serene and noble dignity about the closing years. Gladstone's career had stirred men's passions deeply and some political ill-will survived, to break out again in foolish malice even after death, when a miserable libel based on his work in reclaiming women of bad character, was revived, repeated and disposed of in the law courts for ever.

In his charities he had no fear of misconstruction and was generous to excess. There was much in him, no doubt, which the average Englishman failed to understand. He was sometimes quite indifferent to opinion. A certain simplicity and modesty of nature made him perhaps too literal and unsuspecting; and the contrast between this genuine simplicity and his reserves, refinements and ambiguities of expression bewildered his critics and provoked accusations of bad faith. But as party feelings cooled such accusations died away. Men looked back upon his 60 years of public service and saw a life "set up on high," not free, indeed, from errors and miscalculations, but lived from first to last among ideals as pure and standards as exalted as any English statesman ever sought. The habits of mind, the scholarship, the theology, the views of science might seem to some old-fashioned or mistaken. But even in science there was always an extraordinary readiness to learn. Outside parliament he was essentially a student, a book-lover, a prolific writer. He could revel in Dante, in Aristotle or Augustine, in *Don Quixote* and Byron, in Blackstone, Chillingworth and Jewel. "Usual occupations . . . Bible, Alfieri, *Wallenstein*, Plato, Gifford's *Pitt, Biographia Literaria,*" is a note of 1833. Devoted to Wordsworth, he was a fine critic of Tennyson. Scott was a life-long favourite, but *Robert Elsmere* engrossed him in 1888. Homer, like Dante, was a constant and familiar companion. He lectured on Homer to the Oxford Union when over 80. He completed his translation of the Odes of Horace on the day of his final retirement in 1894. Re was devoted to theology. In 1895 he was editing Bishop Butler and establishing a library at St. Deiniol's to promote churchmanship and divine learning. Hawarden, a home to him for nearly 60 years—the management and restoration of the Hawarden property taught him many a lesson in finance—became a centre of all kinds of studies as well as a storehouse of documents of high value to the State.

At Hawarden Gladstone was engrossed in literature, in writing and in correspondence. Only his rigid method and economy of time enabled him to keep his correspondence down. He was visited by many friends who delighted in his conversation. The Lyttelton family stood for much in kinship. Lord Acton stood for much in literature. Lord Granville and Lord Spencer, Lord Rosebery and John Morley stood out latterly as intimate colleagues. As time passed the people of England flocked in multitudes to see him. But he was happiest of all in his home life; in a marriage which brought him over 58 years of intimate companionship; in a family whose affection was touched indeed with awe and admiration, but inseparable from enjoyment, playfulness and fun; in children who could remember nothing masterful or dictatorial about him, only the gentlest and kindliest of teachers, a lover of truth and of every form of industry, a hater of every form of waste, an example not of religion thrust upon them, but of religion made unconsciously the basis of ordinary life. Of these children one son, William Henry, served for many years in parliament. Another, Herbert, Viscount Gladstone, became prominent in public life. A grandson, William, succeeded to Hawarden and fell in the World War. And others of the family have maintained in different callings the great traditions inherited from their home. The religion which Gladstone taught them knew no narrow tenets. At first an earnest Evangelical, he became a life-long friend of Tractarian opinions, of Bishop Wilberforce, of Dr. Pusey, of Keble college. He pleaded for tolerance for ritualist developments, for the authority and spiritual freedom of the Church. His sympathies with the Greek Church, too, were strong. But he separated himself decisively from Newman and Manning. He spoke vigorously against the tendencies of Vaticanism and the dangerous claims of Rome. He nominated Dr. Temple to a bishopric; Church patronage gave him many anxious hours. He won the love and trust of Nonconformists. His defence of the Affirmation Bill of 1883 was among his noblest speeches. It was the spirit, not the form, of religion which dominated and inspired his life. From that he drew his rare self-mastery, his conviction of right, his assurance of duty and, in great issues of statesmanship or conduct, his fine fearlessness in leading men.

Gladstone's place in the long line of British statesmen only the future can decide. Walpole and Palmerston had few rivals in the art of managing parliaments. Chatham had no superior in eloquence, Fox in the instinct for debating, Burke in the richness of his mind. Pitt may have had more mastery of his followers, Peel a sense of public duty as unwavering and as fruitful in results. But in the combination of intellectual powers and physical resources, in range of genius, character, achievement, Gladstone stands second to no English public man. The length and fullness of his record are astonishing. Where else can 60 years of such activities be shown? And in every field of politics there is the same rare power of concentration, the same untiring industry, the same mastery of administrative and legislative details, the same passion for the public interest, the same ever-deepening love of human freedom. The greatest financier and practical economist who ever gave life to the commerce of this country, he was also one of the first members of parliament to give serious study to colonial problems, to set himself to solve and settle the endless complexities of Irish government, to make British foreign policy an example to the world. Right with him was might. He did more than any man of his generation to advance the cause of peace and arbitration, to plead for humanity in the government of States. His last words in politics, in 1896–97, were appeals on behalf of Armenia and Greece. Is it any wonder that his name became a household word in southern Europe, that in Italy and Rumania, Bulgaria and Macedonia, men mourned his passing as the passing of a friend?

It is strange, perhaps, that this great worker should have been also the greatest speaker of his age. Several of his predecessors had been masters of the House of Commons, but he was a master on the platform also, unrivalled by virtue of his own intense conviction in his power of convincing multitudes of men. It is stranger still that this outspoken leader of democracy should have been to the last one of the courtliest of courtiers, one of the loyalest of churchmen, one of the most inveterate lovers of the past. To Oxford, as the shadows closed, "the God-fearing and God-sustaining university of Oxford," he sent a touching message of farewell. The fires of life were dying. The "vulnerable temper" had long since been exquisitely disciplined; but the old intimate interests and affections survived. Health broke at last completely. Pain was added to his trials, pain very nobly borne. In May 1898 the end arrived. A vast procession of mourners passed beside his bier at Westminster. He was laid to rest in the Abbey with every honour that his countrymen could pay. Friends and opponents joined in eulogy, but Lord Salisbury's tribute to "a great Christian statesman" touched perhaps the central truth. Far more than genius or renown, or political achievement, it was the sense of Gladstone's moral grandeur which won the final homage of mankind. (C. E. M.)

GLADSTONE, a city of Delta county, Michigan, U.S.A., in the upper peninsula, at the head of Little Bay de Noquet, an inlet of Green bay (Lake Michigan). It is on federal highways 2 and 41, and is served by the Soo Line railway. The population was 5,170 in 1930 and was 4,972 in 1940. It is a division headquarters of the railroad; has a deepwater harbour, with coal docks. There is a bathing beach with large bathing house, park and tourist

accommodations There is fishing in the bay and streams, a golf course and a winter sports park, ski tows and trails. Manufactures include sporting goods, firearms, veneer and other articles. The city was founded in 1880 and incorporated in 1889. Since 1923 it has had a council-manager form of government.

GLAGOLITIC, an early Slavonic alphabet in which is written an early liturgy still used among the Dalmatians and Roman Catholic Montenegrins by special licence of the Pope. (See ALPHABET.)

GLAIR, the white of an egg, and hence a term for a preparation made of this, used in bookbinding and in gilding to retain the gold and as a varnish. The adjective "glairy" is used of substances having the viscous and transparent consistency of the white of an egg.

GLAISHER, JAMES (1809–1903), English meteorologist and aeronaut, was born in London on April 7, 1809. After serving for a few years on the ordnance survey of Ireland, he acted as an assistant at the Cambridge and Greenwich observatories successively, and when the department of meteorology and magnetism was formed at the latter, he was entrusted with its superintendence, which he continued to exercise for thirty-four years, until his retirement from the public service. In 1845 he published his well-known dew-point tables, which have gone through many editions. In 1850 he established the Meteorological Society, acting as its secretary for many years, and in 1866 he assisted in the foundation of the Aeronautical Society of Great Britain. He made a series of balloon ascents between 1862 and 1866, mostly in company with Henry Tracey Coxwell, with the object of carrying out observations on the temperature, humidity, etc., of the atmosphere at high elevations. He died on Feb. 7, 1903, at Croydon.

GLAMIS, village and parish, Forfarshire, Scotland, 5¾ m. W. by S. of Forfar by the L.M S. railway. Pop. (1931) 985 The name is sometimes spelled Glammis and the *i* is mute: it is derived from the Gaelic, *glamhus,* "a wide gap," "a vale." In the village is a sculptured stone, supposed to be a memorial of Malcolm II., although Fordun's statement that the king was slain in the castle is now rejected. About a mile from the station stands Glamis castle, the seat of the earl of Strathmore and Kinghorne, a fine example of the Scottish Baronial style, enriched with certain features of the French château. In its present form it dates mostly from the 17th century. but the original structure was as old as the 11th century, for Macbeth was thane of Glamis. Robert II. bestowed the thanedom on John Lyon, who had married the king's second daughter by Elizabeth Mure and was thus the founder of the existing family. Patrick Lyon became hostage to England for James I. in 1424. When, in 1537, Janet Douglas, widow of the 6th Lord Glamis, was burned at Edinburgh as a witch, for conspiring to procure James V.'s death, Glamis was forfeited to the crown, but it was restored to her son six years later when her innocence had been established. The 3rd earl of Strathmore entertained the Old Chevalier in 1715 and fell on the battlefield at Sheriffmuir. Sir Walter Scott spent a night in the "hoary old pile" when he was about twenty years old, and gives a striking relation of his experiences in his Demonology *and* Witchcraft. The hall has several historical portraits, including those of Claverhouse, Charles II. and James II. of England. At Cossans, in the parish of Glamis, there is a remarkable sculptured monolith, and other examples occur at the Hunters' hill and in the old kirkyard of Eassie.

GLAMORGANSHIRE (Welsh *Morganwg*), a maritime county occupying the south-east corner of Wales, and bounded north-west by Carmarthenshire, north by Carmarthenshire and Breconshire, east by Monmouthshire and south and south-west by the Bristol Channel and Carmarthen Bay. Area 520,456 acs Pop. (1938) 1.154 960 Its extreme breadth from the sea inland is 29 m., while its greatest length from east to west is 53 m.

Structurally and physically it may be considered in two sections—(1) the northern upland section forming a part of the South Wales coal-field; (2) the lower section or Vale of Glamorgan—a region in which old rocks much worn down are covered by newer deposits. The coal-field is a geological basin with its thick, hard grit bands standing out as bold uplands. (See WALES.)

The body of the county forms a sort of quarter-circle between the rivers Taff and Neath. Near the apex of the angle formed by these rivers is the loftiest peak in the county, the great Pennant scarp of Craig y Llyn or Carn Moesyn (1,970 ft.). To the south and south-east extends a great coalfield, its surface forming an irregular plateau with an average elevation of 600 to 1,200 ft., but with numerous peaks about 1,500 ft. or more; Mynydd y Caerau, being 1,823 ft. Out of this plateau have been carved, to the depth of 500 to 800 ft below its general level, three distinct series of narrow valleys, those in each series being more or less parallel. The Cynon, the Great and Lesser Rhondda (tributaries of the Taff) and the Ely flow to the S.E., the Ogwr or Ogmore (with its tributaries the Garw and Llynfi) flow south through Bridgend, and the Avan brings the waters of the Corwg and Gwynfi to the south-west into Swansea Bay at Aberavon. To the east of this high ground and divided from it by a spur of the Brecknock mountains culminating in Carn Bugail (1,570 ft.), is the Rhymney, which forms the county's eastern boundary. On the west other spurs of the Beacons divide the Neath from the Tawe and the Tawe from the Loughor, which, with its tributary the Amman, separates the county on the north-west from Carmarthenshire. The rivers are all comparatively short, the Taff, the chief river, being only 33 m. long.

To the south of this central hill country, which is wet, cold and sterile, and whose slopes form the coal-field's southern edge, there stretches out to the sea an undulating plain. Geologically it is a deeply eroded anticlinorium of Old Red Sandstone largely concealed by Trias and Lias. Silurian rocks form a small inlier about 2 sq.m. in area at Rumney and Penylan, north of Cardiff and consist of mudstones and sandstones of Wenlock and Ludlow age. The Old Red Sandstone. which forms the "ground-work" of the vale, consists in the lower parts of red marls and sandstones, while the upper beds are quartzitic and pebbly, and form bold scarps which dominate the low ground formed by the softer beds below. Cefn-y-bryn, another anticline of Old Red Sandstone (including small exposures of Silurian rocks), forms the prominent backbone of the Gower peninsula. The next formation is the Carboniferous Limestone which encircles and underlies the coal-field, on the south of which, west of Cardiff, it forms a bold escarpment of steeply-dipping beds surrounding the Old Red Sandstone. It shows up through the Trias and Lias in extensive inliers near Bridgend, while in Gower it dips away from the Old Red Sandstone of Cefn-y-bryn. On the north of the coalfield it is just reached near Merthyr Tydfil. The Millstone Grit crops out above the limestone.

After the Coal Measures forming the north of the county (see above) had been deposited, the southern part of the region was subjected to powerful folding; the resulting anticlines were worn down, and then submerged slowly beneath a Triassic lake in which accumulated the Keuper conglomerates and marls which spread over the district west of Cardiff and are traceable on the coast of Gower. The succeeding Rhaetic and Lias which form most of the coastal plain (the fertile Vale of Glamorgan) from Penarth to near Bridgend were laid down by the Jurassic sea. The coast of south Glamorgan ends in low cliffs notched by little streams. A well-marked raised beach is traceable in Gower. Sand-dunes are present locally around Swansea Bay. and between the rivers Ogmore and Neath where Kenfig town lies buried. Moraines, chiefly formed of gravel and clay, occupy many of the Glamorgan valleys; and these, together with the striated surfaces which may be observed at higher levels, are clearly glacial in origin.

Down to the middle of the 19th century most of the Glamorgan valleys mere famous for their scenery, but industrial operations have completely destroyed this in the valleys of the north. The rainfall varies from an average of about 25 in. at Porthcawl and other parts of the Vale of Glamorgan to about 37 in. at Cardiff, 40 in. at Swansea and to upwards of 70 in. in the northern part of the county.

Early Settlement. — The earliest known traces of man within the county are the remains found in the caves of the south coast

of Gower (*q.v.*). These are of Palaeolithic date. Many flint implements have been found on the south coast particularly at the mouth of the Ogmore river. There are many cairns and tumuli on the hills of the north such as those on Garth mountain near Cardiff, Crug-yr-avan and a number east of the Tawe. There is little evidence of a strong megalithic culture, although there is a well-preserved stone circle at Carn Llecharth near Pontardawe, and fine dolmens at Cefn Bryn in Gower and at St. Nicholas and St. Lythan's, near Cardiff. Several prehistoric beakerpots have been found in the vale of Glamorgan and the valley ways, especially that of the Taff, have yielded socketed axes of the late Bronze Age. Important sites on the coast and along the inland valleys are guarded by indigenous hill-top forts occupied probably in Romano-British times.

In Roman times the country from the Neath to the Wye was occupied by the Silures. There are Ogham stones at Loughor and Kenfig. The conquest of the Silures by the Romans began about A.D. 50 by Ostorius Scapula and was continued by Julius Frontinus. The important station of Gaer on the Usk near Brecon was connected by two branch roads, one running from Cardiff through Gelligaer (where there was a strong hill fort) and Penydarren, and another from Neath through Coelbren. An important Roman road ran along the Vale from Caerleon through Cardiff to Neath (Nidum).

Glamorgan was an important centre of Celtic Christianity. Llandaff is associated with St. Dubricius and St. Teilo (6th century). To this period also belongs the establishment of the great monastic settlements of Llancarvan, Llandough and Llantwit Major (Llanilltyd Fawr). After the withdrawal of the Romans, the coasts were raided by Saxons. The Scandinavians who came in the 9th and succeeding centuries left more abundant traces both in the place-names of the coastal areas and in such camps as that on Sully Island, the Bulwarks at Porthkerry and Hardings Down in Gower. Meanwhile the native tribes had been reorganized into a principality known as Glywyssing, till about the end of the 10th century when it acquired the name of Morganwg (the territory of Morgan), a prince who died in A.D. 980. Morganwg then comprised the whole country from the Neath to the Wye.

The Norman conquest was effected at the end of the 11th century by Robert Fitzhamon, lord of Gloucester. His followers settled in the "Vale," which became known as the '(body" of the shire, while in the hill country the Welsh retained their customary laws and much of their independence. Glamorgan, whose bounds were contracted between the Neath and the Rhymney, then became a lordship marcher, its status and organization being that of a county palatine. The inhabitants of Cardiff, the *caput baroniae,* were granted municipal privileges, and in time Cowbridge, Kenfig, Llantrisant, Aberavon and Neath also became chartered market-towns. The manorial system was introduced throughout the "Vale," the manor in many cases becoming the parish. The distinction between the compact villages with English tenure on the lowlands and the Welsh scattered farms with tribal customs on the highlands, was very marked in this county. The distinction is often preserved in the parish names, *e.g.,* Coity Anglia and Coity Wallia near Bridgend. The religious houses included the Cistercian abbeys of Neath and Margam founded in 1129 and 1147, respectively, the Benedictine priory of Ewenny (1141) and that of Cardiff (1147). Dominican and Franciscan houses were also founded at Cardiff in the following century. Gower (with Kilvey) or the country west of the morass between Neath and Swansea had a separate history (see GOWER).

For the first two centuries after Fitzhamon's time the lordship of Glamorgan was held by the earls of Gloucester, who acquired it originally through marriage. The first earl built Cardiff Castle and was patron of Geoffrey of Monmouth. The lordship passed by descent through the families of Clare (who held it from 1217 to 1317), Despenser, Beauchamp and Neville to Richard III., on whose fall it escheated to the crown. Raids from the hills were frequent. Cardiff Castle was seized by the Welsh about 1153. At last Caerphilly Castle was built to keep them in check, but this provoked an invasion in 1270 by Prince Llewelyn ap Griffith, who besieged the castle. In 1316 Llewelyn Bren headed a revolt in the same district. In 1404 Owain Glyn Dwr swept through the county, burning castles and carrying all before him. By the Act of Union of 1535 the county of Glamorgan was incorporated as it now exists, by the addition to the old county of the lordship of Gower and Kilvey, west of the Neath.

The lordship of Glamorgan, shorn of its quasi-regal status, was granted by Edward VI. to William Herbert, afterwards 1st earl of Pembroke, from whom it has descended to the present marquess of Bute.

The rule of the Tudors promoted the rapid assimilation of the inhabitants of the county, and by the reign of Elizabeth even the descendants of the Norman knights had largely become Welsh both in speech and sentiment. Welsh continued to be the prevalent speech, except in the peninsular part of Gower and perhaps Cardiff, till the last quarter of the 19th century. Since then it has lost ground in the maritime towns and the south-east corner of the county generally, while it is failing to hold its own even in the industrial districts of the north.

In common with the rest of Wales the county was mainly Royalist in the Civil War, but later dissatisfaction made the county declare for Parliament. There was, however, a subsequent Royalist revolt in Glamorgan in 1648, but it was crushed by Colonel Horton at the battle of St. Fagan's.

Industrial Development. — Down to the middle of the 18th century the county had no industry of importance except agriculture. The coal which underlies practically the whole surface except the Vale of Glamorgan and West Gower was little worked till about 1755, when it began to be used instead of charcoal for the smelting of iron. The iron works were mostly on the northern outcrop of the coal-field and by 1811 there were 25 blast furnaces in the county, among them those of Aberdare, Dowlais and Merthyr Tydfil. Down to about 1850, if not later, the chief collieries were owned by the ironmasters and were worked for their own requirements, but when the suitability of the lower seams in the district north of Cardiff for steam purposes was realized, an export trade sprang up and soon assumed enormous proportions, so that "the port of Cardiff" (including Barry and Penarth), from which the bulk of the steam coal was shipped, became the first port in the world for the shipment of coal. This remarkable development coincided with the ever increasing demand for railway construction, steam ships and navies.

The rapid opening up of the deeper seams in the southern section of the industrial region meant a great influx of population which settled around the pit-heads. The steep sides of the valleys would not allow of town development and so the workmen's houses grew up in the Rhondda and some other valleys in long straggling rows in the valley bottoms. The mining villages therefore, while lacking all traditions of settlement from the past, offered few facilities for the development of a new corporate civic life. Large numbers of small colliery companies exploited these valleys from which the coal was rushed to the coast for export as long as the demand lasted. There was little or no development of by-product trade in the valleys—a factor that caused serious difficulties for the east of the county when the general demand for steam coal fell considerably after the war of 1914–18.

The evolution of the south-west of the county where the coal-field reaches nearest the sea was different. The triangle formed by Port Talbot, Ystalyfera and Loughor has concentrated on the metallurgical industries which have focused on Swansea "the metallurgical capital of Wales."

The manufacture of iron and steel is carried on at Dowlais, Merthyr Tydfil and at Port Talbot, Briton Ferry, Pontardawe, Swansea, Gorseinon and Gowerton. During the last quarter of the 19th century the use of the native ironstone was almost wholly given up, and the necessary ore is now imported, mainly from Spain. As a result several of the older inland works, such as those of Aberdare, Ystalyfera and Brynaman were abandoned, and new works established on or near the sea-board; *e.g.,* the Dowlais company in 1891 opened large works at Cardiff. The tin-plate industry is mainly in the Swansea-Llanelly area, though

there are works near Llantrisant and at Melin Griffith near Cardiff, the latter being the oldest in the county. Copper-smelting is carried on on a large scale in the west of the county, at Port Talbot, Cwmavon, Neath and Swansea, and on a small scale at Cardiff, the earliest works having been established at Neath in 1584 and at Swansea in 1717. There are nickel works at Clydach near Swansea. Swansea has almost a monopoly of the manufacture of spelter or zinc. Lead, silver and other metals or their by-products are treated in or near Swansea. Limestone and silica quarries are worked, while sandstone and clay are also raised. Swansea and Nantgarw were formerly famous for their china, and coarse ware is still made at Ewenny.

The development of the anthracite coalfield lying to the north and west of Swansea (from which port it is mostly shipped) dates mainly from the closing years of the 19th century when the demand for this coal grew rapidly. Its extended use in modern industry together with the organization provided for its international marketing tends to concentrate the industrial development of Glamorganshire more and more in the south-western section.

The low-lying land on the south from Caerphilly to Margam is very fertile, and here the standard of agriculture is fairly high. Everywhere on the Coal Measures the soil is poor, while vegetation is also injured by the smoke and rubbish tips. Leland (c. 1535) describes the lowlands as growing good corn and grass but little wood, while the mountains had "redde dere, kiddes plenty, oxen and sheep." The land even in the "Vale" seems to have been open and unenclosed till the end of the 15th or beginning of the 16th century, while enclosure spread to the uplands still later. About one-fifth of the total area is still common land, more than half of which is unsuitable for cultivation. The total area under cultivation in Glamorganshire is under half of the total area of the county. The chief crops raised are oats, turnips and swedes, barley, wheat, potatoes and mangolds. Dairying has been largely abandoned for stock-raising. Good sheep and ponies are reared in the hill-country. Pig-keeping is much neglected, and despite the mild climate very little fruit is grown.

Communications. — The physical features are well suited for communication purposes. The coal trains could run easily from the high ground of the coalfield to the "Vale" and thence to the coal exporting ports on the coast, the uphill return journey being done with empty wagons. Thus a large number of small private lines ran down from the coal valleys focusing on Cardiff, Barry, Port Talbot and Swansea, which are well supplied with dock accommodation. Gradually the smaller railway lines became amalgamated and since 1923 they have all been run by the G.W.R. The G.W.R. main line runs between the highland and the sea, serves Cardiff, Bridgend, Port Talbot, Neath, Swansea and Loughor. It sends numerous branches up the northern valleys. Swansea is connected with Brecon and with Mid Wales and Shrewsbury by L.M.S. lines. The canals of the county are the Glamorgan canal from Cardiff to Merthyr Tydfil (25½ m.), with a branch (7 m.) to Aberdare, the Neath canal (13 m.) from Briton Ferry to Abernant, Glyn Neath, the Tennant canal connecting the rivers Neath and Tawe, and the Swansea canal (16½ m.), running up the Swansea Valley from Swansea to Abercrave in Breconshire. Comparatively little use is now made of these canals, excepting the lower portions of the Glamorgan canal.

Population and Administration. — The rapid rise of population with the development of its industries and coal-mining is one of the most remarkable features in the social life of Wales during the last century. In the three decades between 1831 and 1861 the population increased 35·2, 35·4 and 37·1 per cent. respectively, and from 1881–91, 34.4 per cent. The average increase in the decennial periods subsequent to 1861 were about 25% until 1901 when the population stood at 859,931. In 1938 it had reached 1,154,960.

It has been shown that before the railway's advent this increase in population was derived mainly from the neighbouring counties of Caermarthen, Brecon and Cardigan, but subsequent immigrants have been drawn from a much wider field.

The county is divided into seven parliamentary divisions, each returning one member. These divisions are Aberavon, Caerphilly, Gower, Llandaff and Barry, Neath, Ogmore and Pontypridd. In addition there are three members for Cardiff, and two each for Merthyr, Swansea and the Rhondda Urban District. There are six municipal boroughs, Port Talbot, Cardiff, Cowbridge, Merthyr Tydfil, Neath and Swansea. Cardiff, Merthyr Tydfil and Swansea are county boroughs.

Glamorgan is in the south Wales circuit, and both assizes and quarter sessions are held at Cardiff and Swansea alternately. All the municipal boroughs have separate commissions of the peace, and Cardiff and Swansea have also separate courts of quarter sessions. The county has 13 other petty sessional divisions; Cardiff, the Rhondda and the Merthyr and Aberdare district have stipendiary magistrates. The county is in the dioceses of Llandaff and Swansea and Brecon.

BIBLIOGRAPHY.—A collection of records edited by G. T. Clark under the title *Cartae et alia munimenta quae ad dominium de Glamorgan pertinent* was privately printed by him in four volumes (1885–93). *A Descriptive Catalogue* of *the Penrice and Margam Abbey MSS.* (6 vols.) was privately issued (1893–1905) under the editorship of Dr. de Gray Birch. *The Book of Llan Dâf* (edited by Dr. Gwenogvryn Evans, 1903) contains documents illustrative of the early history of the diocese of Llandaff. Cardiff has published its *Records* in 5 vols. G. T. Clark, *Genealogies* of *Glamorgan* (1886) and *Mediaeval Military Architecture* (1884); Royal Commission on Industrial Unrest (1917), Report on Region VII.—South Wales; W. Rees, *South Wales and the March* (1923); A. E. Trueman, "Population Changes on the South Wales Coalfield," *Geogr. Journal,* 1919.

GLANDERS or **FARCY** (*equinia*), a specific infective and contagious disease prevailing in most parts of the world. Caused by Bacillus mallei, it affects chiefly the horse, ass, and mule but is communicable to man. In Equidae it is one of the most serious of maladies, and specially affects the lungs, respiratory mucous membrane, and the lymphatic system. It occurs particularly among horses kept in foul, crowded, badly ventilated stables or such as are over-worked, badly fed, or debilitated. It may be contracted by inhalation of the bacilli, ingestion of the virus with food or water, or inoculation of a wound of the skin or a mucous membrane. Carnivorous animals — lions, tigers, dogs, and cats — have become infected through eating the flesh of glandered horses; and men attending diseased horses are liable to be infected (see below).

Sometimes a distinction is made between glanders with nasal ulcers and other symptoms of respiratory disease, and glanders of the skin, or *farcy,* but there is no essential difference. Both are due to the same organism, and both may be acute or chronic. Acute glanders is always rapidly fatal, and chronic glanders may become acute or terminate by apparent recovery.

The symptoms of acute glanders are initial fever, thirst, loss of appetite, hurried pulse and respiration, 'emaciation, languor, and disinclination to move. Sometimes the legs or joints are swollen; but the characteristic symptoms are a greyish-yellow viscid discharge from one or both nostrils, a peculiar enlarged and nodulated condition of one or both submaxillary lymphatic glands, which though they may be painful very rarely suppurate, and on the nasal membrane smdl yellow pimples or pustules, running into deep, ragged-edged ulcers, and sometimes on the septum large patches of deep ulceration. The discharge from the nose adheres to the nostrils and upper lip, and causes snuffling and frequent snorting. The lymphatic vessels of the face often appear as painful subcutaneous "cords" passing across the cheek. These vessels sometimes present nodules which break and discharge a glutinous pus. As the disease progresses, the ulcers on the nose increase in number, enlarge or become confluent, extend in depth, and may perforate the septum. The nasal discharge, now more abundant and tenacious, is streaked with blood and offensive, the respiration is noisy or roaring, and there may be coughing with bleeding from the nose. Painful oedematous swellings appear on the muzzle, throat, between the fore legs, at the flank or on the limbs, and "farcy buds" may form on some of the swollen parts. Pneumonia and pleurisy, with extreme prostration, and diarrhoea precede death, which is due to asphyxia or to exhaustion.

Chronic or latent glanders generally presents few definite symptoms. The suspected animal may have a discharge from the nose, or an enlarged submaxillary gland, or both, and small unbroken nodules may exist on the septum, but usually there is no visible ulceration of the nasal membrane. In some horses suspicion of glanders may be excited by lameness and sudden swelling of a joint, by profuse staling, sluggishness, general loss of condition or by refusal of food, rise of temperature, swollen fetlocks, with dry hacking cough, nasal catarrh, and other symptoms of a common cold. With rest in the stable the horse improves, but a one-sided nasal discharge continues, the submaxillary gland enlarges, and, after an interval, ulcers appear in the nose or "farcy buds" form on a swollen leg. In occult glanders the horse may appear to be in good health and be able to perform ordinary work. In these cases the existence of glanders can only be discovered by resorting to the mallein test.

In cutaneous glanders, or farcy, symptoms occur on the skin of a limb, usually a hind one, or on the body, where the lymphatics become inflamed and ulcerated. The limb is much swollen, and the animal moves with pain and difficulty. The lymphatic vessels appear as prominent "cords," hard and painful on manipulation, and along their course arise nodular swellings—the so-called "farcy buds." These small abscesses break and discharge a yellow, glutinous, blood-stained pus, leaving sores which heal very slowly.

Medical treatment of glanders or farcy should not be attempted. The disease is dealt with under the contagious diseases (animals) acts. Horses which present suspicious symptoms, or those which have been in contact with glandered horses, should be isolated and tested with mallein. Animals which are found affected should immediately be destroyed, and their harness, clothing, and the utensils employed with them thoroughly cleansed, while the stalls, horse-boxes, and places which the horses have frequented should be disinfected. Forage left by glandered horses should be burned.

Mallein, the toxin formed by B. *mallei*, was discovered in 1888 by Helman, a Russian military veterinary surgeon, and the first complete demonstration of its diagnostic value was given in 1891 by Kalning, also of Russia. It is present in a sterilized and filtered broth culture of glanders bacilli. Subcutaneously injected in a glandered horse, mallein causes a marked rise of temperature and an extensive painful swelling at the seat of injection.

In man, glanders is relatively a rare disease. It occurs chiefly among those who are much in contact with horses, such as grooms, coachmen, cavalry soldiers, veterinary surgeons, etc., but has caused the death of several bacteriologists who were carrying on researches with B. *mallei*. Usually the bacillus is communicated from a glandered animal either through a wound or scratch or through application to the mucous membrane of the nose or mouth. After an incubation period of three or four days, or longer in some cases, there is a general feeling of illness, with pains in the limbs and joints like those of acute rheumatism. If the disease has been introduced through an abrasion, local pain and inflammation occur and extend up the lymphatics. An ulcer with offensive discharge is formed, and blebs appear in the inflamed skin, along with diffuse abscesses. The disease now may stop short, but more commonly rapidly grows worse. Anywhere in the body cutaneous and subcutaneous foci appear which ultimately open and become extensive sloughing ulcers. The condition is then a specialized variety of pyaemia or blood-poisoning.

The mucous membranes suffer like the skin, and this is particularly the case with the interior of the nose, where in many instances the disease first shows itself. Not infrequently the bronchi become affected, and abscesses form in the lungs. In the acute form the case generally terminates fatally in from two or three days to as many weeks.

A chronic form of glanders and farcy is occasionally met with, in which the symptoms advance much more slowly, and cause less urgent constitutional disturbance. Recovery from this form is recorded; but in general the disease proves fatal by exhaustion of the patient, or by suddenly becoming acute. On the other hand, acute glanders is never observed to become chronic.

The sole treatment available is maintenance of the patient's strength. Cauterization should be resorted to if the point of infection is early known.

GLANDS, in anatomy, are composite masses of tissue varying widely in complexity and size but agreeing in the formation of a secretion. Every gland is formed by an ingrowth from an epithelial surface. This ingrowth may from the beginning possess a tubular structure, but in other instances may start as a solid column of cells which subsequently becomes tubulated. As growth proceeds, the column of cells may divide or give off offshoots, in which case a compound gland is formed. In many glands the number of branches is limited, in others (salivary, pancreas) a very large structure is finally formed by repeated growth and sub-division. As a rule the branches do not unite with one another, but in one instance, the liver, this does occur when a reticulated compound gland is produced. In compound glands the more typical or secretory epithelium forms the terminal portion of each branch, and the uniting portions form ducts and are lined with a less modified type of epithelial cell.

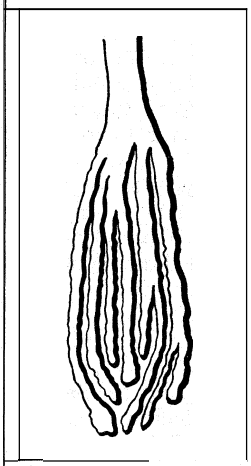

FIG. 1.—A COMPOUND TUBULAR GLAND, HIGHLY MAGNIFIED. ONE OF THE PYLORIC GLANDS OF THE STOMACH OF THE DOG

Glands are classified according to their shape. If the gland retains its shape as a tube throughout it is termed a *tubular* gland, *simple* tubular if there is no division (large intestine), *compound* tubular (fig. 1) if branching occurs (pyloric glands of stomach). In the simple tubular glands the gland may be coiled without losing its tubular form, *e.g.*, in sweat glands. In the second main variety of gland the secretory portion is enlarged and the lumen variously increased in size. These are termed *alveolar* or *saccular* glands. They are again subdivided into simple or compound alveolar glands, as in the case of the tubular glands (fig. 2). A further complication in the case of the alveolar glands may occur in the form of still smaller saccular diverticula growing out from the main sacculi (fig. 3). These are termed *alveoli*.

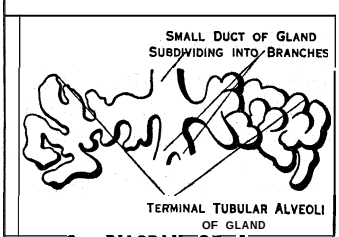

FIG. 2.—DIAGRAM OF A TUBULO-ALVEOLAR GLAND

The typical secretory cells of the glands are found lining the terminal portions of the ramifications and extend upwards to varying degrees. Thus in a typical acinous gland the cells are restricted to the final alveoli. The remaining tubes are to be considered mainly as ducts. In tubulo-alveolar glands the secreting epithelium lines the alveolus as well as the terminal tubule.

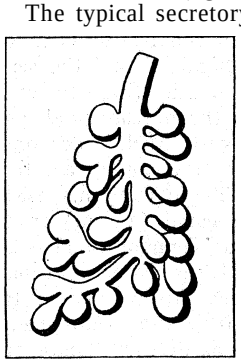

FIG. 3.—A COMPOUND ALVEOLAR GLAND
One of the terminal lobules of the pancreas, showing the spherical shape of the alveoli

The gland cells are all placed upon a basement membrane. In many instances this membrane is formed of very thin flattened cells, in other instances it is apparently a homogeneous membrane, and according to some observers is simply a modified part of the basal surface of the cell, while according to others it is a definite structure distinct from the epithelium. In the secretory portion of the gland and in the smaller ducts the epithelial layer is one cell thick only. In the larger ducts there are two layers of cells, but even here the surface cell usually extends by a thinned-out stalk down to the basement membrane. The detailed characters of the epithelium of the different glands of the body are given in a separate article (see ALIMENTARY CANAL, etc.). It will be sufficient here to give the more general characters possessed by these cells. They are cubical or conical cells with distinct oval

nuclei and granular protoplasm. Within the protoplasm is accumulated a large number of spherical granules arranged in diverse manners in different cells. The granules vary much in size in different glands, and in chemical composition, but in all cases represent a store of material ready to be discharged from the cell as its secretion. Hence the general appearance of the cell is found to vary according to the previous degree of activity of the cell. If it has been at rest for some time the cell contains very many granules which swell it out and increase its size. The nucleus is then largely hidden by the granules. In the opposite condition, *i.e.*, when the cell has been actively secreting, the protoplasm is much clearer, the nucleus obvious and the cell shrunken in size, all these changes being due to the extrusion of the granules.

GLANVILL (or GLANVIL), **JOSEPH** (1636–1680), English philosopher, was born at Plymouth and educated at Oxford. After the Restoration he was successively rector of Wimbush, Essex, vicar of Frome Selwood, Somersetshire, rector of Streat and Walton. In 1666 he was appointed to the abbey church, Bath; in 1678 he became prebendary of Worcester Cathedral, and acted as chaplain in ordinary to Charles II. from 1672. He died at Bath Nov. 4, 1680. Glanvill's first work (a passage in which suggested the theme of Matthew Arnold's *Scholar Gipsy*). *The Vanity of Dogmatizing*, etc. (1661), shows how philosophical scepticism might be employed as a bulwark for faith. The endeavour to cognize the whole system of things by referring all events to their causes appears to him to be doomed to failure from the outset. We know isolated facts, but we cannot perceive any such connection between them as that the one should give rise to the other. In the words of Hume, "they seem conjoined but never connected." All causes then are merely the occasions on which the one first cause operates. Glanvill rejected the scholasticism and Aristotelianism of his own university for the Platonism of Cambridge, writing in 1662 the *Lux Orientalis* which reproduced Henry More's theory of the pre-existence of the soul. In spite of his admission of the defects of our knowledge, Glanvill yielded to vulgar superstitions, and actually endeavoured to accredit them both in his revised edition of the *Vanity of Dogmatizing*, published as *Scepsis scientifica* (166 j), and in his *Philosophical Considerations concerning the existence of Sorcerers and Sorcery* (1666). The latter work was based on the story of the drum alleged to have been heard every night in a house in Wiltshire (Tedworth, belonging to a Mr. Mompesson), a story which made much noise in the year 1663, and which is supposed'to have furnished Addison with the idea of his comedy *The Drummer*. Glanvill's *Sadducismus Triumphatus*, printed posthumously in 1681, also defends witchcraft; but he supported a more honourable cause in his defence of the Royal Society of London, as *Plus Ultra, or the Progress and Advancement of Science since the time of Aristotle* (1668), a work showing his empirical tendencies.

See F. Greenslet, *J. Glanvill* (New York, 1900).

GLANVILL, RANULF DE (or GLANVIL, GLANVILLE) (d. 1190), chief justiciar of England, was born at Stratford, Suffolk, but the date of his birth is not known. He appears to have possessed a considerable estate, and founded the priory of Butley, the abbey of Leiston, and a hospital at Somerton. He first comes to the front as sheriff of Yorkshire, from 1163 to 1170, when all sheriffs were dismissed by Henry II.'s orders. In 1174 he became sheriff of Lancashire, and custodian of the honour of Richmond. In 1174 he was one of the English leaders in the battle of Alnwick, where William the Lion, king of the Scots, surrendered to him, and from that time he comes into prominence. He was re-appointed sheriff of Yorkshire in 1175, holding this post until the end of Henry II.'s reign. In 1176 he became justice of the king's court and justice itinerant in the northern circuit, and in 1180 chief justiciar of England. In Henry's frequent absences he became, in effect, viceroy of England. He was removed from office by Richard I. on his accession, and imprisoned until he had paid a ransom, according to one authority of £15,000. He accompanied Richard, however, to the crusade in July 1190, and died at Acre, probably before Oct. 21 of that year.

Glanvill was a man of great energy and versatile talent, and was on many occasions useful to Henry II. as a diplomatic agent. His chief importance lies, however, in his part in the legal changes of Henry's reign, including the re-establishment of the *curia regis*. The whole administration of justice was greatly facilitated by the institution of the circuit of judges, and by simplified methods of procedure. In this reign also the first steps were taken to limit the scope of canon law, by bringing under the common law large numbers of persons who had benefited by so-called clerical immunities. Perhaps at the king's suggestion, Glanvill wrote, or superintended the writing of, the *Tractatus de legibus et consuetudinibus regni Angliae*, a practical treatise on the forms of procedure in the king's court, first printed in 1554. This was the first coherent code of law compiled in England, and paved the way for plaintiffs who had hitherto been tried by local or feudal courts, to formulate a case before the *curia regis*, in which the procedure was uniform, and the judgments aimed at consistency.

An English translation of Glanvill's treatise: with notes and introduction by John Beames. was published in London in 1812. A French version is found in various mss. but has not yet been printed. (*See* also ENGLISH LAW, HISTORY OF).

GLAPTHORNE, HENRY (fl. 1635–1642), English poet and dramatist, published *Poenzs* (1639), many of them in praise of an unidentified "Lucinda"; a poem in honour of his friend Thomas Beedome, whose *Poems Divine and Humane* he edited in 1641; and *Whitehall* (1642), dedicated to his "noble friend and gossip, Captain Richard Lovelace." *Argalus and Parthenin* (1639), his best work, is a pastoral tragedy founded on an episode in Sidney's *Arcadia; Albertus Wallenstein* (1639), his only attempt at historical tragedy, represents Wallenstein as a monster of pride and cruelty. Glapthorne's other plays, though they hardly rise above the level of contemporary productions, contain many felicitous isolated passages.

GLAREOLIDAE: *see* PRATINCOLE.

GLARUS, one of the Swiss cantons, the name being taken from that of its chief town. Its area is 264 square m., of which 173·1 sq m. are classed as "productive" (forests covering 41 sq.m.). It is composed of the upper valley of the Linth which rises in the glaciers of the Todi, 11,887 ft., and has carved out for itself a deep valley, with comparatively level floor, occupied by a number of villages. Glacier passes lead from its head to the Grisons, also the rough footpath over the Kisten Pass, but a carriage road over the Klausen Pass gives access to the canton of Uri. The Sernf valley or Kleinthal, which joins the Linth at Schwanden, a little above Glarus itself, has a track leading to the Grisons over the Panixer Pass and the Segnes Pass. Just below Glarus town, another glen (coming from the south-west and leading by the Pragel Pass to Schwyz) joins the main valley, and is watered by the Klön. It is separated from the main glen by Glärnisch (9,580 ft.), while the Sernf valley is similarly cut off from the Grossthal by the high ridge running northwards from the Hausstock (10,342 ft.) over the Karpfstock (9,177 ft.). In the east the Riesetenpass leads to the valley of Weisstannen, and the Widersteinerfurkel leads to the Murgtal, both being valleys of the St. Galler Oberland. There is a sulphur spring at Stachelberg, near Linthal village, and an iron spring at Elm, while in the Sernf valley there are the Plattenberg slate quarries, and just south of Elm those of the Tschingelberg. A railway runs through the whole canton from north to south past Glarus to Linthal village, while from Schwanden there is an electric line (opened in 1905) up to Elm.

In 1941 the population of the canton was 34,775, five-sevenths of which were Protestants and two-sevenths Catholics, ail German-speaking. The density per square m. was 127. After the capital, Glarus (*q.v.*), the largest villages are Nafels, Ennenda (opposite Glarus, of which it is practically a suburb), Netstal, Mollis and Linthal. The slate industry existing since the beginning of the 17th century, the cotton spinning introduced in 1714, the cotton printing established in 1740 and the weaving are the most important manufactures. There is little agriculture, while the breeding of cattle is important, for it is a region of mountain pastures which can support thousands of cows The canton produces green cheese made of skim milk. whether of goats or cows. mixed with buttermilk and coloured with powdered *Melilotus caerulea*. The curds

are brought down from the huts on the pastures, and, after being mixed with the dried powder, are ground in a mill, then put into shapes and pressed. The canton forms a single administrative district and contains 28 communes. It sends representatives elected by the Landsgemeinde to the Federal Ständerat and Nationalrat. The canton still keeps its primitive democratic assembly or Landsgemeinde (meeting annually in the open air at Glarus on the first Sunday in May), composed of all male citizens of 20 years of age or more. It acts as the sovereign body, so that no "referendum" is required, while any citizen can submit a proposal. It names the executive of 6 members, besides the Landammann or president, all holding office for three years. The communes (forming 18 electoral circles) elect for three years the *Landrat*, a standing committee of members in the proportion of 1 for every 500 inhabitants or fraction over 250. The present constitution dates from the year 1887.

GLARUS (Fr. *Glaris*), the capital of the Swiss canton of the same name 42½ m. S.E. by rail from Ziirich, is connected by rail with Elm and Linthal. It is built on the left bank of the Linth (opposite it is the industrial suburb of Ennenda on the right bank), at the north-eastern foot the Vorder Glärnisch (7,648 ft.), while on the east rises the Schild (7,501 ft.). In May 1861 practically the whole town was destroyed by a fire fanned by a violent *Föhn* wind, rushing down the Linth valley. The town is 1,578 ft. above the sea-level, and in 1930 had a population of 5,387, almost all German-speaking, while 1,431 were Roman Catholics.

The DISTRICT OF GLARUS is said to have been converted to Christianity in the 6th century by the Irish monk, Fridolin, who was the founder of the Benedictine nunnery of Sackingen, on the Rhine between Constance and Basel, that about the 9th century became the owner of the district. The Habsburgs gradually drew to themselves the exercise of all the rights of the nuns, so that in 1352 Glarus joined the Swiss Confederation, and gained complete freedom after the battle of Nafels (1388). Zwingli the Reformer was priest here 1506–16 and Glarus early adopted Protestantism, but there were many struggles between the two parties, and to secure peace it was arranged that, besides the common *Landsgemeinde*, each party should have its separate *Landsgemeinde* (1.623) and tribunals (1683). The parish church is used by both Roman Catholics and Protestants. The slate-quarrying industry appeared early in the 17th century, while cotton-spinning was introduced about 1714, and calico-printing by 1750. In 1798, in consequence of the resistance of Glarus to the French invaders, the canton was united to other districts under the name of canton of the Linth. The old system of government was restored in 1814, but in 1836 by the new Liberal constitution one Landsgerneinde only was retained. Pop. (1941) 34,700.

GLAS, GEORGE (1725–1765), Scottish seaman and merchant adventurer in West Africa, son of John Glas (*q.v.*), was born at Dundee in 1725. He commanded a ship which traded between Brazil, the north-west coasts of Africa and the Canary islands. During his voyages he discovered on the Sahara seaboard a river navigable for some distance inland, and here he proposed to found a trading station. The spot is plausibly identified with Gueder, a place in about 29° 10′ N., possibly the haven where the Spaniards had in the 15th and 16th centuries a fort called Santa Cruz de Mar Pequeiia. Glas made an arrangement with the Lords of Trade whereby he was granted £15,000 if he obtained free cession of the port he had discovered to the British Crown; the proposal was to be laid before parliament in the session of 1765. Having chartered a vessel, Glas, with his wife and daughter, sailed for Africa in 1764, reached his destination, made a treaty with the Moors of the district, and named his settlement Port Hillsborough.

In Nov. 1764 Glas and some companions, leaving his ship behind, went in the longboat to Lanzarote, intending to buy a small barque. From Lanzarote he forwarded to London the treaty he had concluded for the acquisition of Port Hillsborough. A few days later he was seized by the Spaniards, taken to Teneriffe and imprisoned at Santa Cruz. (See Calendar of Home *Office* Papers 1760–65.) In March 1765 the ship's company at Port Hillsborough was attacked by the natives and several members of it killed. The survivors, including Mrs. and Miss Glas, escaped to Teneriffe. In October following, Glas was released from prison, and, with his wife and child, he set sail for England on board the barque "Earl of Sandwich." On Nov. 30 Spanish and Portuguese members of the crew mutinied, killing the captain and passengers. Glas was stabbed to death, and his wife and daughter thrown overboard. (The murderers were afterwards captured and hanged at Dublin.) After the death of Glas the British Government appears to have taken no steps to carry out his project.

In 1764 Glas published in London, *The History of the Discovery and Conquest of the Canary Islands*, which he had translated from the ms. of an Andalusian monk named Juan Abreu de Galindo, then recently discovered at Palma. To this Glas added a description of the islands.

GLAS, JOHN (1695–1773), Scottish divine, founder of the Glasite church, was born at Auchtermuchty, Fife, where his father was parish minister, on Oct. 5, 1695. He became minister of Tealing, Dundee, and in 1725, in a letter to Francis Archibald, minister of Guthrie, Forfarshire, he repudiated the obligation of national covenants. In the same year his views found expression in the formation of a society "separate from the multitude" numbering nearly a hundred, and drawn from his own and neighbouring parishes. Its members pledged themselves to follow Glas's doctrine. From the scriptural doctrine of the essentially spiritual nature of the kingdom of Christ, Glas in his public teaching drew the conclusions: (1) that there is no warrant in the New Testament for a national church; (2) that the magistrate as such has no function in the church; (3) that national covenants are without scriptural grounds; (4) that the true Reformation cannot be carried out by political and secular weapons but by the word and spirit of Christ only. This argument is most fully exhibited in Glas's treatise entitled The Testimony of *the King* of *Martyrs* (1729).

Glas was summoned (1726) before his presbytery, and he was in 1728 suspended from the discharge of ministerial functions, and finally deposed in 1730. The members of his society for the most part continued to adhere to him, thus constituting the first "Glassite" or "Glasite" church. The seat of this congregation was shortly afterwards transferred to Dundee (whence Glas subsequently removed to Edinburgh), where he officiated for some time as an "elder." He next laboured in Perth for a few years, where he was joined by Robert Sandeman (*see* GLASITES), who became his son-in-law, and eventually was recognized as the leader and principal exponent of Glas's views; these he developed in a direction which laid them open to the charge of antinomianism. Ultimately in 1730 Glas returned to Dundee, where the remainder of his life was spent. In 1739 the General Assembly removed the sentence of deposition which had been passed against him, and restored him to the character and function of a minister of the gospel of Christ, but not that of a minister of the Established Church of Scotland. He died in 1773.

A collected edition of his works was published at Edinburgh in 1761 (4 vols., 8vo), and again at Perth in 1782 (5 vols., 8vo). Glas's *True Discourse of Celsus* (1753), from Origen's reply to it, is a competent and learned piece of work. The *Testimony of the King of Martyrs concerning His Kingdom* (1729) is a classic repudiation of erastianism and defence of the spiritual autonomy of the church under Jesus Christ.

GLASGOW, city, county, royal burgh and port, Lanarkshire, Scotland, situated on both banks of the Clyde, 401½ m. N.W. of London by the West Coast railway route, and 47 m. W.S.W. of Edinburgh by the L.N.E.R. The valley of the Clyde is closely confined by hills, and the city extends far over these. The commercial centre of Glasgow, with the majority of important public buildings, lies on the north bank of the river, which traverses the city from west-south-west to east-north-east, and is crossed by a number of bridges. The uppermost is Dalmarnock Bridge, dating from 1891, and next below it is Rutherglen Bridge, rebuilt in 1896, superseding a structure of 1775. St. Andrew's suspension bridge gives access to the Green to the inhabitants of Hutchesontown, a district which is approached also by Albert Bridge, leading from the Saltmarket. Above this bridge is the tidal dam and weir. Victoria Bridge (1856) took the place of a bridge erected by Bishop Rae in 1345, and demolished in 1847. Then follows a suspension bridge (1853) by which foot-passengers from the south

side obtain access to St. Enoch Square and, finally, the bridge variously known as Glasgow, Jamaica Street, or Broomielaw Bridge (1835). Towards the close of the century it was reconstructed and reopened in 1899, but owing to its inadequacy to cope with the constantly increasing traffic George V. bridge, a short distance downstream, was opened in 1927. Between the two road-bridges is a bridge belonging to the L.M.S.R.

Buildings. — The municipal buildings (1889) stand on the eastern side of George Square, the heart of the city, and several additional blocks have been built or rented for the municipal staff. A sanitary department was opened in 1897, including a bacteriological and chemical laboratory. Added buildings, connected with the older ones by two bridges, were completed in 1923. Up till 1810 the town council met in a hall adjoining the old tolbooth. It then moved to the structure at the foot of the Saltmarket, now used as court-houses, and, after two further moves, the present quarters were occupied. On the south side of George Square is the General Post Office. On the west side stand the Bank of Scotland and the Merchants' House, the head of which (the dean of gild), along with the head of the Trades' House (the deacon-convener of trades) has been *de facto* member of the town council since 1711, an arrangement devised with a view to adjusting the frequent disputes between the two gilds. The Royal Exchange is a fine Corinthian building. Argyll Street, the busiest thoroughfare, leads to Trongate, where a few remains of the old town are now carefully preserved. On the south side of the street, spanning the pavement, stands the Tron Steeple, a stunted spire dating from 1637, all that is left of St. Mary's church, burned down in 1793. On the opposite side, at the corner of High Street, stood the ancient tolbooth, or prison, a turreted building, five storeys high, with a fine Jacobean crown tower. The only remnant of the structure is the tower known as the Cross Steeple.

St. Mungo's Cathedral. — The cathedral stands in the north-east quarter of the city 104 ft. above the Clyde. It is a beautiful example of Early English work, impressive in its simplicity. Its form is that of a Latin cross, with imperfect transepts. At the centre rises a fine tower, with a short octagonal spire. The choir, locally known as the High Church, serves as one of the city churches, and the extreme east end of it forms the Lady chapel. The chapter-house, which projects from the north-eastern corner, was built in the 15th century and has a groined roof supported by a pillar. The crypt beneath the choir is borne on 65 pillars and lighted by 41 windows. The sculpture of the capitals of the columns and bosses of the groined vaulting is exquisite and the whole is in excellent preservation. Strictly speaking, it is not a crypt, but a lower church adapted to the sloping ground of the right bank of the Molendinar burn. The dripping aisle is so named from the constant dropping of water from the roof. St. Mungo's Well in the south-eastern corner was considered to possess therapeutic virtues, and in the crypt a recumbent effigy, headless and handless, is faithfully accepted as the tomb of Kentigern. In 1115 an investigation was ordered by David, prince of Cumbria, into the lands and churches belonging to the bishopric, and from the deed then drawn up it is clear that at that date a cathedral had already been endowed. When David ascended the throne in 1124 he gave to the see of Glasgow the lands of Partick besides restoring many possessions of which it had been deprived. Jocelin (d. 1199), made bishop in 1174, was the first great bishop, and is memorable for his efforts to replace the cathedral built in 1136 by Bishop John Achaius, which had been destroyed by fire. The crypt is his work, and he began the choir, Lady chapel, and central tower. The new structure was sufficiently advanced to be dedicated in 1197. James Beaton or Bethune (1517–1603), the last Roman Catholic archbishop, fled to France at the Reformation in 1560, and took with him the treasures and records of the see, including the Red Book of Glasgow dating from the reign of Robert III. The documents were deposited in the Scots College in Paris, were sent at the outbreak of the Revolution for safety to St. Omer, and were never recovered. This loss explains the paucity of the earlier annals of the city. The Reformers threatened to mutilate the cathedral, but the prompt defence of the craftsmen was the means of saving it.

Excepting the cathedral, no Glasgow church possesses historical interest. This is due largely to the long survival of the severe sentiment of the Covenanters. There are several fine modern churches. St. Enoch's (1780) has a good spire (the saint's name is said to be a corruption of Tanew, mother of Kentigern).

EDUCATION

University. — The university, founded in 1450 by Bishop Turnbull under a bull of Pope Nicholas V., survived in its old quarters till far in the 19th century. The *paedagogium,* or college of arts, was at first housed in Rottenrow, but was moved in 1460 to a site in High Street, where Sir James Hamilton of Cadzow, first Lord Hamilton (d. 1479), gave it four acres of land and some buildings. Queen Mary bestowed upon it thirteen acres of contiguous ground, and her son granted it a new charter and enlarged the endowments. Before the Revolution its fortunes fluctuated, but in the 18th century it became very famous. By the middle of the 19th century, however, its surroundings had deteriorated, and in 1860 it was decided to rebuild it elsewhere. The ground had enormously increased in value and a railway company purchased it for £100,000. In 1864 the university bought the Gilmore Hill estate and adjacent property and the new buildings (1870) were placed on the ridge of Gilmore Hill — the finest situation in Glasgow. On the south the ground falls in a series of terraces towards Kelvingrove Park and the Kelvin. On the west stand the houses of the principal and professors. The third marquess of Bute (1847–1900) gave £40,000 to provide the Bute or coinmon hall, divided by a screen from the Randolph hall, named after another benefactor, Charles Randolph (1809–1878). The library includes the collection of Sir William Hamilton, and the Hunterian museum, bequeathed by William Hunter, the anatomist, is particularly rich in coins, medals, black-letter books and anatomical preparations. The observatory on Dowan Hill is attached to the chair of astronomy. Exhibitions were founded by John Snell (1629–1679), a native of Colmonell in Ayrshire, for the purpose of enabling students of distinction to continue their career at Balliol College, Oxford. The governing body includes the chancellor, elected for life by the general council, the principal, also elected for life, and the lord rector elected triennially by the students voting in "nations" according to their birthplace (*Glottiana,* natives of Lanarkshire; *Transforthana,* of Scotland north of the Forth; *Rothseiana,* of the shires of Bute, Renfrew and Ayr; and Loudonia, all others). There are 50 professors and some 4,500 students. The universities of St. Andrews, Glasgow, Aberdeen and Edinburgh unite to return three members to parliament. Queen Margaret College for women, which occupies a handsome building close to the botanic gardens, was incorporated with the university in 1893. Muirhead College is another institution for the education of women.

A number of new chairs have been founded and lectureships instituted in branches of medicine, chemistry, physics, literature and history. Extensions have been built, including a zoology building and a west wing with a War Memorial chapel, which cost about £122,000. The students' welfare scheme has been assisted by grants from the Government and the Carnegie Trust, and some £12,000 has been spent on the erection of a pavilion on the athletic ground at Westerlands.

There are two educational endowments boards which apply a revenue of about £10,000 a year mainly to the foundation of bursaries. The Royal Technical College in George Street originated in the foundation by John Anderson (1726–1796), professor of natural philosophy in the university, who opened a class in physics for working men, provided for the instruction of artisans and others unable to attend the university. In 1799 Dr. George Birkbeck (1776–1841) succeeded Garnett and began those lectures on mechanics and applied science which, continued elsewhere, ultimately led to the foundation of mechanics' institutes in many towns. In later years the college was further endowed and its curriculum enlarged by the inclusion of literature and languages, but the scope of its work is now limited to medicine (physics. chemistry and botany also). The medical school is housed in Anderson's Medical College, in Dumbarton Road. The Glasgow and West of Scotland Technical College, formed in 1586 out of a

combination of the arts side of Anderson College with three other colleges, is subsidized by the corporation and the endowments board, and is especially concerned with students desirous of following an industrial career. St. Mungo's College, which has developed from an extra-mural school in connection with the Royal Infirmary, was incorporated in 1889, with faculties of medicine and law. The United Free Church College, finely situated near Kelvingrove Park, the School of Art and Design, and the normal schools for the training of teachers, are institutions with distinctly specialized objects.

The High school in Elmbank is the successor of the grammar school (long housed in John Street) which was founded in the 14th century as an appanage of the cathedral. Other secondary schools include Glasgow Academy, Kelvinside Academy and the girls' and boys' schools endowed by the Hutcheson and other educational trusts.

Art Galleries, Libraries and Museums.—Glasgow merchants and manufacturers have been constant patrons of art, and their liberality may have had some influence on the younger painters who towards the close of the 19th century, broke away from tradition and, stimulated by training in the studios of Paris, became known as the "Glasgow school." The art gallery and museum is in Kelvingrove Park. Opposite it is the huge Kelvin Hall, burnt down in 1926, but rebuilt in the following year. The Institute of Fine Arts, in Sauchiehall Street, is mostly devoted to periodical exhibitions of modern art. There are also pictures on exhibition in the People's Palace on Glasgow Green, and in the museum at Camphill. The faculty of procurators possess a valuable library which is housed in their hall in West George Street. In Bath Street there are the Mechanics' and the Philosophical Society's libraries, and the Physicians' is in St. Vincent Street. The Mitchell library, was moved to North Street in 1911. It is governed by the city council. Another building in this street accommodates both the Stirling and Baillie libraries; the Stirling is particularly rich in tracts of the 16th and 17th centuries. The Athenaeum in St. George's Place, largely concerned with evening classes contains a library and reading-room.

Charities.—The old Royal Infirmary, designed by Robert Adam and opened in 1794, adjoining the cathedral, occupied the site of the archiepiscopal palace, the last portion of which was removed towards the close of the 18th century. It was rebuilt in 1912, and recent extensions have demolished the block containing the ward in which Lord Lister first applied his discovery of antisepsis. On the northern side are the buildings of the medical school attached to the institution. Hutcheson's Hospital, founded by George and Thomas Hutcheson in the 17th century for poor old men and orphan boys, and adorned with statues of the founders, is situated in Ingram Street, and by the increase in the value of its lands has become a very wealthy body; it is able to subsidize schools apart from the charity.

ADMINISTRATION AND FINANCE

Parks and Open Spaces.—The oldest open space is the Green (140 acres), on the right bank of the river, adjoining a densely-populated district. It once extended farther west, but a portion was built over at a time when public rights were not vigilantly guarded. It is a favourite area for popular demonstrations. The Kelvin burn flows through Kelvingrove Park, in the west end, and the ground is naturally terraced, while the situation is beautified by the adjoining Gilmore Hill with the university on its summit. The park contains the Stewart fountain erected to commemorate the labours of Lord Provost Stewart and his colleagues in the promotion of the Loch Katrine water scheme, statues of Lord Lister, Lord Roberts and Carlyle, and a war memorial. The other parks on the right bank are, in the north, Ruchill, acquired in 1891, and Springburn, acquired in 1892, and, in the east, Alexandra Park, in which is laid down a nine-hole golf-course, and Tollcross, acquired in 1897. On the left bank Queen's Park, occupying a commanding site, was considerably enlarged in 1894 by the enclosure of the grounds of Camphill. The other southern parks are Richmond, acquired in 1898, Maxwell, which was taken over on the annexation of Pollokshields in 1891; Bellahouston, acquired in 1895; and Cathkin Braes, presented to the city in 1886 by James Dick, a manufacturer, containing "Queen Mary's stone," a point which commands a view of the lower valley of the Clyde. In the north-western district of the town 40 acres between Great Western Road and the Kelvin are devoted to the Royal Botanic Gardens. More recent acquisitions include zoo ac. of the Balloch Castle estate (Loch Lomond park); the Rouken Glen, Linn, Newlands, Glenconner, Dawsholm, Ruchill and Frankfield parks.

Communications.—The L.N.E.R. terminus is situated in Queen Street, and consists of a high-level station (main line) and a low-level station for Balloch, etc., used in connection with the City and District line, largely underground, serving the northern side of the town. The Central terminus of the L.M.S.R. for Carlisle, Edinburgh, etc., in Gordon Street, comprises a high-level station and a low-level station for Balloch and the Cathcart District railway, and also for the connection between Maryhili and Rutherglen, which is mostly underground. Both the underground lines communicate with certain branches of the main line, either directly or by change of carriage. The older terminus of the L.M.S.R. in Buchanan Street now takes the northern and eastern traffic and the station in St. Enoch Square serves the south-west of Scotland and Carlisle. The Glasgow Subway—an underground cable passenger line, 6½ m. long, worked in two tunnels and passing below the Clyde twice—was opened in 1896. There are at certain points free steam ferry boats or floating bridges for conveying vehicles across the harbour, and there are three tunnels under the river. Steamers, carrying both goods and passengers, constantly leave the Broomielaw quay for the piers and ports on the river and firth, and the islands and sea lochs of Argyllshire.

Trade.—Natural causes, such as proximity to the richest field of coal and ironstone in Scotland and the vicinity of hill streams of pure water, account for much of the great development of trade in Glasgow. It was in textiles that the city showed its earliest predominance, which, however, has not been maintained, though several cotton mills are still worked. The leading feature in the trade has always been the manufacture of light textures. Thread is made on a considerable scale, but jute and silk are of comparatively little importance. Carpets are woven and some factories are exclusively devoted to the making of lace curtains. The allied industries of bleaching, printing and dyeing have prospered. The use of chlorine in bleaching was first introduced in Great Britain at Glasgow in 1787, on the suggestion of James Watt, whose father-in-law was a bleacher; and it was a Glasgow bleacher, Charles Tennant, who first discovered and made bleaching powder (chloride of lime). Turkey-red dyeing was begun at Glasgow by David Dale and Gecrge M'Intosh, and the colour was long known locally as Dale's red. A large quantity of grey cloth continues to be sent from Lancashire and other mills to be bleached and printed in Scottish works. These industries gave a powerful impetus to the manufacture of chemicals, and the works at St. Rollox developed rapidly. Various chemical industries are prominent. Glass-making and paper-making are carried on, and there are several breweries and distilleries. Many miscellaneous industries are carried on such as clothing, confectionery, cabinet-making, biscuit making, boot and shoe making, saw mills, pottery and rubber goods. Since the days of the brothers Robert Foulis (1705–1776) and Andrew Foulis (1712–1775), printing, both letterpress and colour, has been identified with Glasgow, though less than with Edinburgh. The discovery of the value of blackband ironstone, till then regarded as useless "wild coal," by David Mushet (1772–1847), and Neilson's invention of the hot-air blast threw the control of the Scottish iron trade into the hands of Glasgow ironmasters, although the furnaces themselves were mostly erected in Lanarkshire and Ayrshire. The expansion of the industry was such that, in 1859, one-third of the total output in the United Kingdom was Scottish. Mild steel is manufactured and some crucible cast steel is made. In addition to brass foundries there are works for extraction of copper and smelting of lead and zinc. Locomotive engines are built, all kinds of builder's ironwork is forged, arid the sewing-machine factories in the neighbourhood are important. Boiler-making and marine engine works, in many cases in direct connection

with the shipbuilding yards, are numerous. Shipbuilding, indeed, is the greatest of the industries of Glasgow. Excepting a trifling proportion of wooden ships, the Clyde-built vessels are made of steel, the trade having owed its immense expansion to prompt adoption of this material. Every variety of craft is turned out, from battleships and great liners to dredging-plant and hopper barges.

The Port. — The Clyde Navigation trustees are responsible for 18 m. of the river Clyde, from Port Glasgow to Glasgow. The harbour occupies 206 acres. For the most part it is lined by quays and wharves, which have a total length of 8¼ m., and from the harbour to the sea vessels drawing 26 ft. can go up or down on one tide. In the middle of the 18th century the river was fordable on foot at Dumbuck, 12 m. below Glasgow and 1½ m. S.E. of Dumbarton. The earliest shipping-port of Glasgow was Irvine in Ayrshire, but lighterage was tedious and land carriage costly, and in 1658 the civic authorities endeavoured to purchase a site for a spacious harbour at Dumbarton. Being thwarted by the magistrates of that burgh, however, in 1662 they secured 13 acres on the southern bank at a spot some 2 m. above Greenock, which became known as Port Glasgow, where they built harbours and the first graving dock in Scotland. Sixteen years later the Broomielaw quay was built, but it was not until the tobacco merchants appreciated the necessity of bringing their wares into the heart of the city that serious consideration was paid to schemes for deepening the waterway. In 1768 John Golborne advised the narrowing of the river and the increasing of the scour. By the building of numerous jetties, the constant use of steam dredgers, and the blasting of rock, the channel was gradually deepened, and much land reclaimed. By 1900 it had a minimum depth of 22 ft., and, as already indicated, the largest vessels make the open sea in one tide, whereas in 1840 it took ships drawing only 15 ft. two and even three tides to reach the sea. From 1812 to 1820 Henry Bell's "Comet," 30 tons, driven by an engine of 3 horse-power, plied between Glasgow and Greenock, until she was wrecked, being the first steamer to run regularly on any river in the Old World. When the quays and wharves ceased to be able to accommodate the growing traffic, the construction of docks became imperative. In 1867 Kingston Dock on the south side, of 5⅓ acres, was opened, but soon proved inadequate, and in 1880 Queen's Dock (two basins) at Stobcross, on the north side, of 30 acres, was completed. In 1897 Prince's Dock (three basins) on the opposite side, of 72 acres, was opened, fully equipped with hydraulic and steam cranes and all the other latest appliances. The Rothesay dock (20 ac.) at Clydebank, opened in 1907, and the warf at Renfrew, are included in the harbour. The L.M.S.R. has access to the harbour for goods and minerals at Terminus Quay to the west of Kingston Dock, and a mineral dock has been constructed by the Trust at Clydebank, about 3½ m. below the harbour. In 1924 the provision of further dock accommodation on land acquired by the Trust between Shieldhall and Renfrew was begun. It is connected by railway lines and a road joining the new trunk road of the Glasgow corporation scheme. The shipping attains to colossal proportions. The imports consist chiefly of grain and flour, leather, tobacco, timber, oil, iron-ore, bacon and other foodstuffs; and the exports principally of cotton, jute and linen goods, yarn, coal, machinery and spirits.

Government. — By the Local Government (Scotland) Act 1889. the city was placed entirely in the county of Lanark, the districts then transferred having previously belonged to the shires of Dumbarton and Renfrew. In 1891 the boundaries were enlarged to include six suburban burghs and a number of suburban districts, the area being increased from 6,111 acres to 11,861 acres. In 1912 Govan, Partick, Pollokshaws and several suburban districts were included in the city, making the total area 19,183 acres and giving Glasgow again its position as 2nd city of Great Britain in point of size. In 1926 the burgh was further enlarged by the acquisition of parts of Renfrewshire, Dumbartonshire and Lanarkshire, including the Yoker district. In 1893 the municipal burgh was constituted a county. Glasgow is governed by a corporation consisting of 113 members, including 14 bailies and the lord provost. As a county Glasgow has a lieutenancy (successive lords provost holding the office) and a court of quarter sessions, which is the appeal court from the magistrates sitting as licensing authority. Under the corporation municipal ownership has reached a remarkable development, the corporation owning the supplies of water, gas and electric power, tramways and municipal lodging-houses. In 1859 water was conveyed by aqueducts and tunnels from Loch Katrine to the reservoir at Mugdock, a distance of 27 m., whence after filtration it was distributed by pipes to Glasgow. In 1914 works were completed to raise Loch Katrine 5 ft. and to connect with it by tunnel Loch Arklet (455 ft. above the sea), with storage for 2,050,000,000 gallons. The two lochs together possess a capacity of twelve thousand million gallons. The entire works between the loch and the city were duplicated over a distance of 23½ m., and an additional reservoir, holding 694,000,000 gallons, was constructed and a dam built 1¼ m. west of the lower end of Loch Arklet, designed to create a sheet of water 2 3 m. long and to increase the water-supply of the city by ten million gallons a day. The water committee supplies hydraulic power to manufacturers and merchants. Huge gas works were opened at Govan in 1921, and a large electric generating station at Dalmarnock Bridge in 1920. By lapse of time and congestion of population, certain quarters of the city, in old Glasgow especially, were slums and rookeries of the worst description. The municipality obtained parliamentary powers in 1866 to condemn for purchase over-crowded districts, to borrow money and levy rates. The work was carried out, and when the act expired in 1881 whole localities had been recreated. Under the amending act of 1881 the corporation began in 1888 to build tenement houses and lodging-houses. The powers of the improvement trustees were practically exhausted in 1896, when it appeared that the funds showed a deficiency of £423,050. Assessment of ratepayers for the purposes of the trust had yielded £593,000, and it was estimated that these operations had cost the citizens £24,000 a year. In 1897 an act was obtained for dealing in similar fashion with insanitary and congested areas in the centre of the city, and on the south side of the river. The drainage system was entirely remodelled, the area being divided into three sections, each distinct, with separate works for the disposal of its own sewage. Housing conditions and unemployment were again very bad after the World War, and led to a "rent strike." The position became very difficult in 1925 and a Rent Commission was appointed. Among other works in which the Corporation has interests there may be mentioned its representation on the board of the Clyde Navigation Trust and the governing body of the West of Scotland Technical College. Since 1918 Glasgow has returned 15 members to Parliament.

Throughout the 19th century the population grew prodigiously. Only 77,385 in 1801, it was nearly doubled in twenty years, being 147,043 in 1821, already outstripping Edinburgh. In 1901 it stood at 761,709, in 1931 at 1,088,417 and in 1938 at 1,127,825.

HISTORY

Some historians hold that the name of Glasgow comes from Gaelic words meaning "dark glen," descriptive of the narrow ravine through which the Molendinar flowed to the Clyde. But the more generally accepted version is that the word is the Celtic Cleschu, afterwards written Glesco or Glasghu, meaning "dear green spot" (glas, green; cu or ghu, dear), supposed to have been the name of the settlement that Kentigern found here when he came to convert the Britons of Strathclyde. Kentigern or Mungo ("dear one") became the patron-saint of Glasgow, and the motto and arms of the city are identified with him—"Let Glasgow Flourish by the Preaching of the Word," usually shortened to "Let Glasgow Flourish." It is not till the 12th century, however, that the history of the city becomes clear. About 1178 William the Lion made the town by charter a burgh of barony, and gave it a market with freedom and customs. At the battle of the Bell o' the Brae, on the site of High Street, Wallace routed the English under Percy in 1300; he was betrayed to the English in 1305 in Robroyston. Plague ravaged the burgh in 1350 and thirty years later; the regent Arran, in 1544, besieged the bishop's castle, and there was a subsequent fight at the Butts (now the Gallowgate).

Most of the inhabitants mere opposed to Queen Mary and many actively supported Murray in the battle of Langside—the site now occupied by the Queen's Park—on May 13, 1568, in which she lost crown and kingdom. Under James VI. the town became a royal burgh in 1636, with freedom of the river from the Broomielaw to the Cloch. The people made common cause with the Covenanters to the end of their long struggle. Montrose mulcted the citizens heavily after the battle of Kilsyth in 1645, and three years later the provost and bailies were deposed for contumacy to their sovereign lord. Plague and famine devastated the town in 1649, and in 16jz a conflagration laid a third of the burgh in ashes. Even after the restoration its sufferings were acute. It was the headquarters of the Whiggamores of the west and its prisons were constantly filled with rebels for conscience' sake. The government scourged the townsfolk with an army of Highlanders, whose brutality only served to strengthen the resistance at the battles of Drumclog and Bothwell Brig. The Union was hotly resented, but marked the dawn of almost unbroken prosperity. By the treaty of Union Scottish ports were placed, in respect of trade, on the same footing as English ports, and the situation of Glasgow enabled it to acquire a full share of the ever-increasing Atlantic trade. Its commerce was already considerable and in population it was now the second town in Scotland. It enjoyed a practical monopoly of the sale of raw and refined sugars, had the right to distil spirits from molasses free of duty, dealt largely in cured herring and salmon, sent hides to English tanners and manufactured soap and linen. It challenged the supremacy of Bristol in the tobacco trade—fetching cargoes from Virginia, Maryland and Carolina in its own fleet—so that by 1772 its importations of tobacco amounted to more than half of the whole quantity brought into the United Kingdom. The tobacco merchants built handsome mansions and the town rapidly extended westwards. With the surplus profits new industries were created, which helped the city through the period of the American War. Most, though not all, of the manufactures in which Glasgow has always held a foremost place date from this period. It was in 1764 that James Watt succeeded in repairing a hitherto unworkable model of Newcomen's fire (steam) engine in his small workshop within the college precincts. Shipbuilding on a colossal scale and the enormous developments in the iron industries and engineering were practically the growth of the 19th century.

See *The* Scottish *Geographical Magazine* (Jan. 1921).

GLASITES, a Christian sect, founded in Scotland by John Glas (*q.v.*). It spread into England and America, but is now practically extinct. The name Glasites or Glassites was generally used in Scotland; in England and America the name Sandemanians was more common. Glas dissented from the Westminster Confession only in his views as to the spiritual nature of the church and the functions of the civil magistrate. But his son-in-law Robert Sandeman added a distinctive doctrine as to the nature of faith which is thus stated on his tombstone: "That the bare death of Jesus Christ without a thought or deed on the part of man is sufficient to present the chief of sinners spotless before God." In their practice the Glasite churches aimed at a strict conformity with the primitive type of Christianity as understood by them. Each congregation had a plurality of elders, pastors or bishops, who were chosen according to what were believed to be the instructions of Paul, without regard to previous education or present occupation, and who enjoy a perfect equality in office. In all the action of the church unanimity was considered to be necessary; if any member differed in opinion from the rest, he must either surrender his judgment to that of the church, or be shut out from its communion. The Lord's Supper was observed weekly; and between forenoon and afternoon service every Sunday a love feast was held at which every member was required to be present. Mutual exhortation was practised at all the meetings for divine service, when any member who had the gift of speech (χάρισμα) was allowed to speak. The practice of washing one another's feet was at one time observed; and it was for a long time customary for each brother and sister to receive new members. on admission, with a holy kiss. The lot was regarded as sacred; the accumulation of wealth they held to be unscriptural and improper, and each member considered his property as liable to be called upon at any time to meet the wants of the poor and the necessities of the church. Churches of this order were founded in Paisley, Glasgow, Edinburgh, Leith, Arbroath, Montrose, Aberdeen, Dunkeld, Cupar, Galashiels, Liverpool and London, where Michael Faraday was long an elder. Their exclusiveness in practice, neglect of education for the ministry, and the antinomian tendency of their doctrine contributed to their dissolution. Many Glasites joined the general body of Scottish Congregationalists, and the sect may now be considered extinct. The last of the Sandemanian churches in America ceased to exist in 1890.

See James Ross, *History of Congregational Independency in Scotland* (Glasgow, 1900). (*D.* M.)

GLASS, CARTER (1858–), American politician, was born at Lynchburg, Va., on Jan. 4, 1858. He received his education in the Lynchburg schools and learned the printer's trade, which he followed for several years, eventually becoming proprietor of the Lynchburg *Daily News* and *Daily Advance*. He was elected to the Virginia State senate for two terms (1899–1903) and was a member of the Constitutional Convention in 1901. He was elected in 1902 to the national House of Representatives, and thereafter was continuously re-elected until his resignation in 1918. As chairman of the House banking committee he was active in framing and passing the Federal Reserve Bank law. In 1918 he entered President Wilson's cabinet as secretary of the Treasury. Under his guidance the fifth Liberty Loan was floated in April, 1919. In Nov. 1919 he resigned after his appointment to the United States Senate, where he remained by election (1924, 1930, 1936).

GLASS. Glass is one of man's most versatile creations. In almost every phase of modern civilization it plays a role of ever-increasing importance. In this article we are concerned primarily with its general characteristics, its history, and its growing impact upon human affairs.

The word "glass" has three connotations. The first refers to any one of a great variety of commercial products—bottles, jars, tumblers, electric light bulbs, window panes and the like. The second concept is that in which glass is considered primarily from the chemical point of view, as a material resulting from the fusion and subsequent cooling of a mixture of certain substances. This way of describing glass is empirical and restrictive. It does not indicate the fundamental differentiae or the principal characteristics of the glassy state. In a general way it may be said that glass is not glass because it consists of certain chemicals, although chemicals are certainly necessary to create it. Sulphuric acid, on the contrary, is a chemical first and a liquid second. Its interest lies almost entirely in its chemistry. But glass is a physical condition first. and its chemistry, although necessary, is really subordinate. This illustrates the third concept of the word glass: as descriptive of the physical condition in which certain substances can exist.

At room temperature a glass is obviously a hard, rigid solid, in the ordinary, rather loose meaning of those terms, and it apparently remains a solid as its temperature is increased several hundred degrees centigrade. As the temperature is still further increased, it gradually softens, almost imperceptibly at first, and finally becomes a viscous liquid, without exhibiting any sharp melting point. At high temperatures glasses are ordinary liquids which, like all liquids, assume the shape of the container and flow under the action of any small force. When this liquid is cooled it does not devitrify, that is, it does not undergo a discontinuous change into a stable crystal or aggregate of crystals. At the temperatures at which glasses might be expected to crystallize they are still liquids, liquids of such great viscosity that they can be cooled through their freezing points without devitrification. They thus become "undercooled liquids." The increase in viscosity is a continuous process from the very hot liquid to the rigid glass at ordinary temperatures. Glasses have smooth cooling curves without the sharp break which indicates the freezing point of a liquid which crystallizes as it cools. Morey summarizes this behaviour and defines a glass as follows: "A glass is an inorganic substance in a condition which is continuous with, and analogous to, the liquid state of that substance, but which, as the result of

Syrian, 14th century. 6. Blue Persian flask of the 16th or 17th century. 7. Spanish (Cataionian) enamelled glass bowl of the 16th century. 8. French blue jug enamelled in coiours. 16th century

having been cooled from a fused condition, has attained so high a degree of viscosity as to be for all practical purposes rigid." Certain organic substances, which might otherwise be included, are definitely excluded by this definition on the basis that they differ greatly in composition, methods of manufacture, and properties from the substances we have known for thousands of years as "glass."

FROM GEORGE AGRICOLA, "DE RE METALLICA" (PUB. BY FROBEN IN 1556)

A LATE 16TH CENTURY GERMAN GLASS FURNACE, REPRODUCED AFTER A CONTEMPORARY DRAWING

In the centre is the main oven, where glass was melted in pots behind each working hole. In the right foreground is a large wooden case packed with vessels of various shapes, and in the rear one of the workmen is shown "blowing" hot glass into the desired shape, after its removal from the oven

The mixture, or "batch," from which glass is made contains (a) and (b) and, depending upon many circumstances, one or more of (c), (d), or (e):

(a) Fundamental materials
   1. Almost invariably—silica (sand)
   2. Usually—soda and lime
   3. Often—potash, lead oxide, boric oxide, etc.
(b) Excess glass from a previous melt ("cullet")
(c) Oxidizing agents
(d) Decolorizing agents
(e) Colouring or opacifying agents.

Cullet is almost always used, not only for economy but also because it actively assists in the melting. Oxidizing agents are used in certain special circumstances — for example, to prevent the reduction of lead oxide to metallic lead by the action of furnace gases. In connection with (d) it should be said ,that if minor impurities could be kept out of the glass batch there would usually be no difficulty in producing colourless glass, and this is certainly the best way to do it. However, it is often expedient to add decolorizing agents whose purpose is usually either to mask the colour produced by the impurity or to diminish the effect by oxidizing the impurity and keeping it oxidized. The purposes of the colouring or opacifying materials are self-evident. When these chemicals are thoroughly mixed together in the proper proportions, then fused at a high temperature, the fused mass being cooled rapidly enough to prevent the deposition of crystalline material, the resulting substance is a glass. Even when glass is available, in the proper condition for fabrication into useful articles, the peculiar characteristics of the material allow it to be handled only in certain definitely limited ways. Many of these were devised hundreds of years ago and have not been changed basically. After a glass article has been formed it usually must be annealed to remove detrimental stresses introduced during manufacture, and sometimes it is subjected to several other special treatments *(see* GLASS MANUFACTURE).

Although a very considerable number of elements. inorganic salts and mixtures of various kinds can be obtained as glasses by proper manipulation, silica is the outstanding glass-forming oxide, and the commercial glasses are almost always silicate glasses. This was just as true two thousand years ago as it is today. Even the very ancient glasses have much the same composition as the soda-lime-silica glasses, usually simply called "lime" glasses, which comprise perhaps 90% of the total tonnage melted today. It is questionable whether the ancients added the lime intentionally or accidentally, but analyses definitely show its presence, and it was an absolutely necessary adjunct to overcome the water solubility of the soda-silica mixture alone. Moreover, these lime glasses melt at a low temperature, have a viscosity behaviour appropriate for repeated working, and have very little tendency to devitrify—all of which are characteristics which made them ideal for the crude equipment of the ancients.

ORIGIN AND EARLY PROGRESS

Glass at the Dawn of History.—The manufacture of glass is one of the arts based on fire. Where and when such manufacture began we do not know. Perhaps glass was first produced accidentally by the fusion of sand and soda in an open fire as related by Pliny. Experiments show conclusively that glass can be made in this way. Perhaps it was formed by the burning of grain and subsequent fusion of the ash as the result of fire caused by lightning. Such "lightning stones" have been found and analyzed. In any event, it seems likely that the first deliberate attempts to make glass were a consequence of the potter's art, the most ancient of the arts dependent on fire. Historically, the development of coloured glazes for coating pottery or stone beads seems to have preceded the manufacture of objects made wholly from glass. Either ancient man at this time did not look upon glass as having beautv and utilitv in its own right. or he did not recognize the similarities between a glaze and a glass and was forced to discover the latter independently.

For many years it was thought that glass was first made artificially in Egypt. There is now much evidence that it originated in Asia Minor, probably Mesopotamia. Sir W. M. Flinders Petrie, to whom we must credit much of our knowledge of ancient glass, says *(Transactions* of British Newcornen society, vol. 5, p. 72):

"The earliest glaze known is that on stone beads of the Badarian age in Egypt, about 12,000 B C. This is green. That civilization was intrusive, probably from Asia. Green glaze was applied to powdered quartz basis for making small figures about 9000 B.C., and was ever after so common in moulded beads that it was certainly of Egyptian manufacture.

"The oldest pure glass is a moulded amulet of deep lapis lazuli colour, of about 7000 B.C. Fragments of green opaque glass inlay appear in the 1st dynasty about 5000 B.C. Striped black and white glass amulets came in the 11th dynasty, about 3800 B.C. An elaborate fused glass mosaic of a calf is in jewelry of 3300 B C. from Dahshur. Blue translucent beads appear about 1570 B.C. All of these occurrences of dateable glass in Egypt were probably due to importation from Asia."

Frankfort found a cylinder of light blue glass at Tell Asmar, northwest of Baghdad, which he believes dates to 2700–2600 B.C. In this same region, glass beads were plentiful in the excavation of a cemetery dating to 24jo B.C. Whatever archaeological disagreements there may be over the authenticity of these dates,

they do definitely establish the manufacture of glass as an industry of great antiquity.

The manufacture of glass emerged from historical obscurity and became a stable, continuous industry in Egypt at the beginning of the 18th dynasty. The oldest piece of glass which may be definitely dated is a large ball-bead of this period with the cartouche of Amenhotep (1551–1527 B.c.). Small decorative glass bottles bearing the cartouche of King Thotmes III (1527–1475 B.C.), and glass beads inscribed to his queen, have also been found. The remains of glassworks built during this period can still be seen. This was a time of great fertility in Egyptian art, and much of the glass was more durable than that made in later periods and exhibited superior craftsmanship in its creation. The Egyptians possessed an amazing knowledge of metallurgy — they used tin oxide to make white opaque glass; turquoise blue came from the use of copper, and the same metal was employed for red and green glasses. Transparent glass was rare at this time, not only because it would have been difficult to make, without knowledge of *decolorizing* agents, but equally because transparency was unnecessary. Glass was used almost exclusively for personal adornment and, because of the difficulty and expense of manufacturing it, was considered equal in value to the natural gems, with which it was frequently combined.

Glass was used, a little later, for hollow vessels such as unguent jars and small vases. They were not blown — the art of glass blowing was not yet known — and when one understands the difficulties under which these ancient peoples laboured, because of the limitations of their methods and equipment, it is possible to appreciate fully the patience, ingenuity and delicate craftsmanship often exhibited in their products. Hollow vessels were moulded by winding rods of hot, softened glass around a central core of sand built up on a metal rod. Alternatively, such a core might be dipped several times into a pot of molten glass, the glass being built up to the required thickness bit by bit. About 1200 B.C. the Egyptians learned how to press glass into open moulds and this made possible the production of bowls, dishes and cups which could not be made by the sand-core method. Sometimes hundreds of coloured glass threads, each no more than a thousandth of an inch in diameter, might be applied to a vase which would then be softened by reheating and thus pulled into bright, variegated patterns. All of this meant that glass was a luxury in Egypt, a precious luxury to be carefully preserved from generation to generation.

From about 1550 B.C. until the beginning of the Christian era, Egypt remained the nucleus of glass manufacture. The industry gradually became centralized at Alexandria, from which place the Phoenician traders carried it to all the countries of the Mediterranean.

The Invention of the Blowpipe. — The invention of the blowpipe, even though time and place cannot be fixed with certainty, must be considered one of the truly great discoveries of mankind. It caused an industrial revolution which changed glass from a luxury into a necessity. It gave revealing glimpses of the true capabilities of the material and made possible the quantity production of glass articles in shapes and designs previously impossible to produce. The glass prepared without the aid of the blowpipe has been compared to pottery made by hand before the invention of the potter's wheel.

Kisa assigns the invention to the period between 300 B.C. and 20 B.c., and most authorities feel that blown glass owes its origin and development to Phoenician workers of that time. All are agreed that the blowpipe was then about the same size and shape as it is today — a hollow iron tube 4 to 5 ft. long, a knob at one end, a mouthpiece at the other. This simple device, in the hands of skilled workmen, made possible the creation of an almost endless variety of hollow glass objects. In "offhand" blowing the worker makes a "gather" by dipping the knob-shaped end of the blowpipe into a pot of hot, viscous glass If the blowpipe is then dexterously removed, a mass of the hot glass will adhere to one end. If the worker now blows through the mouthpiece, gently or vigorously, the gather can be blown into a hollow bulb, thick or thin. By swinging and rotating this bulb of still hot glass, by rolling and otherwise manipulating it with a few simple tools, and by reheating it from time to time as it cools in working, a hollow vessel of almost any symmetrical shape can be created. This method is still used for the very finest art glass. The process can be expanded to include almost any shape by blowing the glass into moulds.

At about the beginning of the Christian era, means were found for producing the first relatively clear, transparent glass. The experiments leading to this result may have been stimulated by the advanced technique of the blowpipe, because transparency and freedom from colour are very desirable qualities in blown ware. An early name for such glass was "crystal" glass, because of the desire to produce a glass as colourless and transparent as pure rock crystal. The term is still in common use to distinguish such glass from coloured, translucent or opaque varieties.

The First Golden Age — Rome. — The first four centuries of the Christian era justly may be called the first golden age of glass. Due in part to the invention of the blowpipe, and in part to the commercial stability of the Roman Empire, the manufacture and use of glass became widespread. Glass manufacture flourished in every country conquered by Rome — in Egypt and Syria, in Greece and Italy, and in the western provinces of Gaul and Brittany. The Roman Emperor, Alexander Severus, imposed a tax on the glass manufacturers of Rome in A.D. 220. These manufacturers had become so numerous that a section of the city was assigned to them. Constantine during his rule (A.D. 306–337) remitted the tax and thus may have accelerated further the growth of the industry during the 4th century. During this period certain kinds of glass actually had become a household necessity, although others remained a personal luxury.

In the older religions of Greece and Rome the practice of cremation necessitated the use of some suitable receptacle for the ashes of the dead. Glass often was used for such funerary furniture, particularly during the 1st and 2nd centuries. During this time the Roman glassmakers were making coloured vases of such great beauty that they were more precious than gold or silver vases and could be possessed only by the wealthy. In making cameo vases they superimposed glass of one colour over glass of another colour and then carved cameo designs through the outer layer. The Portland vase found in the tomb of Alexander Severus is such a vase and is one of the most highly prized objects of antiquity. The scene. cut out of a layer of opaque white glass, stands out from an unbelievably beautiful deep blue background.

By the end of the 3rd century, window glass begins to be mentioned. Lactantius, in A.D. 290, writes that "our soul sees and distinguishes objects by the eyes of the body as through windows filled with glass." Jerome, A.D. 331, speaks of sheets or plates of glass produced by casting on a large flat stone; this method was probably the earliest forerunner of modern flat glass manufacture.

The glassworkers of this age were masters of almost all the technical processes of manufacture and decoration which have subsequently proved to be of major importance. They mastered the difficult art of offhand blowing and also knew how to manipulate the glass with tongs to produce studs or bosses on the outer surface. They produced mosaic glass in many forms, some with the colours intermingled at random and others in a definite but highly complicated colour sequence. Thus, glass threads of many colours might be so arranged that when fused into a solid rod the rod would have a multi-coloured cross-section in the form of a flower, a rosette or a geometrical ornament. Disks would be cut from the rod, laid side by side, and encased in colourless, transparent glass. This mosaic — a thing of beauty itself — was then worked up into the justly famous Millefiori vessels.

Painting and gilding were also employed. The onyx glass of Alexandria was created by cutting out designs, in high relief, from layers of glass of various colours. It was perhaps inspired by the semiprecious onyx stone with its orderly translucent and opaque strata. The Portland vase is an example of this genre. Harden lists the following classes of ware of this period, found at Karanis in Roman Egypt: (1) dishes and plates; (2) shallow and deep bowls, some on a stem; (3) beakers and goblets; (4) conical

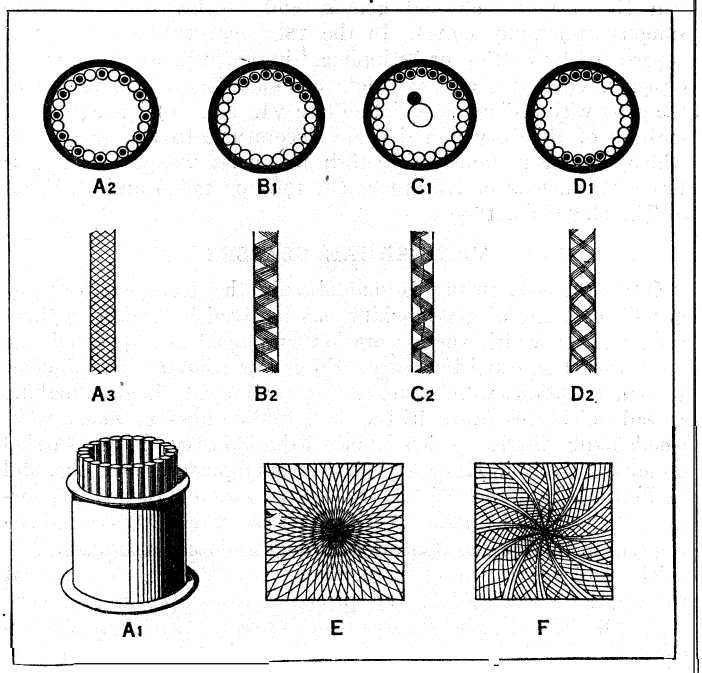
lamps; (5) drinking cups and goblets on a stem; (6) jars; (7) flasks; (8) jugs and bottles; (9) toilet bottles; and (10) miscellaneous items—lids, bracelets, finger rings and ring stones, amulets, rods, spoons, lenses, gaming pieces, pierced buttons, disks stamped in relief, fragments of inlay, and fragments of window glass. An amazing array of glass objects made by man 15 centuries ago!

Glass During **the** Dark Ages.—Comparatively little is known about the manufacture and use of glass between the fall of the Roman Empire and the 11th century. This gap of over 600 years is partly a consequence of the invasion of western Europe by the barbaric tribes of Germany. It is also partly due to the growing influence of the Christian religion which prohibited the burial of valuable objects with the dead. The glass products of the period are therefore scarce principally because they were no longer well or widely preserved. It is ironic that the Church should have taken away such a valuable source of glass relics, because in later ages the Church had a highly beneficial, if indirect, effect upon glass manufacture.

At the end of the 3rd century the Byzantine Empire became established with its capital at Constantinopie. There glass manufacture was carried on after the fall of Rome. During the Dark Ages of the West there was a period of great progress in the Islamic world, and the Byzantine workers brought to glass a highly developed artistic taste, particularly in the use of colour. In the 6th century the Emperor Justinian employed skilled glass-workers to make stained-glass windows for the great church of Constantinople. The use of glass for windows spread continuously, but slowly, first to France, a century later to England. One of the earliest records of the use of stained-glass windows is that by Adalberon, Bishop of Reims, when rebuilding the cathedral in A.D. 969–988. Slowly, year by year, and century by century, the use of stained glass in church windows grew until, during the later Middle Ages, no church could be considered complete without this form of decoration. These glorious stained-glass windows were more than windows alone, and more indeed than a form of decoration, no matter how beautiful. They were literally sermons in glass, sermons in colour for an illiterate age.

Spun Glass.—The amazing skill of the early glassworkers is demonstrated in spun glass, a Venetian development which probably stemmed from earlier Egyptian and Roman work. The threads are made as follows: a certain quantity of coloured glass-metal, *e.g.,* milk-glass (opal-glass) whitened with stannic oxide, is taken out of the crucible with an iron rod and rolled backwards and forwards on the "marver," or slab, until it adheres to the outside of the iron in the form of a thin tube. The iron is then dipped into colourless glass-metal, which now forms a coating round the tube of milk-glass. The cylinder thus composed—white inside and colourless outside—is heated and pulled out until it becomes a long thread of about 3 to 6 mm. diameter. From the threads thus prepared, bundles of a large number of threads are then made. This is an exceedingly delicate operation. Round the inside of a short earthenware cylinder, threads of milk-glass of the kind above described are arranged alternately with small rods of colourless glass in a definite symmetrical order (figs. A1 and A2). The hollow left in the centre is filled up with colourless glass-metal, so that the whole fuses together into a single compact rod of glass.



FROM LABARTE, "HISTOIRE DES ARTS INDUSTRIELS" (COPR BONNAIRE)

SPECIMENS OF GLASS WORK. FOR PARTICULARS SEE TEXT

This rod, on the circumference of which there are of course parallel white threads at equal intervals, is pulled out until its diameter has shrunk to almost nothing; and simultaneously the rod is twisted in both directions, with the result that the threads of white glass, which had previously been parallel, are now twisted round one another like the strands of a rope (fig. A3).

Innumerable variations can be obtained by altering the arrangement of the white threads. If, for example, we put seven of them all together on the side of the earthenware cylinder (fig. R1) and fill up all the remaining space with uncoloured glass, by pulling out and twisting we get a wide spiral consisting of seven parallel strands (fig. B2); if we put four white threads on each of two opposite parts of the cylinder, in the finished rod we shall find two four-stranded spirals crossing (figs. D1 and D2). If we carry one threadinto themiddleof the cylinder, it will form a white central column with spirals twining round it; and if we shift it slightly out of the centre, the central thread itself will produce a corkscrew effect inside the spirals (figs. C1 and C2).

By other complicated arrangements of the white threads a great number of most attractive intricate patterns can be obtained. Vessels made in this way are called *vasi a ritori.*

In making a *vaso* a *ritorti,* a cylindrical mould is again employed. The rods are again arranged in any desired order, with or without uncoloured rods between them, on the inside of the cylinder. They are then gently heated, and into the hollow cylinder which they form, a bulb of colourless glass is blown from above; they adhere to this bulb, and on further heating and expansion they fuse completely with its surface. They are then pinched together just above the end of the bulb, so that they all meet at one point, while the intervals between them on the surface of the spherical bulb increase as it expands As the bulb is blown out still more, its walls become thinner, and the rods are naturally pressed flat, so that the patterns inside them are squeezed out wide. The bulb is now subjected to the usual further processes. If it is not rotated, the rods run together like meridians on a globe; but if it is rotated while the other processes are going on, they form rhythmical spirals which cover the entire vase with their symmetrical whirling curves (figs. E and F).

A simpler method of combining the rods with the bulb has obtained latterly at Murano. The rods are laid in the desired order on a metal plate and are then heated, whereupon the hot glass bulb is rolled over them and they adhere to it.

A type of spun glass that differs from the others is reticulated glass *(vasi a reticelli).* It is made as follows a considerable number of rods containing only one strand of milk-glass are welded onto the glass bulb at equal intervals, in such a way that the rods are not completely fused with the bulb, but take the form of ribs standing slightly out. The bulb is elongated and rotated at the same time, so that the threads now run spirally round it. A second bulb is produced in the same manner, but is rotated in the opposite direction during the process of elongation, so that the spiral twists run in the opposite direction to those on the first bulb. Both bulbs are then cut open, fitted one inside the other in the form of open cylinders, and fused by heating. The spiral threads now cross one another in a network, and as the separate raised rods leave small hollowed-out trough-shaped grooves between them, nothing remains inside the meshes of the network but little air-bubbles. (C. J. P)

GLASSWORK IN EUROPE

Venice.—Although our earliest knowledge of the Venetian glass industry dates from as far back as the 11th century, no sign of artistic form is met with in Venetian glass until the beginning of the Renaissance—about the middle of the 15th century—and then there is not a trace of oriental influence. As early as 1291 the glass-ovens were removed en bloc to the neighbouring island of Murano, owing to the danger of fire; and draconian penalties were provided for glass-workers taking the secret of the process abroad. In the 16th century the Venetians found the proper expression for the sense of form that marked the Renaissance at its height, and also acquired the

true style in glass-work, which arises solely out of the technique of glass-making. It was this period that gave birth to those spirited, graceful, airy forms of vessel which are due purely to the glassblower's labour (Plate IV., Nos. 2–4). The contour of these glasses — bowl-shaped, calyx-shaped or bell-shaped — is of unprecedented elegance, and the baluster-stem, tapering down to a simple flat foot, varies widely in formation. The stem is often adorned with masks, lions' heads or pinched-out "wing" appendages (Plate IV., No. 1). In the 17th century glass was not spared by the prevalent baroque spirit; its forms become eccentric, complicated, and too rich in ornament. In the 18th century the predominance of Venetian glass was at last destroyed by the Bohemian and Silesian cut-glass. Besides the colourless soda-glass, Venice produced throughout her best period a wide range of coloured glassware. In the early days a great favourite was the marbled "agate" or "jasper" glass (Plate IV., No. 9). "Millefiori" glass (Plate IV., No. 10) was inspired by discovered antiquities, and the astonishing skill of the Muranesi is witnessed by the invention of spun-glass (Plate IV., Nos. 6 and 7) and its by-form, reticulated glass (Plate IV., No. 8), in the first half of the 16th century. To the same period belongs decoration in the forms of painting behind glass and diamond-engraving, while the wonderfully artistic kind of Venetian glass which is ornamented with enamel-painting dates from the early period (c. 1460–1530). Goblets, beakers, bowls, jugs, flasks (see DRINKING VESSELS) and other vessels were painted in multi-coloured enamel; in the early period the body of the glass was almost always coloured (blue, green or violet). Milk-glass was also often used for this purpose; but from 1490 onwards colourless transparent glass predominates. Triumphal processions and love-scenes, biblical and mythological scenes, half-length portraits (see Plate V., No. 6) and coats-of-arms, and in the later period complicated grotesques, were favourite forms of decoration. In the 16th century many aristocratic German families had their coats-of-arms and portraits painted on glasses and goblets by Venetian enamellers.

"Venetian glass" became a generic name; but much so-called Venetian glass was made not at Venice, but in other Italian glass-works (Treviso, Mantua, Padua, Ferrara, Ravenna, Bologna, Florence, et~.)to which the technique was generally brought by renegade Venetians. The most serious competition however, that Venice had to meet came from Altare, near Genoa; the glass-makers there, who formed a close corporation, went abroad (to France, Flanders, etc.) year after year, but always returned to their homes and families. Glass-works on Venetian lines, *à* la *façon* de Venise, were founded all over Europe, mainly in the 16th and 17th centuries, by renegade Venetian glass-blowers and men from Altare. In 1550 one was founded at Antwerp, in 1662 at Brussels, and others at Liége, Amsterdam (1597), Haarlem, The Hague, Vienna (as early as 1428); Hall, in Tirol (1534), where distinguished work, easily recognisable by its peculiar characteristics, was produced; Nuremberg, Munich, Cassel, Cologne, Kiel, Dessau, Copenhagen, Stockholm, Lyons, Argentières, Nantes, Nevers, Orleans, Paris; and in London as early as the middle of the 16th century and also later. Many of the productions of these foreign daughter-establishments of Venice — only a few examples of which are shown here — cannot.be distinguished, or only with difficulty, from the genuine Venetian ware; at the same time, however, a number of these glass-works a la *veneziana* developed forms of their own. often of considerable artistic charm (Plate IV., No. 5).

Spain, France, the Netherlands. — In the middle ages the ancient Roman glass-works in Spain received the imprint of two different influences: in the south, the oriental influence, transmitted through the Moorish domination; in the east (Catalonia), the influence of Venice. The principal centre in the south was Almeria, famous for its artistic glassware as early as the 13th century. Here we find a mingling of indigenous and oriental motifs and ornament. Eccentric, fantastically-shaped vessels covered with handles, threads, rosettes, etc., are characteristic of southern Spanish glass (Plate III., No. 4). In and around Barcelona, on the other hand, we find, in addition to native forms (undoubtedly, however, originating in the East), a marked Venetian influence. The shapes of the 16th-century enamelled glasses show a strong Venetian tendency, while their typical painting-generally pale green tendrils with multicoloured beasts and birds — point rather to the East; on the other hand, many forms revealing oriental influence (*e.g.*, decanters with long spouts) bear the thread-ornament derived from Venice. Work *à* la *façon* de Venise was also done in various inland Spanish factories, as at Cadalso (Castille) and Toledo; at Villanueva de Alcorcon, and later at La Granja de San Ildefonso, there were glass-works from 1712 onwards — royal property from 1734 — which produced ground and cut, gilt and painted articles, and also lustres and mirrors. They were influenced by French and German work. At the same time Spain and Portugal formed a considerable market for the Bohemian glass-works in the 18th century.

In France the immigration of Italian glass-workers from Venice and Altare began as early as the 15th century; but there were also many native glass-works, especially in Normandy and Lorraine. Apart, however, from a small body of 16th-century enamelled glass, to which a French origin can be definitely assigned (Plate III., No. 8), and some graceful small glass figures from the Nevers works, France never produced glass of any artistic value. Greater attention was paid to glass for purely utilitarian purposes, such as window-panes, mirror-glass (see INTERIOR DECORATION), and other products of a more industrial kind. A manujacture *des* verres *à* la *façon* de Venise founded by Colbert in 1665 at Paris (Faubourg St. Antoine) grew later into the immense St. Gobain works. Whereas in the 18th century France was still wholly subordinate to other countries in the matter of fancy glassware, in the 19th century there was a strong upward movement, the result of which has been that France now leads in many branches of the fancy-glass industry.

In the Netherlands, where in the 16th and 17th centuries there were many glass-factories working both on Venetian lines and after German patterns, the new English lead-glass began to exercise a strong influence about the end of the 17th century. A large number of new works were established by Englishmen or operated with English hands, as at Haarlem, Middelburg, Ghent, and 's Hertogenbosch. In Holland glass-cutting was practised in the 18th century; the best master, Jacob Sang, lived at Amsterdam. The pride of Dutch glass-decoration, however, consisted in scratching and dotting with the diamond. Throughout the 17th century scratching with the diamond was a popular method; dilettante artists, like the three sisters Roemers and Willem J. van Heermskerk, adorned glasses and bottles with beautiful sinuous calligraphy (*q.v.*). In the 18th century scratching was superseded by dotting or "stippling," in which process the entire design is composed of small dots hammered into the surface of the glass with a diamond-point (Plate VI., No. 11). The greatest masters of this airy and delicate decoration, to the success of which the clear, faultless English flint-glass was essential, are Frans Greenwood of Dordrecht (d. 1761 or 1762) and D. Wolff of The Hague (d. 1809).

THE GERMAN GLASSES

Germany. — Germany is undoubtedly the European country in which the art of glass-making has received its widest application, and in which the decoration employed has covered the most varied and artistic range. From the Rhine, where ancient Roman traditions were never wholly extinguished, glass-making spread quickly eastward in the later middle ages to many well-wooded hilly districts which favoured the industry. It was carried on most actively in Hesse and the surrounding forest regions, and in Bohemia and the neighbouring territories of Bavaria, Thuringia, Saxony and Silesia. As early as about 1400 all the glass-workers in the Hessian factories formed a close corporation.

The late mediaeval German glasses are almost all made of the green "forest" glass; the principal forms are simple cup-shaped beakers with bosses or spiral fluting on the sides (*Maigelein*) (Plate VI., No. 1), and beakers about the size of the fist, with knobs or prunts, which were called "cabbage-stalks" (*Krautstrunk*) because they resembled a cabbage-head with the leaves

4. Pieces designed by B. Mauder, executed at the State technical school at Zwiesel, Eastern Bavaria
5. Table set of muslin glass, after designs by Josef Hoffmann; Viennese
6. Painted glass, designed by B. Mauder, executed at the State technical school at Zwiesel

stripped off (Plate VI., No. 5). By the side of these there developed taller and larger glasses, with or without prunt decoration, almost always green, but in an extraordinarily wide range of shades. Slender wine-glasses were given a squared pattern or decorated with glass threads welded around the sides. Out of the knobbed beaker there developed in the first half of the 16th century the "rummer" (*Römer*) (Plate VI., No. 4), the beautiful classic form of the German green wine-glass, which has maintained its popularity to the present day. In the 16th and 17th centuries there was a great demand for the *Kuttrolf* or Angster—a comic shape consisting of a bulbous vessel with from two to five thin tubes like windpipes intertwined and uniting in an enlarged bowl like a mouth (Plate VI., No. 2). Other comic glasses are in the shapes of animals (bears, pigs, birds, etc.), boots, pistols and so forth. The principal drinking-vessel of these centuries, however, was the cylindrical tankard, often of huge dimensions, which is also called the "welcome" (Willkomm). The second half of the 16th century saw the introduction into Germany of painting with opaque enamels on hollow-glass, and for about 100 years this remained the most favoured type of glass-decoration. The idea came irom Venice (*q.v.*), but soon spread to all the German glass-works, and ware of this kind was produced in vast quantities. The most beautiful enamelled glasses, from the point of view of colour, come from the Bohemian works (see Plate V., No. 7). Multicoloured dotted borders on a ground of gold leaf close the design below the lip of the glass; the design itself may be of many different types—coats-of-arms, the imperial eagle with the electors, dukes, counts, cities, farmers, etc., according to the "quaternion" system on the wings; the electors with the emperor, political allegories, apostles, biblical scenes, allegories of the virtues, ages of life, hunting scenes, genre pictures, playing-cards, views of churches, cities and many other pictures, often full of figures. The Schaper glasses, named after their inventor, Johann Schaper (d. 1670 at Nuremberg), were a particular specialty; they were small beakers and goblets painted generally with black lead, sometimes with other transparent enamels, in very charming designs (Plate VI., No. 3). Lacquer-painting and scratching with the diamond were also used here and there (*e.g.*, in Nuremberg, Silesia and Saxony) for decorating glass with telling effect.

About 1600, Caspar Lehmann, court jewel-cutter to the Emperor Rudolf II. at Prague, applied the process of cutting jewels and crystals to glass. This was the decisive step towards the form of glass-decoration that has ever since held the first place—glass-cutting. We know of only a few goblets and dishes cut by Lehmann himself (d. 1622); his pupil and successor in office, Georg Schwanhardt, took the technique with him to Nuremberg, which kept the lead in fashion till towards the end of the 17th century. The specialty of this town was the tall Nuremberg goblet, composed of hollow pillars, and adorned with distinguished landscapes and portraits by masters of the art (Georg Schwanhardt and his sons Heinrich and Georg the Younger, Hermann Schwinger, H. W. Schmidt, G. F. Killinger and others) (Plate VI., No. 7); similar work was done by one or two glass-cutters of the Hess family at Frankfort-on-the-Main. About 1700, however, the Bohemian and Silesian glass-cutters came into the first rank. In those districts cut-glass of unprecedented technical perfection and artistic delicacy was produced in numerous workshops, almost always in intaglio, but sometimes-especially on the Silesian side of the Riesengebirge—in brilliantly-handled relief. Every phase in the development of style, from the Baroque through the Regency (foliate and fillet patterns—Laub- und Bandelwerk) and the Rococo to the Louis XVI. style, can be followed in these gracefully-shaped glasses and goblets, which have also been blown since about 1675 in the faultless crystal-glass (chalk-glass) of Bohemia. Of the countless variations of Silesian and Bohemian glass, a few examples are given in Plate VI., Nos. 9 and 10. Thuringia, Hesse, Saxony, Brunswick and other districts have produced special types of glass and special forms of decoration; next to Silesia and Bohemia, a distinguished place is taken by Brandenburg, where the celebrated alchemist and master glass-maker Johann Kunckel invented the magnificent gold ruby-glass about 1680 at the Potsdam works. These works, established by the Great Elector and removed to Zechlin about 1736, produced magnificent, and incidentally very large, goblets, mainly by command of the court. The greatest glass-cutters were Martin Winter (d. 1702) and Gottfried Spiller (d. after 1721), both of whom worked in Berlin. The latter in particular exercised astonishing technical ingenuity and artistic power in producing veritable masterpieces in relief and intaglio (Plate VI., No. 8). His only equal—artistically perhaps even his superior—was Franz Gundelach (see Plate VI., No. 6), who worked in Cassel as glass-cutter to the Hessian court.

A special technique, practised only in the 18th century in Bohemia, was that of the "gold sandwich" glasses (*Zwischengold-glaser*), in which two glass beakers are made to fit exactly together and one is slipped over the other, the outer glass thus serving as a cover and protection for a highly decorative gold etching design on the outer surface of the inner glass (Plate VI., No. 12). This technique was practised in monastic workshops, and found a late imitator in J. J. Mildner of Guttenbrunn (Lower Austria), who, from about 1785 to 1808, produced delicare giasses on which "gold sandwich;' medaihons and fillets are frequently combined with diamond engraving.

In the first half of the 19th century, German, and particularly Bohemian, glass-making enjoyed another considerable rise in importance. Besides cutting and engraving, painting with transparent enamel colours was in great favour (Samuel Mohn, d. 1815; Gottlob Samuel Mohn, d. 1825; Anton Kothgasser, d. 1851). Tinted glasses of all kinds, coloured in the metal, flashed and etched, were produced, as well as the popular lithyalin (an imitation of agate and other semi-precious stones), spun glass and "millefiori" in imitation of the old Venetian inventions, and many other types. Technically, the *Biedermeier* period reached an absolutely amazing height; but artistically it could not equal the best productions of other ages, particularly the 18th century. Subsequently, about 1860, a new movement set in under the leadership of the Viennese glass-manufacturer Ludwig Lobmeyr (1829–1902); inspired by the cut crystal work of the Renaissance, it ushered in a new renaissance in the art of glass-cutting, the modern development of which is explained below.

MODERN EUROPEAN GLASS

Like every other branch of industrial art the production of glass suffered neglect during the 19th century. The last ripples of the Empire period and the times of Biedermeier occasionally produced a valuable specimen, but then the effort seemed completely spent. When ornamental glass was mentioned, people thought of the heavy cut glass, of which the Bohemian factories and those of Baccarat in France and of Val-Saint-Lambert in Belgium had the monopoly. It was not until the general revival after the middle of the 19th century that there came a renaissance in this sphere. The pioneer was the Frenchman Gallé, but his work aimed at a treatment of the glass-material altogether different from that followed in the course of the previous centuries. He produced opaque coloured glass. About the same period the Viennese firm of Lobmeyr attempted to raise the standard of Bohemian glass by perfecting methods of cutting and engraving. Old models, however, were closely followed and as a result a development in a modernist direction did not become noticeable until the 20th century, when, under the influence of young Austrian craftsmen like Hoffmann and those of the Wiener Werkstatte, new shapes and decorations gradually became more general and even spread to the German glass-industry. This renaissance movement had an influence also on the Italian (*i.e.*, the Venetian) glass industry, but their excellent products remained too faithful to the shapes typical of the Venetian efflorescence. But the 20th century saw a considerable general improvement. Almost every centre of glass production has tried, in the course of recent years, to apply to the principles of modern industrial art. Important progress in this direction was made by the Swedish factory at Orrefors, which produces cut and engraved blown glass. The French movement

continued to be of importance, while in Holland the glass-factory of Leerdam made important experiments which are particularly significant because they make a modern use of all the technical possibilities of industrial glass-making. Before going into details about this development in various countries, a brief reference to certain technical details should be given.

Materials and Treatment. — In the first place it should be noted that glass can be grouped into three divisions according to the elements which are fused together to form it. There is, first of all, glass made with soda and lime, which is utilized for ordinary household articles and for window panes. There is, furthermore, potash and lime glass, which provides the "metal" for fine glass work; and, finally, lead glass, which is the same as crystal, and is distinguished by a particular lustre and brilliancy of colour.

Glass can be submitted to manipulations of different kinds in order to enhance the beauty of the object made from it. To begin with, glass can be blown into a mould or into a series of moulds of gradually differing shapes. To this class belongs the so-called "optic" glass, which is obtained by making vertical dents in the shape. These dents may become the basis of an ornamental motif. Next, there is the ancient Venetian method which applies ornaments by means of threads, blobs and festoons of glass. There is, furthermore, the colouring of the glass mass, which can be effected without impairing the translucency of the glass, and also the methods of covering the glass surface with ice-flowers, and of crackling the surface.

It is technically possible to blow two layers of glass one above the other. The most striking form of this process is the so-called Ueberfangglas which super-imposes two layers of different colours. When both layers are of the same colour, ornaments can be applied in between the two. It is a very subtle and difficult process, but it can be effected successfully where technical ability is allied to artistry. Colour, as enamel, can also be burnt into the glass while it is in the annealing furnace, which makes it possible to apply all kinds of ornaments to the basic material.

There are two methods of cutting glass. Diamonds or facets can be cut into the glass on smooth iron discs by means of sand or cutting-powder. The rough surface must then be polished on discs covered with leather, felt, or wood. The other method is the cutting of figures by means of the "amaril" wheel. In this process the object must be held in the hand and put into contact with the fixed rotating wheel, while damp sand or powder must be continually applied. It is not possible to see precisely what one is doing and a steady hand and considerable ability are therefore required. When applied to Ueberfangglas the effect can be obtained by allowing the differently coloured under-layer to become visible through the top layer. The modern practitioner of industrial art has found it difficult to adapt cutting and especially engraving to modern conceptions, but even this has in the end been done with success in Czechoslovakia and in Sweden — the cut glass of Hoffman is among the best glass that has ever been produced. The old method of glass engraving by means of a diamond is no longer used. At present the glass, which has been covered with a layer of wax or lacquer, is etched with hydrofluoric acid. A few French artists allow the process to go so far that they obtain differences of surface of as much as 10 millimetres. A technique of an entirely different kind is that of the *pâte-de-verre*. Glass powder, which has been finely ground, is baked in moulds with or without the addition of various colour oxides. This treatment is allied to that of the ceramist. Considerable care must be observed both in heating and in annealing. Among the methods which are suitable for mechanical application there is also that which consists in pressing glass, mostly coloured glass, into moulds. It is applied by artists for the production of household articles. The effect of the smooth sides is not so pleasant as that obtained by cutting, but the method is so much cheaper that it enables many people to acquire products of excellent quality which would otherwise be beyond their means.

DEVELOPMENT

Belgium. — In the 17th century Liége was the centre of the glass industry, but it almost completely lost its importance in the course of the 18th century, and at the beginning of the 19th century Liége glass had no particular significance — at any rate from the artistic point of view. Like Liége, Namur had at that period but one glass furnace where fine glass was still made. It belonged to the Zoude family. In the course of the 19th century, crystal manufacture began to flourish in the neighbouring Val-Saint-Lambert. The produce of this factory is scarcely distinguishable artistically from that of the ordinary crystal factories, although recently a few pieces of good shape and rational ornamentation have been produced. K. Graffart has executed some engraved work which is not without merit. In the industrial area of central Belgium the Verreries du Centre at Houdeng-Coegnies produce vases and household articles which can stand comparison with the products of Val-Saint-Lambert.

Holland. — During the last quarter of the 19th century the idea of making household articles which should be beautiful came into its own, and its protagonists turned their thoughts to glass. The architect H. P. Berlage occupied a prominent place in this movement. In 1900 he designed a set of table-glass which was executed in the French factory of Baccarat. About the same period a member of an old firm of Amsterdam glass merchants, Gerard Muller, made his own designs for household glass. Since then numerous glass sets of his design, usually executed in the Josefinenhütte at Schreiberhau, have appeared, and they are noticeable by the purity of their shape and by their noble simplicity. A drinking-service of his design, with hollow blown foot and large bowl, which he has christened "Cyrano," is very beautiful and has an entirely original shape. Each object in this set has been specially constructed with a special view to the purpose for which it is intended. There are also from him bowls and dishes with facet cutting which are striking by their simplicity and dignity.

It is, however, at the big glass factory of Leerdam that the richest unfolding of the possibilities of artistic glass is found. This factory, formerly directed by Jeeckel-Mijnssen, is now under the control of P. M. Cochius. Its activity started when the architect K. P. C. de Bazel was commissioned to design a drinking service. De Bazel, whose delicate art is revealed not only in his architecture, but also in his furniture designs, felt particularly attracted by the brittle material which is glass, and until his death in 1923 his activity in this new sphere continually increased. He designed some ten different drinking-services, all of which excel by their delicate and slender shape. Some of them are very simple; the later types are richer in shape, while minute but carefully considered cutting gives them real dignity. The services include not only glasses, goblets and carafes, but also finger-bowls, dishes and flower vases. De Bazel has also designed individual flower vases of a pleasant though particularly practical shape. He has also produced four memorial cups in crystal (*jaarbekers*, dated 1918, 1919, 1920 and 1924), with engraved inscriptions. That of 1924 in particular, executed in cut crystal of dark purple hue, is a noble piece of work. The inscription round the rim is dull gilt and reads worstelend *waakzaam* (wakeful and struggling). He also made designs for a complete service in pressed glass, entirely constructed upon a regular decagon, which is being brought into trade in blue, brown, purple and green.

In 1923, Dr. H. P. Berlage designed a breakfast-service, severely constructed in yellow-coloured pressed glass, while he also designed a few of the dated annual cups, among which that of 1925 is distinguished by a shape which is at once monumental and slender.

Since 1917 the decorative artist C. deLorm has produced drinking-sercices and other table-glass. His work is distinguished by the fullest attention to all the requirements of utility without impairing in the least the aesthetic value of the article. The artist A. D. Copier has been on the staff of the factory since 1923. He started with two drinking-services inspired by the shapes of flowers and fruit, and he extended his activity over the whole sphere of household glass. His work has resulted in the production of a large variety of bowls, vases and cups, executed in different colours, which have favourably influenced the general taste in Holland. Not less well shaped, and decidedly more striking and personal, are similar articles designed by the decorative artist

CONTEMPORARY EUROPEAN DOMESTIC GLASS

1. Glass with coloured ornamentation applied inside the material, by Henri Navarre; a technique developed by this designer. French
2. Bowls and vase of *pâte* de *verre* by François Decorchemont. French
3. "Graal" glass in which the coloured design is burnt into the glass. Swedish
4. Dish by C. Lebeau. Dutch
5. Crystal vase from the State technical school at Haida. Czechoslovakian
6. Undecorated glass from the Paolo Veneni factories, Murano. Italian
7. Undecorated domestic glass from the Orrefors factory. Swedish
8. Bowl from the Paolo Veneni factories, Murano. Italian
9 & 10. Undecorated domestic glass from the Orrefors factory. Swedish

C. Lebeau, who has also worked at Leerdam. Followed by Copier, he started another line of activity by producing specimens of decorative art, as "Unica." Lebeau's work at Leerdam lasted only a time, and he then went to the Moser factory at Winterberg, while Copier continued to work at Leerdam. The activity of these two artists has produced a rich variety of all kinds of glass-work of a much higher quality than has been attained elsewhere. It has placed Dutch glass at the summit of artistic production. Every technical possibility has been exploited: "optic," "crackled," "iced-glass," *Ueberfang*, "irisation," "colouring," have all been applied singly or in combination. In'this kind of work Lebeau has proved himself stronger and more personal than Copier. Copier has, however, sometimes displayed a very tender delicacy. In 1927 the ceramist C. Lanooy and the decorative artist J. Gidding began to execute work for the same factory. While they produce household articles and ornamental glass by means of the above mentioned technical processes, they have re-introduced the method of enamelling by applying colour evenly upon the glass. They use either a few delicate lines or else complete designs, such as fish motives. Much good glass-work may still be expected from these two artists.

Among other Dutch artists who do glass-work we may mention C. Agterberg, who designed glasses and vases which were made in Bohemia, and some very simple drinking- and breakfast-services, ornamented solely with a black enamelled line. J. Jongert and F. van Alphen have turned their attention to the artistic execution of bottles and flagons and have proved that in this direction also innovation and improvement can be effected.

Czechoslovakia, Austria and Germany. — The development of the art of glass-making in German-speaking countries must be considered mainly as one whole, because their glass factories, arts and crafts schools, glass-manufacturing centres and artists continually exchange both views and personnel one with another. It is difficult therefore to separate Austria and Germany; while Czechoslovakia, which has so many glass factories within its borders and near its frontiers, cannot be entirely separated from the other two countries.

The application to glass of the new conceptions of industrial art took place in German-speaking countries only at a late period. Originally it was limited to the designing of drinking-services, a matter to which numerous architects and decorative artists have given their attention. Among the long list of names which can be found in Pazaurek's book we shall only mention Peter Behrens, K. Koepping, Kolo Moser, T. Schmuz-Bauditz and W. v. Wersin. Little is observable of attempts to endow other glass products with a particular value resulting exclusively from shape. One might at most reckon among such attempts the objects designed for the Deutsche Werkstatte in Munich by K. Rehm and Else Viëtor, by Wolfgang and Herte von Wersin, about the years 1910–14. This work was also partly executed at Murano. However meritorious in many respects, it remained too solidly linked up with Venetian traditions. It is for that reason that more importance attaches to a strongly developed movement in these countries whose aim was the improvement of cut and engraved glass—an aim which has naturally resulted in improvements of shape. Ludwig Lobmeyr was one of the pioneers of this movement. He was at the head of a Viennese glass factory which has been in existence for over a century. As early as **1870** he secured the collaboration of good Viennese artists for the design of his more important pieces. So far as shape was concerned, his products continued to be severely limited to the imitation of models from the Italian Renaissance. Yet even in the direction of shape a certain independence was manifest. The main significance of the movement was that work was done in one definite direction. It was possible for able engravers like A. Bohm and K. Pfohl, and more especially K. Pietsch, F. Ullmann and F. Knochel, who were entrusted with the execution of these designs, to practise upon good work, until a tradition was established which has greatly benefitted work of a more personal character. We meet with this tradition in the glass factories of Haida, Schreiberhau and elsewhere, as a result of the work of the excellent technical schools of Steinschonau and Haida, in the region of Lausitz, while the school of Zwiesel in eastern Bavaria has a particular significance for the glass districts of Bavaria.

The technical school of Steinschonau dates from the year **1856.** H. Zoff, who directed the school from **1899** to 1914, and A. Beckert who became director in **1918,** have exercised a great influence on the glass produced in the area. The latter especially is a very able designer of glass ornamentations, which are executed at the school. Among the good glass-engravers who have been trained there and have produced the best pieces for the factories of the surrounding area we may mention F. Ullmann (1846–1921), who worked with Lobmeyr from **1887; A.** Helzel, and various members of the family Pietsch. Frederic Pietsch works for the firm of Conrad and Liebsch, which executes numerous designs made by this school. The same thing is done by the firm Lorenz Brothers, which furthermore executes work by Munich artists such as P. Emmerich and P. Süsz. The technical school of Haida is much younger. It was established in **1870,** and became important under the direction of D. Hartl in **1881,** and still more so under that of H. Strehblow. This school, which has on its staff excellent men such as R. Cizek and J. Schroder, is a source of inspiration to the numerous glass factories within its area; not only does it produce a number of well-trained and expert technicians, but it also provides good designs which are executed at, among others, the factories of J. Oertel and, especially. C. Hosch. K. Hosch made glasses designed by C. J. Pohl, coloured black with cut and engraved ornamentation. J. Oertel also executes designs for the Wiener Werkstatte.

In other parts of Czechoslovakia, which is so rich in glass-making centres, attention is attracted by the artistic glass of the Klostermuhle factory, which belongs to the firm of Lotz, where good work was being done about 1900 under the management of von Spaun; and by the factories of L. Moser at Meierhofen, near Karlsbad, and at Winterberg, where, especially in the latter, fine glass has been made recently by the Dutchman C. Lebeau. Since the revolution Prague has acquired a considerable importance. At its school for industrial art, the teacher Josef Drahonovski guides the development of the factories by his designs, among which there have been very beautiful ornamental cups, one being a present from the Sokol Gymnastics club to President Masaryk. Other work of value is being done by Kotera and, especially, by J. Horejc for the Viennese glass firm of J. and L. Lobmeyr. This firm of Lobmeyr has set the tone in Vienna for more than a century and has done very much for the revival of artistic glass, but until the beginning of the 20th century its productions were mainly commissions in imitation of famous models and motives, particularly those of the Italian Renaissance. Since then a change has come. The development in a modern direction is due to the firms of Bakalowitz and of J. Lotz Witwe. These two houses collected the younger artists, among them Kolo Moser, the most important of them, who has since died. The Arts and Crafts school, which received its impetus from Josef Hoffmann and to which belonged O. Dietrich, U. Janke, H. Jungnickel and D. Peche, had much influence on Viennese glass. The noted glass artist M. Powolny belongs to this school. He is the most important of them all. Hoffmann has designed coloured glass models of a strong and forceful character that are cut in square facets. The glass of Peche on the other hand is full of airy playfulness. Powolny combines strength of shape and of cut with extremely delicate engraving. Hoffmann and his school, as well as Powolny, have also designed glass for the Wiener Werkstatte. Among their pupils a few women artists of delicate taste deserve mention, viz.: M. Flögel, A. Schroder and V. Wieselthier. There are also artists like J. Zimpel and 0. Haerdtl. At present most of them also work for Lobmeyr, while the Bimini-Werkstatte produces fine blown glass after designs by J. Berger and F. Lampl.

The revolution having made connections with the glass factories of Czechoslovakia much more difficult, the Edelglaswerke of L. Forstner, a pupil of Kolo Moser, founded in Stockerau, has acquired considerable importance, and has produced beautiful work in cut "copper-ruby" glass and in different kinds of *Ueberfang* glass.

Finally, a brief word about Germany. In the north-east of Bavaria, the Arts and Crafts school of Zwiesel, under the direc-

tion of B. Mauder, is the principal centre. While cut and engraved white glass is the main glass product of Czechoslovakia, Bavaria concerns itself chiefly with painted coloured glass, although engraving is also carried on there, in particular, after designs by Mauder and A. Pech. In Silesia the school of Breslau, under S. Haertl, is of importance, while in Stuttgart the very able teacher W. von Eiff, an extremely proficient glass-engraver, exercises considerable influence.

Italy. — Italian glass owes the prominent position which it occupied until the end of the 17th century to the workshops of the little island of Murano near Venice, where this industry was concentrated. But after this period of efflorescence Venetian glass fell from the first rank and, notwithstanding attempts at revival, it has not reconquered its former position even in the 19th and 20th centuries. This is because these efforts, especially those of Salviatti, aimed in the main at continuing the old manner of the glorious period. A certain improvement, no doubt, was obtained, owing to the fact that over-elaborate ornamentation was abandoned and simpler and severer lines were adopted. This is especially due to the factories of Paulo Veneni, where the designers Francesco Zecchin and Napoleone Martinuzzi are at work. But up to the present they do not seem to have freed themselves from the domination of old models, as regards either colour or shape. Work of a really personal character is still rare, however able and technically perfect the products may be.

France. — The revival in France came in the days of the World Exhibition at Paris in 1870, not from the old glass factories but from the fine handwork of enthusiastic artists. The first of these is Th. J. Brocard, who set himself to imitate the old art of the followers of Islam, and succeeded in imitating them very closely. He made enamelled and coloured glasses, mosque-lamps, etc., as well as imitations of 16th century German goblets, in which he displayed a high technical aptitude. At the same time, E. Rousseau and E. Gallé were busy and soon created general admiration by their original work, shown at the exhibitions of applied arts in 1884. A third artist, E. Léveillé, soon followed in practically the same direction.

E. Rousseau (b. 1827), originally a ceramist, was seized, fairly late in life, by a passion for glass. If his assiduous search did not always lead to new methods, his results were often most unexpected. His system of applying opaque-coloured ornaments on clear and transparent glass was something very striking. Equally novel was his way of producing a play of colour by introducing into the volume of the clear glass metal-oxides or glass dust. In 1885 he started a collaboration with Léveillé, who after Rousseau's death in 1891, continued to work in his tradition. Good samples of the work of both artists can be seen in the Museum of Decorative Arts in Paris. In many respects they are the immediate predecessors of such very modern workers as Marinot. At the outset, however, their fame was obscured by that of Emile GallC, born at Nancy in 1846. After having learned his craft abroad, GallC established a glass factory in his birthplace in 1874. His first attempts aimed at giving colour to his material without causing it to lose its transparency. He first produced a blue colour by means of cobalt-oxides, which was the great success of the exhibition of 1878. Afterwards he succeeded in applying numerous other colours. There is at the Museum of Decorative Arts a very beautiful vase, dating from 1884, with ornamentations in green and black in the clear glass, which is modelled in relief. In 1889 he was able to announce that he could apply all colours from orange or lacquer-red to violet and purple. He also practised glass-engraving. Originally he disapproved of the use of acids, but gradually he gave up this attitude, and started researches into the production of coloured opaque glass with etched ornaments and of glass in double layers, with the ornamentation cut into the outer layer. About 1897 he was melting into his glass pieces of other glass or enamels of a different colour. Finally he devoted his efforts to the search for the so-called *pdte de verre*, in which others were to follow him with more success. His contributions were novel in many respects as regards the material used, but in shaping his form he was not always equally happy — whenever his shapes are not extremely simple they become disagreeable, over-burdened with flower-ornamentations or even altogether in the form of flowers. The leading place left open by GallC was taken over by René Lalique, originally a designer of small ornaments, who soon after the exhibition of 1900 devoted himself to the making of glass. Although Gallé had also designed household glass, he aimed mainly at the production of unique pieces by the application of diverse and difficult technical methods. Lalique, on the other hand, applied to his work all the resources of modern mechanical production. The application of enamels and engraving by means of the wheel have become exceptional. The usual process now is that of moulding or blowing into set matrices. This is considerably more expensive and therefore necessitates mass production.

The system of moulding allows three main combinations: (a) The decoration can be applied completely or partly in relief to the object; it can then be enamelled (*i.e.*, coloured) or rendered mat by cutting. (b) The decoration can be pressed into the object in bas-relief, thereby heightening the illusion owing to its greater transparency. *(c)* The whole object is covered with a decoration which is enamelled and cut either mat or polished.

The colour of the glass can also be modified. Lalique usually borrows his decorations from nature (fish, deer, flowers, sometimes human figures). His work aims at pleasant elegance rather than at profundity. For this reason he has given much attention to articles of general utility (perfume flasks, table glass), though he has also executed large decorative works in glass, such as the not very successful fountain of the Esplanade des Invalides, during the exhibition of 1925 in Paris, and also a mural decoration ornamented with fountains in the steamer "Paris."

Meanwhile, further work had been devoted to the other glass technique, that of *pdte de verre*. The real initiator of this process was Henri Cros, whose efforts went much further than those of GallC. He was not always equally successful in this difficult work, but his large reliefs, such as those which are now at the Luxembourg museum, the Victor Hugo museum and the Museum of Decorative Arts in Paris, dating from approximately 1892, display a decided skill. An artist who made even more interesting experiments was A. Dammouse, who in 1898 began work on this process, which is based on a more or less ceramic treatment of glass-powder. He manufactured vases and goblets, usually of small size, shaped like the calyxes of flowers, softly coloured (blue, purple and yellow-brown), which are notable for their refined delicacy. In 1900 his example was followed by G. Despret, who had been at the head of the glass manufacture of Jeumont since 1884. In collaboration with G. Nicolet, Despret made little statues and what-not ornaments. Of more artistic value, however, is the work of F. Décorchemont, who also began as a ceramist and in 1900 followed the example of Dammouse. He made considerable technical progress in obtaining a certain measure of translucency. His vases and cups, coloured dark blue and heavy green, brown or lilac, picturesquely varied by touches of less translucent colour, nearly always bear a geometrical ornamentation on the outside.

For the sake of completeness we may further mention the names of Argy-Rousseau, Walter, and Joachim and Jean Sala (father and son) who also worked in *pâte de verre*. Although frequently not without a certain roughness, their products, as can be seen for instance in their fruit-bowls, possess a picturesqueness which would be more effective if the material were more satisfactory.

It is not among the artists of the *pâte de verre* that we must look for the continuation of the glass-tradition of Rousseau, Léveillé and GallC, but rather among those who have maintained the process of glass-blowing. Of these the foremost is Maurice Marinot. His followers include P. and A. Daum and Henri Navarre, who works on more original lines. Maurice Marinot started his career as a painter, but a visit to the glass factory of Bar-sur-Seine gave him a predilection for glass-work. He exhibited his first attempts at the Salon des Indépendants of 1912. Marinot practises the craft in all its stages and handles the blowing-tube himself. He adorned his first glasses with small coloured opaque enamels. His motifs were birds, heads of women, flowers or festoons, with no other significance than a vivid colouring which enhances the transparency of the clear glass. Without altogether

FRENCH AND CZECHOSLOVAKIAN GLASS

1. Enamelled glass by Marcel **Goupy,** a French designer
2. Cut and engraved vases from the State technical school at Haida, Czechoslovakia
3. Vase by E. **Leveillé,** who with Rousseau and Gall6 in the 19th century started in France a revival of interest in the designing and manufacture of fine glass
4. Bowl of etched glass by Maurice Marinot, French
5. Vase by E. **Rousseau (1827–91),** French; an example of this artist's method of applying ornaments in opaque colour to clear glass
6. Vase by **Émile Gallé** (1846–1904), a French designer

abandoning his original methods he afterwards started to shape vases and bottles with very thick walls, in which, round the ornamentation that was usually composed of sharp angular lines, he made fairly deep indentations by treating the glass with acids. The result was to give more unity to the glass and the ornamentation. Marinot proceeded further in this direction by producing smooth glass without any exterior ornament, but very thick and ornamented by air bubbles inside the material. The air bubble usually counted as a fault in the old glass-craft, but Marinot made it into an ornament by rhythmic repetition. A further step in this direction is the use of colour-oxides inside the material, by which the glass sometimes is made almost opaque. A factory directed by P. and A. Daum at Nancy started by following Gallé's example and produced decidedly satisfactory work. This factory now uses its own designs, shapes and colours, but applies the process of strong indentations obtained by acids which was initiated by Marinot. This work has enough originality and shows enough artistic ability to deserve special mention. Such is equally the case with the work of Henri Navarre, which was represented, for the first time at the exhibition of 1925, by thick-walled vases where inside the material a vaguely indicated, but regular ornamentation in blue, brown or black had been applied. This work was done anonymously for a factory indicated by the letters Umab. When this factory failed, Navarre started independent work in the Verrerie de la Plaine Saint Denis, near Paris. His ornamentation is still applied in the same manner but has acquired more strength.

Another and very able artist in the technique of glass enamelling, who also designs articles of general utility in earthenware and porcelain, is Marcel Goupy, who represents the genuine French taste, which never strays from delicacy. He is undeniably the most gifted among a group of artists in decoration, of whom, in order to be complete, we mention also Maurice Dufrêne, Manzana Pissarro, Henri Farge, Simonet and Jean Luce. All these artists also produce household and table-glass which is generally very elegantly shaped. Although the ancient factory of Baccarat has remained on the whole outside modern artistic development, it has entered upon new ways with the production of table-glass designed by G. Chevalier and A. Bullet. The Verrerie de la Compagnie des Cristalleries de Saint Louis produces work designed by Maurice Dufrêne.

Sweden. — Modern glass production in Sweden is an interesting development which caused general admiration at the Paris exhibition of 1925, where it became clear that for decorative as well as for household glass, Sweden had a right to a prominent place among European countries. This is all the more remarkable because the development of Swedish glass maufacture has been so extraordinarily rapid. Formerly Sweden played no important part in glass production. There was an old factory established in 1741 at Kosta, near Karlskrona, which mainly produced plain household glass and only in the course of the last 25 years, after its amalgamation with the Reymyre factory, began to produce cut glass also. Among others, Gunnar Gunnarson Wennerberg did work in the manner of the Frenchman Gallé. But good glass cutters had to come from the Bohemian technical school of Steinschonau. The ablest among them is Richard Bayer. A factory established in Dec. 1917, the Svenska Krystallglasbruker, under the direction of Edvin O. Ollers, showed promise, but had only a brief existence. On the other hand, the Orrefors Bruck established at Orrefors in 1898, which is now directed by Edvard Stromberg (b. 1872), is still flourishing. Stromberg learned the craft at Kosta, and established his own factory at Sandwik in 1905. In 1918 it was amalgamated with that of Orrefors, which thereupon acquired considerable importance. The factory of Orrefors is mainly concerned with the production of household glass, which has a pretty shape and outline, is slender and delicate and is characterized especially by the topaz, amber or brown colouring of the material. Ornamental glass is also produced with designs in colour, burnt into the glass. This is known as Grail glass. This work, which is very varied, is designed by Edvard Hald and Simon Gate, two Swedish artists who do not limit themselves to the design of shaped and coloured glass but also design engraved and polished ornamental glass with remarkable artistic talent. There are numerous engraved ornamental goblets. Without definitely following old models, Gate in his designs mainly applies the ornamental methods of the old art of glass-engraving. On the other hand, Hald appears to be endowed with a richer and more original ornamental gift. It is not impossible that his international training has pointed the road to him in a happy manner. There is no doubt that in his work the somewhat playful ornament of the Viennese has given its peculiar charm to the Scandinavian background, without in the least impairing its individuality. He is particularly happy in representing the human figure, a remark which equally applies to Gate. The cutting done by these two artists has considerable merit. The engravers who worked under them, such as the Swedes G. W. P. Abels and B. E. Ryd, and the German W. H. Eisert, have been trained to forceful work displaying no hesitation and characterized by a perfect and exquisite finish. (See STAINED GLASS; MOSAIC.)

ENGLISH GLASS

The British people have contributed much to the well-being of the world by their manufacture of glass. Crystal glass, plate glass, window glass and bottles are all produced in large quantity by British factories, but of these, crystal or flint-glass, is best known. Flint-glass is really a glass of lead, a heavy brilliant crystal-like glass, composed of lead potash and sand; as powdered flints happened to be used at first, instead of sand, the name flint-glass remained. It is essentially a useful glass, and from its very nature is incapable of the artistic development seen in the fragile and easily worked glass of Venice. The British glass-makers did however make the most of a beautiful but intractable material and their work is marked at most periods by seemliness and good taste; simple useful shapes were chosen for glass vessels of all kinds, and decorated in ways most appropriate to the nature of flint-glass, with cutting as the most obvious means; many other experiments in decpration were tried, but all were abandoned in favour of cutting and engraving, which have been practised in England for over 200 years and still retain their popularity.

The 16th and 17th Centuries. — Flint-glass was introduced about 1675. Before that time glass for table service had been made in England on a small scale, but it was really Venetian, light in weight and of fragile material, and in form mere copies of simple Venice examples, made by Italian glass-makers, or their English pupils. Few of them have come down to us intact, but fragments, excavated in London and elsewhere, have revealed their actual shape and quality. Edward VI. induced a few wandering Venetian glass-makers to settle for a while in London, and again in 1570 Italian glass-makers appeared. Elizabeth procured the services of a Venetian, Jacob Verzellini, and in 1575 granted him a patent or monopoly for making Venetian specimens (Plate XIV., fig. 3). In 1592 the glass monopoly was transferred to Sir Jerome Bowes, and in 1615 to Sir Robert Mansell, who had good results with the help of Italian glass-workers (figs. 1 and 2, p. 408). The Protectorate put an end to glassmaking by monopoly, and for some time John Greene and other London glass-sellers imported their wares from Venice, which were generally made according to English designs (fig. 3). One good result came from these early experiments in glass-making. In 1615, owing to the demands of the navy, the glass-makers were forbidden to burn wood as fuel, and in consequence they had to use coal furnaces and closed glass pots giving intense heat, an essential to flint-glass making. Again, about 1660, Italian glass-makers were brought over to London, and with the help of one of them (Seignior De Costa) George Ravenscroft evolved the famous flint-glass about the year 1675, marking his glass with a glass seal, bearing the device of a raven's head (fig. 4); his rivals followed suit, so that five different glass trademarks of this period are now known. This custom of marking glass was

FIG. 7.— HIGHLY CUT GLASS WITH KNOPPED STEM AND DIAMOND CUT BOWL

dropped about 1690, when flint-glass had become generally known. Ornate drinking-glasses made about this time (fig. 5), were due to the prevailing taste for highly ornamented table service, for which the silversmiths were mainly responsible, but just before 1700 this fashion changed, and there followed a period of simple tableware, lasting nearly 25 years.

The 18th Century.— In the 18th century the decoration of drinking-glasses was mainly stem decoration, and there were five different kinds of stem in fashion during this period without counting minor variations (Plate XIII.). These are known to collectors today as the baluster stem, the plain stem, the air-twisted stem, the opaque-twisted stem, and the cut stem. From 1747 to 1760 all kinds were being made simultaneously; but out of this welter of competing fashions, only two styles survived: the cut stem for fashionable glasses and the plain stem for those of ordinary use. The taste for elaborate stem decoration arose first of all from the national craving for intricate artistic ornament of all kinds, which started about 1720. Stem decoration of glasses was encouraged in 1746 when the Government laid a tax upon glass according to its weight rather than its value, so that it became most profitable to make and sell elaborately decorated glass.

Venetian glasses of the 17th century, whether made abroad or in England, had generally hollow stems blown into various shapely mouldings, known as baluster stems; this name is still given to all stems with one or more distinct mouldings, or swellings. The difficulty of making an entirely hollow stem in flint-glass soon led British glass-workers to make a solid baluster stem, or one with only a small hollow core, like a large teardrop (Plate XIII., fig. 1). These drinking glasses were heavy and had at first large bowls and short stems. Gradually the stem was lengthened out and more elaborately modelled, and the bowl was reduced in size (Plate XIII., fig. 2).

After the Glass Excise Act (1745) heavy glass was no longer profitable to make, but more slender versions of the baluster stem survived till 1768, having simple "olive buttons" in the stem, and often engraved (Plate XIII., fig. 3).

Tall goblets with plain stems were made in the 17th century as suitable for special beverages. Until 1746 they were generally of substantial size, of good quality and still used for special kinds of wine (Plate XIII., fig. 11), but the excise duty made these simple types unpopular, and thenceforward wine glasses with plain stems were generally made smaller and lighter, to be used in the tavern and household (Plate XIII., fig. 12).

Drinking-glasses with the air-twisted stem were in fashion in England from about 1735 to 1760, and in Ireland till somewhat later. An air-twist in the stem was made originally by inserting a number of large air bubbles in the thickened base of a partly formed bowl and then drawing down the bowl into a stem and at the same time twisting the stem; the air bubbles were thus contracted and formed into corkscrew air-lines within the stem. At first the result was a coarse, irregular spiral (Plate XIII, fig. 4), but with practice the regularity and symmetry of the air spiral were improved. Air-twisted stems were sometimes made separately, and were then welded to the bowl as well as to the foot of the glass (Plate XIII., fig. 5); such stems are remarkable for their extraordinary intricacy (Plate XIII., fig. 6). An almost national type of decoration, the air-twisted stem could only be made well with the best flint-glass. The glasses cost at the time 7d. each.

Drinking-glasses with the opaque-twisted stem originated in Bohemia; they came into fashion in England about 1746 as a means of evading the glass tax, which omitted the taxation of the enamelled kind. The stem was here formed of opaque enamel glass threads, encased within clear glass. This result was obtained with the aid of a cylindrical mould first lined with clear glass, and the centre then filled with one or more canes of enamel glass; it was then heated in order to weld the contents together. Next the large lump of striped glass was withdrawn from the mould, reheated, twisted and drawn out like a long rod, to be cut up later into short lengths, which formed the stems of a set of glasses. At first, while the process was in an experimental stage, the glasses had a single broad band of enamel glass, like a twisted tape, within the stem (Plate XIII., fig. 7). Later kinds have spirals of many fine enamel threads most ingeniously arranged (Plate XIII., fig. 8). As many as 56 fine threads have been counted in a single stem. White and coloured enamel glass was used to form the opaque spiral. In 1777 the Second Glass Excise Act taxed enamel glass, and the glasses soon went out of use.

Glasses with cut stems had the surface of the stem cut into small grooves, or facets, which formed a regular and continuous diamond pattern round the stem. The glass was cut by being held firmly against a revolving iron wheel called the "scalloper's mill"; the cut facets were then smoothed with a stone wheel and finally polished with a wood and brush wheel. The decoration of glass by cutting and engraving came from Bohemia and was introduced into London shortly before 1720. After 1745 cut wineglasses grew in popularity, until by 1777 they were almost the only fashionable kind produced. Furthermore, they were made shorter and the style of cutting began to change. Stems were often cut with long upright grooves like the flutings on a pillar (fig. 6). Just before 1800 further changes were made, both in shape and style of cutting, the bowls being more heavily cut than the stems (fig. 7). Since then there has been little change in the style of cutting, although after 1845, when the glass excise was abolished, taller goblets were again made.

Cut glass has never been cheap; in 1755 simple types cost 7d. each (Plate XIII., fig. 9) and more elaborate pieces as much as 2s. (Plate XIII., fig. 10).

Glass vessels were also decorated by having various designs scratched or cut upon the bowl. The earliest method was simply to scratch the design on the bowl with a diamond point (Plate XIV., fig. 1), but after 1720 engraving was generally done in the Bohemian manner, by cutting the glass with small copper and stone

THE DEVELOPMENT OF THE WINE GLASS IN THE 18TH CENTURY

The five main kinds of wine-glass stem are shown, illustrating, in each group except the last, a transition from simple to elaborate decoration. **1–3.** Baluster stems. **4–6.** Air-twisted stems. **7–8.** Opaaue twisted stems. **9–10.** Cut stems. **11–12.** Plain stems

wheels (Plate XIII., figs, 3 and g), which is a more difficult and delicate method of cutting glass. Etching on the glass with acids was not much practised in England until more recent times.

The most interesting engraved glasses, from a sentimental point of view, are those relating to the fallen house of Stuart, and no other country in the world possesses such a series of interesting political glasses (Plate XIV., fig. 5).

Cut Glass.—The introduction of glass-cutting was commercially an event of supreme importance to the welfare of glass-making in Great Britain and Ireland. At first Bohemian glass-cutters were employed by a few of the more enterprising London glass sellers; John Akerman, employing a man named Haedy. advertised "diamond-cut flint glasses" in 1719. Haedy eventually acquired a business of his own, which prospered for three generations. Benjamin Payne, another London glass seller, advertised "diamond-cut flint glass" many times from 1735 onwards; he too must have employed a Bohemian glass-cutter. Thomas Betts, a London glass-cutter (1738–67) at first employed a Bohemian. Andrew Pawl, but afterwards instructed pupils himself. Jerom Johnson (1739–61), a self-taught London glass-cutter, became successful and is found selling cut-glass for exportation in 1749. These men laid the foundation of the cut-glass trade in London, where it was "greatly in vogue" in 1747. Bohemian glass-cutters continued to come over and assist in the production of fine cut glass, *e.g.,* Tresler, Laurikus, Ayckbowm, Gerner and Benedict, whose work in London between 1750 and 1800 is now well known. After 1750 the art of glass-cutting spread gradually to other parts of the country. And by the middle of the 18th century London cut-glass had displaced the Bohemian cut glass in European markets.

Originally, the most popular articles in cut glass were lustres (Plate XIV, fig. 2) and sets of dessert glasses (Plate XIV, fig. 1); but by 1742 all manner of cut-glass articles mere being advertised. At first cutting was confined to hollow diamond patterns until 1770, when the fluted patterns came into fashion; finally, convex or raised diamond patterns and prismatic cutting were introduced (c. 1800). These last were quite British in type, and are the styles of cutting most in favour today. Specimens of Irish cut glass, which began to be made on a large scale in 1780, sufficiently illustrate this stage of the national glass-cutting (Plate XIV., fig. 6); in design no very great advance was made after 1825. From 1835 onwards there was a return to the simple fluted style of cutting for mine-glasses, but they were then of a shape unsuitable for this decoration.

The present cut-glass designs are more or less copied from those of the period 1800–30, popularly called Waterford. The use of steam engines to drive the cutting machines led the glass-cutters to sacrifice the natural blown forms of glass for the sake of a masterly display of deep and accurate cutting, and glasses became too deeply and profusely cut, emitting a blaze of prismatic light, but having an unpleasantly rough surface. The worst types produced were early Victorian; John Ruskin, impressed with the vulgarity of these glasses, wrote a sweeping condemnation of all cut-glass, which for a time brought the craft into discredit and undoubtedly injured the national glass trade. Decoration by cutting almost disappeared for a time, Latterly, however, cut-glass has recovered much of its former popularity. The distinguishing features of modern flint-glass are its purity and its cold perfection. Glass-making is now treated scientifically for, with world wide competition to face, economy and efficiency are essential to the prosperity of the trade, which owes not a little to the foundation of a Society of Glass Technology at Sheffield university, and to the researches and experiments carried on there under the supervision of Prof. W. E. S. Turner.

AMERICAN GLASS

The development of American glassmaking, both from commercial and aesthetic standpoints, is unlike that of ancient, oriental or European endeavours in the same field. From the semi-mythical period on, the industry has encountered almost insurmountable handicaps and has had to solve problems in respect to glass manufacture different from those of other lands. Stringent migration laws from Old World glasshouses, regarding their workers. resulted in a great scarcity of operatives for early American furnaces; the assistance and patronage of guilds and trades societies enjoyed by European artisans was non-existent in the United States; poor pot-clay and silica bed ingredients, the constant recurrence of conflagrations, an apathetic attitude on the part of the general public during the 17th and 18th centuries, and the tendency of the workmen to turn agriculturists, doomed nearly every attempt to failure almost before it had started.

The 17th Century.— The earliest glass furnaces were situated along the Atlantic seaboard, the first attempt at glassmaking being in the spring of 1609. The previous autumn, the London company had sent eight Dutch and Polish glass-blowers to Jamestown. Va., who began the manufacture of crude articles for the settlers and for exportation purposes. Extant records state that this production was the first made-in-America article to be exported. The operations were short-lived. The next attempt was promoted by the same company in 1621, when Venetian workmen were sent over from London for the purpose of fabricating beads used for barter with the Indians in return for large tracts of their land. After several years the undertaking collapsed.

The first centralized industry was in the Dutch settlement of New Amsterdam on Manhattan island, where glass was probably manufactured continuously from 1645 to 1767. Evert Duycking and his son Gerrit made America's first coloured art glass for the windows of the Dutch Reformed Church and other churches in the vicinity between 1654 and 1674.

The 18th Century.— Caspar Wistar, who emigrated to Philadelphia from Germany, sent to Belgium for four glassworkers in 1739. He erected a small furnace in South Jersey, where window and bottle glass and chemical apparatus were blown. Upon Caspar's death in 1752 his son Richard took over the plant, enlarged its capacity, and carried on the work until 1781. The majority of the surviving authenticated examples are termed "off-hand" blown glass, *i.e.,* pieces which the workmen fashioned for their friends or families apart from the regular production. The blowers often added a bit of colouring matter to the last run of glass in the pot, then exercised their greatest skill in fashioning these useful and ornamental objects. This off-hand blown glass forms the preponderance of examples in the American collections until the advent of the historical blown and moulded flask and the invention of the mechanical pressing-machine.

What we term the "South Jersey technique" was probably practised in a limited way by all of these blowers. It was not until the beginning of the 19th century that it flowered in several separate sections of the expanding country. South Jersey types of glass are sturdy, substantial, capacious, bold of execution, yet well-balanced and graceful. There is a delicacy of curve in the handle and an artistry in the crimping of foot. Although a piece may combine plastically applied threads about the neck, superimposed decoration around the body, crimped handle and foot, it does not appear top-heavy, or over-elaborated.

The Pitkin glassworks, Connecticut, built in 1783, was probably the first native plant to utilize the "half-post" or double-dipped German method of bottle blowing. These perpendicularly, closely ribbed and fluted flasks, later copied by the Keene works (N.H.), became one of the outstanding types in the collectors' catalogue. The bottle, embodying every method of manipulation and every technique practised in America, is the outstanding glass product, holding the same relative position in America as that of the drinking glass in England.

Some of the most beautiful glass ever blown in America was made in Mannheim. Lancaster county, Pa, by Henry William Stiegel, who mas born in Germany in 1729 and emigrated to the New World in 1750. Although he is frequently called "Baron" Stiegel, this title is erroneous, for he held no patent to nobility. He needed none. Taking the advice of patriotic Americans, he

purchased a one-third interest in a tract of land near Elizabeth Furnace, calling it Mannheim, and then proceeded to erect a good-sized glasshouse and other appurtenances. Stiegel then departed for Europe, where he learned some of the finer points of glass-making and hired trained operatives from Bristol, Venetian and Bavarian houses—glass cutters, engravers, etchers, gilders, workers in vitrifiable enamels and in the pattern-mould expanded technique. The lead flint metal mixers and the colour compounders brought their formulae with them and the workmen brought their tools and probably some of their moulds. The first run of glass occurred at Mannheim in 1765.

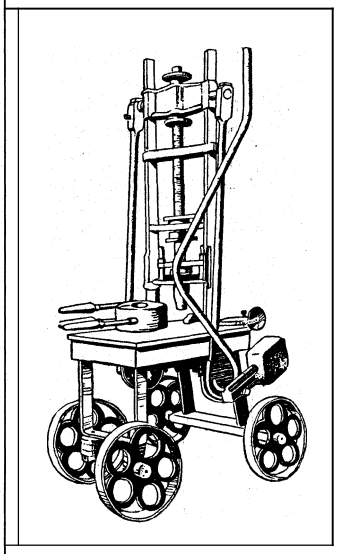
This was probably the, beginning of lead-flint glassmaking in America. Everything augured success, but in two years the general depression preceding the Revolution, coupled with the increasing personal extravagances of Stiegel, gradually led to complete financial failure. Unmindful of the signs of the times, he erected a larger furnace in 1769. The last firing occurred in 1774. The name Stiegel as applied to American glass, like that of Wistarburg and Sandwich, has unfortunately become almost generic. Quantities of glass, old and new, native and foreign, good and bad, are thoughtlessly or deliberately called by these names. Modern imitations add to the confusion. Attribution and authentication of surviving pieces requires time, patience and caution.

The most outstanding types of glass made by Stiegel are as follows: (1) Plain surfaced blown and hand-manipulated ware. (2) Expanded types blown into part-sized pattern-moulds. (3) Panelled or fluted types, blown into full-sized moulds. (The above groups are found in remarkably beautiful colourings, such as cobalt, emerald, amethyst and yellow.) (4) The use of vitrifiable enamels upon a clear white or a blue surface. (5) Cut, etched or engraved methods of ornamentation. (6) Gilded ornamentation, usually in combination with No. 5.

In 1797 Major Isaac Craig discovered coal in a hillside along the Monongahela river at Pittsburgh. This marked the beginning of glassmaking across the Appalachian range of mountains. Anthracite and bituminous coal gradually supplanted wood as fuel for the glasshouse furnaces. The erection by Craig and James O'Hara of an eight-pot window and bottle-glass house adjacent to this first coal bank was the beginning of the great Pittsburgh glass industry.

The 19th Century.—Numerous attempts at window and bottle glass manufacture were made in upper New York state, New Hampshire, Vermont, Massachusetts and New Jersey from 1800 to 1840, the off-hand blown examples from the Redwood, Redford, Salisbury, Saratoga, Stoddard, Glassboro and other houses generally manifesting the South Jersey technique. The glass pressing-machine was invented in 1827, and in this momentous decade occurred the imprint of national heroes and historical objects upon whisky flasks and cup-plates. The first historical flask was probably designed by Thomas Stebbins of Coventry, Conn., or by Frederick Lorenz, who purchased the O'Hara works in 1819. There were at least 250 glasshouses in America prior to 1870.

Two Englishmen, Robert Towars and James Leacock, built a small bottle-glass furnace in Philadelphia in the Kensington district. After passing through various ownerships, it was purchased and enlarged by the picturesque, self-styled "Dr." Dyott who established the patent medicine business upon a firm foundation in the United States. Dyott manufactured the containers at this furnace, and concocted the contents elsewhere. That he impressed his name, or that of Kensington, on so many of the bottles is a boon to the present-day collector. The two leading tableware and flint-glass manufactories in Massachusetts were the New England Glass company, of Cambridge, established in 181j, and the Boston and Sandwich Glass company, incorporated in 1825. Prior to 1818 none of the manufacturers could solve the secret of compounding red-lead or litharge, which prevented America from making crystal glass or lead flint which could be cut in the English manner. Deming Jarves, then an owner of the Cambridge works, built a set of furnaces for experimentation in the compounding of litharge, his first attempt meeting nith success. For years Jarves held the monopoly of the red-lead business in America. In 1827 Enoch Robinson, of the Cambridge industry, invented the first crude pressing machine, which was almost immediately improved by Jarves, then a part owner of the Sandwich plant. By 1838 the invention was perfected and pressed glass became popularized, although it did not become a household commodity until about 1845. America was now sending these machines to all the glass centres of the world. Both these firms made lovely blown glass before and after the installation of the mechanical pressers, their insufflated types evidencing an infinite variety of geometrical, arched and baroque patterns. English and French designs were copied by the mould model designers in the making of this contact mould ware, the mould itself always being full sized, and generally three sectional, although it was occasionally of four parts. No comprehensive name for this kind of glass has yet been devised. The metal is usually very thin, and the glass is frequently iridescent. It has been found in many colours. Other houses, such as Pitkin, Stoddard, Amelung, Zanesville, Kent and Greensboro, also manufactured this type of glass.



AN EARLY TYPE OF PRESS, SHOWING THE MOULD WITH ITS HANDLES ON THE TABLE OF THE PRESS

The Cambridge and Sandwich industries manufactured large quantities of glass for more than 50 years, the former attaining fame for their cut flint ware in the Waterford manner, for their pressed glass and their fine opalescent examples. Many European designers were engaged by both houses, the Sandwich works making fine lace-like patterns on their pressed ware, the metal of which was of a superior quality. Every shade and range of colouring known to glassmaking was employed, the coloured opaque glass becoming as deservingly famous as the blown and pressed candlesticks and lamps and their overlay manipulation. Sandwich also made a great variety of salts and cup-plates. In Pittsburgh two contemporary flint-glass works, Bakewell, Page and Bakewell, and James B. Lyon. turned out both blown and pressed ware of fine quality. Bakewell's probably produced more meritorious cut, etched, engraved and gilded glass than any American factory. Lyon, acknowledged by his contemporaries as the finest glassmaker of his day, was the first manufacturer to adopt pressed glass as a main line instead of blown glass. He was awarded many honours and medals in his field of endeavour. Fisher and Gillerland of New York city, the McKees and James Bryce of Pittsburgh and several other houses made an enormous amount of very good glass which has been incorrectly attributed to Sandwich. Patterns could not be protected, mould-makers were migratory, and popular designs such as the bell-flower were turned out by all these manufacturers.

The leading Zanesville, O., glassworks was granted an operating privilege in 181j. This bottle-house is credited with the introduction of the long-necked, bulbous-bodied, swirled and expanded bottles found in a variety of colours. The scroll and violin types of bottles probably originated at Wellsburg, W.Va., the Louisville, Ky., plant adopting the violin shape as a main line of production. These bottles are found in a greater variety of sizes and colourings than any others made in America. The invention of the snap-case, used for holding the bottom of the bottle while in the making, occurred in 1857. This eliminated the rough mark of the pontil rod. In 1858 the discovery of petroleum created a thriving business in glass lamps and chimneys, but the later introduction of artificial gas as an illuminant ruined many glassworks.

After the Civil War, the Barns-Hobbs-Brockunier flint glassworks at Martins Ferry. O., gave the industry three important

innovations: (1) the Leighton process—the use of soda-lime in the batch to supplant litharge, which greatly reduced the cost of production, but robbed such pressed glass of its resonant quality; (2) the use of benzene in the glory-hole or polishing furnace; (3) the mechanical application of cold air to the moulds for the purpose of chilling them. The discovery of natural gas in midwestern districts led to increased glass production and ultimately to an enormous mass-tonnage in Pennsylvania, Ohio, West Virginia, Indiana and Oklahoma.

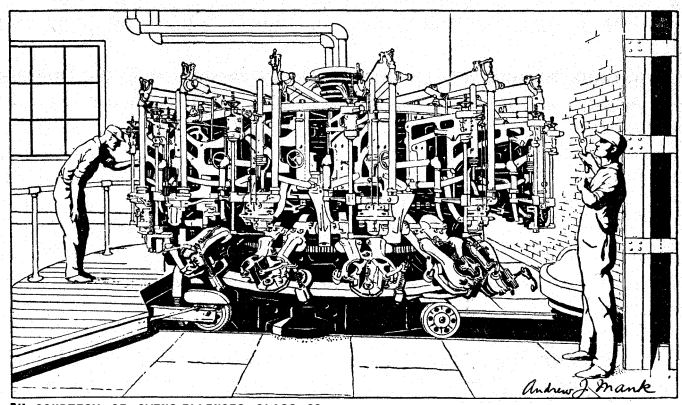
American forms and ornamentations of glassware became decadent in the era of poor taste in all the arts and crafts between 1860 and 1890. In 1870 America was making: (1) plate glass, including rough, ribbed or polished plate and rolled cathedral plate; (2) window glass, including cylinder and sheet; (3) table glass, including flint, lead or lime glass, both blown and pressed, lamp chimneys and flint druggists' and chemists' ware; (4) green glass, including green, black, amber and other bottle glass, fruit-jars, carboys, demijohns and other hollow ware and green druggists' ware. Cut glass attained a high degree of excellence and a great vogue in America around 1890.

The **20th** Century.— In 1900 the manufacture of glass in most plants was not basically different from the manufacture of 500 or 1,000 or 1,500 years before. The secrets of the trade were guarded jealously and were often handed down from father to son, generation after generation. Always a skilled trade, demanding rare dexterity and careful judgment, it was nevertheless dependent on the individual worker, labouring under crude conditions with a material imperfectly understood and controlled. In contrast to this, the 20th century brought an enhanced understanding of glass technology and of the necessity for strict physical and chemical control at all stages of the manufacturing process. Much of this progress can be credited to U.S. workers. It is reflected in expansion in two directions: (1) increasing mechanization of glass manufacture, which improved quality, increased productivity per man-hour, and decreased costs and selling prices; and (2) the creation of a whole host of new glass products which were unknown in the 19th century.

In 1899 Michael J. Owens invented the automatic bottle machine which still bears his name. (See BOTTLE MANUFACTURE) This machine introduced a new era in glass production methods, an era which saw greater and greater use of the machine in all phases of glass manufacture—in the unloading of raw materials, in their mixing and transportation, in feeding the batch to the furnace, in the automatic feeding of the glass gob, in its fabrication by highly perfected mechanisms, and in the manufacture of flat glass, bottles, of tubing, electric light bulbs, and many other glass articles. For example, the Corning "ribbon" machine will deliver from 500,000 to 750,000 electric light bulbs in a 24-hr. day, where formerly a handworker with his helper produced perhaps 1,200 in an 8-hr. shift. The machine blows and completes more bulbs in one minute than two men could turn out, by hand, in four hours. (See GLASS MANUFACTURE.) Much of this glassworking machinery was made possible by Peiler's invention of the "gob" feeding device which delivers to the moulds a glass charge of predetermined size, shape, weight and temperature.

Although Michael Faraday introduced boric oxide into the hatch early in the 19th century, the borosilicates'did not come into commercial use until 70 years later and then for a quite different purpose from that which Faraday had in mind. Now they are everywhere—in the 200-in. telescope mirror for Mount Palomar, in the kitchen oven and on top of the stove, in the chemical laboratories of schools and factories, in glass pipe-lines and high-tension insulators, and a thousand other products. The borosilicate glasses have almost revolutionized both the layman's and the engineer's conception of glass. The first important group of such glasses was manufactured by Corning Glass Works in 1915 under the trade mark "Pyrex." These glasses have roughly one-third the expansion of ordinary lime glass, great resistance to heat shock, high electrical resistance, and excellent chemical stability. Although they are somewhat more expensive to manufacture than lime glass, their superior characteristics have led to their successful use in fields from which glass previously was excluded.

During World War I and soon thereafter, methods were developed for continuously drawing both window and plate glass.



BY COURTESY OF OWENS-ILLINOIS GLASS CO.

THE MODERN FIFTEEN-ARM BOTTLE MACHINE

Prior to 1899 about 10 days' time was required to produce a piece of polished plate glass from the raw materials. Today, continuous methods make it possible to deliver a plate-glass window 22 hr. after the raw materials enter the batch house. ('Safety" glass was introduced extensively in 1928 (see GLASS, SAFETY).

Glass building blocks—"walls of daylight"—and fibre glass were introduced in 1931 (see GLASS FIBRES). The immediate acceptance of the building blocks was one more example of the widespread trend toward the increased use of glass in architecture and building construction. Homes, schools, theatres, stores. factories, office buildings and public buildings gain a large part of their right to be called "modern" because of their use of walls and partitions of glass block, opaque coloured glass façades, double-glazed windows, plate-glass windows, tempered-glass doors, skylights and partitions of fire-resistant wire glass, and ornamental windows, friezes, pilasters, and sculptured pieces of special architectural glass.

The widely publicized zoo-inch telescope mirror at Mount Palomar was successfully cast Dec. 2, 1934. This disk, made by Corning Glass Works, Corning, N. Y., was unquestionably the greatest single undertaking in glass manufacture and one of the really monumental achievements of mankind. A tremendous 20-ton piece of glass, 201 in. in diameter and 26 in. thick, it is indeed the largest piece of glass ever made for any purpose. The disk was made in the form of a grid, somewhat like a waffle iron. For astronomical purposes the surface must be optically correct within one-twentieth of a wave length of light, so that the slightest sagging under its own enormous weight cannot be tolerated. The open waffle-grid not only reduces weight but, just as important, allows the use of multiple supports within the structure, in the plane of the centre of gravity. The special borosilicate glass was melted and fired in a continuous furnace, transferred to the casting oven (containing the mould) by ladles, and then annealed in an electric kiln.

In 1939 the remarkable 96% silica glass was introduced by Corning Glass Works. As the name implies, this glass in its final form consists of approximately 96% silica, the remainder being chiefly boric oxide. As a consequence of the unusual composition, it has a coefficient of expansion less than one-tenth that of ordinary lime glass—in fact, not much higher than that of fused silica itself. It is so extremely resistant to thermal shock that tubes, rods or plates can be heated red hot and plunged into water without damage. The electrical resistance and chemical durability are very great. One type of this glass has exceptional transmission for the middle ultra-violet, down to 220 $m\mu$, as well as for the near ultra-violet and visible portions of the spectrum. These characteristics have led to the use of 96% silica glass in high temperature applications, and for special chemical, optical and electrical products.

It has been found possible to handle certain glasses by techniques similar to those used in the manufacture of porcelain or steatite. This discovery permitted the production of unusual and complicated shapes which are impractical for other methods of manufacture. The principal applications by 1943 were electrical in nature, for coil forms, bushings, radio insulators, and so on.

Another product of the glass maker's ingenuity is foam glass —a glass that floats on water. Made by introducing gassing agents into crushed glass, it has a density about one-fifteenth that of ordinary glass. The structure is cellular, there being a multitude of entirely enclosed gas pockets each surrounded by thin glass walls. When immersed in water, moisture absorption is about 2% by weight and is entirely due to the fact that some of the tiny cells are opened at the surface when the material is cut. The cellular structure gives foam glass excellent insulating characteristics and it is proposed both as a substitute for cork and as a new material for the high temperature field. Opaque and black in colour, foam glass can be sawed, drilled, and shaped, and is damaged only locally by ordinary mechanical impact. It has sufficient strength to be self-supporting. Like all other kinds of glass, it has the advantage of being water-proof, vermin-proof and rot-proof.

Although many of the developments in glass are industrial or scientific in character, much fine glass is still being made almost entirely for its aesthetic value. Many glassmakers have returned to quite orthodox methods which emphasize perfection of glass quality and appreciation of the fundamental characteristics of this unique material. The Swedish factory at Orrefors and the Lobmeyer factory in Vienna have done outstanding work. In the United States, Steuben seems to have become firmly established as a principal creator of fine art glass, although there are several other manufacturers whose work is very good indeed.

Production statistics for the United States are given in the table and in the articles BOTTLE MANUFACTURE and GLASS MANUFACTURE. The productivity per worker is very much greater in the United States than in any other country—a tribute to the diversity of product and to the efficient use of mass production methods in that country.

Glass Production in the United States—1939

Flat Glass

GLASS, SAFETY. Safety glass has been defined as glass so treated or combined with other materials as to reduce the likelihood of injury to persons by objects from exterior sources or by the glass itself when it is cracked or broken. Such glass is made in one of three ways. The first consists in embedding a wire mesh in the glass; the second, in laminating a sheet of plastic between two sheets of glass; and the third, in heat-treating a single layer of glass.

Experiments on the preparation of wired glass were made as far back as 1855 by Newton in England, but the first successful commercial manufacture appears to have been by Siemens in Dresden in 1891 based on Tenner's process. The Schuman method was invented' in America in 1892 and is known as the "solid process." In this process the wire mesh is pressed into the molten glass on a flat table with a corrugated roll and the surface is then further rolled with a smooth-faced roller. The method sometimes known as the "sandwich process" was invented by Appert in France in 1893. In this case, after the wire mesh has been rolled into a layer of glass as it is being cast, a second layer of glass is cast over the first before the latter has solidified. In both processes mild steel wire mesh (wire 0.5—0.6 mm. diameter), free from dust, grease, rust or other impurity which might develop bubbles. is normally employed, although a 34% nickel steel has been used in France in an attempt to obtain a thermal expansion approximately that of the glass. The glass sheet must be thick enough to have strength to withstand the internal stresses set up between glass and metal because of the difference in expansion coefficients. Wired glass has its greatest utility as a fire protection in buildings.

Laminated Glass.—The invention of this type of glass, popularly and romantically ascribed to Edouard Benedictus of France, was actually anticipated by John Wood of England, who was granted a patent for making such glass in 1905. Since the first commercially successful "Triplex" glass made under the Benedictus patents, several important developments have taken place. First, celluloid (a cellulose nitrate plastic) was replaced by cellulose acetate plastic which is inherently more stable than celluloid. A contemporary development was the use of ultraviolet absorbing glass to protect the celluloid plastic from the damaging light rays. In 1943, by far the major portion of the world's production of laminated glass was made with a polyvinyl acetal plastic, which replaced the older cellulosic plastics because of its greater flexibility at low temperatures.

A description of the operations involved with the vinyl type of plastic will indicate the principles on which all of these processes have been based. The panes of glass to be reinforced can be either flat or curved; and although drawn sheet glass is sometimes used, the best type is prepared from thin, polished plate, the panes normally employed varying in thickness from 1/16 in. to $\frac{3}{4}$ in., depending upon the purpose for which the

lamination is to be used. After cutting to the proper size. the panes of glass are thoroughly cleaned and dried and then sheets of vinyl plastic, also thoroughly cleaned and cut to the proper size, are placed between the panes of glass and the resulting sandwich is bonded together by the application of heat and pressure. The vinyl plastic is selfbonding and very resistant to water penetration. Hence, no additional adhesive and edge sealer are needed, as was the case in the original Triplex process. The vinyl laminated glass is more resistant to impact than the celluloid lamination and its strength is more uniform over the range of temperatures normally encountered outdoors.

When such a laminated glass is struck a heavy blow, the cracks radiate from the centre of attack, but the "splinters" remain firmly adhering to the intermediate plastic layer. It is, therefore, used in the glazing of motor cars and aeroplanes to reduce injuries should the glass become broken. Bullet-resisting glass is a laminated glass made of several layers of glass interspersed with several layers of plastic.

Heat-Treated Glass.—The principle on which this glass is constructed is the same as that on which Prince Rupert drops are made. A sheet of glass is heated to just below its softening point and then is uniformly and rapidly cooled with a blast of air. This rapid cooling puts the outside layers of glass under compressional strain, and since glass generally fails under tension this product is much stronger than untreated glass to bending, twisting and tensional stresses but is surprisingly weak to the impact of sharp objects capable of puncturing the surface. When it fails, it loses its form entirely and breaks into a large number of comparatively small and harmless pieces. In America it is generally used for the back light glazing in motor cars. Also, it is extensively used in places where glass is subjected to pressures uniformly distributed over the surface. (G. B. WA.)

GLASS, ULTRA-VIOLET RAY TRANSMITTING. Glasses having the property of transmitting radiations of shorter wave length than occur in the visible spectrum, that is, shorter than 400 mμ (the sign mμ representing $\frac{1}{10,000,000}$ cm.) have been known for many years. Fused silica or quartz provides a glass transmitting rays down to 190 mμ, while in 1907, E. Zschimmer prepared in small quantities a number of glasses having transmission limits varying from 186 mμ to 280 mp. As the most active rays which affect a photographic plate are those of short wave length, lenses which transmit well in the ultra-violet are advantageous in camera work. Schott, at Jena, introduced such a glass under the name of Uviol. Good ultra-violet transmission is important especially for stellar photography.

The great stimulus to the development of ultra-violet transmitting glass was the study by Bernard at Samaden and Rollier at Leysin of the beneficial effect of high Alpine sunlight on tuberculosis patients, and the employment of electric arc lamps having a high output of ultra-violet rays for combating rickets. The rays of therapeutic value are confined to a small region from about 297 to 307 mμ. Owing to atmospheric absorption, the shortest solar rays available, even in the Alps, are 295 mp, but ordinary window glass seldom transmits rays shorter than 310 mμ. The question naturally arose as to the possibility of preparing window glass to transmit the therapeutic rays This was first successfully done by Lamplough in 1925 with Vita-glass. Like quartz, fused boric oxide is transparent to very short rays, and Vita-glass resembles ordinary window glass except that it contains about 2% boric oxide and is of low iron and titanium oxide content.

For high transparency in the ultra-violet region, iron oxide in the ferric condition must be rigorously excluded. Of the several glasses on the U.S. market, Corex D was designed primarily for sun lamps and has a low transmission value below 290 my where the rays are not therapeutically beneficial.

The following measurements made at the U.S. Bureau of Standards on samples 2 mm. thick indicate the transmission in the region of therapeutic value of a number of specimens of glasses now available.

After short service the transmission of most such glasses diminishes considerably and then remains constant. The amount of the decrease is indicated in column 3, which shows transmission values after stabilization.

GLASSBRENNER, ADOLF (1810–1876), German humorist and satirist, was born at Berlin on March 27, 1810. After being for a short time in a merchant's office, he took to journalism, and in 1831 began to edit *Don Quixote,* a periodical which was suppressed in 1833 for its outspokenness. He next, under the pseudonym Adolf Brennglas, published a series of pictures of Berlin life, under the titles *Berlin wie es ist und—trinkt* (30 parts, with illustrations, 1833–49), *and Buntes Berlin* (14 parts, with illustrations, 1837–58), and thus became the founder of a popular satirical literature associated with the capital. He said many things in jest which the censor would not have permitted in "serious" journalism. In 1840 he married the actress Adele Peroni (1813–1895), and moved in the following year to Neustrelitz, where his wife had obtained an engagement at the Grand ducal theatre. In 1848 Glassbrenner entered the political arena and became the leader of the democratic party in Mecklenburg-Strelitz. Expelled from that country in 1850, he settled in Hamburg, where he remained until 1858; and then he became editor of the *Montagszeitung* in Berlin, where he died Sept. 25, 1876.

Among Glassbrenner's humorous and satirical writings may be mentioned: *Leben und Treiben der feinen Welt* (1834); *Bilder und Träume aus Wien* (2 vols., 1836); *Gedichte* (1851, 5th ed. 1870); the comic epics, *Neuer Reineke Fuchs* (1846, 4th ed. 1870) and *Die verkehrte Welt* (1857, 6th ed. 1873); also *Berliner Volksleben* (3 vols., illustrated; Leipzig, 1847–51). Glassbrenner published some charming books for children, notably *Lachende Kinder* (14th ed., 1884), and *Sprechende Tiere* (20th ed., Hamburg, 1899). *See* R. Schmidt-Cabanis, "Adolf Glassbrenner," in *Unsere Zeit* (1881).

GLASS CLOTH: *see* GLASS FIBRES.

GLASS FIBRES. Glass in its molten state behaves much as honey does; it is viscous and strings out tenuously when poured. As the threadlike strands cool, they become fine rods or fibres. Because of this characteristic, it is probable that the first form of glass produced by man was a fibre, drawn quite unintentionally when the hot mass was manipulated.

Craftsmen in the middle ages used coloured glass fibres as "spun glass" decoration in stemware and goblets, and early skilled workers grouped coloured rods or fibres together, shaped them into flowers and leaves and coated them with clear glass to form objets d'art known as millefiori. Until the close of the 19th century, little attention was paid to the utilitarian potentialities of glass fibres.

In 1893, Edward Drummond Libbey set up a glass fibre-producing unit at the Columbian Exposition and, by weaving the fibres together with silk threads, made various curios including lamp shades, neckties and a gown for Georgia Cayvan, celebrated actress. The Infanta Eulalia of Spain was presented with a glass gown of similar design. These gowns, though dramatic, were impractical because the fibres were too coarse to permit the fabric to be folded.

Efforts to produce glass fibres commercially began after the turn of the century and were reflected in a number of patents, mostly European, issued prior to 1914. Most of these early European processes, as well as the process used by Libbey in 1893, were based upon machines that drew out fibres from the heated end of glass rods and wound them on large revolving drums. The fibres became known as "spun glass." Before and during World War I, Germany thus produced coarse glass "wools" and fibres to replace imported asbestos and other high-temperature insulation materials,

Simultaneously with the later development of the drum-minding process, efforts were made in Europe to produce glass fibres by centrifuging molten glass from openings in a cylinder revolving at high speed. By 1929, improvements were developed independently in Germany by Rosengarth and Hager and in the United States by Harford and Stafford. The so-called "Hager" process is still in use in European countries where small-scale production operations are adequate.

In the United States, Friedrich and Dimmock began production of glass fibres by the drum-winding process about 1923 and, before 1927, had established a market for their fibres for use in electric storage batteries, in ornamental applications, and for various other purposes.

In the early 1930s, U.S. glass producers began research into new forms of glass as a means of seeking new markets. Work was done on centrifugal processes and on adaptations of the familiar methods of making other forms of mineral wool from rock and furnace slags; *i.e.,* by blowing a thin stream of molten rock or slag with a high-pressure jet of steam Results encouraged Games Slayter, John H. Thomas and several associates to begin in July 1931, the development of processes that later largely displaced earlier methods because of their economy of operation and their superior control of fibre characteristics.

Before the end of 1931, the first of three new basic processes was developed to the point of pilot plant production of relatively coarse fibres suitable for air filter applications. Much finer fibres in "wool" form were soon developed and found early application as thermal insulation in buildings and in naval combat ships. In 1935 and 1936, two textile fibre processes were brought into limited production. Subsequent commercial developments through 1942 were refinements and improvements of these processes.

Glass Mineral Wool.—The first process forms fine or coarse fibres gathered in a random jack-straw arrangement in the form of packs or bats. Coarse fibres may be made in diameters ranging from .004 in. to .010 in. Fine fibres are produced in sizes ranging from about .00035 in. to .001 in. and form a resilient, white, fleece-like mass properly known as glass mineral wool. (The term "spun glass" is not appropriate to these products.)

Production begins with the accurate formulation of the batch of silica sand, limestone and other selected mineral ingredients as in standard glass manufacturing operations. The batches are melted in large gas-fired glass-melting "tanks" or furnaces. (*See* GLASS MANUFACTURE.) At the forehearth end of the tank the glass drains down through small orifices formed in bushings of temperature-resistant metal. As the streams of molten glass pour down, they are caught by jets of high-pressure air or steam. The action attenuates the glass into fibres that may be long or short, coarse or fine, according to the accurate control exercised over the glass temperature, the size of the orifices and the pressure of the jets.

The fibres pass downward through a cone-shaped forming hood to a travelling conveyor, on which they gather in the desired thickness. Glass mineral wool thus formed has a density of $1\frac{1}{2}$ lb. per cu.ft., compared with the density of about 14 lb. common to the "spun glass" wool produced by earlier European processes.

The fibres are customarily lubricated with a microscopic film of an inert mineral oil, or they may be treated with a thermosetting binder and carried through compression rolls and ovens to produce semi-rigid to rigid sheets or "boards." The basic wool may be processed and fabricated to form bats, blankets, boards, blocks, pipe insulation and cements for many uses as thermal insulation and for sound absorption purposes.

Glass Textiles.—The second and third of the three U.S. processes produce fibres or filaments suitable for textile uses. Both begin with the formation of virgin glass into small marbles (about $\frac{5}{8}$ in. in diameter) that are inspected to eliminate impurities that might interfere with subsequent operations. The glass marbles are then remelted in small electric furnaces which have perforated metal bushings through which the molten glass pours in fine streams. From this point on, the two textile fibre processes differ.

The staple fibre process is substantially the same as the wool process, in that the honey-like streams of glass are attenuated into fibres by jets of steam or air. The fibres are gathered as a thin webbing on a revolving drum immediately below. The ebbing is drawn off the drum, gathered as a loose strand of fibres known as sliver (pronounced sly-ver) and immediately wound on a tube. The strand or sliver may then be further drafted, twisted and plied to form a yarn resembling a cotton or worsted yarn The term "staple fibre" is given to this process and material because the individual fibres are of limited length (9 in to 12 in.) as contrasted with the other textile fibre, known as "continuous filament," the length of which is limited only by packaging requirements and may be measured in miles.

A modification of the staple fibre process is used to produce glass "bonded mat," a wafer-thin sheet of fine glass fibres held together with a binding agent such as starch The fibres are gathered as a webbing on a continuous conveyor instead of a drum and are treated with the selected binding agent, calendered and dried, and subsequently cut into sheets of the desired size. Mat thicknesses range from .010 in. to about .050 In., according to their intended use.

In the continuous filament process the bushings in the electric furnaces are provided with 100, 200 or more small orifices. As the molten glass flows downward in parallel streams, the operator gathers the strands and feeds them down to a high-speed winder below. The tension placed on the strands by the winding operation mechanically draws each filament to a diameter considerably smaller than the orifice through which the glass leaves the furnace.

Both textile fibres are exceedingly fine and correspondingly flexible. The normal fibre diameter is .00022 in. A strand of 100 filaments is still too fine for commercial weaving; customarily, two to four strands are twisted and plied to produce a fine yarn.

Yarns and fabrics made from staple fibres resemble cotton or worsted; they have a mat texture produced by the free ends of the Individual fibres. Continuous filament textiles resemble natural silk or rayon; they have a high lustre and a sleek surface. Coloured glass yarns and fabrics were introduced in 1940 in a limited range of blue and tan shades by incorporating suitable mineral pigments in the glass itself.

Properties of Glass Fibres.—Individual glass fibres are inorganic, incombustible, non-absorbent, non-hygroscopic and chemically stable. The diameter of textile and "wool" fibres is so small in relation to their individual mass and length that they bend freely and do not break until bent to a radius several times the diameter of the fibre. Thus, in a yarn composed of fibres so fine that several hundred filaments are required to construct it, there is little likelihood that any individual filament will ever be bent to the breaking point, even when the fabric into which the yarn is woven is folded upon itself.

The tensile strength of fine glass fibres substantially exceeds that of any other commercial fibre. Fine textile fibres or filaments have a theoretical breaking strength of about 350,000 to 500,000 lb. per sq.in. While the realized strength of the fibres is substantially less than the theoretical strength, because of the tendency to break where fibres have been scratched or nicked by abrasion against each other, the residual strength of glass fibre yarns and fabrics remains very high. The stretch of glass fibres is only about 2%.

Glass fibres have a vastly greater surface area than an equivalent weight of glass in solid form; hence, their chemical durability is related not only to the inherent resistance of the glass itself but also to the fibre diameter and the service conditions encountered. Accordingly, various glass compositions are used. Glass fibres for general thermal insulating and acoustical work are produced from highly durable, low-alkali glass compositions. A different glass composition is used for chemical filtration and related applications; another, containing no alkali metal oxides, is used for electrical applications; and another for coarse and medium filter fibres.

Glass mineral wool has a unique density-conductivity relationship. At its natural density of $1\frac{1}{2}$ lb. per cu.ft, the conductivity

"k" (B.T.U./hour/sq.ft./inch/°F.) at 70° F. mean temperature is .27. When the density is increased by compressing the wool to about 9 to 12 lb. per cu.ft., the conductivity is lowered to approximately .24. Further increases in density show a gradual rise in conductivity. There is a gradual increase in conductivity with rising mean temperatures.

In textile yarns and fabrics, the intimate contact of fibre to fibre and the lack of entrapped air spaces increase the conductivity materially. Thus, in electrical applications, where the internal heat induced in motor windings must be rapidly dissipated, glass fibre insulation shows desirable heat conduction properties.

Both wool and textile forms of fibrous glass have high heat resistance and can be used in all temperature ranges to approximately 1000° F. By adding refractory clays in the production of insulating blocks and cements, the temperature limit can be raised to 1200° or 1400° F.

Glass has long been recognized as an excellent electrical insulation material. When made flexible by conversion to fibres or fabrics, the inherent electrical properties are retained, but leakage and moisture penetration can occur through the interstices of the fabrics. Therefore, glass electrical insulation materials, like cotton or asbestos, must be used with suitable electrical varnishes and impregnants. The temperature resistance of glass considerably exceeds that of standard electrical varnishes and impregnants but permits the use of those capable of withstanding greater heat than organic fibres and thus has enabled engineers to design equipment tolerating higher operating temperatures than are practical for cotton and with less bulk than is practical for asbestos. The introduction of resins with temperature resistance substantially above previously available varnishes extended opportunities for utilizing the strength, space factor and heat resistance of glass insulation.

The resistance of glass to all acids except hydrofluoric, its electrical insulation value and the high porosity of mats of glass fibres, early suggested its use in electric storage batteries to help retain the active ingredient on the positive plates. Glass fibre mats were used in storage batteries for heavy industrial applications as early as 1925. The proper use of glass retainer mats made it possible to increase the service life of automotive batteries by more than 100%.

Uses of Glass Fibres.—The unique combination of properties possessed by glass fibres and the variety of sizes and forms made commercially practical by the development of the U.S. processes have resulted in the development of many uses.

Glass mineral wool and products made therefrom are used as building insulation, as thermal insulation in domestic equipment (ranges, refrigerators, water heaters, etc.), as industrial insulation (cold storage and refrigerated equipment, boilers, retorts, ovens, process equipment, piping, duct work, etc.), as marine insulation in merchant and naval ships of all types, and as thermal insulation in aircraft, railroad passenger, freight and tank cars, busses, trucks and military vehicles. It is also used for sound-absorption and acoustical purposes in buildings and equipment.

Glass fibre mats are used as storage battery retainer mats, as a strainer type air filtering medium and in some electrical, acoustical and light-diffusing applications. Coarse glass fibres are used to produce impingement-type replaceable air filters, eliminator mats in air washers, and contact or diffusion mats in rectiiying towers used in alcohol distillation and in other types of fractionating processes.

Glass electrical textiles are used as sliver or yarns in the insulation of wires and cables, as cords for binding coils in magnetic equipment, as braided sleeving for the insulation of lead wires, and as plain or varnished cloth or tape for wrapping coils and other parts. The cloths are also used to form laminated sheet materials and glass-mica insulations.

Glass service fabrics are used in various military and naval applications, and as reinforcement for plastics, as pipe lagging cloths and tapes, as chemical filtration fabrics, in filters for blood plasma and oils, and wherever an incombustible, nonshrinking and nonstretching fabric is needed.

Glass decorative fabrics have been produced as drapery materials, shower curtains, table cloths, lamp shades, neckties (in combination with silk or rayon), women's shoes and hats, etc. Glass threads have also found use in surgery as a suture material for certain types of work. Medical research has established that glass fibres cannot be inhaled into the lungs and are innocuous either in the intestinal tract or in the blood stream. Workers handling glass fibre products, particularly in wool form, may experience a transitory skin irritation of purely mechanical character, which produces no allergic reaction and soon passes as they become accustomed to the material. No physiological reactions of the body to glass fibres have been demonstrated.

(T. S. R.)

GLASS MANUFACTURE. Glass has been defined (see the article GLASS) as "an inorganic substance in a condition which is continuous with, and analogous to, the liquid state of that substance, but which, as the result of having been cooled from a fused condition, has attained so high a degree of viscosity as to be for ail practical purposes rigid."

Most definitions of glass stress the transparency of the material, yet many commercial glass articles are translucent or opaque. However, it will always be found that lack of transparency is due to the fact that some other material, usually crystalline, is dispersed or suspended in the article, in a glassy matrix which is itself transparent. The material may be a colloidal suspension, as in some gold or copper ruby glasses; a suspension of microscopic or submicroscopic particles, as in some opaque glasses; or a mass of small or large crystals, as in some white and opal glasses. **A** much more essential feature of the glassy state is the fact that in every case the structure is nonperiodic. Although X-ray studies show that a definite structural scheme is involved, no unit of the structure repeats itself identically at regular intervals in three dimensions. Hence the material is non-crystalline, and has the dominant characteristics of a liquid; both of these facts agree with the definition given in the first paragraph.

That the principles of glass manufacture are not well understood or appreciated by the layman is not surprising. The U.S. industry is not large. In 1939 it was 38th in value of product in the bureau of census list of 351 chief manufacturing industries. Moreover, it had been surrounded by a certain aura of mystery. Supposed trade secrets were carefully guarded and were often handed down within a family from generation to generation. But of even'greater importance is the admitted fact that the characteristics of glass are very different from those of any other familiar material and that the manufacturing methods are correspondingly unusual.

From the modern point of view, the usable commercial compositions must satisfy these stringent requirements: (1) the batch materials must be as inexpensive as possible, consistent with the fulfilment of other prerequisites; (2) the materials must fuse and become fluid at a reasonable industrial temperature, and the liquid usually must be freed of gas bubbles; (3) the glass must be sufficiently viscous so that it can be manipulated at temperatures above its freezing range, without devitrification, yet not so viscous that workability must be sacrificed; (4) the glass must be so very viscous in and below its freezing range that it will not devitrify in cooling; (5) the glass must be chemically durable; (6) the glass must have the desired physical properties in its intended application.

The last requirement listed above represents a relatively modern attitude. The type of product is no longer limited by the characteristics of the particular kind of glass which may happen to be available in the plant. The glass chemist now consciously seeks the one composition which best fits the requirements of product application. As a result we now have glasses specially suited for use as bottles or containers, others which are best for windows or glass building blocks, and still others created for use as electric light bulbs. Some must have unusual optical characteristics, such as those used for spectacles and other lenses. Some must have a very small coefficient of expansion in order to withstand severe temperature changes when used in glass pipe-lines

or as cooking ware. Others must have high volume resistivity and low electrical losses for use as radio insulators in special high frequency circuits. In many cases, not one but several. distinctive properties are utilized simultaneously. The approximate range of physical values obtainable from various glasses is shown in Table I.

It will be understood that no one glass will have all of the indicated minimum or maximum values. Nevertheless, it will be evident that tremendous differences in each characteristic can result from changes in composition. Some of these compositions are listed in Table II.

Raw Materials.—Figure 8 shows the complex interrelationship between the various steps in glass manufacture. The present and subsequent sections in this article will follow this flow chart from top to bottom.

The glass-forming oxides are not always directly available as such. The glass manufacturer must sometimes search far afield for compounds which will yield oxides during melting, without adding other substances undesirable in the glass. On the other hand, sometimes several substances, each with its own advantages and disadvantages, are available as sources for a single oxide. The complete list of glass-forming materials is therefore quite impressive. However, with a few exceptions which will be noted later, these raw materials are needed to produce just 10 oxides which are used, in various combinations, in most commercial glasses.

Silica is the principal constituent of almost all commercial glasses, usually comprising 60 to 80% of their weight. The sand used in glass manufacture is essentially quartz, the most common form of silica. All sands contain iron oxide, Fe_2O_3, a very strong colouring agent, and this must be kept to a minimum, the actual amount depending on the subsequent use of the glass. Limits for containers are discussed in the article BOTTLE MANUFACTURE. Optical glass, fine crystal art ware, and special illuminating glasses must have less than 0.02% iron oxide; for common domestic ware 0.05–0.06% is permissible; and window glass often contains 0.10%. The principal sources of silica in the United States are the Oriskany quartzite of Pennsylvania and West Virginia and the St. Peter sandstone of Illinois and Missouri.

Soda is the most important glass-making oxide next to silica. It is usually added as soda ash (sodium carbonate), but sometimes as sodium bicarbonate, or sodium nitrate. Potash is used as pearl ash (potassium carbonate) or as potassium nitrate. Early glassmakers obtained potash by evaporating the lye made by leaching wood ashes. Many of these enterprises failed for no other reason than that the local wood supply was soon exhausted. Sodiuin oxide is often replaced by potassium oxide, particularly

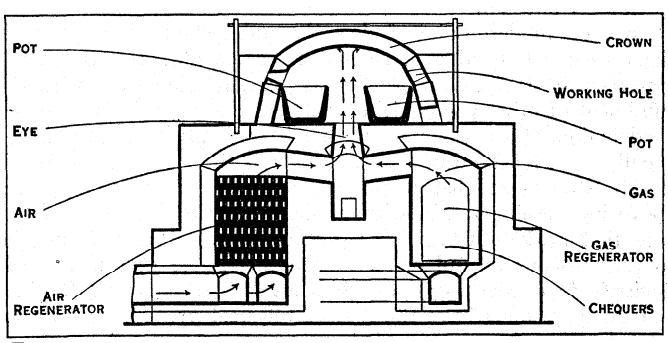

FIG. 1.—CROSS-SECTIONAL PLAN OF A REGENERATIVE FURNACE MELTING GLASS IN POTS

in optical glasses, because it gives greater brilliance to the ware. Glasses containing both sodium and potassium oxides are superior in chemical durability. On the other hand, these alkali oxides have an adverse effect upon electrical resistivity, dielectric strength and dielectric constant.

Lime is added as calcium carbonate (limestone, calc-spar, precipitated lime) and in the United States sometimes as burnt or slaked lime. When dolomitic lime is used, magnesia is also introduced into the batch. Lead oxide is usually added as red lead or litharge. Barium oxide is obtained from the carbonate or sulphate. Zinc oxide is obtained by direct oxidation of the metal.

Alumina is often present in modern glasses. It improves chemical durability and reduces the tendency to devitrify. The amount which can be profitably added is determined by balancing these advantages against the disadvantages of greater viscosity, hence higher melting temperature, and much greater attack on the furnace refractories.

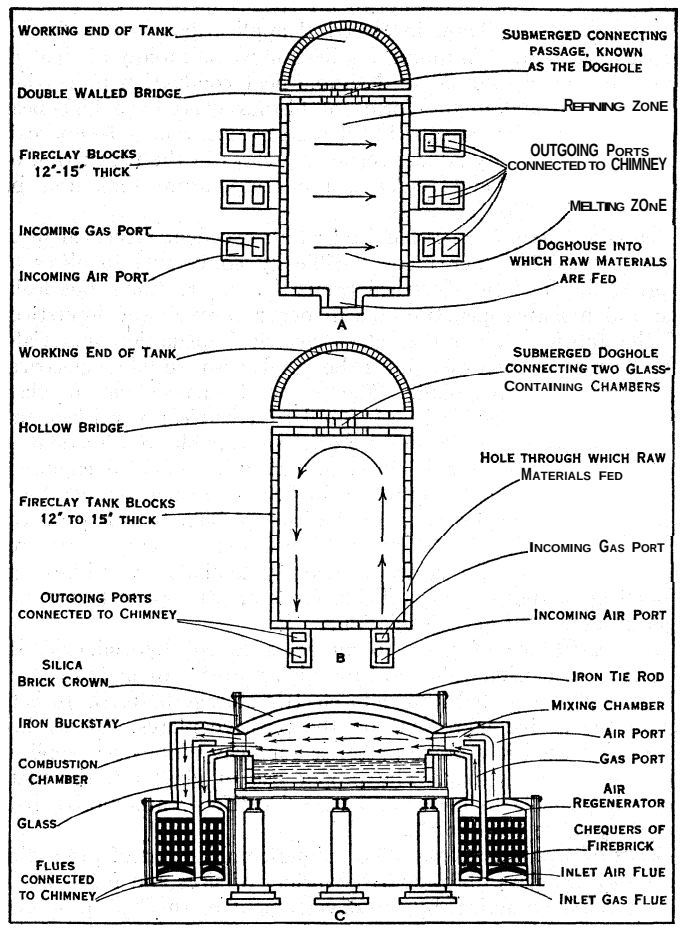

FIG. 2.—PLANS OF TWO TYPES OF TANK FURNACES FOR MELTING GLASS
A. Plan of cross flame furnace. B. Plan of horseshoe flame furnace. C. Cross-section of cross flame furnace.

Boron oxide is generally known only in the glassy state. The glassmakers' main sources are borax and boric acid. It is used to make the glass easier to melt, to decrease the tendency to devitrify, and to increase chemical durability. Boron oxide, in quantities up to about 15%, is a very powerful agent for reducing the coefficient of expansion. Silica also reduces the coefficient, whereas the alkalis increase it. Consequently, all the very low expansion glasses, like Pyrex-brand glasses (Table 11), are high in silica content and low in alkali, with boric oxide usually present.

Other minor constituents are often added to obtain certain desirable effects. A number of substances are added as colouring agents. The actual colour which results depends on the kind and

TABLE I.—*Range of Physical Values Obtainable from Various Glasses*

Property	Range of Values
Softening point	500°C.–1510°C.
Annealing point	350°C.–890°C.
Expansion coefficient	8×10^{-7}–140×10^{-7} cm. per cm. per deg. C
Thermal conductivity	0.0018–0.0028 cal. per cm. per deg. C. per sec.
Elasticity coefficient	6,500,000–12,500,000 lb. per sq. in.
Tensile strength	4,000–1,500,000 lb. per sq in
Compressive strength	90,000–180,000 lb. per sq. in.
Refractive index	1.461–1.625
Dielectric constant	3.5–17.9
Volume resistivity	10^{8}–10^{18} ohms per cc.
Specific gravity	2.125–8.120

amount of the agent, the general composition of the glass, and frequently on time, temperature, and furnace atmosphere. The chemistry of coloured glass is complicated and not thoroughly understood. Iron oxides give green, brown and sometimes red. Oxides of copper may give reds or blues; nickel oxide gives purple to brown; chromium oxide gives yellowish-green; and so on. Cobalt oxide is a very powerful colourant—one part in 500,000 is detectable, one in 100,000 is quite distinct, and one in 10.000 is intense. Colloidally-dispersed gold and copper are sometimes used in ruby glasses, although most of these are now made with selenium. Phosphates and fluorides are used for opal glasses. Manganese, nickel, and selenium oxides are used as decolourizers. Arsenic, antimony and other materials are used as "fining agents," to assist in the removal of bubbles from the glass.

In view of the very many substances which can be and are used in glass it is perhaps surprising that most commercial glasses are relatively simple in composition. They can be classified under these subdivisions: (1) vitreous silica: (2) alkali silicates; (3) lime glasses; (4) lead glasses; (5) borosilicate glasses; and (6) special glasses.

(1) Glass composed of silica alone is properly called "silica glass" or "vitreous silica," no matter how it is prepared. Vitreous silica is the end member of all the silicate glasses and is the simplest glass chemically and physically. It is also the archetype of the low expansion "96% silica" glass made by Corning Glass Works. The melting point of the high crystal form of silica is 1,710° C. For this and other reasons it is very difficult and expensive to make. This is unfortunate, for it has unusual and outstanding chemical and physical properties. The coefficient of expansion, for example, is only 5·5 x 10^{-7} cm. per cm. per deg. C.

(2) Next to vitreous silica, the simplest glasses are the two component alkali silicates. It is an altogether remarkable fact that the addition of just 25% of soda to silica lowers the melting point from 1,710° C. to 793° C., a decrease of more than goo degrees. The resulting substance is readily soluble in water and the solutions find widespread application as water glass.

(3) To overcome the water solubility of the alkali silicates, other materials must be added. One of the most satisfactory is lime. The lime also causes a further reduction in the melting point until finally the lowest temperature of the triple eutectic is reached at about 725° C. This eutcctic has the composition: silica—73.5% ; soda—21.3%; and lime—5.2%. All of the window and plate glass. container glass, and tableware compositions shown in Table II stem from this soda-lime-silica eutectic, slightly modified to give the most desirable properties for each application. Building blocks and some fibre glass are made from similar compositions. All are called "lime" glasses.

FIG. 4.— ACTION OF HARTFORD SINGLE FEEDER

(4) Glasses having lead oxide content of 25 to 50% are quite common. Some, with a content as high as 92% have been made, and such glass, having a density of approximately 8 00, is as heavy as cast iron. The lead glasses have a range in refractive index from 1·507 to 2·179 and the mean dispersion varies from 0·0092 to 0·0988, a range of 10 to 1. These glasses are very important in the optical field, for obvious reasons. The very finest tableware and art objects also utilize these characteristic properties.

(5) Borosilicates are fundamentally different from lime or lead

glasses. They are intrinsically superior in chemical durability and in resistance to heat shock. The latter is primarily due to the low coefficient of expansion (32×10^{-7} for one Pyrex brand glass), which should be compared with 90×10^{-7} for most lime glasses. Borosilicates have high softening points, great resistance to abrasion, and excellent electrical characteristics.

(6) Some special glasses—coloured, opal, opaque—have been mentioned. A development of great interest has resulted in producing a glass which, in its finished form, consists of approximately **96%** silica, the remainder being chiefly boric oxide. Some of its properties are shown in Table III.

Melting **the** Glass.—Manual, semi-automatic, and fully automatic systems are available for the collection and weighing of the various batch materials before delivery to the mixer. Power-driven mixers of the rotating barrel or pan type are usually employed. A four-minute mix is .sufficient for most batches, but more time is needed for complicated coloured glasses. Cullet (waste glass, or glass articles rejected because of breakage or physical appearance) sometimes makes up 75% of the batch by weight, very often 50%, seldom less than 25%. Batch may be transported and the melting units charged by hand or in various mechanical ways.

Two general types of melting units are in use: (1) pot furnaces, as shown in fig. 1; and (2) tank furnaces, fig. 2. In both cases producer gas, oil and natural gas are the usual fuels. Wood, charcoal and coal are only of historic interest. Electric heat is occasionally used for lehrs or for small, special furnaces. In every case the refractories are of great importance, for by acting both as containers for the glass and as retainers for the heat, sometimes simultaneously, they really make glass manufacture possible. Advances in the industry would have been impossible without corresponding advances in the quality of the refractories. At the same time, despite steady improvement, they are still responsible for many of the principal defects in glass, for they are slowly dissolved by the glass and, if allowed, the process will continue to destruction.

In primitive times melting was done in clay pots only two or three inches in depth and diameter. The modern pots and pot furnaces are not very different. They are being superseded by

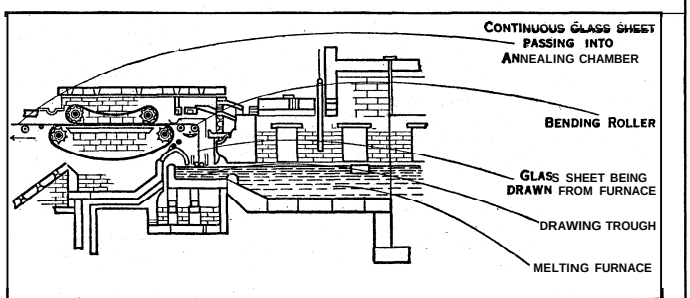

FIG 5.— PRINCIPLE OF THE COLBURN (OR LIBBEY-OWENS) SHEET-GLASS DRAWING PROCESS

the tank furnaces, but there are certain circumstances under which they are still used advantageously. For production of optical glass, art glass, coloured glass, or glass of other special compositions, used in limited quantities, pot melting is indispensable. The pots are made of specially matured fire-clay, are round or oval in cross-section, and may be open or covered. They hold from 500 to 3,000 lb. of glass. Except in the manufacture of optical glass, in which only one pot is used in the furnace, the number of pots will range from **6** to 20. Some of the smaller furnaces are direct-fired, but most of them are regenerative.

F. and W. Siemens developed the idea of melting glass in a furnace whose walls serve both to restrict and retain the heat and to hold the glass. They also invented the system of regenerative firing for use with these furnaces. This system had a revolutionary effect on all industries requiring high temperatures.

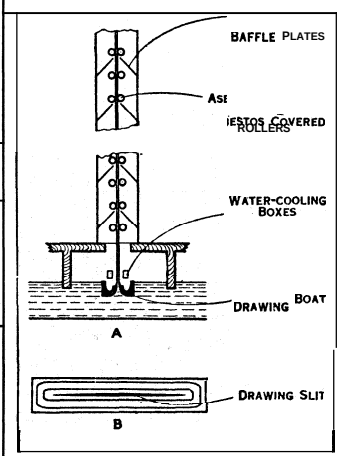

FIG. 6.— PRINCIPLE OF THE FOURCAULT SHEET-GLASS DRAWING PROCESS

There are many types and sizes of tank furnaces in use. The smallest are the "day" tanks which 5 to 10 tons of glass are melted and refined in one day, to be worked out the next day. The hand tank is a very flexible, economical, melting unit when quantities are involved which are somewhat larger than can be easily handled by pot melting. The largest tanks are probably those used in the manufacture of window glass. Some of these are **136** ft. long, 28 ft. wide, with a glass depth of 5 ft. Their capacity, when full, is 1,050 tons, and they require about 50,000,000 cu.ft. of gas per month. As the name implies, continuous tanks operate by feeding the batch through the "dog-house" at one end at the same rate as that at which it is withdrawn from the working end. Some tanks have operated nearly three years before repairs were necessary. This type of unit is obviously

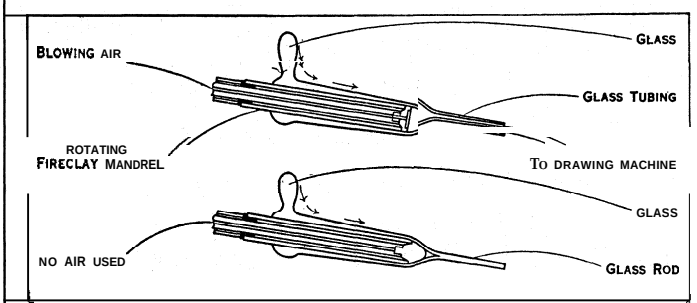

FIG. 7.— DIAGRAMMATIC REPRESENTATION OF THE DANNER AUTOMATIC METHOD OF DRAWING GLASS TUBING AND GLASS ROD

adapted to high-speed mechanical production. The temperature at the melting end of a continuous tank may be 1,500° C. when melting lime glass and 1,600° C. when melting *a* borosilicate.

GLASSWORKING

The conversion of molten glass into finished products is a process requiring great skill since, unlike many of the metal making industries, the raw material is not only melted but is transformed on the spot into innumerable forms. Slowly, through hundreds and thousands of years, the art of fashioning beautiful and useful articles from glass has developed. At first production was "offhand," without the benefit of even the simplest mould equipment. Later other methods were developed until there were five fundamental processes: (1) blowing; (2) pressing; (3) drawing; (4) rolling; and (5) casting. There are many combinations **of** (1) and (2), some of which are described in the article BOTTLE MANUFACTURE. Each of the first four can be largely manual, yet each also has its counterpart in machinery for continuous, automatic manufacture.

Offhand Glassworking.— The glass employed in "offhand" glass blowing is usually melted in pots, because the quantities of ware involved are seldom large. After melting and "fining" ("plaining"), the glass is allowed to cool several hundred degrees. largely by radiation, during a period of "settling" or "standing off." The soft lead glasses frequently used are usually cooled to

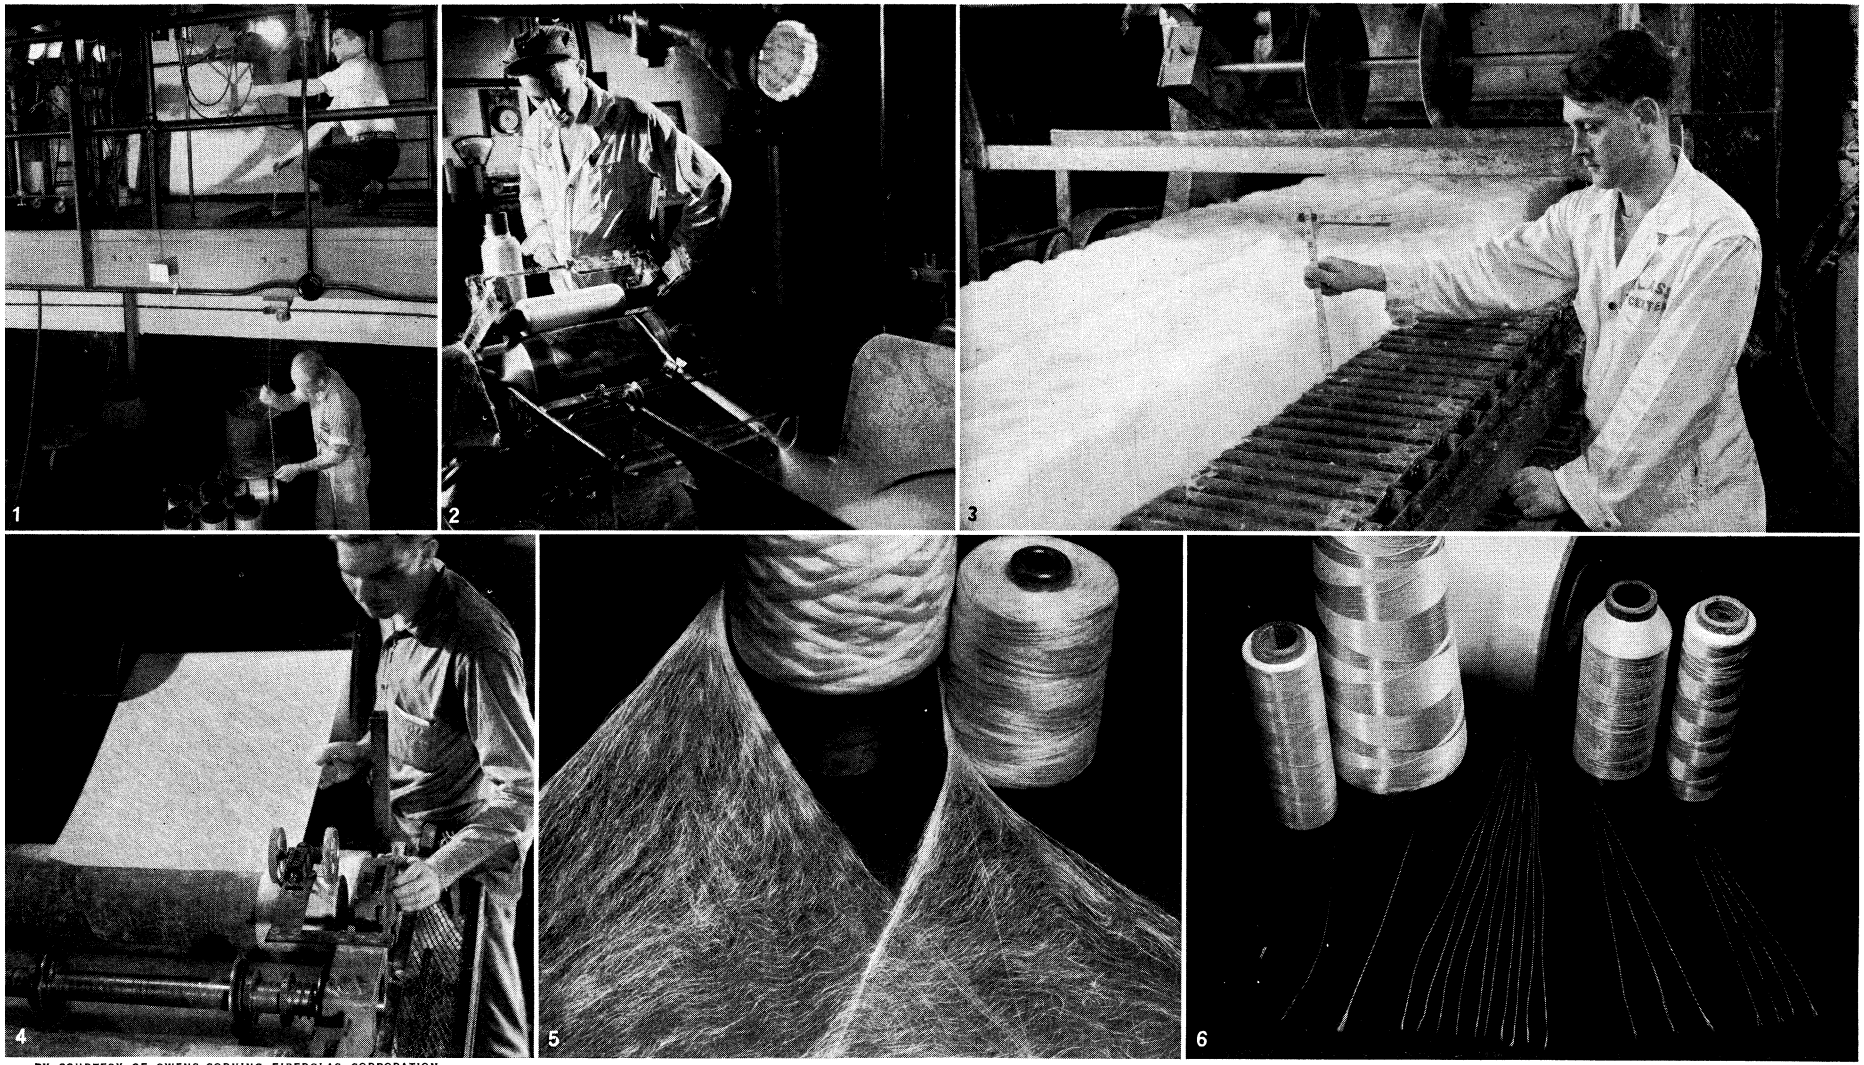
GLASS MANUFACTURE



BY COURTESY OF OWENS-CORNING FIBERGLAS CORPORATION

THE MANUFACTURE OF GLASS FIBRE

1. Manufacturing continuous filament glass fibres for textile use. Glass cullet in the form of marbles is melted in the electric furnace shown at the top of the picture. Bushings with multiple openings at the bottom of the furnace allow 100 to 400 individual filaments to be drawn simultaneously and gathered as a single strand. The man below is supervising the winding of filament. This process of manufacture is one of the four basic types; the other three are illustrated in figs. 2, 3 and 4
2. Production of glass in the form of staple fibre. Fibres are drawn by steam or air pressure from an electric furnace above the drum at the extreme right. They pass by a drying and tempering flame and gather as a web on a wide revolving drum. The web is drawn from the drum to form a sliver (pronounced *sly'-ver*) from which rovings or yarns may be subsequently formed
3. Production of glass mineral wool. Molten glass is drawn from large melting tanks or furnaces through small orifices and torn into shreds by steam or air pressure. The fibres gather on a conveyor as a white fluffy material having a natural density of 1½ lb. per cubic foot. This is the basic form of glass mineral wool and is used to fabricate many types of thermal and acoustical products
4. Forming glass fibre "bonded mat," a wafer-thin sheet of glass fibres. The fibres are produced by the staple fibre process except that the web is treated with a suitable binder and is gathered in sheet form. This product is used for storage battery retainer mats and air filters and to provide a paintable surface for glass mineral wool used in acoustical applications
5. Two forms of glass staple fibre. At the left is the plain form spread out to show the interlacing of many individual fibres. This form can be drafted and twisted for constructing moderately fine to heavy yarns. The type at the right contains a double strand of continuous filament in the centre of the staple fibres so that they may be handled without further drafting to form a high bulking material for electrical cable insulation and other purposes
6. Forms of glass yarn used for electrical insulation purposes. Left: a tube and cone of yarn suitable for weaving into fabrics. Centre background and right: various packagings of yarn, multiple wound to provide several strands in parallel arrangement. These forms are used for serving on magnet wires or cables to form an electrical insulation

about 1,000° C., at which temperature they are thick, viscous fluids, bright red in colour. If the glass is allowed to cool too much it is so viscous that gathering is difficult and accurate weight control impossible. If it is too hot, it is difficult to make a gather at all and the ware may be full of trapped "blisters" or "bubbles," because of the rapid working to which it must be subjected. Each shop has its own tools and benches and a small reheating furnace known as a "glory hole." The tools used in shaping handmade objects are simple, few in number, and quite crude. Many of these same tools were used in mediaeval times.

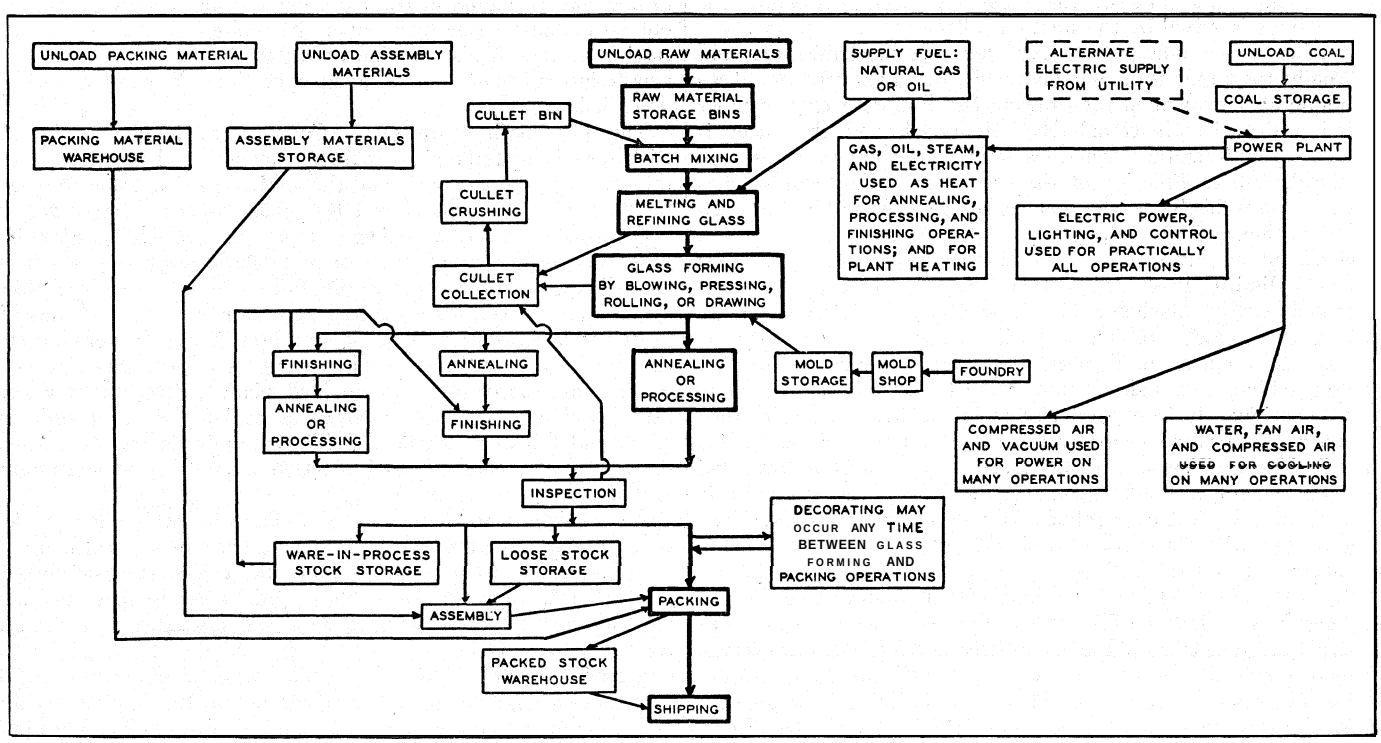
The initial operation consists in gathering approximately the proper quantity of hot glass on the end of a blowpipe. The glass is taken from a small area in the pot which has been skimmed, and kept free of objectionable stones or scum by use of a fireclay "ring" floating on the glass. The workman must judge accurately the amount he gathers for each piece of ware. The general mass of the object—by choice and necessity almost always round or ovoid in shape, and invariably symmetrical—is produced by blowing, by pressure of the breath, to form a bulb. Before the blowing operation, and during it, the blowpipe is roiled back and forth many times and the bulb is shaped with the charred wooden paddle. This action is very essential, because if the worker were to blow into the hot gather at once he would probably blow a bubble right through it, in the direction where it happened to be thinnest originally. He must, instead, first form a very viscous, chilled layer on the surface, a layer which will resist and sustain the internal pressure of the workman's breath. Subsequent gathers are brought from the furnace and joined to the original bulb while hot. Tools are used to shape the added glass until finally the stem is completed. Another gather is formed into the foot. The object is then attached at the foot to a punty, and excess glass is sheared away by cutting, much as a housewife cuts hot taffy candy. Further heating permits shaping to the final desired shape, and the object is then cracked off the punty and annealed.

Lamp-workers convert their raw materials, usually ready-made tubing and cane, into innumerable articles, from beads to prancing horses. These are the glass blowers whose art is sometimes displayed at fairs and expositions. Most of their work is done with commercial tubing of varying compositions, diameters and lengths. To shape this glass it is held over burners fed with gas, compressed air and oxygen, until it reaches a temperature at which the viscosity is just right for further working. At that moment it can be drawn out to many times its original length and can be bent, twisted and otherwise shaped. An almost infinite variety of objects can be made by lamp-working. In addition to the novelties and curios we have been discussing and the beads and artificial gems of like nature, there are other, more prosaic branches of the industry: (1) glass eyes; (2) scientific and surgical apparatus, ampoules, glass condensers, X-ray tubes, thermometers, etc.; and (3) electric lamps and radio tubes. Where small items must be made in great quantity, as in the case of Mazda lamps, radio tubes, or vials, the lamp-working industry is highly mechanized. In a growing number of cases glass-to-glass and glass-to-metal seals are being made by hand or by machine, following the general principles of lamp-working.

Mould Blown Glass.—Glass moulds are almost always made of cast iron and usually can be used either singly, by hand, or with slight changes in multiples in glassworking machines. "Hot" blow moulds run at a temperature approaching red heat, whereas "paste" moulds, lined with a lubricant, are intermittently cooled by water. Usually both are of the "open and shut" type, made in two sections hinged at one side so they can be opened to remove the piece. Paste moulds are circular in cross-section, thus allowing the glass to be revolved while it is being blown and giving an excellent surface finish. "Hot" moulds need not be circular.

Blowing machines for containers are described in BOTTLE MANUFACTURE. The Corning "ribbon" machine is the fastest automatic glass forming mechanism ever built. The multiple paste moulds, carried on a moving endless belt, convert a continuous ribbon of glass into as many as 700 bulbs per minute.

Pressed Glass.—Press moulds are usually made from gray cast iron and normally consist of three parts. The "bottom" or mould proper forms the outside surface of the article, as shown in fig. 3. The plunger forms the inside surface. A ring seated in the top of the mould defines the top edge of the article because the plunger, tapered at other points, is straight here and fits the ring closely. Simple pieces, such as tumblers or shallow baking dishes, are pressed in one-piece block moulds equipped with "valves," that is, bottom plates which will move up against the bottom of the glass to dislodge it. More complicated pieces re-



COURTESY, C. J. PHILLIPS, FROM "GLASS: THE MIRACLE MAKER," PITMAN PUBLISHING CORP., PUBLISHERS, NEW YORK, N.Y.

FIG. 8.—FLOW DIAGRAM OF A TYPICAL GLASS PLANT

quire "open and shut" moulds In the making of pressed articles, the molten glass is gathered on the end of a punty, the gather is swung over the open mould, and the press operator severs the thick intervening thread of glass. The ring is slipped on and the mould is pushed into place on the press table or rotated to bring it into alignment with the plunger. The plunger is now pressed down into the hot glass, squeezing it from the bottom of the mould up and around the sides until the mould is filled.

The automatic press comes to the final stage of automatism when it is used with a continuous melting tank, a mechanical feeding device, and an automatic "takeout" for removing the ware. The gob feeder has applications to all types of ware made by pressing or blowing or a combination of the two. The principles of operation are shown in fig. 4. In some cases the gob falls directly into the mould; in others it slides down a trough into the mould.

Drawing Glass.—This process is exemplified by the manufacture of window glass and of glass tubing. Window glass production evolved through four successive stages: (1) the crown method; (2) the hand-cylinder method; (3) the machine-cylinder method; and (4) the continuous sheet drawing method. The first three are of historical interest only.

The three methods now in use—the Colburn (Libbey-Owens-Ford), Fourcault, and Pennvernon (Pittsburgh Plate Glass)—have in common the fact that molten glass is drawn continuously, day and night, mile after mile of it, from large continuous tank furnaces. Fundamentally, therefore, these processes are the same, differing only with respect to certain details by which the sheet is started, formed and annealed. In the Colburn process (fig. 5) the sheet is drawn vertically and while still mobile is passed over a metal roller mounted a short distance above the bath. This roller changes the drawing direction from vertical to horizontal, and the sheet then travels on driven rolls through the annealing furnace. This process with modifications also produces drawn blanks which are subsequently ground and polished to plate glass.

In the Fourcault process (fig. 6), a slotted floating clay member called the "debiteuse" is depressed in the molten bath. By hydrostatic pressure, glass exudes through the slot, whence it is drawn vertically by paired asbestos rolls to a height of approximately 21 feet. These paired asbestos rolls, spaced on 12 to 16 inch centres, are mounted in a metal enclosure to control the rate of cooling. Congealing of the sheet has occurred before the drawn sheet is seized by the traction rolls.

In the Pennvernon process the elevating mechanism is substantially the same as in the Fourcault, but Pennvernon utilizes a unique arrangement in the drawing bath. Here a clay member called a draw-bar is completely submerged, and the sheet is formed by uniting the bath skins immediately above the centre of the draw-bar. Freezing of the sheet occurs before it reaches the traction rolls. Thus, the sheet is touched by nothing between its formation and congealing.

Glass tubing and glass rod are obtained by drawing the glass from a cylindrically shaped "gather," by hand, or from a refractory cylinder, by machine. The draw may be vertical as in the case of thermometer tubing, or horizontal in other cases. By far the largest tonnage of glass tubing is made on the Danner or Vello machine. Fig. 7 shows that in the Danner process the glass is fed continuously from a tank to an inclined rotating refractory cylinder. Air passing centrally through the refractory maintains sufficient pressure so that the hot glass drawn from the lower end emerges as a continuous tube. A drawing mechanism pulls it several hundred feet over rollers through an annealing section to a cutoff saw where it is cut to desired length and then graded for diameter and wall thickness.

Rolling Glass.—Plate glass differs from window glass in several respects. First, the chemical composition usually is slightly different, although both are essentially soda-lime-silica glasses. Second, much plate glass is made by the semicontinuous process of rolling, whereas all window glass is made by one or another of the wholly continuous drawing processes. Third, the rough-rolled glass—which may be sold as a separate product for factory windows, skylight, office partitions, etc., with or without a pressed surface design—in most cases is subjected to the additional operations of grinding and polishing. These give it a plane, optically true surface—even smoother and glossier than the natural fire-polished surface of window glass. Both stages of manufacture. the formation of the rough glass blank and the finishing of these blanks, underwent radical changes after 1920.

Until 1923, plate glass was produced entirely by the "casting" method, both in the United States and elsewhere. The glass was melted in regenerative pot furnaces, each holding 12 to 20 pots. At the proper time a pot was removed from the furnace by a crane, skimmed and then partly inverted over a flat, cast-iron casting table about 16 ft. wide and 30 ft. long. The table was covered with fine sand to prevent sticking and chilling of the glass. The molten glass was poured in a continuous stream just ahead of an enormous water-cooled cast-iron roller. After passing over the molten glass the roller was raised on wedges so that the sheet could be pushed from the table into the first of a series of lehrs. At this stage of manufacture it was known as rough-rolled glass

Grinding and Polishing.—The machinery for grinding and polishing was ponderous and costly. Various pieces of rough glass were fitted into a plaster of paris "bed," on a circular table 25 to 30 ft. in diameter. The table was then transferred to a grinding frame where large iron disks. shod with smaller iron disks, were made to revolve with gradually increasing pressure upon the surface of the sheets. First coarse sand and water, then finer sand, and finally emery and water, were fed to the grinding surfaces, gradually wearing away the large-scale irregularities. The grinding operation was completed in about 1 hr., and the table was then transferred to the polishing machine. Here a similar process took place, using felt-shod wheels and a finer abrasive, rouge (iron oxide) and water. About half the original thickness of the rough blank was removed by this grinding and polishing.

The methods now in use may be classified as (1) semicontinuous: the Bicheroux and Pittsburgh Plate Glass Co. processes; and (2) continuous: the method introduced by the Ford Motor Co. and the Pittsburgh Plate Glass Co. between 1922 and 1924, and the method used since 1925 by the Libbey-Owens-Ford Glass Co.

Semicontinuous Processes.—The Bicheroux process derives its name from a German, Max Bicheroux, who developed a new type of rolling machine shortly after World War I. The glass is melted in pots and is poured in front of iron forming rolls which rotate but do not move lengthwise over the molten glass as in the old casting process. This machine produces sheets of predetermined length, intermittently. Subsequent operations are similar to those described above.

The Pittsburgh Plate Glass Co. process is similar to the Bicheroux in that the glass is melted in pots and passed through rollers. The pots are larger and the method of delivering the glass to the rollers, and removing it therefrom, is somewhat different.

Continuous Processes.—These represent the first major improvement in the manufacture of plate glass. Both stages of production, the creation of the blank, and the grinding and polishing operations, are continuous and largely automatic. The glass is melted in large continuous tanks and flows from the refining end through a gate and over a wide spout in a continuous stream, passing downward along an inclined plane between two water-cooled rollers. The glass emerges as a flat ribbon of uniform width and thickness which is pulled by multiple rollers through the lehr. After cutting and inspection it passes into continuous grinding and polishing machines.

Annealing and Tempering.—Glassware which has cooled from working temperature, without special heat treatment, is often in an unequally strained condition. This is because glass is a relatively poor conductor of heat and so the temperature distribution in any piece of glassware shortly after it has been formed is likely to be very nonuniform. As the glass cools, these temperature gradients cause mechanical stresses and strains which may cause a large amount of breakage before the cooling is completed, or in subsequent usage. In most cases an annealing operation is therefore started, as quickly as possible after the article is formed. The purpose of this operation is two-fold: (1) to

reheat the article to some constant temperature. in the annealing range, so that most or all of the strain will be relieved by viscous flow; and (2) to cool the glass subsequently at such a rate that, when cold, the product retains no more than a small predetermined strain.

Most lehrs are now of the "muffle" type. The flame gases surround all four sides of the muffle, but the ware itself is protected from these gases. A power-driven woven wire conveyor carries the ware through various zones at temperatures and speeds depending upon the kind and type of article. Thin-walled articles, such as electric light bulbs and some tubing, may be annealed in a few minutes. Containers are often annealed in 1 to 2 hours in lehrs 65 to 75 ft. long. Lehrs for window glass, plate glass and thick articles may be several hundred feet long. It took more than a year to anneal the huge zoo-inch telescope disk for Mt. Palomar observatory in California.

"Thermally toughened" glass is made by reheating a piece of glassware, after it has been formed, to a temperature well above its annealing point (often, to the softening point), and then rapidly cooling the surfaces by means of air jets or immersion in oil or various molten salts. The rapid chilling places the exposed surfaces in compression, balanced by tension inside, and this system of stresses is as permanent as the glass body itself. It is obvious that the intent of the toughening process is opposite to that of annealing. It might therefore be called "controlled disannealing." In its original meaning the word "anneal" signifies continued heating. As applied to metals, this process is the opposite of tempering or hardening. The same distinction has been carried over to the glass field, where thermally toughened glass is also properly called "tempered," or "case hardened." Because of the manufacturing methods employed it is also known as "chilled" glass.

About 1892 Schott was producing thermally toughened lamp chimneys, water gauge glasses for steam boilers, and other technical ware. Many patents were later issued for specific methods of producing such ware. Flat glass, some types of cooking dishes, gauge glasses, safety goggle ienses, spectacle lenses, lantern globes, explosion-resisting roundels, and suspension insulator shells are all thermally toughened, often with spectacular results.

FINISHING AND DECORATING

Relatively few glass articles can be considered finished "as made." In most cases, particularly with blown or press-and-blow ware, finishing or decorating treatments are necessary. Even if no actual decoration is required, tumblers, stemware, electric light bulbs, and similar blown ware must be "cracked off," and the resulting rough edge must he smoothed. This is done in various ways by the external application of heat. However, glass can also be cut by scoring it externally or internally by holding it against a revolving steel wheel or cutting tool. Thick glass can be cut under water by a revolving steel disk or "saw."

Some cut-off ware—tumblers, for example—is further treated by holding it against water-cooled grinding wheels which smooth the edges and grind them square. The tumblers then pass through gas flames which melt the edges to a smooth contour. This is called "glazing," or "fire polishing" and is followed usually by an annealing process to remove any strains which may have been induced.

There are many types of cutting and grinding operations and they may follow one another in varying sequences. Sometimes the cut-off is sufficiently smooth so that glazing can follow at once, without intermediate grinding. In other cases the grinding itself is the final operation. Grinding is often followed by "polishing," using finer, softer abrasives to restore the pristine beauty of the glass or to obtain a very smooth, accurately finished surface. Holes can be drilled in glass, punched by forcing a sharp steel pin through a preheated area, or punched electrically.

Decoration may be merely the changing of a transparent to a translucent article, by the removal of very little glass, as in grinding, sandblasting and etching. Or it may be the transformation of a plain plate or bowl to one with intricate designs by removing a considerable quantity of glass, as in cutting. Sometimes it involves fired enamels or silvering which partly or completely obscure the glass itself, which then serves only as a suitable base for the treatment.

In 1771 the Swedish chemist, Scheele, discovered that hydrofluoric acid was the only chemical which readily attacked glass, combining with the silicates to form silico-fluorides which could be washed from the surface, from which they readily sloughed away. It is now known that when the strong, commercial, 60% acid is used, the glass surface becomes translucent and is roughened, the more so the greater the lime content of the glass. A solution of sulphuric and hydrofluoric acids gives a much smoother, more sparkling surface, which may be perfectly transparent, particularly with lead glasses and some of the borosilicates. "White acid," a solution of ammonium bifluoride, gives the surface a smooth, satin finish, evident on frosted electric light bulbs which are sprayed on the inside with this mixture. Trademarks and graduations on technical glassware are often etched with a rubber stamp dipped in the acid.

In making cut glass the decoration is laid out with a small brush and special ink. A slowly revolving wheel of sandstone or carborundum cuts the design. There are three fundamental types of cutting: "hollow cut," produced by a convex wheel; "bevel cut," which is V-shaped; and "panel cut," which is flat. The rough white surface left by the cutting wheel is removed, and the original lustre is restored either by hydrofluoric acid etching or by polishing on felt wheels fed with a very fine abrasive such as putty powder. Cutting is also done by machine on ware of poorer quality.

Copper-wheel engraving differs from cutting in that the result is a shallow intaglio, which because of an optical illusion seems to be in bas relief. As many as 50 different copper wheels, varying in diameter from $\frac{1}{8}$ in. to 4 in., may be used to carry out a simple design. Linseed oil and emery powder are fed to the revolving wheel, and the glass is pressed upward against it. The most delicate and beautiful designs can he made in this manner. Firmness of form, sharpness of edge, and easy flowing curves distinguish the finished product from that produced by any other method.

After 1941 glass tubing was made with one or more thin layers of metal fused to the surface so that such tubes can be soldered directly to metal caps or strips having principal dimensions of 1 in. or even more. This results in a strong hermetic seal between the glass and the metal, a result difficult to achieve economically in any other way.

OPTICAL GLASS

Optical glass differs from other types of glass in two essential characteristics. The first of these is its freedom from imperfections, of which the most common are unmelted particles, commonly called stones; bubbles; and chemical inhomogeneity, which produces regions or streaks of differing refractive index called striae. The elimination of striae is the most difficult problem in the manufacture of optical glass. The glass must also be physically homogeneous and free from mechanical strain, which is effected by an annealing treatment under conditions determined by the composition of the glass.

The second fundamental characteristic of optical glass is that it can be obtained in a wide range of optical properties. For the manufacture of corrected lens systems, glasses must be available having not only a wide range of refractive index (n,) but also of dispersion; and for many special cases there is required knowledge not only of the mean dispersion ($n_F - n_C$) but also of the partial dispersions $n_D - n_C$, $n_F - n_D$, and $n_{G'} - n_F$. These properties, and a quantity commonly given in optical glass catalogs is the v-value: $v = \frac{(n_D - 1)}{(n_F - n_C)}$. Glasses are available having refractive indices from 1.48 (fluor crowns) to 1.8 (extra dense flints) or even higher.

The different types of optical glass usually have names roughly descriptive of their chemical composition and are grouped as either crowns or flints. This difference once was significant and indicated that the crown glass in question did not greatly differ in composition from ordinary window glass and had a low refrac-

TABLE IV.—*Six Representative Bausch & Lomb Glasses*

Type	Symbol	n_D	ν	Sp.gr.	$n_{A'}$	n_C	n_F	$n_{G'}$

Light barium crown	LBC-2	1·57259	57·4	3·21	1·56619	1·56956	1·57953	1·58521
Dense barium crown	DBC-3	1·61688	57.2	3·57	1·60411	1·60773	1·61841	1·62450
Barium flint	BF-1	1·58380	46·0	3·31	1·57598	1·58013	1.59282	1·60033
Dense flint	DF-2	1·61700	36·6	3·60	1·60684	1·61218	1·62904	1·63929
Extra dense flint	EDF-1	1·64000	33.8	3·91	1·63754	1·64355	1·66275	1·67458

tive index and dispersion, and that the flint 'was a glass characterized primarily by the presence of lead oxide, which gave it higher index and dispersion. Later, the line of demarcation between crowns and flints became wholly arbitrary. The original crown type was modified by the replacing of some silica by boric oxide, giving the borosilicate crowns; by replacing some or all of the lime by zinc oxide or barium oxide, giving the zinc crowns and barium crowns; and by modifying the properties of the flints by the inclusion either of barium oxide or of boric oxide, giving the barium and borosilicate flints. In the original crown-flint series, the relation of refractive index to dispersion was essentially a linear one, which placed serious limitations on the lens designer, and much research was devoted to finding glasses having a different run of dispersion. This research resulted in great benefit to the entire glass industry because of information which it developed concerning the relationship of physical properties to chemical composition. This is one of the reasons that optical glass has an importance in glass technology far out of proportion to its insignificant contribution to the total value of glass manufacture.

Optical glass is melted in cylindrical fire clay "pots" which must be made as highly resistive as possible to the corrosive action of the molten glass. Both the material of the pots and the ingredients of the glass must be kept as free as possible from iron oxide because the presence of traces of iron oxide affect the colour of the resultant glass. The pots of glass are removed from the furnace, slowly cooled, after which pot and glass are broken up and selected pieces of the glass softened by heat and pressed or sagged into rectangular slabs. These slabs are polished for inspection, the inferior portions rejected, and the first quality glass either sawed or pressed into lens or prism blanks.

Glass is obtained chemically homogeneous and free from striae by stirring, a process discovered about 1790 by a Swiss watchmaker, Pierre-Louis Guinand. The manufacture of optical glass was long kept a profound secret by the descendants of Guinand, who were associated with the founding of optical glass plants in France, England and Germany. Before World War I, much of the secrecy in composition had been removed by the increase in general scientific knowledge of glass and during that war, the manufacture of optical glass was greatly increased. In the United States, the manufacture of optical glass was continued after the war by the Bausch & Lomb Optical Company in Rochester, N.Y., and the Bureau of Standards in Washington, D.C. A selection of glasses manufactured by the Bausch & Lomb Optical company is given in Table IV, together with their optical properties.

In the 1940s, optical glass manufacture on a large scale was undertaken by Research Enterprises Limited at Leaside, Ont., Canada, and also by Corning Glass Works at Parkersburg, W.Va.

PRODUCTION DATA

The first attempt to obtain a world-wide statistical picture of the glass industry is given in Table V, reprinted, with revisions, from Morey. The data were obtained from the bureau of foreign and domestic commerce, U.S. dept. of commerce. It represents conditions before the outbreak of World War II in 1939. The most significant fact which appears is the pre-eminent position of the United States both as a consumer and producer of glass.

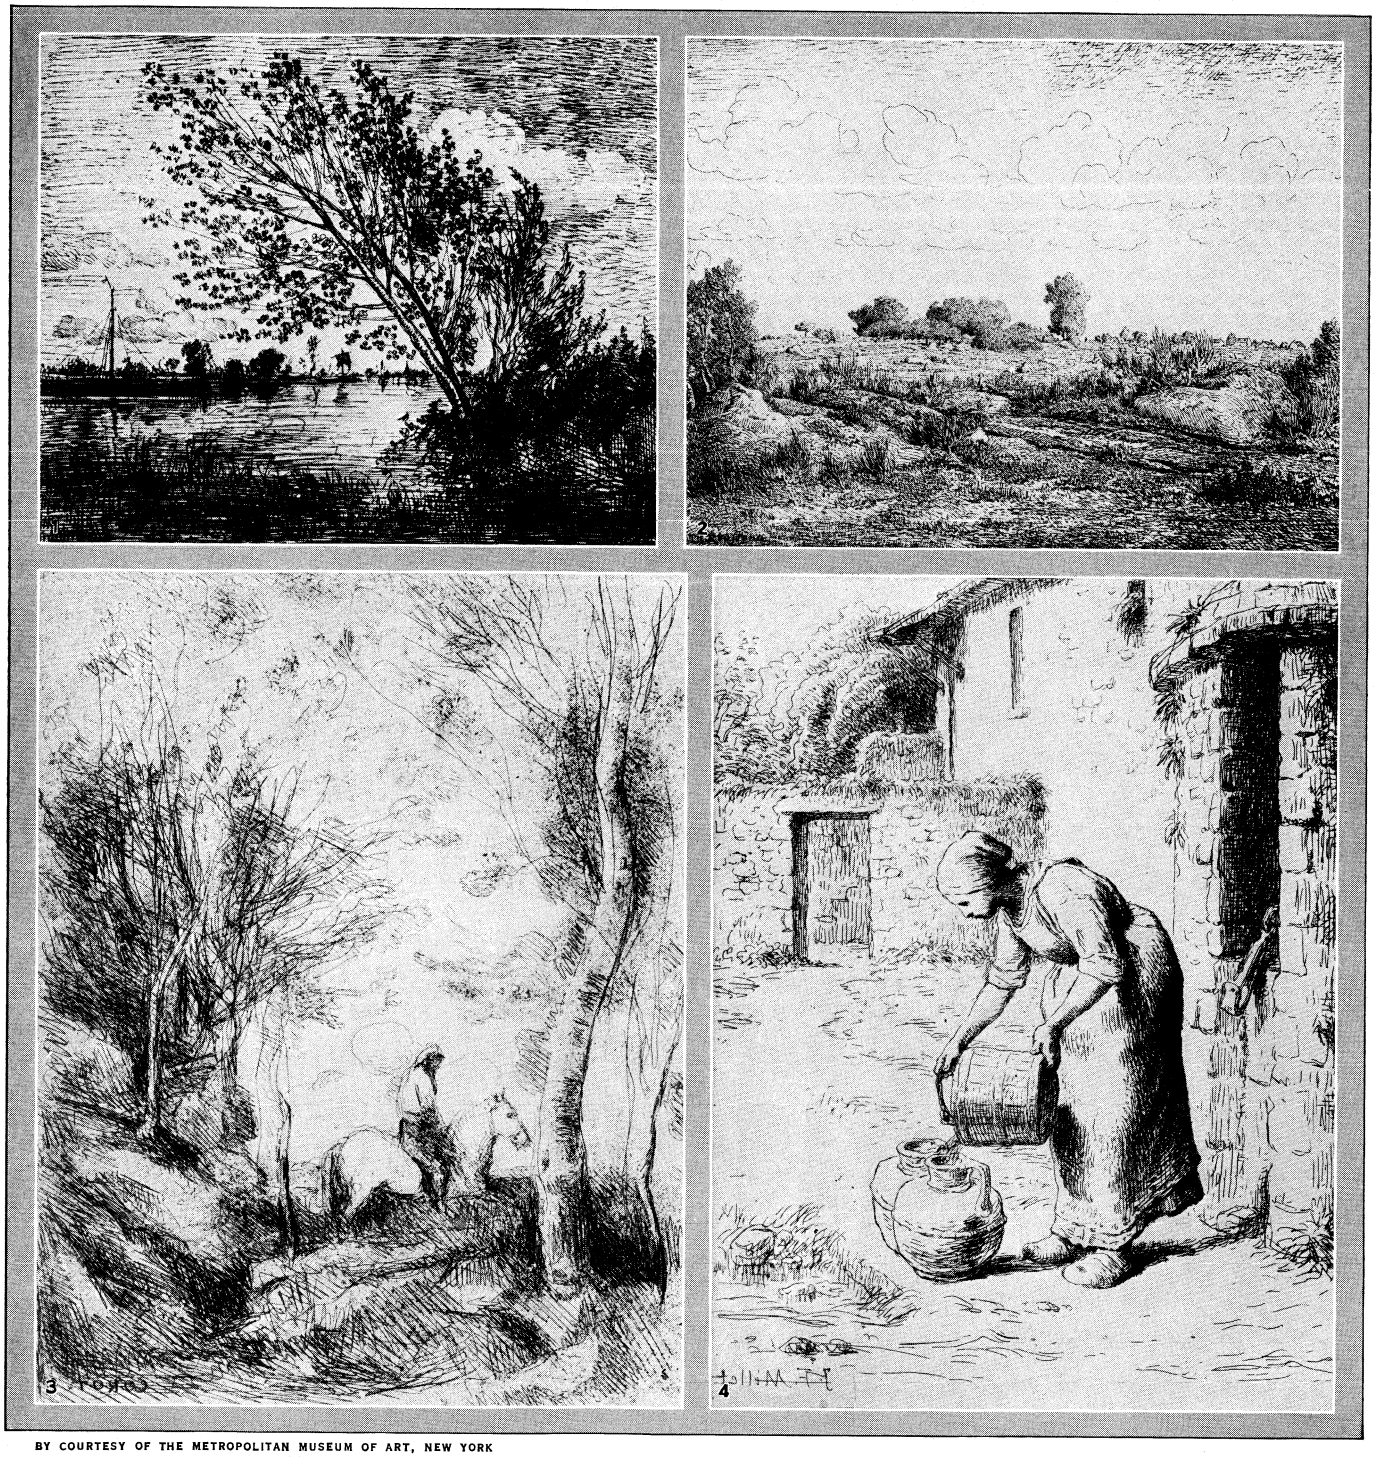
GLASS-PAPER. An abrasive material much used for smoothing the surface of wood manufactures. It consists of thick cartridge paper coated with powdered glass. The paper is coated with liquid glue and the glass particles powdered over the surface before the glue has set. (*See* also SAND-PAPER and EMERY.)

GLASSPORT, a borough of Allegheny county, Pa., U.S.A., 10 mi. S.E. of Pittsburgh, on the Monongahela river and served by the Pittsburgh and Lake Erie railroad. Pop. was 6,959 in 1920 (25% foreign-born white) and was 8.748 in 1940 by the federal census. The leading industries are glassmaking, copper welding and steel foundry work. Glassport was settled about 1900.

GLASS PRINTS, or, as the French call them, *cliche's-verres,* were an imitation of etchings in the making of which the Barbizon group of artists, Daubigny, Rousseau, Millet and Corot, would amuse their leisure during the years between 1855 and 1860. On a blackened piece of glass, covered with a white opaque varnish, they would draw their subjects with an etching-needle, as on a copper-plate, then they would take an impression on a sensitized paper exposed to the light behind the glass. The effect was curiously like an etching, though the print was really rather in the nature of a photograph, for no pressure had been used to crush the paper into bitten lines which did not exist. Daubigny was, we fancy, the most successful maker of these *clichés-verres,* though the needling of his lines, not being subjected to any mordant process, looked rather like lines drawn with a pen and ink, as in *Le Bouquet d'Aunes,* for instance, which, of course, has not at all the essential character of etching. There was another form of glass prints popular in England in the later decades of the 18th century, which transferred to glass many contemporary mezzotint and stipple colour-prints, mostly of the cruder kind, but occasionally some of a more pretentious artistic order. The glass, cut to the size of the print, was covered with a thin coating of turpentine, then the print, well damped, was laid on this, face downwards. The paper was most carefully rubbed away with the finger, until only the veriest film of the print was left with its design on the turpentine-covered glass. When this was dry, the

GLASS PRINTS



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, NEW YORK

GLASS PRINTS BY THE BARBIZON GROUP

Glass prints or ***cliche's verres*** were an imitation of etchings made by artists of the Barbizon group between 1855 and 1860. The print was made by covering a blackened glass with white opaque varnish, and drawing the subject on it with an etching needle. An impression was then taken on a sensitized Paper exposed to the light through the glass. The print was in reality a kind of photograph, though resembling an etching in effect

1. Le Bouquet d'Aunes, by Charles François Daubigny (1817–78)
2. La Plaine de la Plante à Biau, by Theodore (Étienne Pierre) Rousseau (1812–67). Scene at Barbizon, near the Forest of Fontainebleau
3. Le Grand Cavalier sous bois, by Jean Baptiste Camille Corot (1796–1875). Landscape with a human figure characteristic of Corot's mood and style; in reversed form
4. Femme vidant un seau, by Jean Franpois Millet (1814–74). Country scene and subject typical of Millet's work; in reversed form

impression was painted on the back, sometimes richly, sometimes simply, even crudely, but often with a brilliancy of colouring superior to that of the original print on paper. These glass coloured prints enjoyed a brief contemporary vogue, but they died out with the old coloured stipple and mezzotint. Some 25 years ago there was a fashion in collecting them, but the field, it appears, was soon exhausted, and the actual old prints are valued too highly for it to be extended. (M. C. S.)

GLASSWORT, *Salicornia herbacea* (also known as marsh samphire), a salt-marsh herb, widely distributed in the northern hemisphere, with succulent, jointed, leafless stems, in reference to its former use in glass-making, when it was burnt for barilla. *Salsola* Kali, an allied plant with rigid, fleshy, spitlous-pointed leaves, which was used for the same purpose, was known as prickly glasswort. Both plants belong to the family Chenopodiaceae.

GLASTONBURY, a market town and municipal borough in the wells parliamentary division of Somerset, England, 6 mi. S. of Wells, on the main road from London to Exeter, and on the Somerset and Dorset railway. Pop. (1938) 4,4jj. Area 7.9 sq mi. The town lies in the midst of orchards and water-meadows reclaimed from the fens which surround the Tor, a conical height of some 500 ft., which rises abruptly from the moor and is crowned by the ruins of St. Michael's chapel. The chief buildings, apart from the abbey, are the churches of St. John the Baptist, Perpendicular in style, with a fine tower and some 15th century monuments; and St. Benignus, commonly called St. Benedict's, dating from 1493–1524; St. John's hospital, founded 1246; the Tribunal; the George inn and the town hall (1930). The Antiquarian museum in Magdalene street has a good collection of objects from the Glastonbury lake village, discovered in 1892 and consisting of sixty mounds within a space of five acres. There is a Roman Catholic missionaries' college. In the 16th century the woollen industry was introduced by the duke of Somerset; and silk manufacture was carried on in the 18th century. Tanning and tile-making, and the manufacture of gloves, boots and sheepskin rugs are practised. Near the museum is the Abbey gateway, the restored Gatehouse of which was formerly the Red Lion inn.

The Lake Village.—Near Glastonbury, in the Brue district oi the Somersetshire lowland, which is about 14–16 mi. long and 2–5 mi. wide, has been found a lake village in what is now meadow land, but was, in the 16th and 17th century maps, a pool, "Meare Pool." Most of the Brue lowland is floored by peat, varying from a foot to several yards in thickness, near the lake village it is 13–15 ft. thick. The site is some 18 ft. above present sea-level, and A. Bulleid thinks that about the time the British village site was first occupied the country was a maze of meres and broads, with branches of the Brue still influenced by inroads of the sea. The village site lay west of a water channel which is the boundary between the parishes of Glastonbury and Meare, and was probably navigable in mediaeval times. The village was built on a timber sub-structure resting on the swamp and including piles of logs laid across one another, as well as mortised timbers. On this substructure were laid mounds of clay, and on these again were built the dwellings, with a border palisade surrounding the whole village; coarse wattle work bound the upper parts of the palisades together and they enclosed a space of about 10,530 sq. yards. There were 89 clay mounds, most with one to four dwelling floors, but a few with larger numbers (one had ten). Each dwelling floor was circular, the diameter ranging from 14 to 40 ft., or more commonly 18–28 ft. The wall was a line of posts (3–9 in. diameter), 6–15 in. apart, set around a circle. The roofs seem to have been of reed thatch. A few rectangular dwellings probably existed. Most of the hearths in the houses were baked clay, but some were of stone. A pivoted door has been found, as well as doorsteps and pathways.

A very considerable collection of fibulae is made up entirely of late Celtic types; they were probably made on the spot as crucibles, bronze wire, dross, slag, etc., have been found. They almost all belong to the La Tène III. type, though two are earlier. Ten penannular brooches, very late Celtic or almost Romano-British, were also found, as was a fine bronze bowl Thirty-five finger rings have been collected as well as various other ornaments and a bronze mirror. Three bronze terret-rings or loops for harness have been recovered, as well as a large variety of other bronze objects; 32 objects in lead and 18 in tin are accounted for by Gray and armlets and other objects in Kimmeridge shale are a feature, as in many other places in the west of England. Long-handled weaving-combs are specially important finds, and 89 have been found in the lake village, nearly all made of red-deer antler, with a few of bone. The situation of the village has led to the preservation of a number of wooden objects which give many clues to the skill of the people. Remains of two boats, a loom, an axle-box and a ladder, etc., have been identified.

Of iron objects, 109, some with wooden handles, have been catalogued. One piece of tin-money of the earlier part of the first century A.D. and a number of currency-bars are a further link between Glastonbury and the La Tène III. civilization of the regions further north-east and south-east The quantity of pottery discovered was very large, but only a very few fragments, on the flood soil above the village, could be conjecturally connected with Roman influence. The pottery obviously belongs to the Late Celtic period, but is mostly of rather coarse paste. Reid found remains of peas, beans, wheat, barley, etc., while the domestic animals included a small breed of horse, an ox (Bos *longifrons*), two breeds of sheep, a goat, a small type of pig and a dog. Forty-four human remains have been found, and are thought by Boyd Dawkins to indicate a massacre. The crgnia which could be examined had breadth-length indices about 76·5 to 78. The general conclusion is that the village was the abode of cultivators and craftsmen, probably not entirely cut off from the sea via the meres, and that the place was occupied in the last century B C. and part of the 1st century A.D. This valuable work furnishes the best indication so far available of the life of the British people at the time of the Roman invasion. British earthworks and Roman roads and relics prove later occupation. The name of Glastonbury, however, is of much later origin, being a corruption of the Saxon *Glæstyngabyrig*. By the Britons the spot seems to have been called Ynys yr Afalon (latinized as Avallonia) or Ynysvitrin (*see* AVALON), and it became the local habitation of various fragments of Celtic romance.

See Arthur Bulleid and H. St. George Gray, *The Glastonbury* Lake Village (1911 and 1917).

The Benedictine Abbey of St. Mary.—The earliest account we have of the beginnings of this famous monastery comes from William of Malmesbury, who wrote (*c.* 1125) a book, On *the Antiquity* of *the Church* of Glastonbury. He says that "annals of good authority" tell us that a little wattle church, dedicated to the Blessed Virgin, had been built there by missionaries whom the pope sent from Rome at the request of King Lucius in the year 166. He was aware of a still earlier story, but he would not commit himself to it. After his death his work was re-edited, and details were added to show that the missionaries were not the builders, but merely the restorers of the old wattle church which had been built a century before by companions of St. Philip the Apostle, who had placed Joseph of Arimathea at their head. We may fairly assume that Malmesbury really saw this ancient church while he was staying at Glastonbury from 1125 until about 1130 or a little later. In his Gesta *Regum* he states that King Ina (c. 700) built from the foundations the Church of the Blessed Apostles, as an appendix to the old church. This church, too, we may be sure existed, as it is mentioned in a 10th century Saxon genealogy. From the decadent state into which English monasticism had fallen after the Danish invasions, Glastonbury was rescued by Dunstan, who had been educated within its walls and afterwards became its abbot, about 942.

Ina's church, which may have been partly ruinous, St. Dunstan restored. He lengthened it considerably by the addition of a tower and made it square with its length by adding aisles. That this church was standing while Malmesbury was at Glastonbury would appear to be certain from the careful description he gives of the position of certain tombs of Saxon abbots and bishops within it. The first Norman abbot, Turstin, had begun a new

church on Norman lines, probably leaving the Saxon church of Dunstan alone. His successor, Herlewin, pulled down all that Turstin had put up, and started afresh, as he did not consider the building was sufficiently dignified for so important an abbey. Whether this Norman church obliterated or incorporated St, Dunstan's church we do not at present know, for the excavations carried out by the Society of Antiquaries of London jointly with the Somerset Archaeological Society during 1927–28, while they appear to have revealed the remains of Ina's church and the additions made to it by St. Dunstan, did not go far enough to show the relation of the later Norman building to these earlier structures.

On May 25, 1184, this great church, all the monastic buildings, and, most serious of all, the venerable old wattle church, were consumed in a terrible fire. Four years previously the abbot had died, and his successor had not been appointed as the king was glad to keep the revenues in his hands. Henry II. now did his part with unusual generosity, placing the whole of the revenues at the disposal of Ralph Fitz Stephen, to whom the king entrusted the work of rebuilding after the fire. First the Lady chapel was built on the site the old church had once occupied for so many centuries. This was finished and consecrated within three years. The foundation for the main church, the ruins of which are now standing, were put in on a magnificent scale, but the progress of the work was checked by the death of Henry II. and the conflict of the monks with Savary, bishop of Bath, who had succeeded in making himself abbot. Of the various additions made under successive abbots, one of considerable interest was the building of a Galilee to join the west end of the great church to the Lady chapel. This was effected during the time that John of Taunton was abbot, between 1274 and 1291. The east wall of the Lady chapel was removed, an open arch substituted, and then a building of the same width and length as the chapel itself filled the space between it and the west wall of the new church.

As the Lady chapel was said to record by its length the exact size of the original wattle church, now that it had been added to it was feared that this celebrated measurement would in time be lost. To guard against this, a cross or pillar was built at a later date outside the chapel, 48 ft. northwards from the original easternmost buttress, so that the length from east to west could be easily calculated. A bronze plate, giving the story of St. Joseph's wattle church was fixed to the monument. In Aug. 1921, the foundations of this pillar, about 7 ft. in diameter, were uncovered. Another important alteration also affected the Lady chapel. Abbot Richard Bere, the last abbot but one (1493–1524) hollowed out a crypt under the floor of this chapel and the adjoining Galilee under-pinning the walls for the purpose. It was this crypt chapel that mas dedicated to St. Joseph of Arimathea, and that contained his statue.

Of the monastic buildings themselves nothing remains standing except the Abbot's Kitchen, as it is popularly called, a solid and substantial building, square in plan, but rendered octagonal interiorly by great fireplaces which are planted across the angles. The central ventilating shaft is a fine and ingenious piece of work and leads the roof up to a decorated octagon in which it finishes. Of other parts of the monastery nothing can now be seen except the undercroft of the refectory, excavated in 1911, under the direction of Bligh Blond, and the line taken by the cloisters leading to the church. The foundations of the rest of the monastery remain to be uncovered in time. The dissolution of the abbey commenced on Aug. 25, 1539, when Dr. Layton visited the place. The venerable abbot, Richard Whiting, was taken at his manor at Sharpham, and sent up to London and lodged in the Tower, on account of "divers and sundry treasons." Cromwell, in his *Remembrances* writes, "Item, the abbot of Glaston to be tryed at Glaston and also executed there with his complycys" (Cott. mss. Titus B. 1, fol. 41). The abbot was sent down to Wells, where he was "arraigned and next day (Nov. 15, 1539) put to execution for robbing of Glastonbury church." The execution took place on Glastonbury Tor. His body was quartered and his head fixed on the abbey gate. A darker passage does not occur in the annals of the English Reformation than this murder of an able and high-spirited man, whose worst offence was that he defended as best he could from the hand of the spoiler the property in his charge.

In 1907 the site of the abbey, with the remains of the buildings, which had been in private hands since the granting of the estate to Sir Peter Carew by Elizabeth in 1559, was bought by Mr. Ernest Jardine for the purpose of transferring it to the Church of England. Bishop Kennion of Bath and Wells entered into an agreement to raise a sum of £31,000, the cost of the purchase; this was completed, and the site and buildings were formally transferred at a dedicatory service in 1909 to the Diocesan Trustees of Bath and Wells, who are to hold and manage the property according to a deed of trust. This deed provided for the appointment of an advisory council, consisting of the archbishop of Canterbury, the bishop of Bath and Wells and four other bishops, each with power to nominate one clerical and one lay member. The council has the duty of deciding the purpose for which the property is to be used "in connection with and for the benefit of the Church of England." To give time for further collection of funds and deliberation, the property was re-let for five years to the original purchaser. The Abbot's Kitchen was purchased in 1921 and has been added to the original trust.

The two legends most closely connected with the story of the abbey are those of King Arthur and St. Joseph of Arimathea. It was claimed that the former was buried there and that the latter was the builder of the original wattle church. These legends "are truly venerable traditions, which greatly influenced the story of the past and have left an abiding rnark on the nomenclature of the present. They are not very ancient, when the long life of the abbey is taken into account. From first to last they occupied only the last three centuries and a half of its history. They were unknown to William of Malmesbury when he wrote his book, On *the Antiquity of the Church of Glastonbury,* about the year 1125, although he had free access to all the abbey's records before the Great Fire, and made, as we know, excellent use of his opportunities of investigation. Our earliest date for any of them is 1191 (*Two Glastonbury Legends,* p. 50, by the Very Rev. J. Armitage Robinson). The Glastonbury thorn (*Crataegus praecox*), which flowers at Christmas as well as in the spring, a late legend asserted sprang from the staff of Joseph of Arimathea. It is probably nothing more than a perpetuated *sport* from the common thorn obtained by grafting. Trees raised from seeds of *C. praecox* revert to the ordinary type.

The abbey was overlord of the town of Glastonbury until the Dissolution. Henry II. granted a charter by which the men of Glastonbury were exempted from the jurisdiction of royal officials, and this exemption was recognized by Edward I. when on a visit to the abbey in 1278, he yielded to the abbot's plea and held his court of justice at the chapel of St. Gildas at Street, which was just outside "the Twelve Hides." The borough was incorporated by Anne in 1706, and the corporation was reformed by the act of 1835. In 1319 Glastonbury received a writ of summons to parliament but made no return, and has not since been represented. A fair on the 8th of September was granted in 1127; another on the 29th of May was held under a charter of 1282. Fairs known as Torr fair and Michaelmas fair are now held on the second Mondays in September and October and are chiefly important for the sale of horses and cattle. The market day every other Monday is noted for the sale of cheese. Glastonbury owed its medieval importance to its connection with the abbey. At the Dissolution, a number of foreign weavers, chiefly Flemings, were introduced to check the decay of the town, and some settled among the ruins of the abbey. The cloth trade flourished for a century and was replaced by silk-weaving and stocking-knitting, but these all died out.

GLATIGNY, JOSEPH ALBERT ALEXANDRE (1839–1873), French poet, was born at Lillebonne (Seine Inférieure), received an elementary education at Bernay, was apprenticed to a printer at Pont Audemer, where he produced a three-act play, and joined a travelling company of actors to whom he acted as prompter. Inspired primarily by the study of Théodore de Banville, he published his *Vignes* folles in 1857; his best collection of lyrics, Les *Flèches d'or,* appeared in 1864; and a third volume, *Gilles* et *pasquins,* in 1872. After Glatigny settled in Paris he improvised at café concerts and wrote several one-act plays. On an expedition to Corsica with a travelling company of actors he was on one occasion arrested and put in irons for a week through being mistaken by the police for a notorious criminal. His marriage with Emma Dennie brought him great happiness, but the hardships of his life weakened his health and he died at Skres on April 16, 1873.

See Catulle Mendès, *Légende du* Parnasse *contemporain* (1884), and Glatigny, *drame funambulesque* (1906).

GLATZ (Slav. *Kladsko*), a town in the Prussian province of Silesia, Germany, on the left bank of the Neisse, 58 mi. S.W. of Breslau. Pop. (1939) 21,875. The town with its narrow streets winds up the fortified hill which is crowned by the old citadel. Across the river, on the Schäferberg, lies a fortress built by the Prussians about 1750. Before the town on both banks of the river there is a fortified camp by which bombardment from the neighbouring heights could be hindered and which afforded accommodation for 10,000 men. The inner ceinture of malls was razed in 1891 and their site is now occupied by new streets. There are a Lutheran and two Roman Catholic churches, one of which, the parish church, contains the monuments of seven Silesian dukes. Among the other buildings the principal are the Royal Catholic gymnasium and the military hospital.

Glatz existed as early as the 10th century, and received German settlers about 1250. It was besieged several times during the Thirty Years' War and during the Seven Years' War and came into the possession of Prussia in 1742. In 1821 and 1883 great devastation was caused here by floods. The county of Glatz was long contended for by the kingdoms of Poland and of Bohemia. Eventually it became part of the latter country, and in 1534 was sold to the house of Habsburg, from whom it was taken by Frederick the Great during his attack on Silesia.

GLAUBER, JOHANN RUDOLF (1604–68), German chemist, was born at Karlstadt, Bavaria. He resided successively in Vienna, Salzburg, Frankfurt and Cologne before settling in Holland, where he made his living chiefly by the sale of secret chemical and medicinal preparations. Though his writings abound in universal solvents and other devices of the alchemists, he made some real contributions to chemical knowledge. Thus he clearly described the preparation of hydrochloric acid by the action of sulphuric acid on common salt, the manifold virtues of sodium sulphate—sal *mirabile,* Glauber's salt—formed in the process being one of the chief themes of his *Miraculum mundi;* and he noticed that nitric acid was formed when nitre was substituted for the common salt. Further he prepared a large number of substances, including the chlorides and other salts of lead, tin, iron, zinc, copper, antimony and arsenic, and he even noted some of the phenomena of double decomposition; he also made a number of useful observations on dyeing and gave a clear description of the preparation of tartar-emetic. One of his most notable works was his *Teutschlands Wohlfarth* in which he urged that the natural resources of Germany should be developed for the profit of the country, giving various instances of how this might be done.

His treatises, about 30 in number, were collected and published at Frankfort in 1658–59, at Amsterdam in 1661, and, in an English translation by Packe, at London in 1689.

GLAUBER'S SALT, first described by J. R. Glauber, occurs native as the mineral mirabilite in Spain, the western States of North America, and the Caucasus. Sodium sulphate is the active principle of many mineral waters, *e.g.,* Friedrichshall, Carlsbad waters. It occurs in sea water and is a normal constituent of the blood. (See ALKALI MANUFACTURE.)

Glauber's salt is decahydrated sodium sulphate, $Na_2,SO_4,10H_2O$ (*see* HYDRATE); it separates from cold aqueous solutions of sodium sulphate in colourless monoclinic prisms which effloresce in dry air and at 32·38° C melt in their water of crystallization. Its maximum solubility in water is at 32·38° C, and above that temperature it no longer exists as decahydrate but changes to anhydrous salt, which becomes decreasingly soluble as the temperature rises. Glauber's salt readily forms supersaturated solutions in which crystallization is induced by adding a particle of the salt. In medicine it is employed as an aperient, being one of the safest and most innocuous. For children or patients who refuse other drugs it may be mixed with common salt.

GLAUCHAU, a town of Germany, in the Land of Saxony, on the right bank of the Mulde, 7 m. N. of Zwickau and 17 m. W. of Chemnitz by rail. Pop. (1939) 33,586. It has important manufactures of woollen and half-woollen goods. There are also dye-works, print-works, and manufactories of paper, aluminium, thread and machinery. Glauchau possesses a weaving school. Some portions of the old castle date from the 12th century; the Gottesacker church contains objects of this period. Glauchau was founded by a colony of Sorbs and Wends, and belonged to the lords of Schonburg as early as the 12th century.

GLAUCONITE, a green mineral, a hydrous silicate of iron with potassium. It especially occurs in the green sands and muds which are gathering at the present time on the sea bottom at many different places. The wide extension of these sands and muds was first made known by the naturalists of the "Challenger," and it is now found that they occur in the Mediterranean as well as in the open ocean, but they have not been found in the Black sea or in any freshwater lakes. These deposits are not in a true sense abyssal, but are of terrigenous origin, the mud and sand being derived from the wear of the continents, transported by marine currents. The depth in which they accumulate varies a good deal, viz., from 200 up to 2,000 fathoms, but as a rule is less than 1,000 fathoms, and it is believed that the most common situations are where the continental shores slope rather steeply into moderate depths of water.

The glauconites, though crystalline, never occur well crystallized but only as dense clusters of very minute particle; which react feebly on polarized light. They have one well-marked characteristic, inasmuch as they often form rounded lumps. In many cases it is certain that these are casts, which fill up the interior of empty shells of Foraminifera. It is now believed that glauconite is essentially the same as the green iron silicate that forms the primary substance of so many iron ores of marine origin, and that the presence of potash is merely due to colloidal adsorption; the source of the potash is, however, by no means clear.

In a small number of Tertiary and older rocks glauconite occurs as an essential component. It is found in the Pliocene sands of Holland, the Eocene sands of Paris and the "Molasse" of Switzerland, but is much more abundant in the Lower Cretaceous rocks of northern Europe, especially in the subdivision known as the Greensand. Rounded lumps and casts like those of the green sands of the present day are plentiful in these rocks, and it is obvious that the mode of formation was in all respects the same. The green sand when weathered is brown or rusty coloured, the glauconite being oxidized to limonite. Calcareous sands or impure limestones with glauconite are also by no means rare, an example being the well-known Kentish Rag. In the chalk-rock and chalk-marl of some parts of England glauconite is rather frequent, and glauconitic chalk is known also in the north of France. Among the oldest rocks which contain this mineral are the Ordovician of the Leningrad district and southern Sweden, as well as the basal Cambrian quartzite in Shropshire, but it is very rare in the Palaeozoic formations, possibly because it undergoes crystalline change and is also liable to be oxidized and converted into other ferruginous minerals. It has been suggested that certain deposits of iron ores may owe their origin to deposits of glauconite, as for example those of the Mesabi range, Minnesota. (J. S. F.)

GLAUCOUS, a word meaning of a sea-green colour, in botany covered or whitened with a bloom, like a plum or a cabbage-leaf.

GLAUCUS, a word meaning "bright," and the name of several figures in Greek mythology, the most important of which are the following:

1. GLAUCUS, surnamed Pontius, a sea divinity. Originally a fisherman and diver of Anthedon in Boeotia, having eaten a certain magical herb, he leaped into the sea, where he was changed into a god, and endowed with the gift of unerring prophecy. According to others he sprang into the sea for love of the sea-god Melicertes, with whom he was often identified. He was worshipped in most parts of the Greek world by fishermen and sailors. In art he is depicted as a merman covered with shells and seaweed. Various legends, none very important, connect him with the saga of the Argonauts and other cycles. He was famous for his amours, especially those with Scylla and Circe. See especially Athenaeus, 296, 297.

2. GLAUCUS, of Potniae near Thebes, son of Sisyphus by Merope and father of Bellerophon. According to the legend he was torn to pieces by his own mares (Virgil, Georgics, iii. 267; Hyginus, *Fab.*, 250, 273).

3. GLAUCUS, the son of Minos and Pasiphae. When a child, while playing at ball or pursuing a mouse, he fell into a jar of honey and was smothered. His father, after a vain search for him, consulted the oracle, and was referred to the person who should suggest the aptest comparison for one of the cows of Minos which had the power of assuming three different colours. Polyidus of Argos, who had likened it to a mulberry (or bramble), which changes from white to red and then to black, soon afterwards discovered the child; but on his confessing his inability to restore him to life, he was shut up in a vault with the corpse. Here he killed a serpent which was revived by a companion, which laid a certain herb upon it. With the same herb Polyidus brought the dead Glaucus back to life. According to others, he owed his recovery to Asklepios.

4. GLAUCUS, son of Hippolochus, and grandson of Bellerophon, mythical progenitor of the kings of Ionia. He was a Lycian prince who, along with his cousin Sarpedon, assisted Priam in the Trojan War. When he found himself opposed to Diomedes, his guest-friend, they ceased fighting and exchanged armour. Since the equipment of Glaucus was golden and that of Diomedes bronze, the expression "gold for bronze" (Iliad, vi. 236) came to be used proverbially for a bad exchange. Glaucus was afterwards slain by Ajax, son of Telamon.

See further Roscher's *Lexikon,* s.v.

GLAZE: see GLAZING; POTTERY AND PORCELAIN.

GLAZEBROOK, SIR RICHARD TETLEY (1854–1935), K.C.B. (1920), Kt. (1917), C.B. (1910), was born on Sept. 18, 1854, and educated at Liverpool college and at Trinity college, Cambridge, where he became a fellow in 1877. In 1898 he was appointed principal of University college, Liverpool, and in 1899 director of the National Physical laboratory, a post which he held until 1919. In 1908 he became chairman of the Aeronautical Research committee, and from 1920 to 1923 was Zaharoff professor of aviation and director of the department of aeronautics at the imperial college of technology.

He was the author of many scientific textbooks, and papers on scientific subjects, and the editor of the *Dictionary* of *Applied Physics.*

GLAZING. The business of the glazier is confined to the mere fitting and setting of glass, even the cutting up of the plates into squares being generally an independent art, requiring a degree of skill and judgment not necessarily possessed by the building artificer.
