In all this it was mightily helped by the development—since Newton's time, in fact mainly in the 19th century—of two great and important new branches, the sciences of electricity and magnetism. These are agents which, like light, operate through what we call empty space or vacuum, and therefore seem primarily associated not with matter as such, but with the more fundamental ether. The fact that mankind has no sense organ for their direct appreciation involved the consequence that, unlike sound, light and heat, they had to be discovered as well as critically examined and studied. Nevertheless in our own time these new powers have become dominant; they have been taken up by engineers, and applied on an extensive and beneficent scale, so that they are now more or less familiar to everybody. The applications of electricity and magnetism are of great and growing importance, but that is not what constitutes their vivid interest to a physicist. Their importance is that they give a clue and greatly extend our

knowledge of the properties of the ether, which had only very partially been displayed in the familiar form of light. Indeed, Clerk Maxwell, perhaps the greatest man of science in the 19th century, made the far reaching discovery that light itself was an electromagnetic vibration, a fact which has now blossomed into the engineering application of radio telegraphy.

The phenomenon called radiation, of which visible light is one small portion, contains the key to the interaction between ether and matter, and is the link between the physics of the 19th and that of the 20th century. All matter is always radiating, and if it does not cool or otherwise lose energy it is only because it absorbs exactly the quantity and quality which it emits. Stagnation of any kind is non-existent in the material universe. Every particle quivers, and the ether quivers in sympathetic unison. The problem of their interaction is being attacked and partially solved by the mathematical physicists of the 20th century.

It may be asked, indeed it often is asked, how discoveries can be made by means of calculation. The answer is quite definite. The mathematical physicist probes down into the fundamental activities, so as to be able to formulate in his mind what is really going on, and to express the actions which can be observed in a definite and quantitative form called an equation, especially in that form called a differential equation, which expresses interactions among the smallest parts. The discovery of the relation between electricity and magnetism on the one hand, and light on the other, will serve as an illustration of the process. Clerk Maxwell took the known phenomena of electricity and the known phenomena of magnetism, together with their interaction so brilliantly discovered and examined by the early physicists of all countries at the beginning of the 19th century culminating in the work of Faraday, and threw them into the form of equations. These, when combined and manipulated in accordance with the laws of pure mathematics, resulted in a differential equation in time and space, containing nothing but electric and magnetic quantities, which nevertheless corresponded with the known equation for waves, such as those of sound or of light or on the surface of water. He perceived therefore that electromagnetic experiments could in the future probably give rise to such waves, and that they would travel at a speed which could be calculated in terms of the electric and magnetic constants of a vacuum, *i.e.*, of the ether. He inaugurated a set of experiments which would determine, not indeed those constants separately, for they are still unknown, but their product, *viz.*, the product which appeared in his differential equation as determining the speed of the waves. He found that the velocity with which his waves ought to travel was identical with that of light, and thus came to the conclusion, and was ultimately held to prove for all time, that light was an electromagnetic phenomenon. On this basis a whole new development began, and continues to this day.

Applications of Differential Equations. — It is worth while illustrating the bearing of a differential equation, and the way in which it embodies a whole series of phenomena which can be dissected from it by the arts of pure mathematics in a purely mechanical though recondite manner, and then handed back to the physicist for interpretation. Naturally the physicist and the mathematician may be combined in the same individual in exceptional cases, and as has recently been said (*Nature*, May 26, 1928): "It is interesting to speculate whether the intellectual gulf separating the great physical scientists from the rest of their fellows is not greater now than at any previous period in the world's history—whether they have not usurped the place of the metaphysicians." That was true in Newton's day, and is true now; though no one claims that any single individual possesses the exceptional power displayed by Newton.

A differential equation which may serve as an illustration is the following:

$$A \frac{d^2 H}{dt^2} + B \frac{dH}{dt} = C \left(\frac{d^2 H}{dx^2} + \frac{d^2 H}{dy^2} + \frac{d^2 H}{dz^2} \right).$$

H is any quantity, no matter what, representing some salient feature in the kind of subject dealt with; it is allowed to have a slope of variable gradient in any of the three directions in

space, and to have a rate of variation and indeed an accelerated or variable rate of variation in time. The equation expresses the relation between these extremely abstract possibilities as affecting the (perhaps unknown) quantity H , while A , B , C are physical constants characteristic of the special conditions appropriate to some particular problem, each being capable of a physical interpretation in any definite case.

When the conditions are such that A is zero, the equation can be made to represent the whole theory of the conduction of heat; and it was thus worked out by the great mathematician Fourier into a complete analysis of diffusion by a series of harmonics. It gives primarily the flow of heat through a conductor of any shape, and it was applied by Lord Kelvin, after Fourier, to the cooling of the earth, and to diffusion in gases and liquids, and to many other phenomena. In fact the same differential equation represents his theory of signalling through an Atlantic cable. The working out of the consequences of any equation may be treated as a mathematical exercise; the interpretation of those consequences in any particular case belongs to the physicist. When the conditions are such that only B is zero, the equation represents the phenomenon of waves, or at least of such waves as travel with a definite velocity independent of wave-length, like air waves and ether waves.

When C is zero the equation represents the settling down of a disturbance, whether electrical or material, after the forces which originated the disturbance have ceased to act. The neutralization of the C term avoids reference to space-considerations and makes it an equation in time alone, like a law of cooling or of leakage, which last is so simple a case as not even to involve A ; while if the right-hand side be changed to CH the equation represents all the laws of electrical oscillations as worked out by Lord Kelvin in 1853 and now applied in wireless wave meters. The A term then represents inertia, or the magnetic property called self-induction; the B term signifies resistance, especially the kind of electrical resistance involved in Ohm's law. When the conditions are such that A and B are both zero, things have become stationary, and the equation reduces to the one so extensively applied by Laplace to solve static gravitational problems. It embodies the conditions which gravitational fields must satisfy, and develops into part of the theory of astronomy.

When none of the coefficients is zero, and all three terms have to be taken into account (especially if a term involving H is added in some cases), the equation represents waves or diffusions travelling through a more complicated medium, at speeds varying with or at least dependent on the wave-length. Waves such as these can occur in the ether when it is interfered with or loaded by electrified particles, or when a medium is a polarizable insulator or a conductor. It can be made to represent the reflection of light by metals, as well as the transmission of waves through the Heaviside layer of ionized air, now becoming familiar to wireless amateurs. It also gives the Heaviside theory of cable signalling, which is more complete than Lord Kelvin's was, and which, applied in practice in America and elsewhere, has much improved long-distance telephony. Needless to say the equation in full form can do much more than that. It, or rather an interlacing set of such equations, represents the most general kind of wave; and the kingdom dominated by waves is now rapidly expanding.

The solution of such equations taxes the powers of all but high mathematicians and may lead to new functions of vast interest and importance. Skilled manipulation of the symbols by a pure mathematician is neither aided nor hindered by information about the particular things they may be intended to represent. The laws are just as valid and self-consistent even if the symbols represent imaginary quantities, as they sometimes do. In the interpretation of the integrated solution however there must be a return to reality.

The vast multitude of facts and phenomena which can thus be treated by a differential equation, so that previously unsuspected consequences can be deduced, is surely of high interest even to those whose education does not enable them to follow the details. The reason why they are so powerful in enabling latent facts to be brought to light is plain enough. It is because the actual proc-

esses at work are compactly, precisely and completely formulated, in all their interactions, by these equations, so that they embody the essence of the phenomenon; their solution and consequences can subsequently be worked out by the few who possess sufficient skill and insight. This method of procedure—from formulation, through solution, to interpretation—is indeed the highest example of the advantage possessed, and the power gained, by those who have successfully attained the aim of all science, "*rerum cognoscere causas.*"

MODERN PHYSICS

So long as we are dealing with massive bodies or with great groups of particles, the laws of dynamics, based upon Newton's laws of motion and applied without any breach of continuity, were sufficient and reigned supreme. This kind of dynamics dominated the 19th century, but just at the end, as a fitting prelude to the 20th century, a number of discontinuities began to be discovered. The first discontinuity was indeed old, viz., the atomic theory of matter, and was only evaded by the fact that we inevitably dealt with great numbers of atoms. In the years 1897 to 1900 however Sir J. J. Thomson, elaborating some 1879 experiments of Sir William Crookes in a partial vacuum, discovered and finally clinched the discontinuity of electricity; in other words he realized the electron, which had previously been only surmised rather vaguely by a few. Zeeman and Lorentz had just showed that electric charges were the agents really responsible for the generation of radiation, a fact further illustrated and enforced by Rontgen's discovery of X-rays. After their isolation electrons were weighed and measured by Thomson, and found to possess the fundamental properties of matter. The nature of radiation as emitted by electrons was analysed and examined in precise detail by the spectroscope. Then another discontinuity was discovered by Max Planck, for, as soon as single atoms and their constituent particles were attended to, a new discontinuity appeared, apparently in radiation, but rather in what turned out to be a quantity connected with the orbital revolutions of an electron, akin to the sweeping out of equal areas which Kepler long ago had formulated for the planets; and Bohr formulated his astronomical theory of the structure of the atom. So through various channels it was found that these fundamental electric units, which were presumably structures in the ether, lay at the root of matter itself, and that matter was actually an electrical phenomenon. Discontinuities are natural and inevitable when dealing with individual minute particles; they were only masked in previous days because this minute treatment had not been attempted, though a hint had been given in that direction by the failure of the kinetic theory of gases, as ordinarily applied, to explain the irregular movements of very small bodies exposed to molecular bombardment.

The Theory of Relativity.—Then came the theory of relativity, which adopted, generalized, and boldly formulated a number of vague but growing suspicions. In particular it postulated a universal and unalterable constitutional velocity in the ether now known as c , which had been recognized in Clerk Maxwell's theory as of an electromagnetic nature, but the nature of which is still unknown. This, like Planck's constant h , is found to enter into every department of physics, not only conspicuously when minute bodies are dealt with, but secretly throughout. All matter is moving through the ether, so that the constitutional velocity c of that medium enters into and modifies even the Newtonian laws of motion, thus giving a complexity which sometimes seems strange to ordinary or evolutionary experience, and with a little ingenuity can be made to appear paradoxical. Many other results of high interest follow, and the gravitational function of the medium shows signs of yielding to mathematical treatment.

The revolutionary outcome of all this is that the ether in its various forms of energy dominates modern physics, though many prefer to avoid the term "ether" because of its 19th century associations, and use the term "space." The term used does not much matter. Faraday began the discovery that it is in space that the real phenomena occur. Every differential equation is an expression in space with its three dimensions and the other abstraction called time; and some attempt has been made to unify

these two great abstractions by aid of the velocity c . This however is rather verging on metaphysics, unless it is merely regarded as a legitimate convenience in calculation to deal with four similar variables instead of three and an odd one.

One definite outcome of the bold generalisations or challenges of relativity is that energy, which since its conservation was established has always been recognised as protean in form, now includes not electric charges alone but matter itself as one of its forms, so that atoms of matter might be turned into other forms of energy, if only we knew how. The idea already has some cosmological significance, for it is believed by Jeans to be the cause or mechanism of the radiation of the sun and other stars. The atom of matter is electrically constituted; it is composed of equal amounts of positive and negative electricity in its normal condition. High temperature signifies great activity or immense speeds among the atoms. They can be dissociated or broken up by collision, and their opposite ingredients may occasionally clash, lose their identity, or at least their locality, and pass quickly away as a quantum of radiation. The interior of stars is known to be at an exceedingly high temperature, and accordingly their mass is believed to be gradually decreasing, their matter dying and passing away as radiation into the depths of space. Whether there is ever or anywhere a recuperative action is at present unknown. When, if ever, such action is discovered—as is not unlikely—it will have a cosmological and philosophical bearing.

It is interesting, as illustrating Newton's exceptional foresight and speculative skill, that at the end of a disquisition on the changes and interchanges of known forms of energy (though the term "energy" as a dominating physical term was not adopted till long afterwards), he should conclude thus: "And among such various and strange transmutations, why may not Nature change bodies into light, and light into bodies?"

Interaction of Matter and Radiation.—Meanwhile strange reactions have been discovered between matter and radiation. Radiation is generated by electrons, and accordingly itself suffers discontinuity. Maxwell calculated that it must exert pressure: it is now found to exert pressure after the same bombarding fashion as the molecules of a gas exert it. Radiation is generated and absorbed not continuously but in quanta, and these quanta exert a bombarding action as if they were particles or corpuscles; yet they must be waves, because they exhibit interference and diffraction phenomena—a study of which, in optics, began with Newton himself. Wave quanta with extra high frequency of vibration are more efficient projectiles, and eject such suitable electrons as they encounter with more energy than do those with a more ordinary rate of vibration. This connection between energy and frequency is a development of Planck's quantum, which, like much else, is due to Einstein's bold and forcible conceptions. The outcome of all this is that the old barrier between the corpuscular theory and the wave theory is being removed. There is truth in both. High speed particles are accompanied by waves, somewhat akin to the waves at the bows of a steamer, and the apparently sharp distinction between a wave and a corpuscle is subject to a compromise which includes both.

We have long studied matter by means or by the aid of radiation or waves; we are now beginning to see that momentum, which seemed a property of matter, is possessed by waves, and that the familiar thing which we call matter is after all a manifestation or localization of ether-energy, in a form not as yet completely known or understood. Ether energy—the one fundamental existence—seems to manifest itself alternatively, or even as it would seem indiscriminately, sometimes as what we might call a particle and sometimes as a wave. De Broglie seems to have initiated this idea, which has been taken up and elaborated by Schrodinger and others. The result is that, whereas we once thought that we knew a great deal about an electron, its size and its speed, we are now confronted with some uncertainty. It is all very well to speculate and theorize, but all theories must be verified and brought to the test of experiment; and experiment—even indirect observation—on this minute scale is barely possible.

The difficulty can easily be rendered intelligible. We have to use some physical means to examine the behaviour of anything. We

cannot see a thing unless it is illuminated, or unless it emits light itself; and, if we are examining something very minute, the illumination itself, which consists of quanta with a definite momentum, may be altering the conditions of the very thing we want to observe. How then can we determine the position and speed of an electron? Heisenberg has shown that we cannot do both. If one determination is accurate, the other is vague. We are not even sure now of the size of an electron, for if it carries waves with it, those waves must occupy a certain region, which, though perhaps small compared with an atom, is far greater than anything we can call the electric nucleus. Indeed a highly accelerated electron, like one of those in Bohr's inner atomic orbits, seems to spread like a sinuous disturbance over the whole orbit, so that only in the outer and larger orbits is there any close correspondence between ordinary dynamics and actual fact. That there is a correspondence at all is satisfactory, but there is much detail in the ultimate minutiae which at present escapes us.

The difficulty of examining very small things by reason of the perturbations introduced by our measuring instruments can be illustrated in a simple manner. To take the temperature of a hot bath is easy enough, but a thimbleful would be chilled or otherwise altered by the thermometer employed. It is in fact difficult to observe any very small quantity without introducing perturbations. Heisenberg has actually formulated a law of uncertainty, in a singularly definite manner, showing that Planck's quantum is involved. There is an uncertainty in the position of an electron, and an uncertainty about its speed or momentum. The product of the two uncertainties is equal to Planck's constant h .

There are still more recent developments. Speculation is active, the revolution is in progress and fresh discoveries are constantly being made. The whole constitutes an elaborate network of interlocking and coincidences, which must have a deep-seated meaning when we can unravel the tangled skein. All we can do now is to hint at the stages that are being reached, to realize that nothing like the last word has been spoken, to wonder at the genius which has so greatly illuminated and yet partly confused us and to have faith in the advent of a great generalization. (O. J. L.)

PHYSICS, ARTICLES ON. The astonishing advances which the science of physics has made since the Eleventh Edition of the Encyclopaedia Britannica was prepared have been met by a complete and drastic revision of the physics articles. How far the researches of the present century have changed the outlook is evidenced by the fact that the Eleventh Edition contains nothing on relativity, on atomic structure or on the quantum theory, three questions which dominate modern physics, and influence every branch. Not only have articles by the highest authorities on the new topics been introduced, and the less fundamental articles on older subjects been cut down in size in such a way as to make the balance accord with actuality, but every article has been either completely rewritten or revised so as to make it part of a proportioned and organic body of information on modern physics.

The articles SCIENCE and PHYSICS give a general view of the scope of physics, and its place among the sciences. The fundamental nature of space and time in the physical world, and of gravitation, is discussed under RELATIVITY and SPACE-TIME, while the history of the growth, and another aspect of the nature of, the relativity problem is given under ETHER. An account of experiments and observations which played a great part in preparing the way for relativity will be found under MICHELSON-MORLEY EXPERIMENT and ABERRATION OF LIGHT. Measurements of the VELOCITY OF LIGHT, the constancy of which is fundamental, are described under the article so entitled. The historical, experimental and theoretical aspects of the subject are thus all readily accessible.

The subject-matter of physics can be broadly classed as matter and radiation. The physical nature of matter is expounded under KINETIC THEORY OF MATTER, which deals mainly with gases. Supplementary to this article is BROWNIAN MOVEMENT. The transition from gas to liquid is handled from the general theoretical point of view in the article LIQUEFACTION OF GASES, which also deals with technically important aspects of the subject. The mod-

ern view of solids comes under SOLID STATE, THEORY OF. For the arrangement of atoms and molecules in crystalline solids the article X-RAYS AND CRYSTAL STRUCTURE should be consulted. Crystals have a regular ordered structure: in many ways the antithesis of the crystalline state is the colloidal state, dealt with under COLLOIDS. Important general properties of liquids have special articles SURFACE TENSION and VISCOSITY devoted to them. These articles, then, deal with the general properties of matter: the field of radiation is covered in RADIATION, RAYS, which deals broadly with the various kinds of waves comprised in the electromagnetic spectrum.

The peculiar task of physics in the present century has been to effect a synthesis of the properties of matter and radiation in terms of units of electric charge, of matter and of radiation. Modern atomic physics, which comprises this field, is well represented in the Encyclopædia. The unit of electricity is the ELECTRON, to which an article is devoted. A vast body of work that established and developed the electron theory is described under ELECTRICITY, CONDUCTION OF, IN GASES. The connecting link between matter and radiation is furnished by the nuclear theory of the atom, which asserts that an atom consists of a minute, positively-charged massive nucleus, surrounded by groupings of electrons in motion. The general nuclear theory is explained under ATOM, the properties of the nucleus, and their profound consequences for physics and chemistry, under NUCLEUS, ISOTOPES, and POSITIVE RAYS. TRANSMUTATION OF THE ELEMENTS presents another aspect of nuclear theory. RADIOACTIVITY is an article of first importance for the understanding of modern physics. The theory of emission of light and X-rays by an atom, described under ATOM, is based upon the QUANTUM THEORY, discussed in a key article which leads up to the new developments known as wave mechanics. X-RAYS, NATURE OF; SPECTROSCOPY; BAND SPECTRUM; RESONANCE POTENTIALS; THERMIONICS; PHOTOELECTRICITY; COMPTON EFFECT; RAMAN EFFECT deal with the experimental and theoretical side of radiation phenomena which have a prominent place in atomic physics, while WILSON CLOUD CHAMBER describes a method of experimenting on single atoms and electrons which has had far-reaching results.

The general body of physics is dealt with under comprehensive articles devoted to the main conventional divisions—HEAT, LIGHT, SOUND, ELECTRICITY, MAGNETISM, with important supplementary articles, among which may be mentioned: under heat, THERMODYNAMICS; CALORIMETRY; THERMOMETRY; under light, OPTICS; SPECTROSCOPY; FLUORESCENCE AND PHOSPHORESCENCE; under electricity, ELECTRICITY, CONDUCTION OF; ELECTROLYSIS. Important instruments and their uses are described under: CONDENSER; MICROSCOPE; MICROSCOPY; MIRROR; BINOCULAR INSTRUMENT; INTERFEROMETER; INSTRUMENTS, ELECTRICAL; ACCUMULATOR; INDUCTION COIL; COMPASS; SELENIUM CELLS; VACUUM.

Applied physics is another aspect of the subject which receives full representation. The meteorological side is represented by ELECTRICITY, ATMOSPHERIC and the geophysical by TERRESTRIAL MAGNETISM; EARTH CURRENTS and GRAVITATION. Some of the chief heads under which the bearing of physics in everyday life and industry is described in detail are: ACOUSTICS; AERODYNAMICS; ELECTRIC LAMPS AND VALVES, MANUFACTURE OF; ELECTROMAGNET; GRAMPHONE; LENS; PHOTOGRAPHY; PHOTOMETRY; TELEGRAPH; TELEPHONE; TELEVISION; X-RAYS, Applications of. Every aspect of wireless is included in the scheme: ELECTRIC WAVES deals with Hertz's original discovery and the subsequent laboratory developments; WIRELESS TELEGRAPHY deals, in two divisions, with the theoretical and practical aspect of the subject, while THERMIONIC VALVE; MICROPHONE; LOUD SPEAKER; RADIO RECEIVER describe apparatus vital to BROADCASTING, all aspects of which are discussed under that title. (E. N. DA C. A.)

PHYSICS IN MEDICINE. The science of physics concerns itself with energy in its various manifestations and the properties of matter, and in consequence plays a part in medicine whose value and importance are ever increasing. It furnishes means of investigating the structure of the animal body and the functions of its members; it assists in the detection of abnormality

and disease, and in the preparation, control and administration of therapeutic remedies; finally, it enables man to acquire a measure of control of his environment by scientific heating, lighting, ventilation and drainage, and the development of means of transport for himself and his necessities.

In particular, such processes of the living body as muscular contraction, the circulation of the blood, the respiratory intake and output of the lungs, the nervous impulse and its journeyings and the maintenance of the energy balance by food intake are in a measure explicable in terms of physics and physical chemistry.

Source of Bodily Energy.—To consider some of these in detail, first the question of the energy value of food may be cited. According to the principle of conservation of energy—if this is valid for transformations of energy occurring in the living animal—the same amount of energy should be evolved from the utilisation of food inside the body as outside, provided the resulting chemical end-products are the same in the two cases and have the same physical state. This has been shown to be the case by the direct measurement over a sufficiently long period, of the heat given out by resting man or animal when placed in a suitable calorimeter, and by also separately measuring the heat evolved in the oxidation of a quantity of food equal to that which was consumed in this period. When due allowance is made for substances which are excreted unchanged or only partially oxidized, and for the work of evaporation, it is found that the agreement is beyond doubt. This is of considerable importance, for if it were not the case, then it would be quite uncertain whether or not man received energy from unknown sources and physics would be of little use in medicine. As it is, the fact that the oxidation of food is the only source of bodily energy of man, makes possible the prescription of diets adequate to a variety of conditions, whether of health or disease.

Not only does the principle of conservation of energy apply to the body as a whole, it is also applicable to the units which go to form it, *i.e.* to all those energy changes and oxidations necessary for life which occur in the cell. Now the living cell consists of a watery solution containing colloids, crystalloids and substances in suspension, enclosed in a cell wall or membrane. Therefore the study of the physical properties of solutions, colloids and membranes in the laboratory should, and does, afford much information concerning its behaviour. Below some of these properties are examined with this object.

Hydrogen Ion Concentration.—It is well known that solutions which conduct electricity (electrolytes) do so in virtue of the electrically charged "ions," positive and negative, derived from the dissociation of the molecules of the dissolved substances. Pure water is only slightly ionized, yielding hydrogen ions carrying a positive electrical charge and an equal number of hydroxyl ions with a negative charge, the product of the concentration of hydrogen ions and hydroxyl ions being constant for a given temperature. When a substance is dissolved in water it, in general, produces a change in its chemical neutrality, owing to the disturbance in the balance existing between the concentration of hydrogen and hydroxyl ions. Thus an acid dissolved in water yields hydrogen ions as a direct result of solution, and leads to an increase in hydrogen ion concentration and a decrease in the concentration of hydroxyl ions. Similarly the solution of a base produces hydroxyl ions and leads to a decrease in hydrogen ion concentration and an increase in the concentration of hydroxyl ions.

Acidity then is due to the preponderance of hydrogen ions over hydroxyl ions, and alkalinity is due to the converse. Neutrality is an equilibrium of hydrogen and hydroxyl ions. Certain substances—called amphoteric electrolytes—produce both hydrogen ions and hydroxyl ions on dissociation, and may therefore combine as acids with bases, or as bases with acids. Proteins are of this class, and so of course, is water.

An alteration in acidity is the causative factor in the regulation of respiration, the activity of muscle, and the excitability of nerve and plays an important part in regulating excretion and secretion.

The powerful effects of variation in hydrogen ion concentration

on physiological processes require the existence of mechanism for the prevention of considerable changes of this kind. One of the main functions of blood is to provide this. It can itself withstand the addition of relatively considerable amounts of free acid or free alkali without much change in its reaction, largely owing to the presence of carbonates and phosphates. The electrolytic dissociation theory provides the only satisfactory explanation of this.

Colloids and Membranes.—The colloidal state is recognised as a permanent suspension of solid particles or liquid globules in a continuous medium of a different kind. In contrast to true solutions, colloids are heterogeneous systems in which the suspended particles are large enough to possess the special properties peculiar to surfaces. It is easily seen that, since molecules at the surface of separation of two phases are attracted more powerfully in the direction of the phase to which they belong than in the opposite direction, the interface will be in a state of tension. Consequently any change in the area of a surface film will result in a loss or gain of surface energy. Again, particles of colloid solutions usually possess an electrical charge, which is localized on its surface. Such particles are to a large extent prevented from aggregating together and falling as precipitates by the mutual repulsion of their electrical charges.

The deposition of charged ions on a colloidal particle or any surface would confer on the surface a charge of corresponding sign. This process is called *adsorption* and it may or may not be accompanied by chemical action between the constituents of the surface and the adsorbed material. The neutralization of electrical charges by adsorption of oppositely charged ions from added neutral salts results in precipitation. A similar effect may be produced by oppositely charged colloids.

An important case of adsorption is that occurring at the semi-permeable membrane which covers cells. Physical principles show that any material which lowers surface energy will be accumulated in the surface. Certain substances, such as proteins, may form solid deposits in the surface films owing to their concentration brought about in this way. These deposits are capable in some cases of being redissolved if carried into the interior of the cell. Hence the cell membrane must have a variable structure in equilibrium with its contents.

Osmotic Pressure.—Semi-permeable membranes, *i.e.*, membranes which allow water to pass freely, but hold back dissolved substances exhibit another important property. Water will tend to diffuse more rapidly through the membrane towards that side on which the concentration of dissolved substance is greater, than in the reverse direction. This would cause a difference in hydrostatic pressure on the two sides if an increase in volume of the more concentrated solution is prevented by a non-yielding envelope. This pressure is called *osmotic pressure* and the unilateral passage of fluid *osmosis (q.v.)*. Solutions which exert the same osmotic pressure are said to be *isotonic*.

It is easy to see that the solutions which bathe a cell not enclosed in a rigid envelope must, for equilibrium, possess the same osmotic pressure as the cell contents. Otherwise the cell will contract through loss or expand through gain of water, and will be destroyed unless the osmotic pressures can be equalized in this way. In any case if any change of concentration occurs, the functional activity of the cell will be affected. The membrane covering individual cells and blood corpuscles is impermeable to salts, glucose, etc.; that forming the walls of the capillary blood vessels is permeable to these but not to colloids.

The osmotic pressure of colloids although it is very small compared with that of solutions of electrolytes, has been shown by Starling to play an important part in the formation of urine. Oedema also, according to some authors, is a phenomenon of osmosis.

The chemical behaviour of colloidal particles is very inert compared with the same amount of material in true solution. This permits of the use in medicine of colloidal preparations of metals and other powerful drugs to secure a slow and prolonged action of continuous minute doses of the active ionized form into which they break down.

The reference already made to the properties of colloids and electrolytes and to some of the parts they play in the animal body, are properties and phenomena which demanded for their elucidation the use of the microscope, ultra-microscope, polarimeter, electrometer, etc.

Physics of Muscle and Nerve.—The study of the action of muscles and nerves illustrates perhaps in a still more definite manner, the dependence of medical on physical science. This dependence is twofold, in that the investigation and rational explanation of physiological phenomena has had to await, not only the development of physical theory for the realm of inanimate matter, but also the invention and technical perfection of detecting and recording instruments of the greatest sensitivity and highest precision.

In order to maintain living muscles and nerves outside the animal for long periods they are bathed in an artificial saline solution, which, as we have seen, must be isotonic with them and have the same hydrogen ion concentration. Now much of the difficulty in investigating vital processes is due to the microscopic size of the living cell, which results in changes which are also small. Largely owing to the development of sensitive galvanometers and also to the modern thermionic amplifier and cinematograph camera, it is possible to detect extremely small variations of energy if they occur in the form of electrical changes or can be converted into that form. Minute changes of temperature—and therefore the production of small quantities of heat—can be measured by the electrical currents generated in thermocouples or by changes in electrical resistance of metallic conductors.

Methods of Investigation.—In studying the activity of an isolated nerve or muscle preparation, it is usual to employ a brief electric current as stimulus, since it is possible to repeat it without producing permanent damage and the duration and intensity can be so readily and accurately controlled. By these means, it has been possible to measure with some accuracy the heat produced in a muscle by a single stimulus, and also that liberated over long intervals at rest, or in recovery after prolonged stimulation. The results prove that oxidation is necessary to maintain the normal life and structure of an animal cell in a living but completely resting condition. Further it has been shown that muscular contraction is a surface phenomenon, since the energy developed is proportional to the length of the fibres and not their volume.

Similarly it has been shown that the nervous impulse is excited by a stimulus which in all probability consists in an accumulation of ions in certain parts of the nerve fibre. The arrival of the impulse at any point on the nerve is indicated by the active region developing a negative electrical potential with regard to the neighbouring inactive regions. If then, electrodes are placed in contact with the active and inactive regions and connected through a galvanometer, a current will pass through the circuit towards the active region. It is found that the energy involved in the transmission of the impulse is derived from that stored in the fibre itself, and not from the stimulus: the latter only acts as a trigger.

Radiation.—Not the least service rendered by physics to medicine is the demonstration and exploitation of the fact that, in addition to those radiations—light and radiant heat—which are directly perceived through the senses, there exist others which have a profound influence on the animal body. The spectrum of electromagnetic radiation is now known to comprise, in descending order of wave lengths, the Hertzian waves of wireless communication, infra-red rays, the visible spectrum, ultra-violet rays, X-rays and the gamma rays of radio-active substances. The shorter wave lengths of the visible spectrum and the still shorter ones mentioned above, all possess the power of either stimulating or destroying the animal cell, according as the quantity of energy absorbed is small or excessive. The action of the rays is *selective* in that different cells exhibit different degrees of response to a given quality and intensity of radiation.

Some radiations, notably those from certain parts of the ultra-violet spectrum, have a specific action on biological material, *i.e.*

the absorption of a given amount of radiant energy of this wave length will provoke a much greater response in a given cell or organism than the absorption of an equal amount of energy of another wave length.

These two effects—the specific and the selective effects of different radiations—are of great importance in radiation therapy.

The mechanism of the action of radiation on the cell has not been traced in all its stages. Ultimately, however, it is attributable either to the heat produced by the energy absorbed, or to the ionizing (photo-electric) effect on the atoms of the cells involved. The principal methods of physical dosage measurement in radiation therapy also depend on these two last mentioned properties. Exact dosage measurements have shown that the biological reactions produced by different kinds of radiation obey similar laws in that they all require a minimum duration and have a threshold value of intensity below which no effect is produced.

PHYSIOCRATIC SCHOOL, the name of a group of French economists and philosophers. The heads of the school were François Quesnay (*q.v.*) and Jean Claude Marie Vincent, sieur de Gournay (1712–1759). The principles of the school had been put forward in 1755 by R. Cantillon, a French merchant of Irish extraction (*Essai sur la nature du commerce en général*), but it was Quesnay and Gournay who gave them a systematic form, and made them the creed of a united group of thinkers and practical men, bent on carrying them into action. The members of the group called themselves *les économistes*, but it is more convenient, because unambiguous, to designate them by the name physiocrats (Gr. φύσις nature, and κρατείν to rule), invented by P. S. Dupont de Nemours (1739–1817).

The general political doctrine is as follows: Society is composed of a number of individuals, all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own interest, and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each just so far as it is inconsistent with the rights of the others. Government though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere this implies the right of the individual to such natural enjoyments as he can acquire by his labour. That labour, therefore, should be undisturbed and unfettered, and its fruits should be guaranteed to the possessor; in other words, property should be sacred. Each citizen must be allowed to make the most of his labour; and therefore freedom of exchange should be ensured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The Single Tax on Land.—The physiocrats then proceed with the economic analysis thus: Only those labours are truly "productive" which add to the quantity of raw materials available for the purposes of man; and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course, metals) over their cost of production. On the amount of this *produit net* depends the well-being of the community and the possibility of its advance in civilization. The manufacturer merely gives a new form to the materials extracted from the earth; the higher value of the object, after it has passed through his hands, only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another; what the trading classes gain thereby is acquired at the cost of the nation, and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are "useful" indeed, but they are "sterile," drawing their income, not

from any fund which they themselves create, but from the superfluous earnings of the agriculturist. The revenue of the state, which must be derived altogether from this net product, ought to be raised in the most direct and simplest way—namely, by a single impost of the nature of a land tax.

The special doctrine relating to the exclusive productiveness of agriculture arose out of a confusion between "value" on the one hand and "matter and energy" on the other. A. Smith and others have shown that the attempt to fix the character of "sterility" on manufactures and commerce was founded in error. And the proposal of a single *impôt territorial* falls to the ground with the doctrine on which it was based. But such influence as the school exerted depended little, if at all, on these peculiar tenets, which indeed some of its members did not hold. The effective result of its teaching was mainly destructive. It continued in a more systematic form the efforts in favour of the freedom of industry already begun in England and France.

The Rule of Nature.—These conclusions as to the revolutionary tendencies of the school are not at all affected by the fact that the form of government preferred by Quesnay and some of his chief followers was what they called a legal despotism, which should embrace within itself both the legislative and the executive function. The reason for this preference was that an enlightened central power could more promptly and efficaciously introduce the policy they advocated than an assembly representing divergent opinions and fettered by constitutional checks and limitations. Turgot used the absolute power of the Crown to carry into effect some of his measures for the liberation of industry, though he ultimately failed because unsustained by the requisite force of character in Louis XVI. But what the physiocratic idea with respect to the normal method of government was appears from Quesnay's advice to the dauphin, that when he became king he should "do nothing, but let the laws rule," the laws having been, of course, first brought into conformity with the *ius naturae*. The partiality of the school for agriculture was in harmony with the sentiment in favour of "nature" and primitive simplicity which then showed itself in so many forms in France, especially in combination with the revolutionary spirit, and of which Rousseau was the most eloquent exponent. The members of the physiocratic group were undoubtedly men of thorough uprightness, and inspired with a sincere desire for the public good, especially for the material and moral elevation of the working classes. Quesnay was physician to Louis XV., and resided in the palace at Versailles; but in the midst of that corrupt court he maintained his integrity, and spoke with manly frankness what he believed to be the truth. And never did any statesman devote himself with greater singleness of purpose or more earnest endeavour to the service of his country than Turgot, who was the principal practical representative of the school.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds. Its members, writing on dry subjects in an austere and often heavy style, did not find acceptance with a public which demanded before all things charm of manner in those who addressed it. The physiocratic tenets, which were in fact partly erroneous, were regarded by many as chimerical, and were ridiculed in the contemporary literature; as, for example, the *impôt unique* by Voltaire in his *L'Homme aux quarante écus*, which was directed in particular against P. P. Mercier-Larivière (1720–1794). It was justly objected to the group that they were too absolute in their view of things; they supposed, as Smith remarks in speaking of Quesnay, that the body politic could thrive only under one precise régime—that, namely, which they recommended—and thought their doctrines universally and immediately applicable in practice. They did not, as theorists, sufficiently take into account national diversities or different stages in social development; nor did they, as politicians, adequately estimate the impediments which ignorance, prejudice and interested opposition present to enlightened statesmanship. The physiocratic system, soon ceased to exist as a living power; but its good elements were incorporated into the more

complete construction of Adam Smith.

PHYSIOGNOMY, a term which denotes a supposed science for the "discovery of the disposition of the mind by the lineaments of the body" (Bacon); is also used colloquially as a synonym for the face or outward appearance, being variously spelled by the old writers.

Physiognomy was regarded by those who cultivated it as a two-fold science: (1) a mode of discriminating character by the outward appearance, and (2) a method of divination from form and feature. On account of the abuses of the latter aspect of the subject its practice was forbidden by the English law. By the act of parliament 17 George II. c. 5 (1743) all persons pretending to have skill in physiognomy were deemed rogues and vagabonds, and were liable to be publicly whipped, or sent to the house of correction until next sessions. The pursuit thus stigmatized as unlawful is one of great antiquity: in ancient times physiognomy was a profession.

The first systematic treatise which has come down to us is that attributed to Aristotle, in which he devotes six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness, of genius and stupidity, of timidity, impudence, anger and their opposites, etc. Then he studies the physiognomy of the sexes, and the characters derived from the different features, and from colour, hair, body, limbs, gait and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard. The general character of the work may be gathered from the following specimen. While discussing noses, he says that those with thick bulbous ends belong to persons who are insensitive, swinish; sharp-tipped belong to the irascible, those easily provoked, like dogs; rounded, large, obtuse noses to the magnanimous, the lion-like; slender hooked noses to the eagle-like, the noble but grasping; round-tipped *retroussé* noses to the luxurious, like barndoor fowl; noses with a very slight notch at the root belong to the impudent, the crow-like; while snub noses belong to persons of luxurious habits, whom he compares to deer; open nostrils are signs of passion, etc.

While the earlier classical physiognomy was chiefly descriptive, the later mediæval authors particularly developed the predictive and astrological side, their treatises often digressing into chiromancy, onychomancy, clidomancy, podoscopy, spasmatomancy and other branches of prophetic folk-lore and magic.

Along with the medical science of the period the Arabians contributed to the literature of physiognomy; notably 'Ali b. Ragel, Rhazes and Averroes. Avicenna also makes some acute physiognomical remarks in his *De animalibus*, which was translated by Michael Scot about 1270. Among mediæval writers Albertus Magnus (born 1205) devotes much of the second section of his *De animalibus* to physiognomy. The famous sage of Balwearie, Michael Scot, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis physiognomia*, much of which is physiological and of curious interest. It was probably composed about 1272, but not printed until 1477. This was the first printed work on the subject.

The 16th century was rich in publications on physiognomy. Treatises were published, among others, by John de Indagine, Cocles, Andreas Corvus, Michael Blondus, Janus Cornaro, Anselm Douxciel, Pompeius Ronnseus, Gratarolus, Lucas Garicus, Tricassus, Cardanus, Taisnierus, Magnus Hund, Rothman, Johannes Padovanus, and, greatest of all, Giambattista della Porta. The earliest English works were anonymous: *On the Art of Foretelling Future Events by Inspection of the Hand* (1504), and *A Pleasant*

Introduction to the Art of Chiromancie and Physiognomie (1588). Dr. Thomas Hill's work, *The Contemplation of Mankynde, containing a singular Discourse after the Art of Plzysiognomie*, published in 1571, is a quaintly written adaptation from the Italian authors of the day.

The development of a more accurate anatomy in the 17th century seems to have diminished the interest in physiognomy by substituting fact for fiction; and consequently the literature, though as great in quantity, became less valuable in quality. The principal writers of this age were T. Campanella, R. Coclenius, Clement, Timpler, J. E. Gallimard, Moldenarius, Septalius, Saunders, C. Lebrun (a precursor of Charles Bell), Elsholz, de la Bellière, J. Evelyn (in the appendix to *Numismata*), Baldus, Bulwer (in his *Patkomyotomia*), Fuchs, Spontoni, Ghiradelli, Chiaramonti, A. Ingegneri, Finella, De la Chambre, Zanardus, R. Fludd and others of less importance.

The 18th century shows a still greater decline of interest; the only name worthy of note is that of J. K. Lavater (*q.v.*). The popular style, good illustrations and pious spirit of his works gave them a popularity they little deserved, as there is no system in his work, which chiefly consists of rhapsodical comments upon the several portraits.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, whose *Essay on the Anatomy of the Expression*, published in 1806, was the first scientific study of the physical manifestation of emotions in the terms of the muscles which produce these manifestations. In the later editions of this essay the thesis is elaborated with greater detail. Moreau's edition of Lavater, in 1807, was somewhat along the same lines. In 1817 Dr. Cross of Glasgow wrote his defence of a scientific physiognomy based on general physiological principles. The experiments of G. B. A. Duchenne (*Mécanisme de la physiognomie humaine*, Paris, 1862) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These observations confirmed by experimental demonstration the hypothetical conclusions of Bell. The machinery of expression having thus been indicated, the connection of the physical actions and the psychological state was made the subject of speculation by Herbert Spencer (*Psychology*, 1855). These speculations were reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated the following as fundamental physiognomical principles:—

(1) Certain complex acts are of direct or indirect service, under certain conditions of the mind, in order to relieve or gratify certain sensations or desires; and whenever the same states of mind are induced the same sets of actions tend to be performed, even when they have ceased to be of use. (2) When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action. (3) When the sensorium is strongly excited nerve-force is generated in excess, and is transmitted in definite directions, depending on the connections of nerve-cells and on habit.

The last of these propositions is adversely criticized by P. Mantegazza as a truism, but it may be allowed to stand with the qualification that we are ignorant concerning the nature of the influence called "nerve-force." It follows from these propositions that the expression of emotion is, for the most part, not under control of the will, and that those striped muscles are the most expressive which are the least voluntary. To the foregoing may be added the following three additional propositions, so as to form a more complete expression of a physiognomical philosophy:—

(4) Certain muscles concerned in producing these skin-folds become strengthened by habitual action, and when the skin diminishes in elasticity and fulness with advancing age, the wrinkles at right angles to the course of the muscular fibres become permanent. (5) To some extent habitual muscular action of this kind may, by affecting local nutrition, alter the contour of such bones and cartilages as are related to the muscles of expression. (6) If the mental disposition and proneness to action are inherited by children from their parents, it may be that the facility in, and disposition towards, certain forms of expression are in like manner matters of heredity.

Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne and Darwin, and in the later publications of Theodor Piderit, *Mimike und Physiognomik* (1886) and

Mantegazza, *Physiognomy and Expression* (1890), to which the student may be referred for further information.

For information on artistic anatomy as applied to physiognomy see the catalogue of sixty-two authors by Ludwig Choulant, *Geschichte und Bibliographie der anatomischen Abbildung*, etc. (Leipzig, 1852), and the works of the authors enumerated above, especially those of Aristotle, Franz, Porta, Cardan, Corvus and Bulwer. For physiognomy of disease, besides the usual medical handbooks, see Cabuchet, *Essai sur l'expression de la face dans les maladies* (Paris, 1801); Mantegazza, *Physiology of Pain* (1893), and Polli, *Saggio di fisiognomia e potognomia* (1837). For ethnological physiognomy, see amongst older authors Gratarolus, and amongst moderns the writers cited in the various textbooks on anthropology, especially Schadow, *Physiognomies nationales* (1835) and Park Harrison, *Journ. Anthropol. Inst.* (1883). For the physical characteristics of criminals see Lombroso, *L'Uomo delinquente* (1897); Ferri, *L'Omicidio* (1895); von Baer, *Der Verbrecher* (1893); Laurent, *Les Habitués des prisons* (1890); Havelock Ellis, *The Criminal* (1901); A. Lenz, *Grundriss der Kriminalbiologie* (Vienna, 1927); L. Grimberg, *Emotion and Delinquency* (1928).

PHYSIOLOGICAL ARTICLES. The special articles in Physiology form natural complements to those of the medical programme. DIGESTION; HEART AND CIRCULATION; NUTRITION; EQUILIBRIUM; MUSCLE AND MUSCULAR EXERCISE; PAIN, SIGNIFICANCE OF; BIOCHEMISTRY; SMELL AND TASTE; ENZYMES and REPRODUCTION and SEX, are among the most important articles in this section. See also MEDICAL ARTICLES.

PHYSIOLOGY is the science which treats of the functional working of the body in health, as opposed on the one hand to anatomy which treats of the structure of the body and pathology which treats of its function as distorted by disease. In all forms of animal life except the lowest, the body is made up of organs. With regard to the functions of all the more important organs special articles will be found under their respective names (see HEART; INTESTINE; LIVER; LUNG; etc.).

The activities of these organs are co-ordinated by the nervous system (see BRAIN; NERVE; SPINAL CORD; SYMPATHETIC SYSTEM) and the hormones (see HORMONES). Nevertheless the body is in a sense more than a number of co-ordinated units. The body has an architecture which has been evolved along well defined lines and which it is the business of the present article to trace as far as may be possible.

The phrase "well defined lines" rather than "well defined principles" has been used advisedly; for it may often be a matter of speculation, whether, even when a frequent repetition of the same sort of architectural conceit occurs, any principle is really involved; or whether merely the same sort of accident has taken place in the same sort of way. To the most reflective type of mind physiology presents no more fascinating problem, than that of the extent to which the structure of the body is the result of some well ordered plan either of "evolution" or "design." In the strict sense of the word "principle" would imply such a plan, but in what follows the word will be used more loosely to include phenomena that recur with sufficient frequency to simulate an orderly sequence, even though the recurrence may in reality be little more than accidental.

Constancy of Internal Environment.— This principle is associated particularly with the name of the great French physiologist Claude Bernard. Innumerable examples might be given in illustration of it but a few must suffice. Moreover the examples might be either in the realm of the physical or of the chemical properties of the environment. The first to be discussed, namely constancy of internal temperature, is physical and is chosen not because it is more important than others, but because the constancy has crept into the animal kingdom very slowly and its implications are to some extent traceable. A unicellular organism, such as the amoeba, exists at a temperature indistinguishable from that of the water in which it lives. Every accident which affects the temperature of the water affects that of the amoeba; the only defence which the creature can put up against a too rigorous environment, whether of heat or cold, is to flee if it can to more genial surroundings. Within those limits all the processes of its body, of digestion, of respiration, of movement, must take place at the temperature of the water in which the unicellular organism finds itself. Compare the condition of affairs in man, the most

highly organized creature; the temperature of the body is within very narrow limits (1) constant from one time to another; (2) the same over the whole body; and (3) maintained at a level quite different from—and independent of—that of the surrounding medium.

In the development of man, this constancy has been brought about by stages. The root of the matter lies in the fact that the organism itself produces heat; the amoeba is so small and its cooling surface relatively so great, that the heat produced by the organism itself is a negligible factor in determining its temperature; but if enough amoebae were packed together the heat which they produced would have less opportunity of escape and so the centre of the mass would attain a higher temperature just as the heat produced in a hay rick raises the temperature of the interior of the rick. Therefore a high body temperature argues a certain considerable *size* as one of the properties of the body. That the body temperature should be uniform over the whole body is accomplished by the circulation of the blood. The maintenance of the constancy of environment inside the body by the device of circulating the same fluid throughout all its interstices appears very early in the development of animal life and maintains the constancy in many other respects besides that of temperature.

The constancy of the body temperature with regard to time is on the other hand something which has been attained at a late stage in the development of the animal kingdom. The so called "warm blooded animal," in reality the animal whose temperature remains at an even level, did not appear until long after the vertebrate level had been reached. Yet this device was developed apparently independently both in birds and mammals.

So manifest are the advantages of a constant temperature that its late development seems almost surprising. The body from one point of view consists of innumerable and ceaseless chemical reactions. These reactions take place at given velocities, the velocity of each reaction depending upon the reaction itself and the temperature at which it is taking place. Imagine the whole machine adjusted perfectly to work at 30° Cent., each reaction progressing at a velocity which (a) is most suitable for its own purpose, and (b) fits into the general scheme so nicely that the whole multitude of reactions take place harmoniously. Now alter the temperature from 30° to 10°; some of the reactions are affected much by the alteration, some little; chaos must result and the whole machine be thrown out of gear. Therefore a third condition (c) is necessary, namely, that the effect of temperature on the velocities of the reactions must be such that when the temperature is altered the reactions alter in speed harmoniously with one another. This fresh condition naturally limits the number and nature of the chemical processes, which are available. Some chemical operation might be most desirable and could take place at 37° C, but its insertion into the body would be merely vicious if, by refusing to keep pace with its fellows, it brought the mechanism to a standstill at 10° C. By maintaining a uniform temperature condition (c) is dispensed with and the body is free to select what chemical reactions are most suitable under the constant condition without reference to the extent to which they may be affected by alteration of the temperature.

The constancy of the body temperature is maintained by a nice adjustment of the heat loss of the body to the heat formation; for the mechanism of this adjustment see the article on ANIMAL HEAT; here it need only be said that the adjustment is controlled entirely by the nervous system.

Alkalinity of the Blood.—The second property of the internal medium, which is maintained at an approximately constant level, is the alkalinity of the blood. Great prominence has been given to the study of the hydrogen ion concentration of the blood within the last decade. So far as is known the limits within which the alkalinity of the blood may vary are between pH 8.00 and pH 7.00. The work of L. J. Henderson and of Hasselbalch has gone to show that the hydrogen ion concentration depends not upon the actual quantity of acid or alkali present but upon the balance between the two. In a system consisting of carbonic acid and sodium bicarbonate in solution the hydrogen ion concentration

$$cH = K \times \frac{(CO_2)}{(NaHCO_3)}$$

where K is a constant and (CO₂) and (NaHCO₃) the molecular concentrations respectively of carbonic acid and sodium bicarbonate, from which it follows that addition of water to the system will not alter the hydrogen ion concentration.

Every action of the body tends to upset this equilibrium usually in the sense of putting more acid into the blood; muscular exercise for instance adds carbonic and sometimes lactic acid to the circulating medium. How then is the constancy maintained? First by the action of the respiratory system. Increase of the hydrogen ion concentration of the blood leads to increased activity of the respiratory centre, and greater consequent loss of carbonic acid by the body in the breath. Secondly the kidney comes into play and if the concentration of acid in the blood falls alkali is secreted in correspondingly excessive amounts in the urine. Whether the central nervous system controls the output of alkali by the kidney is not known. The actual secreting cells of the kidney are not regarded as being operated by nerves; if therefore the nervous system plays a part it probably does so by controlling the blood supply.

Two examples have been taken for consideration but the reader can from any book on physiology learn of many more, such as the constancy of sugar, of protein, of the calcium-phosphorus ratio of oxygen, of haemoglobin and so forth. Yet these are not absolutely constant in the blood but their variation is within small limits—any considerable deflection from which is in health soon redressed.

The Principle of Maximal Activity.—The most elementary consideration of the architecture of any structure demands some discussion of the sizes of the various components. This question has received little attention from the physiological point of view. The anatomist has tabulated the average dimensions of the various organs but the physiologist has little to say about the reasons which determine these sizes. What little there is on this subject in the literature of physiology is not always to the point. The human body at rest may be compared to a battleship with her fires lit, her ammunition on board and her guns ready for action. Any description of such a ship is, however, given in terms of the energy she puts forth, not when at rest, but when in the fullest possible activity; she has a speed of so many knots, her hitting power is so and so. Only expressed in those terms the dimensions of her various parts become intelligible. So it is with the body, but the difficulties of studying it, or any of its parts, when the maximum of energy is being developed is very great. Some decision must be come to as to the units in which the energy is to be expressed. In the case of a motor car it is expressed in terms of fuel consumed—so many miles to the gallon or to the litre. In the case of man it may also be expressed in litres—litres of oxygen used in consuming the fuel. A man may use as much as four litres of oxygen per minute. This oxygen is of course used in the tissues themselves and therefore must be carried to them. To carry four litres of oxygen efficiently requires probably about 30 litres of blood, therefore 30 litres of blood must pass out of the heart per minute. That fact fixes the size of the aorta and presumably the dimensions of the heart itself. Moreover the blood has to be oxygenated and therefore the dimensions of the lungs are also fixed. Thus the limiting factor in deciding the size of any organ has nothing to do with the events taking place in the resting body but with the maximum activity with which the organ is concerned.

A striking instance is furnished by the splenic vein. Many observers have noted that the splenic vein is large out of proportion to the quantity of blood which usually passes along it. Only recently has it been appreciated that the spleen may hold at a time perhaps one-fifth of the total quantity of blood in the body and that it may contract suddenly expelling possibly $\frac{3}{4}$ of a litre of blood in a few seconds.

What is true of the body as a whole is true of the individual organs

The following table gives the quantity of oxygen which they are capable of using in the dog or cat:—

Voluntary muscle	Nerves cut	0.003	Tone at rest	0.006
			Gentle contraction	0.020
			Active contraction	0.080
			Contracting	0.007
Unstriated muscle	Rest	0.004		
Heart	Slow and feeble contraction		Normal contractions	0.05
		0.007	Very active	0.08
Submaxillary gland	Nerves cut	0.03	Chorda stimulation	0.10
Pancreas	Not secreting	0.03	Secreting after injection of secretin	0.10
Intestines	Not absorbing	0.02	Absorbing peptone	0.03
		0.01		
Liver	Fasting animal	0.01	Fed	0.03
		0.02		0.05
Suprarenal	Normal	0.045	animal	

Thirty years ago physiologists were exercised with the study of the extent to which organs could be cut away without fatal results. Bradford found that the whole of one kidney and the half of the second could be removed in animals without fatal results; it was observed also that the removal of one lung did not appear to be very serious. Men marvelled at the fact that the organs were so unnecessarily large; the standard which they applied was that of rest and not the conditions under which the kidney or the lung was required to function on the greatest scale of which it is capable.

Again it is well known that but a small portion of many of the endocrine organs, if left in the body, will apparently prevent the obvious sequelae of removal of the whole. Why then should the body contain so much more of the organ than appears necessary and why in many cases will the part left grow perhaps to the original size? Presumably because there are moments when the whole organ is required. It is in relation to such that its size is regulated.

The Principle of Mobilized Units.—When an organ becomes active it may be conceived of as doing so in one of two ways (of course the two may be combined). The first is that each unit of which the organ is composed may become heightened in activity; the second is that a single unit is capable of only two states, the active and the resting and that the degree of activity of the organ depends simply on the relative number of active and of resting units which it contains.

For many years the view has been held with regard to the heart, that that organ cannot give a partial contraction; if it contracts at all it gives the full contraction of which it is capable in the condition in which it may be at the moment. This was known as the "all or none" principle. It seemed to indicate that not only did each fibre of the heart muscle contract to its full extent but that when contraction took place, all the fibres in the heart contracted. These are two separate points. For the moment the applicability of the "all or none" principle to the cell will be considered. More recently the principle has been applied both to striated muscle and to nerve. As now conceived each fibre of which a skeletal muscle is composed, contracts to its full extent if it contracts at all, but, unlike the heart, not all the fibres need necessarily contract. Thus the degree of shortening of the muscle will depend upon the number of fibres which are thrown into contraction and not upon the degree of contraction of each.

Very beautiful records have recently been obtained of the impulses which pass up sensory nerve fibres; the same principle holds good. There is a standard impulse which can pass up, that is a property of the nerve. The gradation of the sensation depends upon the number of such which pass along the nerve in a given time, and on the number of nerve fibres which are stimulated simultaneously.

With regard to the applicability of the "all or none" law to secreting cells there is nothing known.

Passing from the consideration of cells to that of organs, one finds that there is frequently a unit between the cell and the organ; the lung consists of alveoli, the same is true of the salivary gland, the kidney consists of tubules, and so forth. Till recently it was assumed that in any one organ all the units are

at work all the time, the activity of each unit being graded in the same degree as that of its fellow. With regard to the kidney Richards and Wearn have shown it to be otherwise, the degree of activity of the organ being the expression of the number of tubules which are in action at any time; for the tubules appear to work in shifts. Haldane has found reasons for suspecting the same principle to operate in the case of the lung. In normal quiet breathing he regards only a portion of the lung as being involved, while when the respiration is more laboured a larger number of alveoli become ventilated. The application of the principle of mobilized units to the lung rests, however, on a less sure basis than its application to the kidney. In the latter case the glomeruli have been seen to go in and out of action, the blood flow through them being at times suspended; in the lung it is a matter of inference.

The most striking instance of the mobilization of units is that of the capillaries as observed by Krogh. In a muscle for instance the capillaries run parallel to the muscle fibres. When the muscle is at rest the majority of these capillaries are entirely closed, no blood whatever running along them. As the muscle becomes more and more active, a correspondingly greater number of capillaries open till the maximum may be many times the number at rest.

Principle of Substantial Reserves.—The principal materials (gross) which the body requires are carbohydrate, fat, protein, water and oxygen. In the case of each the body carries some sort of store beyond that placed at the immediate seat of metabolism.

Carbohydrate.—The blood contains about 7 grams of sugar; that is a little more than half an hour's supply for the whole body. The remaining carbohydrate is stored as glycogen. Of this about half is distributed throughout the tissues generally and may therefore be regarded more or less as being at the seat of its metabolism. The remaining half, amounting to 75 grams or half a day's supply, is to be found in the liver which acts as a store for the body as a whole. Thus the body has a store of about one half day's supply of carbohydrate,—250–300 grams being the figure put down in the standard dietaries for daily consumption. That is not to say that after 12 hours' abstinence there is no carbohydrate left in the body, but it means that the organism is gradually falling back on something else.

Fat is stored on a much greater scale than carbohydrate. The amount of fat stored in the body naturally differs in different individuals within very wide limits, but it has been established as the result of numerous experiments that a portion of the fat laid down in the body is directly derived from what is eaten. Thus if some oil of low melting point be taken in the food it may at once be recognised as entering into the store of fat reserved in the body.

Whilst it is quite clear that carbohydrate eaten may be stored as carbohydrate and used as such, and while it is equally clear that fat eaten may be stored as fat, the more arresting question arises—Is not much of the fat of the body essentially a store of carbohydrate? In order to establish this thesis it would be necessary to prove (1) that carbohydrate taken may be laid on as fat; and (2) that when carbohydrate is needed fat may be reconverted into carbohydrate or at all events used as carbohydrate is used. That carbohydrate taken in the food may be laid on as fat was proved by the classical experiment of Lawes and Gilbert. In this two young pigs were chosen from the same litter and while one was killed and analysed, the other was fed on "grains," a diet which is practically free from fat, consisting of protein and carbohydrate. The amount of fat put on by the growing pig was greater than could be accounted for on the assumption that it was formed from protein. Indeed since the days of Lawes and Gilbert it has become increasingly doubtful whether fat can be formed from protein on any considerable scale in the mammal.

To pass to the possible reconversion of fat into carbohydrate,—that is at the moment a subject on which the highest authorities are in controversy. It may be that when muscle is in want of carbohydrate and cannot get any from the usual sources fat is reconverted, but it may not be so. If it is not, however, there appears to be but one possibility, namely, that the muscle can

derive energy from fat without its passing through the carbohydrate stage. In either case the muscle would be availing itself of fat entering the body as carbohydrate. Therefore the fat would be a potential, if not an actual reserve of carbohydrate.

Oxygen.—Oxygen is stored to some extent in the body. At one time the conception was held that oxygen was stored actually in the tissues as so-called "intra-molecular" oxygen. That conception was founded on two others—(1) that a frog's muscle could contract in an atmosphere free from oxygen; and (2) that the contraction was essentially an oxidation. Now the idea of "intra-molecular oxygen" has been given up and we must look for no further store of oxygen than is to be found in the haemoglobin of the body. What is to be found there and in the lungs suffices to preserve consciousness for a few, perhaps two or three, minutes, and life for a somewhat longer time. The blood on the average is circulated round the body (at rest) rather more than once per minute and not so much as twice; on that circuit about one third of its oxygen is taken out. If therefore one assumes that all the blood goes round the body in 45 seconds and that there is enough oxygen in the blood for three circuits that would give oxygen enough for 13; seconds. In addition in such a case as that of drowning there is reserved oxygen in the lungs to the extent of what would supply the body for about two to three minutes. But if the body has no great store of oxygen on which to fall back, it has a considerable store of the material which transports oxygen and that is probably much more important. So far as is known about 80 per cent of the haemoglobin of the body is in circulation; the rest is stored, some in the spleen, some probably in the red marrow and the rest in situations as yet not fully explored.

The Principle of Specific Chemical Response.—There are a number of relatively simple chemical substances, any of which if injected into the body cause the body to produce some other substance which unites with and in a sense neutralises it. To give three examples:—If a fatty acid be administered to the alimentary canal, the acid will be absorbed by the villi, the cells of which will produce glycerine and the result will be a neutral fat. If on the other hand benzoic acid be administered it will get so far as the kidney and there the kidney cells will produce glycine, turning it into hippuric acid. Lactic acid similarly if thrust into the general circulation will be excreted as ammonium lactate, the ammonia being produced not by the cells of the body generally but by those, or certain of those, in the kidney. We have now arrived at the confines of the great subject of immunity—and perhaps outside the region of the present article.

The Principle of Dual Control.—The body has two ways of doing a great many things. Examples of this principle are so numerous as to be found in almost any system of the body. To take the point at which two of the most important systems of the body—the nervous and the respiratory systems—touch, let us consider the nervous control of respiration.

The essence of respiration is a rhythmic outflow of alternate inspiratory and expiratory impulses from the brain to the muscles concerned. That rhythm is probably, but not certainly, inherent in the brain itself, but it is regulated by influences which play upon the brain. These influences fall into two general categories—those which arrive along the nervous paths from the lungs and elsewhere and those which are borne to the brain in the blood stream.

An increase of total respiration may then take place in either of two ways—(a) many forms of irritation in the lung produce an increased total ventilation which is abolished by cutting the vagi and which may therefore be regarded as being due to special stimuli passing up along these nerves, (b) increase of carbonic acid in the blood even in the absence of nervous stimulation will so act upon the respiratory centre as to increase the total ventilation. During muscular exercise both the nervous and the chemical factors come into play; the nervous is the first to be initiated and therefore it may be regarded as the most sensitive; but even were it not involved a sufficient regulation could probably be carried out by the carbonic acid in the blood.

The respiratory centre furnishes another example. This time

it is a combination of a nervous with a physical regulation. The facts are principally based on the observations of Professor Richet. If a dog lies down in the sun he will very shortly commence to pant in rapid, shallow respirations passing air over his tongue and through his respiratory passages. According to Professor Richet this tachypnoea is associated with an actual lowering of the body temperature and is due to stimuli from the warm skin reaching the respiratory centre via the sensory nerves. But even did not this nervous regulation of the body temperature take place another would supervene of perhaps a cruder character, for as soon as the body temperature began to rise, the warmer blood reaching the respiratory centre would itself produce an increased ventilation. Here again the nervous effect is the first to be invoked and presumably the more delicate.

The digestive system abounds with examples of duality. Of the three principal forms of food which are digested, carbohydrates, proteins and fats, the organs for the secretion of the digestive ferments are in all cases reduplicated. Starch is turned into sugar both by the saliva and by the pancreas, protein is broken down to the peptone stage both by the pepsin of the stomach and the trypsin of the pancreas, while to quote Leathes "two fat splitting enzymes are present in the intestinal contents, one being provided by the pancreatic juice and the other by the intestinal juice. . . . The action of the intestinal juice is however overshadowed by that of the pancreatic juice."

Not only are the ferments which effect digestion duplicated but there is a measure of duplication about the mechanisms responsible for their secretion. The processes of the alimentary canal are actuated, some by nervous stimuli, some by chemical, but in large measure by both. The secretion of saliva is entirely actuated by nervous stimuli; gastric juice is secreted largely as a result of nervous stimuli, but its flow is maintained by chemical bodies. In the secretion of pancreatic juice chemical stimuli play the more prominent part, nervous stimuli not however being entirely absent; whilst the secretion of the intestine is—so far as is known—due entirely to hormones. If the whole process from end to end be reviewed, some of the statements made about the respiratory centre are applicable. The process of digestion is initiated by nervous and maintained by chemical stimuli. As Dr. Anrep has pointed out, the further the food gets from the surface of the body, the less is it under the influence of the nervous, the more is it under the influence of the hormonal system.

The vascular system no less than the alimentary is subject to both hormones and to nervous stimuli, inasmuch as nearly all its parts are innervated by the sympathetic system (for adrenaline acts on the nerve endings of that system). Thus Florey has shown in the intestine of the dog, that a sudden sound will cause the mucous membrane to pale in a matter of a few seconds. If the nerves to this piece of intestine be severed the noise will still cause the intestine to pale, but after a much longer time—in about a quarter of a minute. The paling is in each case due to constriction of the small vessels. In the first, case the constriction is initiated by nervous stimuli reaching the mucosa along the branches of the splanchnic supply; in the second the blanching is due presumably to adrenaline secretion. The case is not however entirely parallel to that of the nervous and chemical government of the pancreas inasmuch as the adrenaline secretion is itself due to nervous stimulation, so that the reduplication is merely a reduplication of the paths by which the nervous system can control the calibre of the vessels.

What applies to the blood vessels applies, so far as the relative rôles of the nervous and the endocrine systems are concerned, to many other structures in the body which will at once occur to the reader. Many organs have not only a chemical and a nervous mechanism but also a double nervous supply. That however will be treated later in this article under Antagonistic Nerves.

Two organs in the mammals stand out as having no substitutes, the lungs and the generative organs, and in each case the fact is a little interesting because lower down in the animal kingdom that simplicity does not exist. Apart from the existence of gills, in the frog there is a cutaneous respiration so that it, even

in air, has two alternatives. As regards reproduction of course the most primitive form is simply by fission. Reproduction by fission exists in many forms of life collaterally with sexual reproduction, but in all the higher types of the animal kingdom it has been given up.

The Principle of Antagonistic Nerves.—There are numerous places in the body in which the actual condition of the organ at any moment is obtained by the balancing of antagonistic influences upon it. Four examples may be given.

(1) The rate of the heart beat is regulated by two nerves, one of which, the vagus, when stimulated, makes the heart go slower, while the other, the sympathetic, drives it faster. Normally its pace is neither so fast nor so slow as that of which it is capable, a fact to be accounted for by the balance of influences passing down the two nerves; if this balance alters the rate changes.

(2) The diameter of the pupil of the eye is under the control of two nerves, one of which if stimulated dilates the pupil while the other constricts it; the actual size depends upon the relative influence of the two at any one moment. (3) The movements of the joints (say of the thigh joint) in walking are obtained by the balancing of the muscles which move the joint. It is not merely that alternately one set of muscles comes into action whilst the antagonistic set goes out of action: but each set is the whole time in a greater or less degree of tone. The whole action of the thigh depends upon the relative degree of the various muscles which exert an antagonistic action. (4) In the highest animals delicate manual movements have been secured by the antagonism of the thumb to the fingers, especially to the first finger.

The four examples cited, if examined, show little similarity in the mechanism by which the antagonism is produced. In the first the nerves act presumably in the same structure in the heart tissue. In the pupil the two sets of nerves act on different muscles. These do not pull directly against one another like men in a tug of war; the muscle which tends to close the pupil is a ring, that which tends to open it is radial. In the thigh you have definite groups of muscles pitted against one another and pulling the bone in opposite directions, while in the finger and thumb there are actually different organs.

Thirty years ago thought was focussed on antagonistic nerves because they were supposed to initiate opposite phases of protoplasmic activity in the organs which they supplied. All living matter was conceived as capable of anabolism (building up) and katabolism (breaking down); the slowing of the heart due to vagus stimulation was supposedly the expression of accentuated anabolic activity, the quickening of the heart due to sympathetic stimulation was held to indicate increased katabolism. Of the known cases of antagonistic nerves there are so few in which the two sets of fibres end in the same tissue that their connection with anabolic and katabolic activity has passed out of the picture.

It seems likely that their principal interest lies in the fact that by use of such antagonisms nature has built up a body capable of potentialities which it (the body) would not otherwise possess. By the balancing of the finger against the thumb more accurate and more delicate movements can be made than those of which either finger or thumb separately is capable. By the balancing of the thigh muscles against one another an accuracy of poise is secured which would not otherwise exist. The same is clearly true of the pupil, and had we the necessary discernment we could probably see the application of the general principle involved to the heart and blood vessels.

The Principle of Integrative Adaptation.—When the body is subjected to such adverse conditions that constancy of the composition of the blood cannot be maintained, the lack or excess of some one constituent may be of considerable gravity. In such circumstances some form of adaptation frequently takes place. This adaptation consists in an alteration in quite a number of factors each of which changes only a little though when the whole series of changes are integrated the net result is a very large degree of adaptation to the new environment. In such cases the body is not restored to its original degree of efficiency, but it has moved a considerable distance in that direction.

Examples may be drawn from the response of the body to

exercise, to high altitudes, to anaemia and so forth, for which the articles on ANOXAEMIA, MUSCULAR EXERCISE, VASCULAR SYSTEM and ANAEMIA may be consulted, (J. BAR.)

PI, the Greek letter π , used to denote the ratio of the circumference of a circle to its diameter: 3.14159

PIACENZA (Lat. Placentia), a town and episcopal see of Emilia, Italy, the capital of the province of Piacenza, 42½ mi. S.E. of Milan and 91 mi. N.W. of Bologna by rail. Pop. (1936) 49,527 (town), 54,210 (commune). It lies on the Lombard plain, 217 ft. above sea-level, near the Po, which here is crossed by road and railway bridges each about 600 yd. long, just below the confluence of the Trebia. It is still surrounded by walls with bastions and fosse in a circuit of 4 miles. The cathedral was erected between 1122 and 1233, in the Lombard Romanesque style. The campanile is 223 ft. high. The entire edifice was restored after 1898, and the frescoes by Guercino, Lodovico Garacci and Procaccini seem inappropriate to its severe style. In Sant' Antonino the deputies of the Lombard league swore to the conditions of peace ratified in 1183 at Constance. San Francesco is a Gothic edifice begun by the Franciscans in 1278. S. Savino, a Romanesque building of A.D. 903 (rebuilt in 1107 and restored in 1903) contains a mosaic pavement with curious representations, including one of a game of chess. S. Sisto (1499) once contained Raphael's Sistine Madonna, now in Dresden, sold in 1754 to Frederick Augustus III. Its place is occupied by a copy by Avanzini, and there are also several good intarsias by Bartolomeo da Busseto. Of the secular buildings the most interesting is the Palazzo Comunale, begun in 1281, built in marble and brick, with beautiful windows, one of the finest buildings of its kind in Italy. The Palazzo dei Tribunali and the Palazzo degli Scoti are early Renaissance brick buildings with terra-cotta decorations. The huge Farnese palace was begun after Vignola's designs by Margaret of Austria in 1558, but it was never completed, and since 1800 it has been used as barracks. The town has a motor car factory. It is an important agricultural centre. Petroleum wells have been bored hereabouts.

Piacenza was made a Roman colony in 218 B.C., in which year it afforded protection to the remains of the Roman army after the battle of the Trebia (*q.v.*). In 205 it withstood a siege by Hasdrubal. Five years later the Gauls burned it; and in 190 it was recruited with 3,000 families. In 187 it was connected with Ariminum and the south by the construction of the Via Aemilia. Later on it became a very important road centre; the continuation northwards of the Via Aemilia towards Milan, with a branch to Ticinum, crossed the Po there, and the Via Postumia from Cremona to Dertona and Genoa passed through it. Later still Augustus reconstructed the road from Dertona to Vada, and into Gallia Narbonensis, and gave it the name of Julia Augusta from Placentia onwards. The rectangular arrangement of the streets in the centre of the town, through which passes the Via Aemilia, is a survival from Roman times. Placentia is mentioned frequently as an important military point in Roman times. It was one of the leading members of the Lombard League. In 1447 the city was captured and sacked by Francesco Sforza. Having been occupied by the papal forces in 1512, it was in 1545 united with Parma (*q.v.*) to form an hereditary duchy for Pierluigi Farnese, nephew of Paul III. In 1796 it was occupied by the French. In 1848 Piacenza was the first town of Lombardy to join Piedmont, but was reoccupied by the Austrians till 1859.

PIANOFORTE. The group of keyed stringed musical instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music. During the 10th century the "organum" arose, an elemen-

tary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it, and the organ (*q.v.*), the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. About the same time arose a large stringed instrument, the organistrum, the parent of the now obsolete hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St. George de Boscherville, one of the strings was manipulated by means of a row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum.

In the 11th century (the epoch of Guido of Arezzo [*q.v.*], to whom the beginning of musical notation is attributed), the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely of demonstrating the proportionate relations of the intervals, but also of initiating pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex monochords, which were constructed with scales so that four lines indicated authentic and the four plagal tones. This arrangement found great acceptance, for Aribo, writing about fifty years after Guido, says that few monochords were to be found without it. Aribo strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a *caprea* (wild goat). Jean de Muris (*Musica speculativa*, 1323) describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St. Mary's church, Shrewsbury. The latest date to which this figure may be attributed is 1460.

In the Weimar *Wunderbuch*, a MS. dated 1440 with pen and ink miniatures is given a "clavichordium" having 8 short and apparently 16 long keys. The artist has drawn 12 strings in a rectangular case, but no tangents are visible. A keyboard of balanced keys existed in the little portable organ known as the regal, so often represented in old carvings, paintings and stained windows. Vitruvius, *De architectura*, lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in *The Pneumatics of Hero of Alexandria*, translated by Bennet Woodcroft (London, 1851).

The name of regal was derived from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Atholl, and it bears the very late date of 1630. The Brussels regal may be as modern. (See Victor C. Mahillon, *Catalogue Descriptif* [1880], I. p. 320, p. 454.) We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the sub-

FIG. 1.—PRIMITIVE CLAVICHORD (BEFORE 1460); EARLIEST EXISTING REPRESENTATION OF A KEYED STRINGED INSTRUMENT, FROM ST. MARY'S, SHREWSBURY

stitution of tangents (fixed in the ends of the balanced keys) for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. Ed. van der Straeten (*La Musique aux Pays Bas*, i. 278) reproduces a so-called clavichord of the 15th century from a MS. in the public library at Ghent. The treatise is anonymous, but other treatises in the same MS. bear dates 1503 and 1504. In the Weimar *Wunderbuch* is a pen-and-ink sketch of the "clavicimbalum" placed upon a table, in which we recognize the outline of the harpsichord, but on a smaller scale.

The earliest known record of the clavichord occurs in some rules of the minnesingers, dated 1404, preserved at Vienna. (See Ambros, *Geschichte der Musik* [1892], ii. 226.) The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicimbalum—the keyed cymbal, *cembalo* (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite mediaeval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer.

There were two forms of the psaltery: (1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous *Trionfo della Morte* in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but according to Mersenne (*L'Harmonie universelle* [Paris, 1636], livre iii., p. 107), the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicimbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia. In 1472, chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St. Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood, as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic

FIG. 2.—DIATONIC CLAVICHORD KEYBOARD (GUIDO'S SCALE) FROM VIRDUNG, BEFORE 1511, SHOWING THE SHORT KEYS B FLAT

organs with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getuscht und ausgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass staff to G above the treble. But Virdung tells

us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical genera of the Greeks—the diatonic, chromatic and enharmonic. But the last-named was not attained until equal temperament tuning was developed by J. S. Bach. Virdung gives woodcuts of the clavi-

FIG. 3.—VIRDUNG'S CLAVICHORDIUM (1511); FACSIMILE WOODCUT, REVERSED TO CORRECT THE KEYBOARD

chordium, the virginal, the clavicimbalum and the clavicitherium. We reproduce three of them (figs. 3, 6 and 8), omitting the virginal as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive praxis musicae*, Strasbourg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the clavicitherium, are transposed, another cause of error.

Still commonly known as monochord, Virdung's clavichord was really a box of monochords, all the strings being of the same length. We observe in this drawing (fig. 3) the short sound-board, which always remained a peculiarity of the clavichord, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of incidence for the tangents against the strings the keys were splayed, an expedient further rendered necessary by the "fretting"—three tangents being placed to give three different notes from each single group of strings tuned in unison. In the drawing the strings are merely indicated. The German for fret is *Bund*, and such a clavichord, in that language, is known as a "gebundenes Clavichord" both fret (to

FIG. 4.—MANICORDO (CLAVICHORD) D'LEONORA DI MONTALVO (1659); KRAUS MUSEUM, FLORENCE

rub) and *Bund* (from *binden*, to bind) having been taken over from the lute or viol. The French and Italians employ "touche" and "tasto" (touch). Praetorius who wrote a hundred years later than Virdung, says two, three and four tangents were thus employed in stopping.

Clavichords were made with double fretting up to about the year 1700—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach

was now able to produce, in 1722, *Das wohltemperirte Clavier*, his famous collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned to what is now known as "equal temperament."

The oldest clavichord, here called manicordo (as French *manicorde*, from monochord), known to exist is that shown in fig. 4. The lowest octave is here already "bundfrei" or fret-free. The strings are no longer of equal length, and there are three bridges, divisions of the one bridge, in different positions on the sound-

FIG. 5.—CLAVICHORD TANGENT Showing position when front of keyboard is depressed; the tangent rises into contact with the strings and forms the end-point of the speaking length. The back string is kept from vibrating by means of the "Listing" cloth

board. Mersenne's "manicorde" (*Harmonie Universelle*, Paris, 1636, p. 115), shown in an engraving in that work, has the strings still nearly of equal length. but the sound-board bridge is divided into five. The fretted clavichords made in Germany in the last years of the 17th century have the curved sound-board bridge, like a spinet. In the clavichord the tangents always formed the second bridge, deciding the pitch, besides acting as the sound exciters (fig. 5). The common damper to all the strings was a "list" of cloth, interwoven behind the tangents. As the tangents quitted the strings the cloth immediately stopped all vibration. As regards compass Handel's clavichord now in the museum at Maidstone (an Italian instrument dated 1726, and not fretted), has a compass of 33 octaves (F to A).

The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin, but it remained longest in use in Germany—until even the beginning of the 19th century.

The next instrument described by Virdung is the virginal (& *ginalis*, proper for a girl), a parallelogram in shape, having the same projecting keyboard and compass of keys as the clavichordium. Here we trace derivation from the psaltery, in that the sound-board covers the entire inner surface of the instrument

FIG. 6.—VIRDUNG'S CLAVICIMBALUM (SPINET), 1511; REVERSED FACSIMILE WOODCUT

and the disposition of the strings is triangular. The virginal in Virdung's drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavicimbalum, this is rectified, and the drawing, reversed on account of the keyboard, can be accepted as roughly representing the instrument so called (fig. 6). There would be no difference between the clavicimbalum and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinetta," a name

unnoticed by Virdung or by his countryman Arnold Schlick, who, in the same year 1511, published his *Spiegel der Orgelmacher* (Organ-builders' Mirror), and named the clavichordium and clavicimbalum as familiar instruments. In the first place, the keyboard, beginning apparently with B natural, instead of F, makes the clavicimbalum smaller than the virginal, the strings in this arrangement being shorter; in the next place it is almost certain that the Italian spinet compass, beginning apparently upon a semitone, is identical with a "short measure" or "short octave" organ compass, a very old keyboard arrangement, by which the first three notes while appearing to be B, C and C sharp were tuned to G, C and A. The origin of this may be deduced from the psaltery and many representations of the regal, and its object appears to have been to obtain dominant basses for cadences, harmonious closes having early been sought for as giving pleasure to the ear.

Authority for this practice is to be found in Mersenne, who, in 1636, expressly describes it as occurring in his own spinet (*espinette*). We read (*Harmonie Universelle*, Paris, 1636, liv. 3, p. 107)—"Its longest string is little more than a foot in length between the two bridges. It has only thirty-one keys [marches] in its keyboard, and as many strings over its sound-board, so that there are five keys hidden [he now refers to the illustration] on account of the perspective—that is to say, three diatonic and two chromatic, of which the first is cut into two; but these sharps serve to go down to the third and fourth below the first step, C sol [tenor clef C], in order to go as far as the third octave, for the eighteen principal steps make but an eighteenth, that is to say, a fourth more than two octaves." Mersenne's statement sufficiently proves, first, the use in spinets as well as in organs of what we now call "short measure," and, secondly, the object of divided sharps at the lower end of the keyboard to gain lower notes.

As regards the kind of plectra earliest used we have no evidence. The little crow-quill points project from centred tongues in uprights of wood known as "jacks" (fig. j), which also carry the dampers, and rising by the depression of the keys in front, the quills set the strings vibrating as they pluck them in passing. J. C. Scaliger in *Poetices libri septem* (1561, p. 51. c. 1.) states that the clavicimbalum and harpichordium of his boyhood were called spinets on account of those quill points (ab *illis mucronibus*), and attributes the introduction of the name "spinetta" to them from *spina*, a thorn, the meaning being extended to any small pointed object such as a quill. We will leave "harpichordium" for the present, but the early identity of "clavicimbalum" and "spinetta" is certainly proved, Scaliger's etymology remained unquestioned until Signor Ponsichi of Florence discovered another, but less acceptable derivation. He found in a rare book entitled *Conclusioni nel suono dell' organo, di D. Adriano Banchieri* (Bologna, 1608), the following passage, which translated reads: "Spinetta was thus named from the inventor of that oblong form, who was one Maestro Giovanni Spinetti, a Venetian; and I have seen one of those instruments, in the possession of Francesco Stivori, organist of the magnificent community of Montagnana, within

which was this inscription—*Joannes Spinetus Venetus fecit, A.D. 1503.*" Scaliger's and Banchieri's statements may be combined, as there is no discrepancy of dates, or we may rely upon whichever seems to us to have the greater authority, always bearing in mind that neither invalidates the other. In France the word "épinette" still stands for both "spinet" and "chicken-house" which seems to strengthen the first-named theory. A spinet dated 1490 was shown at Bologna in 1888; another old spinet in the Conservatoire, Paris, is a pentagonal instrument made by Francesco di Portalupis at Verona, 1523.

The Milanese Rossi were famous spinet-makers, and have been accredited (*La Nobiltà di Milano*, 1595) with the recessing of the

keyboard, which had previously entirely projected; by this recessing a greater width was obtained for the sound-board. The spinets by Annibale Rosso at South Kensington, dated respectively 1555 and 1577, show this alteration, and may be compared with the older and purer form of one, dated 1568, by Marco Jadra (also known as Marco "dalle spinette," or "dai cembali"). The apparent compass of the keyboard in Italy generally exceeded four octaves by a semitone, E to F; but we may regard the lowest natural key as usually C, and the lowest sharp key as usually D, in these instruments, according to "short measure."

FIG. 8.—VIRDUNG'S CLAVICYTHERIUM (UPRIGHT HARPSICHORD), 1511; REVERSED FACSIMILE WOOD-CUT

equivalent to the contemporary Italian clavicordo and Flemish *clavisingel*. From the latter we arrive at the French clavecin the spinet being simply a "petit clavecin."

Mersenne (*op. cit.*, liv. iii., p. 158) gives three sizes for spinets—one 2½ ft. wide, tuned to the octave of the "ton de chapelle" (a half tone above the present English medium pitch), one of 3½ ft. tuned to the fourth below, and one of 5 ft. tuned to the octave below the first, the last being therefore tuned in unison to the chapel pitch. The octave spinet, of trapeze form, was known in Italy as "ottavina" or "spinetta di serenata." It had a less compass of keys than the larger instrument, being apparently three and two-third octaves, E to C—which by the "short measure" would be four octaves, C to C. These little spinets were placed upon the larger ones in performance and used to heighten the

FIG. 7.—SPINET "JACK" Showing the quill which twangs the string on its upward journey, but, being hinged, slides quietly past on its return

FIG. 9.—CRISTOFORI'S ESCAPEMENT ACTION (1720) The hinged lever, when struck by the jack, transmits the blow to the butt, thus having the effect of throwing the hammer towards the strings

brilliant effect. In the double rectangular clavisangel of the Netherlands, in which there was a movable octave instrument, we recognize a similar intention. There is a fine spinet of this kind at Nuremberg. Praetorius illustrates the Italian spinet by a form known as the "spinetta traversa," an approach towards the harpsichord, the tuning pins being immediately over the keyboard. This transposed spinet, more powerful than the old trapeze one, became fashionable in England after the Restoration, when Haward, Keene, Slade, Player, Baudin, the Hitchcocks, Mahoon, Haxby, the Harrir family, and others made such "spinets" during a period for which we have dates from 1664 to 1784. Pepys

bought his "Espinette" from Charles Haward for £5, July 13, 1664. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the naturals.

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della musica antica e moderna*, Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp, proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as derived from the harp and psaltery respectively.

The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo and clavecin. Much later, after the restoration of the Stuarts, "harpichord" was accepted and naturalized in England as harpsichord, which we will define as the long instrument with quills, shaped like a modern grand piano. We can point out no long instrument of this kind so old as the Roman cembalo at South Kensington. The outer case is of finely tooled leather. It has a compass of nearly four octaves, E to D, and the natural keys are of boxwood.

The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este by Count Valdrighi of Modena (see Van der Straeten, vi., 122), we are disposed to regard, not as an anticipation of Cristofori's subsequent invention of the pianoforte, but as an ordinary cembalo with power to shift by a stop, from two unisons (forte) to one string (piano), at that time a Flemish practice, and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition.

About the year 1600, when accompaniment was invented for monody, large cembali were made for the orchestras to bring out the bass part, the performer standing to play. Such an instrument was called "archicembalo," a name also applied to a large cembalo, made by Vito Trasuntino, a Venetian, in 1606, intended by thirty-one keys in each of its four octaves, to restore the three genera of the ancient Greeks.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century. We find them imported into England. The following citations, quoted by Rimbault in his *History of the Pianoforte*, are from the privy purse expenses of King Henry VIII.

"1530 (April). Item the vj daye paied to William Lewes for ii payer of virginalles in one coffer with iiij stoppes brought to Grenewiche iii. li. And for ii payer of virginalles in one coffer brought to the More other iii. li."

Now the second instrument may be explained ("virginals" meaning any quilled instrument) as a double spinet, like that at Nuremberg by Martin van der Beest, the octave division being movable. But the first cannot be so explained; the four stops can only belong to a harpsichord, and the two pair instrument to a double-manual. Again from the inventory after the king's death (see *Brit. Mus. Harl. MS. 1419*) fol. 247—

"Two fair pair of new long Virginalls made harp-fashion of Cipres, with keys of ivory, having the King's Arms crowned and supported by his Grace's beastes within a garter gilt, standing over the keys."

This is probably another double keyboard harpsichord. We read

FIG. 10.—CRISTOFORI'S PIANO E FORTE (1726); KRAUS MUSEUM, FLORENCE

in an inventory of the furniture of Warwick Castle, 1584, "a faire paire of double virginalles," and in the Hengrave inventory, 1603, "one great payre of double virginalles." Hans Ruckers, the great clavisngel maker of Antwerp, lived too late to have invented the double keyboard and stops, evident adaptations from the organ, and the octave string was already in use when he began his work. Until the last harpsichord was made by Joseph Kirkman, in 1798, scarcely an instrument of the kind was constructed, except in Italy, without the octaves. The harpsichord as known throughout the 18th century, with "piano" upper and "forte" lower keyboard, was the invention of Hans Ruckers's grandson, Jean Ruckers's nephew, Jan Couchet, about 1640. Before that time the double keyboards in Flemish harpsichords were merely a transposing expedient, to change the pitch a fourth, from plagal to authentic and vice versa, while using the same groups of keys.

After the Antwerp make declined, London became pre-eminent for harpsichords—the representative makers being Jacob Kirkmann and Burckhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirkmann continued through marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time, by which Haendel became Handel, and Schmidt Smith, Kirkmann dropped his final *n* and Tschudi became Shudi, but he resumed the full spelling in the facies of the splendid harpsichords he made in 1766 for Frederick the Great, which are still preserved at Potsdam. By these great makers the harpsichord became a larger, heavier-strung and more powerful instrument, and fancy stops were added to vary the tone effects. To the three shifting registers of jacks were added the "lute," the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge, and the "harp," a muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used, the left-hand one a combination of a unison and lute.

The right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius, to whom also the harp stop may be rightly attributed. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (?Haward) as early as 1676, as we learn from Mace's *Musick's Monument*, p. 235. The French makers preferred a kind of knee-pedal arrangement, known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and becoming in England a favourite addition to harpsichords, was early transferred to the organ, replacing the rude "nag's-head" swell.

To keep his collection of musical instruments in playing order Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*, a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte*. We learn from it that in 1709 Cristofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer-butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori, dated respectively 1720 and

1726, which show a much improved construction, for the whole of an essential piano movement is there. The earlier instrument (now in the Metropolitan Museum, New York) has undergone considerable restoration, but the 1726 one, which is in the Kraus Museum at Florence, retains the original leather hammer-heads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have

FIG. 11.—SILBERMANN FORTE PIANO (1746), STADTSCHLOSS, POTSDAM

the "check" (Ital. *paramartello*), which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings.

Thicker stringing, to withstand even Cristofori's light hammers, demanded in its turn a stronger framing than the harpsichord had needed. Accordingly to make his structure firm Cristofori considerably increased the strength of the block which holds the tuning-pins, and as he could not do so without materially adding to its thickness, he adopted the bold expedient of inverting it; driving his wrest-pins, harp-fashion, through it, so that tuning was affected at their upper, while the wires were attached to their lower, ends. Then, to guarantee the security of the case, he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils, but did not found a school of Italian pianoforte-making. The 1711 essay of Scipione Maffei was translated into German, in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavichord maker (see Dr. Oscar Paul's *Geschichte des Claviers*, Leipzig, 1868). Incited by this publication, and perhaps by having seen in Dresden one of Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz., that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it.

Whatever Silbermann's first experiments were based upon, he ultimately adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys and the style of joinery of the case. In the Silbermann grand pianofortes at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch

prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank and action complete. Fig. 11 represents the instrument on which J. S. Bach played in the Stadtschloss, Potsdam.

It has been repeatedly stated in Germany that Frederici, of Gera in Saxony, an organ builder and musical instrument maker, invented the square or table-shaped piano, the "fort bien," as he is said to have called it, about 1758-60. No square piano by this maker is forthcoming, though an "upright grand" piano, made by Domenico del Mela in 1739, with an action adapted from Cristofori's has been discovered by Signor Ponicchi of Florence. Victor

FIG. 13.—SCHROETER'S MODEL FOR AN ACTION (1721); SHOWING THE KEY READY TO LIFT THE HOPPER, AND MAKE IT STRIKE THE HAMMER SHANK

Mahillon of Brussels, however, acquired a Frederici "upright grand" piano, dated 1745. In Frederici's upright grand action (fig. 12) we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg; a fact which needs further elucidation. We note here the earliest example of the leather hinge, afterwards so common in piano actions. An attempted combination of harpsichord and pianoforte appears very early. The English poet Mason, the friend of Gray, bought such an instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

It was only under date of 1763 that Schroeter published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marburg's *Kritische Briefe* (Berlin, 1764). Now, immediately after, Johann Zumpe, a German in London, who had been one of Shudi's workmen introduced (there is some tradition that Mason had to do with the invention of it) a "square" piano, which was destined to become the most popular domestic instrument. Zumpe was in fact not the inventor of the square piano, which appears to have been well known in Germany before his date, a discovery made by Mr. George Rose. In Paul de Wit's Musical Instrument Museum—formerly in Leipzig, afterwards transferred to Cologne—there is a small square piano by Hildebrandt 27 in. long 10 in. wide and 4½ in. high, having a contracted keyboard of 3 octaves and 2 notes. The action of this small instrument is practically identical in every

FIG. 12.—FREDERICI'S UPRIGHT GRAND PIANO ACTION (1745)

FIG. 14.—ZUMPE'S SQUARE PIANO ACTION (1765); GIVING A DIRECT BLOW WITH THE JACK NEAR THE BUTT END OF THE HAMMER

detail with that of the square pianofortes made much later by Zumpe (Paul de Wit, *Katalog des musikhistorischen Museums*, Leipzig, 1903. No. 55, illustration, p. 38). Inside is inscribed: "Friedrich Hildebrandt, Instrumentenmacher in Leipzig, Quer-gasse," with four figures almost illegible. Paul de Wit refers the instrument to the middle of the 18th century. It has all the

appearance of being a reduced copy of a well-established type, differing very little from the later models.

Burney tells us all about Zumpe; and his instruments still existing would fix the date of the first at about 1765. Fétis narrates, however, that he began the study of the piano on a square piano made by Zumpe in 1762. In this simple action (fig. 14) we have the nearest approach to a realization of Schroeter's idea. It will be noted that Schroeter's damper (fig. 13) would stop all vibration at once. This defect is met by Zumpe's "mopstick" damper.

Another piano action had, however, come into use about that time or even earlier in Germany. The discovery of it in the

FIG. 15.—EARLIEST KNOWN PIANO ACTION ON THE GERMAN PRINCIPLE OF ESCAPEMENT, WHEREBY THE PIVOT RISES WITH THE KEY AND THROWS THE BUTT AGAINST A FIRM RESISTANCE

simplest form is to be attributed to V. C. Mahillon, who found it in a square piano belonging to Henri Gosselin, painter of Brussels (fig. 19). The principle of this action is that which was later perfected by the addition of a good escapement by Stein of Augsburg, and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and permit of its transformation into a square piano. It will be observed that the hammer is, as compared with other actions, reversed, and its pivot rises with the key, necessitating a fixed rail against which the hammer butt strikes. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind. He had found the instrument that for the rest of his short life replaced the harpsichord. V. C. Mahillon secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action (fig. 16), two unisons, and the knee pedal.

Mozart's own grand piano, preserved at Salzburg, and the two grand pianos (the latest dated 1790) by Huhn of Berlin, preserved

FIG. 16.—STEIN'S ACTION AFTERWARDS CALLED VIENNESE (1780)
The pivot of the hammer rises with the key and the blow is caused by the end of the hammer coming into contact with the escapement

at Berlin and Charlottenburg, follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as celeste, which no doubt Stein had also. The wrest-plank is not inverted; nor is there any imitation of Cristofori. Stein's instrument was accepted as a model in Berlin as well as Vienna, to which city his business was transferred in 1794 by his daughter Nanette, known as an accomplished pianist and friend of Beethoven, who at that time used Stein's pianos. Streicher, a pianist, who married Nanette, further improved the

Viennese instrument, famous for its lightness of touch.

We will quit the early German piano with an illustration (fig. 17) of a square piano action in an instrument made by Johann Gottlob Wagner of Dresden in 1783, and embodying the Cristofori principle rather than the Viennese.

Burney, who lived through the period of the displacement of the harpsichord by the pianoforte, is the only authority to whom

FIG. 17.—GERMAN SQUARE ACTION (1783); ESCAPEMENT IS EFFECTED AT THE POINT WHERE THE HOPPER FALLS INTO THE NOTCH. PIANO BY WAGNER, DRESDEN

we can refer as to the introduction of the latter instrument into England. He tells us without giving the exact date that the first hammer harpsichord that came to England was made by an English monk at Rome, a Father Wood, for an English gentleman, Samuel Crisp of Chesington; the tone of this instrument was superior to that produced by quills, with the advantage of piano and forte expression so that, although the touch and mechanism were imperfect, yet in a slow movement like the "Dead March" in Saul it excited wonder and delight. Fulke Greville afterwards bought this instrument for 100 guineas, and it remained unique in England for several years, until Plenius, the inventor of the lyrichord, made a pianoforte in imitation of it. In this instrument the touch was better, but the tone was inferior. Plenius produced his lyrichord, a *sostenente* harpsichord, in 1745, and Mason imported a pianoforte ten years later. Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success. Of these Americus Backers (d. 1776), said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, based upon Cristofori's, and may have made the instrument referred to in an old play-bill of Covent Garden in Messrs. Broadwoods' possession, dated May 16, 1767, which has the following announcement.

"End of Act 1. Miss Brickler will sing a favourite song from *Judith*, accompanied by Mr. Dibdin on a new instrument call'd Piano Forte."

Backers's "Original Forte Piano" was played at the Thatched House in St. James's Street, London, in 1773. Ponsicchi has found a Backers grand piano at Pistoria, dated that year.

The escapement lever is suggested by Cristofori's first action, to which Backers added a contrivance for regulating it by means of a button and screw (see fig. 18). The check is from Cristofori's second action. John Broadwood and Robert Stodart were friends, Stodart having been Broadwood's pupil; and they were the assistants of Backers in the installation of his invention. On his deathbed he commended it to Broadwood's care, but Stodart appears to have been the first to advance it—Broadwood being probably held back by his partnership with his brother-in-law, the son of Shudi, in the harpsichord business. (The elder Shudi had died in 1773.) Stodart soon made a considerable reputation with his "grand" pianofortes, a designation he was the first to give them. In Stodart's grand piano we first find an adaptation from the lyrichord of Plenius, of steel arches between the wrest-plank and belly-rail, bridging the gap up which the hammers rise. These are not found in any contemporary German instruments, but may have been part of Backers's. Zumpe's small square piano had met with great success; he was soon enabled to retire, and his imitators, who were legion, continued his model with its hand stops for the dampers and sourdine, with little change but that

which straightened the keys from the divergences inherited from the clavichord.

John Broadwood took this domestic instrument in hand to improve it, and in the year 1780 succeeded in entirely reconstructing it. He transferred the wrest-plank and pins from the right-hand side, as in the clavichord, to the back of the case, an

FIG. 18.—GRAND PIANO ACTION (1776). THE "ENGLISH" ACTION OF AMERICUS BACKERS

The button screw throws the jack out of the notch in the butt after making the blow; improved by Messrs. Collard (1835), who reversed the lever and hammer butt

improvement universally adopted after his patent, No. 1379 of 1783, expired. In this patent we first find the soft and sustaining pedals, since universally accepted, but at first in grand pianofortes only. John Geib patented (No. 1571 of 1786) the hopper with two separate escapements, one of which was soon adopted in the "grasshopper" of the square piano, it is believed by Geib himself;

FIG 19.—BROADWOOD'S GRAND PIANO ACTION (1884), ENGLISH DIRECT MECHANISM

The hopper is thrown from the notch in the butt, by the slanting blow given by the set-off button when the hopper rises

and Petzold, a Paris maker, appears to have taken later to the escapement effected upon the key.

To return to John Broadwood—having launched his reconstructed square piano, he next turned his attention to the grand piano to continue the improvement of it from the point where Backers had left it. He called in the aid of professed men of science—Tiberius Cavallo, who in 1788 published his calculations of the tension, and Dr. Gray, of the British Museum. The problem

was solved by dividing the sound-board bridge, the lower half of which was advanced to carry the bass strings, which were still of brass. Even the first attempts to equalize the tension and improve the striking-place were successful in improving the tone greatly. To please Dussek, Broadwood in 1791 carried his five-octave, F to F, keyboard, by adding keys upwards, to five and a half octaves, F to C. In 1794 the additional bass half octave to C, which Shudi had first introduced in his double harpsichords, was given to the piano.

The first square piano made in France is said to have been constructed in 1776 by Sebastian Erard, a young Alsatian. In 1786 he came to England and founded the London manufactory of harps and pianofortes bearing his name. Erard took out his first patent for a "repetition" action in 1808. He did not, however, succeed in producing his famous repetition or double escapement action until 1821; it was then patented by his nephew Pierre Er-

FIG. 20.—COLLARDS GRAND PIANO ACTION (1884); ENGLISH ACTION. WITH REVERSED HOPPER AND CONTRIVANCE FOR REPETITION ADDED. OPERATING UNDER THE BUTT

ard. When the patent expired in England in 1835 it had proved a loss from the difficulties of carrying out the invention. This induced the House of Lords to grant an extension of the patent.

Erard invented in 1808 an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal, through holes in which the strings are made to pass, bearing against the upper side. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, Bord.

The first to see the importance of iron combined with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, known as the inventor of the ever-pointed pencil. He was living at Philadelphia, U.S.A., when he invented and first produced the familiar upright pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish piano-maker, had in 1798 tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument is in a complete iron frame, independent of the case; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the tall cabinet pianoforte, with hinged sticker action, in 1807. All that he could, however, patent in it was the simple damper action, turning on a pivot to relieve the dampers from the strings. The next

steps for producing the short or cottage upright piano were taken by Robert Wornum, who in 1811 produced a diagonally, and in 1813 a vertically, strung instrument. Wornum's improved crank action (fig. 23) was not complete until 1826, when it was patented for a cabinet piano; but it was not really introduced until three years later, when Wornum applied it to his little "piccolo." The principle of this centred lever check action was introduced

FIG. 21.—ERARD'S DOUBLE ESCAPEMENT ACTION (1821)

The escapement of repetition is effected by a spring pressing the hinged lever upwards, to allow the hopper which delivers the blow to return into position, before the key has risen again

into Paris by Pleyel and Pape, and thence into Germany and America. (Pleyel exhibited a small upright piano in Paris in 1827, but Pierre Erard did not turn his attention to upright pianos until 1831.)

Early in the 19th century William Allen, a young tuner in the employ of the Stodarts, devised a metal system of framing intended primarily for compensation, but soon to become, in other hands, a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by atmospheric changes by compensating tubes and plates of the same metals, guaranteeing their stability by a cross batoning of stout wooden bars and a metal bar across the wrest-plank. Allen consulted Stodart's foreman, Thom; and Allen and Thom patented the invention in January 1820. The firm of Stodart at once acquired the patent.

We now arrive at an important epoch in pianoforte construction—the abolition of the wooden construction in favour of a combined construction of iron and wood, the former material gradually asserting pre-eminence. Allen's design is shown in fig. 24. The long bars are really tubes fixed at one end only; those

FIG. 22.—STEINWAY'S GRAND PIANO ACTION (1884)

The double escapement as in Erard's (fig. 21) but with shortened balance and usual check. The hopper escapes from under the roller owing to the ball-crank lever coming into contact with the set-off button

of iron lie over the iron or steel wire, while those of brass lie over the brass wire, the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings without danger to the durability of the case and frame. In 1821, a fixed iron string-plate, the invention of one of Broadwood's workmen, Samuel Hervé, was applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even

resistance to the tension of the strings and the reduction of their length behind the bridge. Long iron resistance bars were experimented on as substitutes for the wooden bracing by Joseph Smith in 1798; but to James Broadwood belongs the credit of trying them first above the sound-board in the treble part of the scale in 1808, and again in 1818; he did not succeed, however, in fixing them properly. Sebastian and Pierre Erard seem to have been first in the field in 1823 with a complete system of nine resistance

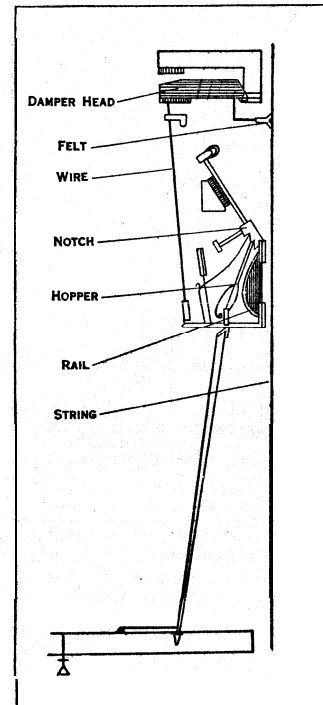

FIG. 23.—WORNUM'S UPRIGHT ACTION (1826), ORIGINAL OF THE NOW UNIVERSAL ACTION IN UPRIGHT PIANOS

The Hopper in its ascent drove the hammer forward at the same time contacting the rail which threw the upper end of the hopper out of the notch forming what is known as the escapement. Meanwhile the damper-head is raised by the wire, and the felt is taken from the string

grand pianoforte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found. After the Great Exhibition of 1851 he employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar. After 1862 he covered his wrest-plank with a thick plate of iron into which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string.

The introduction of iron into pianoforte structure was differently and independently effected in America, the fundamental idea there being to use a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphaeus Babcock was the pioneer of this kind of metal construction. He also cast an iron ring for a square piano in 1825, which, although not a success, gave the clue to a single casting resistance framing, successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was improved upon by Jonas Chickering (1797-1853) of Boston, who applied it to the grand piano as well as to the square, since which time this prin-

bars from treble to bass; with a simple mode of fastening them through the sound-board to the wooden beams beneath, James Broadwood, by his patent of 1827, claimed the combination of string-plate and resistance bars, which was clearly the completion of the wood and metal instrument, differing from Allen's in the resistance being fixed. Broadwood left the bass bars out, but added a fourth bar in the middle to the three in the treble he had previously used. But the weight of the stringing was always increasing, and a heavy close copper covering of the bass strings had become general. The resistance bars were increased to five, six, seven, eight and, as we have seen, even nine, according to the ideas of the different English and French makers who used them in their pursuit of stability.

A method of fastening the strings on the string-plate depending upon friction, and thus dispensing with "eyes," was a contribution of the Collards, who had retained James Stewart, a

man of considerable inventive power, who had been in America with Chickering. This invention was introduced in 1827. Between 1847 and 1849 Mr. Henry Fowler Broadwood, grandson of John Broadwood, invented a

ciple has been universally adopted.

We have now to consider over- or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century clavichords were sometimes overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Gerock & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanic in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Ex-

hibition of 1851 contained a grand piano, made by Lichtenenthal of St.

Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. Later, in 1855, Henry Engelhard Steinway (originally Steinweg; 1797–1871), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading to important results.

It would be inaccurate to say that no outstanding developments have taken place in pianoforte construction during the last fifty years, but few new principles have been discovered, and improvement has taken place almost entirely in the direction of applying in greater and greater measure scientific knowledge to methods and practices previously empirical (see **PIANOFORTE MANUFACTURE**) thus resulting in improvement in volume and richness of tone.

Summing up matters it may be said that the modern pianoforte retains six important characteristics of the clavichord, in that it has an independent sound-board (*i.e.*, the ends of the strings are not fastened to it), dampers to prevent vibration of the strings not in use, "listing" cloth to deaden the vibration from the ends of the strings beyond the bridges, groups of three strings tuned in unison and a tone production which depends upon a blow instead of a plucking (as in the spinet and harpsichord).

Five of the ideas developed in the harpsichord have also sur-

vived or have been revived from time to time, namely, the sustaining pedal, the celeste felt for soft playing, the transposing keyboard, the soft stop for practising very quietly, and the double manual (*viz.*, as recently introduced by Emanuel Moór).

As regards the sustaining pedal the importance of this cannot be over-estimated, for not only does it allow of harmonies being maintained when necessary without holding the keys down, but it also modifies the tone quality by allowing all strings to take part simultaneously by means of their resonance. Moreover the sound-board is encouraged to increase its amplitude of vibration, thus increasing the tonal volume, which in skilful hands can be made to reach a maximum intensity of over twenty times that of the most powerful harpsichord. Contrariwise, the tone can be attenuated and diminished by means of the soft pedal, which brings the hammers nearer the strings, or (as in the case of grand pianos) shifts the hammers so that they strike two instead of three strings.

The "celeste" pedal and "soft stop" devices both involve the introduction of a strip of felt between the strings and the hammers at the point of contact, thus reducing the force of the blow.

For school pianos, which are used for practising almost continuously throughout the day, the soft stop is a most useful adjunct and when properly designed need not interfere unduly with the touch of the instrument.

The transposing device, a feature of the once popular player piano, has been found both difficult to apply to the piano and to keep in perfect order owing to the necessity for shifting the keys relative to the action, a movement which upsets the delicate regulation of the repetition, and renders the device unsatisfactory.

Finally, the double keyboard, as invented by Emanuel Moór, represents a new development, possibly extending the resources of both performer and composer to some degree. Such a revolutionary departure will doubtless take time to become commercially possible, but some musical opinion is entirely in its favour. Briefly stated, the second keyboard lies just behind and above the normal standard notes, and operates those strings which are an octave higher. Consequently it is possible to play extended chords, arpeggios and double octaves with some facility. There is also an octave coupler which further increases the possibilities of the instrument from the point of view of volume. To what extent the principle will ever secure general adoption it will be rash to prophesy, but as to its ingenuity and musical value there is no room for doubt.

The principles discovered in strung the early actions (Erard 1821 and Robert Wornum 1826) still stand firm and all subsequent improvements have been built thereon.

The separate parts of the modern action are produced by automatic machinery, and assembled by hand with great skill and accuracy.

The pianoforte manufacturer has long recognized the advisability of allowing this important component to be made for him

by specialists, the hammers and hammer shanks being fitted after the action has been installed.

Present-day development is largely directed towards overcoming the physical handicaps to richness and volume of tone imposed by smaller overall dimensions to fit smaller rooms. The sound-board is made as sensitive as possible, supported in a rigid frame-work which absorbs little or no energy from the board at its edges. The modern sound-board sustains a continual down-pressure from the strings of nearly half a ton, whereas the early grand pianos had scarcely a hundred-weight pressure thereon. The string tension has tripled (from 60 to 180 lb. per string in some instances) with the ability of the wire drawers to supply stronger and stronger wire, and the iron founder has had to devise castings which stand a total stress of 16 tons and upwards without occupying too much room, or covering too large a portion of the surface of the sound-board. Some early makers had the mistaken idea that an iron structure entailed the production of a "metallic" tone in the instrument; but those who adhered to the use of the wooden frame were soon left behind, mainly owing to the extreme susceptibility of the pitch of such pianos to temperature and humidity changes, which rendered the tuning very unstable.

FIG. 28—A WEBER PIANO SHOWING THE EMANUEL MOOR DUPLEX COUPLER KEYBOARD

As regards the future, experiments are now being made in the field of electrical amplification of string tone, by means of electrostatic and electro-magnetic "pick-up" devices applied to the struck strings or the structure of the piano. Amplification has so far resulted in also considerably increasing the duration of tone, causing blurred and confused results in the playing of rapid passages and staccato notes.

These effects have so far kept such new instruments acoustically outside the category of pianos due to altered tonal characteristics.

PIANOFORTE MANUFACTURE. There are eighty-eight notes in the full compass keyboard of the pianoforte, which gives a range of $7\frac{1}{3}$ octaves. The 49th tone from the bass end of the scale is called "Pitch A," and has a frequency of 440 double vibrations per second, adopted in the United States and Great Britain as the standard pitch from which all others are tuned. Since each note has to vibrate twice as fast as the note of the same name an octave below, and there are twelve semitones to the octave, it follows that the semitone ratio from note to note must be the twelfth root of 2, namely 1.05946, which is a geometrical progression giving the now generally adopted "equal temperament" tuning. Purely mathematical considerations make it essential that the string lengths should also proceed in geometrical progression, but in a slightly smaller octave ratio than 2:1. In Germany the ratio most favoured is 1.875:1, and in Great Britain 1.89:1. Both of these ratios approximately allow of half-size increases in the gauge of wire used, twice per octave, without departing far from the uniform tension initially decided upon. The English Music Wire Gauge advances one-thousandth of an inch in diameter per half size, while the New Westphalian Gauge advances 0.025 millimetre per half size, but there are irregularities in the English Gauge at various places, for reasons apparently unknown.

FIGS. 1, 2, & 3 — METHODS OF CONNECTING STRINGS TO SOUNDBOARD 1. Connecting of bass bridge to a sensitive part of the soundboard, 2. Slight dip of string after leaving bridge on its way to hitch-plate, 3. Two methods of avoiding the use of wooden-plank in extreme climates. (A) the screw pushes wrest-nip forward and holds it friction-tight, (B) the pin is held in a tapered hole by a nut

In small instruments, whether grands or uprights, it is impossible to carry theoretical string lengths throughout the piano, and compromises have to be made by shortening and thickening them in order to maintain the necessary high tension. Since short

and thick strings give a different and inferior tone quality it must not be expected that small instruments will give a pure and balanced "timbre" throughout the scale.

Cold drawn steel wire of the highest quality is specially made for the pianoforte trade, with a minimum breaking strength of 150 tons per square inch. Two types are now in favour, the polished and the plated. The latter has been successfully developed, and is especially useful for export models.

Length of Strings.—In practice the strings of the 88th note are always between 5.0 and 5.5 centimetres in length, the shorter length being used for small instruments. From this starting point the succeeding lengths are calculated mathematically until it becomes necessary to employ heavier strings weighted by means of one or two layers of copper wire closely and tightly spun upon them. In order to gain in length and to fix the bridge to a sensitive part of the sound-board, well away from its edges, about fifty of the bass strings (12 singles and 19 bichords) are planned to cross over the others, reaching to a separate and higher bridge. This method of "overstringing" is now general in all but the cheapest pianos. The lengths of the copper-covered strings are not calculated mathematically but are made so that the lowest note is as long as possible. Additional length is often secured by means of a "suspended" bridge, as shown in fig. 1, which transmits the vibrations of the bridge to a point which should be at least six inches from the edge of the sound-board.

It has been found that a tension of about 160 lb. is advisable for the uncovered strings, and the diameter of wire is calculated

from the formula $\frac{160}{n^2 l^2}$, after which the nearest gauge to this diameter is selected, it being impracticable to manufacture a different diameter for each note. In the formula, "n" is the number of vibrations per second, "T" the tension in lb., and "l" the length of the vibrating portion of the string, in centimetres.

For the copper-covered strings some makers employ the formula $\frac{20\,000\ T}{n^2 l^2}$ which gives the all-over diameter of the required string. Others calculate the weight per centimetre instead of the diameter, using the formula $\frac{111,250\ T}{n^2 l^2}$, afterwards spinning strings of the required weight, as found by experimental determinations. For bichord bass strings a considerable increase of tension is provided, varying from 10 to 15%, and for the single bass strings a further increase of 15% and upwards, according to the size of the instrument.

The Sound-board.—As the strings vibrate they transmit pressure differences to the bridge attached to the sound-board (the bridge at the other end being as rigid as possible). The large area of the sound-board is thus set in motion, and this in turn agitates the air in its immediate vicinity, the aim being to provide a sensitive and extremely elastic board, capable of reproducing the most complicated wave-forms, with as little loss of energy as possible. In addition, the board must be made of material of low density and of uniform texture.

The timber of the spruce family (*Picea excelsa*), when cut "on the quarter," answers all these requirements, the best qualities transmitting sound-waves along the grain at the rate of 16,000 feet per second and upwards. The transmission across the grain is about one-fourth of this speed, a difficulty which is surmounted by gluing bars of the same material across the back of the board at right angles to the grain. Research in the mode of vibration of the sound-board has led in the present decade to refinements in design; a new sound-board called "Diaphragmatic" is embodied in all Steinway pianos since 1937.

Most sound-boards are made with the grain running diagonally so that the long bridge runs almost parallel to the grain. The thickness is usually about $\frac{3}{8}$ " all over, some manufacturers insisting, however, that the treble end should be thicker. Sound-boards are always fitted so that they are slightly "bucked" or high in the middle, as though part of the surface of a sphere of about 60 ft. radius. This shape is secured in several ways, usually the best being to subject the board to a dry temperature of 120° F.

for some hours, and then to glue on the bars, in a slightly hollowed form.

The subsequent expansion as the board takes up its usual 10% of moisture from the air coupled with the "set" secured in the hollowed form produces the desired curvature. Since the board is always under pressure from the strings it follows that it behaves as an arch, which shape is retained through the rigidity of the rim to which it is fixed.

The "Down-bearing."—Good contact is maintained between strings and bridge by leaving the bridge a little higher than the general level of the two extremities. The resulting pressure of the strings on the sound-board is known as the "down-bearing," the regulation of which is one of the most critical processes in pianoforte manufacture. It is agreed that about one-fortieth of the tension is a suitable amount for each string to press upon the bridge. Translated into degrees this means that the bridge must stand high enough to allow the string to dip one and a half degrees after it passes over the bridge on its way to the hitch-pin on the iron frame.

Allowance has to be made for the fact that as the tension is applied the whole board is pressed down somewhat, and the amount of such sinking depends upon its dimensions, barring and support round the edge. The extra height is not measured at the bridge, but by means of a straightedge laid across where the string will pass, the amount of clearance at the hitch-pin is allowed for. (See fig. 2.) It does not matter so much what the exact pressure is, but inequalities of pressure cause very serious results, affecting those strings which lie between places of excessive pressure, and robbing them of their adequate contact with the bridge. Good contact-between strings and bridge is also maintained by means of bridge-pins which lie in the line of the strings and are inserted at an angle of 70 degrees with the plane of the bridge.

By passing the string to the left of the front pin and to the right of the back pin a frictional grip is secured. This practice is almost universal, an outstanding departure being Messrs. Broadwood's method of screwing studs to the bridge and passing the strings through these. Previous efforts to provide a studded bridge have been discarded owing to the studs working loose and causing falseness of tone, but Messrs. Broadwood claim to have overcome this difficulty.

Tone and Overtones.—Pianoforte tone is compound, each note consisting of a fundamental tone and its overtones, which, sounding together, form the "harmonic series," with their vibration rates in the ratio of 1:2:3:4, etc. For instance, the tone of "middle C" has for harmonics the following notes, the frequencies of which are inserted in brackets: C (261.6), the fundamental; C (523.25), G (783.99), C (1046.5), E (1318.57), G (1567.9), B flat (1864.6j), C (2093), D (2349.3) and so on. If these notes be played together as a chord it will be at once detected that the harmonics blend together pleasingly, with the exception of the seventh and ninth which are dissonant. By striking the strings at one-eighth of their length from the fixed end, it is believed that the best tone quality is produced, whether by discouraging the 7th and 9th harmonics or by encouraging the 4th is not yet scientifically proved. This strike proportion is used for all notes from the bass up to or near the 51st note, after which other considerations make it necessary to strike the string gradually nearer the end, the fraction at the extreme treble being empirically decided upon at about $\frac{1}{8}$. Since the discordant harmonics of these notes are very weak and even beyond the limits of human audition it does not matter if they are produced, the striking point being arranged to allow of a quicker recoil of the hammer from the string.

Toning the Hammers.—The process known as "toning" or "voicing" the hammers is an attempt to control the time of contact between hammer and string, a soft hammer staying long enough to damp out some of the unwanted overtones, while a hard-nosed hammer accentuates them. If a string vibrates a thousand times per second, its "periodic time" is one-thousandth of a second, and experiment proves that the best tone is emitted if the hammer is toned so that contact is maintained for about half this period,

English and German felts are used wherever the highest quality is required, their resiliency being the desirable property. Great pressure is used in modern hammer-making and the density at the treble end where the hammer dimensions are small, is more than double that of the bass hammers. The toner, by means of pricking the felt, lessens the hardness at and beneath the nose of the hammer. In this he is entirely guided by his ear, the aim being to eliminate undesirable tone components and secure an evenly graded scale, with no audible break between the treble and bass strings.

The Action.—The hammers are actuated by a system of levers known as the "action," which is now made by firms specializing in this unit alone, rather than by the piano manufacturer himself. The noses of the hammers rest at a distance of two inches from the strings, but if a note is held down after having been played, the hammer is "checked" when it has rebounded five-eighths of an inch, so that the blow can be repeated rapidly. When the key is half-way down, the felt "damper" is lifted from the strings and remains lifted until the key is released.

Pedals.—The tone is modified by means of two pedals, the left-hand pedal taking the hammers nearer to the strings and thus decreasing the force of the blow. Sometimes the whole action is shifted to the right, so that the hammer only strikes two strings instead of three. The right-hand pedal lifts all the dampers from the strings so as to sustain harmonies as long as required, and not merely for increased power. In America a central pedal is often added, called the "Sostenuto," which, instead of lifting all the dampers, affects only those which happen to be already lifted, keeping them so until the pedal is released. Thus one is able to sustain a chord, leaving the hand free for other notes.

The ideal point of contact for the dampers is at the same place as the striking point, and in grand pianos this is approximately arranged, the dampers lying along the strike line above the strings, and operated by gravity only. In upright pianos a position just under the strike line is favoured, such actions being known as "under-damper," and the pressure obtained by springs. The cheaper piano is sometimes provided with an older type wherein the damper is operated by gravity at a point just above the hammers. This is known as the "over-damper" action, and although the vibrations of the strings are of less amplitude above the hammer-line than below it, a well-made over-damper action is still in favour by certain Continental makers of repute, owing to its more effective silencing of the harmonics.

Touch.—The depth of touch for the keys has been standardized in all countries at 9 millimetres, with an additional millimetre to allow for the locking of the check and the free escapement of the "Jack" lever. The pivoting of the key has to be so placed as to give the correct amount of lift at the other end, usually about 6 millimetres, but varying a-little with the different makes of action. The best "touch" is secured if the keys slope backwards a little when at rest, becoming exactly level when half depressed. At this point begins the extra load due to the lifting of the dampers, but the momentum already gained is sufficient to render it unnoticeable. A "touch weight" is used during the regulating of the action, so that when it is placed upon the end of the key, and suddenly released, the force exerted is just sufficient to make the note sound faintly. This "dead weight" of touch is not standardized, but averages 60 grammes in the bass, down to 48 grammes in the treble.

Frame.—The iron frame, which takes most of the load exerted by the pull of the 220-odd strings, is cast in one piece at the foundry, from an iron pattern which has been made 1% larger than the finished frame, in order to allow for the contraction of the casting during cooling.

Tuning Pins.—The tuning pins of mild steel, about 7 millimetres in diameter, are driven into a wrest-plank of quartered beech or maple, usually of ply construction to prevent splitting. The holes are bored slightly smaller than the pins, a ratio of 15:17 giving the correct amount of tightness. Since the plank is bolted to the iron frame and glued to the wooden back it follows that the load is shared between the frame and the back, the tendency in cheaper construction being to eliminate the wooden back alto-

gether. The wrest-plank is often covered with a web of iron into which maple plugs have been driven, the tuning pins passing through these plugs into the plank. This method has proved popular and has been adopted in many upright and grand pianos. Patent methods of securing the tuning-pins have been introduced from time to time, but the method above described would seem likely to survive all others, being efficient, inexpensive and free from complications.

For tropical climates, an all-metal wrest-plank has been designed, the wrest-pins being held "friction tight" from the back of the plank. Fig. 3 shows an Australian and a German method of providing sufficient hold for the pin, at the same time allowing it to be adjusted finely by the tuner. In order to prevent the two surfaces from rusting together, a very fine grade of graphite is used as a lubricant. The washers have a projection which fits into a slot running down the threaded portion of the pin, which ensures that they move with it during all adjustments.

FIG. 4.—STEINWAY GRAND CASE-WORK, SHOWING PARTS

Standardization.—The similarity in methods and design of the leading manufacturers in all countries is accounted for by the necessity for standardization of the keyboard, its height from the floor, the provision of room for the knees, the situation of the pedals, and the natural laws controlling the vibration of stretched strings. In the upright piano the wooden back forms a convenient base to which the ends of the case are glued, besides being the means for securing rigidity for the edges of the sound-board and a support for both iron frame and wrest-plank.

The peculiar form of the grand piano enables an immensely strong inner rim to be built up in one continuous bend, into which bracings are dove-tailed, and to which the key-bottom (supporting the key-board) is secured. This inner rim, on which the sound-board and iron frame are fastened, may be six inches deep, and from 1¼" to 1½" thick. Additional rigidity is further provided by gluing this unit to an outer rim, also of ply formation, about a foot deep and from 1" to 1¼" thick. The skeleton formation of the case-work of a large Steinway grand is shown in fig. 4, but it must be remembered that the lateral stiffness of such a structure varies inversely as the cube of its length, and therefore small grands do not need such elaborate re-inforcement, the very smallest (4 ft. 3 in. to 4 ft. 6 in. in length) often having no bracings at all.

PIANOLA: see PLAYER-PIANO.

PIANOSA (anc. *Planasia*), an island of Italy, belonging to the province of Leghorn, and forming part of the commune of Camponegli' Elba, from which it is 11 mi. S.W. Population 908. As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq.mi. The discovery of numerous fossilized bones of animals show that it was still united to the mainland in the quaternary period. Traces of human habitation in the neolithic period have been found. Augustus banished to it his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name. It was depopulated in 1553 by the Turkish fleet, and only resettled in 1835.

PIARISTS, the popular name of a Catholic educational order, the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, founded by Joseph of Calasanza at Rome in the beginning of the 17th century. Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV, and had all the privileges of the mendicant

orders conferred upon it. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany and Austria.

BIBLIOGRAPHY.—See M. Heimbucher, *Orden und Kongregationen* (1897) ii. 271; articles by O. Zockler in Herzog-Hauck's *Realencyklopadie für protestantische Theologie* (1904), vol. xv.; C. Kniel in Wetzer und Welte's *Kirchenlexikon* (1895), vol. ix. and art. "Piarists" in the *Catholic Encyclopaedia*.

PIAROAN, an independent linguistic stock of South American Indians, named from the Piaroas, one of its most important tribes. The Piaroan tribes live in the region of the Venezuelan-Colombian border, along the Orinoco river between the Sipapo and the Matabeni, and on the course of the latter river, the Zama and lower Vichada. The Piaroas are described as a forest rather than a river people, using bark canoes constructed for temporary purposes only. Their houses are communal, and are circular and conical in shape, built of thatch. They are agricultural, using manioc as their main food and but little maize.

See J. Chaffanjon, *L'Orenoque et le Caïra* (Paris, 1889); A. von Humboldt, *Personal Narrative of Travels to the Equinoctial Regions*, etc. (London, 1818).

PIASTRE, a monetary unit of Turkey, Egypt, and Indo-China, 100 piastres making one Turkish or Egyptian pound. In Turkey until 1933 the piastre was a silver coin containing 1,203 grammes of silver, 830 fine; at this date it was replaced by a nickel coin, the silver being gradually withdrawn; in Egypt, also formerly of silver (1.4 grammes, 833 fine) it is now of nickel, and at par equals 97½ to the £; the piastre of Indo-China is equal to 10 francs, and is now issued only in paper.

PIATRA (Neamtu), the capital of the department of Neamtu, Rumania, situated on the left bank of the river Bistritza, where it cuts a way through the Carpathian foothills. Pop. (1930) 30,211. A branch railway passes through the town, and at Bacau meets the main Czernowitz-Galatz line. The church of St. John's (or the Prince's) monastery was founded in 1497 by Stephen the Great. There are saw-mills and textile factories in Piatra, which has a considerable trade in wine and timber, and is also a popular summer resort. Neamtu is one of the most densely forested regions in Moldavia.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on Jan. 8, 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. He retired from public life, owing to a severe illness, in 1897.

PIAUI or **PIAUHY**, a northeastern state of Brazil, bounded north and west by Maranhão, east by Ceari, Pernambuco and Baia, and south by Baia. It has a few miles of Atlantic coast line on the north, and the Rio Parnaíba forms the boundary line with Maranhão throughout its entire length. Area, 94,819 sq. mi.; pop. (1940) 826,320. Part of the state on the Atlantic coast and along the lower Parnaíba is low, swampy and malarial. South of this the country rises gradually to a high plateau with open *campes*. This plateau region is drained by numerous tributaries of the Parnaíba, chief of which are the Urussui, the Canindé and its tributary the Piaui, the Gurgueia and its tributary the Paraim, which drains the large inland lake of Parnaguá, the Longa, and the Poti, which has its source in the state of Ceará. The Parnaíba is navigable for boats of 3 ft. draught up to Nova York, a few miles above the mouth of the Gurgueia. The climate is hot and humid in the lowlands and along the lower Parnaíba, but in the uplands it is dry with high sun temperatures and cool nights. The principal industry is stock-raising, which dates from the first settlement in 1674 by Domingos Afonso Mafrense, who established here a large number of cattle ranges. A secondary industry is the raising of goats. The agricultural products are cotton, sugar and tobacco. Much cotton is grown, and some of it manufactured. Forest products include rubber, carnauba wax and dyewoods. The exports include hides, skins, rubber, wax, tobacco and cotton. The capital is Teresina, on the right bank of the Parnaíba, 250 mi. above Parnaíba (town), with which it is connected by a line of light-draught river boats. The town dates from 1852, is attractively situated, and is regularly laid out with broad,

straight streets crossing each other at right angles. The population of the *município* in 1940 was 68,520, which includes a large rural district. Other *municípios* with their populations in 1940 are Oeiras (38,634) founded in 1718 under the name of Moxa; Amarante (16,613); Valença (41,027); and Campo Maior (30,406).

PIAVE, a river in Italy, which played an important part in the latter period of the World War on the Italian front. It rises under the Paralba pass in the Carnic Alps and flows in a south-westerly direction past Belluno as far as Feltre and then turns to the south-east, flowing into the sea at Cortellazzo to the north-east of Venice, with another, older mouth nearer to Venice. Its course is 220 km. in length. Its depth and width vary very considerably according to the seasons of the year, a fact which had an important bearing on the operations along its banks. In its lower reaches its bed is a vast extent of gravel only filled in times of heavy rains or at the melting of the snows. After the Austro-German break-through at Caporetto in October 1917, the remains of the Italian II. army and all the III. fell back on the Piave between Pederobba and the sea and were reconstituted behind that river. The Austrians made repeated attempts to cross the river in the Nov. and Dec. battles, but were eventually driven back on to the left bank. For a time some British troops held a sector of the Piave front, but they were afterwards transferred to the Asiago plateau. On June 15, 1918 the Austrians delivered a general attack along the greater part of the Italian front, known as the battle of the Piave, their object being to break through into the rich agricultural area of the Veneto. They concentrated their attacks on the sector between Falzè di Piave and Nervesa (opposite the Montello hill, rising along the right bank), and on that between the Grave di Papadopoli, a gravel covered island in the river, and Musile. Two Austrian forces succeeded in getting across and occupied half of the Montello and some other points, but were forced by Italian counter-attacks to recross the Piave, after suffering heavy losses. Later an Italian local attack resulted in the conquest of the area between the old and the new Piave near the estuary. In Oct. 1918 an Italian offensive on a large scale was effected. The battle, which takes its name from Vittorio Veneto, east of the Piave, began on October 23, but did not extend to the Piave until the 27th. On that day a small mixed Italian force crossed the river near Valdobbiadene and a part of the X. army also crossed the Piave at the Grave di Papadopoli (this army, commanded by the earl of Cavan, comprised two British divisions). The bridges of the VIII. army were swept away by the current and the regiments which had got across were isolated, and as the British forces which had crossed were not strong enough to outflank the Austrians on the dominant position of San Salvatore, Gen. Cavaglia, commander of the VIII. army, sent his XVIII. corps across on the British bridges; while that corps advanced up the river the British pushed east towards the Monticano; thus by the 29th the Austrian forces on the Piave were cut in half. On the 30th the bulk of the Italian attacking forces were across the river and the Austrians in full retreat.

PIAZZA ARMERINA, a city of Sicily, in the province of Caltanissetta, 43 m. W. of Catania; 2,360 ft. above sea-level. Pop. (1936) 22,815 (town), 24,527 (commune). It has a 16th-century cathedral, with a fine Norman campanile, and some of the houses and churches show Norman or Gothic architecture. The town was founded in the 12th century, and the inhabitants are of Lombard origin, and still speak a dialect of their own.

PIAZZI, GIUSEPPE (1746–1826), Italian astronomer, was born at Ponte, in the Valtellina, on July 16, 1746. He discovered, on Jan. 1, 1801, the first asteroid or minor planet, to which he gave the name of Ceres. He died at Naples on July 22, 1826.

See B. E. Maineri, *L'Astronomo Giuseppe Piazzi* (Milan, 1871); R. Wolf, *Biographien*, Bd. iv. p. 27; *Monatliche Correspondenz* (1810; portrait), xxi. 46; *Astr. Jahrbuch*, liv. 218; *Bulletin des sciences* (1826), vi. 339; *Edin. Journal of Science* (1827), vi. 193; *Memoirs Roy. Astr. Soc.* iii. 119; R. Grant, *Hist. Phys. Astronomy*, pp. 238, 510, 549.

PIBRAC, GUY DU FAUR, SEIGNEUR DE (1529–1584), French jurist and poet, was born at Toulouse. He studied law there with Jacques Cujas, and afterwards at Padua. In 1548 he

was admitted to the bar at Toulouse, and rose to be *juge-mage*, an office in Languedocian cities about equal to that of *prévôt*. He was selected in 1562 as one of the three representatives of the king of France at the council of Trent. In 1565 he became general advocate to the parlement of Paris, and extended the renaissance in jurisprudence which was transforming French justice. In 1573 he was sent by Charles IX. to accompany, as chancellor, his brother Henry (afterwards Henry III.) to Poland, of which Henry had been elected king. He was employed in negotiations with the so-called *politiques*, whom he managed to keep quiet for a while. In 1578 he became the chancellor of Marguerite of France, queen of Navarre. He died in 1584. He was the friend of Ronsard, de Thou and L'Hôpital, and left, among other literary remains, elegant and sententious *quatrains*.

PICA, the European representative of a group of diminutive rodent mammals, also known as tailless hares, mouse-hares, or piping hares, constituting the family *Ochotonidae* with the single genus *Ochotona*. From the more typical hares and rabbits they differ by the short and rounded ears, the absence of a tail, the shorter hind-limbs, and by complete collar-bones. The soles of the feet are hairy, and the fur is soft and thick. Picas are inhabitants of cold and desert regions. They dwell in the chinks between rocks, or in burrows, although one Himalayan species frequents pine-forests. They are very active, and most of the species utter a piping or whistling cry. They store up a supply of grass for winter use. The Himalayan *roylei* may be seen in the daytime, but most kinds are nocturnal. The Siberian species, *O. alpina*, ranges into eastern Europe, but Central Asia is the headquarters, although a few species range into Arctic America and the Rocky Mountains. In size picas may be compared to guinea-pigs. There are several extinct genera.

See **RODENTIA**; also J. L. Bouhote, "The Mouse-hares of the genus *Ochotona*," *Proc. Zool. Soc.* (London, 1905).

In printing pica is a type in size smaller than "English" and bigger than "Small pica." It is also known as 12 point. The following passage is printed in pica:

Types are of various sizes, and the sizes are classified according to the dimensions of their "ems" or bodies.

"Pica" is the common standard of measurement in printing offices. The unit is a single letter of pica type called an "em."

PICARD, JEAN (1620-1682), French astronomer, was born on July 21, 1620, at La Flèche, Anjou. After acting as prior of Rillé, Anjou, for some years, he went to Paris and was admitted to the Academy of Sciences as an astronomer in 1666. In 1671 he went to examine Tycho Brahe's observatory, Uraniborg, in Denmark, and returned with some of the originals of Tycho's work. Picard's measurement between Mahoisine and Amiens provided the first accurate measure of a degree of a meridian, and was used by Newton to verify his theory of gravitation. Picard founded *La Connaissance des Temps* in 1679, and edited it until his death on July 12, 1682.

His works are published in the 6th and 7th vols. of the *Memoires* of the Academy of Sciences.

PICARD, LOUIS JOSEPH ERNEST (1821-1877), French politician, was born in Paris on Dec. 26, 1821, and joined the Parisian bar. In 1871 he accompanied Jules Favre to Versailles to arrange the capitulation of Paris, and in February he became minister of the interior in Thiers's cabinet. Attacked both by the Monarchist and the Republican press, he resigned in May. Later in the year he was sent as ambassador to Brussels. On his return to Paris in 1873 he resumed his seat in the Left centre, and in 1875 became life senator. He died in Paris on May 13, 1877.

PICARDY, an old province of France, bounded north by Hainaut and Artois, on the east by Champagne, on the south by the fle de France, and on the west by Normandy and the English channel. Its maritime frontier ran from the mouth of the Aa to the cliffs of Caux, and it included the whole of the basin of the Somme and part of that of the Oise. The chief towns of Picardy were Amiens, Boulogne, Abbeville, Laon, Soissons, Montreuil,

Péronne, Beauvais, Montdidier, St. Quentin and Noyon. Its principal rivers were the Somme and the Oise. Picardy formed part of the archdiocese of Reims. Its bishoprics were Amiens, Beauvais, Senlis, Soissons, Noyon and Laon, and it contained the ancient abbeys of Corbie, St. Valéry and St. Riquier. In 1789 the province of Picardy was covered by the three bishoprics of Amiens, Noyon and Boulogne. It was one of the provinces of the five great *fermes*. Its area now forms the department of the Somme and parts of the departments of Pas de Calais, Aisne and Oise.

The name of Picardy does not appear until the 13th century. At that time the province was divided into the two bailliages of Amiens and Vermandois, but its regular organization as part of the kingdom of France only dates from the beginning of the 16th century, when it was divided into north and south Picardy. North Picardy, or Picardy proper, formed one of the great military governorships of the kingdom, while south Picardy was included in the fle de France.

Under the Romans, Picardy was part of *Belgica secunda*; it was inhabited by the Morini, the Ambiani, the Veromandui, the Bellovaci and the Suessiones, whose names still appear in Amiens, Vermandois, Beauvais and Soissons. In the 5th century Picardy became the centre of Merovingian France. Clovis had his first capital at Soissons; Charlemagne had his at Noyon, and Laon was the capital and the refuge of the later Carolingian sovereigns.

During the later feudal period Picardy was the home of the counts of Vermandois, of Clermont and of Ponthieu, the sire of Coucy, and others. The dukes of Burgundy were anxious to annex Picardy; in 1435, by the famous treaty of Arras, the royal towns and lands in the valley of the Somme were ceded by King Charles VII. to Burgundy. However, after the death of Charles the Bold in 1477 Picardy was finally united with the crown of France. The province was early an industrial district. Flemish immigrants brought with them the lucrative trade of weaving cloth, and the Somme towns were soon competing with those of Flanders. The Picard towns were noted for their love of independence, which often brought them into collision with the kings of France during the 13th century. At a later time the province received a number of Spanish immigrants. In the middle ages the Picards formed one of the four "nations" recognized in the organization of the University of Paris.

See A. Labourt, *Essai sur l'origine des villes de Picardie* (Amiens, 1840); P. N. Grenier, *Introduction à l'histoire générale de la province de Picardie* (Amiens, 1856); and H. Carnoy, *Littérature orale de la Picardie* (1883).

PICARESQUE NOVEL, THE. This special form of the *roman d'aventures* may be defined as the prose autobiography of a real or fictitious personage who describes his experiences as a social parasite, and who satirizes the society which he has exploited. The picaroon, or rogue type, is represented by Encolpios, Ascyrtos and Giton in the *Satyricon*, which tradition ascribes to Petronius; it persists in Lucian, in the *Roman de Renart*, in the *fblliaux* and in other works popular during the middle ages. But in its final form the picaresque novel may be regarded as a Spanish invention. The word *picaro* is first used, apparently, in a letter written by Eugenio de Salazar at Toledo on April 15, 1560; the etymology which derives *picaro* from *picar* (to pick up) is unsatisfactory to philologists, but it suggests the picaroon's chief business in life. A connection with French *picoreur* (*praedator*) is possible. The earliest application of the expression *picaro* to a character in fiction occurs in Mateo Alemán's *Guzmán de Alfarache* (1599). But a genuine *novela picaresca* existed in Spain before the word *picaro* became generally current.

Spanish Examples. — The earliest specimen of the kind is *La Vida de Lazarillo de Tormes y de sus fortunas y adversidades*, an anonymous tale long attributed, on insufficient grounds, to Diego Hurtado de Mendoza (*q.v.*). The authorship of this brilliant book and the circumstances of its publication are obscure; however, it was certainly issued not later than 1554 (in three editions), and was thrice reprinted before 1559, when it was placed on the Index. Imitations of so successful a story were inevitable, and as early as 1555 there appeared at Antwerp *La segunda parte de Lazarillo de Tormes*, an anonymous sequel

which completely misinterpreted the irreverent wit of the original. The first part had been prohibited because of its attacks on the clergy; in the second part the hero is presented as a devout youth transformed into a tunny. Another sequel, by Juan de Luna, was published at Paris in 1620. Meanwhile, many surreptitious copies of the first part were introduced into Spain; the Inquisition finally gave up the attempt to suppress it, and in 1573 an expurgated edition was authorized. In 1599 Mateo Alemán (*q.v.*) published the *Primera parte de Guzmán de Alfarache*. It is modelled upon *Lazarillo de Tormes*, being the autobiography of the son of a ruined Genoese money-lender; but the writer indulges in a tedious series of moralizings. This contrasts sharply with the laconic cynicism of *Lazarillo de Tormes*; but *Guzmán de Alfarache* is richer in invention, in variety of episode and in the presentation of character. Its extraordinary popularity tempted a Valencian lawyer named Juan José Martí to publish a *Segunda parte de la vida del pícaro Guzmán de Alfarache* (1602) under the pseudonym of Mateo Luján de Sayavedra; but in 1604 Alemán brought out the true continuation. A third part, written in Spanish by the Portuguese Felix Machado de Silva, Marques de Montebilo, was first printed in 1927. The *Viaje entretenido* (1603) of Agustín de Rojas is a realistic account of the writer's experiences as a strolling actor and playwright, and, apart from its considerable literary merits, it is an invaluable contribution to the history of the Spanish stage as well as a graphic record of contemporary low life.

The next in chronological order of the Spanish picaresque tales is *La Picara Justina* (1605), the history of a woman picaroon, which it has long been customary to ascribe to Andrés Pérez, a Dominican monk; there is, however, no good reason to suppose that the name of Francisco López de Ubeda on the title-page is a pseudonym. The *Picara Justina* has wrongly acquired a reputation for indecency; its real defects are an affected diction and a want of originality. The *Picara Justina* is now read solely by philologists in quest of verbal eccentricities. Gines de Pasamonte, one of the secondary figures in *Don Quixote* (1605-15), is a singularly vivid sketch of the Spanish rogue, and in the comedy entitled *Pedro de Urdemalas* Cervantes again presents a brilliant panorama of picaresque existence. He returns to the subject in *Rinconete y Cortadillo* and in the *Coloquio de los perros*, two of the best stories in the *Novelas ejemplares* (1613). In the *Viaje del mundo* (1614) the zealous missionary Pedro de Cevallos interpolates amusing tales of what befell him in the slums of Andalusia before he fled from justice to America. In *El Pasajero* (1617) Cristóbal Suárez de Figueroa fills in the sketch of the knavish innkeeper already outlined by Cervantes in *Don Quixote*. Evidence of the widely diffused taste for picaresque literature is found in *Enríquez de Castro* (1617), a story in Spanish by the Frenchman François Loubayssin de Lamarca.

The roving instinct of Vicente Martínez Espinel (*q.v.*) had led him into strange and dangerous company before and after his ordination as a priest, and his *Relaciones de la vida del escudero Marcos de Obregón* (1618) is remarkable for a baffling compound of fact with fiction written in the lucid style of which Espinel was a master; it was largely utilized by Le Sage in *Gil Blas*. Within five months of its publication at Madrid a fragmentary French version by the Sieur d'Audiguier was issued at Paris, and at Paris also there appeared a Spanish picaresque story entitled *La desordenada codicia de los bienes ajenos* (1619), ascribed conjecturally to a certain Dr. Carlos Garcia, who reports his conversation with a garrulous gaol-bird, and appends a glossary of slang terms used by the confraternity of thieves. Every kind of picaroon is portrayed with intelligent sympathy by Alonso Jerónimo de Salas Barbadillo, who is always described as a picaresque novelist; yet he so constantly neglects the recognized conventions of the Spanish school that his right to the title is disputable. Thus in *La Hija de Celestina* (1612) he abandons the autobiographical form, in *El sutil cordobés Pedro de Urdemalas* (1620) he alternates between dialogue and verse, and in *El Necio bien afortunado* (1621) the chief character is rather a cunning dolt than a successful scoundrel. The pretence of warning newcomers against the innumerable occasions of sin in the capital is solemnly kept

up by Antonio Lilián y Verdugo in his *Guía y avisos de forasteros que vienen a la corte* (1620), but in most of his tales there is more entertainment than decorum.

An unusual gravity of intention is visible in Jerónimo de Alcalá Yañez y Ribera's *Alonso, mozo de muchos amos* (1624-26), in which the repentant *pícaro* Alonso, now a lay brother, tells the story of his past life to the superior of the monastery in which he has taken refuge.

At about this time there lived in Spain an ex-nun named Catalina de Erauso, who fled from her convent, dressed herself in men's clothes, enlisted, was promoted ensign and saw more of life than any other nun in history. Her adventures arrested the attention of De Quincey, who would seem to have read them in a Spanish original which has been admirably translated since then by the French poet José Maria de Heredia. The Spanish original, in its existing form, was issued no earlier than 1829 by Joaquín Maria de Ferrer, whose character is not a satisfactory guarantee of the work's authenticity; but its interest is unquestionable. No such suspicion attaches to the *Vida de Alonso de Contreras*, first published in 1899, in which every convention of the picaresque novel is faithfully observed, and the incidents are no doubt substantially true, though this ex-captain, like most converts, judges his own past with unnecessary harshness. This subtle form of vanity also pervades the *Comentarios de el desengañado de sí mismo* of Diego Duque de Estrada, a rakish soldier and inferior dramatist whose autobiography (begun in 1614 and continued at intervals during many years) was not printed till 1860. A far higher order of talent distinguishes the *Capitulaciones de la vida de la corte y oficios entretenidos en ella*, a bitterly unsparring review of picaresque life written by the great satirist Francisco Gómez de Quevedo y Villegas (*q.v.*). These thumbnail sketches were the preparatory studies worked up into the more elaborate *Vida del buscón Don Pablos* (1626), the cleverest and most revolting book of its class.

The *Varia fortuna del soldado Pindaro* (1626) added nothing to the established reputation of Gonzalo de Céspedes y Meneses. Alonso de Castillo Solórzano (*q.v.*) tempted the public with three picaresque stories published in quick succession: *La Niña de los embustes*, *Teresa de Manzanares* (1634), the *Aventuras del Bachiller Trapaza* (1637) and a sequel to the latter entitled *La Garduña de Sevilla* (1642). But the style was no longer welcomed with the old enthusiasm in Spain. The *Bachiller Trapaza* was destined to be continued by Mateo da Silva Cabral in Portugal and to be exploited by Le Sage who likewise utilized in *Gil Blas* episodes taken from *El Siglo pitagórico* (1644), the work of Antonio Enriquez Gómez (*q.v.*). The primitive rogue returns to the scene in *La Vida y hechos de Estebanillo González* (1646). Le Sage drew upon him in the *Historie d'Estevanille González*.

Outside Spain.—Meanwhile, the rogue had forced his way into other European literatures. The Antwerp continuation (1555) of *Lazarillo de Tormes* brought the original to the notice of northern readers, and this first part was translated into French by Jean Saugrain in 1560, a new edition being called for in the following year. A Dutch version was issued anonymously in 1579, and it seems extremely likely that the book had been translated into English before this date.

The first known edition of David Rowland's version of *Lazarillo de Tormes* is dated 1586, but as a licence to print a translation of this tale was granted on July 22, 1568-69, it is probable that a 1576 edition which appears in the Harleian catalogue really existed. Numerous reprints (1599, 1639, 1669-70, 1672, 1677) go to prove that *Lazarillo de Tormes* was very popular, and that Shakespeare had read it seems to follow from an allusion in *Much Ado about Nothing* (Act. II., sc. i.): "Now you strike like the blind man; 'twas the boy that stole your meat, and you will beat the post." To Thomas Nash belongs the credit, such as it is, of being the first to write a picaresque novel in English: *The Unfortunate Traveller; or the Life of Jack Wilton* (1594). Nash led the way, and a reference to "Spanish pickaroos" in Middleton's *Spanish Gipsie* indicates that the picaroon type had speedily become familiar enough for London playgoers to understand the reference. Interest in picaresque literature was kept alive in

England by James Mabbe's admirable version (1622) of *Guzmán de Alfarache*; by *The Son of the Rogue or the Politic Thief* (1638), an anonymous translation, done through the French, of *La desordenada codicie*; and by another anonymous translation (1657), likewise done through the French, of Quevedo's *Buscón*. The result of this campaign was *The English Rogue described in the Life of Meriton Latroon, a witty Extravagant* (1665), by Richard Head and Francis Kirkman.

It is not till Defoe's time that the English picaresque novel acquires any real importance. There is a female picaroon in *Moll Flanders*, and, as Defoe read Spanish, it is conceivable that Moll Flanders was suggested by the *Picara Justina*; but this resemblance does not make a picaresque novel of *Moll Flanders*. The satirical spirit which is lacking in *Moll Flanders* is abundantly present in *Colonel Jack*, which bravely aims at exhibiting "vice and all kinds of wickedness attended with misery." Henceforward the picaroon is naturalized in English literature, and is gloriously reincarnated in Fielding's *Jonathan Wild* and in Smollett's *Ferdinand, Count Fathom*.

The Dutch translation of *Lazarillo de Tormes* (1579) did not enable the picaresque novel to strike root in Holland, yet from it is derived one of the best Dutch comedies, *De Spaensche Brabander Jerolimo* (1616) of Gerbrand Bredero. A German translation of *Guzmán de Alfarache* was published by Aegidius Albrecht in 1615; both *Lazarillo* and *Rinconete y Cortadillo* were translated by Niclas Ulenhart in 1716, and in 1627 there appeared an anonymous version of the *Picara Justina*. The Spanish tradition was followed by Martin Frewden in a continuation (1626) of *Guzmán de Alfarache*, but the only original picaresque novel of real value in German is Grimmhausen's *Simplicissimus*. The attempt to acclimatize the picaresque novel in Italy failed completely.

The first translation of the *Novelas ejemplares* was published at Paris in 1618 by Rosset and d'Audiguier; and French translations of *Guzmán de Alfarache*, of *Marcos de Obregón*, of *La Desordenada codicie*, of the *Buscón* and of the *Picara Justina* were printed in 1600, 1618, 1621, 1633 and 1635 respectively. Scarron frankly mentions Castillo Solórzano's *Garduña de Sevilla in the Roman Comique* (1651), and his *Précaution inutile* and *Les Hypocrites* are convincing proofs of close study of Spanish picaresque stories: the *Précaution inutile* is taken from *Guzmán de Alfarache*, and *Les Hypocrites* is merely a translation of Salas Barbadillo's *Hija de Celestina*. The *Roman bourgeois* (1666) of Antoine Furetière is generally described as a picaresque novel, but it is concerned with the foibles of the middle class rather than with the sly devices of common vagabonds.

The Spanish picaroon lives again in *Gil Blas*, where, with a dexterity almost rarer than original genius, a master of literary manipulation fuses materials unearthed from forgotten and seemingly worthless Spanish quarries. *Gil Blas* is a creation of the gentler, sunnier French spirit; like Beaumarchais's Figaro he is a Spaniard born, reared and humanized in Paris, and these two are the only picaroons whose relative refinement has not been gained at the cost of verisimilitude. But the old original scoundrel was not yet extinct: in the interval between the appearance of the *Barbier de Séville* and the *Mariage de Figaro* Restif de la Bretonne produced a sequel (1776) to the *Buscón*—a sequel so dull as to be wellnigh unreadable. The untamed Spanish rogue had become impossible towards the end of the 18th century: in the 19th he was deliberately rejected when Théophile Gautier wrote his *Le Capitaine Fracasse*. Yet Gautier conscientiously provides a Spanish atmosphere. *Le Capitaine Fracasse* is the last important book which continues the picaresque tradition. But picaresque fiction can never be exhausted while human nature is unchanged. Pereda (q.v.) in *Pedro Sánchez* (1884) touches the old theme with the accent of modernity; and the *picaroon* flourishes afresh in the novels of Baroja.

PICASSO, PABLO (1881–). The initiator of Cubism in modern painting. He was born on Oct. 23, 1881, at Malaga, in Spain. His father was an artist and professor at the Academy at Barcelona, and under him Pablo received his first lessons in art. After many visits to Paris, he settled there in 1903. Though a Catalan by birth, he developed his art in France, where he became one of the leaders of the Post-Impressionist school.

His early work displays a clear contour, a carefully planned space arrangement, and plastic modelling in cool, greenish-grey tones, almost monochrome. One might trace therein the influence of Daumier and of Toulouse-Lautrec. Like the latter, he chose the subject matter of his pictures from the life of the circus, and from the morbid side of life in a big city, and he rendered with intense sincerity of feeling the strained and sad look of young soubrettes of Montmartre, of acrobats and harlequins. He thus, from the beginning, followed a line distinct from that of Matisse and his Fauvist following, who took pleasure in colour and flat patterns, as such, and who never entirely broke with the traditions of Impressionism. To this early period are: "La Famille Soler" (1903), a rhythmically composed family group; "L'Aveugle" (1903), archaic in the delineation of form; "La Boule" (1905), a composition with two acrobats.

The Cubistic formula was gradually evolved by Picasso and Georges Braque, between 1906 and 1910, while studying the composition of still life groups consisting mainly of bowls with fruit, bottles, glasses, and musical instruments. It was Braque who first introduced into his designs nails and bits of printed paper, delighting in the harmonious distribution of certain black letterpress on white paper. Picasso then added pieces of wood and other tangible objects, which led to a form of art where sculpture and painting were combined.

During Picasso's earlier Cubist period, the surfaces of his canvases were delicately toned in brown or grey by dots in pointillist fashion displaying some constructive design—mainly abstract, though here and there realistic fragments of recognizable objects were introduced. The gradations of light and dark suggested shading and space. At a later period this three dimensional element disappeared; colour notes were introduced and the design formed a purely two dimensional pattern.

The artist did not seek to imitate form, but to create form. As opposed to the Impressionist pre-occupation with the rendering of ever-changing and superficial appearances, he wished to make images, which, by the clearness of their structure, should convey an idea of life and reality. Carrying his convictions to the logical extreme, he discarded all resemblance to natural form, and endeavoured to create a purely abstract language of form—a visual music. Thus, though these pictures may seem to most of us theoretic abstractions, the artist tried to convey a deep reality. "For reality alone, even when concealed has power to arouse emotion." In these realistic and mystical conceptions he shows himself a true son of Spain.

After 1918, Picasso again based his pictures on natural form. His paintings became magnificently plastic and monumental. His clear, incisive outline drawings are executed with forcible directness and with rigid economy of means.

Picasso's inventive gift, which led him from one experiment to another, inspired many followers. Painters such as Metzinger, Gleizes, Leger, Villon, and sculptors such as Archipenko and Lipschitz, to name only a few, followed in his wake. He was one of the first to appreciate the weird expressiveness of negro sculpture; his style led to an appreciation of "significant form" and of con-

structive design in all branches of art. He became the paramount influence in modern art, besides Cézanne, who is sometimes claimed as the initiator of the Cubist movement; though the great artist of Aix, with his intense feeling for nature, would probably have disowned this offspring.

Picasso's influence was also felt on the stage. He himself produced a series of designs for curtains, scenery and costumes for certain Russian ballets. The history of his collaboration with Jean Cocteau and Erik Satie in the ballet *Parade* (1917) is told by Cocteau in *Le coq et L'Arlequin* (English trans. 1921). Other ballets for which he produced designs were *Tricorne* (1920), *Cuadro Flamenco*, an Andalusian dance (1921), and *Pulcinella* (1926). In the creation of these artistic ensembles his great qualities as a designer, the unlooked for beauty of his harmonies, his astonishing audacities, stand him in good stead.

The most representative collection of his later work is in the possession of G. F. Reber, Lausanne. The best early works are with Lotte von Mendelssohn Bartholdy in Berlin. Other important works are with Paul Rosenberg, Paris; A. Flechtheim, Düsseldorf, and with the Barnes Foundation, Philadelphia.

Picasso illustrated several books, notably André Salmon, *Le Manuscrit trouvé dans un chapeau*. He executed portrait drawings of contemporary writers and musicians such as Stravinsky, J. Cocteau, M. Jacob, Apollinaire, A. Salmon, etc. He also etched several plates.

See Guillaume Apollinaire, *Les Peintres Cubistes* (1912); Max Raphael, *Von Monet zu Picasso* (Munich, 1922); Leone Rosenberg, *Cubisme et Tradition* (1920); Maurice Raynal, *Picasso* (1921); André Salmon, *L'Art Vivant and Picasso* (1920). (I. A. R.)

PICAYUNE, the name in Florida and Louisiana of the Spanish half-real = $\frac{1}{2}$ of a dollar, $6\frac{1}{4}$ cents, and hence used of the United States 5 cent piece; from the French *picailon*, an old copper coin of Piedmont, and possibly related to the Italian *piccolo*, little, small. In America the word is used of anything trifling or contemptible.

PICCININO, NICCOLO (1386-1444), Italian *condottiere*, born at Perugia. He served under the Visconti of Milan in campaigns against Francesco Sforza from 1425 to 1444.

PICCINNI, NICCOLA (1728-1800), Italian composer, was born at Bari, Naples, on Jan. 16, 1728. He was educated under Leo and Durante, at the Conservatorio di Sant' Onofrio in Naples. His first opera, *Le Donne dispettose*, was produced in 1755, and in 1760 he composed, at Rome, *La Cecchina, ossia la buona Figliuola*, an *opera buffa* which attained a European success. It was followed by many others, one of which, also an *opera buffa*, *Il Viaggiatori* (Naples 1774), had nearly as great a success as *La Cecchina*. In 1776 Marie Antoinette invited him to Paris. He had married in 1756 his pupil Vincenza Sibilla, a singer, whom he never allowed after her marriage to appear on the stage. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him, apparently against his will, to Gluck, by persuading the two composers to treat the same subject—*Iphigénie en Tauride*—simultaneously. The Parisian public now divided itself into two rival parties, which, under the names of Gluckists and Piccinnists, carried on an unworthy and disgraceful war. Gluck's *Iphigénie* was first produced on May 18, 1779. Piccinni's *Iphigénie* followed on Jan. 23, 1781, and, though performed seventeen times, was soon forgotten. Of the works of Piccinni's Paris period the best is *Didon* (1783), which kept the stage for half a century. In 1789, after the outbreak of the French Revolution, Piccinni returned to Naples, where he was at first well received by King Ferdinand IV.; but the marriage of his daughter to a French democrat brought him into irretrievable disgrace. For nine years after this he maintained a precarious existence in Venice, Naples and Rome; but he returned in 1798 to Paris, where a small place was found for him at the Conservatoire. He died at Passy, Paris, on May 7, 1800.

See P. L. Ginguené, *Notice sur la vie et les ouvrages de Niccola Piccinni* (Paris, 1801); E. Demoiresterres, *La Musique française au 18^e siècle*, Gluck et Piccinni, 1774-1800 (Paris, 1872); E. Blom, *Stepchildren of Music* (1926). For a list of his operas, which number over 80, see *Rivista musicale italiana*, viii. 75.

PICCOLO, a small flute of less than half the dimensions of the large concert flute and pitched an octave higher. The principles of construction and the acoustic properties are the same for the piccolo as for the flute, with the exception that the piccolo does not contain the additional tail-piece with the extra low keys, which give the flute its extended compass.

PICCOLOMINI, the name of an Italian noble family, prominent in Siena (*q.v.*) from the beginning of the 13th century onwards. In 1220 Enghelberto d'Ugo Piccolomini received the fief of Montertari in Val d'Orcia from the emperor Frederick II. as a reward for services rendered. They obtained great wealth through trade, and established counting-houses in Genoa, Venice, Aquileia, Trieste and in various cities of France and Germany. Supporters of the Guelph cause in the civil broils by which Siena was torn, they were driven from the city in the time of Manfred, restored after the Angevin victories, expelled again during the brief reign of Conradin and again restored with the help of Charles of Anjou. Their commercial influence passed to the Florentines. Many members of the house were distinguished ecclesiastics, generals and statesmen in Siena and elsewhere; two of them were popes, viz., Aeneas Silvius Piccolomini (Pius II., *q.v.*) and Francesco Piccolomini (Pius III., *q.v.*).

See Richter, *Die Piccolomini* (Berlin, 1874); A. Lisini and A. Liberati, *Albero della famiglia Piccolomini* (Siena, 1899); and articles by A. Lisini in the *Miscellanea storica senese*, 3rd series 12, and 4th series, 17 and 189.

PICCOLOMINI, OCTAVIO, PRINCE (1599-1656), duke of Amalfi, Austrian general, was born on Nov. 11, 1599 in Florence, and carried a pike in the Spanish service at the age of sixteen. On the outbreak of the Thirty Years' War he served in Bohemia and Hungary, then in Spain and Italy. In 1627 he re-entered the Imperial service as colonel and captain of Wallenstein's lifeguard. He was disgraced for practising extortion at Stargard in Pomerania, but hisadroitness soon secured him the rank of "colonel of horse and foot." In the Mantuan War Piccolomini acted both as subtle diplomatist and as plundering soldier of fortune when Gustavus Adolphus invaded Germany.

Piccolomini was interned at Ferrara as a hostage for the ratification of a treaty, but joined in urging Wallenstein's reappointment as commander-in-chief. He was not immediately promoted on the duke's reappearance, and served under General Holk, an officer brought in from the Danish service, in the preliminary operations and in the battle of Lutzen. After Lutzen, the Emperor made Piccolomini a *general-feldwachtmeister*. At the same time, however, Holk was created a field marshal at Wallenstein's instance, much to his rival's chagrin. In 1633 Piccolomini commanded an important detachment posted at Königgrätz to bar the enemy's advance from Silesia into Bohemia. In May he accompanied Wallenstein on his advance into Silesia, but disapproving of the duke's policy, joined in a military conspiracy, which ended in the murder of Wallenstein (Feb. 29, 1634). Piccolomini's own part in the tragedy is commemorated in Schiller's *Wallenstein*. His material rewards for his activities in connection with the downfall of Wallenstein were his marshal's bâton, 100,000 gulden and the beautiful estate of Nachod in the Riesengebirge.

In 1638 Piccolomini was made a count of the empire, and in 1639, won a great victory over the French (relief of Thionville, July 7, 1639), was rewarded with the office of privy councillor from the emperor and with the dukedom of Amalfi from the king of Spain. But instead of being appointed, as he hoped, Gallas's successor, he was called in to act as *ad latus* to the Archduke Leopold Wilhelm, with whom he was defeated in the second battle of Breitenfeld in 1642. After this he spent some years in the Spanish service, being granted the title of grandee and the order of the Golden Fleece. Having re-entered the Imperial army, he was again disappointed of the chief command by the selection of the brave veteran Peter Melander, Count Holzapfel; but in 1648 he was at last appointed lieutenant-general of the emperor, and thus conducted as generalissimo the final campaign of the Thirty Years' War at the end of which he was made prince. He died on Aug. 11, 1656. He left no children (his only son Josef Silvio, the "Max" of Schiller's *Wallenstein*, was murdered

by the Swedes after the battle of Jankau in 1645), and his titles and estates passed to his brother's son.

PICENE, $C_{22}H_{14}$, an aromatic hydrocarbon found in the products of the destructive distillation of lignite and peat tars and in the residues from the rectification of Californian petroleum. Picene crystallises in colourless leaflets with a blue fluorescence; it melts at $364^{\circ}C$ and boils above $500^{\circ}C$. A study of its oxidation by E. Bamberger and F. D. Chattaway (1893) gave picene-quinone (an ortho-diketone) and picenic acid. The latter when distilled with lime yielded $\beta\beta$ -dinaphthyl. These facts support the above constitutional formula, $C_{22}H_{14}$.

BIBLIOGRAPHY.—A. E. Everest, *The Higher Coal Tar Hydrocarbons* (1927).

PICENES. The Picenes do not figure at all prominently in the writings of ancient historians. They played a considerable rôle, however, in the confederacy of Italian states which challenged the hegemony of the growing Roman republic, and were punished at the end of the Social War by the complete suppression of their independence. The Picene capital was Ascoli, a little south of Ancona, on the eastern foothills of the Abruzzi.

The territory of the Picenes extended, to judge from the uniform character of the archaeological remains, all along the Adriatic coast from Rimini to the river Sangro; south of which again the Samnite mountaineers of Aufidena exhibited a civilization of identical character, though far less opulent. Inland, the Picene influence, and very probably the same population, extended as far as the midrib of the Apennines. A very ancient settlement at Terni, made long before 1000 B.C., may plausibly be attributed to them, and some writers think that they had a certain number of stations even in Latium. This would be perfectly natural if the Picenes were the principal survivors of a fairly homogeneous Neolithic population which once extended over the whole north and centre of Italy. According to this theory the Neolithic people were conquered and overwhelmed first by the invaders of the Bronze Age and then by the Villanovans (see VILLANOVANS). Neither of these incursions, however, penetrated further down the east coast than Rimini, at which point they were checked and diverted by the fighting forces of the Picenes.

This people retained its independence down to the third century B.C. when it finally succumbed to the Romans. It represents a phase of culture in the Early Iron Age diametrically opposed to that of the Villanovans, derived from a different source and developed under different inspiration. The first contrast between Villanovans and Picenes is in respect of their burial customs. The Villanovans cremated their dead, and the small percentage of inhumations occurring here and there within their territory may be ascribed to the survival of some few of the original Neolithic inhabitants. The Picenes on the other hand used no rite except inhumation; they buried their dead in the earth, generally in the contracted position customary among the aborigines, and cremation was entirely unknown in their part of the country.

The beginning of archaeological research in Picenum dates from the discovery by E. Brizio, in 1892, of two large and important cemeteries at Novilara, near Pesaro. Two remarkable stelae had been found in this neighbourhood 30 years earlier, with lines written in a script resembling the Etruscan in its general character, but expressing a wholly different language which is inferred to be Sabellic (*q.v.*). Several more of these stelae were found at Novilara itself, and at neighbouring places including Fano, but they still await translation. Two of them are engraved with rude but very interesting pictures of native life, representing naval battles and scenes of hunting and fighting. They are further ornamented with spiral designs, which misled earlier investigators, who saw only their superficial resemblance to sub-Mycenaean patterns. It is now established that the stelae are at any rate not older than 700 B.C.

In the Novilara cemeteries were found, besides stelae, numerous other objects and ornaments which make it possible to recon-

struct some outlines of the economic history of the Adriatic coast. About a dozen tombs at Novilara are as early as the 10th and 9th centuries B.C., while a few sporadic finds at Ancona and neighbouring points are no less ancient. From the contents of these it can be seen that the east coast of Italy was participating as early as the 10th century in the important trade in Baltic amber, which came down a main trunk route to the head of the Gulf of Venice. It can be seen also that Pesaro and Ancona were in no way dependent upon Bologna, inasmuch as many of the fibulae are of types quite unknown to the Villanovans though perfectly familiar in Greece and Sicily.

It is to commercial relations, rather than to any movement of immigration, that the composite character of Picene civilization should be attributed. In spite of the numerous details of their life which suggest analogies with the Balkans, or with Greece of the Dipylon period, there is no evidence that the population was derived, or substantially recruited, from either of these sources. The general stock of the inhabitants remained as it always had been, predominantly composed of the Mediterranean race originally derived from North Africa.

The essential characteristic of the Picenes is that they were primarily and above everything else fighting men. It has been pointed out that even before the dawn of the Iron Age they were obliged to defend their borders. They succeeded in maintaining their independence for many centuries. It is not surprising, therefore, that many tombs at Novilara contained weapons. The favourite arm was the spear, and the next in frequency was the dagger, of which there were several patterns. Swords seem to have been rather the weapons of the élite, and were extremely handsome. Helmets are fairly frequent, shields very rare, in the graves.

From graves of the 8th and 7th centuries B.C. at Novilara a complete picture may be recovered of the arms and equipment of a Picene foot soldier. His favourite sword was a broad and short weapon of iron, intended, like a sabre or a tulwar, for the heaviest cutting. Its edge was on the inside, and the hilt curved back at an angle like that of an ancient Bosnian hewing-knife. In fact there can be no doubt that swords of this kind were originally imported from the Balkans where the general type has always been well known. The curiously shaped sheath was made of wood, covered with sheets of bronze finely engraved with geometric patterns. Other swords found at Novilara are definitely Greek in origin, being of shapes familiar from the paintings on Dipylon vases. Similarly the helmets and shields are of Greek patterns, but the daggers, except when they seem to be original Italian products, follow the stock forms derived from the Hallstatt series prevalent all over Europe. The entire outfit is thus curiously hybrid in character, and quite unlike that of any other Italians. Not less characteristic than the armament of the men were the ornaments and apparel of the women. A certain number of objects were imported from the factories of Etruria or Bologna. Such are the bronze manicuring sets hung upon chatelaines attached to the waist, and the bronze ear-cleaners terminating in the figure of a monkey or of Aphrodite surrounded by doves. But the narrow girdles made of chain mail in links, the huge and elaborate pendants terminating in imitation sea-shells, the handsome torques and pectorals make an ensemble quite unlike anything found among Villanovans or Etruscans.

The rich cemeteries discovered along the coast in the neighbourhood of Ancona have been little studied, and no full publication of them is yet available. All the material obtained from them may be seen in the Ancona museum, in the large buildings of a disused monastery in the city. The richest cemetery was that of Belmonte, but the collections from Cupra-marittima, Grotta-mare and several smaller sites are also very important. Belmonte, in particular, which dates to the 6th and 5th centuries B.C., has yielded some very fine examples of Ionic Greek work in the minor arts. There are bronze bowls decorated with figurines of cast bronze, a favourite representation being that of Herakles as the tamer of lions and horses; jugs and vessels of hammered bronze and many superb carvings in amber, of which there was a prodigal abundance at this period. At Rapagnano were found two

shield-bosses of bronze, ornamented with scenes of combat between mounted men and foot soldiers in the best Ionic style. Greek influence was entirely predominant in Picene art from the 6th century onwards, but it is important to observe that it found its way, not through Etruria, but quite directly from the Greek colonies of southern Italy. This is proved by the simultaneous presence in these tombs of the very distinctive and peculiar Apulian geometric pottery, which is unknown in Etruria.

Indeed, so far as present evidence avails, and allowing that it is dangerous to prophesy in regard to a region only partially explored, Etruscan influence on the Adriatic coast was very slight and unimportant. A tumulus of the 7th century found at Fabriano is almost entirely Etruscan in its contents, but as yet this is an isolated example. A certain amount of trade was undoubtedly carried on across the Apennines, but there is little in the general complex of Picene life which suggests a strong Etruscan impress. On the contrary, it remains a curiously individual and virile civilization, in spite of its many borrowings. The backbone of Picene commerce was constituted by a lively trade with Istria, which may be clearly traced by means of a comparative study of the objects found in the graves. Nothing, except the existence of a trade-system which centred at the head of the Gulf of Venice, could explain the remarkable circumstance that, in places as far apart as the Italian lakes, Istria, Picenum and Bosnia, there have been found torques, pendants and amulets so precisely similar that they must have been distributed by the same firm of agents.

See E. Brizio in *Monumenti Antichi*, vol. v.; D. Randall-MacIver, *The Iron Age in Italy* (1927); and for a literary treatment from other points of view, F. von Duhn, *Italische Graberkunde*, vol. i. (1924). (D. R.-M.)

PICENUM, a district of ancient Italy, situated between the Apennines and the Adriatic, bounded north by the Senones and south by the Vestini. The whole territory was divided up among Latin-speaking settlers by the Lex Flaminia in 232 B.C.

It was in Picenum (at Asculum) that the Social War broke out in 90 B.C. Under Augustus it formed the fifth region of Italy, and included twenty-three independent communities. It was reached from Rome by the Via Salaria and the Via Caecilia.

At the end of the 2nd century A.D. the north-eastern portion of Umbria acquired the name Flaminia, from the high road. For the time it remained united with Umbria for administrative purposes, but finally passed to Picenum in the time of Constantine, and acquired the name of *Flaminia et Picenum Annonarium*, the main portion of Picenum being distinguished as *Suburbicarium*. When the exarchate of Ravenna was founded the part of Picenum Annonarium near the sea became the Pentapolis Maritima, which included the five cities of Ariminum, Pisaurum, Fanum Fortunae, Sena Gallica and Ancona. The exarchate was seized by Luitprand in 727, and Ravenna itself was taken by Aistulf in 752. In 753, however, the Emperor Pepin handed it over to the pope, a grant confirmed by Charlemagne.

PICHEGRU, CHARLES (1761-1804), French general, was born at Arbois, or at Les Planches, near Lons-le-Saulnier, on Feb. 16, 1761. His father was a labourer, but the friars of Arbois gave the boy a good education, and the Père Partault took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sublieutenant. At the Revolution he became leader of the Jacobin party in Besançon, and when a regiment of volunteers of the department of the Gard marched through the city he was elected lieut.-colonel. Quickly promoted to the command of the army of the Rhine, in co-operation with Hoche and the army of the Moselle, Pichegru reconquered Alsace and forced the lines of Haguenau and relieved Landau. In Dec. 1793 Hoche was arrested and Pichegru became commander-in-chief of the army of the Rhine-and-Moselle, succeeding Jourdan in the army of the North in Feb. 1794.

It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated

Clerfayt at Cassel, Menin and Courtrai, while Moreau, his second in command, defeated Coburg at Tourcoing in May 1794; then after a pause, during which Pichegru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselaer and Hooglede, while Jourdan came up with the new army of the Sambre-and-Meuse, and utterly routed the Austrians at Fleurus on June 27, 1794. Pichegru began his second campaign by crossing the Meuse on Oct. 18, and after taking Nijmegen drove the Austrians beyond the Rhine. Then, instead of going into winter-quarters, he prepared his army for a winter campaign. On Dec. 28 he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on Jan. 19 and Amsterdam on Jan. 20, and soon occupied the whole of Holland. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of "Sauveur de la Patrie," subdued the *sans-culottes* of Paris, when they rose in insurrection against the Convention on 12 Germinal (April 1). Pichegru then took command of the armies of the North, the Sambre-and-Meuse and the Rhine, and crossing the Rhine in force took Mannheim in May 1795.

When his fame was at its height he allowed his colleague Jourdan to be beaten, betrayed all his plans to the enemy, and took part in organizing a conspiracy for the return of Louis XVIII. His intrigues were suspected, and when he offered his resignation to the Directory in Oct. 1795, it was promptly accepted. He retired in disgrace. In the Council of Five Hundred (May 1797) he was the royalist leader, and planned a *coup d'état*, but on the 18th Fructidor he was arrested, and deported to Cayenne in 1797. Escaping, he reached London in 1798, and served on General Korsakov's staff in the campaign of 1799. He went to Paris in Aug. 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but was arrested on Feb. 28, 1804, and on April 15, was found strangled in prison. He was a man of enormous strength and great personality.

There is no really good life of Pichegru; perhaps the best is J. M. Gassier's *Vie du général Pichegru* (1815). For his treason, trial and death, consult Montgaillard's *Mémoires concernant la trahison de Pichegru* (1804); Fauche-Borel's *Mémoires*; Savary, *Mémoires sur la mort de Pichegru* (1825); and G. Pierret, *Pichegru, son procès et sa mort* (1826); and Sir J. R. Hall, *General Pichegru's Treason* (1915).

PICHER, a city of Ottawa county, Oklahoma, U.S.A., in the north-eastern corner of the state, near the Kansas boundary; on federal highway 69 and served by the Miami Mineral Belt, Northeast Oklahoma, Frisco and electric railways. The population was (1930) 7,773 and 5,848 in 1940 by the federal census. It is one of the principal mining centres in the "Tri-State region," which produces 60% of the zinc and 15% of the lead mined in the United States. The city is built entirely on leased land, owned by the Quapaw Indians. The first mine was opened in 1915. The city was incorporated in 1920, and has grown rapidly.

PICKENS, ANDREW (1739-1817), American soldier in the Revolutionary War, was born in Paxton, Pa., on Sept. 19, 1739. His family settled at the Waxhaws (in what is now Lancaster county), S.C., in 1752. He fought against the Cherokees in 1761 as a lieutenant. In the Revolutionary War he rose to brigadier-general (after Cowpens) in the South Carolina militia. On Feb. 14, 1779, with 300-400 men, he surprised and defeated about 700 Loyalists on Kettle Creek, Wilkes county, Ga.; and later in the same year at Tomassee defeated the Cherokees, who were allied with the British. Upon the surrender of Charleston (May 1780) he became a prisoner on parole, which he observed rigidly until, contrary to the promises made to him, Maj. James Dunlap plundered his plantation; he then returned to active service. His command (about 150 men) joined Gen. Daniel Morgan immediately before the battle of Cowpens, in which Pickens commanded an advance guard (270-350 men from Georgia and North Carolina) and twice rallied the broken American militia; for his services Congress gave him a sword. With Col. Henry Lee he harassed Lieut.-col. Banastre Tarleton, who was attempting to gather a Loyalist force just before the battle of Guilford court house; and with Lee and others, he captured Augusta (June 5, 1781) after a siege. At Eutaw Springs (Sept. 8, 1781) he commanded the left wing and was

wounded. In 1782 he defeated the Cherokees again. After the war he was active for several years in state politics, and in 1793-95 was a representative in Congress. He died in Pendleton district, S.C., on Aug. 17, 1817. He married in 1765 Rebecca Calhoun, an aunt of John C. Calhoun. Their son, ANDREW PICKENS (1779-1838), served as a lieutenant-colonel in the War of 1812, and was governor of South Carolina in 1816-18.

See E. B. Pickens, "Life of General Pickens," *Journal of Amer. Hist.*, vol. xviii., pp. 131-136 (1924).

PICKENS, FRANCIS WILKINSON (1805-1869), American politician, was born in Togadoo, St. Paul's parish, S.C., April 7, 1805, son of Andrew Pickens (1779-1838) and grandson of Gen. Andrew Pickens (1739-1817). He was educated at Franklin college, Athens, Ga., and at South Carolina college, Columbia, and was admitted to the bar in 1829. In 1832 he was elected to the State house of representatives, where he submitted a report denying the right of Congress to exercise any control over the States. He was a Democratic member of the national house of representatives in 1834-43, served in the South Carolina senate in 1844-45, was U.S. minister to Russia in 1858-60, and in 1860-62 was governor of South Carolina. He strongly advocated the secession of the Southern States; signed the South Carolina ordinance of secession; sanctioned firing upon the "Star of the West" (Jan. 9, 1861), which was bringing supplies to Anderson, and the bombardment of Ft. Sumter. He died at Edgefield, S.C., on Jan. 25, 1869.

PICKEREL, the name used, especially in America, where there are several species which never reach a large size, for certain small pike (*q.v.*); in England small specimens of *Esox lucius*, the only species represented, are usually termed jack.

THE EASTERN PICKEREL, AVERAGE LENGTH ABOUT 2 FEET

PICKERING, EDWARD CHARLES (1846-1919), American physicist and astronomer, was born in Boston on July 19, 1846. He was graduated in 1865 in the Lawrence Scientific school of Harvard, where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology, where he established the first laboratory in America, in which students were instructed by actual contact with physical instruments and measurements. In 1876 he was appointed professor of astronomy and director at the Harvard college observatory. In 1877 when most observatories were devoting themselves to the old "astronomy of position" Prof. Pickering, who was a physicist rather than an old school astronomer, chose as his particular field of labour the photometry of the stars, thus presaging the trend of the new astronomy along lines of physics. He invented the meridian photometers (see PHOTOMETRY: Stellar), with which the brightness of more than 45,000 stars has been measured at Cambridge and Arequipa (Peru) observatories, and the resulting system generally adopted as an international standard. Prof. Pickering, personally, made more than 1,500,000 photometric settings.

Through the establishment of an observatory at Arequipa (1891), after two years of study it became possible to include measurements made on the stars throughout the Southern heavens within the scope of the Harvard college observatory's work.

The work of the observatory under Prof. Pickering may be summarized as including photometry, in which photometric magnitudes for 80,000 stars have been determined; a scale of photographic magnitude; a system of classification of variable stars; and a system of stellar spectroscopy which has been universally adopted. As a result of Pickering's work, the Harvard "photographic library" of stars contains more than 250,000 photographic plates. He died at Cambridge, Mass., on Feb. 3, 1919.

For bibliography and further biographical material see *Biographical Memoirs of National Academy of Sciences*, vol. vii., pp. 52-57. See also *Proceedings of the American Academy of Arts and Sciences*, vol. lvii., pp. 502-506 (Boston, 1922); *Monthly Notices of Royal Astronomy Society*, vol. viii., pp. 360-365.

PICKERING, TIMOTHY (1745-1829), American politician, was born at Salem, Mass., on July 17, 1745. He graduated

from Harvard college in 1763 and was admitted to the bar in 1768. In the pre-Revolutionary controversies he identified himself with the American Whigs; and in 1776 he was a representative from Salem in the general court of Massachusetts. Early in 1775 he published *An Easy Plan of Discipline for a Militia*. In the same year he became judge of the court of common pleas for Essex county, and in the winter of 1776-77 he led an Essex regiment of volunteers to New York. He subsequently served as adjutant general, later as quartermaster general and was also a member of the board of war. In April, 1783, he drew up a plan for the settlement of the North-West territory, which provided for the exclusion of slavery. In 1785 he became a commission merchant in Philadelphia; but in Oct., 1786, soon after the legislature of Pennsylvania had passed a bill for erecting Wyoming district into the county of Luzerne, he was commissioned to organize the county. He offered to purchase for himself the Connecticut title to a farm, and in 1787 he was appointed a member of a commission to settle claims according to the terms of an act, of which he was the author, confirming the Connecticut titles (see WYOMING VALLEY and WILKES-BARRE). In 1790 he negotiated a peace with the Seneca Indians, and he concluded treaties with the Six Nations in 1791-94. Under Washington he was postmaster general (1791-1795), secretary of war (1795), and after December, 1795, secretary of state, to which position he was reappointed (1797) by Adams. In 1783, while he was quartermaster general, he had presented a plan for a military academy at West Point, and, as secretary of war, he supervised the West Point military post with a view to its conversion into a military academy. As head of the state department he soon came into conflict with Adams. His hatred of France made it impossible for him to sympathize with the president's efforts to settle the differences with that country peaceably. He was dismissed, after refusing to resign, in 1800. Returning to Massachusetts, he was elected a United States senator in 1803-11 and a member of the House of Representatives in 1813-17. As an ultra Federalist—he was a prominent member of the group known as the Essex junto—he strongly opposed the purchase of Louisiana and opposed the War of 1812. He died at Salem, Mass., on Jan. 29, 1829.

The standard biography is that by his son, Octavius Pickering (1791-1868), and C. W. Upham, *The Life of Timothy Pickering* (Boston, 1867-1873). In the library of the Massachusetts Historical Society at Boston, there are 62 manuscript volumes of the Pickering papers, an index to which was published in the *Collections of the society*, 6th series, vol. viii. (Boston, 1896).

His son, JOHN PICKERING (1777-1846), graduated at Harvard in 1796. He wrote on the languages of the North American Indians. He was a founder of the American Oriental Society and published a *Comprehensive Dictionary of the Greek Language* (1826).

Timothy Pickering's grandson, CHARLES PICKERING (1805-1878), was naturalist to the Wilkes exploring expedition of 1838-42, and in 1843-45 travelled in East Africa and India.

PICKERING, WILLIAM HENRY (1858-1938), American astronomer, was born in Boston, Mass., on Feb. 15, 1858, and in 1879 graduated at the Massachusetts Institute of Technology. He served as an assistant and instructor in physics at his Alma Mater from 1880 to 1887, and then became an assistant in astronomy at the Harvard college observatory. In 1889 he was made assistant professor of astronomy. He led expeditions for observing total solar eclipses to Colorado, 1878; Grenada, West Indies, 1886; California, 1889; Chile, 1893; and Georgia, 1900. While in southern California in 1889 he selected the Mt. Wilson site and established a temporary observatory there. In 1891 he established the Arequipa station of the Harvard observatory in Peru. He also established a meteorological station at an altitude of 16,650 ft. upon Mt. Chachani, and accomplished the ascent of El Misti, 19,200 feet. He surveyed and determined the altitude of many other Peruvian mountains and returned to the United States by way of the Straits of Magellan in 1893. In 1894 he erected the observatory and telescope for Dr. Percival Lowell (*q.v.*) at Flagstaff, Ariz., and in 1900 erected a station for the Harvard observatory at Mandeville, Jamaica, in the West Indies. In 1899 he discovered Phoebe, 9th satellite of Saturn,

and explained its contrary revolution. The doubtful 10th satellite, *Themis*, which he announced in 1905, remains unconfirmed. In 1904 he again went to California to make observations of the moon, in 1905 to Hawaii, and in 1907 to the Azores to compare their crater formations with those in the moon. His work in planetary photography and photometry was especially notable. In later years he turned more and more to the study of Mars.

Besides many papers in astronomical journals (see especially *Popular Astronomy*), he wrote *A Walking Guide to the Mt. Washington Range* (1882); *Investigations in Astronomical Photography* (1895); *Visual Observations of the Moon and Planets* (1903); *An Atlas of the Moon* (1903); *Lunar and Hawaiian Physical Features Compared* (1906); *A Search for a Planet Beyond Neptune* (1909); *A Statistical Investigation of Cometary Orbits* (1911); *Mars* (1921).

PICKERING, urban district and town in the North Riding of Yorkshire, England, 32 mi. N.N.E. from York by the L.N.E.R., on which it is an important junction. Pop. (1938) 3,887. Area, 24.4 sq.mi. The town lies at the foot of the York moors at the entrance to one of the river ways into the Vale of Pickering. It is the centre of an agricultural and pastoral area with a broad belt of arable land in the vale given to cereal and fodder crops. North of Pickering is a moorland grazing area. Agricultural implements are manufactured there, and limestone and freestone are quarried in the vicinity.

A castle existed at Pickering before the Conquest, and the present ruin on a hill to the north of the town is partly Norman but mainly 14th century in style. A fragmentary keep and several towers remain. It was the prison of Richard II. before his confinement at Pontefract. During the Civil War, it was held by the royalists and suffered greatly in siege.

PICKETING: see TRADE UNIONS.

PICKETT, GEORGE EDWARD (1825–1875), American Confederate soldier, born at Richmond, Va., Jan. 25, 1825. Upon graduation at West Point in 1846 he was assigned to the 8th United States infantry; served with distinguished valour in all the battles of Gen. Scott in Mexico, including the siege of Vera Cruz and the storming of Chapultepec, where, it is said, he was first to scale the parapets and unfurl the American flag over the castle. After peace was restored, Pickett was transferred to Washington Territory where he was destined to play an important role in the north-west boundary controversy. In 1859 he was ordered to occupy San Juan island, where he prevented the landing of a superior force of British troops. On the outbreak of the Civil War he resigned his command (June 1861) and offered his services to the Confederacy. He was commissioned captain and after a short time was made a colonel. In Feb. 1862 he was appointed a brigadier-general and assigned to the command of a Virginia brigade of infantry. During that year he rendered able service in the battles of Williamsburg, Seven Pines, Gaines Mill and Fredericksburg. While leading his men at Gaines Mill he was severely wounded, but upon returning to his command in September he was made a major-general. At Gettysburg, his division was held in reserve until July 3 when it led the attack on Cemetery hill. The charge of Pickett's men is one of the most famous episodes of military history. Over three-quarters, 3,393 officers and men out of 4,500 were left on the field. He subsequently commanded the Confederate forces in North Carolina but after the failure to take Newbern, he turned north to defend Petersburg. His troops participated in the assault on Grant's line at Cold Harbor and performed excellent service in the closing campaign of 1865 at Dinwiddie court house and Five Forks. After the Civil War he went to Richmond and later to Norfolk where he was engaged in the insurance business. His death occurred in Norfolk on July 30, 1875.

See La Salle Corbell Pickett, *Pickett and his Men* (1899, rev. ed., 1913), and A. C. Inman, editor, *Soldier of the South; Gen. Pickett's War Letters to His Wife* (1928).

PICKFORD, MARY (1892–) (stage name of Gladys Smith), American motion picture actress, born at Toronto, Canada, April 8, 1892. Her first stage appearance was at the age of five; at eight she went on tour. She went to New York under the auspices of Belasco, creating the part of Betty Warren in *The Warrens of Virginia*. Her first motion picture work was undertaken with D.

W. Griffith as an extra; but she returned to Belasco, taking the part of Juliet in *A Good Little Devil* at the Republic theatre in New York. In 1913 she returned to the screen with Famous Players Company, and rose to the first rank. In 1916 the Mary Pickford Film Corporation was organized. In 1918 she became an independent producer and the following year was prime mover in forming the United Artists Corporation. She married Douglas Fairbanks in 1920, was divorced in 1935, and married Charles Rogers in 1937.

PICKLE. In the wider sense the term "pickle" is applied to any saline or acid preservative solution; in the narrower to vegetables preserved in vinegar. The word appears to be an adaptation of the Dutch *pekel*, brine, pickle; cf. Ger. *Pokel*. A solution of copper or zinc sulphate is used as a "pickle" for railway ties or other wood, a brine containing salt and saltpetre as a preservative for meat, lime-water as "pickle" for eggs. Domestic pickles are made from small cucumbers, onions, cauliflowers, cabbages, mangoes, unripe walnuts and other fruits and vegetables, by either steeping or boiling them in salt-brine and vinegar.

PICKLEWEED: see IODINE-BUSH.

PICO, an island in the Atlantic ocean, belonging to Portugal, forming part of the Azores archipelago; pop. about 25,000 and area 175 sq. miles. Pico rises to the height of 7,613 feet. The soil is of volcanic origin. The island was formerly famous for its Fayal wine (Fayal is, however, an adjacent island), but in 1852 the vines were destroyed by disease. Similar destruction affected the fruit trees (orange) and a period of emigration followed. The distress was alleviated by the planting of fig-trees and the cultivation of apricots. The chief town is Lagens do Pico.

PICO DELLA MIRANDOLA, GIOVANNI, COUNT (1463–1494), Italian philosopher and writer, the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory not far from Ferrara, afterwards absorbed in the duchy of Modena, was born on Feb. 24, 1463. In his fourteenth year Pico went to Bologna, where he studied for two years, and was much occupied with the Decretals. He then spent seven years wandering through Italy and France and collecting a precious library. Besides Greek and Latin he knew Hebrew, Chaldee and Arabic; and his Hebrew teachers introduced him to the Kabbalah. He settled in 1486 at Rome, where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of philosophy and theology, but the pope prohibited them, and Pico had to defend the impugned theses in an elaborate Apologia. His personal orthodoxy was subsequently vindicated by Alexander VI. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries and it was by him that Reuchlin was led into the same delusive path.

In his 28th year Pico published the *Heptaplus*, a mystical exposition of the Creation. Next he planned a great seven-fold work against the enemies of the Church, of which only the section against astrology was completed. After leaving Rome he again lived a wandering life, often visiting Florence, to which he was drawn by his friends Politian and Marsilius Ficinus, and where also he came under the influence of Savonarola. Three years before his death he parted with his share of the ancestral principality, and designed, when certain literary plans were completed, to give away all he had and wander barefoot through the world preaching. But these plans were cut short by a fever which ended in his death at Florence on Nov. 17, 1494.

His works were published at Bologna in 1496 by his nephew, with a biography, which was translated by Sir Thomas More as *Life of John Picus, Earl of Mirandola*, in 1510. See Walter Pater's *Renaissance* (1878); the study by J. Rigg, prefixed to the reprint of More's *Life in the "Tudor Library"* (1890). Mortetani, *La filosofia cabbalistica di Pico della Mirandola* (Empoli, 1898); and A. Levy, *Die Philosophie Picos della Mirandola* (1908).

PICRIC ACID or **LYDDITE**, is a yellow crystalline solid melting at 122.5° C and owes its name to the intensely bitter and persistent taste of its yellow aqueous solution. As experiments regarding the use of picric acid as a high explosive were once conducted at the town of Lydd (Sussex), the name Lyddite became attached to the acid. The term melinite is employed in France and Germany, and shinosite indicates the Japanese variety of this

explosive. As its graphic formula (inset) indicates, it is a benzenoid derivative with three hydrogen atoms of the benzene nucleus replaced by nitro (NO₂) groups, and one replaced by a hydroxyl (OH) group, whence its name and formula 2:4:6 trinitrophenol HO·C₆H₂(NO₂)₃. It is a typical example of a nitro-compound of the aromatic series, and was formerly employed as an acid dyestuff giving yellow shades on wool or silk. Although acting as a poison when administered in quantities exceeding a few milligrams, its saturated aqueous solution may safely be applied to burns and scalds with the object of subduing the pain, which it effects by paralysing the sensory nerve endings.

The ordinary method of manufacturing picric acid is to dissolve phenol in strong sulphuric acid thus making a phenolsulphonic acid, $C_6H_5OH + H_2SO_4 = HO \cdot C_6H_4 \cdot SO_3H$, which on treatment with a moderate excess of nitric acid regenerates sulphuric acid, and at the proper temperature gives finally trinitrophenol. This separates as an oily liquid which becomes solid on cooling. It is washed with cold water to remove excess of acids and then dissolved in hot water, from which it crystallizes in yellow scales, plates or needles, depending on the concentration of solution. The picrates of ammonia and of the alkali metals sodium and potassium are most soluble, whereas the lead salt and a few others are sparingly soluble in water. Certain organic bases, such as acridine, give more insoluble salts than metals. When heated above its melting point picric acid puffs or burns with a smoky flash: a small amount may sublime as a yellow powder. This burning does not appear to be dangerous when only small quantities are dealt with unless the external heating be rapid and extensive, so that the whole bulk under experiment is heated up; in that case the simple burning passes over into a kind of detonating decomposition. The metallic salts of picric acid are most liable to this violent form of explosion, in fact it is almost the only form of explosion they exhibit either on heating or under percussion. The picrates of lead, bismuth and other heavy metals are extremely sensitive to friction or percussion as well as heating, especially when dry. The pure acid itself is not dangerously sensitive to percussion, although a powerful and quick glancing blow will often induce decomposition. The explosion of a very small amount of a picrate—as the lead or potassium salt—in contact with the acid, especially if the latter be in a compact state, generally induces a complete detonation. At one time picric acid was much in favour either as an ingredient of an explosive mixture with some special objective use or alone. Among the mixed explosives containing picric acid may be mentioned Brugères powder, a mixture of 54 parts of ammonium picrate and 45 of potassium nitrate; Designolles' powder, potassium picrate, potassium nitrate and charcoal; and Emmensite, of similar composition, suggested by Mr. Emmens, U.S.A. Many others were designed for blasting or similar purposes.

(W. R. Ho.)

PICRITE, in petrology, an intrusive igneous rock of ultrabasic composition somewhat similar to peridotite (*q.v.*). The name, given by Tschermak in 1866, is derived from *πικρός*, "bitter," owing to the high percentage of magnesia (bitter earth) these rocks contain. The picrites are dark, heavy rocks largely composed of olivine and augite, with a small but variable amount of plagioclase feldspar. Hornblende and biotite may also be present. The picrites usually occur in sills or sheets, and seldom in large plutonic masses (unlike peridotites). Varieties of picrite include augite, enstatite and hornblende picrite.

The minerals of picrites are very frequently decomposed. Serpentine partially or wholly replaces olivine, while hornblende (pilitite), talc and chlorite appear as secondary products after the same mineral. Augite passes into hornblende or chlorite, and the essential feldspar is often represented by epidote, prehnite and white mica. In some picrites, as in the peridotites, a "lustre mottling" is given by the poikilitic inclusion of olivine grains in large crystals of augite or hornblende. In the porphyritic varieties a residual brown glass may be present. Such rocks are known as picrite-porphyrates.

Many picrites clearly possess alkaline affinities. Thus the augite

picrites of the Midland valley of Scotland and of the type locality in Moravia contain interstitial analcime and are closely related to the teschenites with which they are associated. Other picrites are more clearly calc-alkaline, being associated with diorites or dolerites. The hornblende picrites of Carnarvonshire, Anglesey and other places belong here. In the Devonian rocks of the Fichtelgebirge and Nassau picrites accompany dolerites and proterobases, as they do also in Cornwall and Devon. The term picrite-basalt is reserved for felspar-poor basalts rich in olivine. (C. E. T.)

PICROTOXIN, a neutral principle obtained from the *Cocculus indicus*, which is the fruit of the *Anamirta paniculata*. It is used in medicine externally as an antiparasitic. Internally it has been successfully used to check the night-sweats of phthisis. In large doses it is a powerful poison, causing unconsciousness, delirium, convulsions, gastro-enteritis and stimulation of the respiratory centre followed by paralysis, from which death sometimes results. Formerly *Cocculus indicus* berries were sometimes added to beer to increase the intoxicating effects. The chemical formula of picrotoxin is C₁₅H₁₆O₆·H₂O.

PICTISH. The language of the ancient Picts is of uncertain origin and of doubtful affinity. "The Picts have left us a number of inscriptions in the Ogham character. No attempt to interpret these inscriptions as any form of Celtic has produced anything but bosh. Whatever may have been the Pictish language, these inscriptions assure us that it was certainly not Celtic." (R. A. S. Macalister in *Antiquity* II., 7, 1928, p. 373.) Examination of the symbols found upon monumental stones in Pictland suggests analogies with certain elements in Bronze age sculpturings—a highly probable affinity if the Picts were the survivors of Bronze age aborigines, influenced by La Tène culture.

The term *Pict* itself may be connected with the Latin *Pictones* and *Pictari* of Gaul. In Irish they are known as *Cruithne*, in Welsh as *Prydyn*, which (*cf.* Prydein, or British) significantly resembles the earliest Greek name for the British Isle, *Prettonic Islands*. From the matrilineal succession of their chieis (the records being doubtful) it has been inferred that their social structure differed from that of other Gaelic speaking peoples. Pictish extended to the north of Ireland, and was finally ousted by the Goidelic speech of the Scots, which was derived from Ireland.

See T. R. Holmes, *Caesar's Invasion of Britain* (1907).

PICTOGRAPHY. In the history of writing a very large number of conventional marks are demonstrably reductions from still older forms, which have often developed out of pictographs. Pictography has left its traces in all parts of the world, but was most widely developed in the New World as a system lasting down to modern times.

Very simple pictures are drawn upon birch bark, indicating by their order the subjects in a series of song-chants with sufficient precision to enable the singer to recall the theme of each in his recitation. An account can be kept of sales or purchases by representing in perpendicular strokes the number of items, and adding at the end of each series a picture of the animal or object to which the particular series refers. Thus three strokes followed by the picture of a deer indicate that the hunter has brought three deer for sale. A conventional symbol (a circle with a line across it) is used to indicate a dollar, a cross represents ten cents, and an upright stroke one cent, so that the price can be quite clearly set forth. This practice is followed in many other parts of the world. In clay tablets discovered by Sir Arthur Evans at Knossos, in Crete, a somewhat similar method of enumeration is followed; while at Athens conventional symbols were used to distinguish drachmae and obols upon the revenue records.

In comparatively recent times the Dakota Indians invented a chronological table, or winter count, wherein each year is recorded by a picture of some important event which befell during that year. In these pictures a considerable amount of symbolism was necessary. A black upright stroke indicates that a Dakota Indian was killed, a rough outline of the head and body spotted with blotches indicates that in the year thus indicated the tribe suffered from smallpox. Sometimes, in referring to persons, the symbol is of the nature of a rebus. Thus, Red Jacket, an Indian chief, was killed in the winter of 1807-8; this fact is recorded by a red coat

with two arrows piercing it and blood dripping. There is, however, nothing of the nature of a play upon words intended. Here the Mexicans proceeded a stage further, as in the often quoted case of the name of *Itz-coatl*, literally knife-snake, which is ordinarily represented by a reptile (*coatl*) with a number of knives (*itz*) projecting from its back. It is, however, also found divided into three words, *itz-co-atl*—knife-pot-water—and represented by a different picture accordingly. The Mexicans, moreover, to indicate that the picture was a proper name, drew the upper part of the human figure below the symbol, and joined them by a line, a practice adopted also among their northern neighbours when, as in names like Little-Ring, the representation would hardly be sufficiently definite. Simple abstract notions could also be expressed in this picture-writing. Starvation or famine was graphically represented by a human figure, with the ribs showing prominently. A noose among the Mexicans was the symbol for robbery, though more logically belonging to its punishment. In a Californian rock-painting sorrow is represented by a figure from whose eyes drop tears. This could be abbreviated to an eye with tears falling from it, a form recorded by Schoolcraft as existing among the Ojibwa Indians. The symbol is so obvious that it is found with the same value among Egyptian hieroglyphics.

To the more elaborate civilizations of the old world, the development of writing from pictography can be ascribed—the Assyrians (see CUNEIFORM), Egyptians (see HIEROGLYPHS) and Chinese (see CHINESE LANGUAGE). Here more complex notions had to be expressed. The development of the system can be traced through many centuries, and shows a tendency to conventionalize the pictorial symbols employed. Out of conventionalized forms develop (a) syllabaries, (b) alphabets. As regards the latter the historical evolution is traced in the article ALPHABET. The account given under CHINESE LANGUAGE gives a good idea of the development of a syllabary from pictographic writing.

PICKTON, SIR THOMAS (1758–1815), British general, born at Poyston, Pembrokeshire, joined the army in 1773 as an ensign. On the disbandment of the 75th regiment in 1783 Picton quelled a mutiny among the men by his prompt personal action and courage. After living in retirement on his father's estate for nearly 12 years, he went out to the West Indies in 1794. He took part in the capture of St. Lucia (for which he was promoted lieutenant-colonel) and in that of St. Vincent. After the reduction of Trinidad, Abercromby made him governor of the island. He administered the island with such success that the inhabitants petitioned against the retrocession of the island to Spain, and their protest, with Picton's and Abercromby's representations, ensured the retention of Trinidad as a British possession.

In October 1801 he was gazetted brigadier-general. But by this time the rigour of his government, as reported by his enemies, had led to a demand by humanitarians at home for his removal. He was charged with permitting the application of torture under the Spanish law which he had to administer. Colonel William Fullarton (1754–1808) procured the appointment of a commission to govern the island, with Picton as its junior member. Picton resigned, and on his return to England in Dec. 1803 he was arrested by order of the privy council. He was tried in the court of king's bench before Lord Ellenborough in 1806 on one of the charges, on which the court returned a merely technical verdict of guilty, which was superseded in 1808 by a special verdict on retrial. The inhabitants of Trinidad, who had already given him a sword of honour and had petitioned the king not to accept his resignation, subscribed £4,000 toward his legal expenses, which sum Picton contributed in return to the relief of the suffering caused by a widespread fire in Port of Spain.

In 1810, at Wellington's request, he was appointed to command a division in Spain. For the remaining years of the Peninsular War, Picton was one of Wellington's principal subordinates. The commander-in-chief, it is true, never reposed in him the confidence that he gave to Beresford, Hill and Craufurd, but in the resolute, thorough and punctual execution of a well-defined task Picton had no superior in the army. His debut was unfortunate. On the Coa in July 1810 Craufurd's division became involved in an action, and Picton, his nearest neighbour, refused to

support him, as Wellington's direct orders were to avoid an engagement. Details of the incident will be found in Oman, *Peninsular War*, vol. iii. Shortly after this, however, at Busaco, Picton found and used his first great opportunity for distinction. He repulsed the French attack with skill and resolution. After the winter in the lines of Torres Vedras, he added to his reputation and to that of his division at Fuentes d'Onor. In September he was given the local rank of lieutenant-general, and in the same month the division won great glory by its rapid and orderly retirement under severe pressure from the French cavalry at El Bodon. In the first operations of 1812 Picton and Craufurd stormed the two breaches of Ciudad Rodrigo, Craufurd being mortally wounded. At Badajoz, a month later, the successful storming of the fortress was due to Picton's daring self-reliance and penetration in converting the secondary attack on the castle, delivered by his division, into a real one. He was himself wounded in this terrible engagement, but would not leave the ramparts, and the day after, having recently inherited a fortune, he gave every survivor of his command a guinea. His wound and an attack of fever compelled him to return to England to recruit his health, but he reappeared at the front in April 1813. The conduct of his division under his leadership at the battle of Vittoria and in the engagements in the Pyrenees raised his reputation as a resolute and skilful fighting general to a still higher point. Early in 1814 he was offered, but after consulting Wellington declined, the command of the British forces operating on the side of Catalonia. He thus bore his share in the Orthez campaign and in the final victory before Toulouse.

On June 24, 1814, Picton received for the seventh time the thanks of the house of commons for his great services and in 1815 he was made a G.C.B. When Napoleon returned from Elba, Picton, at Wellington's request, accepted a high command in the Anglo-Dutch army. He was severely wounded at Quatre Bras June 16, but concealed his wound and retained command of his troops, and at Waterloo on June 18, while repulsing a serious attack, he was shot through the head by a musket ball. His body was brought home to London and buried in the family vault at St. George's, Hanover Square. A public monument was erected to his memory in St. Paul's cathedral, by order of parliament, and in 1823 another was erected at Carmarthen by subscription, the king contributing 100 guineas to it.

See Robinson's *Life of Sir Thomas Picton* (London, 1836), with which, however, compare Napier's and Oman's histories of the Peninsular War as to controversial points.

PICOU, a seaport, port of entry, and capital of Pictou county, Nova Scotia, 60 mi. N.E. by N. of Halifax, on a branch of the Canadian National railway. Pop. (1941) 3,069. It has several valuable industries, and is the shipping port for the adjacent coal mines. The Academy was founded in 1818 and played an important part in the early educational history of the province of Nova Scotia.

PICTS, an early people inhabiting Scotland, of uncertain affinities, probably pre-Celtic. They are first mentioned in A.D. 306. In 640 they defeated the Romans and harried the Roman provinces (see STRATHCLYDE) until conquered in 846 by Kenneth (*q.v.*) MacAlpin. Tradition associates the Picts with the great stone monuments.

PICUS, the Latin name of the woodpecker. This bird being sacred to Mars was widely revered in ancient Italy. Occasionally Picus is met with as a minor deity, associated with Faunus, as in the (late and artificial) legend of Picus, Faunus and their capture by Numa, Ovid, *Fast.*, iii, 291 ff. Like many of the minor deities, Picus was rationalized into an ancient king, and a pedigree was made out as follows: Saturn (*q.v.*), Picus, Faunus (*q.v.*), Latinus (*e.g.* Virgil, *Aen.*, vii 45–49). Hence, in various late accounts (a) as Saturn was identified with Cronus, Picus was made equivalent to Zeus; see Halliday in *Class. Rev.*, xxxvi, p. 110 (1922). (b) For some unknown reason, Varro (*ap.* Augustine, *de civit. Dei*, xviii, 15) interpolated into the genealogy, as father of Picus, Stercutius (Sterces, Sterculius, the spirit of manuring fields). (c) Picus is confused with Picumnus, a minor deity worshipped along with Pilumnus the spirit of the pestle (*pila*) (Non-

ius Marctllus, p. 834, Lindsay, citing Macer). (d) Ovid tells a romantic story to the effect that Picus loved a nymph Canens ("the Singer"), repulsed the advances of Circe (*q.v.*) and was turned by her into a woodpecker (*Met.*, xiv, 312 ff.). This seems to be Ovid's own invention; most authors (as Virgil, *Aen.*, vii, 189, Plutarch, *quaest. Rom.* 21) who tell the story of the metamorphosis, say Circe was his wife.

See Carter in Roscher's Lexikon, art. "Picus."

PIDDOCK, a bivalve mollusc which bores into chalk cliffs below the low-water line. Piddocks belong to the genus *Pholas*, of the class Lamellibranchia (*q.v.*), and are remarkable in being phosphorescent. (See PHOSPHORESCENCE.) The shell is curiously shaped in adaptation to their boring habit.

PIDGIN ENGLISH. Wherever the English-speaking adventurer has gone among native races in search of trade and profit he has spread Pidgin of one type or another. In the popular mind Pidgin is associated almost exclusively with the English-Chinese jargon spoken on the China coast. This idea was out of date before the middle of the 19th century. Pidgin has almost achieved the status of a world language.

In varying forms, and with varying mixtures of native words, it is current among millions of people in Africa, India, Malaya, the orient, Australia and the islands of the Pacific. In many areas it has developed distinct dialects, some of which are almost completely unintelligible to each other.

The basis of Pidgin is simple, no matter what dialectal form it takes: 300 or 400 English nouns, 40 or 50 verbs, another 100 or so adjectives, pronouns and adverbs, and two or three dozen common native words.

The word Pidgin is a clue to the nature and limitations of this language. "Pidgin" is believed to be a corruption, probably native to the China coast, of the English word "business." It was originally the language of the business or trade that developed between Chinese and Englishmen; other Pidgin dialects have also developed mainly because of trade.

Since the great majority of the original English traders in the Indian and Pacific oceans were ill-educated, since most of their crews were illiterate, foul-mouthed scourgings from English slums, and since their primary motive was to snatch as much booty as possible for the smallest possible price, they had little time to spare for preserving the integrity of their mother tongue. The jargon they developed was the lowest common denominator of understanding between white and native. It was the maximum concession the Englishman would make to natives who failed to comprehend the English language in *foto* on first hearing.

No effort was made to shape or mould Pidgin into an intelligent language. As a result it is an unruly, bastard jargon, filled with nursery imbecilities, vulgarisms and corruptions. In spite of these handicaps, or perhaps because of them, it extended its sphere of influence, especially in the Pacific. If Pidgin is an unruly, weed-grown jargon, it is above all utilitarian, and its currency among millions of natives is a measure of its utility, not only for contact between white and native, but for contact among the natives themselves.

Pidgin English has the original Basic English. The parallel between Pidgin and Basic is so close that it is impossible to analyze either without being impressed by their remarkable similarity. Basic English, it must be remembered, is a scientific "language" of 850 words, each of which has been carefully selected so that the collective result represents a complete method of saying everything for all everyday purposes. Pidgin, on the other hand, is a haphazard and unscientific "language," usually of considerably less than 600 words and practically never exceeding 1,000. The collective result is identical.

Analysis of these two languages shows additional similarities. Slightly more than 70% of the words in Basic are nouns; in Pidgin about 65% of the words are nouns. About 18% of Basic words are adjectives and adverbs; in Pidgin the figure is about 13%. Verbs in Basic represent only 2% of the total, however; in Pidgin they rise to between 7 and 10%. The remaining 10% in Basic represent grammatical sundries; the remaining 12 to 15% in Pidgin comprise a scanty collection of pronouns and preposi-

tions and words from native dialects. Nearly one-third of the scientifically selected words of Basic are found in unscientific Pidgin. This comparison is interesting because it reveals a natural bondage between these two primary languages.

The Pidgin that developed in the 17th century on the China coast has numerous characteristics which set it apart from other Pidgin dialects. First, there are the Chinese words included, e.g., *amah*, nurse; *chow*, food, to eat; *cumshaw*, a present; *taipan*, a boss. Second, there are the English words which have been given peculiar Chinese pronunciation, e.g., *plopa*, proper; *fin*, friend; *Melican*, American. Third, the "-ee" verbal endings, e.g., *loosee*, to lose; *makee*, to make; *tinkee*, to think. The "-ee" suffix also appears in a few other words, e.g., *maskee*, all right, never mind, and *muchee*, much. Chinese Pidgin is easily recognized by these characteristics, in spite of the fact that numerous words found in its vocabulary occur in identical or almost identical form in other Pidgin dialects. Maskee, which is probably derived from the Portuguese "masqui," is current throughout Pacific Pidgin. So are *bymby*, by-and-by; *allasame*, similar; one time, once; *savvy*, to understand. In Australian Pidgin a car is *eatum* wind cart; the origin is almost certainly in the Malayan Pidgin wind waggnn, a car.

These similarities should not, however, lead us to suppose that all Pidgin dialects are derived from the jargon used on the China coast. The major Pidgin dialects of the orient, West Africa and the South seas may be regarded as almost completely independent growths, overlapping because many of the words in their vocabularies are basic words and because native imitations of English speech-sounds have led in numerous cases to almost identical corruptions.

Here is an example of Chinese Pidgin, given by Charles G. Leland in his Pidgin-English Sing-Song:

Chinaman he makee allo-tim so-fashee China-side. Supposey one piecee fata flog he bull-chilo, supposey that chilo too muchee largo man, all-same olo man—he must catchee floggum, no other ting can do, wat-tim fata nik-ki he. Can makee cly-cly, no more can do. All-same fashion, putlutta floggee yangshee lutta, yeungki floggee nippa, haszeman floggee waifo, mata floggee kaichilos, massa floggee kungpatto, kungpatto floggee shaman.

Translation:

A Chinaman always acts in this way in China. Suppose a father wants to flog his son; if that child is as big as a grown man, the father must catch him to flog him. He can't do anything else if he wishes to strike him. He can make him cry, but nothing more. In the same way an elder brother heats a younger brother, an uncle beats a nephew, a husband beats his wife, a mother beats her daughter, a master beats his steward, and a steward beats a servant.

The difference between this type of Pidgin and the jargon used by natives and whites in the far northern areas of Australia will be immediately evident by reference to this Australian Pidgin version of part of Psalm 23, given by E. Sheppard Sayer, in his Pidgin English:

Big Name watchem sheepsheep, Watchum blackfella. No more belly cry fella hab. Big Name makum camp alonga grass, takum blackfella walkabout longa, no fightem no more hurry wata. Big Boss longa sky makum inside glad; takem walkabout longa too much goodfella.

Translation:

The Lord is my shepherd; I shall not want. He maketh me to lie down in green pastures; he leadeth me beside the still waters. He restoreth my soul: he leadeth me in the path of righteousness for his name's sake.

Not only is the phrasing of this type of Pidgin different, but the words used are of a different type. Whereas the Chinese Pidgin speaker nearly always uses "-ee" as a verbal suffix (an exception is the "-um" ending of "floggum" in the quotation from Leland), the Australian aboriginal and many Pacific natives use an "-em," "-im" or "-um" suffix. This Pacific suffix is a survival of the word "him" used after a verb.

Another Pacific characteristic is the intrusive *fella*, which is indispensable to the Pidgin speaker, although it is practically meaningless. It is a survival of "fellow" used for "one," e.g., *i gudfella*, that's good, *i.e.*, that is a good one.

The differences between Chinese and Australian Pidgin are not accidental. Few, if any, of the original white inhabitants of Aus-

tralia—most of them were convicts from English prisons—had any knowledge of Chinese Pidgin. The Australian jargon was developed independently as a means of contact between white and black. The first immigrants reached Australia in 1788. Within ten years Pidgin was firmly established. From Australia it spread to neighbouring islands. In New Zealand, sealers and whalers attempted to use Pidgin as a means of contact with Maoris in the early years of the 19th century. Pidgin was, however, scorned by the Maoris, who learned the English language with remarkable ease. Whereas Pidgin is used throughout northern Australia, it is practically nonexistent in New Zealand. Many Maoris learned to speak English better than their white compatriots in New Zealand.

Since Pidgin developed on the east coast of Australia at the end of the 18th century, considerably before the Pacific islands were opened up for trade, Australia must be regarded as the primary source of Pacific Pidgin. This Pacific Pidgin is often referred to as Beach-la-mar—a corrupted form of *bêche-de-mer*, a name for the trepang.

The link between Australian and New Guinea Pidgin is naturally close; the New Guinea native's vocabulary includes many words which were first introduced in Australia, among them *spell*, to rest; *sool*, to scold; *plant*, to bury; *bush*, jungle; *go bush*, to run away; *gammon*, not true; *walkabout*, to travel, decamp.

Here is an example of New Guinea Pidgin taken from *Frend Belong Mi*, a monthly magazine in Pidgin established in 1935 by the Roman Catholic mission at Alexishafen for the use of natives:

Wairless i gudfelo samting. Em i samting bilong hariap tru. Wanfelo master i sindaun long haf long liklik mashin, finger bilong em i faitim mashin, nau elektrik bilong mashin i salim tok i go longwe mor. Olrait, longwe mor wanfelo adershelo master i sindaun long liklik mashin, em i save hirim disfelo tok.

Translation:

Wireless is good. It is swift. A man sits down at a small machine and taps with his finger and electricity sends his message a long way. A long way away another man sits at another machine and understands the message.

The kinship between this New Guinea Pidgin and Australian Pidgin is immediately obvious. The different way in which the words are spelled may be regarded as a little beside the point, because Pidgin is essentially a spoken language. However, several large mission groups have, for many years, been publishing books in Pidgin for native consumption, and the question arises: How far is Pidgin being modified by its reduction to printed forms? It is somewhat unfortunate, not so much for the future of Pidgin English as a language, as for the education of native races, that the mission stations which have entered the printing trade in order to win converts should have made no attempt to adopt a common phonetic standard. They have worked independently, with the result that new "visual" Pidgin dialects were created in areas under mission control.

Here, for instance, is the Lord's Prayer as rendered in print by the Catholic missions at Alexishafen and Vunapope and the Methodist mission at Rabaul:

Alexishafen: Fader bilong mifelo, yu stop long heven—ol i santuim nem bilong yu—Kingdom bilong yu i kam—Ol i hirim tok bilong yu long ground olsem long heven. Tude givim mifelo kaikai bilong de—forgivim rong bilong mifelo—olsem mifelo forgivim rong—ol i mekim long mifelo. Yu no bringim mifelo long traिम—tekewe samting no gud long mifelo. Amen.

Vunapope: Papa bolong mipela i stap antap—naim bolong ju i tambu—lotu bolong ju i kam—mipela daun olosem ol antap i harim tok bolong ju—ju bringim kaikai tede bolong mipela—ju larim mipela i olosem mipela i larim ol, ol i mekim nogut mipela—ju no bringim mipela klostu long rot i nogut—ju lusim ol samting nogut i raus long mipela. Amen.

Rabaul: Papa bilog mi fela, iu stop an top alog peles bilog iu, i qud mi fela sigsig out tru alog nem bilog iu; i moa beta ol a fasin bilog iu i stop alog oltuqeta peles. I qud mi fela mekim tru ol a lo bilog iu, ol a sem oltuqeta nian i savi mekim alog peles bilog iu. I qud iu givim mi fela kaikai inafim mi fela alog tude. I qud iu no mekim koros alog mi fela alog ol a fasin no qud mi fela mekim, ol a sem mi fela no qat koros alog ol a man i savi korosim mi fela. Iu no bringim mi fela alog ol a samtig no qud; i moa beta iu luk outim mi fela so mi fela no ken mekim ol a fasin no qud. Bikos ol a lo, na oltuqeta strog, na oltuqeta samtig i qud i bilog iu, na i no ken finis. Amen.

These confusing variations in phonetic form and translation occur throughout the books printed by the missions.

The Alexishafen mission has published more Pidgin books than other missions. It has printed Pidgin Bibles, song books, stories of the Gospels, prayer books, a Pidgin vocabulary and a *Primer* used for teaching young natives in mission schools. The monthly magazine, *Frend Belong Mi* (mentioned above), is mainly religious in nature, but contains crossword puzzles, jokes, fairy tales, problems, astronomy, notes on animals and insects, all in Pidgin.

The government administration of New Guinea refused to use Pidgin in any of its native schools and has issued no official publications in Pidgin. In native schools conducted by the administration pure English is taught, and the medium used is the native dialect of the locality in which the school is situated.

It must be regarded as unfortunate that New Guinea administration attempts to weed out Pidgin did not receive mission support. The difficulty of weaning natives from Pidgin is sufficient without being increased. This was well realized by German traders in the New Guinea islands in the closing quarter of the 19th century. They found that Pidgin English was so firmly rooted that the natives refused to speak German. Baron von Hesse-Wartegg urged that "Pidgin nonsense" should be replaced "by a sensible German language." "There is yet time to eradicate Pidgin English," he added. "Another 10 years without such an effort will see such a deep establishment of it that this might be impossible; and in another 50 years the German reich will possess here a protectorate whose population of missionaries will speak only English. For the world standing of Germany this would certainly be sad and shameful."

By the time of World War II, all that remained of German attempts to weed out Pidgin English was a handful of German words absorbed into Pidgin text; among them *raus*, shift, go away (from *heraus*); *bung* or *boong*, a market; *mark*, a shilling or other silver coin; *pusss-pusss*, love (from German dialectal *pusssi*, a kiss).

The original French settlers of New Caledonia found similar difficulties. Long before French immigrants arrived, Pidgin English had been spread among the New Caledonian natives. Many traces of that Pidgin remain incorporated in the French speech used in New Caledonia and the New Hebrides. A form of Pidgin French is also current.

Among well-known picturesque phrases in Pidgin are: *bullamakau*, beef, meat in general, whence *bullamakau banana*, a sausage; *haus moni gammon*, banknotes, as distinct from *haus moni tru*, coins; *grass belong face*, whiskers; *dog belong Sydney*, a goat; *basket belong trouser*, a pocket; *lamp belong Jesus*, the sun; *ticky-ticky wata*, oil; *paper talk* (or, in Australian Pidgin, *paper yabber*), a letter.

In World War II the importance of soldiers in contact with natives in southwest Pacific islands knowing Pidgin was realized by both U.S. and Australian army authorities. A special handbook was issued to servicemen on tropical duty. Here are two examples from the book, showing how Pidgin went to war:

Yufela yu lookim barid all Japan i sit down long im long fight? Is there barbed wire in front of the Jap trenches?

Yufela yu stand fast. Yu no can walkabout. Suppose yufela walkabout me killim yu long musket. Don't move or I'll shoot.

(S. J. BR.)

PIECE-OF-EIGHT, an obsolete Spanish coin, properly the *piastre* or *peso*, commonly also called a dollar, coined of silver, and divided into eight *reals*, whence "piece-of-eight." Its value was four shillings. In 1797, when the Bank of England suspended payment, millions of these coins were put into British circulation. countermarked with a small oval bust of George III. The piece-of-eight was current in the Spanish-American colonies.

PIECE-WORK, a term used to describe the method of industrial remuneration in which the worker is paid by the piece or job. In practice, where piece-work is arranged in trades that are organized, the payment per unit of work is arranged by negotiation between the employers and employed, as for example, in the English cotton industry. Very often the agreements arrived at

are extremely complicated, with various percentage variations upon a basic rate, so that the expression of piece-rate becomes very difficult for one outside the industry to understand. Agreements as to piece-work are often subject to a minimum wage arrangement. See WAGE-SYSTEMS IN INDUSTRY.

PIEDMONT (pī-ād'mōnt), is a territorial division of north Italy, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime and Ligurian Alps.

In 1859 it was divided into the four provinces of Alessandria. Cuneo. Novara and Torino (Turin) to which Aosta and Vercelli were added in 1927 and later Asti. It has an area of 11,332 sq.mi. The people are chiefly engaged in agriculture—which is helped by irrigation.

In 1938, the products were:

Crop	Acres	Tons
Wheat	753,350	616,847
Rye	108,186	66,028
Oats	40,261	30,313
Rice	180,804	415,236
Maize	370,006	799,388
Beans	106,951	35,384
Sugar beets	7,163	51,307
Hemp	2,223	1,102
Garden produce	19,760	81,350
Potatoes	84,474	374,341
Forage	2,482,103	3,588,427
Vines	550,316	106,674,915 (nine-gallons)

Many are also occupied in the reeling and throwing of silk and in the manufacture of cotton (no fewer than 50,000 workers, of whom 37,000 are women), woollens and clothing; there are also considerable manufactures at Turin, Savigliano, etc. The Piedmontese dialect has been rather strongly influenced by French.

The total population of Piedmont was in 1931, 3,497,799, in 1936, 3,506,134. There are numerous summer resorts in the Alpine valleys.

The chief railway centres are Turin, communicating with the Mont Cenis line and with the Riviera by the railway over the Col di Tenda. The communications with Liguria are difficult owing to the approach of the mountains to the coast, but the electrification of the lines from Genoa to Turin and Milan greatly improved the travelling facilities of this region.

Piedmont (Ital. *Piemonte*; Low Lat. *Pedemons* and *Pedemontium*), in Roman times until 49 B.C. formed a part of Gallia Transpadana, and in Augustus' division of Italy formed with what was later known as Lombardy the 11th region. It formed part of the Lombard kingdom, and it was not till about A.D. 1000 that the house of Savoy (*q.v.*) arose.

PIEDMONT, a residential city of California, U.S.A., on the heights adjoining Berkeley and Oakland. It has few shops and no factories, and its building regulations prohibit the construction of multiple dwellings. The population was 9,866 in 1940 by the federal census.

PIEDMONT REGION. A term of special application in the U.S. to the low plateau which lies just east of the Appalachians, especially in Pennsylvania, Virginia, and the Carolinas.

PIEDRAS NEGRAS, formerly Ciudad Porfirio Diaz, a northern frontier town of Mexico in the State of Coahuila, 840 mi. N. by W. from Mexico City, on the Rio Grande del Norte. 720 ft. above sea-level, opposite the town of Eagle Pass, Texas. Pop. (1930) 15,878. An international bridge connects the two towns. and the Mexican International railway has its northern terminus in Mexico at this point. The town has an important transfer trade with the United States, and is the centre of a fertile district devoted to agriculture and stock-raising. Coal is found in the vicinity.

The Mexican Government maintains a custom-house and military post here. The town was founded in 1849.

PIENZA, a town of Tuscany, Italy, in the province of Siena. 9 mi. west of the town of Montepulciano by road, 1,611 ft. above sea-level. Pop. (1936) 1,191 (town); 4,532 (commune). The

place was originally called Corsignano and owes its present name to Aeneas Silvius Piccolomini, Pope Pius II. (*q.v.*) who was born here in 1405. The buildings which he caused to be erected by Bernardo Rossellino in 1460-1463 form a noble group of early Renaissance architecture round the Piazza del Duomo. The latter retains Gothic details in the interior, but the facade is simple Renaissance work. The other three sides are occupied by the episcopal and municipal palaces, and the Palazzo Piccolomini; the last, resembling the Palazzo Rucellai at Florence, is the finest, and is well furnished: in front of it is a beautiful fountain, and opposite it the fine Palazzo Ammannati. The canons' house contains a museum with some fine ecclesiastical vestments including an excellent 13th century cope of English origin, and enamels.

PIER. In architecture (*q.v.*) it usually denotes a vertical support in masonry, brickwork or concrete which carries an arch or superstructure. In this sense it is applied both to those portions of a structure which are visible above ground and to isolated or detached supports underground described as foundation piers. The term is sometimes applied to the solid parts of a wall between windows or voids, and also to the isolated masses of brickwork, masonry or concrete to which gates are hung.

Bridge Piers.—In the construction of bridges (*q.v.*) and viaducts, pier denotes the solid structure upon which the bridge superstructure (including arches) is supported. Occasionally in the case of high piers supporting viaducts and bridge superstructures the upper portions are constructed of open-braced iron- or steel-work.

Foundation piers for bridges are formed of solid masonry, brickwork or concrete and, sometimes, reinforced-concrete is employed for the purpose. In places where timber is abundant, as in some parts of the United States and Canada, wooden cribs filled with rubble stone or concrete have been used for raising the foundations of piers out of water.

Special provisions must be made for the foundations of piers where the ground is soft for some depth, or loose water-bearing strata are encountered, and especially where the piers of large

THREE TYPES OF PIER USED IN ARCHITECTURE

bridges crossing rivers have to be constructed under water. Among the means employed in these situations are steel and iron cylinders, wells, caissons, bearing piles or some form of coffer-dam within which the foundations may be constructed. (See CAISSON, FOUNDATIONS, COFFER-DAM.)

Piles are sometimes employed to provide both the foundations and the piers carrying a structure of viaduct character. Thus screw piles, having wide bearing-blades of cast-iron in the form of

a screw-thread turned about a central shaft or column of cast-iron or steel, are sometimes sunk through soft strata till they reach a firm bed, or one sufficiently consolidated by the superincumbent layers to enable it to support the weight imposed on the broad blades. Hollow, cast iron, cylindrical piles with a broad circular disc at the bottom to increase their bearing surface, have also been used for piers founded in sandy or silty strata of considerable thickness. They are sunk by hydraulic jetting, *i.e.*, the scouring away of the soft material from under the disc by means of a jet of water emitted under high pressure from a pipe lowered within the pile. Water jets are also employed to facilitate the sinking of screw and other forms of piles. (See FOUNDATIONS.)

Harbour Piers.—The term pier is often applied to works sheltering harbours such as the Tynemouth piers which are strictly breakwaters (*q.v.*). Landing stages also, whether solid or open, have for a long time been called piers, as the Admiralty pier and the Prince of Wales' pier at Dover, the former essentially a breakwater with provision for berthing vessels and landing passengers on its sheltered side. The jetties (*q.v.*) thrown out from the shore to protect the entrance to a river harbour are also sometimes described as piers. In North America the term is commonly employed for a wharf structure that projects into a river, fairway or harbour.

Promenade Piers.—Open promenade piers form a common feature at seaside resorts. Promenade piers are usually supported on open pile work of timber, cast iron or steel, but in recent years, reinforced concrete has been frequently employed both for the pile supports and superstructure. The open construction exposes little surface to waves or storms and does not interfere with the drift of shingle and sand along the coast. It is essential that the beams or girders carrying the deck of a promenade pier should be at an elevation well above the level of the crest of the highest wave. Timber piles are best suited for withstanding the shocks of vessels at landing stages, at which places they are generally used. In the case of reinforced-concrete landing stages, a falsework of timber is sometimes constructed in front of the main structure for this purpose. Screw piles are frequently used for promenade piers on sandy foreshores.

The pioneer of promenade piers in England was the old chain pier at Brighton, erected in 1822-3. It was founded on oak piles, was 1,136 ft. long and was destroyed by a gale in Dec. 1896. The length of promenade piers depends mainly on the distance from the shore at which sufficient depth is reached for steamers. Thus piers at Southend (Essex) and Southport (Lancs.) have been constructed across the wide sands in the estuaries of the Thames and Ribble respectively; the former over $1\frac{1}{4}$ m., the latter nearly a mile in length.

Works on bridge and other foundations are noted at the end of the article CAISSON. (N. G. G.)

In Architecture.—A pier in architecture is a vertical support carrying arches, a vault, a floor or a roof; especially one rectangular in plan; also, in mediæval work, any support between the nave and aisles of a church. During the late Roman imperial period, pier design was carefully studied and in connection with such buildings as the basilicas, cross-shaped and other compound piers were developed to carry the cross arches and the groins or intersections of the vaulting. With the increasing use of vaulting for church naves and aisles, during the 11th and 12th centuries, pier design was still further developed. Although in England Norman piers are frequently great round columns, on the continent of Europe piers became common in which each arch or vaulting rib above was carried by a separate member of the pier. The earliest logical expression of this idea is found in Italian Lombard work, where a square pier has frequently an engaged column attached to each face; the one on the nave side carrying the cross-rib of the nave vault, that on the aisle side carrying the aisle vault cross-rib, and those on the other two sides carrying the pier arches between nave and aisles.

During the later Romanesque, pier plans were further complicated by the addition of smaller members to carry the subsidiary mouldings of the arches above, and larger members to carry the diagonal vaulting ribs. (See BYZANTINE AND ROMANESQUE ARCHI-

TECTURE.) During the 13th and 14th centuries the piers of French Gothic churches were kept comparatively simple in plan, with great importance given to the capital at the level of the spring of the pier arch. Often it took the shape of a circular column with a few, large, simple attached vaulting shafts, as in Rheims cathedral (c. 1240). Toward the end of the 14th century, perhaps due to English influence, the column idea disappeared and was replaced by the more logical plan in which the pier was elaborately membered, not only by the additional development of vaulting shafts, but by breaking up the edges with projecting mouldings under the mouldings of the arches. Capitals became of less importance and vaulting shafts were carried unbroken through from floor to vault spring, capitals being placed merely on the separate mouldings of each arch or rib.

During the Flamboyant period this development was carried to its logical extreme; capitals were omitted entirely, and the pier plan became the combination of the various arch and vault rib mouldings continued down to the floor. Against this complexity a reaction was inevitable, and the other type of French Flamboyant pier developed, with smooth surface, either circular or wavy in plan, with the various vault rib and arch mouldings carried by the pier merely dying into it at their intersections. In England, during the Early English period, although circular piers are occasionally found, they were more frequently surrounded by entirely independent colonnettes, often of black Purbeck marble, which act as vaulting shafts and are tied to the body of the pier only at intervals by horizontal through stones with moulded edges. During the Decorated period attached shafts continued in use but the surfaces of the central core appearing between them were often richly moulded, and, in some cases, detached shafts disappeared entirely and the pier became a solid mass with surfaces lavishly moulded with strong projecting high lights and deeply cut shadows.

In the late Decorated period mouldings of the pier were sometimes the same as those of the arch above and capitals were omitted. This arrangement became much more frequent during the Perpendicular period. Pier-moulding profiles were softened and flattened like other mouldings of the period. (See GOTHIC ARCHITECTURE.) With the coming of the Renaissance pier design was much simplified, returning to the generally cross-shaped or twelve-cornered systems found in late Roman work, with all the projecting members treated either as classic impost, engaged columns or pilasters.

Technically, the word pier is also applied to the solid portions of a wall between windows or other openings; and to the vertical posts at gateways, to which the gates are hung. The word pier is used of structures of timber or masonry projecting from a quay or sea wall and used either for loading and unloading ships, or in the case of summer resorts, for furnishing promenade space into the water. In America the word is loosely used synonymously with dock or landing stage.

PIERCE, FRANKLIN (1804-1869), fourteenth president of the United States, was born at Hillsboro, New Hampshire, Nov. 23, 1804. His father, Benjamin Pierce (1757-1839), served in the American army throughout the Revolutionary War, was a Democratic member of the New Hampshire house of representatives from 1789 to 1801, and was governor of the State in 1827. The son was prepared for college at Hancock, Frankestown and Exeter academies and entered Bowdoin in 1820, where he formed a lifelong friendship with Nathaniel Hawthorne. After his graduation in 1824 he studied law and was admitted to the bar in 1827.

Entry into Politics.—Entering politics as a Democrat he became a member of the New Hampshire house of representatives in 1829, and was speaker of that body in 1831 and 1832. The following year he entered the national house of representatives. While he rarely spoke from the floor, he was an influential member of several committees, including the judiciary committee. A friend of President Jackson he supported administration policies. He adhered to a strict construction of the Federal Constitution, defended the Maysville veto, opposed the recharter of the bank of the United States, opposed appropriations to the U. S. military academy and favoured a volunteer army. During

his first term in Congress he married Jane Means Appleton, daughter of the president of Bowdoin college. In 1837 he entered the U.S. Senate. Being its youngest member, he was overshadowed by a galaxy of older and more prominent men such as Benton, Clay and Webster. Before his term expired he resigned his seat (1842) and returned to the practice of law at Concord, N.H., where he became Federal district attorney. In 1845 he was offered the Democratic nomination for governor of New Hampshire, also an appointment to fill an unexpired term in the U.S. Senate, and the next year the position of attorney-general in Polk's cabinet; but he rejected them all, declaring that he had permanently retired from political life.

Service in Mexican War.—Shortly after the outbreak of the war with Mexico in 1846 Pierce enlisted as a private at Concord, but soon became colonel of the 9th Regiment, and later a brigadier-general of volunteers. He was with Gen. Scott in the advance toward Mexico City. During the battle of Contreras he was thrown from his horse and received painful injuries. Despite the advice of Scott to the contrary he insisted on continuing the fight the next day and in the course of the battle he fainted. This fact, variously interpreted, was used both for and against him when he was later a candidate for the presidency. At the close of the war he returned to his law practice.

Election to Presidency.—Pierce became the Democratic nominee for president in 1852 "as a dark horse." Those in the foreground were Lewis Cass, Stephen A. Douglas and James Buchanan, but none of these proved to be available because of factional rivalries. A few politicians, foreseeing a deadlock, had prepared Pierce for the place. At the convention in Baltimore in June his name was first brought forward by the Virginia delegation on the 35th ballot, and on the 49th ballot he received an almost unanimous vote. Both the Democrats and the Whigs were too badly split for any real issues to appear in the campaign. The chief question in the public mind was the finality of the Compromise of 1850, and while both parties declared themselves in favour of it the Democrats were more thoroughly united in its support. As a result Pierce swept the country in the November election, receiving 254 electoral votes against 42 for his opponent, Gen. Winfield Scott.

Presidential Administration.—The youngest man to have been elevated to the presidency, Pierce was handsome, genial and possessed of a certain brilliance, which however was not profound. The Eastern element of the Democratic party which he directly represented was inclined for the sake of harmony and prosperity to oppose anti-slavery agitation and generally to placate Southern opinion. It was hence pro-Southern as a matter not only of political strategy but also of business expediency. Thus in the selection of his cabinet, as in both domestic and foreign policies of his administration, Pierce represented a coalition of Southern planters and Eastern business men. His cabinet included William L. Marcy of New York, secretary of state; Jefferson Davis of Mississippi, secretary of war; James Guthrie of Kentucky, secretary of the treasury; James C. Dobbin of North Carolina, secretary of the navy; Robert McClelland of Michigan, secretary of the interior; James Campbell of Pennsylvania, postmaster-general; and Caleb Cushing of Massachusetts, attorney-general. In his inaugural address Pierce interpreted his election as a popular mandate to maintain the Compromise of 1850 and bury the slavery controversy. He also forecast an aggressive, but honourable, foreign policy; he would "not be controlled by any timid forebodings of evil from expansion." In fact "the acquisition of certain possessions" (doubtless referring to Cuba in particular) was deemed essential to the country's safety and commerce.

Foreign Policy.—In accordance with the declarations of the inaugural Pierre Soulé, who had openly advocated the annexation of Cuba by means other than purchase if necessary, was appointed minister to Spain. When the Spanish Government showed its unwillingness to sell the island, Soulé, at the suggestion of secretary of State Marcy, held a conference with James Buchanan, minister to Great Britain, and John Y. Mason, minister to France, at Ostend, Belgium, as a result of which they issued the famous Ostend Manifesto. This was to the effect that if the

United States were unable to obtain Cuba peacefully, "by every law, human and divine, we shall be justified in wresting it from Spain if we possess the power." In the storm of controversy which followed, the administration disclaimed responsibility for the document and recalled Soulé. The following year William Walker conducted a notorious filibustering expedition into Central America with the purpose of establishing a pro-slavery government to be brought under the control of the United States. He established himself as military dictator, then as president, of Nicaragua, and his regime was recognized by the Pierce administration. More fruitful of permanent results was the expedition sent out under Commodore Perry to Japan (1853) to induce her to open her doors to American trade. Lured by Yankee ingenuity and frightened by Western guns, she responded, and the result was the opening up of Japan. In the Koszta affair (1853) the government vigorously asserted the protection which it would offer those in the process of becoming its naturalized citizens. The administration also effected a reorganization of the diplomatic and consular service and the creation of the U.S. court of claims.

Domestic Policy.—Among the domestic policies of the Pierce administration were preparations for a transcontinental railroad and the opening up of the Northwest for settlement. It was in order to open the way for a southerly route to California through the lowest mountain passes that the Gadsden Purchase of 50,000 sq.m. of territory was acquired from Mexico in 1853 at a cost of \$10,000,000. It was mainly to stimulate migration to the Northwest and facilitate the project of a central route to the Pacific that the Kansas-Nebraska bill was enacted in 1854, receiving the President's sanction. This opened two new territories for settlement with the slavery question to be settled in each by popular sovereignty. Thus the dread conflict was reawakened with the venom of incipient civil war. Pierce's administrative policies with reference to "bleeding Kansas" were pro-Southern. He thus lost much of his former support at the North and made himself unavailable as a candidate for a second term.

Save for a three years' tour in Europe, he lived at Concord, N.H., where he died on Oct. 8, 1869.

PIERO DI COSIMO (1462-1521), the name by which the Florentine painter Pietro di Lorenzo is generally known. He was born in Florence in 1462, and worked in the bottega of Cosimo Rosselli (from whom he derived his popular name). He had the gift of a fertile fantastic imagination, which, as a result of his journey to Rome in 1482 with Rosselli, became directed towards the myths of classic antiquity. In Rome he assisted his master with the frescoes in the Sistine chapel. He proves himself a true child of the Renaissance in such pictures as the "Death of Procris" at the National Gallery, the "Mars and Venus," at the Berlin Gallery, the "Perseus and Andromeda" series, at the Uffizi in Florence, and the "Hylas and the Nymphs," of the late Benson collection. The "Immaculate Conception," at the Uffizi, and the "Holy Family," at Dresden, are good examples of his religious pictures. Piero was distinguished for his landscapes and their cheerful accessories. The only known portraits that can be definitely ascribed to him are, at the National Gallery, the so-called "Bella Simonetta," at Chantilly, the portraits of Giuliano di San Gallo and his father, at The Hague, and a head of a youth, at Dulwich. Vasari related that Piero excelled in designing pageants and triumphal processions for the pleasure-loving youths of Florence. Piero di Cosimo exercised considerable influence upon his fellow pupils Albertinelli and Bartolommeo della Porta and was the master of Andrea del Sarto. Examples of his work are also to be found at the Louvre in Paris, the Liechtenstein collec-

tion in Vienna, the Borghese and Corsini Galleries in Rome, the Berlin Museum, the Spedale degli Innocenti in Florence, and in the collections of Burke in London and Cornwallis West in Newlands Manor.

PIERRE (peer), capital city of South Dakota, U.S.A., and county seat of Hughes county; in the centre of the state, on the east bank of the Missouri river opposite the mouth of Bad river, at an altitude (at the state capitol) of 1,496 ft. It is on federal highways 14 and 83; has a municipal airport; and is served by the Chicago and North Western railway. Pop. 1940 federal census 4,322. Four miles north of the city is a monument marking the geographical centre of the state and the approximate centre of North America. The state capitol (erected 1905-10) is a beautiful building. A four-story annex matching the building was built in 1931. Near the capitol is an artificial lake, fed from an artesian well by water which never freezes, where swans, geese and wild ducks live the year round. The city owns more than a mile of river frontage, and its parks include a wooded island of 1,000 acres. Artesian wells supply the city not only with water but also with natural gas of high heating content. Pierre is the seat of a government Indian school.

The state historical museum (in the capitol building) has many interesting relics, including a leaden plate, buried in 1743 by La Vérendrye on a hill across the river (within the present city of Fort Pierre) to claim the country for France, and discovered by high school children in 1913. Pierre is an important shipping point and centre of wholesale and jobbing interests. It has railroad shops, granite works and other manufacturing industries. The first permanent settlement by white men in South Dakota was made in 1817 by Joseph La Framboise, a fur trader, just below the mouth of Bad river. He called his post Ft. Teton. In 1822 Ft. Tecumseh was built 2 m. up-stream; and in 1832, when its site was washed into the river, Ft. Pierre Chouteau was erected to take its place, a mile farther up-stream and a little back from the river. It was named after Pierre Chouteau, Jr. (1789-1865), who had in 1804 succeeded his father in the Missouri Fur Company, and for 20 years Ft. Pierre (as it soon came to be called) was the chief fur-trading depot of the Upper Missouri country. In 1855 the United States bought the building and other property of the post and laid out around them a military reservation of 270 sq.m. (abandoned in 1857) which was the headquarters of operations against the Sioux and the scene of a council with their chiefs. In the early days steamboats plied regularly on the Missouri river as far as Ft. Benton (Montana) 1,000 m. above Pierre. The first sermon in South Dakota was preached in 1840 by the Rev. Stephen R. Riggs, a missionary to the Dakota Indians, on a spot near the free wagon bridge across the Missouri which bears his name. The city was platted in 1880, incorporated as a village in 1883, and chartered as a city in 1900. One of the few surviving herds of buffalo in the United States is quartered in the river brakes 4 m. north of Fort Pierre.

PIERREFONDS, a town of northern France, in the department of Oise, 9 mi. S.E. of Compiègne by road. Pop. (1936) 990. Pierrefonds has an 11th to 16th century church, and its mineral springs are in some repute. The famous château was begun in the late 14th century by Louis d'Orléans, to whom the domain was given by Charles VI., and finished early in the 15th century. It was later held by the Burgundians, the English and the adherents of the League, from whom it passed to Henry IV. It was dismantled in 1622. The ruins, bought by Napoleon I, were faithfully restored, by order of Napoleon III, in 1858-95, under the direction, first of Viollet-le-Duc and afterwards of E. Boeswillwald. The building is rectangular in shape. A lofty keep defends the principal entrance. The town was partly destroyed in World War I and the Germans occupied it in World War II (June 1940).

PIERROT [Ital. *Pedrolino*], the name given to the leading character in the French pantomime plays since the 18th century; transferred from the Italian stage, and revived especially in recent times. He is always in white, both face and costume, with a loose and daintily clownish garb, and is represented as of a

freakish disposition. Modern pierrot plays have converted the pierrot into a romantic and pathetic figure. (See PANTOMIME.)

PIETAS, in Roman mythology, the personification of the sense of duty towards God and man and towards the fatherland. According to legend, a young woman in humble circumstances, whose father (or mother) was lying in prison under sentence of death, without food, managed to gain admittance, and fed her parent with milk from her breast. To commemorate her filial affection, a temple was dedicated (181 B.C.) by Manius Acilius Glabrio to Pietas in the Forum Holitorium at Rome, on the spot where the young woman had formerly lived. The temple was probably originally vowed by the elder Glabrio out of gratitude for the *pietas* shown during the engagement by his son, who may have saved his life, as did the elder Africanus that of his father at the battle of Ticinus (Livy xxi. 46); the legend of the young woman (borrowed from the Greek story of Mycon and Pero, Val. Max. v. 4, ext. 1) was then connected with the temple by the identification of its site with that of the prison. Pietas is shown on coins as a matron throwing incense on an altar, her attribute being a stork. Typical examples of "piety" are Aeneas, and Antoninus Pius, who founded games at Puteoli in honour of Hadrian.

PIETERMARITZBURG, the capital of Natal, South Africa, 29° 46' S., 30° 13' E.; altitude 2,218 feet. Though only 41 m. inland, it is 73 m. by rail from the port of Durban. The main town is laid out on a low ridge between the Umsundusi River and the Dorp Spruit. Suburbs have grown up on two other ridges across the river to the south-east of the town, and also on the slopes of a marked escarpment, which rises over 1,500 ft. above the town on the north-west side. The low ground between the ridges is occupied either by Indian dwellings and cultivation, or by open spaces, laid out as public parks and sports grounds, with which the city is very well provided. On the west of the town are the botanical gardens. There are memorials of the Zulu, South African and World Wars. The town was founded in 1839 by Dutch immigrants and connected by railway with Durban in 1880.

Among the public buildings are the town hall, containing a remarkably fine organ and a good collection of pictures, the Provincial Council building, the Colonial offices, the Court house, the post office and the museum, which has an exceedingly good collection of the South African fauna. The Voortrekkers' museum is housed in what used to be a Dutch church. The Natal Society library is also admirable. The city is the seat of an Anglican bishop. It is noted for its agricultural show, held every June. There is a large number of high schools for day pupils and boarders, both in the city and outside. In addition there is a training college and a university college, a constituent of the University of South Africa. Means of locomotion are provided by a tramway system, jinrikshas, and motor cars. In 1921 the population included 9,992 natives, 6,944 Asiatics, 1,089 coloured people and 17,998 Europeans. The latter had increased by 1936 to 22,448.

PIETERSBURG, chief town of the Pietersburg district of the Transvaal, 177 m. by rail N.N.E. of Pretoria; altitude, 4,269 ft. Pop. (1921) 2,452 whites, 3,325 natives, 183 Asiatics and 103 coloured: total 6,063. The surrounding country contains minerals. To the east are the Klein Letaba and other low country goldfields; to the west are the Waterberg goldfields. Asbestos, tin and corundum also occur, the latter being exported in fair quantity. Cereals, tobacco, cotton and groundnuts are cultivated and towards the east, citrus estates have developed.

PIETERS HILL, 10 miles S.S.E. of Ladysmith, has given its name to the fourth and finally successful British attempt to relieve Ladysmith at the end of Feb. 1900 (see LADYSMITH and SOUTH AFRICAN WAR). Buller, having tried a frontal attack and two attacks on the right of the Boer lines, now resolved to assail their left, and the operations opened with the successful storming of their positions on the south bank of the Tugela east of Colenso, which fell into British hands after six days of methodical

fighting. Thereafter Buller drew back the bulk of his force to the north bank, its next objective being the group of hills immediately north of Colenso. On Feb. 27, the British right wing captured Pieters Hill, the northern buttress of the ridge, and next day Buller's cavalry entered Ladysmith, which had stood a four months' siege.

PIETISM, a movement in the Lutheran Church, which arose towards the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement as a term of ridicule, like that of "Methodists" somewhat later in England. The Lutheran Church had continued Melancthon's attempt to construct the evangelical faith as a doctrinal system; and it appeared to many faithful adherents to have become a creed-bound theological and sacramentarian institution, where the dogmatic formularies of the Church had usurped the position which Luther himself had assigned to the Bible alone. The influence of the Reformed Church (*q.v.*) on the other hand, in spite of the predestinarianism of Calvin, made less for doctrine than the practical formation of Christian life. The Presbyterian constitution gave the people a share in church life which the Lutherans lacked, but it involved a dogmatic legalism which imperilled Christian freedom and fostered self-righteousness.

The direct originator of the movement for the revival of a practical and devout Christianity was Philipp Jakob Spener, who combined the Lutheran emphasis on Biblical doctrine with the Reformed tendency to vigorous Christian life. Born at Rappoltsweiler in Alsace on the 13th of January 1635, trained by a devout godmother, who used books of devotion like Arndt's *True Christianity*, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, Spener was early convinced of the necessity of a moral and religious reformation of the German Church. He studied theology, with a view to the Christian ministry, at Strassburg and entered upon his first pastoral charge at Frankfort-on-the-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a distinct movement in the German Church, was then originated by Spener by religious meetings at his house (*collegia pietatis*), at which he repeated his sermons, expounded passages of the New Testament, and induced those present to join in conversation on religious questions that arose. They gave rise to the name "Pietists." In 1675 Spener published his *Pia desideria*, or *Earnest Desires for a Reform of the True Evangelical Church*. In this publication he made six proposals as the best means of restoring the life of the Church: (1) the earnest and thorough study of the Bible in private meetings, *ecclesiolae in ecclesia*; (2) the Christian priesthood being universal, the laity should share in the spiritual government of the Church; (3) a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) instead of merely didactic, and often bitter, attacks on the heterodox and unbelievers, a sympathetic and kindly treatment of them; (5) a re-organization of the theological training of the universities, giving more prominence to the devotional life; and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany, and although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by Spener's book, its complaints and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In Paul Gerhardt the movement found a singer whose hymns are genuine folk poetry. In 1686 Spener accepted an appointment to the court-chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. One of his most enthusiastic disciples was August Hermann Francke, who had founded the famous orphanage at Halle, and with the aid of Christian Thomasius and Spener founded the new university there. The theological chairs were filled in conformity with Spener's proposals. Spener died in 1705; but the movement, guided by Francke, spread over Middle and North Germany. One

of its greatest achievements was the organization of the Moravian Church in 1727 by Count von Zinzendorf, Spener's godson and a pupil in the Halle Orphanage.

Pietism, of course, had its weaknesses. Many Pietists maintained that the new birth must always be preceded by agonies of repentance, and that only a regenerated theologian could teach theology, while the whole school shunned all common worldly amusements, such as dancing, the theatre, and public games. There thus arose a new form of justification by works.

As a distinct movement Pietism had run its course before the middle of the 18th century; by its very individualism it had helped to prepare the way for another great movement, the Illumination (*Aufklärung*).

PIETRO DELLA VIGNA or PIER DELLE VIGNE

[PETRUS DE VINEAS OR DE VINEIS] (c. 1190–1249), chancellor and secretary to the emperor Frederick II., born at Capua in humble circumstances, studied law at Padua. He became secretary to Frederick II., who made him *judex magnae curiae*, councillor, governor of Apulia, prothonotary and chancellor. The emperor, "of whose heart he held the keys," as Dante says, sent him to Rome in 1232 and 1237 to negotiate with the pope, to Padua in 1239 to induce the citizens to accept imperial protection, to England in 1234–35 to arrange a marriage between Frederick and Isabella, sister of King Henry III. He proved a skilful and trustworthy diplomat, and he persistently defended the emperor against his traducers and against the pope's menaces. At the Council of Lyons Pietro della Vigna entrusted the defence of his master to the jurist Taddeo of Suessa, who failed to prevent his condemnation. Frederick had his chancellor imprisoned and blinded without giving him a chance to rebut his accusers. He is said to have committed suicide in his prison at Pisa in 1249. His tragic fate gave rise to many legends.

Pietro della Vigna wrote verse in the vernacular tongue, of which two *canzoni* and a sonnet are extant. His letters (*Epistolarum libri vi.*, 2 vols., Basél, 1740), are of historical value. A collection of the laws of Sicily, a *Tractatus de potestate imperiali*; and another treatise, "On Consolation," in the style of Boethius, are also attributed to him.

See Huillard-Bréholles, *Vie et correspondance de Pierre de la Vigna* (Paris, 1864); Presta, *Pier delle Vigne* (Milan, 1880); Capasso and Ianneli, *Pier delle Vigne* (Caserta, 1882); see also **FREDERICK II.**

PIG (a word of obscure origin, connected with the Low Ger. and Dut. word of the same meaning, *bigge*), a common name given to the domestic swine. (For the zoology, see **SWINE**.)

British Breeds.—Twelve breeds are recognised in Britain:—

The *Large White* or large Yorkshire is a breed which has been evolved in the north of England and is now very wide-spread and important. The animals are large, long and deep and when young, even if heavily fed, do not readily become too fat. The head is long, light in the jowl, and wide between the eyes, with long thin ears inclined slightly forward and fringed with long fine hair. The neck is long, but not coarse, the ribs are deep, the loin wide and level, the tail set high, and the legs straight and set well outside the carcass. The whole body, including the back of the neck, is covered with straight silky hair, which denotes quality and lean meat. Pigs of this breed are very prolific, and they may be grown to enormous weights—over 11 cwt. alive.

The *Middle White* is considered to have been produced by crossing the Large White and the now extinct Small White. The latter was a small early maturing and excessively fat type of pig. The Middle Whites are built on a smaller scale than the Large Whites. They are shorter in the heads and legs, and fuller at the jowl, thicker and more compact in the body. The sows are not quite as prolific as those of the Large White breed, but, as their

produce matures earlier, they are much in demand for breeding porkers. If fed to heavy weights the animals become too fat.

The *Lincolnshire Curly Coated* or *Boston* pig is a local breed of great size and capacity for producing pork. It is very hardy and prolific, but somewhat coarse in the bone. It has an abundance of long curly hair, a short face and a straight nose, and the ears, not too long and heavy, fall over the face. It crosses well with the Large White, the Large Black and the Berkshire.

The *Large Black* breed, which vies with the Large White breed for size, has only since 1900 received national show-yard recognition; but there is ample evidence that, with its characteristic whole black colour with a mealy hue, length, fine hair and lop ear, the Large Black existed in the south of England for generations. It has been continuously and carefully bred in Cornwall, Devon, Essex and Suffolk, and from these centres it has rapidly spread all over the country. Large Blacks are exceedingly docile, and the ears, hanging well forward over the eyes, contribute materially to a quietness of habit which renders them peculiarly adapted to field grazing. On account of their hardiness and disposition to early maturity they have proved valuable for crossing. The Large Black Pig Society was incorporated in 1899.

The *Berkshire* is a black pig with a pinkish skin, and a little white on the face, pasterns, and tip of the tail. It has a moderately short head with a deep, compact carcass, and wide, low and well-developed hind-quarters, with heavy hams. The skin carries an abundance of fine hair. The Berkshire is an early-maturity breed which has been somewhat-inbred, and is not so hardy and prolific as most breeds. The boars cross well with common stock. The breed produces meat of outstanding quality and is extremely difficult to beat in carcass competitions; it does best when fed for the pork market.

The *Tamworth* is one of the oldest breeds of pigs and is considered to be directly descended from the wild native pig. The colour is red or chestnut. The head, body and legs are long, and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred, and highly valued as a bacon pig.

The *Cumberland* is a pig of the Large White type. It is, however, shorter and thicker in form; it has a dished face and drooping ears. The hair is fine and sparse. The breed fattens readily and the pork is of good quality.

The *Long White Lop-Eared* was formed by amalgamating the Old Glamorgan and Welsh breeds, which were of a similar type. The general conformation is very similar to that of the Large Black. The animals are hardy and they do well in the open air.

The *Large White Ulster* is of the Large White type but compared with that breed it is shorter in the body, finer in the hair, thinner in the skin and possesses drooping ears. It is very suitable for the bacon trade and is kept in Ulster practically to the exclusion of all other breeds.

The *Gloucestershire Old Spots* is an old local type which was constituted as a pure breed in 1914. The breed is rather thicker in form than is the Large White. The colour is black and white in fairly large clearly defined spots. The head is of medium length; the ears are long and drooping. The animals are hardy and they are very suitable for the heavy pork trade.

The *Wessex Saddleback* and the *Essex* are two breeds of very similar conformation and colour markings. The colour is black with a white "saddle" and white fore-legs. The Essex also has white on the hind legs, the tail and the nose. The animals are of medium size and are considered to be hardy.

Management.—The brood sow should be lengthy and of a prolific strain, known to milk well. She is moderately fed and put to a boar of her own age when large enough, *i.e.*, seven to eight months old. She remains in a state of oestrus for about three days, and if not pregnant comes in heat again in three weeks. Breeding swine, male and female, run most of their time at pasture and receive a liberal allowance of green food or raw roots. The period of gestation is sixteen weeks. Six to eight pigs are reared of the first litter, and ten to twelve afterwards. Many brood sows are fattened to greatest profit after the second or third litter, but on the other hand the animals may be kept as

long as they are satisfactory breeders. Two litters are produced in one year, as pigs are usually weaned at two months old, and the sow will take the boar at from three days to a week after the pigs are removed, according to condition.

The digestive system of the pig is not fitted to deal with fibrous or bulky fodders and the food should be highly concentrated. In practice pigs are fed largely on dairy by-products such as whey and separated milk, milling offals, cereal meals, waste potatoes and kitchen scraps. Pigs do well on mixtures of milk products and cereal meals or offals. If no milk or whey is available the meals or potatoes should be balanced with 10% of white fish meal or meat meal or other foodstuff rich in albuminoids. Kitchen scraps should be cooked and the fat skimmed off before being given to pigs. Potatoes are best fed in a cooked condition. Chalk and other mineral matter are often added.

Every endeavour should be made to provide young pigs with some milk or milk product for a time after weaning. Fattening pigs should be given from $\frac{1}{2}$ to $\frac{1}{4}$ lb. of mixed cereal meals, or their equivalent of other foods, for every week of age. Thus at 12 weeks the pig should get about 23 lb. of dry meal or its equivalent per day; at 20 weeks, about 4 $\frac{1}{4}$ lb.; at 30 weeks, about 7 $\frac{1}{2}$ lb. Another rough rule is to give 1 lb. of meal for every 25 lb. live weight. With dry food, water will of course have to be available. Sows in pig require about 5 lb. of meal or its equivalent per day; sows in milk need 10 or 12 lb. It is usual to spread the ration over three meals per day.

Porker pigs are frequently slaughtered when about 43 months old and 100 lb. live weight; they yield about 65 lb. of dressed carcass. Many pigs are, however, marketed for pork at much greater weights. A typical bacon pig should weigh about 220 lb. live weight or 165 lb. carcass weight and should be ready for slaughter when 7-8 months old.

The United States.—The *Poland China* breed originated in Ohio, principally in the counties of Butler and Warren. The foundation stock consisted of so-called Bedford, Woburn, Russian and Irish Grazer hogs, improved by an introduction of Berkshire blood. The breed was at first white and black spotted, but later the black body with white at the face, feet and tip of tail, became the standard colour. The breed is large in size, boars commonly weighing 1,000 lb., while sows at maturity often weigh as high as 800 lb. Lengthy proportions, combined with height, ruggedness of bone, and meat producing qualities, are especially stressed in this breed. The head of the Poland China is rugged in appearance, medium in length and slightly dished in the profile. The ear is rigid from the point of attachment on the head to approximately one-half to two-thirds of its length, with the tip one-half or one-third broken over. In body conformation, the Poland China is long, deep and tall. The shoulders are smooth and compact, and the back is evenly and smoothly arched. This breed is found in all parts of the United States, as well as in many other countries.

The *Duroc-Jersey* originated in the eastern part of the United States, mainly in New York and New Jersey. The foundation stock, it is thought, came from Africa, Portugal and Spain. In general, the conformation of the Duroc-Jersey resembles that of the Poland China. However, the head is smaller and more refined, and the back is somewhat more evenly arched. In colour this breed ranges from a light golden yellow to what approximates a mahogany brown. The ideal colour, however, is a deep golden yellow inclining to a cherry red.

The *Chester White* originated in Chester county, Pa. The foundation stock consisted of native stock combined with English hogs, particularly the Large Yorkshire. Individual breeders have at various times attempted to establish other breeds similar in character and breeding to the Chester White. A notable example of this is the so-called O.I.C., which means the Ohio Improved

- 7. Tamworth sow
- 8. Berkshire boar

Chester White. This latter so-called breed is organized into a breed association, and the breeders record their animals separately from the Chester White. There seems to be little to distinguish one breed from the other. The Chester White is pure white in colour, although black or bluish spots known as freckles are frequently found on the hide. In size the Chester White does not quite rank with the Poland China or the Duroc-Jersey. Boars at maturity, however, often weigh 900 lb., while the females commonly reach a weight of 700 lb. A medium sized head and ear, clean, trim jowls, and an evenly turned back, are characteristic of the Chester White. Like the Poland China and Duroc-Jersey, one-half to one-third of the tip end of the ear is broken over. This breed is quite popular in the corn belt, but due to its white colour does not stand the sun as well as a dark coloured breed.

The Hampshire breed, while a native of America, originated from English stock, probably the Wessex Saddle Back and the Essex. In colour markings the American Hampshire resembles these breeds. The Hampshire has had its greatest improvement in Ohio, Illinois, Iowa and other corn belt States. The breed has gained its popularity through its fecundity, foraging properties and its ability to yield a high grade carcass. Among the common lard breeds in America the Hampshire is relatively small. It is extremely trim in its lines, is especially clean cut about its head, and is smooth and firm in its bone. The face of the Hampshire is straight in profile and the ears are rigid from point of attachment at the head to the tip end. The promoters of this breed discriminate against heavy jowls, dished faces and any tendency toward roughness.

The *Berkshire* breed is a native of England but has received considerable attention in America. It is classed as a lard breed and has been especially noteworthy because of the high quality of carcass it produces. The Berkshire has the same colour marking as the Poland China but is not so large in size. The ears are rigid and the face is dished.

The *Tamworth* and Large Yorkshire are the two most common bacon breeds in America. Both these breeds received their origin in England and are similar in body conformation. They differ, however, in colour. The Large Yorkshire is white, while the Tamworth is red, similar to the Duroc-Jersey in this respect. The bacon breeds are less popular than lard breeds. (J. S. C.)

PIGEON, a name of Norman introduction for certain birds of the family Columbæ (see DOVE). Perhaps the best known species to which the name is exclusively applied is the passenger pigeon (*Ectopistes migrarius*) of North America. Formerly nesting in countless multitudes in the then "backwoods" of Kentucky, Ohio, and Indiana, this bird is now extinct, the last specimen dying in Cincinnati Zoological Gardens in 1914. The passenger pigeon was about the size of a turtle-dove, but with a long, wedge-shaped tail. The male was a dark slate colour above and purplish-bay below; the female, drab above, dull white beneath. The beautiful fruit-pigeons (Treron) of tropical Africa, India, and the Malay Archipelago are, perhaps, the most delicately flavoured of all birds.

The largest forms are the giant crowned pigeons (Goura) of New Guinea; they have a beautiful filmy, fan-shaped crest on the head. The Nicobar pigeon (Caloenas) is remarkable for the long lustrous neck hackles and its peculiar gizzard.

Pigeons lay two or three white eggs and the naked, helpless young are fed by a secretion from their parents' crops ("pigeon milk").

PIGEON-FLYING, the sport of racing homing-pigeons bred and trained for the purpose. It is of very recent date, although the use of birds as a means of carrying messages (see PIGEON POST) is of great antiquity. Belgium may be considered as par excellence the home of the sport, the first birds flown there probably coming from Holland. Long distance flying began in 1818, with a match of 100m., while in 1820 there was a race from Paris to Liège, and in 1823 from London to Belgium. The Belgian *concours* national, a race of about 500m. from Toulouse to Brussels, was inaugurated in 1881, in which year the first regular races in Great Britain took place.

The sport was introduced into the United States about the

year 1875, although regular racing did not begin until 1878. Since then it has gained widespread popularity. The speed depends very greatly upon the state of the atmosphere. In the race from Montargis to Brussels in 1876 in bright and clear weather, all the prize-winners made the distance of 270m. within 3¼ hours, while in the same race in 1877, on a thick and stormy day, 30 hours passed before the first bird arrived.

Training.—The loft should be on a commanding site. It is best made in the shape of a large room, suitably subdivided, protected from vermin, and provided with drinking troughs, rock salt and crushed mortar for the birds' use. It should be fitted with a sufficient number of nests about 2ft. long, 2oin. in breadth and height. Arrangements should be made for allowing the pigeons to fly out daily for exercise; and they should be trained to re-enter the loft through bolting wires, which open inwards only, into a small chamber, to which an electric arrangement may be fitted so as to sound a bell and warn the owner of the arrival of a bird. The food of birds in training consists of vetch, beans, maize, peas, broken rice and millet, in various proportions according to the country, climate and season of the year, the daily allowance for each bird being about 40 grammes weight.

Training should commence in warm weather, when the bird is about four months old, and consists in taking it out in a closed wicker basket and liberating or "tossing" it at gradually increasing distances from its loft, with several days interval of rest between the flights. The usual preliminary distances are, 1, 2, 5, 10 and 15 or 20m. These tosses should all be made on the same line between the loft and, say, some neighbouring city, in order that a bird may always have to fly in the same general direction during the season. About 100m. may be expected of birds the first season; they do not reach their full distances until about the fifth year. The Belgian fanciers generally divide their birds into two classes, one for breeding and the other for racing, though the latter are allowed to breed within certain limits. Some fanciers always choose birds with chicks in the nest for long journeys, claiming that they return faster with this incentive. A seamless metal ring marked with the owner's name is slipped over the foot of the pigeon when only a few days old, and during its racing career the longer wing-feathers are stamped with the bird's records. At the start of a race the competing birds are tossed together by a starter who takes the time. Upon being released the homer ascends rapidly in spirals until, apparently describing some familiar landmark on the horizon, it will fly straight and swiftly towards it. As the birds enter their home-lofts the time is taken by the owner. A bird is not considered to have got "home" until actually through the door of its loft.

PIGEON POST. The use of homing pigeons to carry messages is as old as Solomon, and the ancient Greeks, to whom the art of training the birds came probably from the Persians, conveyed the names of Olympic victors to their various cities by this means. Before the electric telegraph this method of communication had a considerable vogue amongst stockbrokers and financiers. The Dutch Government established a civil and military pigeon system in Java and Sumatra early in the 19th century, the birds being obtained from Baghdad. Pigeons were employed during the siege of Paris in 1870-71. This led to a revival in the training of pigeons for military and naval purposes. They have also been used by newspapers for reporting. It has been found very important to establish registration of all birds. In order to hinder the efficiency of the systems of foreign countries, difficulties were placed in the way of the importation of their birds for training, and in a few cases falcons were specially trained to interrupt the service in war-time, the Germans having set the example by employing hawks against the Paris pigeons in 1870-71. No satisfactory method of protecting the weaker birds seems to have been evolved, though the Chinese formerly provided their pigeons with whistles and bells to scare away birds of prey.

During the World War pigeons were frequently used to bring back messages from advanced positions and often rendered very valuable service, but the development of wireless telegraphy will restrict their uses.

1872); Brinckmeier, *Anzucht, Pflege, und Dressur der Brieftauben* (Ilmenau, 1891).

PIG IRON. Crude cast iron, run from the blast furnace directly into moulds. The moulds originally were of sand formed in a way which suggested a nursing litter of pigs. (See IRON AND STEEL; BLAST FURNACE.)

PIGMENTS: see PAINTS, CHEMISTRY OF.

PIGMENTS OF SKIN AND HAIR. The pigment of the skin, the pigment of the blood, the pigment of the yolk of the egg, and the pigment of the butterfly's wing may each be regarded as representative of a chemical group of colouring matters, and into those four groups the great bulk of the pigments seen in the animal world may be placed.

The Pigment of the Skin.—The skin consists of two principal layers—the epidermis or superficial portion, and the dermis or deep portion. The dermis is not pigmented in man, nor is the epidermis in the so-called white races. In the negro the epidermis is densely pigmented, the pigment being present in granules. These granules are not uniformly distributed throughout the epidermis, which itself consists of many layers of cells, but they are confined to the layer of cells next to the dermis, and, therefore, farthest removed from the external surface.

The black pigment of the skin, which is called melanin, is situated in granules in the deepest layer of endo-dermal cells, namely, that placed immediately over the dermis. All the cells of the epidermis really are developed from this layer (the Malpighian layer) the constituents of which divide and work their way towards the surface. It might be supposed that all the epidermal cells should there be pigmented, but this is not so; as they get nearer the surface, they lose their pigment. This is well shown in the case of a blister. The fluid forms in the epidermis, separating the deeper from the more superficial portion; the covering of the blister in a negro is not pigmented.

In man the pigment is present as a quite inert deposit, the person being no more negroid at one time than another; but in many lower animals this is not so. The frog, for instance, will at one time be dark, at another pale. The melanin in the frog's skin is laid down in special cells known as melanophores; these may contract in minute balls, in which case the skin is pale, or they may expand, pushing out branches in all directions, in which case they form an almost continuous network of pigmented material.

The degree of expansion of the melanophores is regulated by circumstances, the following table being given by Hogben (abbreviated):—

Normal Responses of Common Frog

Evidently their dark background, low temperature and moistness tend to make the melanophores expand. The mechanism by which expansion of the melanophores in the frog is effected is bound up with a remarkable body situated underneath, and connected with the brain—the pituitary body (see art. HORMONES). This body secretes, no doubt at the bidding of the brain, a hormone into the blood which, acting on the melanophores, causes them to expand.

The pigment cells in the frog, unlike those in man, are situated at different levels; some are in the epidermis and some in the dermis. This arrangement has been exploited very completely by the chameleon. The chameleon possesses two layers of cells, each in the dermis. As an example may be taken an animal which alters in colour from a yellow or very pale green, through green to something nearly black. The cells of the outermost layer, called variously guanophores, leukophores, ochrophores, iridocytes

and interference cells, are yellowish in colour; so far as is known, these cells do not alter either in shape or tint. Underneath these are the melanophores, also a similar but reddish type of cell called erythrophores. To take the melanophores, these send processes towards the surface more or less encircling the guanophores. Darkening in the colour of the chameleon is due to the migration of granules of melanin from the deeper portion of the melanophores into the more superficial tentacles which surround the guanophores. The actual colour which the animal presents is partly due to the mixture of colours which the various pigment cells present, and partly due to the scattering of light between these. The migration of the melanophore granules in the chameleon is due largely to the hormone adrenalin. The current belief that the chameleon takes on the colour of its surroundings is much exaggerated; the colour is influenced largely by light and temperature, and, so far as the author has been able to judge, in a very limited way by temper also; if the chameleon were annoyed it took on a darker colour.

Fish, too, have great powers of colour change within a certain scale of colours, which scale does simulate very closely the colour of the bottom on which they lie. Their colour change is also wrought by melanophores, but these seem more directly to be controlled by the nervous system and less by hormones than those of the frog. Thus, if a nerve going to a particular segment of the skin be severed the possibility of colour change appears to vanish.

The Chemical Nature of Melanin.—Melanin is closely related to two remarkable chemical substances found in the body. The one is the hormone adrenalin (which turns a blackish colour on exposure); the other is a substance, tyrosine, which is one of the breakdown products of protein.

The chemistry of melanin formation has been studied chiefly in the vegetable kingdom. A familiar example is seen when an apple is cut and the cut surface is exposed to air. The melanin is formed from tyrosine in the apple by oxidation; but the mere exposure of tyrosine to air will not produce melanin. There must also be a ferment present which effects the oxidation. This ferment is called tyrosinase. If two solutions—(1) tyrosine and (2) tyrosinase—both of which are colourless—be mixed and shaken with air the mixture first becomes a reddish colour and gradually turns to a dark brown. The reddish pigment appears to be an intermediate body between tyrosine and melanin. Recently, Raper and his colleagues have shown that the rôle of the tyrosinase lies in the formation of this reddish substance, the melanin being a more complicated body derived from the union of two molecules of this red substance.

The pigments in hair are formed on similar lines to those of skin. H. Onslow, the leading authority at the time of his death, wrote: "The colour of human hair depends upon the colour and form of the pigment (*i.e.*, whether it is diffused or deposited in granules) and upon the (air) vacuoles. . . . In light and sandy hair the pigment is chiefly diffused and of a yellowish red colour, but in darker hair the pigment is present as dark brown or black granules." Onslow recognizes three pigments in rabbits giving rise to six colours, the pigments being black, chocolate and yellow, which give rise to rabbits of those colours, and, when the pigments are diluted, to blue, fawn and cream respectively. The pigments may, however, be mixed, or in bands, giving rise to the agouti. With regard to whiteness, Onslow writes: "The hair of an animal may be white for one of three reasons—(1) the absence of either chromogen or enzyme; (2) the absence of both chromogen and enzyme; (3) the presence of an inhibitor of the enzyme."

Whilst most of the pigments in the integument consist either of melanin or some substance closely allied to it, a few are of quite a different origin.

The beak and the legs of fowl, for instance, are often yellow, the pigment being one known as carotin—the same that colours the carrot. Its presence is, in a sense, accidental. It is not manufactured in the animal body, but exists in the vegetables eaten. It is absorbed into the blood during digestion and, being soluble in fat, it accumulates in places where fat exists. More especially is this the case in the yolk of the egg. Hens fed on foods com-

pletely free of pigment after a time lay eggs with colourless yolks; moreover, if fed on food containing other fat soluble pigments, the yolk becomes correspondingly coloured; eggs with bright red yolks are obtained if the dye "Soudan III." be mixed into the food.

It is remarkable that haemoglobin contributes little to the pigmentation of the skin—in man only in pathological conditions. In jaundice the yellow pigment is the same as ordinarily appears in the bile, and is practically haemoglobin stripped of its iron and of its protein. Closely related to bile pigment is uro-porphyrin, which occasionally appears in the skin, and then with very distressing results. The skin becomes exceedingly sensitive to light so that the individual requires veiling in the open air; otherwise he would suffer from sunburn amounting to inflammation.

Another sort of porphyrin is, however, found in the integument of some of the lower animals, as for instance, the brown line on the back of the earth-worm. This is protoporphyrin; it is the pigment which forms the basis of haemoglobin and is most familiar as being that which colours brown eggs.

Finally, the distinction between pigment and *colour* must not be forgotten. Black eyes and blue contain the same pigment—melanin—black more than blue, but the blue hue is obtained from the way in which the light is reflected from the surfaces of the fibres of which the iris is made, and among which a number of pigment cells are disposed. (J. BAR.)

PIGOT, GEORGE, BARON (1719-1777), English governor of Madras, was born on March 4, 1719 and entered the service of the East India Company in 1736. He became governor and commander-in-chief of Madras in 1755. Having defended this place against the French in 1758-59 and occupied Pondicherry on behalf of the company, he resigned office in November 1763 and returned to England, being made a baronet in 1764. In the following year he obtained a seat in parliament, which he retained until his death; in 1766 he was created an Irish peer as Baron Pigot. Returning to India in 1775 to occupy his former position at Madras, Pigot was at once involved in a quarrel with the majority of his council, which arose out of the proposed restoration of the rajah of Tanjore. The governor was arrested by order of his opponents, and was still a prisoner when he died on May 11, 1777. In 1779 the matter was discussed in parliament, and four of those who were responsible for his arrest were tried and fined £1,000 each. Pigot, who left several illegitimate children, was never married, and his barony became extinct.

PIG-STICKING or **HOG-HUNTING** is the sport of chasing the wild boar on horseback with a spear. From the earliest times the pursuit of the wild boar has been a favourite pastime in Europe but the modern sport of pig-sticking is of Indian origin. It is now generally accepted as a fact that pig-sticking was the outcome of bear-spearing, which was popular amongst British sportsmen in Bengal until the beginning of the 19th century when bears had become so scarce that wild boars were substituted as the quarry. Early in the 19th century it seems that the spear was generally thrown and Captain Johnson, writing in 1827, gives directions for throwing the spear, which was a weapon more in the nature of a javelin with different coloured ribbons attached to the butt so as to enable the owner to reclaim his spear. In 1830 Mr Mills, of the I.C.S., seems to have introduced the "jobbing" spear in his district and this weapon was universally used in Bengal. But the jobbing, or thrusting, spear was known before 1830 and was used regularly by officers of Lord Lake's Army as early as 1803 (vide *War and Sport in India: an Officer's Diary, 1802-1806*). At the present time there are really three types of spear in general use: the short Bengal spear which is about 5 feet long and is always used over-hand; the long Bombay spear, which may be as long as 10 to 12 feet and is always used under-hand like a lance; and a spear about 6 to 7 feet long, well leaded at the butt so as to balance about a foot from that end, which is generally used under-hand but which can, should circumstances so demand, be used over-hand. This last is the type of weapon common in the United Provinces and Delhi districts. The best type of horse is one that is fast and quick, yet not too big, as very rapid twists

and turns must be made when following a pig which "jinks," or turns sharp in its tracks. For this same reason the horse must be perfectly balanced and well back on its hocks, while a good shoulder and long rein help it to stand up over bad ground.

A large area of land is controlled and hunted by a "Tent Club" which corresponds to a Hunt in England, and private expeditions after pig in any such area are forbidden by etiquette. A Tent Club is managed by an honorary secretary, which is an unfortunate title as this individual has powers and prestige similar to those of a M.F.H. in England. The season varies in different districts but begins as soon as the heavy undergrowth, which springs up during the monsoon, has died sufficiently to enable riding across country, usually in January, and continues throughout the hot weather until the rains break towards the end of June. April, May and early June are the best months. Meets of a Tent Club take place, as a rule, once a fortnight and last for two to four days. There are two methods of hunting. Where the whole country is covered with girth-high grass and jhow (tamarisk) a long line of beaters advances while the "spears" ride with the line. These are divided into "heats" of three or four and only one heat may ride a boar that is put up, or "reared," by the beaters, the heat nearest the boar taking the hunt. The rider who gains "first spear," that is who spears the boar first, claims the head and tusks as his trophy. But where the boar inhabits thick patches of unridable jungle, as is the case in Central India and Guzerat, as well as in isolated cases in other parts, the heats wait in hiding outside while beaters drive out the boar. The rules for riding are the same in both cases.

There are various pig-sticking competitions the best known of which is the Kadir Cup. The word "Kadir" (pronounced "Karder") merely means the old bed of a large river. All the big Indian rivers are constantly changing their courses and the land which has at one time been under water may be anything from five to thirty miles in width. Such land is a river Kadir and is overgrown with tamarisk and grass, intersected with nullahs (*i.e.*, water courses, dry or full of water), and dotted with *jhils* (swamps). Villages are few and far between, while the ground is the haunt of wild boar and many other species of game, both big and small. A large part of the Ganges Kadir has been controlled by the Meerut Tent Club since before the Mutiny, and the Kadir Cup is run annually in March in this country. Competitors may enter two horses, but not more. Heats of three are determined by lots, and the gainer of the first spear in each heat qualifies for the second round, and so on to the semi-final and final heats. The winning of the Kadir Cup, which was instituted in 1869, constitutes the blue ribbon of pig-sticking.

Other pig-sticking competitions are the Guzerat Cup, which is run in Guzerat on similar lines to the Kadir Cup; the Nagpur Hunt Cup, which goes to the member of the Tent Club who gains the greatest number of first spears in the season; and the Muttra Cup, which was instituted in 1913 and is awarded to a team of three who actually kill the greatest proportion of boars to those hunted. This event is run in the Jumna Kadir near Muttra.

Pig-sticking in India suffered severely during the War owing to the shortage of spears and many old Tent Clubs were automatically disbanded through lack of members and funds. But there has been a great revival since 1919 and almost all the old Clubs have been resuscitated; the sport is as popular now as it has ever been in the past, and in 1927 one of the largest boars ever recorded as being speared was killed in the Gogra Kadir by the Fyzabad Tent Club. This boar measured 37½ inches at the withers and weighed 325 pounds.

The only other country where pig-sticking is practised is in Tangier, where there is a flourishing Tent Club.

Useful books on the subject are: F. B. Simpson, *Letters on Sport in Eastern Ronaal*; A. E. Wardron, *Modern Pig-Sticking*; Sir R. S. S. Baden-Powell, *Pig-Sticking or Hog-Hunting*. (G. Bv.)

PIGWEED, a name applied to various plants, especially lamb's-quarters (*q.v.*) and various species of amaranth (*q.v.*). The winged pigweed (*Cycloloma atriplicifolium*), of the Great Plains region of North America, is closely allied to lamb's-quarters. See illustration on page 924.

PIKE, ZEBULON MONTGOMERY (1779-1813), American explorer and soldier, was born at Lamington, Somerset county, N.J., the son of Zebulon Pike (1751-1834) a captain in the Revolutionary War, who remained in Federal service until 1812. The son entered his father's company as a cadet about 1794, and in 1799 or 1800 was commissioned first lieutenant. When in 1805 President Jefferson wished the upper Mississippi region of the Louisiana Purchase explored, Lieut. Pike, then 26 years of age, was selected to lead the expedition. With 20 soldiers he ascended the Mississippi from St. Louis past the Falls of St. Anthony to a place in Morrison county, Minn. Hence he made an expedition on foot to the fur-trading posts of the Northwest Company, a British concern, at Sandy, Leech and Cass Lakes, and took formal possession for the United States. He returned to St. Louis in April, 1806, and almost immediately was despatched at the head of an expedition to treat with Indian tribes and explore the country west and south-west of St. Louis

ROUGH PIGWEED: SEE PAGE 923

to the headwaters of the Arkansas and Red rivers. After holding a grand council of the Pawnees, he ascended the Arkansas river through the Royal Gorge, and came in sight of the mountain which was named Pike's Peak in his honour. While searching for the Red river he came to the South Platte, marched through South Park, left it by Trout Creek pass, struck over to the Arkansas, which he thought was the Red river for which he was searching, and, going south and south-west, came to the Rio Grande del Norte (about where Alamosa, Conejos county, Colorado, is now) on the 30th of January 1807. There on the 26th of February he and a small number of his men were taken prisoners by Spanish authorities, who sent him first to Santa Fe, then to Chihuahua to General Salcedo, and by a roundabout way to the American frontier, where he was released on the 1st of July 1807. He was promoted captain (August 1806), major (May 1808), lieutenant-colonel (Dec. 1809) and colonel (July 1812). In 1808 he tried in vain to get an appropriation from Congress for himself and his men. He was military agent in New Orleans in 1809-1810, was deputy quartermaster-general in April-July 1812, and was in active service in the War of 1812 as adjutant and inspector-general in the campaign against York (now Toronto), Canada, and in the attack on York on the 27th of April 1813 was in immediate command of the troops in action and was killed by a piece of rock which fell on him when the British garrison in its retreat set fire to the magazine, just as his victorious soldiers were breaking in.

His Account of an Expedition to the Sources of the Mississippi and through the *Western Parts of Louisiana* . . . and a *Tour through the Interior Parts of New Spain* was published at Philadelphia, 1810; rearranged and reprinted in London, 1811, and has been published in many editions since, including translations into the French and Dutch. The standard edition with memoir and notes by Elliott Coues was published in 1895. In 1908 H. E. Bolton published some of the papers taken from Pike in Mexico (originals then in Mexican archives but forwarded to Washington in 1910) in the *American Historical Review* (vol. xiii., 798-827).

See the sketch by H. Whiting in vol. V., Ser. 2, of Jared Spark's *Library of American Biography*.

PIKE, fresh-water fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (Esocidae) of soft-rayed fishes. They are recognized by their elongate compressed body covered with small scales, a long head, long spatulate snout, and large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point back-

wards or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the tail, thus greatly increasing the propelling power of the fish. Although pike lead rather a sedentary life, they are excelled by no other fresh-water fish in rapidity of motion when they dash upon their prey or dart out of reach of danger. In the Old World one species only is known (*Esox lucius*), which prefers lakes and sluggish reaches of rivers. It extends into Lapland in the north and as far south as central Italy and Constantinople, but is absent in Spain and Portugal. The European species occurs also in east-

PIKE (*ESOX LUCIUS*)

ern North America, and is common southwards to northern Ohio. But North American waters are tenanted by other species of pike of which the largest is the muskellunge or maskinonge of the Great Lakes (*E. nobilior*). The other American pike are smaller and generally named "pickerel." Pike are the most voracious of fresh-water fish. Large specimens will seize rats or water-voles, and are said to attack even foxes and small dogs. Individuals of *E. lucius* of 50 lbs. are not scarce, but much larger ones are on record. Pike are wholesome food, and are much esteemed in inland countries. According to the season and the climate they spawn in April or in May and sometimes as early as February.

PIKE, a word which, with its collateral forms "pick" and "peak," has as its basic meaning "anything pointed or tapering to a point." The ultimate etymology is much disputed, and the interrelation of the collaterals is very confused. In Old English there are two forms (pic), one with a long and the other with a short vowel, which give "pike" and "pick" respectively. The first form gave in the 15th century the variant "peak," first with reference to the peaked shoes then fashionable, *þekyd schone*. In Romanic languages are found Fr. *pic*, Span. *pico*, Ital. *piccare*, to pierce, etc. There are also similar words in Welsh, Cornish and Breton. The Scandinavian forms, e.g., Swed. and Nor. *þik*, are probably taken from English. While some authorities take the Celtic as the original, others look to Latin for the source. Here the woodpecker, *picus*, is referred to, or more probably the root seen in *spica*, ear of corn, and *spina*, prickle (English spike, spine). The current differentiation in meanings attached to pike, pick and peak are more or less clearly marked, though in dialects they may vary. Apart from the use as the name of the fish (see above), probably a shortened form of pike-fish, from its sharp, pointed beak, the common uses of the word are for a long hafted weapon with sharply pointed head of iron or steel, the common weapon of the foot-soldier till the introduction of the bayonet (see articles HALBERT and BAYONET), and for a hill with a pointed summit, appearing chiefly in the names of such hills in Cumberland, Westmorland and North West Lancashire.

PIKE-PERCH, fresh-water fishes allied to the perch, but with strong teeth standing between smaller ones. They resemble the pike in their elongate body and head, and are dangerous enemies to other fresh-water fishes. They are excellent eating. In Europe two species occur, the more celebrated being *Lucioperca sandra*. It prefers the quiet waters of large rivers and clear, deep lakes, in which it reaches a weight of 25 to 30 pounds. The second (*L. wolgensis*) is limited to rivers in southern Russia and Hungary. In North America two are distinguished; viz, *L. americana*, which grows to a weight of 20lb., and the smaller *L. canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PIKES PEAK, a famous mountain of the Rampart range of the Rocky Mountains in El Paso county, Colorado, U.S.A. Though surpassed in altitude (14,110 ft) by many summits in the State, few have so commanding a location and none is so well known. From the summit the magnificent Sangre de Cristo range is in the foreground, while on a clear day not only its southernmost summit, Blanca Peak (14,363 ft.) is visible, but also the Spanish

Peaks (12,708 and 13,623 ft.) 100 m. to the south, and Longs Peak 100 m. to the north, and between them Mt. Lincoln, Grays Peak and other giants, while the view extends eastward over a vast sweep of plains. At the base of the mountain are Manitou Springs and Colorado Springs, whence tourists can make the ascent of the peak on horseback, by a cog-railway, 8.75 m. long (opened in 1891), or by a well constructed automobile road.

The lower slopes are covered with evergreen forests but the upper 2,500 ft. of the peak is bare granite. The summit is a comparatively level spot of nearly 60 ac. extent. Pikes Peak was discovered in Nov. 1806 by Lieut. Zebulon M. Pike. In 1819 it was first climbed by the exploring party of Major S. H. Long.

PIKES PEAK OCEAN TO OCEAN HIGHWAY, an American highway extending from New York city to San Francisco, Calif., a distance of 3,564 miles. Its central location makes it one of the most direct routes from ocean to ocean. It runs directly past the base of Pikes Peak, up which is the Pikes Peak motor road, the highest in the world. The roadway is paved, hard and improved from the Atlantic to the Rockies and partly paved, hard, improved and graded the remainder of its length. From New York city to Pittsburgh, Pa., this highway is also known as the William Penn highway. Columbus, O., Indianapolis, Ind., Springfield, Ill., St. Joseph, Mo., Colorado Springs, Colo., Salt Lake City, Utah, Reno, Nev., and Sacramento, Cal., mark the general course of the highway.

PILATE, PONTIUS, of equestrian rank, was Roman governor of Judaea from A.D. 26 to A.D. 36, when he was recalled. He kept the Roman peace in Palestine, but with little understanding of the people (Josephus, *Ant. XVIII.*, iii., 1, 2; iv. 1, 2; *Jewish War*, II., ix., 2-4, Philo ad *Caium*, 38). One disturbance arose when Pilate used Temple funds for an aqueduct. The reference in Luke xiii., 1, to the massacre of Galilean pilgrims in the act of sacrificing suggests the governor's ruthlessness in putting down riot. It must be said, however, that the post of Roman Governor in Judaea was peculiarly difficult, and it was to Pilate's credit that his rule lasted as long as ten years. Both Pilate's part in responsibility for the crucifixion of Jesus Christ and the legal aspects of the trial have been much debated. The Early Church blamed the Jews, and correspondingly tended to exonerate Pilate. The Third and Fourth Gospels, especially, suggest that extraordinary pressure was brought to bear upon the governor by the Jewish priests. Pilate may well have been impressed by the dignity and gentleness of the great Preacher of the Kingdom of God, and may also have given Him opportunity to save Himself (John xviii., 33-38; xix., 9-11). There are many stories, all of uncertain value and in many cases legendary, telling of Pilate's later life and of his suicide. Pilate has been canonized in the Abyssinian church (June 25) and his wife Procla, or Procula, in the Greek (Oct. 27).

PILCHARD or **SARDINE** (*Sardina pilchardus*), a fish of the herring family, found on the Atlantic coasts of Europe north to the English channel, and represented in the Mediterranean by a smaller race (*S. pilchardus sardine*). The genus *Sardina* includes also *S. sagax* of Japan, California, Chile and South Africa, and *S. neopilchardus* of southern Australia and New Zealand. These resemble the European pilchard in being slender, rounded fishes, with feeble teeth, with radiating ridges on the operculum, and with rich oily flesh. The European fish is distinguished by a remarkable peculiarity, every alternate oblique row of scales being enlarged and covering the row behind it, so that the scales appear to number about 27 instead of 54 in a longitudinal series; exceptional specimens, with the scales on one side equal and apparently more numerous, have been described as hybrids between pilchard and herring! Pilchards swim in large shoals and feed on minute pelagic animals; they spawn in summer and their

eggs float in the water; in the larva the dorsal fin is placed far back, and as the fish grows it migrates forwards to its position in the middle of the length of the fish. In Cornwall adult fish, about 10 in. long, are caught and are salted in barrels. The sardine industries of France and Portugal depend on smaller fish, which are tinned in oil. Tinned Californian pilchards and Japanese sardines are also important products.

PILE. As a textile term, this word indicates the surface of a cloth composed of an infinite number of loops of warp threads, or else of an infinite number of free ends of either warp or weft (filling) threads that stand erect from the foundation or ground structure of the cloth. There are two general methods of distinguishing between such cloths; thus:—

1. When the loops are uncut, the pile is usually termed "looped pile."

2. When the same or similar loops are cut, either in the loom during weaving or by a special machine after the cloth leaves the loom, the pile is termed "cut pile."

Other names applied to such cut-pile fabrics in which the effect is formed by the warp threads are "velvet" and "plush," the former being used to define short-pile fabric and the latter to define long-pile fabrics. The word "velveteen" is used to distinguish the fabric when the pile is formed of weft or filling threads that have been cut.

Amongst the loop-pile fabrics may be mentioned Brussels tapestry and imitation Brussels carpeting, as well as Moquettes and the like. In some cases the surfaces of carpets, such as Wilton and Axminster, are formed of cut pile; and again, in other instances, both looped (uncut pile) and cut pile appear on the surface of the same fabric. Imitation sealskins and several other kinds consist of mono-coloured pile, whereas all the above-mentioned carpets have surfaces upon which decorative designs appear in both kinds of pile and in several colours. (See **CARPET**; **CARPET MANUFACTURE**. For pile in building see **FOUNDATIONS**.) (T. W.)

PILGRIMAGE, a journey undertaken, from religious motives, to some place reputed as sacred. These journeys play an important rôle in most pre-Christian and extra-Christian religions: in the Catholic Church their acceptance dates from the 3rd and 4th centuries.

The Pilgrimage in Pre- and Non-Christian Religions—To the Germanic religions the pilgrimage is unknown. On the other hand, it is an indigenous element, not only in the creeds of Asia, but in those of the ancient seats of civilization on the Mediterranean. The fundamental conception is always that the Deity resides—or exercises a peculiarly powerful influence—in some definite locality; and to this locality the devout repair, either in reverence of their god, or in quest of his assistance and bounty.

One of the oldest homes of the pilgrimage is India. There the army of devotees tends more especially to the Ganges—the hallowed river of Hindu belief. On the Ganges lies Benares, the holy city of Brahmanism: and to look on Benares, to visit its temples, and to be washed clean in the purifying river, is the yearning of every pious Indian. Even Buddhism—originally destitute of ceremonial—has adopted the pilgrimage; and the secondary tradition makes Buddha himself determine its goals: the place where he was born, where he first preached, where the highest insight dawned on him, and where he sank into Nirvana.

The habit of religious expeditions to sacred places took deep root among the Egyptians, the Jews, and the Greeks; but the pilgrimage attained its zenith under Islam. For Mohammed proclaimed it the duty of every Mussulman, once at least in his life, to visit Mecca; the result being that the birth-place of the Prophet is now the religious centre of the whole Mohammedan world. (See **ISLAM**; **CARAVAN**; **MECCA**.)

THE PILGRIMAGE UNDER CHRISTIANITY

The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested. It was a religion without temples, without sanctuaries, and without ceremonial. The

saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. The Christian pilgrimage arose from devotion to the memory of Jesus; the faithful repaired to those places which were invested with memories of their Lord's earthly life. Bethlehem and Jerusalem became objects of such visits from the 2nd century; and from references in Eusebius and others, it is evident that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer; and that men travelled for purposes of prayer implies acceptance of the theory of sanctuaries which it is an act of piety to visit.

THE PILGRIMAGE IN THE ANCIENT CHURCH

The East.—In the passages cited above, Bethlehem and the Mount of Olives figure as the main goal of the pilgrim: and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. The one holy site in the town of Jerusalem, before the time of Constantine, was the so-called Coenaculum, which received its name in later years. It was regarded as the house in which—according to the Acts of the Apostles (xii. 12 sqq.)—Mary, the mother of John Mark, lived; and the belief was that there the Lord held the Last Supper, and that there the eleven assembled after the Ascension.

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites, under Constantine the Great, as described by Eusebius in his biography of the emperor (iii. 25 sqq.). At the order of Constantine, the accumulation of rubbish covering the supposed site of the burial-place of Jesus was removed, and the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326–336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. The result was an exaggerated importance attached to these pilgrimages, a view which led to energetic protests, especially from Gregory of Nyssa, who composed a monograph on the pilgrimages (*De iis qui adeunt Hierosol.*). Jerome, like Gregory, insists on the point that residence in Jerusalem has in itself no religious value: it is not locality, but character, that avails, and the gates of Heaven are as open in Britain as in Jerusalem (*Ep.* 58, 3).

But Jerome never denied the religious uses of the pilgrimage; he considered it an act of faith for a man to offer his prayers where the feet of the Lord had stood, and the traces of the Birth, of the Cross, and of the Passion were still to be seen (*Ep.* 47, 2). With the number of the pilgrims the number of pilgrim-resorts also increased. Of Jerusalem alone Jerome relates that the places of prayer were so numerous that it was impossible to visit them all in one day (*Ep.* 46, 9). In the Holy Land the list was still longer: the natives were ready to show everything for which the foreigners inquired, and the pilgrim was eager to credit everything. In her expedition to the East, Paula, the friend of Jerome, visited, among other places, Sarepta and Caesarea. In the first-named place she was shown the tower of Elijah; in the second, the house of Cornelius, that of Philip, and finally the grave of the four virgins. At Bethlehem she saw, in addition to the church of the Nativity, the grave of Rachel; at Hebron the hut of Sarah, in which the swaddling clothes of Isaac and the remains of Abraham's oak were on view (*Hieron. Ep.* 108).

In the West.—While pilgrim-resorts were thus filling the East, their counterparts began to emerge in the West. And here the starting-point is to be found in the veneration of martyrs. Care for the tombs of martyrs was sanctioned by immemorial custom of the Church; but, in this case also, a later age failed to preserve

the primitive conception in its purity; and Augustine himself was obliged to defend the usage of the Church from the imputation that it implied a transference of heathen ceremonial to the sphere of Christianity (*Contr. Faust.* xx. 21). The martyrs were the local heroes of particular communities; but there were men whose life and death were of significance for the whole of Christendom—the apostles. Of these Peter and Paul had suffered martyrdom in Rome, and it was inevitable, from the nature of the case, that their graves should soon become a resort, not only of Romans born, but of strangers also. The Roman cemeteries were visited by numerous pilgrims even in the 3rd century: for the earliest *graffiti* in the papal crypt of the Coemeterium Callisti must date from this period (*De Rossi, Roma sotter.* i. 253 sqq.; *Kraus, Rom. Sott.* 148 sqq.).

Pilgrims were drawn to the graves of the saints convinced that there divine succour was certain; hence came the belief in a never-ending series of miracles there performed. Doubt was unknown. St. Augustine observes that, though Africa was full of martyrs' tombs, no miracle had been wrought at them so far as his knowledge extended. This, however, did not lead him to doubt the truth of those reported by others—a fact that is somewhat surprising when we reflect that the phenomenon caused him much disquiet and perplexity. Who, he asks, can fathom the design of God in ordaining that this should happen at one place and not at another? And eventually he acquiesces in the conclusion that God, who gives every man his individual gift at pleasure, has not willed that the same powers should have efficacy at every sepulchre of the saints (*Ep.* 78, 3).

THE PILGRIMAGE IN THE MIDDLE AGES

The mediaeval Church adopted the custom of the pilgrimage from the ancient Church. The young Germanic and Romance nations did precisely as the Greek and Romans had done before them, and the motives of these devotional journeys—now much more difficult of execution in the general decay of the great world-system of commerce—remained much the same. They were undertaken to the honour of God, for purposes of prayer, or in quest of assistance, especially health. But the old causes were reinforced by others of at least equal potency. The mediaeval Church was even more profoundly convinced than its predecessor that the miraculous power of Deity attached to the bodies of saints and their relics. But the younger nations—French, English and German—were scantily endowed with saints; while, on the other hand, the belief obtained that the home-countries of Christianity, especially Rome and Jerusalem, possessed an inexhaustible supply of these sanctified bodies.

Pilgrimages were consequently undertaken with the intention of securing relics. At first it was enough to acquire some object which had enjoyed at least a mere connection with the hallowed corpse. One enthusiast took a little wax dropped from the taper; another, a portion of the dust which lay on the grave; a third, a thread from the cloth covering the sarcophagus; still another plucked the flowers which visitors had planted above the tomb. Before long, however, these humble trophies failed to content the pilgrims, and they began to devote their efforts to acquiring the actual bodies, or portions of them—frequently by honest means, still oftener by trickery. One of the most attractive works of early mediaevalism—Einhard's little book, *Translatio Marcellini et Petri*—gives a vivid description of the methods by which the bodies of the two saints were acquired and transported from Rome to Seligenstadt on the Main.

Far more important consequences, however, resulted from the fact that the mediaeval mind associated the pilgrimage with the forgiveness of sins. This conception of the pilgrimage, as a means of expiation or a source of pardon for wrong, was foreign to the ancient Church. It is quite in accordance with the keener consciousness of sin, which prevailed in the middle ages, that the expiatory pilgrimage took its place side by side with the pilgrimage to the glory of God. The pilgrimage became an act of obedience; and, in the books of penance (*Poenitentialia*) which date from the early middle ages, it is enjoined as an expiation for many of the more serious sins, especially murder or the less venial forms of

unchastity. The place to be visited was not specified; but the pilgrim, who was bound by an open letter of his bishop to disclose himself as a penitent, lay under the obligation, wherever he went, to repair to the churches and—more especially—the tombs of the saints, and there offer his prayers. On occasion, a chain or ring was fastened about his body, that his condition might be obvious to all; and soon all manner of fables gained currency: how, here or there, the iron had sprung apart by a miracle, in token that the sinner was thereby absolved by God.

As the system of indulgences (*q.v.*) developed, a new motive came to the fore which rapidly overshadowed all others: pilgrimages were now undertaken to some sacred spot, simply in order to obtain the indulgence which was vested in the respective church or chapel. In the 11th century the indulgence consisted in a remission of part of the penance imposed in the confessional, in return for the discharge of some obligation voluntarily assumed by the penitent. Among these obligations, a visit to a particular church, and the bestowal of pious gifts upon it, held a prominent place; and during the whole period of mediaevalism, the number of pilgrims was perpetually on the increase.

The Pilgrim Resorts.—The most important places of resort both for voluntary and involuntary pilgrimages, were still Palestine and Rome. On the analogy of the old *Itineraria*, the abbot Adamnan of Iona (d. 704) now composed his monograph *De locis sanctis*, which served as the basis of a similar book by the Venerable Bede (d. 735). His authority was a Frankish bishop named Arculf, who resided for nine months as a pilgrim in Jerusalem, and visited the remaining holy sites of Palestine in addition to Alexandria and Constantinople. Of the later itineraries the *Descriptio terrae sanctae*, by the Dominican Burchardus de Monte Sion, enjoyed the widest vogue. This was written between the years 1285 and 1295; but books of travel in the modern tongues had already begun to make their appearance. The initiative was taken by the French in the 12th and 13th centuries, and the Germans followed in the 14th and 15th; while the *Book of Wayes to Jerusalem* of John de Maundeville (*c.* 1336) attained extreme popularity, and was translated into almost all the vernacular languages.

As a result of this steady increase in the number of pilgrims, the old arrangements for their accommodation were found deficient. Consequently hospices arose which were designed exclusively for the pilgrim. Those on the Alpine passes are common knowledge. The oldest, that on the Septimer pass, dates from the Carolingian period, though it was restored in 1120 by the bishop Wido of Chur: that on the Great St. Bernard was founded in the 10th century, and reorganized in the 13th. To this century may also be assigned the hospice on the Simplon; to the 14th those on the St. Gothard and the Lukmanier. Similarly, the Mediterranean towns, and Jerusalem in particular, had their pilgrim-refuges. Service in the hospices was regularly performed by the hospital-fraternities—that is to say, by lay associations working under the authorization of the Church. The most important of these was the fraternity of the *Hospitale hierosolymitanum*, founded between 1065 and 1075; for hence arose the order of St. John, the earliest of the orders of knighthood (*See* ST. JOHN OF JERUSALEM, KNIGHTS OF.) In addition to the hospital of Jerusalem, numerous others were under its charge in Acre, Cyprus, Rhodes, Malta, etc. Associations were formed to assist pilgrims bound for the East; one being the *Confrérie des pèlerins de Terre-Sainte* in Paris, founded in 1321 by Louis de Bourbon, count of Clermont (afterwards first duke of Bourbon).

But since, in the middle ages, the Holy Land was no longer held by a Christian Power, the protection of the pilgrims was no less necessary than their sustenance. This fact, after the close of the 11th century, led to the Crusades (*q.v.*), which in many respects are to be regarded as armed pilgrimages. For the old dream of the pilgrim, to view the country where God had walked as man, lived on in the Crusades—a fact which is demonstrated by the letters of Bernard of Clairvaux, with the songs of Walther von der Vogelweide and other Crusaders. And, since the strongest motive in the pilgrimage was the acquisition of indulgences, unnumbered thousands were moved to assume the Cross, when, in

1095, Urban II. promised them plenary indulgence. The conquest of Jerusalem, and the erection of a Christian empire in Palestine, naturally swelled the influx of pilgrims. And though in 1187 the Holy City again fell into the hands of the infidel, while in 1291 the loss of Acre eliminated the last Christian possession in Palestine, the pilgrimages still proceeded. It was not till the Reformation, the wars of the 16th century, and the loss of Rhodes, Candia and Cyprus to the Turks, that any appreciable alteration was effected. When Ignatius de Loyola (*q.v.*) set sail in 1523 from Venice to Palestine, only some thirteen souls could be mustered on the pilgrim-ship, while eight or nine others sailed with the Venetian state-vessel as far as Cyprus. A considerable number had abandoned their pilgrimage and returned home on the news of the fall of Rhodes.

For pilgrimage overseas, as it was styled, the permission of the Church was still requisite. The pilgrims made their journey in grey cowls fastened by a broad belt. On the cowl they wore a red cross; and a broad-brimmed hat, a staff, sack and gourd completed their equipment. During their travels the beard was allowed to grow, and they prepared for departure by confession and communion. Of their hymns many are yet extant ("Jerusalem mirabilis." "In gottes namen faren wir," etc.). Ships belonging to the knights of St. John and the Knights Templars conducted the commerce with Palestine, and the pilgrims formed themselves into unions, elected a "master" and concluded their agreements, as to the outward voyage and return, in common. The expenses of the journey to Palestine were no light matter. In the 12th century they may be estimated at 100 marks of silver (£200) for the ordinary pilgrim. The expenses of the princes and lords were, of course, much heavier. Duke William of Saxony, who was in Jerusalem in 1461, spent no less than £10,000 on his journey. (*See* Prutz, *Kulturgeschichte der Kreuzzüge*, pp. 106 sqq.; Rohricht, *Deutsche Pilgerreisen*, p. 42.)

Great as was the number of pilgrims oversea, it was yet far exceeded by that of the visitants to the "threshold of the apostles," *i.e.*, Rome, which received their greatest impetus through the inauguration of the so-called Year of Jubilee.

Of the other pilgrim-resorts, we shall only emphasize the most important. Priority of mention is due to St. James of Compostela (Santiago, in the Spanish province of Galicia). Here the attraction for the pilgrim was the supposed possession of the body of James the son of Zebedee. The first connection of the apostle with Spain is to be traced in the *Poema de aris b. Mar. et xii. apost. dedic.*, which is ascribed to Aldhelm (d. 709) and contains a story of his preaching in that country. The earliest account of the transference of his relics to the Peninsula is found in Notker Balbulus (d. 912, *Martyrol. in Jul. xxv.*). But in Spain belief in this cherished possession was universal; and, step by step, the theory won credence throughout the West. In England, indeed, the shrine of St. James of Compostela became practically the most favoured devotional resort; and in the 12th century its visitation had attained such popularity that a pilgrimage thither was ranked on a level with one to Rome or Jerusalem. In France St. Martin remained the chief goal of the pilgrim; while Notre Dame de Sous-Terre in Chartres (with a portrait of the "black Virgin"), Le Puy-en-Velay (dep. Haute Loire), and others, also enjoyed considerable celebrity. In England pilgrimages were made to the tomb of the murdered archbishop, Thomas à Becket, in Canterbury Cathedral. The setting of Chaucer's *Canterbury Tales* gives a vivid idea of the motley company of pilgrims; but it seems probable that Germany also sent a contingent. In addition, Walsingham, Peterborough, St. Davids, Holywell, and St. Andrews in Scotland were much frequented. In lower Germany, Cologne and Aix-la-Chapelle, in Switzerland Einsiedeln, were the principal resorts.

In Italy the church of the Archangel on Mt. Gargano was one of the most ancient centres of the pilgrimage. Later the Portiuncula church at Assisi displaced all other resorts, with the exception of Rome; but in the 17th century it was overshadowed in turn by the "Holy House" at Loretto on the Adriatic. According to an extravagant legend, the house of Joseph and Mary in Nazareth was transported by angels, on the night of the 9th-10th of May

1291 to Dalmatia, then brought to the Italian coast opposite (Dec. 10, 1294), till, on the 7th of September 1295 it found rest on its present site. The pilgrimage thither must have attained great importance as early as the 15th century; for the popes of the Renaissance found themselves constrained to erect an imposing pilgrim church above the "Holy House."

The significance of the pilgrimage for the religious life of later mediaevalism cannot be adequately estimated. The possession of any extraordinary relic was everywhere considered a sufficient claim for the privileges of indulgences; and wherever this privilege existed, there the pilgrims were gathered together. All these pilgrimages, great and small, were approved and encouraged by the Church. And yet, during the whole of the middle ages, the voice of suspicion in their regard was never entirely stilled. Earnest men could not disguise from themselves the moral dangers almost inevitably consequent upon them; they recognized, moreover, that many pilgrims were actuated by extremely dubious motives; and they distrusted the exaggerated values set on outward works. The Roman papacy had no more zealous adherent than Boniface; yet he absolutely rejected the idea that Englishwomen should make the journey to Rome, and would willingly have seen the princes and bishops veto these pilgrimages altogether (Ep. 78). The theologians who surrounded Charlemagne held similar views.

When the abbess Ethelburga of Fladbury (Worcestershire) found her projected pilgrimage impracticable, Alcuin wrote to her, saying that it was no great loss, and that God had better designs for her: "Expend the sum thou hast gathered for the journey on the support of the poor; and if thou givest as thou canst, thou shalt reap as thou wilt" (Ep. 300). Bishop Theodulf of Orleans (d. 821) made an energetic protest against the delusion that to go to Rome availed more than to live an upright life (Carm. 67). To the same effect, the synod of Chalons-sur-Saône (813) reprobated the superstition which was wedded to the pilgrimage (c. 13); and it would be easy to collect similar judgments, delivered in every centre of mediaevalism. But, fundamentally, pilgrimages in themselves were rejected by a mere handful: the protest was not against the thing, but against its excrescences.

The Modern Pilgrimage.—The Reformation eradicated the belief in the religious value of visits to a particular locality. It is only pious memory that draws the Protestant to the sites consecrated by ecclesiastical history. On the other hand, while in the Eastern Church things have undergone little change the developments in the Roman Church show important divergences. The Year of Jubilee, in 1525, was unprecedented in its scant attendance, but the jubilees of 1575 and 1600 again saw great armies of pilgrims marching to Rome (see JUBILEE YEAR). Fresh pilgrim resorts sprang up; mediaeval shrines, which had fallen on evil days, emerged from obscurity. The 19th century led to an extraordinary revival of the pilgrimage. Not only did new resorts spring into existence—e.g., La Salette in Dauphiné (1846), and more particularly Lourdes (1858) in the department of Hautes Pyrénées—but the numbers once more attained a height which enables them to compete with the mediaeval figures. The dedication of the church of Lourdes, in 1876, took place in the presence of 30 bishops, 3,000 priests and 100,000 pilgrims. No new motives for the pilgrimage emerged in the 19th century, unless the ever-increasing cultus of the Virgin Mary may be classed as such, all of the new devotional sites being dedicated to the Virgin. For the rest, the desire of acquiring indulgences maintains its influence: but doubting voices are no more heard within the pale of the Roman Catholic Church.

PILGRIM FATHERS. In American history "Pilgrims" is applied to the earliest settlers of the colony of Plymouth, Mass., and its more specific application is to the first emigrants, who sailed in the "Mayflower" in 1620. They were from the beginning Separatists from the Church of England; they had established Independent (Congregational) churches at Scrooby and Gainsborough early in the 17th century, and some of them had fled to Amsterdam in 1608 to avoid persecution, and had removed to Leyden in the following year. They sailed from Delftshaven late in July 1620, from Southampton on Aug. 5, from Plymouth on Sept. 6 and late in Dec. 1620 founded the colony of Plymouth, Massachusetts. (See MASSACHUSETTS; PLYMOUTH and MAYFLOWER.)

PILGRIMS' WAY, THE. From Winchester, in Hampshire, England, to Canterbury, in Kent, runs a road or way which can still be traced, now on the present made roads, now as a lane, bridle path, or cart track, now only by a line of ancient yews, hollies or oaks which once bordered it. To this old track the name of Pilgrims' Way has been given, for along it passed the stream of pilgrims coming through Winchester from the south and west of England and from the continent of Europe by way of Southampton to Canterbury Cathedral to view the place of the martyrdom of Thomas Becket, in the north transept, the relics in the crypt where he was first buried after his murder, in 1170, and the shrine in the Trinity Chapel which rose above his tomb after the translation of the body in 1220. There were two festivals for the pilgrimage, on the 29th of December, the day of the martyrdom, and on the 7th of July, the day of the translation. The summer pilgrimage naturally became the most popular. In 1538 the shrine was destroyed and the relics of the saint scattered, but the great days of the pilgrimage had then passed. Erasmus gives a vivid picture of the glories of the shrine and of all that the pilgrims saw on his visit with Colet to Canterbury in 1514.

This road, although its name of the Pilgrims' Way has for long confined it to the road by which the pilgrims came to Canterbury from Winchester, follows a far older track. Right back into British and even older times the main direction which commerce and travellers followed across southern and western England to the Straits of Dover and the Continent lay from Canterbury along the southern chalk slope of the North Downs to near Guildford, then by the Hog's Back to Farnham. At this point the oldest track went across Salisbury Plain towards Stonehenge and so on to Corwall. From Farnham westward the only portion of this, the oldest track that can now be traced, is a small portion that still bears the name of the Harrow (*i.e.*, hoary, old) road. It was in early times abandoned for the road from Winchester to which the stream of travel and commerce from the Continent and the south and south-west of England was diverted.

The ancient road has been traced fully in Mrs. Ady's book *The Pilgrims' Way* (1893), and the older track in the fullest detail in Hilaire Belloc's *The Old Road* (1904).

PILKINGTON, FRANCIS (d. 1638), English madrigal composer, the details of whose early life are obscure, took his Mus.B. at Lincoln college, Oxford. He was attached to Chester cathedral about 1604, and a few years later was ordained. His chief works include a book containing 21 vocal pieces and a pavin for the lute and bass viol (1605), *The First Set of Madrigals and Pastorals* (1614), and *The Second Set of Madrigals and Pastorals* (1624).

PILLAU, a seaport and watering-place in the Prussian province of East Prussia, on the spit of sand (*Nehrung*) which separates the Frische Haff from the Baltic, on the north of the entrance channel, and 29 m. by rail from Königsberg. Pop. (1933) 7,092. Pillau is the place where Gustavus Adolphus of Sweden landed in 1626. It did not obtain civic privileges until 1725, but was fortified shortly after that date. It has a harbour, which serves as the outer port of Königsberg, and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900–1901 constructed across the Frisches Haff from Pillau to Königsberg. Pillau has a school of navigation, and is a well-known pilot station. Ship-building and fishing are carried on.

PILLNITZ, a German village in the *Land* of Saxony, on the right bank of the Elbe, 5 m. above Dresden. Pop. (1933)

1,231. The new palace was built in 1818 on the site of a building which was burnt. The place became a residence of the electors of Saxony about 1700. By the convention of Pillnitz in August 1791 the emperor Leopold II. and Frederick William II., king of Prussia, agreed to take common action against any attack on the part of France.

PILORY, an instrument of punishment which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame (as are the feet in the stocks) so as to be held fast, exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle, which secured the heads and hands of several persons at the same time, but it was commonly capable of holding only one.

In the statutes of Edward I. it is enacted that every pillory or "stretch-neck" should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially, and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. By the "Statute of the Pillory" (1266) the pillory was made the penalty for many small offences. In 1637 an attack was made on the Press, and the pillory became the recognized punishment of those who published books without a licence or libelled the Government. In 1816 the pillory was abolished except for perjury and subornation, and the perjurer Peter James Bossy was the last to stand in the pillory, at the Old Bailey for one hour on June 22, 1830. It was finally abolished in 1837 at the end of William IV.'s reign. In France the pillory, called *carcan*, was employed till 1832. In Germany it was known as *pranger*. The pillory was used in the American colonies, and provisions as to its infliction existed in the United States statute books until 1839; it survived in the State of Delaware until 1905. (See STOCKS.)

PILNYAK (1894–), Russian novelist. Boris Andreevich Vogau, who later took the pen name of Pilnyak, was born on Sept. 29, 1894 in Mojaisk, Moscow province. His childhood and early youth were spent on the Volga and among the peasants and the land administration "intellectuals." He studied economics at the Moscow commercial institute and began publishing stories in 1915. During the Bolshevik revolution Pilnyak lived in Moscow and also travelled through Russia studying the new conditions. In 1923 he visited England and Germany. His works deal with the first chaotic stage of transition from the old Tsarist Russia to the "new world" of the Soviet Republic. He is the most prominent figure in post-revolutionary fiction. His sympathies are with the peasants as opposed to the town and his stories are deliberately fragmentary and read like diaries and chronicles. His *Tales of the Wilderness* was translated by F. O'Dempsey (1924).

PILOCARPINE. This alkaloid (see ALKALOIDS) is a colourless oil which occurs in *jaborandi* leaves along with isopilocarpine and the related alkaloid, pilosine, $C_{16}H_{16}O_8N_2$ (Pyman, 1912). Pilocarpine, $C_{11}H_{16}O_8N_2$, was isolated independently by Hardy and by Gerrard in 1875. It boils at 260° C under 5mm. pressure, is freely soluble in water, alcohol, or chloroform, but not in ether or petroleum, and is dextro-rotary in solution. The salts crystallize well; the nitrate, which melts at 178° C, and the hydrochloride, whose melting point is 204–205° C, being those used in medicine. On evidence provided mainly by Jowett in England and Pinner in Germany a generally accepted constitutional formula for pilocarpine and isopilocarpine, which are regarded as stereoisomerides, has been put forward.

PILONA, a town of northern Spain on the Infiesto-Oviedo railway in the province of Oviedo; between the right bank of the river Pilofia, a left-hand tributary of the Sella, and the Sierra de Abes (3,268 ft.). Pop. (1930) 17,533. Pilofia is a densely populated mining and agricultural district.

PILOTAGE, as it is now understood, may be described as the art of conducting a vessel in or out of harbour, or in the neighbourhood of navigational dangers. The word "pilot" was formerly used to designate the steersman and later the sailing

master; in fact, the art of piloting was divided into two parts: proper piloting, identical with what we now term navigating (see NAVIGATION), and common piloting, identical with the meaning of the word as given above. See PILOTAGE LAWS.

PILOTAGE LAWS. The present general British pilotage laws are contained in the Pilotage Act, 1913, which Act consolidated and amended the laws of pilotage as they existed under the Merchant Shipping Act, 1894. On the passing of the former Act, the Board of Trade, as the central authority, held enquiries, with the result that pilotage orders were made by it in respect of each District. Each pilotage order defines the limits of the district, names the pilotage authority therefor, states whether pilotage is compulsory or not therein, and empowers the authority to delegate any of its powers or duties to a pilotage committee, on which may sit representatives of both pilots and shipowners. The pilotage authority makes the necessary by-laws for the regulation of pilotage and pilots in its district, but these do not take effect until they are confirmed by the Board of Trade.

The principal pilotage authority is the Corporation of Trinity House, London, exercising jurisdiction in the London district, which extends from Orfordness to Selsea Bill; and in 38 other districts round the coasts of England and Wales. There are, however, about 60 other districts within which other pilotage authorities have jurisdiction.

Compulsory Pilotage. — A ship, whilst navigating in a district in which pilotage is compulsory, for the purpose of entering, leaving or making use of any port in that district, is required to be either under the pilotage of a licensed pilot of the district, or under the pilotage of a master or mate possessing a pilotage certificate for the district, who is bona fide acting as master or mate of the ship. A ship carrying passengers (other than an excepted ship) is, however, compelled to be under pilotage irrespective of whether the district in which she is navigating is a compulsory one or not. Under the Aliens Restriction (Amendment) Act, 1919, pilotage certificates cannot be granted to aliens, except to masters or mates of French nationality trading to the ports of Newhaven or Grimsby.

The following ships are excepted from compulsory pilotage: (1) Ships belonging to His Majesty. (2) Pleasure yachts. (3) Fishing vessels. (4) Ferry boats. (5) Ships of less than 50 tons' gross tonnage. (6) Ships exempted by by-law. (7) Tugs, dredgers, sludge vessels, barges and other similar craft belonging to or hired by a dock, harbour or river authority. (8) Ships calling at a port in a pilotage district for the sole purpose of taking on board or landing a pilot belonging to some other pilotage district.

The Board of Trade has the power, on the representation of parties interested, to revoke or vary any by-laws in a pilotage district, or require the pilotage authority to make by-laws. The licensing of a pilot by a pilotage authority does not involve any liability on the part of the authority for any loss occasioned by any act or default of the pilot.

Pilot Boats. — All pilot boats regularly employed in any district must be approved and licensed by the pilotage authority for that district, who may appoint or remove the masters thereof. Every pilot boat must be distinguished by the name of her owner and port on her stern, and her number on each bow, and the hull of the boat is usually painted black. When afloat the pilot boat must fly a red and white horizontal flag, known as a pilot flag, in a conspicuous position. A pilot flag must also be displayed by a vessel having on board a licensed pilot for the district, or a master or mate holding a pilotage certificate. The master of a ship subject to pilotage in a district must, under a penalty, display a pilot signal and keep it displayed until a licensed pilot comes on board, and if the master accepts the services of a pilot he must give him facilities for getting on board.

The following persons are liable to pay pilotage dues for any ship for which the services of a licensed pilot have been obtained, viz.: (a) the owner or master, or (b) the consignees or agents who have paid or are liable to pay any other charges on account of the ship, and these dues may be recovered in the same manner as fines under the Merchant Shipping Act, 1894. The pilotage dues on foreign ships, subject to compulsory pilotage, trading to and from

the port of London, have to be paid to the chief officer of customs and excise in that port, and such a ship may be detained until such dues are paid. It is an offence, punishable by a fine, if a licensed pilot demands or receives, and a master offers or pays, dues in respect of pilotage services at any other rates, whether greater or less, than those which are fixed by by-law.

Under section 633 of the Merchant Shipping Act, 1894, the owner or master of a ship was not answerable to any person for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of that ship within any district where the employment of a qualified pilot was compulsory by law. Section 15 of the Pilotage Act, 1913, however, reversed this defence of compulsory pilotage, and enacted that the owner or master of a vessel navigating under circumstances in which pilotage is compulsory is answerable for any loss or damage caused by that vessel, or by any fault of her navigation, in the same manner as he would if pilotage were not compulsory. Section 15 of the Pilotage Act, 1913, did not, however, come into effect until Jan. 1, 1918, on which date section 633 of the 1894 Act was repealed. The difference which formerly existed under the Merchant Shipping Act, 1894, between British law and the law of most foreign countries as to the civil liability of the owner or master of a vessel employing a pilot under compulsion of law has therefore been removed since Jan. 1, 1918.

See *The Pilotage Act, 1913*; *Report of Departmental Committee on Pilotage 1911*; Digby & Cole, *Pilotage Law* (1913). (W. J. T. H.)

UNITED STATES

The power of administering all matters relating to pilotage was acquired by the Federal Government as incidental to the authority conferred on it under the Constitution. The first legislative action of the new Government was in 1789, when it delegated its authority to the several States "until further provision is made by Congress." Further legislation enacted subsequently has restricted the broad powers conferred in 1789, but the power of the Federal Government is exclusive only when it is exercised. State laws regarding pilotage are operative so long as they are not in conflict with Federal laws.

Among the acts of the Federal Government restricting the manner in which the several States may control pilotage are: laws which apply to pilotage on waters that are boundaries between States, permitting the master of a vessel to employ a pilot licensed by either State to pilot the vessel to or from such port; laws which prohibit discrimination in rates or pilotage as between vessels operating solely between ports in the State and those engaged in interstate traffic; laws which provide that all coastwise seagoing steamships shall be under the control and direction of pilots licensed under Federal authority; and laws which prohibit State pilots from levying pilotage on coastwise seagoing steamships.

Number and Appointment of Pilots.—In many States no maximum or minimum restriction is placed by statute on the number of pilots that may be appointed, the number being left to the discretion of the several pilotage authorities. In some cases both a maximum and minimum number are prescribed by law and in other States only a maximum number is mentioned. As a rule pilots are licensed by the local pilotage authority, but in several States they are appointed by the governor. In a majority of the States, pilots are licensed for life and lose their licences only because of negligence, incapacity, misconduct or infirmity. In the remaining States licences are granted for periods of one to four years and are renewable. Several grades of licences are generally issued, the grade varying with the draft of vessel which the holder of the licence is considered competent to conduct.

Qualification of Pilots.—In all States the primary qualification for appointment as pilot is actual experience in piloting vessels. A number of States require that applicants for licences as pilots must have served an apprenticeship of a specified number of years on boats of the pilots' association, either in accordance with the law of the State or by regulation of competent authority.

Authority.—In the United States, a pilot occupies the status of an officer of the ship when on board in the exercise of his duty,

and his orders as such must be obeyed by the crew. When the master is on board, the orders of the pilot are considered to be those of the master's. The pilot is subject to the master in the matter of discipline but is not liable to any ship's duty except that of pilot. Once in charge of a vessel at sea, it is the duty of the pilot to stay by the ship until she reaches her destination or some place of safety, unless he is earlier discharged.

Liability of Pilots.—Pilots are generally required to give bond, usually \$500, to secure the faithful performance of their duties and for the payment of all damages that may accrue from their negligence, unskillfulness or unfaithfulness. The bond is not required in some States, the amount is not specified in the laws of others and in still others it is fixed. The courts have held that while a pilot is responsible to the owner of a vessel for negligence or default in the performance of this duty, he is not liable for the vessel's loss when he has used his best skill and judgment, although the result shows that his best judgment was wrong.

Compulsory Pilotage.—Pilotage is generally compulsory upon certain vessels, or classes of vessels, approaching or departing from a harbour. Throughout the States, all public vessels of the United States and all steamships engaged in the coasting trade are exempt from compulsory pilotage. In respect to other vessels or classes of vessels there is wide variation in the laws of the several States. In the great majority of States compulsory pilotage is prescribed for all vessels, both of domestic and foreign registry, engaged in foreign trade, but not for any class of vessel in the domestic trade. In general the rule is that there has been a tender of the services of a pilot if there has been displayed the customary pilot signal on the usual cruising ground of pilot boats at sea, and there is a visible approach of the boat towards the incoming vessel. If the offer of pilot service is refused, the pilot becomes entitled to full fees or half pilotage, according to the local State law, and the liability for payment is enforceable in admiralty.

Compensation.—In general, pilotage fees are fixed by statute, based on the draught of the vessel. In some cases the rates are prescribed by the local pilotage authorities and the net tonnage of the ship is a factor in determining the pilotage charges. In a number of States where pilotage is compulsory, the full rate is not charged if the services of a pilot are refused. The various statutes commonly provide that pilotage fees are to be paid by and are recoverable from the master or owners of the vessel. In addition to fees for the actual work of pilotage, the statutes of practically every State permit certain extra charges to be made to cover loss of time occasioned by detention of vessel in quarantine or by carrying the pilot to sea when the pilot boat was ready to take him off.

Pilot Boats.—The days when a large number of sailing vessels were in the pilot service off the principal ports, each vessel owned and operated independently, have given way. In 1929 at practically every large port in the United States all of the licensed pilots belong to an association, owning and operating one or more specially constructed steamers which are maintained on the pilotage grounds, usually at the bar. These grounds are well known to mariners, who may safely count on finding there at practically all times a pilot boat displaying the Union Jack, with a sufficient number of pilots aboard to accommodate any reasonable number of vessels seeking to enter the port.

BIBLIOGRAPHY.—For legislation on pilotage in the United States, see the Revised Statutes and the Statutes at Large of the United States, and the statutes of the several States in which pilot service is maintained, particularly Title 46, U.S. Code; Laws of 1909, New York, Ch. 42, Sec. 56; Revised Laws of Mass., 1902, as amended; Civil Code of 1906, California, Sec. 2036. (C. M. A.)

PILOT-FISH (*Naucrates ductor*), a pelagic fish of the family of horse-mackerels or *Carangidae*, well known to sailors from its habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and subtropical seas, and is common in the Mediterranean. In summer pilot-fish accompany ships into port as far north as the south coast of England. It accompanies both ships and sharks on account of the supply of food which it derives from them, as does the remora (*q.v.*). All observers, however, agree that neither the

pilot-fish nor the sucking-fish is ever attacked by the shark. The pilot attains to a length of about 12 in. A sharp keel runs along the middle of each side of the tail. The teeth are small, arranged in bands. On a bluish ground-colour, five to seven dark-blue or violet cross-bands traverse the body from back to belly. The pilot-fish spawns in the open sea.

PILOTY, KARL VON (1826-1886), German painter, born at Munich, on Oct. 1, 1826, was the son of Ferdinand Piloty (d. 1844), noted as a lithographer. His picture of "Seni at the Dead Body of Wallenstein" (1855) soon gained for the young painter the membership of the Munich Academy, where he succeeded Schorn (his brother-in-law) as professor. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany. He was a successful teacher, and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max and Griitzner. He died at Munich on July 21, 1886.

PILSEN or **PLZEN**, the second town of Bohemia at the confluence of the Radbuza and Mze in a fertile and productive fruit and cereal basin. The vicinity is rich in coal and iron. The staple product is beer, exported to all parts of the world, which is closely followed by iron and steel goods and machinery, mainly from the Skoda factory; spirits, leather goods, paper and earthenware are also produced in large quantities. The town is the trade and transport centre for the whole of southwest Bohemia and its cereal and cattle markets are famous. It was occupied by Germany in March 1939.

Little is known of Pilsen till the 10th century and it did not become a town till 1272 but since then it has figured largely in Bohemian history and was a centre of Catholic resistance during the Hussite wars. Among its sights are the 13th century Gothic church with a tower 325 ft. high and a 16th century Renaissance town hall. Pop. (1930) 114,150.

PILSUDSKI, JOSEPH (1867-1935), Polish soldier and statesman, was born in Nov. 1867 in Zulow (Zulowo), County of Wilna (Wilno) of an ancient family tracing their origin from the Lithuanian Princes of Ginet, and educated at Wilno and Kharkov.

In 1887 Pilsudski was involved in an anti-Tsarist plot and sentenced to five years' penal servitude in Eastern Siberia, although the trial clearly established his innocence and his deprecation of terrorist methods. He returned to Wilno in 1892 and formed the Polish Socialist party (P.P.S.). In 1894 he began the *Robotnik* (The Workman), a secret paper of radical tendencies, edited, printed and distributed by Pilsudski himself. He was already a force. His courage, keen sense of humour, attractive personality and good breeding made him the idol of the working classes; he was revered by the intelligentsia for the tenacity of his convictions, for his fearlessness and his iron will.

His activities increased rapidly. Armed resistance against atrocities of the Russian government was introduced into the party programme. Armed detachments of workmen protected meetings and demonstrations against the police and military, and bloodshed became frequent. In 1900 Pilsudski and his wife, Marie Tuskiewicz, whom he had married in 1894, were arrested in the offices of the *Robotnik* in Lódz and for a year he was kept in a special cell in the notorious "Tenth Pavilion" of the Warsaw Citadel. Simulating insanity, Pilsudski was transferred to the St. Nicholas Hospital in St. Petersburg, where his friends rescued him by an ingenious plot on May 13, 1901. He lived in London for some time following his escape from imprisonment and returned to Cracow in 1902.

During the Russo-Japanese war Pilsudski planned an insurrection. Frustrated through lack of munitions, he visited Japan to enlist her support, but again proved unsuccessful. After the Russian revolution of 1905 and the convocation of the Duma Polish revolutionary activities were discontinued, but the Russian Constitutional government continued the policy of its predecessors with regard to Poland. Pilsudski transferred his headquarters to Cracow and Lwow and commenced his activities

amongst the refugees from the Russian provinces of the country. Here the idea of a "private Polish army" was conceived. An officers' school was established in Lwow and branches of the "sharpshooters" (Strzelec) formed throughout Galicia. Foreseeing the World War, Pilsudski hoped for a German and Austrian victory over Russia and a French victory over Germany. When war broke out, he consequently sided with Austria. The total strength of his "army" was 3,000 infantry and a squadron of cavalry insufficiently armed and equipped; the remaining 7,000 of his men were despatched to Hungary by the Austrian general command. His brigade took part in numerous battles in which it exhibited great bravery and exemplary discipline, while Pilsudski himself displayed the highest qualities as a leader. He refused, however, to let his legions be used outside of Polish territory. On the collapse of Russia, he turned against Germany and Austria. In July 1916 he resigned the command of the Polish legions in consequence of the abuses of the German and Austrian occupation authorities in Polish territory. At the same time he sought to establish relations with France and Great Britain through his colleagues, MM. Sokolnicki and Narutowicz. On Nov. 5, 1916, the independence of Poland was proclaimed by the Central Powers and Pilsudski accepted the position of Minister of War in the newly formed Council of State. Within a short time he formed the semi-secret Polish military organization, *i.e.*, *Polska Organizacja Wojskowa* ("P.O.W."), which spread throughout the country and helped to disarm Germans and Austrians in 1918.

When the Polish legions in Russia, commanded by Gen. Musnicki, proclaimed Pilsudski their spiritual leader, and when his own legions refused, in July 1917, to take the oath of "fraternity of arms with Germany and Austria," Pilsudski was arrested by the Germans and imprisoned with his chief-of-staff Gen. Sosnowski in the fortress of Magdeburg, whence he was released in 1918 by the German revolutionary authorities. He arrived in Warsaw on Nov. 10 and completed the disarmament of the armies of occupation. The Regency Council, established by the Germans, resigned in his favour and all military organizations in the country submitted to his command. He was vested with dictatorial powers, and elected unanimously chief of State, while the army conferred on him the supreme honour of first marshal of Poland.

For Pilsudski's activities during the next years, *see* POLAND. His own chief interest was centred in the army, with which he was very popular, and at the head of which he undertook the campaigns of 1920 in the Ukraine and against the Russian advance on Warsaw. He had, however, many difficulties with other elements in the State and in 1923 he ceased to be chief of State and retired altogether from the army. In May 1926, however, his notorious dislike of the typically-Polish parliamentary wrangling and faction recalled him. He put himself again at the head of the army; a military demonstration on May 12 led to fighting in Warsaw and the resignation of the president. The national assembly, convoked by his successor, M. Rataj, elected Pilsudski president (May 31); but he refused the honour, and became only minister of war, while his friends MM. Mosiecki and Bartel were elected respectively president and premier. Pilsudski immediately carried through legislation greatly strengthening the position of the president against the parliament; but did not dissolve the latter or establish an open dictatorship, although he constantly prorogued it. In September, indeed, he took over the premiership himself; but seldom appeared in the Sejm, even when it was sitting. The elections of March 1928 gave his adherents a majority. Nevertheless Pilsudski, who had been in bad health, resigned the premiership, retaining, however, the ministry of war, chairmanship of the army council and inspectorate-general of the force. This change made little difference to his position in Poland and the vigorous abuse of the Sejm with which he motivated his actions was not actively resented. He was again premier in 1930. For the events of his real, though veiled dictatorship, *see* POLAND. *See also* R. Landau, *Pilsudski and Poland* (1929).

PIMA, a tribe of Indians on Gila and Salt rivers in southern Arizona, closely related to the Papago, who adjoin them on the south, and to the Pima Bajo in Sonora. They practised irrigation

and lived in permanent though rudely built villages. In their territory are the adobe ruins of Casa Grande and miles of prehistoric ditches. They are divided into five patrilineal totemic groups, make fair pottery and excellent basketry. They differ much from the other sedentary and agricultural natives of the south-west, the Pueblos. Consistently friendly to the whites, they long withstood the Apache courageously, fought back the hostile Yuman tribes, and sheltered those that took refuge with them. Estimated at 2,500 in 1775, they numbered 5,100 in 1921. See F. Russell, *Bur. Am. Ethn. Rep.* xxvi. (1908).

The Piman or Sonoran family, now recognized as a division of the larger Uto-Aztecan one, extended from Arizona to Jalisco, Mexico, and included the Pima, Papago, Opata, Tarahumare, Mayo, Yaqui, Tepehuane, Tepecano, Cora, Huichol and other groups. (A. L. K.)

PIMPERNEL (*Anagallis arvensis*), a small herb of the primrose family (Primulaceae), called also shepherd's clock and-poor man's weather-glass, native to Europe and widely naturalized in North America from Newfoundland to the Pacific coast and southward to Mexico. It is a delicate annual with diffusely branching stems, with small, opposite, somewhat clasping, leaves, black-dotted beneath, and scarlet (rarely white) flowers, about $\frac{1}{4}$ in. across, usually with a darker centre, opening only in bright sunshine, whence numerous popular names.

PIN, a small peg or bolt of metal or wood, not necessarily pointed, employed as a fastening to connect together different parts of an article, as a stop to limit the motion of some moving piece in a machine, as a support on which a small wheel may turn, etc., but most commonly a small metal spike, used for fastening portions of fabrics together, having one end pointed and at the other a bulbed head, or some other arrangement for preventing the spike from passing entirely through the cloth or other material with which it is employed. In one form or another pins of this last kind are of the highest antiquity, the earliest form doubtless being a natural thorn. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France, and again in 1543 an act was passed providing that "no person shall put to sale any pinnes but only such as shall be double headed, and have the heads soldered fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanché and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626, in which year the manufacture was introduced into Gloucestershire by John Tilsby. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several pin-making machines were invented in the United States. During the War of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836 when the Howe Manufacturing company was formed at Birmingham, Connecticut. Previous to this an American, Lemuel W. Wright, had in 1824 secured in England a patent for a machine to make solid-headed pins, which established the industry on its present basis.

Modern Pin Machinery.— In a modern pin-making machine wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which enough of the end projects to form a pin-head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slit sufficient-

ly wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting extremities are held against a revolving cutter, by which they are pointed.

Then follows the finishing process, which consists of giving the pins the coating of tin which makes them silvery in appearance. In the case of brass pins, they are scoured, cleaned in argol (bitartrate of potash) and water and then tinned in a vat in a solution of water, oxalic acid and granulated tin mixed with the pins at a temperature of 100°C. Iron pins are tinned by an electrolytic process in an alkaline solution of a tin salt. After being washed and dried the pins are polished by being revolved in a barrel, mixed with dry bran or fine sawdust, from which they are winnowed as finished pins. The sizes of ordinary pins range from the $3\frac{1}{2}$ -in. stout blanket pin down to the finest slender gilt pin used by entomologists, 4,500 of which weigh about an ounce.

PINACEAE: see GYMNOSPERMS.

PINACOTHECA, the Greek name for a picture gallery, apparently reserved in Greece for one that was public, although used by the Romans for a picture gallery in a private house. In modern usage the term usually means the chamber forming the left wing of the Propylaea of the Athenian acropolis, which was used in ancient times as a picture gallery (Pausanias Bk. II., xxii. 6). Various modern public picture galleries bear the same or a similar name, such as those of Bologna and Turin, and at Munich the old and the new Pinakothek.

PINAR DEL RIO, capital of Pinar del Rio Province, Cuba, about 107 m. S.W. by railway from Havana. Pop. (1938), 64,821. The city is in the fertile valley of the Guama. It is the centre of the tobacco industry of the Vuelta Abajo region. Its port is La Coloma, on the southern coast. The pueblo was created after 1773; but the history of the settlement goes back to 1571, and the parochial church dates from 1710.

PINCHBECK. When brass, the familiar alloy of copper and zinc, contains 12% to 15% of the latter metal, its colour simulates that of gold. In 1732, a London clockmaker, Christopher Pinchbeck, introduced a brass containing about 15% of zinc for the manufacture of imitation gold jewellery, and the yellow metal bore his name; hence the use of the term "pinchbeck" for flash or imitation jewellery. (See BRASS.)

PINCHOT, GIFFORD (1865—), American forester and public official, was born at Simbury, Conn., on Aug. 11, 1865. He graduated at Yale in 1889 and afterwards studied at the École Nationale Forestière, Nancy, France, and for briefer periods in Switzerland, Germany and Austria. Upon his return he began the first systematic forestry work in the United States, in the Vanderbilt forest at Biltmore, N.C. In 1896 he was made a member of the National Forest Commission that worked out the plan of U.S. forest reserves, and in 1897 he became confidential forest agent to the secretary of the Interior, to examine and report upon the reserves. In 1898 he was appointed chief of the division, later the bureau of forestry in the Department of Agriculture, which office he held until 1910. During the period of his administration, the entire forest system and administrative machinery of the bureau was built up, and Pinchot's enthusiasm and publicity work did much for the conservation movement in general. He also served as a member of the committee on public lands, 1903, and the Inland Waterways Commission, 1907. In 1908 he became chairman of the National Conservation Commission, and in 1910 president of the National Conservation Association. He founded the Yale School of Forestry at New Haven, as well as the Yale Summer School of Forestry at Milford, Pa., and in 1903 became professor of forestry at Yale. He was appointed State forester of Pennsylvania in 1920 and began a systematic administration of the large and important forest areas of that State. From 1923 to 1927 and from 1931 to 1932 he was governor of Pennsylvania, and in his first term forced a reorganization of the State Government and the establishment of a budget system. He was also able, in 1923, to settle an important anthracite coal strike by arbitration.

Besides many articles in magazines, he has written *The White Pine* (1896); *The Adirondack Spruce* (1898); *A Primer of Forestry* (1899);

The Fight for Conservation (1909); *The Training of a Forester* (1917); *To the South Seas* (1930); *Just Fishing Talk* (1936).

PINCKNEY, CHARLES (1757-1824), American statesman, was born on Oct. 26, 1757 at Charleston, S.C.; he was the son of Charles Pinckney (1731-84), first president of the first South Carolina provincial congress (1775), and a cousin of Charles Cotesworth Pinckney and Thomas Pinckney. He was studying law at the outbreak of the Revolutionary War, served in the early campaigns in the South, and in 1779 was elected to the South Carolina house of representatives. He was captured by the British at the fall of Charleston (1780), and remained a prisoner until the close of hostilities. In 1787 he was a delegate to the Federal constitutional convention, and on the same day (May 29) on which Edmund Randolph (*q.v.*) presented what is known as the Virginia plan, Pinckney presented a draft of a constitution which is known as the Pinckney plan. Although the Randolph resolutions were made the basis on which the new constitution was framed, Pinckney's plan seems to have been much drawn upon. Furthermore, Pinckney appears to have made valuable suggestions regarding phrasing and matters of detail. On Aug. 18, he introduced a series of resolutions, and to him should probably be accredited the authorship of the substance of some 32 or more provisions of the constitution. Pinckney was president of the State convention of 1790 that framed a new constitution for South Carolina, was governor of the State 1789-92, a member of the State house of representatives in 1792-1796, and again governor in 1796-98. From 1799 to 1801 he was a member of the United States Senate. He entered public life as a Federalist, but later became the leader in organizing the Democratic-Republican party in his State, and contributed largely to the success of Thomas Jefferson in the presidential election of 1800. By Jefferson's appointment he was American minister to Spain from 1801 to 1805. In general his mission was a distinct failure, his arrogance and indiscretions finally causing the Spanish government to request his recall. He was again governor of South Carolina in 1806-08, and from 1819 to 1821 was a member of the National House of Representatives, in which he opposed the Missouri Compromise in a brilliant speech. He died at Charleston, S.C., on Oct. 29, 1824.

PINCKNEY, CHARLES COTESWORTH (1746-1825), American statesman, was born in Charleston, S.C. on Feb. 25, 1746, the son of Charles Pinckney (d. 1758), a prominent figure in colonial times, by his second wife, the celebrated girl planter, Eliza Lucas. When a child he was sent to England, like his brother Thomas after him, to be educated. Both of them were at Westminster and Oxford and were called to the bar, and for a time they studied in France at the Royal Military college at Caen. Returning to America in 1769, C. C. Pinckney began the practice of law at Charleston. He was a member of the first South Carolina provincial congress in 1775, served as colonel in the South Carolina militia in 1776-77, was chosen president of the South Carolina senate in 1779, took part in the Georgia expedition and the attack on Savannah in the same year, was captured at the fall of Charleston in 1780 and kept in confinement until 1782. He was an influential member of the constitutional convention of 1787, advocating the counting of all slaves as a basis of representation and opposing the abolition of the slave-trade. He opposed as "impracticable" the election of representatives by popular vote, and also opposed the payment of senators, who, he thought, should be men of wealth. Subsequently Pinckney bore a prominent part in securing the ratification of the Federal constitution in the South Carolina convention of 1788. In 1796 he succeeded James Monroe as minister to France. The Directory refused to receive him, and he retired to Holland, but in the next year, Elbridge Gerry and John Marshall having been appointed to act with him, he again repaired to Paris, where he is said to have made the famous reply to a veiled demand for a "loan" (in reality for a gift), "Millions for defence, but not one cent for tribute,"—another version is, "No, not a sixpence." The mission accomplished nothing, and Pinckney and Marshall left France in disgust. Gerry (*q.v.*) remaining. When the correspondence of the commissioners was sent to the United States Congress the letters "X," "Y" and

"Z," were inserted in place of the names of the French agents with whom the commission treated—hence the "X Y Z Correspondence," famous in American history. In 1800 he was the Federalist candidate for vice president, and in 1804 and again in 1808 for president, receiving 14 electoral votes in the former and 47 in the latter year. From 1805 until his death, on Aug. 16, 1825, he was president general of the Society of the Cincinnati.

PINCKNEY, THOMAS (1750-1828), American statesman and diplomat, was born in Charleston, S.C., on Oct. 23, 1750, a younger brother of Charles Cotesworth Pinckney (*q.v.*). Educated in England, he returned to Charleston in 1773, and was admitted to the bar in 1774. During the American Revolution his early training at the French military college at Caen enabled him to render effective service to Gen. Benjamin Lincoln, Count d'Estaing and Gen. Horatio Gates. In the battle of Camden he was badly wounded and captured, remaining a prisoner for more than a year. Subsequently he was governor of South Carolina in 1787-89; presided over the State convention which ratified the Federal constitution in 1788; and was United States minister to Great Britain in 1792-96. During part of this time (1794-95) he was also envoy extraordinary to Spain, and in this capacity negotiated (1795) the important Treaty of San Lorenzo el Real; by that treaty the boundary between the United States and East and West Florida and between the United States and "Louisiana" was settled (Spain relinquishing all claims east of the Mississippi above 31° N. lat.), and the United States secured the freedom of navigation of the Mississippi to its mouth. In 1796 Pinckney was the Federalist candidate for vice president, and in 1797-1801 he was a Federalist representative in Congress. During the War of 1812 he was a major-general. He died in Charleston on Nov. 2, 1828. The Pinckneys, like many other South Carolina revolutionary leaders, were of aristocratic birth and politics, closely connected with England by ties of blood, education and business relations. This renders the more remarkable their attitude in the American Revolution, for which they made great sacrifices.

See C. C. Pinckney, *Life of General Thomas Pinckney* (Boston, 1895).

PIN-CLOVER (*Erodium cicutarium*), an annual herb of the geranium family (Geraniaceae), called also hemlock stork's-bill, red filaree and pin-weed. It is widespread as a weed in the old world, and is extensively naturalized in North America from Nova Scotia to the Pacific coast, being especially abundant from Texas and Colorado westward to California and Washington, where it is highly esteemed as a forage plant. The larger white-stemmed pin-clover, musk clover or filaree (*E. moschatum*), native to Europe and locally naturalized in the United States, has become very abundant in California valleys.

PINDAR (Gr. Πίνδαρος, c. 522-443 B.C.), the great lyric poet of ancient Greece, was born at Cynoscephalae, in Boeotia, at the time of the Pythian games (*fr.* 175, Bergk⁴, 193)¹, which is taken by Bockh to be 522 B.C. He would thus be some thirty-four years younger than Simonides of Ceos. He was the son of Daiphantos and Cleodice (or Cleidice). The clan of the Aegidae—tracing their line from the hero Aegeus—belonged to the "Cadmean" element of Thebes, *i.e.*, to the elder nobility whose supposed date went back to the days of the founder Cadmus. Pindar stood, that is, within the circle of those families for whom the heroic myths were domestic records. He had a personal link with the memories which everywhere were most cherished by Dorians, no less than with those which appealed to men of "Cadmean" or of Achaean stock. And the wide ramifications of the Aegidae throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic.

Life.—Pindar is said to have received lessons in flute-playing from one Scopelinus at Thebes, and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his profuse employment of Theban mythology, is

¹The references are to the edition of Pindar by C. A. M. Fennell (1893-99), and the fourth edition of Bergk's *Poetae Lyrici graeci*.

said to have advised him "to sow with the hand, not with the sack." There is an extant fragment in which Corinna reproves another Theban poetess, Myrtis, "for that she, a woman, contended with Pindar" (*ὄτι βανά φούσ' ἔβα Πινδάρου ποτ' ἔριω*)—a sentiment which hardly fits the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was, indeed, indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music, and in the adaptation of both to the intricate movements of the choral dance (*ὄρχηστική*).

Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time, and at the various elements of art which the lyrist was required to temper into a harmonious whole (see, e.g., *Olymp.* iii. 8, vi. 91, xiii. 18, xiv. 15; *Pyth.* xii. 23, etc.). The earliest ode which can be dated (*Pyth.* x.) belongs to the twentieth year of Pindar's age (502 B.C.); the latest (*Olymp.* v.) to the seventieth (452 B.C.)¹. He visited the court of Hiero at Syracuse; Theron, the despot of Acragas, also entertained him; and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi: "He was greatly honoured by all the Greeks, because he was so beloved of Apollo that he even received a share of the offerings; and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god"². His wife's name was Megacleia (another account says Timoxena, but this may have been a second wife), and he had a son named Daiphantus and two daughters, Eumetis and Protomache. He is said to have died at Argos, at the age of seventy-nine, in 443 B.C.

Piety.—Among the Greeks of his own and later times Pindar was pre-eminently distinguished for his piety towards the gods. He tells us that, "near to the vestibule" of his house (*Pyth.* iii. 78), choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the phrygian music of the flute, in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele, which he dedicated at Thebes, were the work of the Theban artists, Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios, and another, by Calamis, to Zeus Ammon. The latter god claimed his especial veneration because Cyrene, one of the homes of his Aegid ancestry, stood "where Zeus Ammon hath his seat," *i.e.*, near the oasis and temple (*Pyth.* iv. 16). The author of one of the Greek lives of Pindar says that, "when Pausanias the king of the Lacedaemonians was burning Thebes, some one wrote on Pindar's house, 'Bum not the house of Pindar the poet'; and thus it alone escaped destruction." This incident, of which the occasion is not further defined, has been regarded as a later invention³.

Better attested, at least, is the similar clemency of Alexander the Great, when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia, or citadel, of Thebes (thenceforth to be occupied by a Macedonian garrison); (2) the temples and holy places; and (3) Pindar's house. While the inhabitants were sold into slavery, exception was made only of (1) priests and priestesses; (2) persons who had been connected by private *ξενία* with Philip or Alexander, or by public *ξενία* with the Macedonians; (3) Pindar's descendants. It is probable enough, as Dio Chrysostom suggests (*ii.* 33), that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I. of Macedon. But he must have been also, or chiefly, influenced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory, not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods, and, above all, to the Delphian Apollo.

Praise of Athens.—During the second half of Pindar's life, Athens was rising to that supremacy in literature and art which

was to prove more lasting than her political primacy. Pindar did not like to see the Parthenon, or to witness the mature triumphs of Sophocles; but he knew the sculpture of Calamis, and he may have known the masterpieces of Aeschylus. It is interesting to note the feeling of this great Theban poet, who stands midway between Homeric epos and Athenian drama, towards the Athens of which Thebes was so often the bitterest foe, but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those "sons of Athens" who "laid the shining foundations of freedom" (*παῖδες Ἀθηναίων ἐβάλοντο φαεινὰν κρηπίδ' ἐλευθερίας*, *fr.* 55, Bergk⁴, 77), while Athens itself is thus invoked: *Ὡ ταῖ λιπαραῖ καὶ ἰστέφανοι καὶ αἰόδιμοι, Ἑλλάδος ἔρεισμα, κλειταὶ Ἀθάναι, δαιμόνιον ποτὸν ἄλλοθεν* (*fr.* 54, Bergk⁴, 76). Isocrates, writing in 353 B.C., states that the phrase *Ἑλλάδος ἔρεισμα*, "stay of Hellas," so greatly gratified the Athenians that they conferred on Pindar the high distinction of *προξενία* (*i.e.*, appointed him honorary consul, as it were—for Athens at Thebes), besides presenting him with a sum of money (*Antidosis*, 166).

One of the letters of the pseudo-Aeschines (*Ep.* iv.) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens, and that the Athenians repaid him twice the sum⁴. The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens, near the temple of Ares (*i.* 8, 4). Besides the fragment just mentioned, several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars, while he gives the glory of Plataea to the Spartans, he assigns that of Salamis to the Athenians (*Pyth.* i. 76). In celebrating (*Pyth.* vii.) the Pythian victory of the Athenian Megacles, he begins thus: "Fairest of preludes is the renown of Athens for the mighty race of the Alcmaeonidae. What home, or what house, could I call mine by a name that should sound more glorious for Hellas to hear?" (*Cf.* also *Nem.* v. 49.)

Pindar's versatility as a lyric poet is one of the characteristics remarked by Horace (*Odes*, iv. 2), and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Ἐπινίκια*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied.

Fragments.—(1) *Ἕμνοι*, Hymns to deities—as to Zeus Ammon, to Persephone, to Fortune. The fragmentary *ἕμνος* entitled *Θηβαίους* seems to have celebrated the deities of Thebes. (2) *Παιᾶνες*, paeans, expressing prayer or praise for the help of a protecting god, especially Apollo, Artemis or Zeus. (3) *Διθύραμβοι*, Dithyrambs, odes of a lofty and impassioned strain, sung by choruses in honour of Dionysus. (4) *Προσόδια*, Processional Songs, choral chants for worshippers approaching a shrine. (5) *Παρθένια*, Chord Songs for Maidens.

(6) *Ἕπορχήματα*, Choral Dance-Songs, adapted to a lively movement, used from an early date in the cult of Apollo, and afterwards in that of other gods, especially Dionysus. To this class belongs one of the finest fragments (84, Bergk⁴, 107), written for the Thebans in connection with propitiatory rites after an eclipse of the sun, probably that of the 30th of April 463 B.C. (7) *Ἐγκώμια*, Songs of Praise (for men, while *ἕμνοι* were for gods), to be sung by a festal company. (8) *Σκόλια*, Festal Songs. The usual sense of *σκόλιον* is a drinking-song, taken up by one guest after another at a banquet. But Pindar's *σκόλια* were choral and antistrophic. One was to be sung at Corinth by a chorus of the *ἱερόδουλοι* attached to the temple of Aphrodite Ourania, when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment, for Theoxenus of Tenedos, has an erotic character.

(9) *Ἐρήνοι*, Dirges, to be sung with choral dance and the music of the flute, either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class

¹According to others, his latest poem is the eighth Pythian ode, 450 or 446.

²*Πινδάρου γένος*, in ed. Ald.

³A. Schäfer, *Demosthenes und seine Zeit*, iii. 119.

⁴Compare Jebb, *Attic Orators*, ii. 143.

(106-110, Bergk⁴, 129-133). A number of small fragments, which cannot be certainly classified, are usually given as *ἐξ ἀδήλων εἰδῶν*, "of uncertain class."

The *Epinicia*.—The *ἐπινίκια* (*sc. μέλη*), or *ἐπινίκιοι* (*sc. ὕμνοι*), "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to the four great festivals: (1) *Ὀλυμπιονίκαι* (*sc. ὕμνοι*): fourteen odes for winners of the wild olive-wreath in the Olympian games, held at Olympia in honour of Zeus once in four years; (2) *Πυθιονίκαι*: twelve odes for winners of the laurel-wreath in the Pythian games held at Delphi in honour of Apollo, once in four years, the third of each Olympiad; (3) *Νεμεονίκαι*: eleven odes for winners of the pine-wreath in the Nemean games, held at Nemea, in honour of Zeus, once in two years, the second and fourth of each Olympiad; and (4) *Ἰσθμιονίκαι*: seven odes for winners of the parsley wreath in the Isthmian games, held at the Isthmus of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympiad. The Greek way of citing an ode is by the nomin. plur. followed by the numeral, *e.g.*, "the ninth Olympian" is *Ὀλυμπιονίκαιθ'*. The chronological range of the collection (so far as ascertainable) is 502 B.C. (*Pyth.* x.) to 452 B.C. (*Ol.* v.).

The general characteristics of the odes may be briefly considered under the following heads: (1) language; (2) treatment of theme; (3) sentiment—religious, moral and political; (4) relation to contemporary art.

Diction.—The diction of Pindar is distinct in character from that of every other Greek poet, being almost everywhere marked by the greatest imaginative boldness. Thus (a) metaphor is used even for the expression of common ideas, or the translation of familiar phrases, as when a cloak is called (*Ol.* ix. 97) "a warm remedy for winds." (b) Images for the highest excellence are drawn from the farthest limits of travel or navigation, or from the fairest of natural objects; as when the superlative hospitality of a man who kept open house all the year round is described by saying, "far as to Phasis was his voyage in summer days, and in winter to the shores of Nile" (*Isthm.* ii. 41); or when Olympia, the "crown" or "flower" of festivals, is said to be excellent as water, bright as gold, brilliant as the noonday sun (*Ol.* i. ad *imit.*). This trait might be called the *Pindaric* imagery of the *superlative*. (c) Poetical inversion of ordinary phrase is frequent; as, instead of, "he struck fear into the beasts," "he gave the beasts to fear" (*Pyth.* v. 56). (d) The efforts of the poet's genius are represented under an extraordinary number of similitudes, borrowed from javelin-throwing, chariot-driving, leaping, rowing, sailing, ploughing, building, shooting with the bow, sharpening a knife on a whetstone, mixing wine in a bowl, and many more. (e) Homely images, from common life, are not rare; as from account-keeping, usury, sending merchandise over sea, the *σκυτάλη* or secret dispatch, etc. And we have such homely proverbs as, "he hath his foot in this shoe," *i.e.*, stands in this case (*Ol.* vi. 8). (f) The natural order of words in a sentence is often boldly deranged, while, on the other hand, the syntax is seldom difficult. (g) Words not found except in Pindar are numerous, many of these being compounds which (like *ἐναρίμβροτος*, *καταφυλλοροεῖν*, etc.) suited the dactylic metres in their Pindaric combinations. Horace was right in speaking of Pindar's "nova verba," though they were not confined to the "audaces dithyrambi."

Subjects.—The actual victory which gave occasion for the ode is seldom treated at length or in detail—which, indeed, only exceptional incidents could justify. Pindar's method is to take some heroic myth, or group of myths, connected with the victor's city or family, and, after a brief prelude, to enter on this, returning at the close, as a rule, to the subject of the victor's merit or good fortune, and interspersing the whole with moral comment. Thus the fourth Pythian is for Arcesilaus, king of Cyrene, which was said to have been founded by men of Thera, descendants of one of Jason's comrades. Using this link, Pindar introduces his splendid narrative of the Argonauts. Many odes, again, contain shorter mythical episodes—as the birth of Iamus (*Ol.* vi.), or the vision of Bellerophon (*Ol.* xiii.)—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical

digression to his immediate theme. It is bold and swift, yet is not felt as harshly abrupt—justifying his own phrase at one such turn—*καὶ τινα οἶμον ἴσαμι βραχύν* (*Pyth.* iv. 247).

Religious, Moral and Political Sentiment.—a. The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence." He will not believe that the gods, when they dined with Tantalus, ate his son Pelops; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, *viz.*, that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as *Ol.* ii. 66 seq.). Pindar was familiar with the idea of metempsychosis (*cf. ibid.* 68), but the attempt to trace Pythagoreanism in some phrases (*Pyth.* ii. 34, iii. 74) appears unsafe. The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the *Θρήνος* (114, Bergk⁴, 137), we may probably regard the esoteric element in Pindar's theology as due to such a source.

b. The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (*φύη*) is the grand source of all human excellence (*ἀρετή*), while such excellences as can be acquired by study (*διδακταὶ ἀρεταί*, *Ol.* ix. 100) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of *ὕγιαις ἄλβος*—"sane happiness," such as has least reason to dread the jealousy of the gods—are substance sufficing for daily wants and good repute (*εὐλογία*). He who has these should not "seek to be a god." "Wealth set with virtues" (*πλοῦτος ἀρεταῖς διδαυδαλμένος*), as gold with precious gems, is the most fortunate lot, because it affords the amplest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate thy foe" (*cf. Pyth.* ii. 83; *Isthm.* iii. 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of generous emulation and of reverent self-control.

c. The political sentiments of the Theban poet are suggested by *Pyth.* xi. 52; "In politics I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in *Pyth.* ii. 87, a democracy is described as *ἄλαβρος στρατός*, "the raging crowd," it is to be noted that the ode is for Hiero of Syracuse, and that the phrase clearly refers to the violence of those democratic revolutions which, in the early part of the 5th century B.C., more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (*ὀλιγαρχία ἰσόνομος*, *Thuc.* iii. 62) had replaced the narrower and less temperate oligarchy of former days (*δυναστεία οὐ μετὰ νόμων*); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (*Ol.* i. 113); he sketches the character of an ideal king (*Pyth.* iii. 71); but nothing in his poetry implies liking for the *τυραννίς* as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence; he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours "Tranquillity, the friend of cities" (*Ἄσυχία φίλοπολις*, *Ol.* iv. 16). The epic poet sang of wars: Pindar celebrates the "rivalries of peace."

Love of Natural Art.—Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent

new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (Ol. ix. 80). Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase *δαίδαλγειν*, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (Ol. vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the hours is opened, and delicate plants perceive the fragrant spring" (fr. 53, Bergk⁴, 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (Pyth. iv. 195); in the lines on the eclipse of the sun (fr. 84, Bergk⁴, 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (Pyth. i. 20). The poet's feeling for colour is often noticeable—as in the beautiful story of the birth of Iamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (Ol. vi. 55).

Relation to Art.—The spirit of art, in every form, is represented for Pindar by *χάρις*—"the source of all delights to mortals" (Ol. i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang,

the instinct of beautiful art was inseparable from the sense of natural beauty. The period from 500 to 400 B.C., to which most of

Pindar's extant odes belonged, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina

were effecting a transition from archaic types to the art which was afterwards matured in the age of Pheidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards sculpture had been applied to the commemoration of athletes, chiefly at Olympia.

In a striking passage (*Nem. v. ad. init.*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Aegina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heraclon and Hebe, (5) the wars of the Centaurs with the Lapithae, and (6) a contest between Heracles and Apollo, are instances of mythical material treated alike by the poet and by sculptors of his day.

Place in Greek Literature.—In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians, Alcman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as die *universalen* Meliker. The Greeks usually spoke, not of "lyric," but of "melic" poetry (i.e., meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyricist. Epic, lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth.

In Pindar we can see that phase of the Greek mind which

produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (Pyth. iv.), the meeting of Apollo and Chiron (Pyth. ix.), the episode of Castor and Polydeuces (*Nem. x.*), the entertainment of Heracles by Telamon (*Isthm. v.*). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Aeschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

The fact that certain glosses and lacunae are common to all our mss. of Pindar make it probable that these mss. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymus (c. 15 B.C.), sometimes presuppose a purer text than ours. Eut the compiler of these older scholia lived after Herodian (A.D. 160). The archetype of our mss., then, cannot have been older than the end of the 2nd century. Our mss. fall into two general classes: (1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit the traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in Pyth. v.; Ambrosianus 1, which has only Ol. 1.-xii.; Medicus 2; and Vaticanus 2—the two last-named being of the highest value. The editio princeps is the Aldine (Venice, 1513). A modern study of Pindar may be almost said to have begun with C. G. Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But August Bockh (1811-21), who was assisted in his commentary by L. Disson, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (*Poetae lyrici graeci*, 1878 new ed. by O. Schröder, 1900) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to mss. A recension by W. Christ has been published in Teubner's series (2nd ed., 1896), also with Prolegomena and commentary (1896); and by O. Schröder (1908). The complete edition of J. W. Donaldson (1841) has many merits; but that of C. A. M. Fennell (1879-83; new ed., 1893-99) is better adapted to the needs of English students. The Olympia and *Pythia* have been edited by B. L. Gildersleeve (1885), the Nemea and *Isthmia* by J. B. Bury (1890-92); the Scholia by E. Abel (1890, unfinished) and A. B. Brachmann (1903). There is a special lexicon by J. Rumpel (1883). The translation into English prose by Ernest Myers (2nd ed., 1883) is excellent; verse translation by T. C. Baring (1875), and of the Olympian Odes by Cyril Mayne (1906), also the edition in the Loeb Classical Library, with Eng. trans. by J. Sandys (1915). Pindar's metres have been analysed by J. H. H. Schmidt, *Die Kunstformen der griechischen Poesie* (Leipzig, 1868-72). On Pindar generally, see L. Schmidt, *Pindar's Leben und Dichtung* (1862); F. D. Morice, Pindar (1879); A. Croiset, *La Poesie de Pindare* (1880); G. Lübbert, *Pindar's Leben und Dichtungen* (Bonn, 1882); W. Christ, *Geschichte der griechischen Litteratur* (1898); F. Dornseiff, *Pindars Stil* (1921). Bibliographical information on the earlier literature will be found in W. Engelmann, *Scriptores graeci* (1881); see also L. Eornemann, in *Jahresbericht über die Fortschritt der classischen Altertumswissenschaft* (ed. C. Bursian, vol. cxvi., 1904), with special reference to chronological questions and *Pythia*, i., ll. iii. Some considerable fragments of the paens were discovered in 1906 by B. P. Grenfell and A. S. Hunt, see Paeans in *Oxyrhynchus papyri* (pt. v. 1908), and A. E. Housman, in *Classical Review* (Feb. 1908). (R. C. J.; X.)

PINDARICS, the name by which was known a class of loose and irregular odes in fashion in England during the close of the 17th and the beginning of the 18th century. The invention is due to Abraham Cowley, who, probably in Paris, and perhaps in 1650, found a text of Pindar and determined to imitate the Greek poetry in English, without having comprehended the system upon which Pindar's prosody was built up. Cowley published, in 1656, 15 *Pindarique* Odes, which became the model on which countless imitators founded their pindarics. The erroneous form of these poems, which were absolutely without discipline of structure, was first exposed by Congreve, exactly half a century later. The laxity of these "pindarics" attracted the poets of the unlyrical close of the 17th century, and they served the purpose not only of Dryden and Pope, but of a score of lesser poets. Although the vogue of these forms hardly survived the age of Anne, something of the vicious tradition of them still remained, and even in the

odes of Wordsworth, Shelley and Coleridge the broken versification of Cowley's pindarics occasionally survives.

PINDARIS, a word of uncertain origin, applied to the irregular horsemen who accompanied the Mahratta armies in India during the 18th century when the Mogul empire was breaking up. Loosely organized under self-chosen leaders, each band was usually attached to one or another of the great Mahratta chieftains. Their special characteristic was that they received no pay, but rather purchased the privilege of plundering on their own account.

The majority of them seem to have been Mohammedans. When the regular forces of the Mahrattas had been broken up in the campaigns conducted by Sir Arthur Wellesley and Lord Lake in 1802-04, the Pindaris made their headquarters in Malwa, under the tacit protection of Sindhia and Holkar. They usually assembled annually in November to set forth over British territory in search of plunder. In one such raid upon the Masulipatam coast they plundered 339 villages, killing or wounding 682 persons, torturing 3,600 and carrying off much valuable property. In 1808-09 they plundered Gujarat, and in 1812 Mirzapur. In 1814 they were reckoned at 25,000 to 30,000 horsemen, half of them well armed. At last the evil became intolerable, and in 1817 the marquess of Hastings obtained the consent of the East India company to the organized campaign known as the Pindari War. The Pindaris were surrounded on all sides by a great army, consisting of 120,000 men and 300 guns, which converged upon them from Bengal, the Deccan and Gujarat under the supreme command of Lord Hastings in person.

Sindhia was overawed and forced to sign the treaty of Gwalior, consenting to aid in the extirpation of the Pindaris, whom he had hitherto protected. The Peshwa at Poona, the Bhonsla raja at Nagpur and the army of the infant Holkar each took up arms, but were separately defeated. The Pindaris themselves offered little opposition. Amir Khan, by far their most powerful leader, accepted the conditions offered to him. His descendant later became Nawab of the state of Tonk in Rajputana. The rest surrendered or were hunted down, the fate of Chitu, one of the most notorious, being to perish in a tiger's den. These military operations were followed by the pacification of Central India under the administration of Sir John Malcolm.

See J. Grant Duff, *History of the Malzrattas* (1826); and Major Ross of Bladensburg, *Marquess of Hastings (Rulers of India Series)* (1893).

PINDEMONTÉ, IPPOLITO (1753-1828), Italian poet and author, was born in Verona, Nov. 13, 1753, the son of a rich and cultured nobleman. From 1784-88 he lived in a villa outside the city of Verona and the calm, quiet life there inspired him to write one of his best known works, *Poesie campestri* (1788). From 1788-91 he travelled extensively throughout Europe, visiting France, England and Germany. The result of his travels was his novel, *Abaritte* (1792) and a poem, "La Francia" (1789), written in commemoration of the opening of the French Revolution, which he had greeted with enthusiasm. His fervour was somewhat dampened later, however, by the destruction of his villa by French and Austrian troops in 1796 and by the Reign of Terror in France. From 1809-22 he published his translation of Homer's *Odyssey*, the first canto of which appeared in 1809, the rest following at intervals thereafter.

One of his best works was "I Cimiteri," a poem he never finished but one which probably inspired Ugo Foscolo's poem "Sepolcri," which was dedicated to Pindemonte. His novel in verse, *Antonio Foscari* e *Teresa Contarini*, is also celebrated. Other works include *Arminio*, a tragedy in verse, *Elogi di Letterati*, a work of biography and literary criticism, and *Prose campestri*, a companion to his earlier *Poesie campestri*. Pindemonte died at Verona, Nov. 18, 1828.

His brother, **GIOVANNI PINDEMONTÉ** (1751-1812), poet, dramatist and politician, was born in Verona, Dec. 4, 1751. At various times during his life he held high positions with governments of several of the Italian states, but he spent much time in exile in France, sometimes because of his own misconduct, sometimes because of the fall of the government he was serving.

He wrote lyric poetry, which is not highly regarded, and ten

tragedies modelled after Shakespeare. He died in Verona, Jan. 12, 1812.

PINDUS, the ancient name for the mountains which separate Thessaly from Epirus, often used by modern geographers in a somewhat extended sense. The folded Alpine chains are continued down the western coast of the Balkan peninsula, where in the north they form the Dinaric Alps. In the neighbourhood of Scutari (Skadar), however, the direction of the coast-line undergoes a marked change, associated with a change in the trend of the mountain folds.

In the extended sense the name Pindus is applied to the chain of fold-mountains which extends from the Šar Planina, in the latitude of Scutari, southwards to about the latitude of the Gulf of Arta, and thus includes most of the mountains of Albania. As a rule massive limestones are less developed in the Pindus than in the Dinaric region, so that the karstic type of landscape is less frequent and less repellent than in the north, the prevailing types of rocks being often schists, grits and greenish eruptive rocks, especially serpentines.

The range rises to a maximum height of about 8,000 feet, and in places the original forests, mainly of oak and beech, have been preserved.

PINE, JOHN (1690-1756), English engraver. It is not known where he learned his art, although he may have studied under the Frenchman, Bernard Picart. He operated a printshop in London and thus was able to publish books illustrated with his own engravings. His first important publication, which is also one of the finest examples of his work, was a group of engravings of the ceremonies attending George I's revival of the order of the Bath (1730). His other productions include a copy of the Magna Carta; an edition of Horace and a part of one of Virgil; copies of the tapestries celebrating the defeat of the Spanish armada which hung in the house of lords; and several maps of London.

In 1749 his friend William Hogarth depicted him as the friar in his painting "The Gate of Calais," and from that date Pine was known, to his considerable irritation, as Friar, or Father Pine. In 1755 he and a number of other English artists formed a committee to found a royal academy, but he died 12 years before the plans became a reality. From 1743 until his death he was Blue Mantle Pursuivant in the Heralds' college and he lived there during the last years of his life. He died May 4, 1756. His two sons, Robert (*q.v.*) and Simon, were both painters.

PINE, ROBERT EDGE (1730-1788), English painter, son of John Pine, was born in London. Nothing is known with certainty about his education, but it is more than likely that his father instructed him in his youth. In 1760 his painting "The Surrender of Calais" won for him first prize for historical subjects in the first exhibition held by the Society of Arts, and three years later he received the same award for his "Canute Rebuking His Courtiers on the Seashore." He became widely known as a painter of portraits, particularly those of contemporary theatrical personalities. His likenesses of David Garrick, painted during this period, are regarded as especially fine. In 1782 he exhibited paintings depicting scenes and characters from Shakespeare's plays and probably in the following year, although the date is not certain, went to the United States, taking the exhibition with him and showing it in Philadelphia. His plan had been to paint the portraits of the leaders of the American Revolution, as well as historical scenes of the important events of the war itself, but this plan never materialized although he did make portraits of a number of contemporary statesmen, including Francis Hopkinson, George Washington, Robert Morris, Benjamin Franklin and John Jay. His picture of Washington later appeared as an engraving in Washington Irving's life of the president. Many of Pine's works went to the Columbian museum in Boston and were destroyed when that institution burned. His American paintings are considered to be, on the whole, inferior to those painted in his native country.

Pine died in Philadelphia, Nov. 18, 1788.

PINE, a name given by the ancients to several resinous, cone-bearing trees. Modern botanists restrict the use of the term to

members of the genus *Pinus* (Pinaceae) which differs from other pinaceous genera in featuring slender, needlelike leaves, borne in fascicles of 2 to 8 (rarely solitary), growing from a basal membranous sheath. Each tuft represents an abortive branch which springs from the axil of a partially deciduous, scalelike leaf, the base of which remains closely adherent to the stem. The numerous staminate catkins are arranged in dense spirals about the bases of young shoots of the season; the 2-celled sessile anthers release an abundance of pollen through longitudinal slits; the ovuliferous flowers are composed of several spirally arranged bracts each subtending a scale with two basal ovules. The fruit of the pines, a cone, requires 2 or rarely 3 seasons to mature. It is composed of numerous woody, armed or unarmed scales spirally arranged about a woody central axis, each bearing 2-winged, or rarely wingless seeds. The cones of several species open at maturity to release their seeds, others remain closed for several seasons; still others require the heat of a forest fire to open them in appreciable quantities. In such instances vast amounts of viable seed are accumulated through the years, which, when released, completely reseed burned-over areas.

The pines, which comprise about 90 species, are widely distributed over the north temperate zone, in the southern portions of which they are chiefly confined to the mountains. In Central America a few are found within the tropics. In more northern regions they frequently form extensive forests which are sometimes hardly invaded by other trees. One species is native to Great Britain; about 30 are indigenous to the United States and Canada. Their soft or hard straight-grained, resinous and often durable woods are suitable for many purposes, and some are among the most esteemed of timber trees.

Of the two-needled species, *P. sylvestris*, the Scotch pine of northern Europe, may be regarded as a type. When produced under optimum growing conditions it is one of the finest of the group, and one of the most picturesque of forest trees. Attaining a height of from 70 to 120 ft., it is of conical habit when young, but in maturity acquires a spreading cedar or mushroomlike top, with a straight trunk, two to four feet in diameter at the base, and gnarled, twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often twisted; the staminate cones fill the air of the forest with their sulphurlike pollen in May or June, and pollinate the purple carpellate cones, which are at first sessile and erect, and then become recurved on a lengthening stalk; fertilization does not occur until the next summer, and the carpellate cones do not reach maturity until the autumn of the following year. They seldom open and scatter their seeds until the third year. *P. sylvestris* is found, in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest slopes of Etna, while in longitude its range extends from the shores of the North sea to Kamchatka. Nowhere more abundant than in the Scandinavian peninsula, this tree is the fir (*fur, jura*) of the old Norsemen, and still retains the name in Great Britain, though botanically now classed as a pine. It grows vigorously in Lapland on the lower ground, while in south Norway it occurs up to 3,000 ft., though the great forests from which "Norway pine" timber is chiefly derived are on the comparatively lower slopes of the southeastern dales; in the highest situations it dwindles to a mere bush. It furnishes the yellow deal of the Baltic and Norway. In Germany, both on the mountains and the sandy plains, woods of "kiefer" are frequent and widely spread, while vast forests in the U.S.S.R. and Poland are chiefly composed of this species; in many northern habitats it is associated with the spruce and birch. In Asia it abounds in Siberia and on the mountains of the Amur region; in the European Alps it occurs at a height of 5,600 ft., and in the Pyrenees it is found at still higher elevations. In Great Britain natural forests of Scotch pine of any extent are found only in the highlands, chiefly on the declivities of the Grampians. The tree is not indigenous in southern Britain, but when planted in suitable ground multiplies rapidly by the wind-sown seeds; on many of the sandy moors and commons natural pine woods of large extent have been thus

formed. The heartwood of the finer kinds of Scotch pine is of a deep brownish-red colour, abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking, is perhaps a little inferior; from its lightness and elasticity it is well-adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from 30 to 40 lb. per cu.ft. Great numbers of young pines are annually cut for railway ties (sleepers), mining timber and numerous agricultural applications; large quantities are consumed for wood pavement. The quality of the timber depends greatly on the soil and position in which the trees are grown. The rapidity of growth is still more variable: in Britain

full maturity is attained in from 70 to 120 years, but in Norway the trunk increases much more slowly; H. Schiibeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 ft. 10 in. in diameter, showed 400 annual rings.

In the economy of the northern nations of Europe *P. sylvestris* is an important tree. In Scandinavia and the U.S.S.R., houses are chiefly constructed of its timber; and log huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, in times of scarcity, is kiln-dried, ground up and mixed with meal.

are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct to the seedbed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of young Scotch pines requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, except for the removal of deadwood.

In Great Britain *P. sylvestris* is subject to many insect depredations: the pine chafer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; the fir weevil, *Hylobius abietis*, eats away the bark, and numerous lepidopterous larvae devour the leaves; the pine sawfly is also injurious in some seasons.

The removal of all dead branches from the trees and from the ground beneath them is recommended, as most of these insects lay their eggs in the decaying parts of the bark and among the dead leaves.

In common with other pines, *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem, causing rotting of the wood. The disease is difficult to eradicate, as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus*, which spreads in the soil by means of its long purple-black, cordlike mycelial strands known as *Rhizomorpha*. Much damage is often caused by species of *Peridermium*, which often invade the soft portions of the inner bark to such an extent as to "ring" the stem or branch, or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water; this causes the parts above the diseased area to perish.

Plantations in England are generally ready for final cutting in from 60 to 70 years, and many are cleared at a much earlier stage of growth, especially when protected from injury by pests. In England the pine is largely employed as a "nurse" for oak trees, its

conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species. This pine is planted for ornament in the eastern United States where it has become sparingly naturalized; it has also proved of value in afforesting treeless lands, as in the national forest in western Nebraska.

Large quantities of turpentine are extracted from this pine in Sweden and the U.S.S.R. by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species.

FIG. 2.—WHITE PINE

1. Foliage spray and closed cone. 2. Fascicle of needles. 3. Male flowers. 4. Female flowers. 5. Open cone. 6. Seed

Tar is prepared from *P. sylvestris*; it is chiefly obtained from the roots.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. pumilio*, the "krumholz" or "knicholz" of the Germans—a recumbent bush, generally only a few feet high, but with long zigzag stems that root occasionally at the kneelike bends where they rest upon the ground. The foliage much resembles that of the Scotch pine, but is shorter, denser and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tirolese Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit.

The red pine, *P. resinosa*, of southeastern Canada and the northern border of the United States from Minnesota eastward (so-called from the colour of its bark), is a tree sometimes 120 ft high, with a trunk 3 ft. or more in diameter. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch pine although much employed in shipbuilding.

P. laricio, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 in. long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece and many Mediterranean countries. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *P. sylvestris*; the heartwood is of a brownish tint. In southern France it has been planted with success on the drift sands of the Bay of Biscay, though it does not bear the full force of the sea blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The black pine, *P. nigra*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree.

P. pinaster, the cluster or pinaster, is an important species from its vigorous growth in the sand drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft.

or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long taproots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine. In England the cluster pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties.

P. pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nutlike seeds (pignons), which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid.

Nearly approaching this is *P. griffithii*, the Bhotan or blue pine, which differs chiefly in its longer cones and drooping glaucous foliage. It is found in Kumaon and Bhutan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 7,000 to 12,000 ft., and attains large dimensions.

P. cembra is the stone pine of Siberia and central Europe. It abounds on the Alps, the Carpathians and the Siberian ranges, in Switzerland being found at an altitude of 4,000 to 6,000 ft. The seeds are oily like those of *P. pinea*, and are eaten both on the Alps and by the inhabitants of Siberia; a fine oil is expressed from them which is used both for food and in lamps. The growth of *P. cembra* is slow, but the wood is of remarkably even grain, and is employed by the Swiss wood carvers in preference to any other.

Numerous species of pine are planted for ornament, afforestation and timber production.

North American Pines.—The 35 or more species and major varieties of pine native to North America north of Mexico may be grouped in two sections, the *soft pines* and the *hard pines*.

The *soft pines* have soft, close-grained wood, with thin nearly white sapwood; the sheaths of the leaf clusters fall off early (deciduous); the leaves contain a single fibrovascular bundle, and, excepting those of the nut pines, the leaves are in five-leaved clusters. There are 12 species, only one of which, the eastern white pine, is found east of the Great Plains, the others occurring in the Rocky mountain region and on the Pacific coast.

American soft pines are readily divided into four groups whose botanical designations and features are set forth below.

White Pines.—The eastern white pine (*P. strobus*), known also as Weymouth pine, because of its large size and the soft even grain of its white wood, is one of the most valuable of North American timber trees. It once formed extensive forests from Newfoundland to Manitoba and along the northern border of the United States from Maine to Minnesota and also southward in the mountains to Georgia, but it has been so long sought for by the lumbermen that most of the old trees have long since disappeared. On a deep rich soil *P. strobus* sometimes attains a height of 200 ft. and a trunk diameter of 4 to 6 feet. The wood of the white pine is durable for indoor use, especially when protected

Soft Pines

Group	Leaves	Cones
White pines <i>P. strobus</i> <i>P. monticola</i> <i>P. lambertiana</i>	in clusters of 3, 4" to 6" long	Long stalked, with thin, unarmed scales; seeds long winged
Stone pines <i>P. albicaulis</i> <i>P. flexilis</i> <i>P. ayacahuite</i>	in clusters of 5, about 3½" long	short stalked, with thick, unarmed scales; seeds short winged or wingless
Foxtail pines <i>P. aristata</i> <i>P. balfouriana</i>	in clusters of 3, about 2" long, persistent for many years	short stalked, the scales armed on the back with a small, often deciduous prickle; seeds long winged
Nut pines <i>P. cembroides</i> <i>P. parryana</i> <i>P. monophylla</i> <i>P. edulis</i>	in clusters of 2 to 4, or solitary, about 2" long	short stalked, few scales, the scales greatly thickened, unarmed, short winged or wingless

by paint, its smooth easily-worked grain rendering it a favourite wood for the house carpenter and joiner. The western white pine (*P. monticola*), a mountain species of the northwestern United States and British Columbia, with light brown wood, is extensively cut for lumber, especially in Idaho.

The sugar pine or giant pine (*P. lambertiana*) of California, the largest of known pines, rises to a height of 200 ft. to 220 ft., with a trunk from 6 ft. to 8 ft., or occasionally 12 ft. in diameter. The head is of a pyramidal form, the lower branches drooping like those of a Norway spruce; its foliage is of a light bright green colour. The pendent cones are very large, sometimes 18 in. long and 4 in. in diameter, with large nutlike seeds, which, pounded and baked, are eaten by the Indians. It is lumbered extensively, the wood being highly valued for indoor carpentry.

Stone Pines.—Stone pines are typically timber-line species, and are more important as protectors of valuable watersheds than for the timber they produce. The whitebark pine (*P. albicaulis*), so-called because of its chalky-coloured bark, extends along the mountains of the Pacific slope from British Columbia to the Sierra Nevada of California and eastward through Idaho to Montana and Wyoming. Limber pine (*P. flexilis*) is essentially a Rocky mountain tree. The Mexican white pine (*P. ayacahuite*) is a Mexican tree which attains its northern limits in the southwestern United States.

Foxtail Pines.—This group attains its name from the fact that the leaves persist on the branches for 10 to 15 years or more and simulate the bushy aspect of a fox's tail. Both are small alpine trees. Bristlecone pine (*P. aristata*) is a tree of the southern Rocky mountains, while foxtail pine (*P. balfouriana*) is found on the Coast and Sierra Nevada ranges of California. Needles of the former have superficial resin canals from which resin is exuded upon the surface of the leaf.

Nut Pines.—Some authorities recognize but one species, *P. cembroides* and classify the other forms as varieties of this species. The single-leaf piñon (*P. monophylla*) features one and sometimes two needles in a fascicle. This tree occurs sporadically through northern Mexico, lower California and the southwestern United States. The Parry piñon (*P. parryana*) is the four-needle piñon of southern California and northern Lower California. Nut pine (*P. edulis*), the most widely distributed tree of the group, like the Mexican piñon has needles in clusters of 2 and 3. The seeds of the group are very large and tasty and are sold in the markets as "pine nuts."

The hard pines have usually heavy, coarse-grained, mostly dark-coloured wood, with pale often thick sapwood; the sheaths of the leaf clusters are persistent, except in the Chihuahua pine (*P. leiophylla*), the leaves have two fibrovascular bundles, and are arranged mostly in three-leaved and two-leaved clusters. There are some 24 species about equally divided in number be-

tween the region east of the Great Plains and the region extending from the Rocky mountains to the Pacific coast.

The group of hard or yellow pines with the leaves usually in three-leaved clusters includes several of the most valuable trees of North America. Among these are the longleaf pine (*P. palustris*), the slash pine (*P. caribaea*), the loblolly pine (*P. taeda*), the pitch pine (*P. rigida*) and the pond pine (*P. rigida* var. *serotina*) of the southern states, and the ponderosa or western yellow pine (*P. ponderosa*) and the Arizona pine (*P. ponderosa* var. *arizonica*) of the Pacific states. Other representatives of the three-leaved group are the Monterey pine (*P. radiata*), the knobcone pine (*P. attenuata*), the digger pine (*P. sabiniana*), and the Coulter pine (*P. coulteri*) of California and Oregon, and also the Chihuahua pine (*P. leiophylla*) of the Mexican border.

The group of hard pines with leaves usually in two-leaved clusters also comprises several important trees. Among these are the red or Norway pine (*P. resinosa*), the gray or jack pine (*P. banksiana*), the spruce pine (*P. glabra*), the shortleaf pine (*P. echinata*), the Virginia pine (*P. virginiana*), the sand pine (*P. clausa*), and the mountain pine (*P. pungens*), of the region east of the Rocky mountains. Here belong also the lodgepole pine (*P. contorta*), found from New Mexico to Alaska. Another representative of the two-leaved group is the bishop pine (*P. muricata*). The rare Torrey pine (*P. torreyana*), confined to the California coast, is a j-needle pine, a condition rare among yellow pines.

Longleaf pine (*P. palustris*), is the most notable yellow pine of the southern states; it abounds on sandy soils from the Carolinas and Florida westward to Louisiana and Texas. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk, sometimes 120 ft. high, furnishes one of the most valued pine timbers of the United States; close-grained and resinous, it is very durable and polishes well; it is largely employed in construction work, and large quantities are exported, especially to Great Britain and the West Indies. This tree is the chief lumber-producing pine of the southern United States; it also yields large quantities of tar and turpentine.

The loblolly pine (*P. taeda*), a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence, the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 to 100 ft. high, having sometimes a girth of 6 or 8 ft. The timber of this pine, though soft and brittle, is much used for lumber and pulpwood, but the forests of it are of no importance to the naval stores industry because of the poor quality of the derived oils and turpentine. The shortleaf (*P. echinata*) and slash pines (*P. caribaea*) are two other very important timber trees in the south. The latter extends over the Florida keys to several islands in the Caribbean.

The ponderosa, western yellow or bull pine (*P. ponderosa*), which grows from 150 to 200 ft. high, with a massive trunk 5 to 8 ft. in diameter, is noted for its soft easily worked wood which is much softer than most other hard pines; it is the most widely distributed American pine, being found in the mountain forests of western North America from British Columbia to South Dakota (Black hills) and south to Texas and Mexico. It is the chief lumber pine of the Pacific states where it is second in importance only to the Douglas-fir (*q.v.*). The Coulter pine (*P. coulteri*) is remarkable for its enormous cones (sometimes 1 ft. long, 6 in. in diameter, and weighing more than 4 lb.); the scales end in long hooked points curving upwards; the leaves are long, rigid and glaucous in hue. Closely related to this is the digger pine (*P. sabiniana*) of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nutlike seeds are eaten by the Indians; the tree sometimes attains a height of 80 ft. and a trunk diameter of 4 ft. The beautiful Monterey pine (*P. radiata*), found sparingly along the California coast, is distinguished by the brilliant colour of its foliage. The Torrey pine (*P. torreyana*), with leaves 12 in. long, found only

in a narrow strip some 8 mi. in length, along the coast near San Diego, Calif., and on Santa Barbara island, is the least widely distributed of all known pines.

The pitch pine (*P. rigida*), found from the coast of Massachusetts southwestward throughout the Appalachian region, is a tree of from 40 to 50 ft. in height, with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. Large quantities of a low grade tar and pitch have been obtained from this species. The tree is one of the few that will flourish in salt marshes.

Pine Lumbering in the United States.—The various native species of pine, several of which form forests of vast extent, constitute the chief source of softwood (coniferous) lumber produced in the United States. According to releases by the United States Forest Service the production of pine lumber in the United States for 1940 was as follows:

Southern yellow	10,162,000,000	bd. ft.
Ponderosa	3,613,000,000	“ “
Eastern white	577,000,000	“ “
Western white	433,000,000	“ “
Sugar	363,000,000	“ “
Lodgepole	59,000,000	“ “
Total	15,207,000,000	“ “

Commercially, the lumber cut from the various kinds of pine is known as *white, yellow, ponderosa, sugar* and *lodgepole* pine, and is classified under these descriptive names in the census of manufactures. White-pine lumber includes that produced from the eastern white or Weymouth pine, the western white pine, the grey or jack pine and the Norway or red pine, the two last named belonging botanically with the yellow pines. Prior to 1900 the eastern white pine was one of the chief lumber-producing trees in America, but the original forests have become so depleted that the tree now contributes only a minor fraction of the lumber marketed as white pine. The lumber from the eastern white, the grey and the red pine is mostly cut in the northern border states from Maine to Minnesota. Western white-pine lumber is practically all produced in Idaho and Washington.

Yellow-pine lumber is cut mainly in the southern states; 70% of the total is produced in 5 states: Mississippi, Louisiana, Alabama, Texas and Georgia, which rank in the order named. The kinds of pine furnishing yellow-pine lumber all belong to the *itch-pine* group, and include the longleaf, loblolly, shortleaf, sand, slash, pitch, spruce, pond, mountain and Virginia pine, the longleaf, shortleaf, loblolly and slash pines ranking among the most important.

Ponderosa-pine lumber, practically all cut from *P. ponderosa*, is produced chiefly in Oregon, 32%; California, 25%; Washington, 14% and Idaho, 12%.

Sugar-pine lumber, cut from a single species (*P. lambertiana*) and produced commercially only in California (97.5%) and Oregon (2.5%), commands the highest average price at the mill of any pine lumber cut in the United States. Lodgepole-pine lumber is produced in small quantities in the Rocky mountain states; Wyoming contributing 48%; Colorado, 42%; Montana, 5% and Utah, 4%, of the total footage.

For further details see A. Engler and K. Prantl, *Die natürlichen Pflanzenfamilien* (1887-1908); A. Veitch, *Manual of the Coniferae* (1915); C. S. Sargent, *Manual of the Trees of North America* (1905, 2nd ed., 1922); L. H. Bailey, *Manual of Cultivated Plants*, (1924); G. B. Sudworth, "Check List of the Forest Trees of the United States," *U.S. Dept. Agric. Misc. Cir.* 92 (1927); W. M. Harlow and E. S. Harrar, *Textbook of Dendrology* (1937, 1941). (E. S. HR.; X.)

PINEAPPLE. The pineapple, *Ananas comosus*, is a member of the family Bromeliaceae. The plant consists of a rosette of stiff succulent leaves on a massive upright stem about two feet long. After 15 or 20 months a determinate inflorescence with lavender flowers appears that is formed on a flower stalk several inches in length. The originally separate flowers together with their bracts consolidate, become fleshy and form the pineapple fruit which ripens 5-6 months later. Seeds are only occasionally formed. There are many varieties of pineapples but those of im-

portance may be classified as falling into the Cayenne, Queen or Spanish groups. The smooth Cayenne variety is practically the only one employed for canning, the others being used chiefly for small local fresh fruit markets.

The pineapple is believed to be a native of Central and South America, although early Spanish and Portuguese explorers found it under cultivation and growing wild in the West Indies. The earliest record concerning it appears to be the statement by Peter Martyr that Christopher Columbus saw pineapples at Guadaloupe Island in 1493. Before the end of the 16th century, however, pineapple plants had been taken by missionaries and navigators

PINEAPPLE (*ANANAS COMOSUS*), FROM A MODERN PHOTOGRAPH OF PINEAPPLES GROWING IN THE OPEN

into India, Africa, China and the East Indies. It was probably one of the first plants to come from America to Africa and Asia. This was possible because the pineapple plant can be kept out of the ground for months and yet grow when set in moist soil. Requiring a tropical or semitropical climate, it is not grown on the continent except to a very limited extent in hothouses. Hothouse culture of pineapples for the European fresh fruit market is, however, one of the principal industries of the Azores.

For planting there are employed *crowns*, the leafy green top of the fruit, *slips* which develop on the flower stalk and *shoots* which originate in the leaf axils of the stem. Shoots that are allowed to remain on the stem produce the second crop commonly called the first ratoon. After one or two ratoon crops, fields are plowed under and replanted. In the wild state the ratoons after fruiting fall over on the ground, become rooted along with crowns and slips and a large area may eventually be growing derived from the same parent plant.

Pineapple leaves possess specialized tissues for storing water that enable the plant to remain alive for long periods without rain. Consequently, there are many thousands of productive acres of semiarid land in Hawaii which would be largely useless were it not for the pineapple plant. Asphalt impregnated black mulch paper through which pineapple plants are set, at the rate of 15,000-20,000 plants per acre, serves to conserve soil moisture and in comparatively wet areas to limit meed growth. The pineapple plant lends itself particularly well to the practice of mulching with paper. Water from light showers or dews that might otherwise be lost by evaporation may flow along the trough-like upper surface of the leaves toward the centre of the plant down through the planting hole in the mulch paper to the soil below. Some fertilizer is used under the paper at planting, but very liberal amounts are often placed in the lower axils of the leaves and are thus carried down by water and made available to the roots.

Chemical fertilizers are employed and the kind, amount and timing of the applications varies enormously with the soil and environment. On some of the larger plantations fertilization is a comparatively precise procedure determined by frequent chemical analyses of representative plants in the field. By this method, even with fluctuating weather, proper adjustment of fertilization to the measured needs of the plants permits a condition of bal-

anced nutrition that favours the development of fruit of uniformly high quality.

In 1941 the total known world pack of canned pineapple and pineapple juice was over 25,000,000 cases (45 lb. net per case). Of this total, over 21,000,000 cases were produced in Hawaii and sold almost entirely in the continental United States. Somewhat over half of the Hawaiian crop was marketed as juice. Elsewhere comparatively little juice was produced. In the year mentioned the Philippines processed about 1,000,000 cases of solid pack pineapple, and a somewhat greater quantity was probably canned in Taiwan (Formosa). Practically the entire Philippine pack and about half of that of Taiwan was sold in the United States. Production in British Malaya was 500,000 cases, 333,000 cases in both Australia and Cuba and less than 100,000 cases each in Puerto Rico, Costa Rica, South Africa and Fiji.

Fresh fruit imports to the United States in 1941 were about 32,000 tons, mostly from the West Indies along with small quantities from Mexico and South America. Florida no longer produces pineapple in commercially significant volume. The sale of fresh pineapples is comparatively small and confined in large part to easily accessible distribution centres.

Highest quality is not developed except when the pineapple is allowed to become fully ripe on the plant. The fruit contains practically no starch but as the pineapple matures, starch in the stem is changed to sugars and transferred to the fruit. Much of this transfer takes place just prior to complete ripeness, when the fruit may nearly double in sugar content. For other than local markets the fruit must be harvested in varying degrees of unripeness to suit the time required in transit. For this reason canned pineapple from fruits allowed to become fully ripe is usually of comparatively high quality. (G. T. N.)

PINE-BEETLE, the name applied to several beetles (see COLEOPTERA) that attack pines and other coniferous trees, particularly in North America. The most important of these are *Dendroctonus ponderosa* which has done great damage to the timber of the Black Hills forest reserve; it attacks the main trunk of the tree.

The wood engraver bark beetle (*Xyleborus coelatus*) attacks the white and yellow pines (*Pinus strobus* and *P. palustris*), while *X. pubescens* feeds on *P. inops*. All these beetles belong to the bark-boring family Scolytidae. (See COLEOPTERA; ENTOMOLOGY: *Economic*.)

PINE BLUFF, a city of Arkansas, U.S.A., 45 mi. S.S.E. of Little Rock, on the south bank of the Arkansas river, at an altitude of 215 ft.; county seat of Jefferson county. It is served by the Missouri Pacific and the St. Louis Southwestern railways, and has a municipal airport of 600 ac., 5.2 mi. southeast of the city. Pop. (1930) 20,760 (33% Negroes); in 1940, 21,290 by the federal census.

The city stands on bluffs overlooking the river. It is the seat of the state industrial school for boys, and of the Agricultural, Mechanical and Normal school for Negroes (opened 1875), a branch of the state university. Its wholesale and jobbing business covers most of southern Arkansas, and parts of Texas, Louisiana and Mississippi. Its manufactures in 1940 were valued at \$16,781,528, and included railway shops, lumber mills and woodworking plants, and factories making locomotive and car castings, brake shoes, cotton-seed delinting, mixed feeds, world's largest archery factory. The cotton exchange handles 250,000 bales in a normal year, of which 50,000-75,000 bales (of strong fibre, and averaging 1½ in. in length of staple) is grown in Jefferson county. There is an ample supply of natural gas and hydroelectric current. The city's assessed valuation for 1940 was \$8,861,140. Bank deposits on April 4, 1941, aggregated \$17,304,445. Pine Bluff was laid out in 1832 and chartered as a city in 1835.

PINEHURST, a winter resort in the longleaf pine region of the sandhills belt of North Carolina, U.S.A., 75 mi. southwest of Raleigh on federal highway 15 and the Norfolk and Southern railroad, 550 ft. above sea level. The resident population (1940) was 1,284, and the number of visitors averages about 10,000 through the season (from October to May). Pinehurst

was established by the late James W. Tufts, Boston soda-fountain manufacturer who purchased 5,000 ac. of cut-over timber land from the late Ambassador to England Walter Hines Page and his brothers.

Frederick Law Olmsted made the original landscape plan and the town is famous for its winding shrubbery-bordered roads and atmosphere of a small New England country village. It is the leading winter resort for golf, the Pinehurst Country club having three 18-hole courses, all laid out by Donald Ross, the championship course being rated by professionals as one of the best in the country. Except for the national championships, the club's annual North and South golf tournaments are the oldest established amateur and professional events in America. Pinehurst is recognized as providing ideal winter conditions for horses. Aside from the many private riding horses brought down each fall by horse lovers, harness horses, steeplechasers, and some runners and show horses are wintered and trained here. There is an excellent airport near Pinehurst and a modern hospital.

The village is well equipped, there being both a public and a private school, a modern motion picture theatre, ample store and shopping facilities, a model dairy, a greenhouse, fireproof garage, library, etc. There is a non-sectarian church for winter visitors known as the Village chapel, a Catholic church and a non-sectarian Community church for the permanent residents. Many fine winter homes have been built in and around the village and most of these are occupied for the full six months of the season. Pinehurst is not incorporated as a municipality, the utilities as well as the principal hotels being owned and operated by Pinehurst, Incorporated.

PINEL, PHILIPPE (1745-1826), French physician, was born at Saint-André, Tarn, France, on April 20, 1745. He studied at Lavaur and afterward at the university of Toulouse, where he took his doctor's degree in 1773. From Montpellier he removed in 1778 to Paris, engaging there chiefly in literary work connected with his profession.

His first publication was a French translation of William Cullen's *Nosology* (1785); it was followed by an edition of the works of G. Baglivi (1788), and in 1791 he published a *Traité medico-philosophique sur l'aliénation mentale* in which he advocated a more humane treatment of the insane. It is on this advocacy and on the practical effect he was able to give to his ideas that his fame rests. His opportunity came with his appointment in 1792 as head physician of the Bicêtre, and two years afterwards of the Salpêtrière.

His chemical lectures at the Salpêtrière formed the basis of his *Nosographie philosophique* (1798) which was further developed in *La Médecine clinique* (1802). Pinel was made a member of the Institute in 1803, and soon afterwards was appointed professor of pathology in the *École de Médecine*. He died at Paris on Oct. 26, 1826.

See notices by E. Pariset and Esquirol in *Mémoires de l'Académie de Médecine* (1828).

PINELLI, BARTOLOMEO (1781-1834), Italian painter and engraver, was born in Rome, where he studied at the Academy of St. Luke. When his father was forced to flee Rome because of debt, Pinelli accompanied him to Bologna and attended school there, returning to Rome several years later. Within a short time after his return he achieved wide popularity, becoming particularly well known for his scenes of Rome and Tivoli. His principal media were water colour and etching and his principal subjects, besides landscapes and views, were historical scenes of ancient Greece and Rome, drawings of costumes of the two countries and the illustration of such authors as Virgil, Dante, Tasso, Aretino and Cervantes.

He died at Rome in 1835.

PINENUT or **PIÑON**: see NUT.

PINERO, SIR ARTHUR WING (1855-1934), English dramatist, was born in London on May 24, 1855, the son of John Daniel Pinero, a Jewish solicitor, whose family was of Portuguese origin, long established in London. A. W. Pinero was engaged in 1874 as an actor at the Theatre Royal, Edinburgh, and came to London in 1876, to play at the Globe theatre. Later in the year

he joined the Lyceum company, of which he remained a member for five years. The first piece of his to see the footlights was *£200 a Year*, played in Oct. 1877, at the Globe theatre for the benefit of F. H. Macklin.

The first play to make a hit was *The Money Spinner* (Theatre Royal, Manchester, Nov. 1880); but in *The Squire* (St. James's Theatre, Dec. 1881) he attempted serious drama, and gave promise of the qualities of his later work. In 1883 and 1884 Pinero produced seven pieces, but the most important of his works at this period were the successful farces produced at the Court theatre: *The Magistrate* (March 1885), which ran for more than a year; *The Schoolmistress* (March 1886); *Dandy Dick* (Jan. 1887), revived in February 1900; *1772 Cabinet Minister* (April 1890), and *1776 Amazons* (March 1893). Two comedies of sentiment, *Sweet Lavender* (Terry's, March 1888) and *The Weaker Sex* (Theatre Royal, Manchester, Sept. 1888), met with success, and *Sweet Lavender* has enjoyed numerous revivals. With *The Profligate* (Garrick, April 1889) he returned to the serious drama which he had already touched on in *The Squire*. Out of deference to the wishes of John Hare the play was fitted with the conventional "happy ending," but the original denouement was restored, with great advantage to the unity of the play, in the printed version.

1776 Second Mrs. Tanqueray (St. James's, May 27, 1893) dealt with the converse of the question propounded in *The Profligate*, but with more art and more courage. The piece aroused great discussion, and placed Pinero in the front rank of living English dramatists. It was translated into French, German and Italian, and the part of Paula Tanqueray, created in the first place by Mrs. Patrick Campbell, attracted many actresses, among others Eleonora Duse.

His later plays include *The Notorious Mrs. Ebbsmith* (1895), *1776 Benefit of the Doubt* (1895), *The Princess and the Butterfly* (1897), *Trelawney of the Wells* (1898), *The Gay Lord Quex* (1899), *Iris* (1901), *Letty* (1903), *A Wife Without a Smile* (1904), *His House in Order* (1906), *The Thunderbolt* (1908), *Mid-Channel* (1909), *Preserving Mr. Panmure* (1911), *The Widow of Wasdule Head* (1912), *Playgoers* (1913), *The Big Drum* (1915), *Mr. Livermore's Dream* (1917), *The Freaks* (1918), *A Seat in the Park* (1922), *The Enchanted Cottage* (1922), *A Private Room* (1928), *Dr. Harmer's Holidays* (1930), *Child Man* (1930) and *A Cold June* (1932). He also wrote (1918) *Monica's Blue Boy*, a play without words, performed to music by Sir Frederic Cowen. He was knighted in 1909.

Pinero died Nov. 23, 1934.

His *Plays* (11 vols. 1891-1895) have prefaces by M. C. Salaman. See also H. Hamilton Fyfe, A. W. Pinero (1902).

PINEROLO, city and episcopal see of Piedmont, Italy, in the province of Turin. Pop. (1936) 15,363 (town); 21,600 (commune).

It is built on a hillside just above the valleys of the Chisone and the Lemina, at a height of 1,234 ft. above the sea, 24 mi. by rail S.W. of Turin.

Till 1696 it was strongly fortified with a citadel on Santa Brigida, a castle on S. Maurizio, and city walls constructed by Thomas I of Savoy. It has a cathedral (St. Donatus), the palace of the princes of Acaia and other buildings of some interest. Pinerolo was bestowed on the bishops of Turin by Otto III in 996, but in 1078 the countess Adelaide made it over to the Benedictine abbey of Santa Maria, in whose possession it remained till 1159.

Thomas I of Savoy captured the castle in 1188, and in 1246 the commune formally recognized the supremacy of Savoy. Passing in 1295 into the hands of Philip, son of Thomas III, Pinerolo became his residence and capital, a distinction which it retained under Amadeus VIII of Savoy.

Francis I of France obtained possession of the town in his descent into Italy, but Emmanuel Philibert received it back from Henry III in 1574. A second occupation by the French occurred under Cardinal Richelieu. The French language was imposed on the people, great fortifications were constructed, and the fortress (Pignerol) was used as a state prison for such men as Fouquet,

De Caumont and the man with the iron mask. Victor Amadeus bombarded the place in 1693, and ultimately compelled Louis XIV to relinquish his hold on it, but before the withdrawal of the French troops the defenses were demolished. In 1748 the town was made a bishop's see.

PING-PONG: see TABLE TENNIS.

PINGUICULA. A genus of carnivorous plants of the family Lentibulariaceae and thus related to *Utricularia* (*q.v.*) and *Genlisea*. It contains about 30 species, widely distributed in the northern hemisphere and along the Andes to Patagonia in South America, always in wet situations with acid soil. The plant consists of a rosette of leaves and simple scapes bearing attractive purple or yellow flowers with entire corollas, bilaterally symmetrical and provided with a nectar secreting spur. The trapping mechanism consists of very numerous stalked mucilage glands on the upper surfaces of the leaves which are usually ovate in form, with upturned margins. The digestive glands, also numerous, are sessile and depressed to the level of the leaf surface. Only very small flies, etc., can be caught, and experimental attempts to study the digestive powers of the plant by placing larger bits of food (fibrin, etc.) caused decay of the leaf. Larger insects always escape. The glands are of simple structure, much like those of *Byblis*. It was shown by Charles Darwin that the leaves are capable of movement, which, however, is not rapid or of great amplitude. When an insect is caught near the margin, the latter folds over the prey, causing for the time being a greater contact of glands with the body. After some time the margin again unfolds, the process occupying some days, but varying with the temperature. Darwin recorded a cycle of reaction within 24 hr. The response takes place when inanimate objects are placed in suitable positions on the leaf surface.

Small leaves, such as those of heaths, and pollen and small seeds were thought by Darwin to be of probable use to the plant, since all contain nitrogen.

The leaves of *Pinguicula* have been used by the Lapps, the Welsh and the peasants of the Italian Alps for the curdling of milk, producing "taettemaelk" (ropy- or long-milk) as it is called in Norway. It is also used therapeutically in the healing of wounds, when mixed with linseed oil, according to J. W. Hornemann. The biochemistry of the coagulation effect is not fully understood.

See J. W. Hornemann, *Forsøg til en Dansk oeconomic Plantelaere* (Copenhagen, 1821); R. C. McLean, "The Anaerobic Treatment of Wounds," *Life and Its Maintenance* (1919); Charles Darwin, *Insectivorous Plants* (1875); F. E. Lloyd, *The Carnivorous Plants* (1942); K. G. Dernby, "Die Proteolytische Enzyme der *Pinguicula vulgaris*," *Bioch. Zeitschr.* 80 (1917). (F. E. L.)

PINK, in botany, the common name for a numerous genus (*Dianthus*) of the pink family (Caryophyllaceae, *q.v.*). There are about 250 species, natives of the old world but found chiefly in the Mediterranean region. They are herbaceous perennials of low stature, often with very showy flowers. Four species grow wild in Great Britain: the Deptford pink (*D. armeria*), the maiden pink (*D. deltoides*), the Cheddar pink (*D. caesius*) and the proliferous pink (*D. prolifer*). Two others, the garden pink (*D. plumarius*) and the clove pink or carnation (*D. caryophyllus*), are more or less naturalized in Great Britain. The carnation (*q.v.*) and picotee are modifications of the clove pink. The sweet-william is derived from the Eurasian *D. barbatus*.

The term pink is also applied to related plants in the genera *Silene* and *Lychnis*, as well as to the sea-pink, or thrift (*Statice armeria*) and the related genus *Limonium*, both members of the family Plumbaginaceae.

PINKERTON, ALLAN (1819-1884), American detective, was born in Glasgow, Scotland, Aug. 25, 1819. In 1842 he emigrated to Chicago, Ill., and in 1843 he removed to Dundee, Kane county, Ill. Here he ran down a gang of counterfeiters and was therefore appointed a deputy-sheriff of Rane county in 1846 and immediately afterwards of Cook county, with headquarters in Chicago. There he organized a force of detectives to capture thieves who were stealing railway property. This organization developed in 1852 into Pinkerton's National Detective Agency,

since well known for its activities in industrial disputes, etc. Some of his notable successes were the capture of the principals in the theft of \$700,000 from Adams Express Company in 1866, and the uncovering of a plot to assassinate President-Elect Lincoln in February 1861, when he arrived in Baltimore on his way to Washington. In 1861 Pinkerton organized a system of obtaining military information in the Southern States, and from this system he developed the Federal secret service. One of his detectives, James McParlan, from 1873 to 1876 lived among the Molly Maguires (*q.v.*) in Pennsylvania and secured evidence which led to the breaking up of the organization. Pinkerton died in Chicago on July 1, 1884. He published *The Molly Maguires* and the *Detectives* (1877), *The Spy of the Rebellion* (1883), in which he gave his version of President-elect Lincoln's journey to Washington; and *Thirty Years a Detective* (1884).

PINKNEY, WILLIAM (1764-1822), American lawyer and statesman, was born in Annapolis, Md., on March 17, 1764. He was admitted to the bar in 1786, and from 1788 to 1792 practised in Harford county. In 1788 he was a member of the State convention which ratified the Federal Constitution for Maryland (1788-92), and in 1795 of the house of delegates (where in 1788 and 1789 he defended the right of slave-owners to free their slaves), and from 1792 to 1795 of the State executive council. From 1796 to 1804 he was commissioner to England to determine the claims of American merchants under the Jay Treaty of 1794 and adjusted a claim of \$800,000 for Maryland on the Bank of England. In May 1806, with James Monroe, then minister at London, he was commissioned to treat with the British Government concerning the capture of neutral ships in time of war: from 1807 to 1811, after Monroe's return to America, he was resident minister in London. He was elected to the Maryland senate in Sept. 1811 and later was attorney-general of the United States, until 1814. In Aug. 1814 he was wounded at Bladensburg. He served in the National house of representatives Jan.-April 1816, and from 1816-18 was minister plenipotentiary to Russia and special minister to Naples, where he attempted to secure indemnity for the losses to American merchants by seizure and confiscation during the rule of Murat in 1809. He was a member of the committee which drew up the Missouri Compromise (*q.v.*). He was a member of the United States Senate from 1820 until his death, at Washington, on Feb. 25, 1822.

See William Pinkney, *The Life of William Pinkney* (1853) (1810-83); Henry Wheaton, *Some Account of the Life, Writings and Speeches of William Pinkney* (1828).

PINNACLE, in architecture, any vertical, decorative motive serving as the upper termination of a building or other form; hence, metaphorically, a summit or topmost limit. The word is distinguished from finial (*q.v.*) as signifying a larger motive, sometimes of considerable complexity, whereas a finial is a single ornament, and from tower or turret by the fact that a pinnacle is always a strictly subsidiary motive. Thus a Gothic tower and spire may be decorated with pinnacles, each one of which is capped by a finial. The chief architectural development of the pinnacle was in connection with buttresses (*q.v.*) of late Romanesque and Gothic buildings, as the addition of a pinnacle to a buttress not only added to the stability by increasing the weight, but also gave a decorative termination to the vertical line. Earlier pinnacles are simple square or rectangular structures capped with gable roofs or small spires, as in St. Remi at Reims (middle 12th century), and in the west front of Rochester cathedral (1130). With the development of the flying buttress (*q.v.*) pinnacles were increased greatly in size, and especially in France, in richness, and usually decorated with colonnettes on the outer corners and arches and crocketed gables above, sometimes with the addition of slender crocketed

PINNACLE. LEFT: NOTRE DAME, PARIS; RIGHT: REIMS CATHEDRAL

spires. Those of Notre Dame at Paris (end of 12th and beginning of 13th centuries) are typical. The most beautiful of the developed Gothic buttress pinnacles are those of the choir of Reims cathedral (c. 1240), in which the solid portion is preceded by an open shrine with a statue of an angel. In England, pinnacles were especially developed during the Decorated Period (*q.v.*) and play an important part in the tower designs in which they serve to soften the transition between a square tower and a spire above. Characteristic examples are those of Beverley minister (c. 1350) and the tower of St. Mary's at Oxford (c. 1300).

The modern emphasis on vertical lines, resulting from steel construction, has led to a recrudescence of the use of pinnacles, and, especially in the tall buildings of America, they are common decorations of the sky line and of the various set-backs.

PINOCLE is a game of cards, similar to the French game of "bezique." It can be played by two, three or four persons.

Short Pinocle is played with two packs, from which all cards below the 9's are left out. The cards remaining are in order of value: 9, knave, queen, king, 10, ace (high). Twelve cards are dealt to each player, four at a time, and the next card is turned as a trump. It is placed under the pack, face up. If it is a 9, it is called the "dix" (pronounced "dece"), and the dealer scores 10 points for turning it. If any other card is turned, either player who has a 9 of trumps, after he has taken a trick, may take up the turned trump into his hand, and put his 9 face up, under the pack, and score 10 points for his 9. The holder of the other dix may lay it on the table, after he has taken a trick, and add 10 to his score.

The scoring is done by "melding," a word which comes from a German verb *melden*, to announce. After either player has taken a trick, he can lay the cards to be melded on the table, face up, and add the value of that meld to the score, but only one meld can be made after each trick taken. The values of the meld are as follows: the dix is 10; a marriage (any king and queen of same suit) 20; a royal marriage (a king and queen of trumps) 40; pinocle (the knave of diamonds and queen of spades) 40; 4 aces of different suits 100; 4 kings of different suits 80; 4 queens of different suits 60; 4 knaves of different suits 40; a royal straight (ace, 10, king, queen and knave of trumps) 150.

In melding, at least one new card must be laid out for each new meld. For instance, with spades for trumps, holding 150, the king and queen should be laid out first, and 40 trumps melded; then, after taking another trick, the ace, 10 and knave are laid down, and 150 melded. Then, if the player has the knave of diamonds, after taking another trick, it may be laid by the queen of spades, and pinocle melded. This order of melding, however, can only be followed when there are enough cards left in stock to be sure the player will have time, as no meld can be made after the last card is drawn from the stock. Otherwise 150 should be melded at once.

The cards left after the trump is turned are called "stock cards," and after each trick is taken in, and laid away, face down, each player draws a card, the winner drawing first. After they draw, no player can meld until he has taken another trick. Each player keeps in mind a count of the cards he has taken in play. They count as follows: aces 11, tens 10, kings 4, queens 3, and knaves 2 points; and he adds the total of those made to his melding score. The player who takes the last trick also adds 10. The total of the points in the two hands, including the last trick, is 250.

A player may follow suit, trump or discard, but after the last stock card has been drawn, each must follow suit or trump. If void both of the suit and trump, he may discard. One who violates this law loses the cards in the tricks he has won, in that hand. The game is 1,000 points, and when a player who has the lead believes that the value of cards in the tricks he has taken, added to the points he has already scored, equals 1,000, he may call "out" and stop the play. If he is short of the points, he loses the game.

Auction Pinocle has generally taken the place of short pinocle. Only in number of cards used, the values of the melds and the values of the cards and dices are the games the same. Only three can play auction pinocle. If a fourth takes part, each dealer in turn takes no cards, and sits out during the play, but wins or loses the same as those who play against the successful bidder.

Fifteen cards are dealt to each player, usually three at a time, and at some time during the deal, three cards are dealt to the table, face down, and remain there. These are often called the "widow" or "dummy." Each player in turn, beginning with the eldest hand, may pass or may bid for the privilege of declaring the trump, and playing the hand. If all pass, the hands are thrown up, and there is a new deal. If bids are made, the first bid usually must be at least 200 or 250 (in some clubs at least 300), but may be whatever more the bidder thinks he can make. Each following bid must be at least 10 more, and the bidding continues until two players have passed. A player who has passed cannot bid again on that hand. When two pass, the bidding stops, and the contract goes to the last bidder, who becomes the contractor. The contractor now turns the three cards in the "widow" face up on the table, and adds them to his hand. He declares a trump, and lays his melds on the table, face up. In addition to the melds given above, the contractor may meld a "round trip" 240, if he holds a king and a queen in each suit, but if he makes this meld, a royal straight counts only 110. If these values, added, make his bid, he has won his contract, and the other players pay; but if, after counting his melds and dices, he is short of the points bid, and his opponents refuse to concede the contract, he may play the hand and try to make up the shortage from the count of the cards in the tricks he takes. If he feels he cannot make his bid, he does not play, but pays.

If the contractor decides to play, he takes all the cards up from the table, lays three not melded, face down from his own hand, which count as a trick for him. If he fails to lay these cards out, he loses. If he lays a trump he must announce it. He now leads, and the other two are partners against him. In the play of the hand, every player must follow suit or trump. If void both of the suit led and trumps, a player may discard any card on the trick. If trumps are led, each player that follows must play a higher card and win the trick if he can. If void of trumps, he may discard. The last trick counts ten for the one who wins it. If the number of points made by the value of the cards in the tricks the contractor wins, added to the points in his meld, make the number that he has bid, he collects for the number of points bid, from the players, no matter how many points he has made. If the bid is 300, and he makes 500 points, he can only collect for 300. If the contractor plays the hand and fails to make his contract, he must pay double.

Each deal is a complete game, and is usually paid for at once by the losers. For convenience, instead of keeping a score, each player usually takes 25 poker chips. At the end of the hand, each player pays 2 chips for any loss under 300, 3 chips for a loss between 300 and 340, 5 chips for a loss from 350 to 390, 10 chips for a loss from 400 to 440, 15 chips for a loss from 450 to 490, 20 chips for a loss of 500. These figures are purely arbitrary. Players give any value they wish to each chip. At the end of the sitting, each player owes for the 25 chips he had at the beginning, and collects for all the chips he has won, or pays for all the chips he has lost.

(C. L. P.)

PINSK, a town of Poland, in the province of Polesie, at the confluence of the Strumen and Pina rivers, 196 mi. S.W. by rail of Minsk. The river Pina connects it with the fertile regions in the basin of the Dnieper, and, by means of the Dnieper-and-Bug canal, with western Poland and Prussia, while the Oginski canal connects it with the basin of the Niemen. Pottery, leather, oil, soap and beer are the chief products of the local industries. The draining of the marshes around Pinsk was begun by the Russian government in 1872. Pinsk (Pinesk) is first mentioned in 1097 as a town belonging to Sviatopolk, prince of Kiev. In 1132 it formed part of the Minsk principality. After the Mongol invasion of 1239-42 it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania; and in 1569, after the union of Lithuania with Poland, it was the chief town of the province of Brest. Pinsk was annexed to Russia in 1795, and restored to Poland in 1918. Soviet troops occupied it in 1939, and it was taken by Germany in 1941, during the Russian invasion.

PINT, a liquid measure of capacity, equivalent to $\frac{1}{8}$ of a gallon (derived probably through Spanish, from Lat. *pincta*, picta, a

painted or marked vessel). The imperial British pint = .57 of a litre, 34.66 cu. in. The United States standard pint = .47 of a litre, 28 $\frac{1}{2}$ cu. in.

PINTO, FERNÃO MENDES (1509-1583), Portuguese adventurer, was born at Montemôr-o-Velho, of poor parents, and entered the service of a noble lady in Lisbon. He embarked for India in 1537 in a fleet commanded by the son of Vasco da Gama, and for 21 years travelled, fought and traded in China, Tartary, Pegu and the neighbouring countries, sailing in every sea, and introducing the musket into Japan. Though he was 13 times a captive and 17 times sold into slavery, his gay and dauntless spirit brought him through every misfortune. He was soldier and sailor, merchant and doctor, missionary and ambassador; moreover, as the friend and travelling companion of St. Francis Xavier, he lent the apostle of the Indies the money with which to build the first Jesuit establishment in Japan.

In Jan. 1554 Pinto was in Goa, waiting for a ship to take him to Portugal, when he decided to devote a large part of his capital to the evangelization of Japan. The viceroy appointed him ambassador to the king of Bungo in order to give the mission an official standing, and on April 18th he set sail with the provincial, Father Belchior Nunes. The missionaries did not reach Japan until July 1556. On Nov. 14, 1556, Father Belchior and Mendes Pinto began their return voyage and reached Goa on Feb. 17, 1557. During his stay of a twelve-month there, Pinto left the company, being dispensed from his vows for want of vocation at his own request, though a modern authority states that he was expelled because he was a *marrano*, i.e., had Jewish blood. He finally returned to Portugal on Sept. 22, 1558, and settled at Pragal near Almada, where he married and wrote his famous book, the *Peregrination*; the ms., in fulfilment of his wishes, was presented by his daughter to the Casa Pia for penitent women in Lisbon, and it was published by the administrators in 1614. Philip II. of Spain gave him (1583) a pension for his services in the Indies. But the reward came too late, for he died on July 8.

Pinto was on the whole a careful observer and truthful narrator, but he invented on occasion, and often repeats stories at second hand. Some witty Portuguese parodied his name into *Fernão, nzenfes? Minto!* ("Ferdinand, do you lie? I do!"); and the English dramatist Congreve only expressed the general opinion of the unlearned when he wrote in *Love for Love*, "Mendes Pinto was but a type of thee, thou liar of the first magnitude." In the narrative portions of his work Pinto's style is simple, clear and natural. He did for the prose of Portugal what Camoens did for its poetry.

The *Peregrination* has gone through many editions subsequent to that of 1614, and in 1865 Castilho published excerpts in his *Livraria classica portugueza* with an interesting notice of Mendes Pinto's life and writings. Versions exist in German (3 editions), French (3 editions), Spanish (4 editions), and in English by Henry Cogan, London (1663, 1692 and—abridged and illustrated, with introduction by Arminius Vambéry—1891). Cogan omits the chapters relating to Mendes Pinto's intercourse with, and the last days of, St. Francis Xavier, presumably as a concession to anti-Catholic prejudice.

See Christovão Ayres, *Fernho Mendes Pinto* (Lisbon, 1904). *Fernho Mendes Pinto e o Japão* (Lisbon, 1906); also *Subsídios . . . para a biographia de Fernho Mendes Pinto* by Jordão de Freitas (Coimbra, 1905).

PINTO. The brown, black and blue spots of discoloration of the whole body endemic in Mexico, Panama, Colombia and Venezuela, and known under the name were first held by Gastambide (*Press med. Belge*, 1881, Nos. 33-41) as due to a vegetable parasite, whose spores and mycelial filaments may be detected among the deeper rows of cells of the rete mucosum. The disease appears to be one of poverty, but it is contagious, and is sometimes seen in the well-to-do. In villages of Tabasco (Mexico) it is said that 9% of the people thus suffer.

PINTURICCHIO (1454-1513), Italian painter of the Umbrian School, whose full name was BERNARDINO DI BETTO (BENEDETTO) DI BIAGIO, the son of a citizen of Perugia, Benedetto or Betto di Biagio. He was probably a pupil of Fiorenzo di Lorenzo; and the two masters appear to have co-operated in the execution of the "Adoration of the Magi" from S. Maria Nuova, now in the Pinacoteca of Perugia. After assisting Perugino in

the execution of his frescoes in the Sistine Chapel, Pinturicchio was employed by Niccolò Buffalini, advocate to the papal consistory, to decorate a little Gothic chapel in Ara Coeli on the Capitol with frescoes illustrating the life of San Bernardino of Siena. These frescoes were probably executed about 1484. They show the master at his best. The colouring is exceedingly harmonious, the landscape backgrounds full of atmosphere. Pinturicchio was employed by the Della Rovere family to decorate a series of chapels in the church of S. Maria del Popolo. The "Adoration of the Shepherds," in the chapel built by Cardinal Domenico della Rovere, was probably done about 1500. In the lunettes under the vault Pinturicchio's assistants painted small scenes from the life of St. Jerome.

The last paintings completed by Pinturicchio in this church were the frescoes on the vault over the retro-choir, a very rich and well-designed piece of decorative work, with main lines arranged to suit their surroundings in a very skilful way. No finer decoration of a quadripartite vault exists.

In 1492 Pinturicchio was summoned to Orvieto, where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome, and was employed by Pope Alexander VI. (Borgia) to decorate a suite of six rooms in the Vatican, which Alexander had just built. Of these rooms, called after their founder the *Appartamenti Borgia*, five still retain his frescoes. The upper parts of the walls and vaults are not only covered with painting, but further enriched with delicate stucco work in relief. Pinturicchio employed many assistants. The second room, however, with scenes from the lives of saints, was painted by the master himself, and contains one of his famous works, "The Dispute of St. Catherine."

On the vault of the sacristy of S. Cecilia in Trastevere, Pinturicchio painted the Almighty surrounded by the Evangelists. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now, like the rest of his work at Orvieto, almost destroyed.

Among his panel pictures the following are the most important. An altarpiece for S. Maria de' Fossi at Perugia, painted in 1496-1498, now moved to the picture gallery, is a Madonna enthroned among saints, graceful and sweet in expression. Another fine altarpiece, similar in delicacy of detail, and probably painted about the same time, is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin, with the apostles and other saints below. Several well-executed portraits occur among the kneeling saints. Other panel paintings by Pinturicchio exist in the cathedral of Spello, in the Siena gallery, at Perugia, and in the collection of the Earl of Crawford at Haigh Hall.

In 1501 Pinturicchio painted several fine frescoes in S. Maria Maggiore at Spello—all very decorative and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardinvs Pinturichivs Pervsinvs." The most striking of all Pinturicchio's frescoes, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1492 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Aeneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract specially provided that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. The series were finished in 1507. Outside the library, over the door, we have the coronation of Pius III. in which he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael. In 1513, the year of his death, he painted a highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. He died at Siena, on Dec. 11, 1513, and is ranked as one of the greater Umbrian painters. His worth has been undervalued, partly owing to the dislike which tinges Vasari's biography of him. Even Crowe and Cavalcaselle hardly did him

justice. G. Morelli has however disproved the myth that Raphael, then a youth of 20, supplied cartoons or drawings for the aged master in his work in the Libreria del Duomo, Siena. These drawings (Venice) are not by Raphael but by Pinturicchio.

See G. Morelli, *Italian Masters in German Galleries* (1883); Vermiglioli, *Mémoire de Pinturicchio* (Perugia, 1837); and the valuable notes and appendix of Milanesi's edition of Vasari, iii. 493-531 (Florence, 1878); E. Steinmann, *Pinturicchio* (Leipzig, 1898); E. M. Phillips, *Pinturicchio* (1901); W. Bombe, *Geschichte der Peruginer Malerei* (1912).

PINWELL, GEORGE JOHN (1842-1875), British water-colour painter, was born at Wycombe, and educated at Heatherley's Academy. Like Frederick Walker and A. B. Houghton, he belonged to a group whose style was derived from drawing upon wood for book illustration. As he died young his works are few, but their promise was great. His earliest drawings appeared in *Lilliput Levée*. He did a little work for *Fun* and executed several designs for the silversmiths, Elkingtons. In 1863 his first drawing appeared in *Once a Week*, and from that time his work was in constant demand in current periodicals. His most important productions, made for the Dalziel brothers, were illustrations of Goldsmith, of Jean Ingelow's poems, Robert Buchanan's *Balloads of the Affections*, and the *Arabian Nights*. Of Pinwell's pictures in colour, which are distinguished by a remarkable, jewel-like quality and marked by his strong love of pure, bright colour and opalescent effect, the chief are the two scenes from the *Pied Piper of Hamelin*, *Gilbert à Becket's Troth*, *Out of Tune* or *The Old Cross*, *A Seat in St. James's Park*, and *The Elixir of Life*.

In 1874 Pinwell fell seriously ill and went to Africa for the winter. He painted several remarkable pictures at Tangier, but he returned to die on Sept. 8, 1875.

See G. C. Williamson, *Life of George J. Pinwell* (1900).

(G. C. W.; X.)

PINZON, a family of Spanish navigators, of Palos in Andalusia, three members of which—Martin Alonzo, Francisco and Vicente Yañez, brothers—were associated with Columbus in the discovery of America.

MARTIN ALONZO PINZON, born about the middle of the 15th century, in the expedition of 1492, commanded the "Pinta," on which his brother Francisco was pilot. On Oct. 6, he suggested to Columbus (when already in the longitude of the Bermudas) to change the course of the expedition from due west to south-west; on Oct. 7 this suggestion was adopted, bringing the fleet to the landfall at Guanahani (San Salvador, Watling Island) in the Bahamas (Oct. 12, 1492). On Nov. 21, near the east end of the north coast of Cuba, he left Columbus, making eastward in search of the supposed gold-land. On Jan. 6, 1493, he rejoined the admiral, but on the return journey again left him and landed at Bayona in Galicia. He died soon afterwards.

VICENTE YAÑEZ PINZON commanded the "Nina" in 1492-1493 and remained loyal to Columbus throughout. In after years he made important discoveries on his own account. In December 1499 he sailed with four caravels across the Atlantic to the south-west, and on Feb. 7, 1500, he landed at Cape S. Agostinho, near its most easterly projection (called by him Cape Santa Maria de la Consolacion). Proceeding southwards a short distance, he then turned north, followed the coast to the north-west, discovered the Amazon estuary, and went as far as what is now Costa Rica. After touching at Haiti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in September 1500. Although he was created governor of the newly discovered lands by Ferdinand and Isabella, he did not take possession. In 1507 he sailed with Juan Diaz de Solis along the east coast of Central America. In 1509, again with De Solis, he coasted the Atlantic side of South America as far as the La Plata estuary, hoping to find an opening westwards leading to the Spice Islands. According to Herrera, he reached 40° S., not recognizing the La Plata and turning back about the mouth of the Rio Negro, but this is probably an exaggeration. After 1523 all traces of Vicente are lost.

PIOMBINO, a seaport of Tuscany, Italy, in the province of Livorno, 8 mi. by rail W.S.W. of Campiglia Marittima (which is 53 mi. S.S.E. of Pisa), 62 ft. above-sea-level, at the southern extremity of the peninsula of the Monte Massoncello Pop. (1936) 19,966 (town); 27,672 (commune). It is the port of embarkation for Elba, the nearest point of which is about 6 mi. to the southwest, and originally belonged to Pisa. It gives the title of prince to the Buoncompagni Ludovisi family, who, however, no longer own it. Large iron-smelting and tin plate works are situated here. In 1938 5,812 ships, of 1,455,000 tons, entered and cleared the port. Of this number, 5,794 ships of 1,393,000 tons were Italian.

PIOTRKÓW, a town of Poland, in the province of Lodz, 90 mi. southwest of Warsaw and 5 mi. west of the river Pilica. Pop. (1938) 51,300. It is a well-kept town, with numerous gardens, and has flour-mills, saw-mills, tanneries, agricultural machinery works, and breweries. One of the oldest towns in Poland. Piotrków was in the 15th and 16th centuries the place of meeting of the diets, and here the kings were elected. The town was captured by German troops in 1939, at the outset of World War II.

PIOZZI, HESTER LYNCH (1741-1821), English writer, well known as the friend (Mrs. Thrale) of Samuel Johnson, was born on Jan. 16, 1741, her father being John Salusbury of Bobbel, Carnarvonshire. In 1763 she married Henry Thrale, a rich Southwark brewer, whose house was at Streatham on the south-east corner of Tooting Bec Common. There was very little sympathy between the lively girl and Thrale, who was 13 years her senior, but gradually she drew round her a distinguished circle of friends.

She was introduced to Samuel Johnson in 1765 by Arthur Murphy, who was an old friend of her husband's. In 1766 Johnson paid a long visit to Streatham, and from that time was more or less domesticated with the Thrales. (See JOHNSON, SAMUEL.) Fanny Burney was another of her friends. She was very sensitive, and sometimes thought that Mrs. Thrale gave herself airs of patronage. Meanwhile, in 1772, Thrale was threatened with bankruptcy. The situation was saved by his wife's efforts, and in the next year Thrale travelled, leaving her in charge of his affairs. He was twice returned for the borough of Southwark, chiefly through her efforts. In 1781 Thrale died, and Dr. Johnson helped the widow with her business arrangements, advising her to keep on the brewery, until she "cured his honest heart of its incipient passion for trade, by letting him into some, and only some, of its mysteries." The brewery was finally sold for £135,000.

Mrs. Thrale had met Gabriele Piozzi, an Italian musician, in 1780. In 1784 they were married. Johnson told Miss Burney that he drove the memory of Mrs. Thrale from his mind, burning every letter of hers on which he could lay his hand. The Piozzis presently left England to travel in Italy. At Florence they fell in with Robert Merry and the other "Della Cruscan" writers ridiculed by William Gifford in his *Maeviad* and *Baviad*, and she contributed some verses to their *Florence Miscellany* in 1785. In 1786 she published *Anecdotes of the late Samuel Johnson, during the last twenty years of his life*, which was severely criticized by Boswell. She was ridiculed by "Peter Pindar" in *Bozzy and Piozzi; or the British Biographers, A Town Eclogue* (1786). But though Miss Burney and some others held aloof, the Piozzis found plenty of friends when they returned to London in 1787. Piozzi died at Brynbellia, a villa he had built on his wife's Flintshire estate in 1809, and Mrs. Piozzi gave up her Welsh property to her adopted son, and spent most of the rest of her life at Bath and Clifton. She retained her vivacity to the last, celebrating her 80th birthday by a ball to six or seven hundred people at Bath. She died at Clifton on May 2, 1821.

From 1776 to 1809 she kept a note-book which she called "Thraliana." Her well-known poem of the "Three Warnings" is to be found in many popular collections. *Letters to and from the late Samuel Johnson* appeared in 1788; *Observations and Rejections made in the course of a Journey through France, Italy and Germany*, in 1789; and in 1801 she published *Retrospection; or a review of the most*

striking and important events, characters, and situations . . . which the last eighteen hundred years have presented to the view of mankind (1801).

See *Letters and Literary Remains of Mrs. Piozzi (Thrale)*, edited with notes and an *Introductory Account of her Life and Writings* by A. Hayward (1861); *Piozziana; or Recollections of the late Mrs. Piozzi by a Friend* (1833), the anonymous friend being Edward Mangin (1772-1852); L. B. Seeley, *Mrs. Thrale, afterwards Mrs. Piozzi . . .* (1891), and G. Birkbeck Hill, *Johnsonian Miscellanies* (1897); also Percival Merritt, *The True Story of the So-called Love Letters of Mrs. Piozzi* (1928), which exposes the! misrepresentation of the "love letters" to William Conway the actor written when she was an old lady and published in 1843. Copies of these letters are shown to be misleading. See also JOHNSON, SAMUEL—: *Bibliography*.

PIPE, a hollow stem of clay, wood or other material with a bowl at one end used for smoking tobacco, opium or other narcotic, or any medicinal substance. See PIPE SMOKING and TOBACCO PIPE.

PIPE and **TABOR**, a popular mediaeval combination of a small pipe or flageolet and a small drum. The tabor being fastened to the performer's left elbow, the hands remained free, the right beating the little drum with a stick to mark the rhythm, while the left held and fingered the pipe with thumb and first two fingers. The pipe and tabor are said to be of Provençal origin.

PIPE CLAY. A natural clay, one of the names given to impure kaolin or china clay. It occurs in beds where kaolin has been washed away from its original site and deposited in a hollow. It is used to make primitive tobacco pipes and for whitening military belts, etc.

PIPE-FISH, the name given to fishes which, with the sea-horses, form the family *Syngnathidae* of the order *Solenichthyes*. The pipe-fishes are long and slender, with the body encased in bony rings, and a small, toothless mouth at the end of a long, tube-like snout; the gill-filaments are reduced in number and appear as rounded lobes or tufts. About 100 species are known from warm seas and a few from rivers. Pipe-fishes frequent seaweeds and swim slowly by rapid undulations of the small dorsal fin.

PIPE-LINE: see PETROLEUM.

PIPER, CARL, COUNT (1647-1716), Swedish statesman, was born at Stockholm on July 29, 1647. In 1689 he was made one of the secretaries of state, and Charles XI recommended him on his deathbed to his son and successor, Charles XII. Piper became the most confidential of the new sovereign's ministers. In 1697 he was made a senator and set over domestic affairs while still retaining his state-secretaryship. In 1698 he was created a count, in 1702 appointed chancellor of Uppsala university and during the first half of the Great Northern War, as the chief of Charles's perambulating chancellery, he was practically prime minister. But he belonged to the school of Bengt Oxenstjerna (*q.v.*) and was therefore an avowed advocate of a pacific policy. He protested in vain against nearly all the military ventures of Charles XII, *e.g.*, the War of Deposition against Augustus of Saxony and Poland, the invasion of Saxony, the raid into the Ukraine. Again and again he insisted that the pacific overtures of Peter the Great should at least be fairly considered, but his master was always immovable. Piper was taken prisoner at Pultava (1709) and died at Schliisselburg on May 29, 1716.

See W. L. Svedelius, *Count Carl Piper* (1869).

(R. N. B.)

PIPERACEAE, the pepper family, a large group of tropical herbs, vines and small shrubs with simple leaves having a characteristic pungent taste, the numerous small flowers, lacking both calyx and corolla, crowded in dense spikes. Most of the species belong in two genera. *Piper* with more than 2,000 described species and *Peperomia* with more than 1,200. Six other small genera are usually recognized. The family is of considerable economic importance, yielding as it does pepper (*q.v.*), the product of several species; black and white pepper, derived from the fruits of *Piper nigrum*; long pepper, the product of *Piper officinarum* and *P. longum*, and Ashanti pepper, the product of *P. chusii*. Cubebs (*q.v.*) is the fruit of *Piper cubeba*. The leaves of *Piper betle* are widely used in the orient for chewing with slices of betel nut (*Areca catechu*) and lime, while kava (*q.v.*) is a stimulating drink widely used in Polynesia prepared from the roots of *Piper latifolium* (*P. methysticum*).

(E. D. ML.)

PIPERAZINE, a colourless crystalline solid melting at 104° C and boiling at 145° C, soluble in water and used medicinally as a uric acid eliminant. Piperazine, $C_4H_{10}N_2$, was first obtained by A. v. Hofmann by the action of ammonia on ethylene dichloride or dibromide. It is manufactured from the latter dihalide and aniline, the intermediate product, diphenylpiperazine, being converted successively into its dinitroso-compound and piperazine.

PIPERINE, an alkaloid (see ALKALOIDS) found in the fruits of certain peppers. It forms white prisms, melts at 128° – 129° C, is almost insoluble in water, but readily so in alcohol or ether, and is a very weak base, salts being only formed with mineral acids, and these are dissociated by water. Alcoholic potash decomposes piperine, $C_{17}H_{23}O_3N$, into piperidine, $C_5H_{11}N$, and piperic acid, $C_{12}H_{16}O_4$, indicating that the alkaloid is a piperidide of piperonylic acid. It was synthesized (Rugheimer, 1882) by the action of piperonyl chloride on piperidine.

PIPERITONE is the sole ketonic constituent of eucalyptus oils, from which it may be either fractionally distilled or extracted with sodium bisulphite. It occurs in the "peppermint group" of eucalyptus leaf-oils, in association with *l*- α -phellandrene, and has been found altogether in 23 species; these grow mainly in south-eastern Australia and Tasmania, and are characterized by a butterfly-wing leaf-venation. A maximum content of about 45% of piperitone is reached in the oil of the Broad-leaved Peppermint (*E. dives*). Piperitone, $C_{10}H_{16}O$, Δ^1 -menthen-3-one, is a colourless liquid (b. p. 232°), with an odour of peppermint. The eucalyptus ketone is laevo-rotatory, with $[\alpha]_D^{20}$ -53.9° ; but *d*-piperitone, having $[\alpha]_D^{20}$ $+62.5^{\circ}$, has been isolated from the essential oil of a Himalayan grass, *Andropogon Jwarancusa*. The optically active ketone racemizes easily, owing to enolization. When hydrogenated according to Paal's method, *l*-piperitone yields mainly *d*-*iso*-menthone, and by reduction in other ways it has been used commercially as a source of *dl*-menthol. It may be oxidized to thymol.

PIPERNO (anc. *Privernum*), now called Priverno, a town of the province of Littoria, Italy, 54 mi. S.E. of Rome by rail. Pop. (1936), 7,812 (town), 13,631 (commune). The mediaeval town was founded in the 10th century on a hill 490 ft. above sea-level, by refugees from the Roman town of Privernum, lower down (118 ft. above sea-level) on the highroad, $1\frac{1}{4}$ mi. to the north, at the mouth of a low pass leading through the Volscian mountains to the valley of the Sacco. Here are scanty remains of the Roman period, though the ruins are largely mediaeval. The ancient Volscian town probably stood on the site occupied by the mediaeval and modern town. Privernum was captured in 329 B.C. and in 318 the tribus Oufentina was founded (see LATTUM). The mediaeval town has a picturesque piazza, with a Gothic cathedral (1283), and a Gothic town-hall; and Gothic churches. Polygonal terrace walls of the Roman or pre-Roman period exist in the vicinity. See H. H. Armstrong in *American Journal of Archaeology* (1911), 44 sqq., 170 sqq., 386 sqq.

PIPE ROLLS or the Great Rolls of the Exchequer are a long series of financial records of the English crown. The first extant Pipe Roll is that for the 31st year of the reign of Henry I. The continuous series begins with the second year of Henry II.'s reign and the annual succession of rolls is almost unbroken till 1834, when the last relics of the ancient financial system of the English mediaeval kings were swept away. The most plausible explanation of the name Pipe Rolls is that when rolled up and stacked in their presses the rolls looked like pipes. Up to the beginning of the 13th century the Pipe Rolls are the only consecutive series of official records which have survived; it was not until the reign of John that the Chancery records were systematically preserved. Therefore, the value of the Pipe Rolls for the last half of the 12th century can hardly be overestimated. By them the narratives of the chroniclers can be checked, and from them most of our knowledge of the actual working of the legal system in Henry II.'s reign comes. They are a mine of information about the personnel of the government and the gradual development of the new administrative offices. They are the best authority for the descents of the great families of feudal England. For the historian of English towns they provide a vast mass of material. Calculations as to the amount of the royal revenue

have been made from them, but such calculations can only be approximate, since much money was paid directly into the king's privy purse and recorded in no roll that survives.

Consisting of a varying number of skins of parchment about 14 inches wide and a yard long sewn together at the top, the rolls are not easy to consult. Their matter too is not easy reading, nor their method of book-keeping easy to understand. The accounts are entered county by county, the sheriff being responsible for the account of his shire. Other accounts, known as foreign accounts, appear sometimes on the rolls, accounts of royal manors by their custodians, accounts of escheats, or of towns. The clerks enter debts long after all hope that they may be paid has passed away. In 1883 the Pipe Roll Society was formed to publish the rolls up to 1200. It hopes to carry the work up to the end of John's reign. In later centuries, the Pipe Rolls lose much of their importance, but interesting matter can be found in the foreign accounts which continue to appear on the rolls. When the escheat rolls begin one great source of foreign accounts is lost to the Pipe Rolls. In this way by a process of splitting off, and the setting up of new accounting offices the ancient sheriff's account recorded in the Pipe Rolls becomes insignificant and stereotyped. The continuation of the series to 1834 is a remarkable illustration of English administrative conservatism. (D. M. S.)

PIPERONAL, an aromatic aldehyde with an agreeable smell, resembling that of heliotrope. It forms long colourless crystals, which melt at 37° C and boil at 263° C and is much used in perfumery. It is only slightly soluble in cold water, but readily soluble in alcohol and in ether. It is also called heliotropine, and is protocatechuic aldehyde methylene ether, $CH_2O_2 \cdot C_6H_4 \cdot CHO$. It is prepared by oxidizing piperic acid with potassium permanganate (R. Fittig, 1869), by condensing methylene iodide with protocatechuic aldehyde (R. Wegscheider, 1893), or by oxidizing isosafrole with chromic acid. When heated with dilute hydrochloric acid to 200° C it yields protocatechuic aldehyde, $C_7H_6O_3$, and carbon. It readily combines with sodium bisulphite and with various bases (ammonia, aniline, methylamine, etc.).

PIPE SMOKING. The original source of the idea of smoking must be sought in the sense of smell. This was much keener in primitive man than in man of the more advanced stages. With the pleasure derived from aroma, there was probably a sense of mystery at the sight of the smoke rising up into the air. Thus there was an element of religious ceremony in the burning of pleasant-smelling substances among primitive folk, in whatever part of the world we may be able to study their ways.

The ritual element is enhanced by another circumstance. Herodotus, in the fifth century B.C., describes a practice of the Scythians, a Mongol people settled in south-eastern Europe, between the Carpathian mountains and the River Don. Throwing the leaves of a certain plant (which was probably hemp) upon a fire, they sit round and, inhaling the smoke, "they grow drunk with the fumes as the Greeks do with wine," until they jump up and begin to dance and sing. Herodotus seemed to regard this simply as an orgy; but inhalation was certainly used to produce a super-normal condition of mind in many parts of the world. When Columbus discovered America, he found the habit established of inhaling tobacco, to induce a state of trance, during which visions were seen, which were accepted as divine revelations. The intoxicating vapour at Delphi which inspired the Pythian priestess may have been artificially produced, since no natural source has been found.

The invention of an implement to concentrate the smoke was an advance. Such an implement is the Y-shaped tube described by G. Fernandez de Oviedo in his *History of the Indies* (1535). The two horns of the "Y" were inserted in the nostrils, and smoke from tobacco burning in a censer was drawn up through the tube. This was the ceremonial method of smoking prevalent in the Antilles when Columbus and his followers reached them, side by side with a common use of the tobacco-leaf rolled up and smoked like a cigar. Bernal Diaz, who accompanied Cortez to Mexico, describes the inhalation of tobacco through a tube. But we have much earlier evidence from Mexico. At the ruined city of Palenque, in the southern province of Chiapas, there are the

remains of a "Temple of the Cross," which seems to belong to the beginning of the second century A.D. Here, on one of two stone slabs on either side of a doorway, is represented a figure of a priest, clad in a jaguar-skin cloak and a head-dress representing a mythical bird, who is blowing out a smoke-offering through a straight tube. This Palenque sculpture is the work of the Mayas, the mysterious race which preceded the Toltecs and the Aztecs in Mexico. Other Maya sculptures portray the straight smoking-tube, both as an emblem in one of the hands of Chac, the god alike of rain-and-thunder and of fertility, and as an apparently ordinary implement for smoking. Lionel Wafer, at the end of the 17th century, speaks of a roll of tobacco, aft. or 3ft. long and as thick as a man's wrist, being lighted by a boy, and the smoke being puffed into the faces of a company who made funnels of their hands and inhaled it.

Whatever the original use of the straight tube (which is found in a variety of materials—bone, wood, cane, stone of kinds not too hard to work, and pottery), the use of it as a pipe for tobacco ages before America was discovered by the early European adventurers is well established. The first modification of the type is that found in the burial-mounds of the Muskogee Indians, in the south-eastern portion of what is now the United States. The tube is bent up at one end, with a widening of the "bowl" formed by this end. Pipes on these lines were obviously the model for the clay pipe as known to Europe, which is only natural, since the first Europeans to introduce the use of the tobacco-pipe into their own countries learned the habit of smoking not from the West Indies, but from the Indians of the eastern mainland.

The next modification of the tube, which is found in Ohio and Virginia in the burial-mounds of another Indian tribe, the Algonquins, converts it from a one-piece to a two-piece pipe. Whatever the material used, usually some kind of stone, the stem was liable to be broken, necessitating a makeshift stem, if the bowl was to continue in use. From this the transition is easy to a bowl alone, into which a wooden stem could be inserted.

While the tobacco-pipe was thus evolving in North America apparently a two-piece pipe arose independently in South America. In the upper part of the southern continent true pipes were not used, though the Y-shaped tube, of which we have already heard, was employed for inhaling snuff. Otherwise cigar-smoking was the ordinary form of indulgence in tobacco. But in South Brazil in 1650 the traveller Jan Nieuhoff found a great Indian tribe smoking pipes with bowls made of nut-shells and with stems of reed or hollowed wood. This kind of pipe, with a small bowl, was the prototype of the pipes of Turkey, Persia and the Far East, since the Portuguese took it with them from Brazil along their trade-route in the Old World. Much larger pipes were also used by the same Brazilian tribe, with bowls of stone, clay, or wood, and are found to-day among their descendants, now living on the Upper Amazon.

The two-piece pipe is also found in the steppes of Central and Western Asia, and the Kalahiri region of South Africa. Both these are woodless countries, scantily inhabited by people mostly nomadic. Here "earth-smoking" is found. The most primitive method is to dig a small pit in the ground, to serve as a bowl; to insert a stick through the earth to the bottom of this pit; and then to withdraw the stick, leaving a hollow tube. The smoker has to lie flat on the ground and apply his mouth to the end of the tube. An improvement on this uncomfortable method is the fashioning of a rough bowl of clay above the surface of the ground, with a tube formed as before with the aid of a stick. Such an earth-pipe, when dry, can be detached and carried about. The insertion of a separate mouthpiece into the end of the hollow tube would convert it into a two-piece pipe. In quite a different part of the world, among some of the North American Indians, a hollow reed stuck into a bowl made of wet clay is said to serve as an emergency pipe.

The credit of the first invention of the pipe cannot be assigned to any one people nor is it certain that smoke proceeded always from tobacco-leaf. There is hemp, which, in many parts of the world at least, long preceded tobacco. There are many herbs, such as henbane, which were commonly used in Europe, for how many

centuries we do not know. Opium-smoking, on the other hand, is a late development. Early evidence concerning the tobacco-pipe comes from America only, for the reason that the tobacco-plant is a native of America. The theory that both the plant and the habit of smoking derived originally from Africa and reached the western coast of America by way of the Indian and Pacific Oceans, rests on an insufficient basis. Smoking, no doubt, is a custom of great antiquity in Africa; but it is the smoking of hemp, as exemplified notably among the Bushmen of the Kalahiri Desert. The evolution in Africa of the pipe for hemp-smoking has, so far as we can tell, been from the earth-pit, through the simple tube, to the *Dakka* (hemp) pipe, which is the ancestor of the water-pipes of various kinds used for tobacco in the East.

Among the Bushmen an animal's horn, generally an antelope's, is used as the water-vessel. Among other African tribes ox-horns, gourds, bamboos and wooden stems are to be seen. It was thus the African hemp-smokers who gave to the smokers of tobacco this idea of using a pipe in which fumes should be filtered and cooled by passing through water.

See A. Dunhill, *The Pipe* (1924); the *British Museum Handbook to the Ethnographical Collection* (2nd ed. 1925); the *British Museum Guide to the Maya Collection* (1923). (A. D.)

PIPIL, a dialect of the Nahuatl or Aztec language. In southern Mexico, Guatemala and western Salvador there are four groups of Indians who speak a Nahua dialect, related to but more primitive than Aztec. These four groups are: (1) *Pipil of Soconusco*, (2) *Pipil* of the upper *Motagua* valley, (3) *Pipil of Escuintla*, and (4) *Pipil of Salvador*. At the time of the Spanish conquest several explanations of the presence of these Mexican Indians in Central America were given by the natives. It was said that the Aztec emperor, Ahuitzotl (1486-1502), sent colonists to spy out the land and prepare for a never accomplished conquest. This tale fails to account for the large and well-built cities occupied by the Pipil. More generally it is thought that they were Toltec (*q.v.*) who either migrated from Mexico with one of the early priest-kings named Quetzalcoatl, or, more probably, fled after the downfall of the Toltec empire in the 11th century. The Spanish historian Juan de Torquemada in support of the last hypothesis has preserved a significant migration legend. Numerous ruined cities are attributed to the Pipil by archaeologists. Of these the most important are Sanra Lucia Cazumalhuapal and Baul in Guatemala and Chalchuapa, Cihuatlan and Tehuacan in Salvador. These sites yield characteristic stone carvings and pottery types. The present culture of the Pipil varies from village to village. In general it reflects that of their neighbours such as the Quiché (*q.v.*).

PIPIT, a sub-family of birds having a great resemblance in habits and appearance to the larks (*q.v.*). They differ however in several important characters. They are associated with the wagtails (*q.v.*) in the Passerine family Motacillidae. Pipits, of which over 50 species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spraguei*, the prairie-lark of the north-western plains, and *Anthus ludovicianus*, the American titlark, which last is nearly allied to the water-pipit of Europe, *A. spipolletta*. To English readers the best-known species is the titlark or meadow-pipit, *A. pratensis*, a bird abundant on pastures, moors, and uncultivated districts generally; but in some localities the tree-pipit, *A. arboreus*, takes its place, and where it does so it attracts attention by its loud song, which is delivered (as in all the pipits) on the wing. Another species, the rock-pipit, *A. obscurus*, scarcely ever leaves the sea-coast and is found almost all round the British Islands. The South African genus *Macronyx*, remarkable for the extreme length of its hind claw, differs and has brighter coloration.

PIPPIN or **PEPIN**, the name of three members of the Carolingian family.

PIPPIN I. (d. 639), incorrectly called Pippin of Landen, was mayor of the palace to the youthful Dagobert I., whom Clotaire II. had placed over the kingdom of Austrasia. He was disgraced when Dagobert became sole king in 629, and had to seek refuge in Aquitaine. Returning at Dagobert's death (638), he governed Austrasia in Sigebert's name, but died the following year.

PIPPIN II. (d. 714), incorrectly called Pippin of Herstal, was son of Adalgiselus (son of Arnulf, bishop of Metz) by a daughter of Pippin I., called in later documents Begga. Towards 678 he placed himself at the head of the great nobles in Austrasia to combat Ebroïn, the mayor of the palace, and Neustria. After some reverses he gained a great victory after Ebroïn's death at the battle of Tertry (687) not far from St. Quentin, which marks the fall of the Merovingians. He appointed one of his grandsons, Theodebald, mayor of the palace of Neustria, reserving for two others (Arnulf and Hugo), the mayoralty of Austrasia. He made war on the Frisians and defeated their duke Radbod; and part of this people became converts to Christianity. He also defeated the Alamanni, and subdued their country. The only part of Gaul not under his suzerainty was Aquitaine. The plans he had formed for reforming the church and convoking councils were interrupted by his death on Dec. 16, 714.

PIPPIN III. (d. 768), the Short, was the younger son of Charles Martel. Before his death in 741 Charles Martel had divided the Frankish kingdom between his two sons Carloman and Pippin, giving Carloman the eastern part and Pippin the western. Since 737 there had been no king in the Frankish realm; in the diplomas the two brothers bear the title of *majores palatii*, while the chroniclers call them simply *principes*. In 743, however, the mayors decided to appoint a king in the person of Childeric III., who was apparently connected with the Merovingian family. But Childeric was a mere figure-head, and had no power. The two brothers presided over the tribunals, convoked the councils at which the Frankish Church was reformed, assembled the host and made war, jointly defeating and subduing Duke Hunald of Aquitaine. In 747 Carloman unexpectedly abdicated, became a monk, and retired to a monastery near Rome, subsequently founding on Mt. Soracte the monastery of St. Silvester. From the time of the abdication Pippin was sole master; and in 751, after consulting Pope Zacharias, he held an assembly of the Franks at Soissons, took the title of king and removed the feeble Childeric to a monastery. He then got himself crowned by St. Boniface, a ceremony which was new to France and which gave the sovereign immense prestige; henceforth the king of the Franks called himself *Gratia Dei rex Francorum*. Pippin's reign is marked by many important events. He received in France a personal visit from Pope Stephen II., who conferred on him the title of Patrician of the Romans and recrowned him. In return for these honours Pippin, at the appeal of the pope, made two expeditions into Italy, in 754 and 756; and he became the veritable creator of the papal state by conferring on the pope the exarchate of Ravenna, which he had wrested from Aistulf, the king of the Lombards. Pippin took Septimania from the Arabs, and after a stubborn war of nearly eight years' duration (760-768) succeeded in taking Aquitaine from its duke, Waifer. He also intervened in Germany, where he forced the duke of Bavaria, Tassilo, to become his vassal. In 763, however, Tassilo abandoned Pippin during an expedition against Aquitaine. Pippin made several expeditions against the Saxons, but failed to subdue them. He entered into relations with the Eastern Empire, exchanging ambassadors with the emperor Constantine Copronymus. During Pippin's reign Frankish institutions underwent some modification. The Frankish assemblies, previously held in the month of March (*champs de mars*), but under Pippin deferred to May (*champs de mai*), came to be more numerous, and served the king of the Franks as a means of receiving the gifts of his subjects and of promulgating his capitularies. At the head of the administration was placed the archchaplain, and an ecclesiastical chancellor was substituted for the ancient *referendarius*. Ecclesiastical reform was continued under Pippin, Bishop Chrodegans of Metz uniting the clergy of Metz in a common life and creating canons. Pippin died on Sept. 24, 768 at St. Denis, leaving two sons, Charles (Charlemagne) and

Carloman, between whom he divided his kingdom.

PIPRĀWA, a village on the Birdpur estate in the Basti district, United Provinces, India. It lies on the Uska-Nepal road at mile 19.75; and about half a mile south of the boundary pillar numbered 44 on the frontier line between British and Nepalese territory. The village is celebrated as the site of the following discovery:—

In 1896 interest having been aroused by the discovery, only twelve miles away, of the Buddha's birthplace (see LUMBINI), William Peppé, then resident manager of the Birdpur estate, opened a ruined tope or burial mound situate at Piprāwa. After digging through 18 ft. of solid brickwork set in clay a massive stone coffer was found lying due magnetic north and south. Its dimensions were, 4 ft. 4 in. by 2 ft. 8½ in. and 2 ft. 2¼ in. high; and it contained five vessels, two vases, a bowl and a casket being made of steatite, and the fifth, also a bowl, of crystal. All these vessels are beautifully worked, the crystal bowl especially, with its fish-shaped cover handle, being a work of art of high merit. The coffer is of fine hard sandstone of superior quality, and has been hollowed out, at the cost of vast labour and expense, from a solid block of rock. Peppé calculated its weight, lid included, at 1,537 lb. It is only the great solidity of this coffer which has preserved the contents. A cover of one of the vases was found dislodged and lying on the bottom of the stone coffer. As this coffer fits very well it must have required a quite violent shock to remove it. This was almost certainly the shock of an earthquake, and the same shock probably caused the split in the stone lid of the coffer itself.

The vessels contained a dark dust, apparently disintegrated ashes, small pieces of bone, and a number of small pieces of jewellery in gold, silver, white and red cornelian, amethyst, topaz, garnet, coral and crystal. Most of these are perforated for mounting on threads or wires, and had been, no doubt, originally connected together to form one or more of the elaborate girdles, necklaces and breast ornaments then worn by the women. On the bottom of the stone box there was similar dust, pieces of bone and jewellery, and also remains of what had been vessels of wood.

An inscription ran round one of the steatite vases just below the lid. The words mean: *This shrine for ashes of the Buddha, the Exalted One, is the pious work of the Sakiyas, his brethren, associated with their sisters, and their children, and their wives.* The thirteen words, in a local dialect of Pali, are written in very ancient characters, and are the oldest inscription as yet discovered in India.

The monument must have been of imposing appearance. The dome was of the shallow type, probably not more than about 35 ft. high exclusive of the ornament on the summit. We have in bas-reliefs of the 3rd century representations of what these ornaments were like—small square erections, like a shrine or small temple, surmounted by a canopy called from its shape a T. They were then more than a third of the height of the dome itself. The total height of this Sākiya tope will therefore have been approximately a little under 50 ft. It was probably surrounded by a carved wooden railing, but this has long since disappeared.

All such monuments hitherto discovered in India were put up in honour of some religious teacher, and this is accepted as a monument put up over a portion of the ashes from the funeral pyre of Gotama the Buddha. The account of the death and cremation of the Buddha, preserved in the Buddhist canon, states that one-eighth portion of the ashes was presented to the Sākiya clan, and that they built a *thūpa*, or memorial mound, over it.

Mr. Peppé presented the coffer and vases with specimens of the jewellery to the museum at Calcutta where they still are. He also gave specimens of the trinkets to the Asiatic Society in London.

PIPSISSEWA (*Chimaphila umbellata*), called also prince's-pine, a plant of the heath family (Ericaceae) flowering from June to August in dry woods in North America from Nova Scotia to British Columbia and southward to Georgia and California. It is found also in Europe and Asia. The flowers are flesh-coloured or pinkish, waxy, five-parted and grow in small terminal groups on a three to ten inch stem. The leaves are dark green, shining, evergreen, sharply toothed and appear in whorls or placed oppositely on the stem. The spotted pipsissewa or spotted winter-green (*Chimaphila ntaclata*) occurs in small areas from Maine and Ontario to Minnesota and southward to Georgia and Missouri. Its leaves are dark green, and mottled with white veins, sharply toothed and tapering to narrow points.

PIQUA (pick'wā), a city of Miami county, Ohio, U.S.A., situated on the Miami river and federal highway 25 (Dixie) and 36, ocean to ocean; served by the Baltimore and Ohio, the Pennsylvania railways and bus lines. Pop. (1920), 15,044 (93% native white); 1940 federal census 16,049. It has grain elevators, large quarries of blue limestone and many diversified manufacturing industries, making textiles, stoves, furniture, blankets, felts and various other articles. On or near the site of Piqua was one of the principal villages of the Chillicothe division of the Shawnee tribe. A town called Washington was laid out in 1807; the present name (that of another division of the Shawnee tribe) was given in 1823. It was chartered as a city in 1850.

PIQUET, a game at cards, probably a development of *ronfa*, a game mentioned by Berni in 1526. The Spanish name of the game was *cientos* (*centum*, a hundred). Piquet was played in England under the name of *cent*, probably as early as 1550.

The dealer deals 12 cards to his adversary and 12 to himself, two at a time, or three at a time. He then places the eight undealt cards, called the "stock," face downwards on the table, the top five being for the elder hand (non-dealer) to take from first in exchange for his own. The players now look at their hands, and *carte blanche* (see later) having been declared, if there is one, put out (without showing them) such cards as they deem advisable in order to improve their hands, and take in an equivalent number from the stock. Each player must discard at least one card. If the elder hand discards less than the five he is entitled to, he must state how many he leaves. He is entitled to look at the cards he leaves, replacing them face downwards on the top of the stock. The younger hand then makes the exchange from the remainder of the stock. If the elder hand leaves any of the top five, the younger may exchange as many as remain in the stock, discarding an equal number. If the younger hand leaves any cards, he announces the number left. He may look at the cards he leaves. If he looks at them he must show them to the elder hand, after the elder has named the suit he will lead first, or has led a card.

If the younger hand elects not to look at the cards left the elder cannot see them. The younger hand must make his election before he plays to the card first led, or, if so required, after the dealer has named the suit he will first lead. Each player may examine his own discard at any time during the hand; but he must keep it separate from his other cards.

The elder hand next declares what he has in his hand.

The "point" must be called first or the right to call it is lost. It is scored by the player who announces the suit of greatest strength, valued thus: ace 11; court cards, 10 each; other cards, the number of pips on each. Thus if the elder hand's best suit is ace, king, knave, nine, eight, he calls "five cards." If the younger hand has no suit of five cards, he says "good." The elder hand then says "in spades," or whatever the suit may be, or shows his point face upwards. If the younger hand has a suit of more than five cards, he says "not good." If the younger hand has also five cards, he says "equal" or "what do they make?" when the elder calls "forty-eight" (or "making eight," short for forty-eight). The younger must not inquire what the point makes unless he has an equal number of cards. If the younger hand's five cards make less than 48 he says "good"; if exactly forty-eight, he says "equal"; if more than forty-eight he says "not good." The player whose point is good reckons one for each card of it; if the point;

are equal neither player scores for point.

"Sequences" are usually called next, the elder hand stating what his best sequence is, and the younger saying, "good," "equal," or "not good," as in the case of the point. Any three or more consecutive cards of the same suit held in hand constitute a sequence. The order of the cards is as follows: ace (highest), king, queen, knave, ten, nine, eight, seven (lowest). A sequence of three cards is called a "tierce"; of four, a "quart"; of five, a "quint"; of six, a "sixikme"; of seven, a "septième"; of eight, a "huitikme." A tierce of ace, king, queen is called a "tierce major"; a tierce of king, queen, knave is called a "tierce to a king" (and so on for other intermediate sequences according to the card which heads them); a tierce of nine, eight, seven is called a "tierce minor." Sequences of four or more cards follow the same nomenclature; e.g. ace, king, queen, knave is a quart major; knave, ten, nine, eight, is a quart to a knave; and so on. A sequence of a greater number of cards is good against a sequence of a smaller number; thus, a quart minor is good against a tierce major. As between sequences, containing the same number of cards, the one headed by the highest card is good; thus, a quart to a queen is good against a quart to a knave. Only identical sequences can be equal. The player whose sequence is good reckons one for each card of it, and ten in addition for quints or higher sequences. Thus a tierce counts three; a quart, four; a quint fifteen; a *sixième*, sixteen; and so on. If the elder hand's sequence is good, he names the suit, or shows it face upwards. If the highest sequence (or the sequence first called) is good, all lower sequences can be reckoned, notwithstanding that the adversary has a sequence of intermediate value. For example, A has a quart to a queen (good) and a tierce minor. He calls and reckons seven, notwithstanding that B has a quart to a knave. B's quart counts nothing. If the highest sequence is equal, neither player scores anything for sequence.

("Quatorzes" and "trios" are the next calls. "Quatorzes" are composed of four aces, four kings, four queens, four knaves, or four tens, in order of value; "trios" of three of any of these. A quatorze, if good, reckons 14; a trio, if good, reckons three; one that is good establishes any smaller quatorzes or trios in his hand.

When the elder hand has done calling he leads a card. Before playing to this card, the younger hand reckons all that he has good, stating of what cards his claims are composed, or showing the cards claimed for. The elder hand leads any card he pleases: the younger plays to it. The younger hand must follow suit if able; otherwise he may play any card he thinks fit. It is not compulsory to win the trick. The leader counts one for each card led, whether it wins the trick or not. If the second player wins the trick he also counts one. The winner of the last trick counts an additional one for the last card. The tricks are left face upwards in front of the player who wins them. They may be examined by either player.

If each player wins six tricks the cards are "divided," and there is no further score. If one player wins more than six tricks he wins "the cards," and adds ten to his score. If one player wins every trick, he wins a *capot*, and scores 40 for the cards, instead of ten.

During the play of the hand, a player is entitled to be informed as to any cards his adversary holds which he has reckoned as good, or has declared to be equal. A player may require his adversary to exhibit any such cards. But if a player, having played three cards of a *sixième*, declared as a quint, is asked how many he has left, he need only reply "Two."

During the progress of the hand each player repeats aloud the amount of his score for the time being. At the end of the hand the points scored are recorded by each player. If there is any difference in the written scores, a player's score of his own hand is deemed to be the correct one.

Carte Blanche.—If either player has no king, or queen or knave in the hand dealt him, he holds *carte blanche*, for which he scores ten. As soon as a player discovers he has a *carte blanche*, he must tell his adversary; this he usually does by saying "discard for *carte blanche*." The adverse discard is then made (as explained under discarding), after which the *carte blanche* is shown by dealing the cards, face upwards on the table; they are then taken

back into the hand.

Pique.—If the elder hand scores, in hand and play, 30 or more, before the younger hand counts anything in that deal, he gains a pique, for which he scores 30.

Repique.—If a player scores in hand alone 30 or more before his adversary reckons anything, he gains a *repique*, for which he adds 60 to his score. Equalities do not prevent piques or repiques. A player who has an equal point or sequence scores nothing for it. Therefore if, notwithstanding the equality, a player makes 30, in hand and play, or in hand, by scores which reckon in order before anything his adversary can count, he gains a pique or a repique.

The order in which the scores accrue is of importance. For the sake of convenience, the elder hand finishes his reckoning before the younger begins. The scores, however, whether made by the elder or younger hand are recordable in the following order: (1) *carte blanche*; (2) point; (3) sequences; (4) quatorzes and trios; (5) points made in play; (6) the cards. This will often affect a pique or repique. Thus, a pique can only be made by the elder hand, as the one he reckons in play when he leads his first card counts before points subsequently made in play by the younger hand. The younger, therefore, cannot make 30 in hand and play before the elder scores one. But the one reckoned by the elder hand when he leads his first card does not prevent his being repiqued, because scores made in hand have precedence of points made in play. The elder leads his first card and counts for it before the younger reckons, simply as a convenient way of stating that he has nothing in hand which is good. Again, say A has a quint (good), a tierce, and a quatorze (good). He scores 32 in hand alone; but, if his point is not good, he does not gain a repique, because the younger hand's point is recordable in order before the sequences and quatorze. *Carte blanche*, taking precedence of all other scores, saves piques and repiques. It also counts towards piques and repiques. A *capot* does not count towards a pique, as the *capot* is not made in play. It is added after the play of the hand is over. A player who reckons nothing that hand as a penalty is not piqued or repiqued if he holds any cards which, but for the penalty, would have reckoned before his adversary reached 30. The game most commonly played now ("short game") consists of 4 hands only, the last and first being doubled, and 100 points added for the game.

See "Cavendish," *The Laws of Piquet and of Rubicon Piquet, adopted by the Portland Club, with a Treatise on the Game* (1882), "Cavendish," *Guide to Piquet* (1898); R. F. Foster, *Hoyle's Games* (1928). (W. DA.)

PIRANDELLO, LUIGI (1867–1936), Italian dramatist and novelist, was born on June 28, 1867, on a country estate near Girgenti (Sicily). He first went to Rome at the age of 19, staying there until 1891, when he went to Germany and graduated in philosophy at the University of Bonn. He subsequently returned to Rome and taught at the girls' high school until 1923. His first literary essays were in verse, a volume entitled *Mal giocando* published in 1889, followed by a poem *Pasqua di Gea* (1891) and *Elegie renane* (1895). Another Sicilian writer, Luigi Capuana, persuaded him to devote himself to fiction, and in 1894 he published his first novel, *L'esclusa*, in which his somewhat bitter realism already finds expression. Besides the novel, *Il turno*, he began to publish short stories: *Amori senza amore* (1894) *Quando ero matto* (1903), *Befe della morte e della vita* (1902, 1903), *Bianche e nere* (1904), etc. In 1904 his most celebrated novel, *Il fu Mattia Pascal*, appeared, the story of a man, who having shammed being dead, tries in vain to begin his life anew in a different atmosphere and under another name. Other collections of short stories followed: *Erma bifronte* (1906), *La Vita Nuda* (1910), *Terzetti* (1912). He set forth his artistic creed in two volumes entitled *Arte e scienza* (1908). In 1913 his novel, *I vecchi e i giovani*, describing the drama of Italian life after the Risorgimento, was published in the *Rassegna contemporanea*. Other volumes of short stories appeared between 1914 and 1926, such as *La trappola* (1915), *Un cavallo nella luna* (1918), *Il carnevale dei morti* (1919), *Tu ridi* (1920), and another novel *Uno, nessuno e centomila* was published in the *Fiera letteraria*.

In 1920 he said of his own art:—

I think that life is a very sad piece of buffoonery; because we have in ourselves, without being able to know why, wherefore or whence, the need to deceive ourselves constantly by creating a reality (one for each and never the same for all), which from time to time is discovered to be vain and illusory. . . . My art is full of bitter compassion for all those who deceive themselves; but this compassion cannot fail to be followed by the ferocious derision of destiny which condemns man to deception.

This despairing outlook attained its most vigorous expression in Pirandello's plays. In his youth he had shown a certain contempt for the drama, but in 1912 he was persuaded by the Sicilian playwright, Nino Martoglio, to dramatize one of his own short stories, *La Morsa*, as a one-act piece. His first three-act comedy, *Se non così* (1917), was produced by Marco Parga at Milan in 1913; and then many plays—dramas and comedies—of which the most celebrated are *Il berretto a sonagli*; *Liola* (1917); *Così è se vi pare* (1918); *L'uomo, la bestia e la virtù* (1918); *Ma non è una cosa seria* (1918); *Come prima, meglio di prima* (1920); *Sei personaggi in cerca d'autore* (1921); *L'imbecille*; *Enrico IV.* (1922); *Vestire gli ignudi* (1922); *La vita che ti diedi*; *L'altro figlio*; *Ciascuno a suo modo*; *La sagra del signore della nave*; *La giara*.

Pirandello's dramatic art was at first criticized for being too "cerebral," for not seeing life as it really is and for arbitrarily deforming it. The Roman critics first discovered the real meaning of Pirandello's ideology and the human sense of his plays. His main themes are: the necessity and the vanity of illusion, the multiform appearances, all of them unreal, of what is presumed to be the truth, man is not what he thinks he is, but he is "one, no one and a hundred thousand," accordingly as he appears to this person or to that, and is always different from what he creates himself in his own mind. Hence the supreme catastrophe, when a moral looking-glass suddenly reveals to him the image of himself which others see, *i.e.*, what he *is* to others. Most of Pirandello's plays deal with a lower middle class milieu, peopled with clerks, teachers, lodging-house keepers, etc., from whose modest vicissitudes he draws conclusions of vast human significance. Typical is *Così è se vi pare*, in which he proves that it is impossible to know the real truth. *Enrico IV.* develops in a broader sense; that is, a drama in which we have a man who renounces his changing, empty and vain existence to play the part of a madman, and pretends to believe himself an historical personage, Henry IV. All this might be merely theatrical trickery if it were not seared by a deep anguish, characterizing a philosophy which has destroyed all faith in the absolute, in reality, in any fixed limits outside individual personality.

Pirandello's plays have rapidly achieved success throughout Italy and abroad, and have been translated into some 15 languages. In 1925 he created an art theatre of his own in Rome, where new Italian and foreign plays are performed, and in the summer of the same year he brought his company on a tour to England to produce his own plays in London (at the New Oxford theatre), to Paris, Basle and 18 theatres in Germany. He died from pneumonia on Dec. 10, 1936. (S. D'A.)

See W. Starkie, *Luigi Pirandello* (1926) and F. Pasini, *Luigi Pirandello* (1927, bibl.).

PIRANESI, GIOVANNI BATTISTA, Italian engraver, was born in the earlier half of the 18th century. He was a Venetian who settled in Rome, where he devoted himself to engraving the ancient monuments. The explanatory texts engraved on many of his plates prove that his work was inspired by archaeological interest; but he was more artist than archaeologist.

The most important of his publications are: *Antichità Romana de' Tempi della Repubblica* (1798); *Le Antichità Romane*, 4 vols. (1756); *Della magnificenza ed architettura de' Romani* (1761); and *Vedute di Roma* (135 plates engraved between 1748 and 1778, with two plates added later by F. Piranesi). He developed a powerful manner of etching. In his foregrounds the broad lines are strengthened with the graver. He achieves bold contrasts of tone which justify the large scale of his prints. Among his finest plates are the fanciful compositions in the *Opere Varie di Architettura* (1750) and in the *Carceri* (1750). He died in 1778.

PIRANO, a seaport of Istria, Italy, in the province of Pola,

22 mi. S.W. of Trieste by rail. Pop. (1936) 5,740 (town), 15,117 (commune). It has picturesque Venetian walls and buildings. On the coast near are extensive salt pans. The Venetians defeated the fleet of Frederick Barbarossa off Pirano in 1177. It surrendered to Venice in 1283 and was incorporated with Austria, together with the rest of Istria, in 1813. It was the birthplace of the violinist Tartini. Near Pirano is the favourite seaside resort of Porto Rose.

PIRATE and PIRACY. Sir J. Fitzjames Stephen in his *Digest of Criminal Law* defined piracy as follows: "Taking a ship on the High Seas or within the jurisdiction of the Lord High Admiral from the possession or control of those who are lawfully entitled to it and carrying away the ship itself or any of its goods, tackle, apparel or furniture under circumstances which would have amounted to robbery if the act had been done within the body of an English county." (Cf. *A. G. for Hong-Kong v. Kwok-a-Sing*, 1873, L.R. 5 P.C. 179.) Piracy, being a crime not against any particular State but against all mankind, may be punished under international law in the competent court of any country where the offender may be found or into which he may be carried. But, whilst the practice of nations gives to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state), they may not be killed without trial except in battle. Those who surrender or are taken prisoners must be brought before the proper tribunal and dealt with according to law.

Following the sinking of merchant vessels at sight by German submarines in the World War, by the Washington Treaties (1921-22) between the United States, the British Empire, France, Italy and Japan, attacks upon, and destruction of, merchant vessels upon visit and search by any person in the service of any Power were declared acts of piracy, and such persons may be brought to trial before the civil or military authorities of any Power within the jurisdiction of which he may be found. It was held by the Federal District Court of New York, in the suits brought against the Cunard Steamship company for damages arising out of the sinking at sight of the "Lusitania" by a German submarine, that such sinking was an illegal act. See *The Lusitania* (1918) 251 Fed. 715; *Scott's Cases*, 784-90. (X.)

HISTORY

It is impossible to say at what period in the world's history piracy began. References to this form of robbery occur in early literature. It was rampant in the Mediterranean in the days of the Roman republic, and it is recorded that Julius Caesar, when a young man, fell into the clutches of a gang of sea-robbers who held him prisoner until ransomed, and that after his release he returned with some soldiers who captured his late gaolers and crucified the whole crew. Amongst the early pirates of which records still exist are the Phoenicians, while there are numerous references to sea-rovers in the *Odyssey*. Out of the dim North, the Vikings (*q.v.*) are known to have come south to plunder the coasts of Britain, Ireland and France, in A.D. 789 and onwards. For many centuries the north-west coast of Africa was the headquarters of the Barbary pirates (*q.v.*) or Moors, as they were commonly called, who had their chief strongholds at Algiers, Salé and Tripoli. From these harbours they sailed out to harry passing ships, or plunder the opposite coast of Spain, carrying back their Christian captives to sell as slaves. In spite of numerous punitive attacks, these fierce sea-robbers were not finally stamped out until 1830. All through the Tudor reigns piracy was rampant around the British isles, particularly in the south of Ireland and in the Scilly isles, where safe retreats existed for the pirate and where receivers of plunder were to be found willing to buy the goods that the pirate had to offer.

As in the case of the land thief, the sea thief could not exist without a market for his ill-gotten goods. It would be useless for a pirate to seize a well-laden merchant ship, if he had nowhere he could dispose of his prize. Sir William Monson in his book *Naval Tracts*, records how he was sent in 1605 to search for pirates in the Shetlands and Hebrides. But it was in Ireland where he found what he looked for. At Broad Haven he met

with an Irish gentleman, of the name of Cormat or Cormac, whose house he describes as being the "well-head of all pirates." Here the Irishman lived in great style and trafficked with the pirate captains, many of whom were the lovers of his daughters.

As life became more difficult for the pirates in the home waters, they migrated further afield, where they could practise their calling with less interference. Thus piracy spread to the far-off West Indies, and the coast of New England, and eventually to the Red sea and Madagascar. For many years the latter island was the happy haunt of the pirates, where they lived in security, married native women, and reigned as petty kings. From here they were able to lay heavy toll on passing ships sailing between England and the East Indies.

The natural haunts of the pirates were in archipelagos and indented coasts, and there at one time or another such places as the Greek islands, the Indian ocean, the coast of Cilicia, the British Isles, Norway and the West Indies became their lurking places.

In England itself, up to the 16th century, piracy was not uncommon, and it was no unusual event for the inhabitants of the Cinque ports to sally forth in their small ships and plunder any passing vessel, and on more than one occasion the fleet of New Romney attacked and plundered the ships of its rival, Yarmouth.

The West Indies.—The West Indies were well prepared for practical exploration both geographically and historically. Since the 16th century the buccaneers (*q.v.*) had preyed upon the Spaniard, and there were innumerable hiding-places, hidden bays in uncharted islands, where pirates could meet in safety and divide the spoils and prepare for their next adventure. During the 17th century the island of Tortuga, or Turtle island, off the coast of Hispaniola, became a regular pirate republic. Good markets for stolen plunder were to be found on the New England coast, and in Jamaica and at New Providence island, as well as in Ireland and certain places in the west of England.

Much of the piracy in the West Indies and America was the direct outcome of the Spanish policy of forbidding her colonists the right of trading with foreigners, in spite of her inability to supply their needs herself. Naturally the Spanish Americans were only too eager to buy smuggled goods, at very low prices, and were not likely to be very particular to enquire where the goods came from. England and France also tried to insist on their colonists trading exclusively with themselves, at their own prices, which, combined with the almost total lack of policing by the regular navies, led to wholesale buying of smuggled merchandise, procured by irregular methods. It was not until the reign of William III., about 1700, that workable laws were made for trying pirates, and even then it was often difficult to get a jury to condemn a pirate who was looked upon as a public benefactor. Owing to the difficulty of policing the seas, particularly in distant waters, the custom arose in the reign of Charles I., and continued until that of George I., of granting free pardons to all pirates who would surrender themselves by a certain date. The result was that when things had become too warm for a pirate, he would make his submission to the authorities and receive the royal pardon, and, as soon as ever his booty was spent, resume his old practices. One of the greatest wholesale pardoning of pirates was carried out by Captain Woodes Rogers at New Providence in the Bahamas in 1718. At this time there were more than 2,000 freebooters entrenched in this pirate stronghold, but Rogers dealt so successfully with them that almost all surrendered.

Organization.—The ranks of the pirates were recruited from a type of seafaring man who disliked steady work with its small rewards, and preferred a life of danger, with a prospect of gaining sudden wealth. After every European war ships would be laid up and crews disbanded. There being no honest employment for all these sailors, they were compelled by circumstances to take any employment at sea that offered itself; and as often as not this consisted of signing on in a ship where no questions were asked, and no wages paid, but where every member of the crew took a share of any profits which might accrue from the voyage.

Very often when a pirate captured a merchant ship the crew of the latter were invited to join the pirates. Some would do so

willingly, others only under compulsion. Most pirates when brought to trial pleaded that they had been compelled to join the pirates, and had done so only to save their lives. It often happened that amongst the members of a captured crew there would be some "sea-artist," as a particularly skilful navigator was called, and he would be compelled to sign on whether he wished to or not. A common source of piracy was the privateer, an armed ship that sailed under a letter of marque, which was apt to drift into piracy, when its legitimate prey was not forthcoming, to supply the prize-money which paid the wages of officers and crew. This fact was pointed out by Cotton Mather (*q.v.*), the New England divine, in one of his "hanging sermons" delivered at Boston to condemned pirates. In one which he preached in 1704 called "A Brief Discourse occasioned by a Tragical Spectacle of a Number of Miserables under Sentence of Death for Piracy," he stated, "the Privateering Stroke so easily degenerates into the Piratical, and the Privateering Trade is usually carried on with an Unchristian Temper, and proves an Inlet into so much Debauchery and Iniquity."

The same view was expressed by Nelson when he declared that all privateers were no better than pirates, although this wide accusation cannot be allowed to include such famous and patriotic privateers as Captain Fortunatus Wright or Commodore Walker. Many a shady privateer was little better than a pirate, and the letter of marque under which he sailed a mere pretence, as in the case of a pirate who plundered Spanish ships in the 17th century, under a commission sold to him by the governor of a Danish West India island, himself a reformed pirate. This document, written in Danish, proved, when translated, to entitle the holder to hunt for goats and wild pigs on the island of Hispaniola and nothing more.

The establishment of a pirate gang usually took one of two forms. The most usual was for a few ringleaders to plot a mutiny on board a merchant ship. At a prearranged signal the mutineers would seize the officers and kill them and any members of the crew who resisted, and throw their bodies overboard.

But many a pirate who eventually rose high in his profession began in a very small way. Often a handful of desperate characters would steal a boat and row or sail along the coast by night, until they surprised the crew of some small schooner, and became masters of her. In this they would venture further afield, until by cunning or force they got possession of a larger ship. The downfall of most pirates was brought about by their utter lack of discipline, for, unless the elected captain was a man of unusual strength of character, as was the famous Captain Bartholomew Roberts, he was unable to keep his crew in order, and sooner or later, disaster overtook them, through careless navigation or at the hands of a better-disciplined hostile ship.

One of the first formalities of a newly created pirate crew was the drawing up and signing of the ship's articles, which would include such rules as the following, taken from those of Captain John Phillips of the "Revenge":

1. Every man shall obey civil Command; the Captain shall have one full Share and a half in all Prizes; the Master, Carpenter, Boat-swain and Gunner shall have one Share and a quarter.

6. That Man that shall snap his Arms, or smook Tobacco in the Hold without a cap to his Pipe, or carry a Candle lighted without a Lanthorn, shall receive Moses's Law (that is 40 Stripes lacking one) on the bare Back.

g. If at any time you meet with a prudent Woman, that Man that offers to meddle with her, without her Consent, shall suffer present Death.

Another matter, considered to be of great importance, was the choice of a flag, whose chief object was to "strike terror into all beholders." The favourite design was a skull and cross-bones; though sometimes a whole skeleton was depicted, holding in one boney hand a rummer or glass of punch, and in the other a sword or dagger. Whenever possible the pirates carried a surgeon, who was treated with a certain amount of respect.

Famous Characters.—The ordinary pirate was merely a criminal who lived for himself alone, and lacked any sense of ambition other than to get rich quickly, and must not be placed in the same category with the Vikings, who although sea-robbers

and murderers, worked in large and, to a certain extent, organized bands; as did the Mediterranean pirates in Roman times who formed a highly organized brotherhood of desperadoes. The ordinary pirates boasted that they "declared war upon the whole world" and possessed no honour even amongst themselves.

A few of the most famous pirates may be briefly mentioned. Captain John Avery, *alias* Bridgeman, familiarly known as "Long Ben" or the "Arch-Pirate," was born at Plymouth about 1665, took to the sea and rose to mate in a merchant ship; headed a mutiny and was elected captain; proved himself a daring pirate leader, and after much success off the Guinea coast and in the West Indies sailed to the Red sea, where he seized a rich ship of the Great Mogul, reported to have on board 100,000 pieces of eight and the Mogul's young and lovely daughter. He took both to Madagascar where he settled down as a reigning monarch. In 1696 he was at Boston, where he bribed the governor to allow him and his crew to land and dispose of their plunder. He died in poverty at Bideford after being tricked out of his ill-gotten gains by certain merchants of Bristol. Charles Johnson wrote a play called *The Successful Pyrate*, which was acted at Drury Lane, in 1713, and which was modelled on Avery's career.

Bartholomew Roberts was, perhaps, the greatest of all pirates. Born in Wales in 1682, he died fighting in 1722. He was credited with having taken over 400 ships during his career, and was remarkable for his discipline, for being a teetotaler, and allowing no women or gambling aboard his ships.

Edward Teach, *alias* Blackbeard, a picturesque blackguard, was killed on Nov. 22, 1718, in a hand-to-hand combat with Lieut. Robert Maynard, of H.M.S. "Pearl."

Captain Misson, a Frenchman of good family, was unique in combining active piracy with socialistic ideals. He reigned for many years over a Utopian republic in Madagascar.

Two women pirates, Anne Bonny and Mary Read, deserve mention, as both rose high in their ancient dual professions.

The famous Captain Kidd was no pirate at all, but the victim or scapegoat of political intrigue.

With the peace of 1815 came a great increase in West Indian piracy, which was assisted by the inability of the Spanish authorities to cope with the pirates while their colonies were seething with revolt. At last the British and American navies combined to root out the evil once and for all in the Atlantic, although piracy lasted in the Greek islands until nearly 1850.

The end of piracy, after centuries, was brought about by public feeling, backed up by the steam-engine and telegraph. The last relic exists to-day in China, where a nest of troublesome pirates still carries on the old trade in spite of the navies of the foreign powers. The Chinese pirates ship themselves as ordinary coolie passengers on a coastal steamer and, at a given signal, produce revolvers and hold up the officers and crew and compel them to navigate the ship to their headquarters at Bias bay, where the ship is plundered and officers and passengers held for ransom.

BIBLIOGRAPHY.—Mommson's *History of Rome*; Monson's "Naval Tracts" in *Churchill's Voyages*, v., 5 (London, 1744-46), and in *Navy Record Society* (1902); *State Trials*, vols. xiii., xiv., xv. (London, 1812); Captain Charles Johnson's *General History of the Pyrates* (1724) gives full and accurate details of the lives, activities and death of the most notorious pirates of the early 18th century; and a second volume, published in London in 1726, does the same for the Madagascar pirates. It used to be said that Charles Johnson was inaccurate and unreliable, but recent research has proved again and again that, whoever he was, he had first-hand knowledge of his subject and is to be relied upon in almost every detail. (P. Go.)

PIRELLI, LTD. and SOCIETÀ ITALIANA PIRELLI OF MILANO, Italy, are now one of the largest industrial organizations throughout all Italy, with a large number of international associations, employing at the end of 1938 over 30,000 hands all over the world, specializing in the manufacture of electric cables, tires of all descriptions, rubber footwear and general india-rubber and gutta-percha goods. Founded in 1872 by Ing. Giovanni Battista Pirelli, they have gradually increased in importance, developing large factories in Italy. Pirelli own or have controlling interests

in other branches connected with the rubber and cable industries, such as cotton-spinning and weaving mills, special rayon mills and copper drawing mills.

The Pirelli concerns outside Italy are controlled by a Swiss holding company, the Pirelli Holding S.A., in which the Italian company has a minority interest, but to which it gives its technical collaboration. The said manufacturing concerns are in Spain, Belgium, the Argentine, Brazil and Great Britain, whilst a Dutch East Indies subsidiary owns a rubber plantation in Java. Financial and commercial Pirelli companies operate also from Brussels, Bucharest, Belgrade, Copenhagen and Alexandria. and Pirelli agents are active in practically every commercial centre throughout the world.

In Great Britain, Pirelli General Cable Works, Ltd., London, with factories in Southampton and Eastleigh, are among the most prominent British manufacturers of electric cables; Pirelli Ltd. own a factory at Burton-on-Trent, manufacturing pneumatic tires and rubber footwear. These English factories employ British labour throughout.

Among the lines in which the Pirelli companies specialize are trans-Atlantic submarine telegraph cables; underground cables for abnormal working pressures, installed in European and American countries; and pneumatic tires. (M. S. L.; X.)

PIRENNE, HENRI (1862-1935), Belgian historian, was born at Verviers on Dec. 23, 1862. He first lectured at the University of Liège, and was professor at the University of Ghent, 1886-1930. His *Histoire de Belgique*, of which seven volumes had appeared in 1932, completely revolutionized the current conceptions of Belgian history and nationality by showing how, from the time of the Germanic invasions, Flemings and Walloons were drawn together by community of tradition and economic interest. Pirenne's works on mediaeval cities and social conditions include *Les anciennes démocraties des Pays-Bas* (1910, Eng. trans. 1915) *Recueil des documents relatifs à l'histoire de l'industrie drapière en Flandre* (with G. Espinas, 4 vol., 1906-24) and *Mediaeval Cities: Their Origins and the Revival of Trade* (Princeton, 1925). He was the first president of the "Union Académique Internationale" (1920-23) and received many foreign honours.

PIRKE ABOTh, lit. Chapters of the Fathers, a collection of proverbs arranged chronologically and giving a *catena* of Jewish scholars. The treatise belongs to the IVth Order (*Neziqin*) of the Mishnah and deals with the history of tradition. This, the so-called Oral Law (*Torah she-be-al Peh*, Deut. iv. 14; v. 22-33, especially 31; and other passages) supplemented the Written Law (*Torah she-be-khethabh*). The Oral Law in Aboth is traced back from Moses, through Joshua, the elders and Prophets, to the Men of the Great Synagogue, a body the existence of which is now merely doubted but which was formerly denied categorically. Through Simon the Just (either Simeon grandson of Jaddua, High priest, 310-291 B.C., or his grandson, 219-199) and Antigonus of Socho, both survivors of the Great Synagogue, tradition is carried on by five pairs of teachers (*Zūgōth*, ζυγόν) to Hillal and Shammai (30 B.C.). Henceforward the sayings of their disciples and successors are given until ch. iv., which concludes with El'azarhaq-Qappar (end of 2nd cent. A.D.). Chapters iii. and iv. are not strictly chronological. Chapters v. and vi. are of later date. Chapter v. combines historical, legendary and didactic elements, miracles are explained and a series of things, sayings and qualities are grouped numerically, e.g., ten *Ma'amaroth* or *Logoi* are said to have created the world; vi. is called the "chapter of the acquisition of the Law" and was probably added for liturgical purposes. Aboth is written in simple Hebrew. The aphorisms are of great intrinsic beauty and are of extreme historical importance not only for Judaism but for the environment of nascent Christianity. The chapters are read, on different occasions, in most Jewish rites.

BIBLIOGRAPHY.—Pirke Aboth may be studied in English in Singer's *Authorized Daily Prayer Book* pp. 184 sqq. I. Abrahams Notes (pp. clxxvi. of the *annotated edition* should be consulted). The reader is also referred (a) to the *Jew. Enc. s.v. Abot*. (b) *Abot in Encyclopaedia Judaica* vol. I. Berlin (1928). (c) R. Travers Herford's two editions (1) in R. H. Charles *Apocrypha and Pseudepigrapha*, vol. II. (1913) and (2) publ. by *Jewish Inst. of Religion Press* (1925), on which see

S. B. Maximon's article on pp. 325 sqq. of *Jewish Studies in Memory of* ' ' (1927). The older editions of C. Taylor and H. Strack are still of great value.

PIRMASENS, a town of Germany, in the Bavarian Palatinate, 40 mi. W. by S. of Speyer, on the railway from Biebrermühle. Pop. (1939) 51,578. Pirmasens owes its name to a St. Pirmin, who is said to have preached Christianity here in the 8th century. It originally belonged to the count of Hanau-Lichtenberg, but passed to Hesse-Darmstadt in 1736. The staple industry is the production of boots and shoes; but organs, leather and machines are also manufactured.

PIRNA, a town of Germany in the *Land* of Saxony, on the left bank of the Elbe, 11 mi. above Dresden, and on the railway to Bodenbach and Prague. Pop. (1939) 36,130. Pirna, a Slavonic settlement, was for years in the alternate possession of Bohemia and Meissen, but it became permanently united with the latter, and thus with Saxony, in 1405. The most notable edifices are the Gothic parish church, built in the 16th century and restored in 1890, and the old town-hall. Excellent sandstone is found on both banks of the Elbe. There are manufactures of glass, machinery, cigars, pottery, slates and enamelled goods and cotton spinning and wood sawing. The Sonnenstein, a fortress on an eminence above the town, was erected in the 16th century.

PIROGUE or **PIRAGUA** (the French and Spanish forms respectively of a Caribbean word for this type of vessel; it has at various times taken many corrupt forms, e.g., *periagua*, *pettiaugua*, *pettyoagar*), originally the native name of a vessel made by hollowing out the trunk of a tree, a "dug-out"; hence applied to many different developments of this type of vessel used in the West Indies and along the American coast. An early improvement was to split the "dug-out" into two sections and insert a flat bottom of planking to widen it; another form had a lee-board, was decked in at either end, and had two masts.

PIRON, ALEXIS (1689-1773), French epigrammatist and dramatist, was born at Dijon on July 19, 1689. His father, Aimé Piron, an apothecary, wrote verse in the Burgundian patois. Alexis began life as clerk and secretary to a banker, and then studied law. In 1719 he went to Paris. In that year jealousy of the regular actors produced an edict restricting the Théâtre de la Foire, or licensed booths at fair times, to a single character on the stage, and Piron made a great success with a piece called *Arlequin Deucalion*, representing Deucalion immediately after the Deluge. In 1728 he produced *Les Fils ingrats* (known later as *L'École des pères*) at the *Comédie Française*. He attempted tragedy unsuccessfully in *Callisthène* (1730), *Gustave Vasa* (1733) and *Fernand Cortès* (1744). Piron returned to comedy with *La Métromanie* (1738). His most intimate associates at this time were Mlle. Quinault, the actress, and her friend Marie Thérèse Quenaudon, known as Mlle. de Bar whom he married in 1741. He died on Jan. 21, 1773. His best title to remembrance lies in his epigrams. The burlesque epitaph on himself, in which he ridicules the Academy—

Ci-git Piron, qui ne fut rien,
Pas même académicien

is well-known. Grimm called him a "machine à saillies."

Piron published his own theatrical works in 1758, and after his death his literary executor, Rigoley de Juvigny, published his *Oeuvres complètes*. M. Bonhomme produced a critical edition in 1859, completed by *Poésies choisies et pièces inédites* in 1879.

PIROT, a town of South Serbia, Yugoslavia. Pop. (1931) 11,338. It lies amid romantic scenery and is the seat of a prefecture and a tribunal. The inhabitants are engaged in the manufacture of jewellery, thin cloth, woollen braid and carpets. The latter, woven on hand looms by women and children, are its speciality, and are noted for their excellent quality, designs and colouring. There are several schools, a large mosque and a curious old square leaning tower. The mediaeval fortress is believed to have been built on the site of the Roman fortress Quimedava, on the military road from Old Naissus (Nish) to Philippopolis. Outside the town is an early modern entrenched camp. Pirot, which is strategically important, was captured by the Serbs in the Russo-Turkish War (1877-78) and was ceded to Serbia by the Treaty of Berlin (1878). In the war between Serbia and Bulgaria in 1885 Pirot was

occupied by the Bulgarians and held by them till peace was signed. It was again occupied by Bulgaria in 1941.

PIRRIE, WILLIAM JAMES, 1ST VISCOUNT (1847-1924), British shipbuilder and engineer, was born at Quebec on May 31, 1847, and educated at Belfast Royal Academic institution. In 1862 he entered the shipbuilding firm of Messrs. Harland and Wolff of Belfast, becoming partner in 1874 and later chairman. His firm built the White Star line steamships, the first being launched in 1870. From 1896 to 1897 he was lord mayor of Belfast. In 1906 he was raised to the peerage as Baron Pirrie. In 1918, towards the close of World War I, he was made controller-general of merchant shipping. In 1921, on the king's visit to Belfast to inaugurate the new parliament of Northern Ireland, he was created a viscount. He died on June 6, 1924.

PISA, a town and archiepiscopal see of Tuscany, Italy, capital of the province of Pisa, on the Arno, 7 mi. from the sea, and 49 mi. W. of Florence by rail. Pop. (1936) 49,471 (town), 72,468 (commune). It retains its mediaeval walls, $6\frac{1}{2}$ m. in circuit; the citadel now contains barracks. The cathedral, the baptistery, and the famous leaning-tower form a group by themselves at the north-west corner of the town. The two former are built in black and white marble, a characteristic found in Pisan churches elsewhere also. (See SARDINIA.)

The architects of the cathedral were Buschetto and Rinaldo, both probably Pisans. The church is in plan a Latin cross, $311\frac{1}{2}$ ft. long and 252 ft. wide across the transepts inside. The nave, 109 ft. high, has double, the transepts single, vaulted aisles: and at the intersection of nave and transepts is a dome. The columns of the nave and side aisles are ancient. The west front is the finest part of the exterior: the range of arches running round the base is repeated by four open arcades. The three bronze doors were re-made after the fire of 1596; that of the south side (1180) is by Bonanno. The mosaics in the apse were designed by Cimabue, and the splendid decagonal pulpit (restored in 1926:

see *Per la ricostruzione del pergamano di Giovanni Pisano*, 1926) is by Giovanni Pisano. The baptistery, begun in 1153, is a circle 100 ft. in diameter and is covered with a cone-surmounted dome 190 ft. high on which stands a statue of S. Ranieri. The lowest range of semicircular arches consists of 20 columns, and the second of 60; and above this is a row of 18 windows in the same style separated by as many pilasters. In the interior, which is supported by four pilasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Nicola Pisano. The campanile or "leaning tower of Pisa," begun by Bonanno in 1174, is round. The walls at the base are 13 ft. thick, and at the top about half as much; they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by 15 columns, and above this rise six arcades with 30 columns each. The eighth storey, which contains the bells, is of much smaller diameter than the rest of the tower, and has only 12 columns. The height of the tower is 179 feet. The tower was $15\frac{1}{2}$ ft. out of the perpendicular when measured in 1829, and $16\frac{1}{2}$ ft. in 1910. There is no reason to suppose that the architects intended that the campanile should be built in an oblique position; it would appear to have assumed it while the work was still in progress. The foundations are not more than 10 ft. deep, and their circum-

THE LEANING TOWER OF PISA
Begun in 1174 and completed in 1350, the campanile is 179 ft. high and leans more than 16 ft. out of the perpendicular

ference only that of the tower. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo (1188-1200) who made the spot peculiarly sacred by bringing 53 shiploads of earth from Calvary. The building, erected in the Italian Gothic style by Giovanni Pisano in 1278-83, is of special interest for its famous frescoes by various Tuscan artists, including a "Last Judgment" by Francesco da Volterra after Orcagna (1370-71); Benozzo Gozzoli (23 Old Testament scenes, 1468-84), and also for the large collection of Roman sculptures which it contains. Other notable churches are: S. Andrea, S. Pierino, S. Michele in Borgo (11th century), S. Sepolcro, erected by Diotisalvi (c. 1150), S. Nicolò, with a four-storied tower (c. 1230), S. Caterina (1252), S. Francesco (13th century) with frescoes by Taddeo Gaddi (in the adjacent monastery is the interesting museum and picture gallery); S. Maria della Spina, an elegant little church of white marble (1325-29); and the Renaissance church of the Tuscan order of St. Stephen from plans by Vasari (after 1562), who also reconstructed the palace of the order.

The main streets of the older part of the town have porticoes. There are wide quays, with fine buildings, on each side of the Arno, but the town, as a whole, is quiet, owing much of its importance to its being the junction for Florence, Lucca, and Volterra, on the main line between Rome and Genoa. The university, founded in 1338, had 1,500 students in 1938-39; it has a natural history and other museums and a botanical garden. There is also an engineering school, a veterinary institute and an agricultural institute. In the vicinity are the royal villa and stud-farm (horses and dromedaries) of San Rossore (the name is a corruption of Lussorio), and the mineral baths of San Giuliano, alkaline-ferruginous, with temperature 91.4° to 105.8° F. At the mouth of the Arno, joined to the city by a steam tramway (on the way is the old church of S. Piero in Grado) is the seaside resort of Marina di Pisa, also known as Bocca d'Arno, a well-known centre for landscape painters.

At Navacchio, 5 mi. E. of Pisa, is a biscuit factory, 4 mi. N. of which is Calci, and near it the large monastery of the Certosa di Pisa.

The ancient Pisae on the right bank of the Arno was only 2 m. from the sea, the delta having increased since. It is believed to have been founded from Pisae in Elis and is first mentioned in history as the place at which a Roman army from Sardinia landed in 225 B.C. Being situated on the coast road (Via Aemilia) it was important as a frontier fortress against Liguria, for the fertility of its territory, and its quarries and timber for shipbuilding. Scanty ruins of Roman baths exist near the modern Lucca gate on the north. The older town occupied the same site. (T. A.)

HISTORY

Little is known of Pisa during the barbarian invasions, but it is an ascertained fact that it was one of the first towns to assert its independence of Byzantine rule. During the first years of the Lombard rule the necessity of defending the Italian coast from the attacks of the Byzantines was favourable to the development of the Pisan navy.

Early Wars.—In 1003 we find records of a war between Pisa and Lucca, which, according to Muratori, was the first waged between Italian cities in the middle ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. Numerous legends and fables of the old chroniclers serve to attest the importance of Pisa in those days. The Saracens repeatedly attacked the town, but were repulsed, and the Pisans themselves assumed the offensive in Calabria, Sicily, and even in Africa. In 1015 a memorable expedition was undertaken by the united forces of Pisa and Genoa against Mogahid, better known in the Italian chronicles as Mugeto, whom they drove from Sardinia. Again invading the island, he was again attacked and defeated by the same adversaries, leaving a brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by native "judges" who were like petty sovereigns, but were now subject to the sway of Pisa. This was

the primary cause of the jealousy of the Genoese and of the wars afterwards made by them upon Pisa. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di mare*), which in 1075 were approved by Gregory VII., and in 1081 confirmed by a patent from the emperor, Henry IV. The oldest of Pisan statutes still extant is the *Breve dei consoli di mare* of 1162.

Commercial Prosperity.—In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses and privileges of all kinds in every Eastern port. Thus while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese and Muslims. In the years 1113 and 1115 it achieved a still greater enterprise. The Pisan fleet of 300 sail, commanded by the archbishop, Pietro Moriconi, attacked the Balearic Isles, where as many as 20,000 Christians were said to be held captive by the Muslims and returned loaded with spoil and with a multitude of Christian and Muslim prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. Immediately afterwards, the 14 years' war with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan Church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese Church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor, Lothair II., the Pisans entered Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Muslims (1187) the Pisans and Genoese again met in conflict in the East, and it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistry was begun in 1152, and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

RIVALRY WITH FLORENCE AND GENOA

The chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelph and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. Owing to the political and commercial interests binding Florence to the Roman court, the Guelph element naturally prevailed there, while growth of its trade and commerce necessarily compelled that republic to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a vigorous resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence, which broke out in 1222, to a ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog—which merely shows that there were already so many general

and permanent reasons for war that no special cause *was* needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garfagnana, and at the same time they despatched 52 galleys to assist Frederick II. in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia, and war was intermittent down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca and all the Guelph cities of Tuscany against its Ghibelline rival: the pope had excommunicated Frederick II. and all his adherents; and, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless the Pisans were undaunted. Summoning Siena, Pistoia and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now 12 elders (*anziani*); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of 40 members. The rout of the Tuscan Guelphs on the field of Montaperti (1260) restored the fortunes of Pisa. But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), sealing the ruin of the house of Hohenstaufen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Guelph and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. At this time Count Ugolino della Gherardesca had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the Guelphs and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman, Giovanni Visconti, judge of Gallura, in Sardinia; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor. In 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid waste its surrounding territories. In 1276 the Pisans were compelled to agree to very grievous terms—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino. Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On Aug. 6, 1284, at the great battle of Meloria 72 Pisan galleys engaged 88 Genoese, and half the Pisan fleet was destroyed. The chroniclers speak of 5,000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa. She had lost her dominion over the sea, and the Tuscan Guelphs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop, Ruggieri, having put himself at the head of the nobles, was elected podestà by the Lanfranchi, Sismondi and Gualandi, and a section of the popular party. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After

a day's fighting (July 1, 1288) the count, his two sons and his two grandsons were captured in the palazzo del popolo (or town hall), and cast into a tower belonging to the Gualandi, and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic prelate opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. In 1293 they secured a profitable peace. They and the other members of the Guelph league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba were exempted from every tax. They likewise received a ransom of 160,000 florins for their Pisan prisoners.

In 1312 the arrival of the Emperor, Henry VII., gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Ugucione della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on Aug. 29, 1315. In 1316, however, he was expelled in an outburst of popular fury. But Pisa's freedom was forever lost. Ugucione della Faggiuola was succeeded by other lords or tyrants of whom the most renowned was Castruccio Castracani, a political and military adventurer of much the same stamp as Ugucione himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them forever—but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (Oct. 2), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them in triumph to Florence, and suspended them in front of the baptistery, where they remained until 1848. Then in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Gian Galeazzo Visconti, known as the count of Virtù, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Gherardesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtù, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa and Monte Cristo. Thus in 1399 Visconti took possession of Pisa, and left it to his natural son, Gabriele Maria Visconti, who was afterwards expelled from its gates. But even in this century of disaster the Pisans continued to encourage not only commerce, but also the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Nic-

cola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and the celebrated frescoes attributed to Orcagna (*q.v.*) were painted on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1464.

The Victory of Florence. — Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on Oct. 9, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner course. In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not hesitate, even in his presence, to assert their own independence, and casting the Florentine emblem, the Marzocco, into the Arno, made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault, and, what was worse, yearly laid waste their territories and destroyed all their crops. Soderini, who was perpetual gonfalonier of Florence, and Machiavelli, the secretary of the Ten, urged on the war. In 1509 Florence encamped her forces on three sides of the distressed city, which at last, reduced to extremity by famine, was compelled to surrender on June 8, 1509. Thenceforth the Florentines remained lords of Pisa. But now, mainly owing to the efforts of Soderini and Machiavelli, the conquerors showed great magnanimity. They brought with them large stores of provisions which were freely distributed to all; endeavoured to succour the suffering populace in every way, and gave other assistance to the wealthier classes. Nevertheless, emigration continued even on a larger scale than in 1406, and the real history of Pisa may be said to have ended. In Naples, in Palermo, in all parts of Italy, Switzerland and the south of France, we still find the names of Pisan families who quitted their beloved home at that time. The Florentines immediately built a new citadel, and this was a great bitterness to the Pisans. The Medici, however, remained well disposed towards the city. Leo X. was an active patron of the university, but it again declined after his death. The grand duke, Cosimo I., a genuine statesman, not only restored the university, but instituted the "uffizio dei fossi" or drainage office for the reclamation of marsh lands, and founded the knighthood of St. Stephen. This order played a noble part in the protection of Tuscan commerce, by fighting the Barbary pirates and establishing the prestige of the grand-ducal navy (*see* MEDICI). Under the succeeding Medici, Pisa's fortunes steadily declined. Ferdinand I. initiated a few public works there, and above all restored the cathedral, which had been partly destroyed by fire in 1595. These dreary times are brightened by one glorious name—that of Galileo Galilei.

PISA, COUNCIL OF (1409). The great schism of the west had already lasted thirty years, and the efforts which had been made to restore unity within the Church by the simultaneous resignation of the two rival pontiffs had been in vain, when in the spring of 1408, the state of affairs being desperate, the idea arose of assembling a council to effect a union without the co-operation of the popes. The initiative came from those cardinals who had one after the other seceded either from Gregory XII. or Benedict XIII. The day, after the opening of the council, proceedings were started against the two popes, who, it was agreed, were to be eliminated. In order to depose them with some show of legality, it was necessary, as a preliminary, to convict them of heresy, and it began to be seen that their tenacity of power, and the ruses by which they evaded the necessity of abdicating, however harmful might be their consequences, did not in themselves constitute a clearly-defined heresy. On the 5th of June 1409 was read the definitive sentence: that as heretics, and therefore separated from the Church, Pedro de Luna (Benedict XIII.) and Angelo Corrarío (Gregory XII.) were *ipso facto* deposed from any office; they must not be obeyed, nor assisted, nor harboured.

In order to complete their task the cardinals present at Pisa, authorized by delegation of the council, shut themselves up in conclave, and elected one of their number, Peter Philarges, cardinal of Milan, as the new pope, who assumed the name of Alexander V. They had hoped to save the Church, but unfortunately the result of their efforts, generous as they were, was that the schism increased in bitterness, and that instead of the unity for which the Church craved, three popes continued to flourish. Both the deposed pontiffs protested against the legality of the council of Pisa; each had numerous partisans, and the thesis, constructed rather to meet the exigencies of the case, which attributed to a synod assembled by the cardinals the right of constituting itself judge of a sovereign pontiff, was far from being established. The council was proceeding to occupy itself with reform when it was dissolved by Alexander V. (August 1409).

PISAN, CHRISTINE DE (1364-c. 1430). French poet, of Italian birth, was born at Venice in 1364. When she was four years old she was brought to her father, a councillor of the Venetian Republic, in Paris, where he held office as astrologer to Charles V. At fifteen Christine married Étienne du Castel, who became Charles's notary and secretary. After the king's death in 1380 her father lost his appointment, and died soon after; and when Christine's husband died in 1389 she found herself without a protector, and with three children depending on her. This determined her to have recourse to letters as a means of livelihood. Her first ballads were written to the memory of her husband, and as love poems were the fashion she continued to write others—*lais*, *virelais*, *rondeaux* and *jeux à vendre*—though she took the precaution to assure her readers (*Cent balades*, No. 50) that they were merely exercises. In 1399 she began to study the Latin poets, and between that time and 1405, as she herself declares, she composed some fifteen important works, chiefly in prose, besides minor pieces.

The earl of Salisbury, who was in Paris on the occasion of the marriage of Richard II. with Isabella of France (1396), took her elder son, Jean du Castel (b. 1384), and reared him as his own; the boy, after Salisbury's death (1400), being received by Philip of Burgundy, at whose desire Christine wrote *Le Livre des faits et bonnes moeurs du sayge roy Charles* (1405), valuable as a first-hand picture of Charles V. and his court. Her Mutation de fortune, in which she finds room for a great deal of history and

philosophy, was presented to the same patron on New Year's Day, 1404. In *La Vision* (1405) she tells her own history, by way of interest. In *La Vision* (1405) she tells her own history, by way of defence against those who objected to her pretensions as a moralist. Henry IV. of England desired her to make his court her home, and she received a like invitation from Galeazzo Visconti, tyrant of Milan. She preferred, however, to remain in France, where she enjoyed the favour of Charles VI., the dukes of Berry and Burgundy, the duchess of Bourbon and others.

Christine was a champion of her own sex. In her *Dit de la rose* (1402) she describes an order of the rose, the members of which bind themselves by vow to defend the honour of women. Her *Épître au dieu d'amour* (1399) is a defence of women against the satire of Jean de Meung, and initiated a prolonged dispute with two great scholars of her time, Jean de Montreuil (d. 1415) and Gonthier Col, who undertook the defence of the Roman de la rose. Christine wrote about 1407 two books for women, *La Cité des dames* and *Le Livre des trois vertus*, or *Le Trésor de la cité des dames*. She was devoted to her adopted country. During the civil war she wrote a Lamentation (1410) and a *Livre de la paix* (1412-1413), but after the disasters of the campaign of Agincourt she retired to a convent. We have no more of her work until 1429, when she broke her silence to write a song in honour of Joan of Arc. Of the circumstances of her death nothing is known but it probably took place about this time.

Her poems were edited by Maurice Roy for the Société des anciens Textes français (1886, etc.), and her *Livre du chemin du long estude*, by Puschel (Berlin, 1887). There are monographs by Raimond Thomassy (Paris, 1838); E. M. D. Robineau (Saint-Omer, 1882); and Friedrich Koch (Goslar, 1885). It is possible that Jean Castel, who was chronicler of France under Louis XI., was Christine's grandson. Hoccleve imitated her *Épître au dieu d'amour*, in his "Letter of Cupid" (*Chaucerian* and other Pieces, ed. W. W. Skeat,

1897). A translation of her *Épître d'Othéa* was made (c. 1440) by Stephen Scrope for his stepfather, Sir John Fastolf, and is preserved in a MS. at Longleat. This was edited (1904) for the Roxburghe Club by W. G. F. Warner as *The Epistle of Othéa*, to Hector, or the Boke of Knyghthode. The Moral Proverbs of *Christyne de Pise*, translated by Earl Rivers, was printed in 1478 by Caxton, who himself translated, by order of Henry VII., her *Livre des faitz d'armes, et de chevalerie*, a treatise on the art of war, based chiefly on Vegetius. Her *Cité des dames* was translated by Brian Anslay (London, 1521).

PISANO, ANDREA (c. 1270-1348), Italian sculptor, was born about 1270, and first learned the trade of a goldsmith. His style was influenced to some extent by Giovanni Pisano. His chief works were executed at Florence, and the formation of his mature style was due rather to Giotto than to his earlier masters. Of the three world-famed bronze doors of the Florentine baptistery, the earliest one—that on the south side—was the work of Andrea; he spent many years on it; and it was finally set up in 1336. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues, and the rest scenes from the life of the Baptist. At the death of Giotto in 1337, Andrea was appointed architect of the campanile, and built the two stories of niches above the work of Giotto. Of the beautiful panel-reliefs which decorate the campanile those representing "The Crane," "Weaving," "Daedalus," "Navigation," "Hercules," "Agriculture," "Theatre" and "Medicine," display the style of Andrea Pisano. The duomo contains the chief of Andrea's other Florentine works in marble. In 1347 he was appointed architect in the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The date of his death must have been shortly before 1349.

See M. Reymond, *La Sculpture Florentine* (Florence, 1897).

PISANO, GIOVANNI (c. 1249-after 1314), Italian architect and sculptor, was the son of Niccolò Pisano. He developed and extended into other parts of Italy the renaissance of sculpture initiated by his father. He spent the first part of his life as a pupil and fellow worker of Niccolò and appears as his collaborator at the fountain of the great piazza at Perugia. Between 1278 and 1283 he was employed on the cloister, which surrounds the Campo Santo at Pisa. In 1284 Giovanni was appointed "capo maestro" of the new cathedral at Siena. He began the magni-

¹The date on the door, 1330, refers to the original wax model.

ficient façade. His design, however, was modified by the architects who succeeded him. From 1298 to 1301 he was employed on the pulpit of San Andrea at Pistoia. Then followed the pulpit of the cathedral at Pisa, completed in 1311. It was taken to pieces some two hundred years later, but fragments are to be seen at Pisa, and in the Berlin museum. The figures for the tomb of the Empress Margaret, now in the Palazzo Bianco at Genoa, were executed soon after the Empress' death in 1311. A number of statues of "The Virgin and Child" have been attributed to him on stylistic evidence. Among these the three most important are at Prato; in the Campo Santo, Pisa; and in the Arena chapel at Padua. The Cathedral of Pisa has a fine figure of the Madonna carved in ivory. Giovanni's early work was inspired by his father Nicola. Later his figures and draperies displayed the expressive flow of lines appertaining to the Gothic style. Like the work of most stonemasons in mediaeval times, his sculpture forms part of an architectural design. The subject matter of his carving was dictated by the liturgy of the church, and his interpretations are imbued with deep religious feeling.

See M. Sauerlandt, *Bildwerke des Giovanni Pisano* etc. (1904); A. Brach, *Nicola und Giovanni Pisano und die Plastik des XIV. Jahrhunderts in Siena* (1904); I. Supino, *Arte Pisana* (Florence, 1904), and *Pisa* (1918); V. Lusini, *Il duomo di Siena* (Siena, 1911); P. Bacci, *Dedalo* I. p. 319.

PISANO, NICCOLA (c. 1225-c. 1278), Italian sculptor and architect settled at Pisa. A document among the archives of the Sienese Cathedral calls him son of "Petrus de Apulia," and most modern writers believe that he not only was a native of the province of Apulia in southern Italy, but also that he gained there his early instruction in the arts of sculpture and architecture. Except through his works, little is known of the history of Niccolò's life. In 1259 as an incised inscription records, he finished the marble pulpit for the Pisan baptistery; this is his most important early work, and is entirely classical in spirit.

It is a high hexagon, on semicircular arches, with trefoil cusps, supported by seven marble columns, three of which rest on white marble lions. In design it presents a combination of Gothic forms with classical details. Five of the sides of the main hexagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Crucifixion and the Last Judgment. These are all works of the highest beauty, and a wonderful advance on anything of the sort that had been produced by Niccolò's predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity; and the stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccolò's study of the antique is most apparent. The veiled and diademed figure of the Virgin Mother, seated on a throne, recalls the Roman Juno; the head of Joseph behind her might be that of Vulcan; while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing and kneeling figures of the Magi.

The beautiful relief of the Deposition from the Cross in the tympanum over a side door at San Martino at Lucca was probably Niccolò's most important work. Then followed the Arca di San Domenico, in the church at Bologna consecrated to that saint. This work was completed in 1267 in collaboration with the Dominican Fra Guglielmo. The most magnificent of Niccolò's works is the great pulpit in Siena cathedral. It is much larger than that at Pisa, being an octagon on cusped arches and columns. The contract for this work (1266) discloses the names of Niccolò's assistants:—Arnolfo (di Cambio) Donato, and Lapo—besides his son Giovanni. In the reliefs of this pulpit can be traced the influence of the great Gothic sculptors of France. They mark the beginning of a new epoch in the history of Italian sculpture; classical repose is sacrificed for expression of religious emotions.

Niccolò's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of three basins rising one above another, each with sculptured decoration; it was begun in 1274 and completed, with the co-operation of Niccolò's son Giovanni, and of Arnolfo di Cambio. Niccolò appears also to have had knowledge of archi-

tecture, for, when he signed the contract for the pulpit in Siena, he stipulated that he might go to Pisa four times a year to attend consultations about the building of the cathedral and baptistery. Many important buildings are ascribed to him by Vasari without corroboration. In 1278 Nicola is mentioned for the last time as working on the fountain in Perugia. The first record of his death occurs in Sienese archives under the date Aug. 30, 1287.

See **SCULPTURE**, and general histories of Italian art; Symonds, *Renaissance in Italy*; K. Frey, *Vasari* I (1911, 1909, p. 423); I. Supino, *Arte Pisana* (Florence 1904); M. Raymond, *La sculpture florentine I* (Florence, 1897); A. Brach, *Nicola and Giovanni Pisano* (Strassburg 1904).

PISANO, VITTORE (1397-1455), commonly called **PISANELLO**, Italian medallist and painter, was the son of a Pisan father called Bartolommeo and a Veronese mother. He was one of the leading artists of his age, and enjoyed great celebrity during his lifetime. Guarino, a distinguished humanist, sings his praises in lines such as these: "Great is the renown that comes to Verona from the excellence of your work," and "Our age has produced you to be numbered with the great sculptors and painters of antiquity." We know nothing concerning Pisanello's artistic education. Vasari, who likes to derive all great art from Florence, states that he studied under Andrea del Castagno in Florence. But he was more probably trained in Verona in the traditions of Altichiero. About 1422 he worked in conjunction with Gentile Fabriano in the great council hall of the doge's palace in Venice. During their stay in Venice the two artists exercised a great influence on the development of Venetian art. Pisanello was much favoured by the princes and potentates of Italy. There is evidence that he worked at various times at Ferrara, Mantua, Milan, Pavia, Naples, Rome, Venice and Verona. He was well received at the courts of his patrons; he designed their costumes, the patterns of the material they used, the harness for their horses, besides painting their portraits and Madonna pictures.

Unfortunately, only very few of his paintings have survived. These are: the fresco of "The Annunciation" in S. Fermo at Verona and the fresco painted on the arch of the Pellegrini chapel in S. Anastasia, in the same city, representing "St. George Mounting his Horse"; three easel pictures may be singled out as representative of the master; the "Miraculous Stag appearing to St. Eustace" in the National Gallery, London; the portrait of a princess of the house of Este in the Louvre; and the portrait at the gallery in Bergamo of Lionello d'Este, who was one of the artist's chief patrons and admirers. These panels are carefully finished to the minutest detail, and are beautifully drawn. The Louvre possesses in the Vallardi book a number of delicate and spirited pen drawings by Pisanello. These detailed studies of nature, in which animals figure very largely, seem to have been his great delight and display the powers of an extraordinary draughtsman. But it is for his medals and plaques that Pisanello is best known. Although he was not, as was at one time asserted, the inventor of the medal, it was he who initiated this form of art as one of the most characteristic productions of the Renaissance. Pisanello's earliest medal was probably that of the Greek emperor John VII. Paleologos, dated about 1438-39.

PISAURUM (mod. Pesaro, *q.v.*), an ancient town of Umbria on the Via Flaminia, 26 m. from Ariminum and 8 from Fanum Fortunae. A Roman colony was founded here in 184 B.C., at the mouth of the river Pisaurus (mod. Foglia; the sea has since receded about half a mile). It was destroyed by the Goths in 539, and restored by Belisarius in 545.

PISCES, the "Fishes," in astronomy, the twelfth sign of the zodiac, represented by two fishes tied together by their tails, and denoted by the symbol X. In Greek legend Aphrodite and Eros, while on the banks of the Euphrates, were surprised by Typhon, and sought safety by jumping into the water, where they were changed into two fishes. This fable, however, as in many other similar cases, is probably nothing more than an adaptation of an older Egyptian tale. The constellation contains only faint stars

without any striking grouping.

Piscis australis or *Austrinus*, the southern fish, is a constellation of the southern hemisphere. It contains Fomalhaut, a star of the first magnitude.

Piscis volans, the flying fish, is a constellation introduced by John Bayer in 1603. The name is now abbreviated to *Volans*.

PISCICULTURE. The species of food-fish that can be kept successfully in ponds throughout their lives from egg to adult are exceedingly limited in number. The various breeds of gold fish and top-minnows (*Cyprinodonts*) are familiar examples and the carp is an example of food-fishes capable of similar domestication. In the United States the eastern brook trout and the black bass are almost as fully domesticated. Various other food-fishes, both marine and fresh-water, can be kept in ponds for longer or shorter periods, but refuse to breed, while in other cases the fry obtained from captive breeders will not develop. Consequently there are two main types of pisciculture: (1) the rearing in confinement to an edible stage of the young of domesticated breeders; (2) the stocking of natural waters with eggs or fry from captured adults.

Fish-rearing.—Of the first type of pisciculture there are several examples of commercial importance in the cultivation of fresh-water fishes. The pond culture of carp is important in China and Germany, but in England it has long fallen out of use and is not likely to be resumed so long as other fresh fish can be obtained and distributed so readily as is now the case. In the United States pond culture of carp has been practically discontinued because of the prejudice of native Americans against the fish and because of its great increase in natural waters which now afford a large commercial yield. In Germany, on the other hand, intensive methods have been applied to pond culture with remarkable results in recent years.

In the United States some species of trout and charr have become so thoroughly domesticated that many commercial trout hatcheries have been established, some of them with a score of ponds heavily stocked with eastern brook trout (*Salvelinus fontinalis*) sorted into different ponds according to size and fed usually on slaughter house offal in addition to such natural food as they may obtain. Under this system the trout grow twice or three times as fast as the wild ones, a growth of from 7 to 11 in. during the first year being no exception. Some of the male fish are killed and sold before they are sexually mature; but most of the fish are kept until they reach sexual maturity in the second fall of their life at the age of 20 months and are then stripped and sold immediately thereafter.

Next in order of importance are the North American basses and sunfishes (family *Centrarchidae*), all of which make "nests." The most important members of the family are the largemouth (*Aplites salmoides*) and smallmouth (*Micropterus dolomieu*) black bass which are propagated in large numbers of State, national and private ponds. Artificial nest-boxes with bottoms covered with material suitable for the species are placed in the ponds, the fish spawn in them and the male guards the nest; and schools of fry. The schools of young, usually numbering several thousand to the nest, are transferred to rearing ponds; and fed on Japanese *Daphnia* raised in small separate ponds and on other food. Young bass are usually planted as fingerlings, 3 or 4 in. long or as yearlings. They could be raised for the market, but the cost would be prohibitive. In addition to the bass seven species of sunfishes are cultivated in the United States by similar, but simpler methods.

In the lagoons of the Adriatic and the salt marshes of various parts of France examples of the cultivation of salt-water fish are to be found analogous to the pond culture of fresh waters. Here, as in ancient Greece and Rome, it is the practice to admit young fish from the sea by sluices, into artificial enclosures or "viviers" and to keep them there until they are large enough to be used. An interesting modification of this method of cultivation has been introduced into Denmark. The entrances to the inner lagoons of the Limfjord are naturally blocked against the immigration of flatfish by dense growths of sea-grass (*Zostera*) although the outer lagoons are annually invaded by large numbers

of small plaice from the North sea. The fishermen of the district consequently combined to defray the expenses of transplanting large numbers of small plaice from the outer waters to the inner Lagoons, where they were found to thrive far better than in their natural habitat. The explanation has been shown by Dr. Petersen to be due to the abundance of food, coupled with the lack of overcrowding of the small fish. This transplantation of small plaice in Denmark has been annually repeated for many years with the most successful results and a suitable subvention to the cost is now an annual charge upon the Government funds.

As a result of the international North sea fishery investigations, it has been proposed to apply the same principle for the development of the deep-sea fishery in the neighbourhood of the Dogger Bank. Experiments with labelled plaice, carried out in 1904 by the Marine Biological Association, showed that small plaice transplanted to the Dogger Bank in spring grew three or four times as rapidly as those on the inshore grounds, and the same result, with insignificant variations, has been obtained by similar experiments in later years. (See Reports of the Ministry of Agriculture and Fisheries cited at the end.) In this case the deep water round the Dogger Bank acts as a barrier to the emigration of the small plaice from the shores. It has consequently been proposed that the small plaice should be transported in millions to the bank by well vessels every spring. It is claimed, as further result of the experiments, that from May to October the young fish would be practically free on the shallow part of the bank from the risk of premature capture by trawlers, and that the increased value of the fish, consequent upon their phenomenal growth rate, would greatly exceed the cost of transplantation. The development of seining on the Dogger Bank since 1919 has probably increased the risk of premature capture, but satisfactory information on this point is lacking. In the experiments made by the English Ministry of Fisheries the transplanted fish retaken by seiners amounted to about 20% of the total recaptured in 1922 and 1923, but the actual months are not stated.

Not unlike the work on plaice is the rescue work carried on in the United States, chiefly by the Bureau of Fisheries, but also by the States of Minnesota, Wisconsin, Iowa and Illinois. With the recession of the waters of the Mississippi river after spring freshets, many fishes become land-locked in temporary ponds or sloughs. By removing them to permanent waters they are saved from death due to drying of the ponds. In 1926 the Bureau of Fisheries seined about 150,000,000 impounded fish and returned them to open waters and similar work is undertaken each year.

In France and Japan the methods of oyster and mussel culture are similar in principle to those just described. A breeding stock is maintained to supply the ground or the "collectors" with spat. and the latter, when sufficiently grown, is then transplanted to the most favourable feeding grounds, care being taken to avoid the local overcrowding which is so commonly observed among shell-fish under natural conditions.

Fish-hatching.—The second and more familiar type of pisciculture is that known as fish-hatching, with which must be associated the various methods of artificial propagation. Fertilization of the spawn is easily effected by "stripping" the eggs from the female into a moistened pan and immediately adding the milt of the male by the same process (the dry or Russian method). Water is next repeatedly added and poured off to wash the milt from the eggs, which soon swell and harden so that they may be transferred to the hatching apparatus without injury. Although simple floating hatching boxes may often be used in natural waters, for large-scale operations hatcheries are constructed and the type of apparatus employed in them depends on the eggs to be hatched. For the smaller and lighter semi-buoyant or demersal eggs, such as those of whitefish (*Coregonus*), shad (*Alosa sapidissima*), etc., tall glass jars are used provided with a central inlet pipe through which water reaches the bottom of the jar and flows upward through the eggs to escape at the top. The dead eggs float and are removed by siphoning. The jars are grouped into "batteries," each of which may be merely a number of jars set on a table and supplied with water from a pipe above them, as in hatching shad. For hatching whitefish and pike-perch

eggs a battery may consist of more than zoo jars arranged in four superimposed tiers on two sides of a complicated system of wooden troughs, which serve to convey water to and from them.

For hatching the larger and heavier demersal eggs of trout and salmon primitive apparatus, still in use in parts of Europe, consists of long wooden troughs in which the eggs lie on gravel in running water. In more modern hatcheries, in order to economize space and utilize the water supply to the best advantage, the troughs are divided into "boxes" by transverse partitions and the boxes are filled with trays or baskets of eggs. The partitions are so constructed that the water which flows along the trough from box to box is given an upward or downward movement through the eggs in each box. For hatching trout eggs ten shallow wooden trays with bottoms of wire gauze each supporting a single layer of eggs are stacked in each box, covered by an empty tray and latched down by a cross-bar. A trough of five boxes carries from 500,000 to 750,000 eggs. The trout fry remain on the trays until a week or ten days before the yolk sac is absorbed and are then planted or transferred to rearing ponds. Four Pacific salmon baskets of wire screen are half filled with eggs (about 30,000), and one basket is placed in each box with the top projecting above the water so that no eggs can escape. The newly-hatched fry fall through the meshes in the bottom of the basket and remain on the bottom of the box until the heavy yolk is so far absorbed that they are able to swim upward. They may be then planted or held and fed in artificial ponds near the hatcheries to be planted when a year or more old.

For the buoyant eggs of cod, use is commonly made of the McDonald or tidal hatching box which is so constructed that a jet of water gives a rotary motion to the eggs while an intermittent siphon causes the water in the box to rise and fall at regular intervals, so that the rotating eggs are carried up and down much as they would be by the waves of the open sea.

The hatching of the eggs, whether of fresh or salt-water fishes presents no serious difficulties, if suitable apparatus is employed; but the rearing of fry to an advanced stage, without serious losses, is less easy, and in the case of sea-fishes, with pelagic eggs, the larvae of which are exceedingly small and tender, is still an unsolved problem, although recent work carried out at the Plymouth laboratory of the Marine Biological Association, in England, is at least promising. It has been found possible to grow pure cultures of various diatoms, and by feeding these to various larvae kept in sterilized sea water, great successes have been attained. In fresh-water culture there may be little advantage in artificial hatching, unless it is followed by a successful period of rearing. Thus the Howieton Fishery Company (England) recommended their customers to stock their streams either with unhatched ova sown in redds or with three-months-old fry. Their experience is "that there is no half-way house between ova sown in redds and three-months-old fry. Younger fry *may* do, but only when ova would do as well and at half the cost." In marine hatcheries, on the other hand, it is the invariable practice to hatch the eggs, although the fry have to be put into the sea at the most critical period of their lives, in an environment which teems with predacious enemies.

Some of the advances made in the United States in recent years in the cultivation of fish and shell-fish are shown by the examples which follow. They suggest the importance of a detailed knowledge of the life-history of the forms to be cultivated and the advantages of rearing to a suitable stage.

Decline in the Pacific salmon fishery led to the establishment of hatcheries until in 1921 there were 90 such establishments maintained by the United States, by the individual States, and by British Columbia. But in spite of the great hatchery output, the fishery continued to decline alarmingly in certain localities. This apparent failure of the hatcheries to rehabilitate the fisheries led the authorities of the United States and British Columbia to promote a co-operative and detailed study of the life history of the Pacific salmon in the hope that this would reveal better means of artificial propagation or enable fisheries restrictions to be intelligently applied, while in 1924, by act of Congress, full control of the Alaskan fisheries was placed in the hands of the

Department of Commerce and has since been exercised by its Bureau of Fisheries.

There are five species of Pacific salmon (*Oncorhynchus*) all of which ascend from the sea into the rivers to spawn and are captured in commercial nets on the upward journey. Unlike the Atlantic salmon, they invariably die after spawning, but the young hatched from their eggs return to the sea after a longer or shorter stay in fresh water. Investigations of the past ten years have added many important details of the life history. The method of investigation consists, in part, in marking the young by removal of some of the fins, releasing them in fresh water at various ages and in various places and recovering the marked fish when they return from the sea to fresh water to spawn. In part it consists of the microscopic study of the markings of the scales of returning adults. From these the age, rate of growth and period of time spent in fresh water may be determined. From these investigations it is now known that the fry may begin their return to the sea soon after hatching (pink and chum salmon), or may remain in fresh water for a year (silver salmon) or from one to four years (red salmon), or, as in the chinook, they may either start for the sea soon after hatching or when 12 or 18 months old. The age at return to fresh water also varies. In the pink it is invariably two years, in the chum from two to five or six years, in the silver three years, in the red three to seven years, in the chinook two to seven or eight years.

The salmon of each species almost invariably come back to spawn in the stream or lake in which they were hatched (parent stream). The most important discovery of recent years is this confirmation of the "parent stream theory" with the resultant conception of each species as made up of numerous self-contained colonies or races of interbreeding individuals. It results that if commercial fishing or other obstruction of a stream prevents so many individuals of any race from returning to their home spawning-ground that an adequate breeding stock is not maintained, that race is depleted or disappears and its racial ground is not afterward colonized by other races. It is then essential that commercial fishing be so conducted as to permit the escapement to the spawning ground of enough breeding fish of each colony to maintain that colony. In Alaska, the U.S. Bureau of Fisheries now requires a "spawning escapement" of 50%. This regulation was first imposed in 1924 and in 1926 the run of pink salmon, a two year fish, was the largest ever known. How large the spawning escapement must be to maintain a racial population in any locality is not yet definitely known. Actual counts made under the direction of Dr. Gilbert have shown that in the Karluk river, Alaska, three red salmon returned in 1926 for each parent fish of the 1921 spawning escapement. This ratio does not include the fish of the 1921 hatch that returned in earlier years or those still to return. If the proportion should prove to hold for all seasons an escapement of less than one-third would serve to maintain the race.

From studies made on the return of young salmon marked and released in fresh water, evidence is accumulating that artificial propagation may be made effective. It has been found that marked fingerlings of the Alaskan sockeye or red salmon, released in the Columbia river in the fall of their first year, fail to return, but if released in the spring of their second year, they return; success does not necessarily depend merely on the release of great numbers of large and vigorous fingerlings, but on their release at the right age, the age at which they naturally begin their seaward voyage. It has been found, further, that since each tributary (Columbia river) supports a separate colony it is inadvisable to transfer fingerlings from one tributary to another. Different racial groups start their spawning migrations at different times and each starts at such a time as to bring it to the spawning grounds when conditions there are suitable for laying of the eggs and development of the young of that race. If fingerlings are released on an alien ground they will return as adults to it, but they may then find the conditions on it unsuited to them at the time of their return. By releasing the fry or fingerlings of each race on its home ground and at the right age better results may be expected from hatchery operations than have been reached up

to this time. Thus in an experiment on the Columbia river the number of returning adults, recaptured after having been marked as fingerlings and released on their home ground when of suitable age, was 30 times that necessary to produce the eggs from which they came (Holmes). Increased runs of Pacific salmon are also reported by Canadian officials as the result of hatchery operations in the Frazer river.

In the United States many of the natural oyster beds have been so exploited that they have disappeared and others are greatly depleted. The great size of the beds, the high cost of labour and the relatively low price of the product make the method of pond culture currently employed in France and Japan impracticable. Culture consists at present wholly of rehabilitating the beds in natural waters and increasing their number (planted beds). About half the 30,000,000 bu. of oysters marketed annually are now obtained from planted beds and in the New England States about 90% are from that source.

It has long been known that fertilized eggs could be obtained by cutting open oysters and stripping the apparently ripe milt and eggs from them, but recently oysters have been induced to spawn naturally in tanks of sea water by permitting the temperature to rise to about 70° F and in this way better results have been obtained. But, for artificial culture, large numbers of the minute larval oysters must be raised to the fixed or spat stage. This has been hitherto impossible owing to the difficulty of retaining them in tanks while supplying them with running water. Until they are several days old they pass readily through felt or the finest silk bolting cloth. A new filtering material, known as "filtros" has now proved entirely satisfactory and several lots of larvae have been reared to the spat stage by investigators of the U.S. Bureau of Fisheries. Seed oysters for planting have become increasingly scarce and costly, but if the method referred to becomes a part of commercial oyster culture they may be produced in quantity at a cost much below that of collecting them from the beds.

In the United States the supply of the species of fresh water mussels from which pearl buttons are made has declined in recent years with the result that much work has been done on methods of cultivating these forms. The larvae (glochidia), after expulsion from the gills of the female mussel, become parasitic on the gills of fish from which they draw their nourishment and from which they fall after transforming into young mussels. In the earlier attempts to increase the mussel supply, fish artificially inoculated with glochidia were released into natural waters and not only fish captured for the purpose, but great numbers of rescued fish (see above) were used. In 1926 fish rescued and released by the U.S. Bureau of Fisheries had been inoculated with nearly 3,000,000,000 glochidia taken from about 40,000,000 mussels. Later experiments showed that the inoculated fish could be held in troughs until the young mussels dropped from them. The latter are then cared for during the first season of their growth. But the number of glochidia that can be safely carried by a single fish is limited, and the inflammation caused by over-infestation results in many deaths. Hence, a method was sought of rearing the glochidia without permitting their attachment to a fish host. Although the inoculation of both fish to be held captive and of those to be released is still practised, it recently has been found that the glochidia may be reared to young mussels in an artificial medium which supplies the nourishment normally drawn from the fish host and makes the use of the latter unnecessary. With perfection of the technique it is practically certain that young mussels will soon be raised and distributed in large numbers without employing fish hosts.

In the lobster (*Homarus*) the eggs are carried attached to the appendages of the lower surface of the abdomen of the female and average 30,000 in lobsters 13 in. long. The larvae hatched from the eggs pass through a remarkable series of transformations at successive moults. During the first four stages they are minute and free-swimming and subject to destruction by storms and countless enemies; but at the close of the fourth stage, or in the fifth, they become ambulatory, descend to the bottom and show an ability to protect themselves. "One lobster at this stage

is worth many thousands in the first" (Herrick). Owing to the hard outer shell it is not possible to "strip" the lobster and cultivation, therefore, consists in rearing the naturally-hatched young through the helpless free-swimming stages to the ambulatory bottom stage capable of self protection. The most successful method is that devised by Mead and his co-workers and first used at Wickford, R.I., under the auspices of the Rhode Island commissioners of inland fisheries.

The unit apparatus is a wooden box 10 ft. square and 4 ft. deep with screened openings in the bottom and on two opposite sides near the top. The boxes, in groups of six, float with tops above water, supported by rafts 75 ft. long anchored in the sea in a protected situation where the water is of suitable quality. Near the bottom of each box a horizontal two-bladed propeller, with a radius of about 43 ft., is made to revolve by means of suitable shafts and gearing driven by a naphtha motor or other power source. The propeller draws water through the screened opening in the bottom of the box and forces it upward in a spiral course to its escape through the side openings. Egg-bearing or "berried" lobsters are placed in one of the boxes just before the eggs are ready to hatch and, as hatching takes place, the fry are carried toward the top of the box and kept in suspension as though in the open sea. For rearing, the fry are transferred to other boxes where they secure natural food from the entering sea water but are also supplied abundantly with other food, preferably chopped, cooked beef, which is kept in suspension by the current and retained in the box by the screens. During the six to eight weeks season 500,000 "fourths" may be reared in 24 boxes. The method is believed to produce about 80 times as many fourths as are necessary to maintain the normal population of adults and heavy captures are therefore possible without depleting the grounds.

Objects and Utility of Fish-hatcheries. — The earlier advocates of artificial propagation and fish-hatching seem to have been under the impression that the thousands of fry resulting from a single act of artificial propagation meant a corresponding increase in the numbers of edible fish when once they had been deposited in suitable waters; and also that artificial fertilization ensured a greater proportion of fertilized eggs than the natural process. For the first proposition there is no evidence, while the second proposition is now discredited. The advantage of artificial hatching lies in protecting the unhatched eggs from the very large destruction to which they are subjected under natural conditions. But it is recognized that the great fertility of fishes is nature's provision to meet a high mortality—greater in sea-fishes with minute pelagic eggs—a condition which entails a greater delicacy of their larvae at the time of hatching. Artificially propagated eggs and fry must submit, **after** planting, to the same mortality as the other eggs and fry around them. Consequently it is useless to plant out eggs or fry unless in numbers sufficiently great to increase appreciably the stock of eggs and fry of the same age already existing. It is this, combined always with the suitability of the external conditions, which accounts for the success of the best-known experiments of American pisciculturists.

The shad fisheries of the streams of the east coast of the United States declined on the whole 74% from 1896 to 1923, and are now totally destroyed in many streams, in spite of plants of fry which reached the large total of 400,000,000 in 1898, but, owing to the difficulty of obtaining breeding fish, has since then, in general, declined to about 35,000,000 in 1923. We have still little knowledge of the habits and life history of the shad, of the extent and direction of its migrations. Its ascent of streams has been often impeded by dams, and pollution has doubtless adversely affected the spawning migration, vitiated the breeding grounds and destroyed the fry. Artificial hatching has failed to maintain the species in Atlantic waters under these handicaps and in the face of intensive fishing. Under more normal physical conditions and with fuller knowledge of the life history of the species it might be effective in these waters as it begins to be in the case of the Pacific salmon. The artificially propagated eggs of the shad from the eastern rivers of the United States were planted in those of California, where the species did not naturally

occur. The conditions were suitable, and the species became at once acclimatized and has increased greatly. Similarly, reservoirs and streams can be stocked with various kinds of fish not previously present. But in the case of indigenous species the breeding stock must be very seriously reduced before the addition of the eggs or fry of a few score or hundreds of fish can appreciably increase it.

In the case of sea-fishes it is becoming increasingly recognized that the millions of cod fry which are annually turned out of the American, Newfoundland and Norwegian hatcheries are but an insignificant fraction of the billions of fry naturally produced. A single female cod liberates, according to its size, from one to five million eggs in a single season. Yet the annual output of fry from each of these hatcheries rarely exceeds 200,000,000, *i.e.*, the natural product of a few hundred cod at most. In Britain, marine hatcheries have been established by the Fishery Board for Scotland in the Bay of Nigg, near Aberdeen, by the Lancashire Sea Fisheries Committee at Peel, and by the Government of the Isle of Man at Port Erin. These establishments have been principally devoted to the hatching of the eggs of plaice. But again the maximum output of fry from any one of these establishments has not exceeded 50,000,000 in any single year. As a single female plaice produces about 200,000 eggs per annum, this output does not exceed the natural produce of a few hundred fish. Under these circumstances the probable utility of the operations could be admitted only if the fry were sedentary and could be planted in suitable localities where young fish were naturally scarce. But the fry drift with the currents as helplessly as the eggs, and the *a priori* objections to the utility of the operations have in no case been met by satisfactory evidence of tangible results.

The Scottish Fishery Board carried out a large scale experiment from 1896 to 1908 which was very illuminating (Fulton, 26th Report). They attempted to measure the density of young plaice on the beaches of Loch Fyne during six years when plaice fry were liberated in the loch and a similar period when none were added. From 1896 to 1901 the quantities of fry added were 4, 21, 19, 16, 30 and 51 millions annually, the number of eggs naturally present in the loch being estimated at nearly 500,000,000 in 1898 (Williamson, 17th Report). Although the figures of young plaice on the beaches yielded an average density which was twice as great in the first period as in the second (88:40 per hour), there was little or no correspondence from year to year between the density of young fish and the number of fry planted. The highest record corresponded with the year of maximum output of fry (1901), but the next highest occurred in 1905, when no fry were planted, and the third occurred in the first year (1896), when the number planted was negligible (4,000,000). Assuming (which is not certain) that the coincidence in 1901 was significant, it nevertheless appears that the natural fluctuations in the number of young plaice were unaffected by the hatching operations except in the one year when the number of fry liberated exceeded 50,000,000 and thus formed an appreciable proportion (10%) of the number estimated to be naturally present. Even these numbers do not provide Loch Fyne with a regular plaice fishery.

In the United States the utility of the cod-hatching operations has, in the past, been often asserted by representatives of the Bureau of Fisheries, but practically the only evidence adduced is the occasional appearance of unusual numbers of cod in the neighbourhood. It has not been established that the fluctuations in the local cod fisheries bear any relation to the extent of the hatching operations, while the earlier reports of the commissioner of fisheries contain evidence that similar fluctuations occurred before the hatching of "Fish Commission Cod" began.

The situation is much the same with regard to the operations of the Newfoundland hatcheries at Dildo. (See Fryer, Reports x-xii. of H.M. inspectors of sea fisheries, E. and W.)

The most exact investigations bearing upon this problem are those undertaken in Norway in connection with the cod-hatching operations at Arendal under Captain Dannevig. Four fjords were selected on the south coast of Norway in proximity to the hatchery, and the usual number of fry (10 to 30 millions) was planted in the spring in alternate fjords, leaving the intermediate fjords

unsupplied. The relative number of young cod in the various fjords was then carefully investigated throughout the succeeding summer and autumn months. It was found that there was no relation between the abundance of young fish and the presence or absence of "artificial" fry. In 1904, 33,000,000 fry were planted in Sondelfjord and young fish were exceptionally abundant in the following autumn (three times as abundant as in 1903, when no fry were planted). But their abundance was equally striking in other fjords in which no fry had been planted, while in 1905 all the fjords were deficient in young cod whether they had been planted with fry from the hatchery or not. (For a summary of these investigations see Papers on "Artificial Fish-hatching in Norway" by Captain Dannevig; and Dahl, Report of the Lancashire Sea Fisheries laboratory for 1906, Liverpool, 1907.)

It would seem clear that the attempts hitherto made to increase the supply of sea-fish by artificial hatching alone have been unsuccessful. The experience gained has doubtless not been wasted, but the direction to be taken by future work is plain. The energy and money devoted to hatching operations should be diverted to discover a means of rearing on a large scale the just-hatched fry of the more sedentary species to a sturdy adolescence. When that has been done it will be possible to deposit the young fish in suitable localities, on a large scale, with a reasonable prospect of influencing the local abundance of the species of fish in question. The increase of the supply of the migratory marine species, such as the cod, depends on a more complete knowledge of habits, life histories and migrations. With this knowledge in hand these fisheries may be maintained or increased either through regulation or by artificial propagation or by both means; until it is in hand the effect of artificial propagation cannot be estimated.

In the smaller bodies of fresh water there is no doubt of the effectiveness of hatchery operations, but in the Great Lakes of North America there is no dependable evidence of their value. Official statistics studied by P. Reighard in 1908 showed, on their face, a correlation between the average intensity of the plants of whitefish fry in certain regions of the Great Lakes during three five-year periods from 1892 to 1906 and the average catch of whitefish for the same periods. Intensive planting was found to be correlated with an increased fishery output and was recommended. On the other hand Dr. Koelz, who has an intimate knowledge of the fisheries operations of the Great Lakes is doubtful of the value of statistics based largely on reports of interested parties, the fishermen. He points out further that the planted fry are a very small fraction of those presumably hatched naturally (0.35% in Lake Huron in 1900).

The decline in the coregonine fisheries of the Great Lakes is further evidence of the inadequacy of present hatchery methods. Whether the whitefish (*Coregonus clupeaformis*) has declined is uncertain, but the bluefin of Lake Superior and the bloater of Lake Ontario (both forms of *Leucichthys nigripinnis*) have become commercially extinct and in 1925 the important Lake Erie herring (*L. artedii*) suddenly gave out and has not since regained its commercial importance. The bluefin and bloater were never propagated artificially, but hundreds of millions of Lake Erie herring eggs have been hatched annually. It appears from these three cases that, for some unknown reason, when the breeding stock of a gregarious fresh-water species has been reduced below a certain numerical minimum the decrease continues. In the case of the bloater it has led to extinction and the important Lake Erie herring, in spite of extensive hatchery operations, appears now to be faced with extinction. The value of artificial hatching as hitherto carried out in the Great Lakes is now questioned in the United States for the reasons stated above and in Canada the abolition of hatcheries has been advocated by Prof. Knight of the biological board of Canada. It is probable that the life histories and migrations of many species approach in intricacy those of the Pacific salmon with its numerous, independent, self-sustaining colonies or races. Until these intricacies are resolved by prolonged research and hatchery operations adjusted to them, it is felt that artificial propagation is, in most cases, carried on

blindly and that success depends on chance.

PISCINA, originally a fish pond; later any artificial pool or tank, such as a bathing or swimming pool. Ecclesiastically the term is used for the stone basin with a drain emptying upon virgin soil, in which the utensils of the mass are cleaned and ritual ablutions performed. In mediaeval churches, especially in England, piscine are most frequently in the chancel, close to the altar and often set in recessed, arched niches of great beauty.

PISEK, a town of Bohemia, on the Otava, in one of the cereal and cattle basins of south Bohemia and on a main line from Prague to Budějovice, Linz and Vienna; occupied by Germany, 1939. Population, 16,973.

PISEMSKY, ALEXEY FEOFLACTOVICH (1820–1881), Russian novelist, was born on his father's estate in the province of Kostroma, on March 22, 1820, the son of a major who had risen from the ranks. From the gymnasium of Kostroma he passed through Moscow university, and spent over 20 years in the government service. His first novel, *Boyarstchina*, was forbidden by the censor. His principal novels are *Tyufyak* ("A Muff"), 1850; *Tsyacha Dush* ("A Thousand Souls"), 1862; and *Vzbalomuchenoe marye* ("A Troubled Sea"), giving a picture of the excited state of Russian society about the year 1862. His *Gorkaya sudbina* ("A Bitter Fate"), depicting the dark sides of the Russian peasantry, obtained for him the Ovaroff prize. He died at Moscow on Feb. 2, 1881. Pisemsky was a realist, and took an objective view of the unrest among the intelligentsia, which made him very unpopular in Moscow literary society. His best work is his description of the life of the common people. He learnt to know them thoroughly when investigating conditions in the Russian interior.

A PISCINA IN EXETER CATHEDRAL

PISHIN, a district of Baluchistan. It consists of a large plain surrounded on three sides by hills, which formerly belonged to Afghanistan but was ceded to the British by the treaty of Gandamak in 1879. This plain is the focus of routes leading from Sind and the Punjab frontier districts to Kandahar, and is intersected by the Sind-Pishin railway. For administrative purposes it is included in the district of Quetta-Pishin; pop. (1931) 147,541.

PISHPEK: see FRUNZE.

PISIDIA, the name given to a country in the south of Asia Minor, immediately north of Pamphylia, by which it was separated from the Mediterranean, while it was bounded on the north by Phrygia, on the east by Lycaonia, Isauria and Cilicia, and on the west and southwest by Lycia and a part of Phrygia. It was a rugged and mountainous district occupied by wild and lawless races of mountaineers. The Pisidians are not mentioned by Herodotus, either among the nations that were subdued by Croesus, or among those that furnished contingents to the army of Xerxes. They furnished a pretext to the younger Cyrus for levying the army with which he designed to subvert his brother's throne, while he pretended to put down the Pisidians who were continually harassing the neighbouring nations by their lawless forays (*Xen. Anab. i. 1, 11, etc.*). They assume a more prominent part in the history of Alexander the Great, to whose march through their country they opposed a determined resistance. In Strabo's time they had passed under the Roman dominion, though still governed by their own petty chiefs.

Notwithstanding its rugged and mountainous character, Pisidia contained in ancient times several considerable towns, the ruins of which exist. The most important are Termessus, near the frontier of Lycia, a strong fortress in a position of great natural strength, and commanding one of the principal passes into Pamphylia; Cremna, another mountain fortress, north of the preceding, impending over the valley of the Cestrus; Sagalassus, a little farther north, a large town in a strong position, the ruins of which are among the most remarkable in Asia Minor, and Antioch, known for distinction's sake as Antioch of Pisidia, and celebrated for the visit of St. Paul. This was situated in the extreme north-east of the district immediately on the frontier of Phrygia, between Lake Egerdir and the range of the Sultan Dag and was reckoned in the Greek and earlier Roman period, *e.g.*, by Strabo, as a city of Phrygia.

We have no clue to the ethnic character and relations of the Pisidians, except that we learn from Strabo that they were distinct from the neighbouring Solymi, who were probably a Semitic race, but we find mention at an early period in these mountain districts of various other tribes, as the Cabali, Milyans, *etc.*, of all which, as well as the neighbouring Isaurians and Lycaonians, the origin is wholly unknown, and in the absence of monuments of their languages must remain so.

PISO, the name of a distinguished Roman plebeian family of the Calpurnian gens which continued in existence till the end of the 2nd century A.D. Nearly fifty of its members were prominent in Roman history, but the following deserve mention.

1. **LUCIUS CALPURNIUS PISO CAESONINUS**, Roman statesman, was the father-in-law of Julius Caesar. In 58 B.C., when consul, he and his colleague Aulus Gabinius entered into a compact with P. Clodius, with the object of getting Cicero out of the way. Piso's reward was the province of Macedonia, which he administered from 57 to the beginning of 55, when he was recalled, perhaps in consequence of the violent attack made upon him by Cicero in the senate in his speech *De provinciis consularibus*. On his return Piso addressed the senate in his defence, and Cicero replied with the speech *In Pisonem*. Piso issued a pamphlet by way of rejoinder, and there the matter dropped, Cicero being afraid to bring the father-in-law of Caesar to trial. At the outbreak of the civil war Piso offered his services as mediator, but when Caesar marched upon Rome he left the city by way of protest. He did not, however, definitely declare for Pompey, but

remained neutral. After the murder of Caesar he insisted on the provisions of his will being carried out, and for a time opposed Antony. Subsequently he became one of his supporters, and is mentioned as taking part in an embassy to Antony's camp at Mutina.

2. LUCIUS CALPURNIUS PISO, surnamed *Frugi* (the worthy), Roman statesman and historian, was tribune in 149 B.C. He is known chiefly for his lex Calpurnia *repetundarum*, which started the system of establishing regular courts for the trial of particular offences in place of the old system of special tribunals being appointed for each case. As praetor (136) and consul (133) Piso fought against the slaves in Sicily.

See ANNALISTS; C. Cichorius in Pauly-Wissowa's *Realencyclopädie* (1897), vol. iii., pt. 1; H. Peter, *Historicorum romanorum reliquiae* (1870), vol. i.; Teuffel-Schwabe, *Hist. of Roman Lit.* (Eng. trans.), § 132, 4. On the lex Calpurnia, *Corpus inscr. latinarum*, i., No. 198, with Mommsen's commentary; A. H. J. Greenidge, *Hist. of Rome, 133-104 B.C.* (1904).

3. GNAEUS CALPURNIUS PISO, Roman statesman, was consul in 7 B.C. and subsequently governor of Spain and proconsul of Africa. In A.D. 17 Tiberius appointed him governor of Syria, with secret instructions to thwart Germanicus, to whom the eastern provinces had been assigned. The indignation of the people at the death of Germanicus, and the suspicion that Piso had poisoned him, forced Tiberius to order an investigation. Piso committed suicide, though it was rumoured that Tiberius, fearing incriminating disclosures, had put him to death.

See H. Schiller, *Geschichte der römischen Kaiserzeit* (1883), vol. i.

PISSARRO, CAMILLE (1831-1903), French painter, was born at St. Thomas in the Danish Antilles, of Jewish parents of Spanish extraction. He went to Paris at the age of twenty, and, as a pupil of Corot, came into close touch with the Barbizon masters. Though at first he devoted himself to subjects of the kind associated with the name of Millet, his interest was entirely absorbed by the landscape, and not by the figures. He fell under the spell of the rising impressionist movement, and threw in his lot with Monet and his friends. Like Monet, he made sunlight, and the effect of sunlight on the objects of nature, the chief subjects of his paintings, whether in the country or on the Paris boulevards. About 188; he took up the method of the pointillists, but after a few years of these experiments he returned to a broader manner. In the closing years of his life he produced some of his finest paintings, in which he set down with admirable truth the peculiar atmosphere and colour and teeming life of the boulevards, streets and bridges of Paris and Rouen. He died in Paris in 1903. Pissarro is represented in the Caillebotte room at the Luxembourg, and in most collections of impressionist paintings. Many of his finest works are in M. Durand-Ruel's collection in Paris.

PISTACHIONUT, the common name for the fruit of *Pistacia vera*, a deciduous, dioecious, sub-tropical, dry-land tree which produces much prized nuts extensively used as food and as colouring material in confections. It is believed to have originated in Syria; it is generally cultivated in the Mediterranean region and to experimental extent in both California and Oregon. The tree has broad-spreading branches but rarely attains as much as 30 ft. in height. It has 1 to 5 pairs of thick, wide, leathery, pinnate leaves and its small fruits form in clusters. The nuts are from one-half to three-fourths of an inch long, bony white and much inclined to split open at one edge, without discharging the kernel. Each nut is encased within a thin, tightly adhering, wrinkled and reddish skin. The kernels are single, solid pieces, with pleasing mild flavour. The principal varieties under cultivation are Aintab, Alemi, Ashoori, Bronte, Buenzle, Koz, Minassian, Red Aleppo, Sfax, Sicilian, and Trabonella. These are interplanted at the rate of about 1 to 20 with Kaz and Peters used as pollinizers. During the 5-year period ending June 30, 1941, the United States imported an average of 3,270,400 lb., of which more than 40% were from Syria. A close relative, *P. chinensis*, the Chinese pistache, is much prized because of the autumnal beauty of its foliage.

(C. A. RD.)

PISTOIA or **PISTOJA**, a town and episcopal see of Tuscany, Italy, capital of the province of Pistoia, 21 mi. N.W. of

Florence. Pop. (1936) 29,532 (town); 72,212 (commune). It is situated on a slight eminence (210 ft.) near the Ombrone, one of the tributaries of the Arno, immediately below the Apennines. It is on the site of the Roman *Pistoriae*, near which in 62 B.C. Catiline was slain and his forces destroyed. Excavations in the Piazza del Duomo led to the discovery of a large private house (end of 1st century B.C.). During the middle ages Pistoia was the scene of constant conflicts between the Guelphs and Ghibellines; here the great struggle took place which resulted in the creation of the Bianchi and Neri factions (Dante, *Inferno*, xxiv. 121). In 1302-06 it was besieged and eventually taken by the armies of Florence and Lucca, and in 1325 it became subject to Castruccio of Lucca. In 1351 it was obliged to surrender to Florence, and thenceforth shared its fate.

The city is still surrounded by walls, dating from shortly after the siege of 1302-06; while two inner lines of streets represent two earlier and inner lines of wall. A number of skilful artists between 1287 and 1399, made the great silver altar and frontal of the cathedral now in a chapel on the south side. The cathedral (13th century) has a campanile (218 ft. high) porch and facade with small arcades in black and white marble in the Pisan style as in other churches of Pistoia. It contains many fine sculptures—the monument of Cino da Pistoia, lawyer and poet, Dante's contemporary (1337), by Cellino di Nese, surrounded by his scholars, and Verrocchio's monument to Cardinal Forteguerra (1474). The octagonal baptistry is by Cellino (c. 1337). Among the earlier churches the principal is Sant' Andrea (1166), enriched with sculpture; in the nave is Giovanni Pisano's magnificent pulpit, imitated from his father's pulpit at Pisa. Other churches are S. Giovanni Fuorcivitas (so called because it was outside the line of the earliest, pentagonal, enceinte of the middle ages), with one of the long sides elaborately adorned with small arcades in the Pisan style, in black and white marble, also with sculpture by Guamons (1162) on the facade. Within are a beautiful group of the Visitation by Andrea della Robbia, and a fine pulpit by Fra Guglielmo of Pisa (1270). S. Bartolomeo in Pantano and S. Pietro Maggiore closely resemble it. San Francesco al Prato is a fine church of the end of the 13th century with interesting frescoes of the school of Giotto. San Domenico, a noble church, begun in 1294, contains the beautiful tomb of Filippo Lazari by Bernardo and Antonio Rossellino (1462-67) and other works of art. The Madonna dell' Umiltà (1494-1567) and S. Maria delle Grazie have fine Renaissance interiors, by the local architect Ventura Vitoni. The Palazzo del Comune and the Palazzo Pretorio, once the residence of the podestà, are both fine specimens of 14th-century architecture. The Ospedale del Ceppo has remarkable reliefs in enamelled and coloured terra-cotta on its exterior. Besides various medallions, there is a frieze of figures in high relief along the whole front—groups representing the Seven Works of Mercy—executed by Andrea Della Robbia between 1514 and 1525.

The word "pistol" is derived (apparently through *pistolese*, a dagger—dagger and pistol being both small arms) from Pistoia, where that weapon was largely manufactured in the middle ages.

PISTOIA, SYNOD OF, a diocesan synod held in 1786 under the presidency of Scipione de' Ricci (1741-1810), bishop of Pistoia, and the patronage of Leopold, grand-duke of Tuscany, with a view to preparing the ground for a national council and a reform of the Tuscan Church. The synod was attended by 233 beneficed secular and 13 regular priests, and decided with practical unanimity on a series of decrees which, had it been possible to carry them into effect, would have involved a drastic reform of the Church on the lines advocated by "Febronius" (see FEBRONIANISM). The decrees were issued with a pastoral letter of Bishop de' Ricci (see SACRED HEART), and were warmly approved by the grand-duke, at whose instance a national synod of the Tuscan bishops met at Florence on the 23rd of April 1787. The temper of this assembly was, however, wholly different. The bishops refused to allow a voice to any not of their own order, and in the end the decrees of Pistoia were supported by a minority of only three. They were finally condemned at Rome by the bull *Auctorem fidei* of the 28th of August 1794.

BIBLIOGRAPHY.—De' Ricci's own memoirs, *Memorie di Scipione de' Ricci, vescovo di Prato e Pistoia*, edited by Antonio Galli, were published at Florence in 2 vols. in 1865. Besides this, his letters to Antonio Marini were published by Cesare Guasti at Prato in 1857; these were promptly put on the Index. See also De Potter, *Vie de Scipion de' Ricci* (3 vols., Brussels, 1821), based on a ms. life and a ms. account of the synod placed on the Index in 1823. There are many documents in Zobi, *Storia civile della Toscana*, vols. ii. and iii. (Florence, 1856). The acts of the synod of Pistoia were published in Italian and Latin at Pavia in 1788.

PISTOL, a small firearm designed for one-hand use, dating from the early 15th century. Tradition ascribes the derivation of the word to two distinct sources, viz., (1) Pistoia, a city in Italy where some claim the weapon originated; and (2) *Pistole*, an ancient coin to the diameter of which it is said the earliest handguns were bored. (Yet another explanation of its origin is that it derives from "pistallo"—meaning *pommel*—the common location of the weapon for mounted troops over centuries of use.)

The advantages of a firearm which could be operated by one hand, leaving the other free for the use of an additional weapon, or for defence, must have been apparent from the earliest days of gunpowder, whence it becomes reasonably certain that the pistol evolved simultaneously with its heavier counterpart—the shoulder weapon. Indeed the most primitive form of small firearm, the "hand cannon," was more a pistol than a musket, but cannot correctly be placed in the former classification since it required one hand to hold it and another to ignite its powder charge. But with the development of the matchlock (c. 1425) it became possible to produce a light and serviceable one-hand piece, and thenceforward the history of the pistol parallels quite closely that of the corresponding shoulder-arm of the period. (See SMALL ARMS, THE DEVELOPMENT OF.)

Through the centuries, the pistol has received the attention of untold thousands of inventors. To render it capable of firing more than once without reloading, it has been produced in every conceivable form—as with two, three, four and more barrels—the number limited only by the weight involved, and with countless other devices incorporated. Revolving types are as old as firearms, though the earlier varieties did not embody, as does the revolver of today, a short, many-chambered cylinder positioned behind a single barrel in such manner that the charge in each chamber is brought successively in alignment with the barrel. Instead they were mere sheaves or bundles of tubes of equal length, and were revolved by *hand*, rather than mechanically as in later specimens. (The latter, in the mid-19th century, acquired the popular designation "pepper-box"—because of the resemblance of the multi-chambered muzzle to a pepper-shaker.) Nevertheless, the true revolver principle (in which cocking the hammer causes simultaneous rotation of the cylinder) is far older than is generally realized, and Samuel Colt (U.S.A.), no matter how much

PHANTOM VIEW OF COLT OFFICIAL POLICE MODEL REVOLVER

the credit due him for improvements he contributed to this type of mechanism, lacks the honour of being its inventor by close to 200 years, perhaps many more. In addition to developing multi-shot varieties, small-arms designers have managed to produce numberless combinations of the pistol with other weapons. Thus we find it incorporated with battle-axes, "holy-water sprinklers," daggers, knives, sabres, whip handles, canes, bludgeons, pocket-books, cigar cases, bicycle handle grips, flashlights, fountain pens and in every other conceivable (and inconceivable) association,

some of the first-named dating from the 15th century, the last, carrying right into the twentieth. The majority of these have been more curiosities than serviceable weapons, but some few have received the stamp of actual (if limited) adoption by the military, as in the case of the Elgin percussion cutlass-pistol (U.S.A., 1837).

The date of earliest employment of the pistol as a military side-arm is obscure. Pollard tells us that it was adopted by the French cavalry in 1550, and that prior to this period it was "common in Germany." George states that the matchlock pistol was unsuited for military service, and expresses the doubt that pistols were in general use by the military prior to the wheel-lock era, or in England sooner than the opening of the reign of Charles I (1625). He bases this assumption on the absence of any reference to pistols in (army) records of the reign of Queen Elizabeth (1558-1603). Thenceforward, however, the pistol held, and holds, a definite if not overly-important place among military small arms throughout the civilized world English-speaking nations, however, were slow to appreciate the advantages of metallic *cartridge* types, and whereas France had adopted, as early as 1853 (for her naval service), a thoroughly satisfactory 12mm. pin-fire revolver, the United States fought its Civil War (1861-6j) almost exclusively with percussion hand-arms, the first delivery of American-made metallic cartridge revolvers to the military taking place in 1871. (Some few had been purchased and carried by individuals in the war then terminated, and exactly aoo [Perrin make] secured in France by the Federal Government.) England also deferred until the late '60s the adoption of a metallic-cartridge weapon, although certain German states (e.g., Bavaria) had preceded her by some years.

Contrary to popular belief, facility in the use of the pistol is not readily acquired, and indeed is infinitely more difficult to gain than in the case of the rifle. Further, the shortness of a pistol barrel, as a result of which a slight twist of the wrist swings the muzzle through a large arc, plus the difficulty of ascertaining at a glance whether certain modern types of pistols are or are not loaded, have resulted in many accidents due to carelessness, and gained for the weapon, among those unfamiliar with it, a reputation for dangerousness far greater than it deserves. In addition, the discovery by the novice that he cannot hit even large targets at close range quickly convinces him that it is a hopelessly inaccurate weapon. Even among the military, its possibilities for wide usefulness as a short-range arm, both of offence and defence, are usually studiously neglected. There remains, nevertheless, an informed and insistent element of military opinion which continues to fight for its more adequate recognition—to the extent indeed of the complete replacement of the foot-soldier's bayonet with a hand firearm.

Classification.—So many types of pistols and revolvers exist that it is next to impossible to set up suitable brackets wherein to place them. Ignoring for the moment all early specimens (*i.e.*, not handling modern metallic cartridges), there are:

(1) Revolvers, (2) Automatic pistols, (3) Other pistols. Of these the first and third are made in a variety of forms for pin-fire, rim-fire and central-fire ammunition. Automatic pistols, however, are chambered for the last two types only, having been perfected after the pin-fire cartridge was already in its decadence. Considering in turn the three basic classes above named, it is found that a revolver is a weapon embodying an element (cylinder) which revolves, whence comes its name (By the same token, an arm containing no such component is not a revolver, despite the generally loose application of the term.) Within the cylinder are bored a number of chambers, disposed equidistant from each other and from the axis about which it revolves. Each chamber is designed to contain a charge (cartridge), all being successively brought in line with the barrel, mechanically locked in position, and discharged at the will of the operator (by pressure on the trigger). Revolving cylinder-rifles (*i.e.*, revolvers in shoulder-weapon form) long enjoyed considerable popularity (especially during the percussion era), even receiving considerable military recognition, especially in the U.S.A., but apparently no new model of this type has been offered for sale since 1880-81,

as they are not suitable save for low-power ammunition for which other, simpler and less expensive mechanisms are everywhere available. (High-power rifles with revolving magazines, as distinguished from revolving cylinders, are by no means unknown, however.) One widely-advertised disadvantage of the revolver is the inevitable escape of some portion of the propellant gases at the junction between cylinder and barrel, and various devices to make this joint more or less gas-tight (as in the Russian "Nagant" service revolver) have been attempted. The added power thus gained is never worth the complexity of the mechanism required to attain it, however, since the percentage of gas lost, save when the gap becomes truly enormous, is almost negligible. In the conventional revolver the long axis of the cylinder is directly below and parallel to the barrel, but other (obsolete) types are not unknown wherein the cylinder revolves in a horizontal plane (Allen & Cochran, U.S.A.) or a vertical one (Noel, France; Protector, U.S.A.). Revolvers may be classified according to their modes of rotating the cylinder, or of extracting the fired case into: Single-action, Double-action, Semi-automatic, Automatic-ejecting, Hand-ejecting, Rod-ejecting, etc. In the single-action arm the acts of cocking the hammer and rotating the cylinder are performed simultaneously by the manual retraction of the former, which comes to rest in a rearward position. Thereafter a squeeze on the trigger is required to cause it to fall and discharge the piece. During the percussion era this was the accepted mode of operation (as introduced by Colt, 1836), though certain excellent double-action types such as the Tranter, Webley and Adams (all British) and the Cooper, Remington and Starr (U.S.A.) also appeared. The most celebrated existent specimen of revolver produced prior to the percussion era, in which cocking and cylinder revolution take place in the manner just described, is one in the Royal United Service Museum, London. This is of the flint-lock type, and of the period of about 1650. Conventional "revolvers" of early date (and these go all the way back to the match-lock period) invariably possess cylinders which must be rotated by hand (*i.e.*, cocking and rotation are separately carried out). The finest examples of this type are flintlocks patented in 1818 by Elisha Collier, an American then living in England. Subsequent to the general adoption of the double-action revolver (1870-go), the single-action type fell in favour, though it later regained considerable popularity for target weapons and is still produced by Colt in its "Single-Action Army" model, a weapon which has enjoyed nearly 70 years of uninterrupted production. The double-action mechanism is so designed that the hammer is cocked, and the cylinder rotated, by mere rearward pressure on the trigger, the hammer then falling and discharging the piece when such pressure is continued. To the layman this appears a most suitable design, involving as it does only a single motion, but the spring resistance within the mechanism which must be overcome by finger pressure on the trigger is so considerable, and so variable at different stages in the rearward progress of that member, that none but an expert can do good shooting when firing "double-action" save at the very closest ranges. In the hands of such persons, however, its greater speed of operation (as against the single-action) makes it the weapon of choice. (Most double-action revolvers may be operated either single- or double-action, though some of the cheaper modern types and some of the better earlier ones will function only on the latter system.) In the semi-automatic revolver the mechanism is actuated, cocking the hammer and rotating the cylinder, by the energy of recoil, which drives the whole superstructure of the piece (barrel-cylinder assembly) rearward on a horizontal platform built into the lower frame, a "recoil spring," compressed during this movement, now uncoiling to force these parts back to their forward (firing) position. The outstanding example of this type is the British Webley-Fosbery arm made in .455 (less often in .38) calibre. Another with practically identical mechanism but far less well known is the .32 calibre pocket model formerly produced by the Union Fire Arms Co. of Toledo (U.S.A.). In an automatic-ejecting revolver (first popularized by Smith & Wesson, U.S.A.), the weapon commonly "breaks open" (for loading and ejecting) at a hinge located below and

forward of the cylinder and a "spider" operating in the axis of that member automatically lifts out and expels the empty cases after the joint has opened sufficiently to permit this. In hand-ejecting models the cylinder ordinarily swings to one side when released by a latch, its axis remaining parallel to that of the barrel, whereupon a rod running through it and terminating in an ejector spider is manually pushed rearward, so withdrawing

WEBLEY REVOLVER: (1) NORMAL FIRING POSITION. (2) SECOND FIRING POSITION SHOWING TRIGGER MECHANISM, (3) THIRD FIRING POSITION, (4) FOURTH FIRING POSITION

the fired cases. In the rod-ejecting type (an excellent example of which is the Colt "Single-Action Army" model already mentioned), the cylinder must be rotated, one chamber at a time, to bring the mouths of these successively opposite the tip of a long, slender rod in a housing attached to the side of the barrel, and held in its normal (forward) position by spring pressure. This rod must then manually be pressed down into the chamber, aligned with it to disengage and eject the empty fired case within, the spring then returning it to its forward position. The operation must be repeated for each chamber to be emptied. Continental practice varies somewhat from that just described (American), but in all systems of rod-ejection each chamber must be separately and individually cleared of its contained empty case.

Other categories into which revolvers may be differentiated are: hammer and hammerless (concealed hammer) types, the former being far the commoner, but the latter (all obviously with double-action mechanisms) widely used in small "pocket" models of .25, .32 and .38 calibre wherein the spur (thumb cocking-piece) of the hammer, if present, might catch in the clothing in an attempt quickly to draw the weapon. Practically all automatic pistols are, strictly speaking, semi-automatic, since in but one or two models (Mauser, Germany), and licensed copies, are they so designed as to permit more than one discharge with each pull of the trigger. But the term "automatic" has gained such wide use that it is perforce employed in this article to designate weapons properly of the semi-automatic class. These may be divided into: Gas-

operated, Straight blowback, Blow forward, Retarded blowback and Short-Recoil types. Of the first named, but one short-lived example (the "Clair," France) was ever produced. This employed the usual gas port and expansion chamber beneath the barrel, the cartridges (French service revolver type of 8mm. calibre) being fed into the mechanism through a tubular magazine in the butt of the piece. The straight blowback, numerous models of which are produced in many countries, is, as in shoulder weapons, confined to ammunition of low power and pressure (e.g., .22 rim-fire). More powerful ammunition is handled in arms of the retarded blowback type, such as the Luger (Germany), known also as "Parabellum," or built on the short-recoil system (Webley, England; Colt, U.S.A.). Examples of the much less used blow-forward action are certain early Mannlicher (Austrian) models and the Schwarzlose (Germany). (For descriptions of the modes of operation of these several mechanisms, which duplicate exactly those embodied in machine guns and semi-automatic rifles, see GUN, MACHINE.) Magazine capacity of automatic pistols varies from about six cartridges (6.35mm. calibre) to as high as twelve (some .22 rim-fire models), the average military type holding seven to ten. Most modern military automatics are clip-loaded, but some (e.g., Mauser, Germany; Steyr, Austria) are charger-loaded.

Calibres.—These vary for revolvers all the way from 5 to 15mm. bore in pin-fire types, i.e., about .20 to .60 calibre; from 2mm. ($\frac{4}{100}$ "") to .46 calibre or more in rim-fire, and from about 2mm. to .577 calibre in central fire. The smallest sizes (2mm.) are, of course, mere curiosities, yet capable of firing tiny ball cartridges which will destroy eyesight, if no worse. Among automatic pistols, freak arms, save as produced in tiny calibres, e.g., the 2mm. Kolibri, Germany, are unusual. The smallest really effective automatic, the German "Lilliput," is of 4.23mm. (about $\frac{1}{12}$ "") calibre; the largest, the .45 Colt (U.S.A.) and the .455 Webley (England). The accuracy of the automatic, save in specimens designed for target work (rare in calibres over .22 rim-fire), is, in average hands, commonly below that of revolvers of comparable weight and size and its construction is such that, except in certain makes which possess "loading indicators" (as the Luger), it is impossible, without opening the mechanism or pressing the trigger, to determine whether or not it contains unfired cartridges. Further, unless it possesses a "magazine safety," now incorporated in all the better makes, but formerly rare or absent, it remains dangerous even after the removal of the loaded magazine. This is due to the fact that, preparatory to firing, a cartridge must

THE LOCK OF A COLT AUTOMATIC PISTOL

be transferred from magazine to chamber. If now left unfired the subsequent removal of the magazine leaves the charge in the chamber undisturbed, but all too many persons are forgetful of this and forthwith consider the arm unloaded and treat it as such. The "magazine safety" renders an accident impossible by locking the firing mechanism automatically immediately the magazine is withdrawn.

Revolver v. Automatic.—Though devotees of the automatic pistol have, ever since the invention of that type of weapon, predicted the early decline and disappearance of the revolver, there is as yet little evidence to indicate that their forecastings are soon to be fulfilled. The automatic has gained acceptance by the military in many countries, but in others of equal importance

the revolver remains in favour. Among civil servants, European police employ the automatic almost exclusively, whereas in the U.S.A. the revolver is practically without competition. Military revolvers now range in calibre from 7.62mm. (Russia) to .380 and (formerly) .455 (England); automatics from 7.63 and 7.65mm. (Germany), to .45 (U.S.A.). The revolver bullet is commonly an unjacketed missile of lead, hardened perhaps with antimony,

MILITARY MODEL OF THE MAUSER

whereas that of the automatic is usually full metal cased (jacketed), uncased bullets being subject to deformation, because of their relative softness, when passing through the mechanism of such an arm. Full-jacketed revolver bullets are not unknown, but have never gained much popularity save with law-enforcement agents whose duties may require their firing through heavy doors, automobile bodies, etc. Muzzle velocities in standard revolvers average 600-850 foot seconds, but there has been developed (by Smith & Wesson, U.S.A.) a "Magnum" type in .357 calibre with a muzzle velocity exceeding 1,500 f.s. and a muzzle energy of 800 foot lbs., thus exceeding that of the .44 calibre Winchester (U.S.A.) repeating rifle, model of 1873, to which has probably fallen more medium and large game than to any other firearm ever produced. From the standpoint of "stopping power," the .38 or .45 calibre leaden revolver bullet of moderate velocity is more efficient than the high-velocity, automatic pistol missile of small (7.63 and 7.65mm) bore as fired by the Mauser and Luger military automatics. For although the latter may exhibit considerably more "calculated" energy on paper, its metal case causes it to penetrate cleanly and its limited diameter results in an almost tiny perforation through the tissues, with little bleeding; and by reason of its high velocity it usually passes on through the target to expend most of its energy upon the scenery beyond. Per contra, the soft lead revolver projectile tends to "mushroom" (expand) on striking bone or other resistant body structure, tearing ragged holes.

Pistols of Other Types.—The evolution of the pistol prior to the development of a satisfactory metallic cartridge (pin-fire, 1846) parallels so closely that of the contemporary shoulder weapon that the reader is referred for a discussion of this to SMALL ARMS, THE DEVELOPMENT OF. Subsequent to that date, it went through the same cycle of unbridled development as did the early cartridge rifle, every conceivable form being constructed and marketed. Thus there is the Belgian "harmonica" pistol, wherein a multi-chambered horizontally-moving breech-block, containing a very considerable number of pin-fire cartridges, is mechanically shifted, a chamber at a time, from right to left, or vice versa, through an aperture in the frame of the piece, each chamber in turn being aligned with its single barrel and so discharged. Then there is the German "Bar" pistol with two barrels superposed and a flat, rectangular, magazine block occupying the position of the cylinder in a conventional revolver. This is bored with four chambers, two upper ones, side by side, and two lower, one of these located directly below each of the upper. The double-action mechanism, actuated twice, discharges two of the chambers, one projectile emerging through the upper, one through the lower barrel. The magazine block is then manually rotated through an arc of 180 degrees, when the two other chambers come into alignment with the barrels and are ready to be discharged. And there are many other multi-shot pistols of the superposed barrel type (two, three and four or more barrels, one atop another) such as the Remington double-derringer (U.S.A.), two-shot; the Marston (U.S.A.), three-shot; the Reform (Germany), four-shot, etc. In addition there are such oddities as the Belgian "gravity" pistol wherein a tubular magazine surmounts the barrel proper. When this is filled with cartridges and the muzzle of the piece tipped upward, thus allowing the rearmost charge in the magazine to approach the breech, the mere cocking of the hammer actuates an ingenious carrier by which it is transferred from magazine to chamber. Another tube-magazine type, closely approximating in its manner of operation the tube-magazine repeating rifle was the Remington (U.S.A.) repeating pistol of .32 calibre. There are also metallic cartridge pepper-boxes, popularized in the U.S.A. by such makers as Sharps, Bacon, Remington, Rupertus, etc., the first-named being widely copied in the British Isles. And apart from these numberless varieties designed for general use in defence and offence, there remains yet another infinity of types intended for special, and restricted, purposes. These include blank-cartridge pistols in single-shot, repeating-

pistol, revolver and automatic-pistol types, gas weapons for temporarily blinding an adversary, executed in every possible form from the standard revolver type to the camouflaged door key, fountain pen and policeman's truncheon. Also encountered are burglar-alarm pistols for attachment to door or window, usually firing blank ammunition but occasionally designed for ball or shot, trap pistols to destroy small game inesting country places, and discharged when the victim nibbles the bait attached, and signal pistols for military use.

PISTOLE. The French name given to a Spanish gold coin in use from 1537; it was a double escudo, the gold unit, and was worth 16s. 11¼d. sterling. The name was also given to the *louis d'or* of Louis XIII. of France, and to other European gold coins of about the value of the Spanish coin.

PISTON: see STEAM ENGINE; INTERNAL COMBUSTION ENGINES; PUMP.

PITCAIRN, a borough of Allegheny county, Pennsylvania, U.S.A., 12 mi. S.E. of Pittsburgh, on the Pennsylvania railroad. Pop. (1920), 5,738 (93% native white); (1940), 6,310 federal census. Railroad company has car shops and freight yards there. Steel freight cars and bricks are manufactured in the borough. This historic community was named Dirty Camp by Col. Bouquet in 1763. The present borough was incorporated in 1894.

PITCAIRNE, ARCHIBALD (1652-1713), Scottish physician, was born at Edinburgh on Dec. 25, 1652. He took his M.A. degree at Edinburgh university in 1668, and after courses in Edinburgh and Paris he obtained in 1680 the degree of M.D. at Rheims. He began practice at Edinburgh, and in 1692 was appointed professor of medicine at Leyden. Among his pupils were Richard Mead and H. Boerhaave, and both of them attributed much of their skill to what they learned from Pitcairne. In 1693 Pitcairne settled once more in Edinburgh. He persuaded the Edinburgh town council to permit himself and certain of his medical friends to treat without fee the sick paupers in "Paul's Work," on condition of being allowed to dissect such of the bodies as were unclaimed by their relatives. In this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine. He died on Oct. 20, 1713.

PITCH. The name of various substances of dark colour and of extremely viscid and tenacious consistency when subjected to heat. (0. Eng. pic, an adaptation of Lat. *pix*, *picis*, Gr. *πίσσα*, *πίτρα*, allied with Gr. *πίτυς*, pine-tree, Lat. *pinus*.) Strictly the term is applied to the resinous substance obtained as a solid residuum by the distillation of wood-tar (see TAR), or the non-resinous substance similarly produced from coal-tar (*q.v.*). The name is also applied to the natural mineral substances, *i.e.*, asphalt or bitumen (*qq.v.*).

PITCH, MUSICAL. The pitch of a musical sound is precisely defined by a vibration number recording the frequency of the pulsations of a tense string, a column of air or other vibrator, in a second of time. In Great Britain and America the complete vibration to and fro is taken as the unit; elsewhere the vibration in one direction only. The only official standard is the French, dating from 1859, preserved by a tuning-fork vibrating 870.9 (double vib. 435.45) at a temperature of 15° Centigrade (59° Fahr.) in a second. The vibration number stated in the edict establishing, in the year named, the diapason normal is 870 (435). Vibrations increase in rapidity as a note rises and decrease as it falls. Any note may be a pitch note. For orchestras custom has settled upon *a'* in the treble clef, for organs and pianos in Great Britain *c''*, and for modern brass instruments *b* flat.

We are not without a clue to the pitch usual in the classic Greek and Alexandrian ages: the vocal octave to which the lyre was adapted was noted as from *e* to *e'*. As in choruses barytone

and low tenor singers always prevail, *d-d'*, at French or at medium pitch, would really be the Greek singing octave; we may therefore regard it as a tone lower than that to which we are accustomed. But to sing the lower Greek modes in or near the vocal octave it was necessary to transpose (*μεταβολή*) a fourth upwards, which is effected in modern notation by a flat placed upon the B line of the staff; thus modulating from our major key of C to that of F. This transposition has had, as we shall see, much to do with the history of our subject, ultimately influencing the ecclesiastical chant and lasting until the 17th century of our era. It does not appear from any evidence that the keyboards—when there were more than one—the early organs were arranged for transposition, but it is certain that the Flemish harpsichords to 1650 were made with double keyboards to accommodate it (see Hipkins's *History of the Pianoforte*, 1897). But a positive identity of pitch cannot be claimed for any period of time, and certainly not for the early organs; the foot-rule of the organ-builder, which had to do with the lengths of the pipes, and which varied in every country and province, could easily cause a difference of a semitone. Scale and wind-pressure are also important factors. But with all these often opposed conditions, we find less variation than might be expected, the main and really important divergence being due to the necessity of transposition, which added a very high pitch to the primarily convenient low one.

The first to attempt to define pitch would seem to have been Arnold Schlick (*Musica ausgeteusch und ausgezogen*, Heidelberg, 1511), who gives a measure, a line of 49 Rhenish inches, which, he says, multiplied sixteen times, should be the lowest F of a small organ. He gives no diameter or wind-pressure. Dr. A. J. Ellis used this indication to have an organ pipe made which with one-sixteenth diameter and a wind-pressure of 3¼ in., at one-fourth Schlick's length, gave *f'* 301.6, from which he derived a just major third of *a'* 377, which would compare very well with an old Greek *a'*. Schlick goes on to say the organ is to be suited to the choir and properly tuned for singing, that the singer may not be forced to sing too high or too low and the organist have to play chromatics, which is not handy for every one. Further, he says pitch cannot be exactly defined, because voices vary; he nevertheless gives the measure above mentioned for the low F, but if a larger organ is built to include the still lower C, then this C must be of the same measurement, the reason being that a greater part of church music ends in "grambus," a word understood by Schlick's editor to mean the transposition of a fourth. The larger high-pitch organ will therefore be at *a'* 502.6.

The Halberstadt organ was, according to Praetorius, built in 1361, and repaired or rebuilt 1495. He gives the longest pipe of this organ, B natural, as 31 Brunswick feet, and the circumference 3½ ft. He further tells us this' pitch was a tone, nearly a tone and a half, higher than a suitable church pitch (*Chorton*), for which he gives a diagram. Dr. Ellis had pipes (now preserved in the Royal Institution, London) made to reproduce both these pitches at 3¼ in. wind-pressure. The Halberstadt pitch was found to be *a'* 505.8; the Chorton, 424.2. Ellis used mean-tone temperament in calculating this lower pitch; but as he used just intonation for the Halberstadt, it seems preferable to substitute it for the Chorton, thus reducing it to *d* 422.8. Praetorius's *Cammerton*, or chamber pitch, formulated in his diagrams for voices and instruments, is, he says, a whole tone higher; equivalent, therefore, to *a'* 475.65. Nearly all the German organs were tuned to this higher pitch. The lower vibration number is justified by the three divisions of the male voice, bass, tenor and alto, as given by Praetorius, whose *Cammerton* very closely corresponds with Bernhardt Schmidt's Durham organ, 1663-1668, the original pitch of which has been proved to have been *a'* 474.1. The Halberstadt pitch is nearly a semitone higher, which again agrees with the statement of Praetorius, and also Schlick's high C organ. Yet it would seem that there had been a still higher pitch used in the old ecclesiastical music. In one passage Praetorius distinctly says the old organ high pitch had been a whole tone above his *Cammerton*, with which we shall find his *tertia minore* combines to make the required interval. The term *tertia minore*, or *inferiore*, is used by Praetorius to describe

a low pitch, often preferred in England and the Netherlands, in Italy and in some parts of Germany. An organist, instead of transposing a whole tone down from the *Cammerton*, would for the *tertia minore* have to transpose a minor third.

Corroboration of this pitch is found in Silbermann's organ in Strasbourg minster (1713-1716), the pitch of which, taken in 1880 and reduced to 59° F (as are all pitches in this article), is a' 393.2. An old organ at Versailles (1789) was very near this example, a' 395.8. Ellis gave Dom Bédos (*L' Art du facture d'orgues*, Paris, 1766) as authority for a mean tone a' 376.6. Sir F. G. Ouseley's comparison of the church and chamber pitches of Orlando Gibbons (vide Ellis's lecture) clearly shows the minor third in Great Britain in the first half of the 17th century. But the narrowing continued. Bernhardt Schmidt, better known in England as Father Smith, was invited about 1660 to build the organ for the Chapel Royal, Whitehall; two years later he built the organ in Durham Cathedral a' 474.1, difference a whole tone, and practically agreeing with the *Cammerton* of Praetorius. The Hampton Court organ of 1690 shows that Schmidt had further lowered his pitch a semitone, to a' 441.7. What happened at Durham was that at some subsequent date the pipes were shifted up a semitone to bring the organ into conformity with this lower pitch, with which it is probable Schmidt's organs in St. Paul's and the Temple, and also Trinity college, Cambridge, agreed.

The final adoption of the low church pitch as in the 18th century was no doubt influenced by the introduction of the violin, which would not bear the high tension to which the lutes and viols had been strained. Harpsichords had long been preferred to the *tertia minore*. The *Chorton* of Praetorius, a' 422.8, is practically the same pitch as that of the fork the possession of which has been attributed to Handel, a' 422.5. It is a very fair mean between G. Silbermann's 18th-century Dresden pitch, a' 415, and the organs of Renatus Harris, a' 428.7. Stein tuned Mozart's piano to a fork a' 421.6, and the Broadwood pianos used at the first London Philharmonic Society concerts (1813) were tuned to a fork c'' 506.8, which gives a mean tone a' 423.7.

According to Schindler (*Niederrheinische Musik-Zeitung*, 1855, Nos. 8 and 9) and the report of the French Commission, 1859, the rise in pitch began at the Congress of Vienna in 1816, the military bands being the cause. With the improvements in wind instruments this continued, as more brilliant effects were gained. In 1823 Weber's *Euryanthe* is recorded as having been played in Vienna at a' 437.5, and in 1834 Kreutzer's *Nachtlager* at a' 440. The measurements are doubtful, but the upward tendency is clear. Scheibler, by his simple and accurate tonometer, has recorded pitches in Vienna about 1834 from a' 433.9 to 440.2. About that time, or it may be a few years earlier, Sir George Smart established a fork for the Philharmonic Society, a' 433.2. Forks intended for this vibration number, stamped "Philharmonic," were sold as late as 1846. But about that year the performing pitch of the Society had reached 452.5. Sir Michael Costa was the conductor 1846-54, and from his acceptance of that high pitch the fork became known as Costa's, and its inception was attributed to him, though on insufficient grounds. In 1874 a further rise in the fork to a' 454 was instigated by Sir Charles Hallé. The British army is required by His Majesty's Rules and Regulations to play at the Philharmonic pitch; but a fork tuned to a' 452.5 in 1890 was the standard for the Military Training School at Kneller Hall until, after an Army Order of Dec. 1928, the military bands followed the Philharmonic Society's adoption in 1896 of the diapason normal.

It was the irrepressible upward tendency that caused the French Government in 1859, acting with the advice of Halévy, Meyerbeer, Auber, Ambroise Thomas and Rossini, to establish by law the diapason normal, *i.e.*, a' 439 at 68° Fahr. or a' 435 at 59° Fahr. Other countries have gradually followed, and, with few exceptions, the low pitch derived from the diapason normal may be said to prevail throughout the musical world. Great Britain was the last to fall in, but the predominance of the low pitch is assured. The proprietors of Queen's Hall, London, did much for it when they undertook the alteration, at great expense, of their large concert organ, which had only just been erected. In 1896 the Philharmonic Society adopted the diapason normal and in 1899

Messrs. Broadwood made a successful effort to get the same vibration number accepted by their competitors in Great Britain. The high pitch remains only where there are large concert organs not yet lowered.

The consideration of temperature as affecting the use of a standard pitch was not attended to when the French Government issued its *ordonnance*. The 15° C attached to the description of the standard fork in Paris was intended for the definition and verification of the fork only. The alteration of the fork due to heat is scarcely perceptible, but wind instruments, and particularly the organ, rise almost proportionately to the increase in temperature of the surrounding air, because sound travels at an enhanced rate as the temperature rises. The coefficient of this rise is equivalent to half a vibration (0.5) per degree Fahr. per second. The French Commission, in establishing the diapason normal, should have chosen a temperature of 20° C. There would then have been less disturbance owing to the breath of the players and heat of the theatres or concert-rooms. As things are, even the established diapason normal implies a variation from 435 to 440 vibrations a second for a', inasmuch as temperature must always be reckoned with.

In writings on music the pitch of a note is indicated in various ways when it is desired to convey this without the employment of actual notation. Thus organists speak of "great C," "double C" and "tenor C" to indicate the notes sounded by pipes of 16ft., 8ft. and 4ft. respectively, the same notes being also indicated alternatively by the lettering CCC, CC and C. Another system is based on the employment of different types (*i.e.*, either capitals or small italic letters), supplemented by small strokes, placed above or below the letters as the case may be. Thus under this system 16ft. C is represented by C, 8ft. C by C without any stroke, 4ft. C by c, the C above ("middle C" on the pianoforte) by c', the C above that (or treble C) by c'', the C above that again by c''', and so on, the intermediate notes in each octave being of course similarly indicated. Or instead of strokes small numerals are sometimes used, *e.g.*, C₂, C₁, c¹, c², c³, etc. The expressions "in alt" and "in altissimo" are also employed for the same purpose, "in alt" signifying the notes in the octave beginning with the C above the treble octave (g'') and "in altissimo" those in the octave above (g''', a''', b''', etc.). (See ALT.) (A. J. H.; X.)

PITCHBLENDE or **URANINITE**, a mineral species consisting essentially of uranium oxide, of importance as a source of uranium and radium. It is a very heavy (specific gravity 9.0-9.7), compact mineral with a conchoidal to uneven fracture, and a brownish to velvet-black colour and pitchy lustre. Crystals are rare; they have the form of regular octahedra or less often of cubes. The hardness is 5½, and the streak is brown with a greenish tinge. The mineral has been known since 1727 to occur at Jáchymov (Joachimsthal) in Bohemia, and it was early called pitchblende because of its appearance; but its true nature was not recognized until 1789, when M. H. Klaproth's analysis of it resulted in the discovery of the element uranium. Analyses of material from different localities exhibit wide variations in chemical composition; in addition to uranium oxides, there are thorium, cerium (and lanthanum), yttrium and lead oxides, each varying in amount from a trace up to 10%. Calcium, iron, magnesium, manganese, silica, water, etc., are also present in small amounts, and the content of uranous and uranic oxides (UO₂, 21-72; UO₃, 13-59%) also vary considerably. The mineral is often described as a uranate of uranyl, lead, thorium and cerium; but in the least altered material from Branchville in Connecticut the uranous oxide predominates, whilst in altered specimens uranic oxide is in excess. In the closely allied mineral, thorianite, thorium predominates (ThO₂, 76; UO₂, 12%). Since the dioxides of uranium, thorium and cerium may be obtained artificially as cubic crystals, it seems probable that pitchblende consists of isomorphous mixtures of these dioxides, the uranic oxide being due to oxidation.

The radio-active properties of pitchblende are of special interest. The fact that this mineral is more strongly radio-active than metallic uranium led to the discovery in it of the elements radium, polonium and actinium. When pitchblende is ignited

or dissolved in dilute sulphuric acid, a gas is evolved which consists largely of helium and argon; terrestrial helium was first recognized in this mineral.

Pitchblende occurs either as a primary constituent of granitic rocks or as one of secondary origin in metalliferous veins. Octahedral crystals ("cleveite" and "bröggerite") occur in the pegmatite veins of southern Norway, being occasionally found in the felspar quarries at Moss, Arendal and other places. Crystals are found under similar conditions at Middletown and Branchville in Connecticut, Llano county in Texas ("nivenite"), Mitchell county in North Carolina, Villeneuve in Quebec and other American localities. Thorianite, found as water-worn cubes in the gem-gravels near Balangoda in Sabaragamuwa province, Ceylon, has also no doubt been derived from crystalline rocks. On the other hand, the mineral found in metalliferous veins, and to which the name pitchblende is more properly restricted, never occurs as crystals, but as compact masses rendered more or less impure by admixture of other minerals, the specific gravity being sometimes as low as 6.5; thorium, cerium, etc., are absent, and radium and helium are present in smaller amounts. This variety occurs with ores of silver, lead, copper, nickel, cobalt, bismuth, etc., at Johanngeorgenstadt, Marienberg and Schneeberg in Saxony, Jáchymov and Příbram in Bohemia, Gilpin county in Colorado, St. Just, Redruth, Grampound Road and elsewhere in Cornwall and at Kasola in Katanga, Belgian Congo.

Often associated with pitchblende and resulting from its alteration is an orange-yellow, amorphous, gum-like mineral called gummite, which is a hydrous uranic oxide with small amounts of lead, calcium, iron, etc.

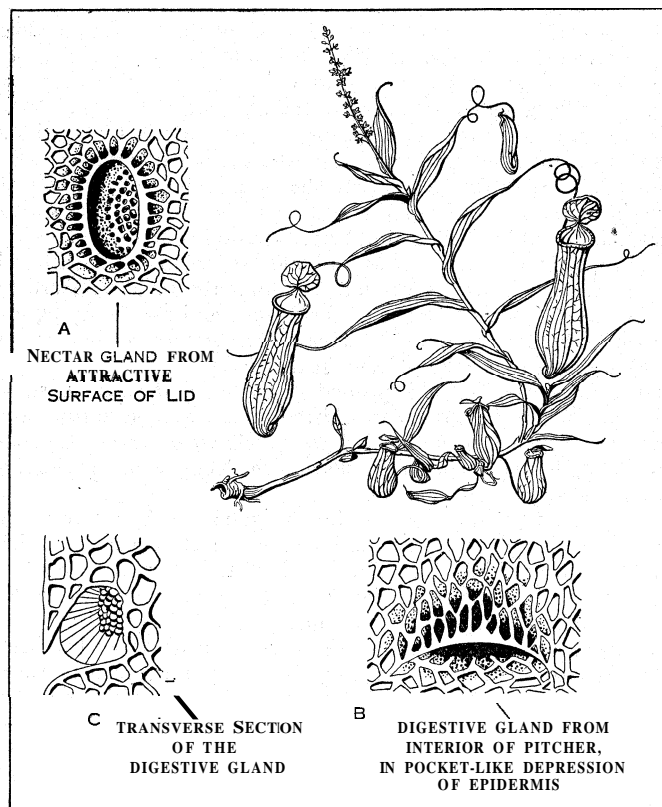

PITCHER PLANTS are certain carnivorous (or insectivorous) plants, the leaves of which bear pitcher-like structures or are as a whole pitcher-like in form. The plant usually thought of in this connection is *Nepenthes*, of the family Nepenthaceae, of which genus there are about 60 species native to tropical Asia, the Philippines, north Australia and Madagascar. The Asiatic islands are especially rich in species, particularly Borneo. They are lax shrubby plants, creeping in the soil or climbing on the surrounding vegetation. While many are jungle plants, some affect relatively drier hillsides. The climbing is done by means of strong tendrils which are elongations of the leaf midrib. These under suitable conditions produce at the apices the pitchers, which stand upright at the hanging ends of the tendrils.

The pitcher is a development of the end of the tendril and is in form either tapering tubular or variously expanded either at the base or upper part; or they may be goblet-shaped. The pitcher usually shows a pair of wings, running longitudinally on the ventral aspect of the outer surface which are extensions of the margins of the leaf base. The mouth of the pitcher has a corrugated rim of various dimensions in different species. This rim consists of the outturned pitcher margin flanked by an outgrowth on its inner surface. These two, in maturity, are indistinguishable and form one organ, the peristome. Its surface is very firm, shining and broken into transverse ridges, both primary and secondary in size, parallel to each other and prolonged at the inner edge of the peristome as teeth, beneath each of which is a large nectar gland. Above the mouth is the lid or operculum which is immobile. It varies in size according to the species from a narrow process to a huge heart-shaped expansion, overshadowing the mouth. A study of the development of the pitcher, especially in the seedling or in forced small shoots, shows that the inflated portion is a development of the midrib of the leaf, while the wings, which are especially well developed under some circumstances, represent the upwardly extended leaf base. In the mature type of pitcher there is an apparent separation of the wings from the proximal part of the leaf base by the tendril, along which the wings, readily seen in seedling leaves, are vestigial. The lid has been thought to consist of two fused leaflets, but a more recent view is that it is a transverse growth. The short straight or curved process on the back of the pitcher just below the lid represents the organic apex of the leaf.

The size of the pitcher varies widely in different species, from the size of a thimble to that of a pint pot or sometimes even larger. The colour also varies considerably, even in different pitchers on the same plant, according to age, light exposure or soil conditions. It may be yellowish to dark green, variously marked by red, and on the peristome the red colouring forms sharp transverse bands. Some pitchers are merely pale green. They are more or less invested by a rough pubescence of stiff branching hairs, especially when young.

Insects, particularly ants, are attracted to the plant by many deep nectar glands which occur in scattered positions on the stems and leaves, including the tendrils. These insects can hardly escape finding the nectar glands which occur plentifully on the inner surface of the lid in most species, and thus are lured to the mouth of the pitcher, about which the peristome forms a perilous foothold, especially for

insects trying to reach the nectar secreted by the large glands found on its inner edge. Even if the surface of the peristome offers no impediment to some insects, as in the case of small ants, there is in most pitchers a curious waxy (glaucous) surface clothing the upper half of the interior of the pitcher. This area has peculiar stomata

which appear under low magnification as crescentic cells—guard cells distorted out of position and hiding in each case its companion guard cell beneath it. There is, moreover, no opening. Since the visible guard cells stand a little above the level of the surface in general, they have been interpreted as stumbling blocks to render the hold of insects' feet insecure. In any event the waxy surface crumbles under their feet, and they fall to their doom. This area has been called the "conducting surface," as distinguished from that below it, the "defensive" region, which could be called the digestive region, since the surface here is crowded with digestive glands, each partly covered with a sheltering overhang of epidermis. Of these there may be as many as 6,000 per sq. cm.

In some pitchers there is no waxy surface, though the two kinds of pitchers may occur on the same plant in some species. Insects which have been lured to the mouth of the trap and attempt to obtain nectar from the marginal glands of the peristome or from the underside of the lid, can, on losing foothold, fall into the trap or pitfall. If they can walk in safety on the peristome, they find it impossible on entering the trap to walk on the waxy surface. Falling into the fluid which as first secreted is bland, the glands are stimulated to secrete a weak acid and a digestive (proteolytic) enzyme when insects are present. The nitrogenous parts of the insect bodies are digested, leaving the chitinous exoskeletons to accumulate. The products of digestion are absorbed by the walls of this region of the pitcher.

The process is essentially similar to that in the sundews (*Drosera* spp.), *Pinguicula*, and other carnivorous plants.

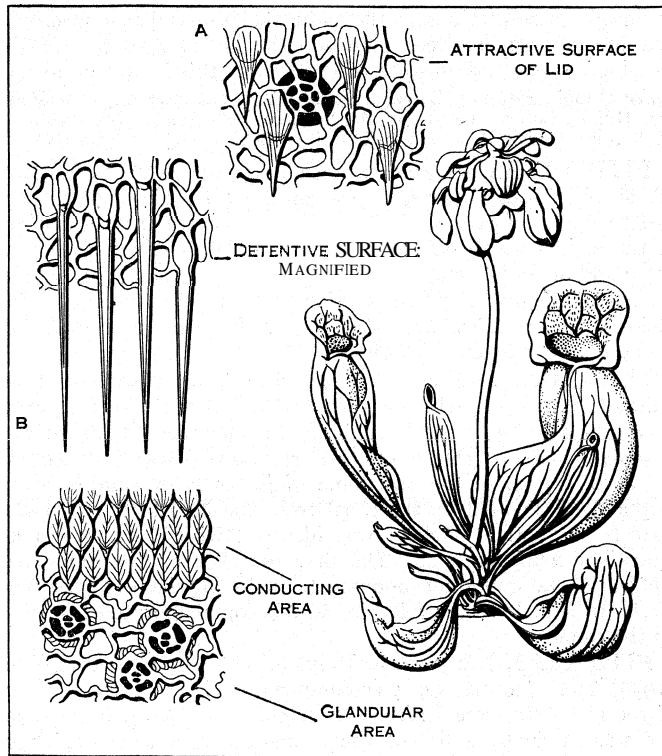

The presence of a digestive enzyme does not preclude the use of the fluid, enriched by insect bodies, by commensal organisms as a

nidus for their growth and nourishment. A rich flora and fauna consisting of desmids, diatoms, protozoa and various kinds of insect larvae have been discovered and described. It is held by some that these organisms are protected from the attacks of the digestive ferments

by the presence in their bodies of anti-enzymes, as has been claimed for endoparasites in the animal body. The small, primitive, monkey-like insectivorous tarsier (*Tarsius spectrum*) is believed to rob the pitchers of their contents. One species of *Nepenthes* (*N. bicalcarata*), has sharp, claw-like hooks, developed from the inner ends of the peristome just beneath the lid (see fig. 2). These have been regarded by some as an adaptation for catching the tarsier if he tries this game on the species.

Another species, *N. intermedia*, has projections of similar dimensions in the same situation, but in this case they are too weak to act in such manner.

Sarracenia, another genus of pitcher plants, is represented by eight or nine species (Wherry). They naturally fall into two groups, distinguished by the posture of the leaves. Two species have recumbent leaves, *S. purpurea* (side saddle plant) and *S. psittacina*. The leaf of the former suggests the horn of plenty (see fig. 3). In the other the leaf lies in a nearly prostrate position, and the entrance lies horizontally and is hidden beneath a hood. In other species the leaf is trumpet shaped (slightly curved in *S. minor*) with the lid either upright or more or less inclined over the mouth. The colour varies considerably from yellow-green (*S. flava*) to deep green variously masked by red, the intensity of which depends in part upon the situation, whether in bright sunlight or shade. The plant consists of a cluster of leaves springing from strong stolons and is herbaceous. The leaf has a broad sheathing base surmounted by a short stalk widening into the pitcher, which develops from the back (abaxial) part of the leaf base, the edge of which is continuous. On the ventral aspect of the pitcher arises a wing, while from the back of the mouth a lamina-like expansion, the lid, arises. The outer surfaces, especially that of the wing leading to the entrance, are supplied with nectar glands which during vigorous growth and for some time during maturity exude nectar which attracts insects to the entrance. The inner surface of the lid and the upper portion of the interior of the pitcher have many glands also; those on the lid and forward edge of the pitcher mouth exude nectar while those within the pitcher are in all probability digestive in function. The lid is armed with strong, downward pointing hairs, and it is a matter of observation that flies attempting to garner the nectar here almost invariably fall into the pitcher. Below its mouth the surface is smooth and glistening. The upper zone immediately surrounding the pitcher mouth is beset with nectar glands and is usually coloured red in *S. purpurea*. The wide zone below has numerous digestive glands, according to J. S. Hepburn and his associates. Below this occurs a "detentive" zone where the surface bears

numerous stiff, straight, retrorse hairs which effectively prevent the escape of insects. The fluid of the pitcher has a ready wetting power so that insects become quickly submersed and drown. The digestion of the prey is partly by the action of digestive ferments (Hepburn et al.) and partly by bacterial action, in one or two species perhaps wholly.

The chitinous coverings of insect bodies are indigestible, and they accumulate till the leaf dies. Doubtless when this occurs some material is released to the soil and helps to manure it. The accumulated mass of insect bodies offers nutriment to commensal insects which take advantage of the situation to lay their eggs within the pitcher where the larvae live on the putrid mass. Birds often slit open the pitchers and feed on the living larvae. In the fluid a mosquito (*Wyeomyia smithii*) passes its immature stages and is believed to be confined to this habitat. The occurrence of clear fenestrations on the lid (*S. drummondii*), on the lid and back of the upper dorsal part of the pitcher wall (*S. minor*) or on the hood and ventral part of the pitcher wall (*S. psittacina*) is an interesting feature and is seen also in *Darlingtonia* (q.v.). These window-like areas serve to attract insects.

Cephalotus follicularis is a native of southwest Australia, the town of Albany being at about the centre of its restricted range. It has the same habit as *Sarracenia* but is a smaller plant. Its leaves are of two kinds, growing in a rhythmic alternation: the foliage leaves, ovate and acute in form, and pitcher leaves, the latter having very much the form of a loose slipper, as stated by A. G. Hamilton, an Australian student of this plant. The simile is apt if we think of the heel as turned up; this is the lid which overhangs the entrance.

The pitcher is about the size of a thumb and has much the shape of the distal half of a large thumb. The mouth is transversely oval and is guarded by strong, hook-shaped claws pointing inward and downward, graduated in size, the largest being in front. Overshadowing the entrance is the lid which has several white strips (fenestrations, radiating from its base, with green-red strips between. These, we may imagine, give the insect visiting the rim the impression of a way of escape but serve only to deflect him into the inside of the pitfall trap. The inner surface of the lid is lined with striated hairs pointing toward its base and hence toward the pitcher's interior. Within the pitcher is a thickened zone (collar) of the wall which ends abruptly a short distance below in an overhanging shoulder, an impediment to escape. Both on the lid and collar are found many nectar glands. The expanded lower portion of the pitcher is strikingly marked by the presence of two large kidney-shaped patches where the wall is thickened, one on each side and placed obliquely. These are glandular in nature. The epidermis consists of cells with strongly wavy walls, interspersed with curious stomata, the guard cells of which are widely spread and immobile. These stomata are plugged by a soft cellulose wall of a cell below and are probably water-excretory, as experiment has indicated. Here also occur large glands, of a structure similar to others of smaller, graduated sizes, scattered throughout most of the rest of this portion of the pitcher. That these glands secrete a digestive agent seems likely from the work of W. J. Dakin.

The external surface of the pitcher bears wings. One runs along the middle line and is doubled along the outer edge. Another two, one on each side, run obliquely along the sides. Two others, quite low and not readily seen, run from the edges of the lid to the stalk, which is attached to the pitcher near the lid; in this feature *Cephalotus* differs from the pitchers of all other species. The development of the pitcher shows that it is morphologically upside down. There are usually produced besides the extreme forms of leaves, foliage and pitcher, intermediate forms which throw light on the morphology of the pitcher.

Genlisea, an aquatic genus with several species in tropical Africa and Brazil, is a relative of *Utricularia* (q.v.). It has traps which are of the pitcher type; they are not, however, pitfall traps, but of the lobster-pot type. Charles Darwin likened them to eel-traps. The plants are small and herbaceous, consisting of a cluster of leaves arising from a short stolon, buried in mud. The leaves are of two kinds: foliage leaves, usually near-spatulate in shape, and trap leaves of peculiar design. The latter leaf consists of a stalk on which arises a bulbous, hollow enlargement. From its top extends a tube, the extremity of which produces two arms which are twisted like corkscrews. They are ribbon-shaped extensions of the tube folded longi-

FIG. 4.—PITCHER PLANT (*CEPHALOTUS FOLLICULARIS*) SHOWING LEAVES, PITCHERS AND TALL FLOWER STEM WITH SMALL FLOWERS. AT LEFT OF STEM IS A LATERAL VIEW OF A TRAP OR PITCHER; AT RIGHT, VIEW OF THE INTERIOR OF THE PITCHER

tudinally and with the edges of the ribbon fixed and held a certain distance apart by large cells, placed like buttons. The interrupted slit thus left permits the entrance of minute animal forms (small crustaceans, worms, larvae, as in *Utricularia*). The escape of the prey after entrance is prevented by numerous sharp, stiff hairs, intermixed with many glands, which may be merely mucilaginous. Both these appendages occur in curved rows, rendering the interior of the arms curiously complicated. Passing down the arms, the prey at length passes into the tube, also lined with long, slender downward pointing hairs so arranged that they form what would be, if large enough, a lobster pot. In this region are digestive as well as mucilage glands, in transverse rows. The prey finally reaches the bulbous expansion, which has two internal ridges carrying numerous digestive glands, and here the process of disintegration is completed. While no experimental work has been done to demonstrate the presence of enzymes, the rapid dissolution of the bodies of prey and the analogy with *Utricularia* make it seem fairly certain that such enzymes are produced.

Like *Utricularia*, *Genlisea* grows only in wet places, partly or wholly submerged, and anchored in the substrate.

See F. E. Lloyd, *The Carnivorous Plants* (1942), in which a full bibliography may be found. (F. E. L.)

PITCHSTONE, in petrology, a glassy igneous rock having a resinous lustre and breaking with a hollow or conchoidal fracture (Ger. *Pechstein*, from its resemblance to pitch). It differs from obsidian principally in its rather dull lustre, for obsidian is bright and vitreous in appearance; pitchstones also contain water in combination amounting to from 5 to 10% of their weight or 10 to 20% of their volume. The majority of the rocks of this class occur as intrusive dikes or veins; they are glassy forms of quartz-porphry and other dike rocks. Their dull lustre may be connected with the great abundance of minute crystallites and microlites they nearly always contain; these are visible only in microscopic sections, and their varied shapes make pitchstones very interesting to the microscopist.

Although pitchstones of Devonian age are known (e.g., the glassy dacite of the Tay bridge in Scotland and the andesite-pitchstones of the Cheviots), most of them are Tertiary or recent, as like all natural glasses they tend to crystallize or become devitrified in course of time. In some of the older pitchstones the greater part of the mass is changed to a dull felsitic substance, while only nodules or kernels of unaltered glass remain. Some are very acid, containing 70 to 75% of silica, and have close chemical affinities to granites and rhyolites; others contain more alkalis and less silica, being apparently vitreous types of trachyte or keratophyre; others have the composition of dacite and andesite, but the black basaltic glasses are not usually classified among the pitchstones. Very well-known rocks of this group occur at Chemnitz and Meissen in Saxony. These rocks are brown or dark green in colour, very frequently perlitic, and show progressive devitrification starting from cracks and joints and spreading inwards through the mass. For a long time the pitchstone dikes of Arran, Scotland, have been famous for the great beauty and variety of skeleton crystals they contain; they are dull green in hand specimens; some of them contain phenocrysts of feldspar, augite, etc., others do not, but in all there is great abundance of branching feathery crystalline growths in the ground mass, minute crystalline rods being built together in aggregates which often recall frost patterns. It is supposed that they consist of hornblende. In addition to these larger growths there are many small microlites scattered through the glass, also hair-like trichites and fine rounded globulites. When phenocrysts are present the small crystals are planted on their surfaces like grass on a turf-covered wall. These pitchstones are believed to proceed from the great eruptive centres of early Tertiary times in western Scotland. Another pitchstone of the same period forms a great craggy ridge or scuir in the island of Eigg (Scotland). In chemical composition this latter rock resembles the trachytes rather than the rhyolites; in Eigg and Skye there are many dikes of pitchstone, mostly of intermediate rather than of acid character, all connected with the great eruptive activity which characterized that region in early Tertiary times.

The following analyses give the chemical composition of a few well-known pitchstones:—

	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	MgO	CaO	Na ₂ O	K ₂ O	H ₂ O
Meissen	72.42	11.26	0.75	0.28	1.35	2.86	3.80	7.64
Corriegills	72.97	11.26	3.24	tr.	1.53	0.61	5.61	5.45
Scur of Eigg	65.81	14.01	4.43	0.89	2.02	4.15	0.08	2.76

The first two of these contain much water for rocks, the ingredients of which are but little decomposed. They are of acid or rhyolitic character, while the third is richer in alkalis and contains less silica; it belongs more naturally to the intermediate rocks (or trachytes).

(J. S. F.)

PITHECANTHROPUS, the name given by Dr. Eugene Dubois, of the Dutch army medical service, to the creature (*P. erectus*) of which he found fossilized remains in Java. These fragments consisted of a thigh-bone, two teeth and the upper part of a skull, and were unearthed in 1891-92 on the left bank of the Bengawan river near Trinil. The skull appears to have

been low and depressed with strong supraciliary ridges; the teeth are very large, and the femur is quite human. The teeth and skull were found together, the femur a few yards away, a year afterwards. The discoverer, however, stated it as his belief that the fragments were portions of the same skeleton and belonged to a creature half-way between man and the higher apes and of the Pleistocene age; and, in spite of opposition, this is now admitted.

See Dubois, *Pithecanthropus erectus* (1894); a later paper read by Dr. Dubois before the Berlin Anthropological society, translated in 1898, *Smithsonian Report*; Sir A. Keith, *Antiquity of Man* (1915).

PITHIVIERS, a town of France, in the department of Loiret. 28 mi. N.N.E. of Orléans, on the railway to Malesherbes. Pop (1936) 6,469. The town is an important centre for the saffron of the region of Gâtinais. The shrines of St. Solomon (9th century) and of St. Gregory, an Armenian bishop (10th), formed the nucleus of the town; and the donjon built in the 10th century for Héloïse, lady of Pithiviers, was one of the finest of the period. There are quarries in the vicinity.

PITHOM, one of the "treasure cities" stated to have been built for Pharaoh by the Hebrews in Goshen during the Oppression (Exod. i, 11). We have here the Hebraized form of the Egyptian Petôm, "House of (the sun-god) Etôm," in Greek. Patûmos, capital of the 8th nome of lower Egypt and situated in the Wadi Tumilat on the canal from the Nile to the Red sea. Succoth (Egyptian Thuket) was identical with it or was in its immediate neighbourhood. The site, now Tell el Maskhuta, has yielded several important monuments, including the best preserved of the trilingual stelae of Darius which commemorated his work on the canal.

PITIGLIANO, a town in Italy, province of Grosseto. Pop. (1936) 4,103 (town), 5,914 (commune). It is the cathedral city of the bishopric named after the neighbouring town of Sovana, and was originally a fief of the countship of Sovana, which in 1293 came by marriage into the possession of the Orsini. In 1410 Sovana was taken by the Sienese, but the Orsini retained Pitigliano, Gentile Orsini assuming the title of count. In 1562 the Medici of Florence seized part of their territories, and acquired the rest by exchange in 1580. The Orsini stronghold still stands in the town, which is perhaps identical with the Etruscan Statonia.

PITMAN, SIR ISAAC (1813-1897), English phonographer. was born at Trowbridge, Wiltshire, on Jan. 4, 1813. He started in life as a clerk in a cloth factory, but in 1831 he was sent to a training college for teachers. After 11 years of teaching in elementary schools he opened a private school in Bath. In 1829 he took up Samuel Taylor's system of shorthand and became an enthusiast in developing the art of phonography. In 1837 he drew up a manual of Taylor's system and offered it to Samuel Bagster (1771-1852). The publisher did not accept the work, but suggested that Pitman should invent a new system (see SHORTHAND) of his own. The result was his *Stenographic Soundhand* (1837). Bagster's friendship and active help had been secured by Pitman's undertaking to verify the half-million references in the Comprehensive Bible, and he published the inventor's books at a low price, thus helping to bring the system within the reach of all. Pitman established at Bath a Phonetic institute and a *Phonetic Journal* for this purpose; he printed in shorthand a number of standard works, and his book *Phonography* (1840) went through many editions. He was an enthusiastic spelling reformer, and adopted a phonetic system which he tried to bring into general use. In 1894 he was knighted. He died at Bath on Jan. 12, 1897.

His Life was written in 1902 by his brother Benn Pitman (1822-1911) and by Alfred Baker in 1908.

PIT PONY. The pit pony is usually a small pony—14 hands high and under—used for hauling the tubs for the conveyance of coal from the working face of the coal seam to a point, variously termed the "flat," "double-parting," "station" or "landing," where the tubs are made up into "sets" or trains and conveyed, either by horses or, more commonly, by mechanical haulage, to the shaft bottom. That is to say, the pit ponies ply between the face and flat, bringing the full tubs out from the hewer and serving him with empty tubs. The use of pit ponies has decreased with the extended development of electrically driven haulage underground

PIT-SHAFT: see COAL AND COAL MINING.

PITT, THOMAS (1653–1726), British East India merchant and governor of Madras, usually called "Diamond Pitt," was born at Blandford, Dorset, on July 5, 1653. From his headquarters at Balasore, he engaged in trade in opposition to the East India Company, whom he opposed also in the law courts. Unable to check him the East India Company took him into its service in 1695, and in 1697 he became president of Fort St. George, or Madras. While in India Pitt bought the fine diamond which was named after him; in 1717 he sold this to the regent of France, Philip duke of Orleans, and it is now the property of the French government. During his stay in England Pitt acquired the manor of Old Sarum, and for a short time he represented this borough in parliament. After his final return from India in 1710 he again became member of parliament for Old Sarum. He died at Swallowfield, near Reading, on April 28, 1726. His eldest son, Robert, was the father of William Pitt, earl of Chatham (*q.v.*); and of Thomas Pitt (d. 1761), whose son became the first Lord Camelford; his second son, Thomas Pitt (*c.* 1688–1729), having married Frances (d. 1772), daughter of Robert Ridgeway, 4th earl of Londonderry (d. 1714), was himself created earl of Londonderry in 1726.

See Sir C. N. Dalton, *Life of Thomas Pitt* (1915).

PITT, WILLIAM (1759–1806), English statesman, second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, was born at Hayes, near Bromley, Kent, on May 28, 1759, in the year of the pinnacle of his father's glory. Both because of his extreme delicacy and because his father was an early critic of the public school system, he was educated at home under the tutorship of the Rev. Edward Wilson of Pembroke Hall, Cambridge, and the earnest supervision of Chatham himself—a plan which tended to the intensive development of the child's unusual precocity. Before he was ten years old he was a good classical scholar: at 13 he had composed a strange political tragedy *Laurentino, King of Chersonese*. In Oct. 1773, in his 15th year, he went into residence at Pembroke Hall, Cambridge, where his tutor was the Rev. Dr. George Pretyman (he changed his name in 1803 to Tomline), to whom Pitt in later years awarded the bishopric of Lincoln, and at the last bequeathed his papers: and who in return became his pupil's first biographer. Pitt had not been at Cambridge long when he fell seriously ill and was obliged to return home. It was then that the family physician, Dr. Anthony Addington prescribed that generous consumption of port wine which was to become the habit of a life. He returned to Cambridge in July 1774; and in 1776, by the privilege of his birth as the son of a peer, graduated as a master of arts without examination. That year saw the Declaration of American Independence, and the next the battle of Saratoga. On April 7, 1778 Pitt was the witness of his father's last dramatic utterance in the House of Lords. A month later Chatham died. Pitt was left with an income of £300 a year; he began to keep his terms at Lincoln's Inn; was called to the bar on June 12, 1780 and joined the western circuit. At the general election in September Pitt was defeated for the University of Cambridge but was returned for Sir James Lowther's pocket borough of Appleby. He entered parliament on Jan. 23, 1781: he was not yet 22 years old.

Parliament.—Pitt was attached to that section of the opposition which had followed his father, and was now led by Lord Shelburne. His maiden speech on Feb. 26 was made in support of Burke's Bill for economical reform, and produced a series of famous eulogies, Lord North admitting it the best first speech he had ever heard, and Burke, with even greater prodigality, declaring him "not a chip of the old block but the old block itself." A year later, when North's ministry was near its fall, Pitt had the self-confidence to announce in the House of Commons (March 8, 1782) that, should he conceivably be asked to join the new ministry, he would never accept a subordinate position in it; nor did he alter his mind when Rockingham, shortly afterwards offered him certain well-paid but unimportant posts, and even though one of them—the vice-treasurership of Ireland—had been held by Chatham before him.

As a private member Pitt now supported a new version of

Burke's reform project, a measure for shortening the duration of parliaments, and another for destroying bribery at elections. On May 7 he presented his own motion for a select committee to inquire into the state of the representation. It was only defeated by 20 votes. Shortly afterwards the death of Rockingham on July 1 provoked a major crisis. The king appointed Shelburne as his successor. Fox, Lord John Cavendish and Burke immediately refused to serve with him; whereupon Shelburne turned to Pitt, who on July 6 accepted the office of chancellor of the exchequer.

The Shelburne Ministry.—The ministry was only to last until the following February. On Jan. 20, 1783, the preliminaries of the Peace of Versailles were signed, and provided the opposition with an easy target. It was essential for Shelburne to obtain more support, and on Feb. 11, by agreement with his chief, Pitt visited Fox to invite him to return to the ministry. Fox replied that he would only serve on the condition that Shelburne resigned the premiership, whereupon Pitt replied "I did not come here to betray Lord Shelburne." The incident is important. It marks the beginning of the ceaseless political warfare between Fox and Pitt; it marks the end of the Shelburne ministry, and the origin of the coalition between Fox and North. Speaking of North's Government only in the previous year, Fox had declared "From the moment when I shall make any terms with one of them, I will rest satisfied to be called the most infamous of mankind," and he had loudly demanded their impeachment: yet he who had poured his blistering scorn upon North's conduct of the war, now joined with North in execrating the terms of the peace. The ministry was defeated (Feb. 21) and two days later Shelburne resigned. For a month the king sought to escape the coalition. But Pitt, who was pressed to accept the Treasury preferred to bide his time, and North could not be lured from Fox. On April 2 the Fox-North coalition under the nominal leadership of the duke of Portland took office.

The Coalition Ministry.—On May 7 Pitt brought forward resolutions for checking bribery at elections, disfranchising corrupt constituencies, and increasing the number of county and London members of parliament. The resolutions were refused by 293 to 149. On June 2 he brought forward another bill which passed the Commons but failed in the Lords, for reforming abuses in public offices: he instanced North's mysterious consumption of stationery, which totalled £1,300 and contained an item of £340 for whipcord.

During September and October Pitt visited France—his only venture outside his own country. In November parliament re-assembled and Fox immediately introduced his India bill. Passed in the Commons the measure was defeated in the Lords (Dec. 17) because George III. plainly informed the peers at large through Lord Temple that he should regard anyone who voted for the bill as his enemy. The Government very properly refused to resign. Whereupon the king, on Dec. 19, depending upon a barely literal interpretation of his constitutional rights, but reflecting by accident the wishes of his people, dismissed his ministers and appointed Pitt as first lord of the treasury and chancellor of the exchequer. The coalition had been jockeyed out of office, and it is not surprising that the House received the news of Pitt's appointment with mirth. It is mistakenly generous, however, to suppose that Pitt assumed office from pure altruism and without a certain confidence in the future. The strident Opposition no longer represented its constituency and Pitt knew it, and while they were wasting their breath deriding the "boyish prank," Pitt was converting the electorate—voters who were to be more valuable to him than the voters in the House of Commons. Almost as important, the influence of the City and of the East India Company was on his side. Until the end of March he struggled on, continually defeated in the House, but steadily refusing to resign. Outside his popularity was growing, while the action of the Opposition in threatening to oppose even the votes of supply cast on them the obvious accusation of factiousness. The hostile majority diminished daily until on March 8 Fox's "representation" was carried by only one vote. On March 24 parliament was dissolved. The essential business had been forced

through. At the ensuing election some 160 of "Fox's Martyrs" were rejected. This was the answer to the charge of unconstitutional action: throughout the struggle Pitt had in fact represented the nation. Pitt was himself elected for Cambridge university, which he represented for the rest of his life.

PITT'S FIRST MINISTRY

Finance—Finance was the first consideration. There was a heavy debt and the fiscal machinery was antiquated. Pitt floated a loan of £6,000,000, offering the tenders to public competition, and funded £6,600,000 of the floating debt. The loss to the revenue which had long resulted from the systematic evasion of the high protective tariffs he countered by a radical reduction of duties—that on tea being reduced from 119% to 12%. To meet the loss he increased the window tax, and many new taxes were instituted to touch the whole people. But he withdrew the tax on raw cotton, and pronounced it as his principle that "manufactures in general ought to be free from taxes."

Pitt, who had been one of the earliest students of Adam Smith, next attempted the establishment of free trade between England and Ireland. The Irish accepted his propositions (Feb. 7, 1785) but in England the measure was met by the organized opposition of vested interest, prejudice, and faction. Pitt was obliged to alter his original scheme, and in that form the Irish, disappointed and inflamed by Fox's subtle tongue, rejected it.

In 1786 Pitt introduced his sinking fund, a measure adapted from a scheme of Dr. Richard Price (*q.v.*). Economically it was undoubtedly mistaken, but it was believed to be a sovereign remedy, and it at least inspired public confidence.

On April 18, 1785, Pitt brought forward a bill proposing to suppress 36 pocket boroughs and to transfer their members to increase the representation of certain towns and counties. £1,000,000 was to be spent upon the purchase of the interests of the various owners. The bill, for which he eloquently pleaded, was rejected by 248 to 174.

India.—Pitt's India Bill, which had been rejected during the first struggle in the spring of 1784, was passed in the summer easily enough. Pitt's bill, unlike Fox's, left the ordinary patronage with the directors of the company while passing to the Crown the political control. Moreover, he had the tact and the wisdom to consult the company and to present as a final draft a measure to which he knew they were prepared to agree. The bill was not without serious defects—especially in its subordination of the governor-general not only to his council, but in all important concerns to the home Government. Warren Hastings resigned at once, and upon his return, his conduct of the Government was called in question. Pitt who had voted against the Rohilla charge (which was not carried) voted in favour of the Benares and the Begum charges. His action decided the issue. The motions were carried, and the impeachment pursued. Pitt has been heavily criticised for his conduct. But the truth that Hastings had been a great administrator could not disguise the fact that here was a patent scandal, which demanded inquiry. Indeed Hastings, through his agent in the House, had himself originated the discussions; and Pitt deliberately chose to support the Opposition in a matter where he honestly believed them to be right, instead of following the usual custom of opposing whatever measure the Opposition proposed.

The Regency Question.—In Nov. 1788 the king's illness provoked a crisis which might have ended Pitt's political career. There was a traditional enmity between the Hanoverian monarchs and their sons, and the whole influence of the prince of Wales (doubly hostile because Pitt would not pay his debts), was directed to the cause of the Whigs. The king being insane it was essential to appoint a regent, and Pitt was inevitably agreed that there could be no other candidate for the office than the prince of Wales. The point at issue lay in the claim of Fox and his party that the prince had a prerogative right to the position. Pitt claimed that he could only become regent by act of parliament, and drew up that act so as to restrain the regent from making peers or granting pensions, while the king's person and household and the patronage of the Crown were to be placed under the direction of

the queen. The bill passed the Commons (Feb. 5, 1789) and while it was under discussion in the Lords the king recovered. The situation had been dangerous, for though the resolutions had been carried, there had been much uneasiness among Pitt's followers. Pitt himself believed that he would be unable to retain office and would have to resume work as a lawyer. The London merchants at this time offered him £100,000 in recognition of his conduct, but Pitt replied that "No consideration on earth shall ever induce me to accept it." At the general election of 1790 he obtained an increased majority. In April 1791 by his Constitutional Act he arranged for the division of Canada into Upper and Lower Canada. The following year he accepted the wardenship of the Cinque Ports which carried a salary of £3,000 a year.

Foreign Policy.—The first important act of Pitt's foreign policy—the commercial treaty with France—was complementary to his reorganization of the home finances. The abandonment of useless trade restrictions was plainly to the benefit of both countries and Fox could think of no better ground of attack than to assert that France was the unalterable enemy of England, to which objection Pitt replied that "to suppose that any nation could be unalterably the enemy of another is weak and childish." In 1787 there was trouble in Holland. The Emperor Joseph II. had been for some time preparing a labyrinthine scheme whereby he should consolidate his dominions by annexing Bavaria, whose elector was to be compensated in the Austrian Netherlands. The scheme was agreeable to France who was intriguing for the overthrow of the Dutch stadholder and complete influence in Holland. War was only avoided after full preparations had been made (an expedition for instance was actually prepared for the capture of the Cape) because Prussia, who was opposed to Joseph II.'s policy was at length persuaded to stand with England. Upon Prussia's entry into Holland the Austro-Russo-French intrigue collapsed and the stadholder was restored. In 1789 England was brought into conflict with Spain who had seized the British trading post at Nootka Sound. Again war seemed imminent (over two millions sterling were spent in naval preparations), but Spain, receiving no support in Europe, was obliged to withdraw. Less successful was Pitt's intervention in the Eastern question. Catherine II. of Russia was at war with Sweden and Turkey. The Triple Alliance (of England, Prussia and Holland) had gained a prestige which placed it in a position to work for the maintenance of the balance of power. But though Austria's support was detached from Russia and Gustavus III. made peace with Catherine, the empress was not to be diverted from her ambitions in Eastern Europe. She gained great success in 1791, and Pitt, without adequate means of supporting his policy, determined to prevent Russia from establishing her power in the Black sea. He demanded that Russia should give up Oczakov, but Oczakov meant nothing on earth to the British public, and Catherine perceiving there was no force behind the ultimatum was unmoved by it. Though armament credits had been voted, Pitt was obliged to retire.

Pitt had not at first anticipated that the French Revolution would involve England in hostilities. In the spring of 1792 he was happily discussing finance, prophesying the reduction of 25 millions of debt in the next 15 years, and declaring in support of his vision that "there never was a time when, from the situation of Europe, we might more reasonably expect 15 years of peace than we may at the present moment." He had no intention of interfering in a matter which concerned France alone, and indeed in its original conception he was not unsympathetic to the aims of the Revolution. On Aug. 10th, the French monarchy fell, and the English ambassador was recalled from Paris, and Chauvelin in London could henceforward be only received unofficially. But this was merely a question of diplomatic routine: friendly relations were not strained until the French, having already declared war upon Austria and Prussia, followed the victory of Jemappes by occupying the Austrian Netherlands, threatening Holland, and overturning the treaties which governed the navigation of the Scheldt. England was bound by treaty to support Holland; and, as she had been through the centuries, she was not less insistently bound in this matter by her own interests. The execution of the king, and among the French people a rising tide of truculence swiftly fol-

lowed. On Feb. 1, while Pitt was outlining the provocations which Britain had received from France that country was despatching yet another in the shape of a declaration of war. The remainder of Pitt's life was to be spent in the shade of the revolutionary wars.

War.—The history of the wars with France is discussed under FRENCH REVOLUTIONARY WARS, NAPOLEONIC CAMPAIGNS, NAPOLEON; FRANCE, etc. It is only possible here to estimate generally the part that Pitt played in the organization of Europe. It has long been a current *clique* to say that Pitt was a great peace minister and a poor war minister. But if Pitt's talents were indeed essentially suited to peace, it is equally true that Napoleon was finally encompassed in disaster by the dogged determination of the English premier, and after his death by the remembered influence of that resolution. To compare him with his father is idle; Chatham had every advantage. His allies were great commanders, his France was effete. But revolutionary France was inspired with a fanatic hope, and England's continental allies proved continually worthless. Year after year Pitt laboured to sustain his coalitions of the Powers; year after year the coalitions melted away before the victorious advances of the French. England, who had no call to be anything but a member of a general European league against France was forced to be the inspiration as well financially as politically of the entire organization.

Home Policy.—At home the war changed entirely the tranquil prospects of national wealth and prosperity. New voices were in the air—voices of political discontent, and shortly the voices too of hunger. Pitt's policy at home at this juncture is of great importance. Because he never again brought forward the question of reform after his failure in 1785, and opposed it whenever it was proposed by others, his sincerity has been openly called in question. His actions certainly demand some explanation. It is in the first place important to admit that there was as yet no national enthusiasm for reform: the cry had been raised largely in protest against the unconstitutional behaviour of the king, and had been lulled since the declaration of peace; moreover those who had been foremost in urging "economical reform" had no such belief in the necessity of parliamentary reform. A statesman—especially one on whom practically the whole conduct of a Government devolves—can not persist in a measure which has been again and again rejected in one form or another. Pitt had a large majority. But the fact that he remained in office for so long has obscured the truth that he was to a very large extent dependent upon the caprices of that majority. A contemporary political estimate recorded the number of those gentlemen who "would probably support his majesty's Government"—roughly the Court Party—as more than three times the size of Pitt's personal party: and there was a further shifting and entirely independent vote. For all his dominance of the House Pitt was sometimes defeated—over the Westminster petition (*see* Fox, CHARLES JAMES), over Ireland, over his proposals in 1786 to fortify Plymouth and Portsmouth. The demand for reform was not seriously supported in the House of Commons. More important still it was not as yet properly vocal outside its walls.

In 1792 Tom Paine's *Rights of Man* had been published, suddenly jolting the English Radical movement into a new mind at the moment when the French doctrines were filtering into England in a fashion admittedly designed to provoke dissensions. The circumstances had become altered. Pitt's refusal to support the motion for the repeal of the Test and Corporation Acts in 1789 and 1790 was unintelligibly craven; but when he refused to support Grey in 1792 he had excuse. "The hurricane season" had set in. Pitt allowed himself to be stampeded by a species of panic which was entirely unjustified by the facts. Talleyrand at this time remarked that those curiously deceived themselves who believed that England was on the verge of revolution. He was a more shrewd observer of truth—but it must be admitted that he had the advantage of looking at Britain not only in perspective but also dispassionately. Deceived or not, Pitt declared that this was no time to revise a constitution, and proceeded to punish severely any who should advocate reform doctrines. It was lamentable; it was essentially unjust; and there is but one excuse—the excuse which in sympathy has condoned many shameful

persecutions, when things are done in panic which are never justified by the patent facts but are believed to be necessary for profound reasons of State that can only be guessed at.

In 1793, and again in 1795–1801 Habeas Corpus was suspended, and bills for the suppression of sedition followed. There succeeded the trials and transportations of men like Skirving, Margat, Gerrald, Muir, condemned for nothing more treasonable than advocating parliamentary reform or universal suffrage. Societies for constitutional reform were raided and suppressed. It is unpleasant to find that the records of the confiscated papers of those clubs reveal without exception nothing indicative of revolutionary organization. And yet in 1795 Pitt declared that were he to resign he would lose his head within six months. The circumstances were extraordinary, and it is just to suppose that Pitt was honest: he was not the less grievously wrong.

It was not long before the pain of war was felt in England. Pitt had based his confidence in a short period of war upon the pathetic belief that France would be financially incapable of sustaining a prolonged struggle. But the war advanced, and Pitt's subsidies were swallowed up upon the Continent by allies who made little or no return for them. The nation's debt mounted. The coalition crumbled. More money to buy more allies was needed. In 1795 after a season of bad harvests Pitt had to ask for a loan of 18 millions, and to increase the general taxation. Shortly afterwards followed the legacy duties. In 1797 taxation was increased by two millions; the next year produced the income tax.

Ireland.—One of Pitt's major pre-occupations was still Ireland. He had failed in 1785, but he never ceased to plan for the final consummation of his hopes. In 1793 Pitt forwarded the passage in the Irish House of Commons of the Catholic relief bill; but in 1794 he suffered disappointment when Irish opinion was again alienated by the position he was forced to adopt against the antics of Lord Fitzwilliam, who had been made lord lieutenant as a concession to the Portland Whigs who had entered the ministry in that year. Fitzwilliam and his party were anxious for a broad policy of reform and emancipation; but Pitt had laid down a cautious line of action, and it had been determined that Fitzwilliam should do nothing without the consent of the cabinet. But by "an open breach of a most solemn promise" he proceeded to dismiss the Irish Tory officials, and without authorization to promise widely the immediate prospect of a full emancipation. Fitzwilliam was recalled, and Ireland left to nurse an angry grievance. The whole bungling led directly to the disasters which followed; the state of semi-civil war in 1797 and the rebellion of 1798 and that disaffection which could welcome the French invasion. The union of Ireland and England which he had sought earlier for the mutual benefit of both countries was now imperative as a solution to a state of war. On Jan. 23, 1799, Pitt brought forward his proposals for a union of the two countries. Emancipation was not promised (the hostility of George III.'s eccentric conscience precluded the suggestion) but the hope was held out that this would follow in due course. The bill was pressed through the Irish parliament by Cornwallis, the viceroy, and Castlereagh, the secretary for Ireland. The distribution of titles and money played some part in this and more than a million pounds was expended in compensation to the holders of suppressed rotten boroughs. However open to moral criticism the latter decision may have been, it was essential to the support of the bill and it destroyed an entirely dishonest system of representation. As for the measure of the general corruption, that has at least been over-estimated, and in so far as material persuasion was adopted it must be remembered that bribery in the Irish parliament was a deeply respected tradition. Moreover it must have been patent to the guiding minds in Ireland that the present state of affairs was impossible, and the possible benefits of the union, for instance to trade, were obvious. The bill having passed the Irish parliament in 1800, the first united parliament met in Jan. 1801. Pitt had now to enlarge his policy, and once more the solution of Ireland's troubles was tragically postponed. Pitt had not promised emancipation, but those who had voted for the measure had been led to expect that it must follow. With a secrecy which

was perhaps unwise but understandable in the circumstances Pitt drew up his preliminary suggestions for the abolition of religious tests, the commutation of tithes, and provision for Catholic and dissenting clergy. The plan was opposed in the cabinet, principally by Lord Loughborough, the chancellor, who reported the matter to the king. George was enraged, and adamant against the proposals, and on Feb. 5 accepted the resignation which Pitt had tendered on Feb. 3. Immediately afterwards the situation was complicated by the king's relapse. During his temporary insanity, Pitt retained office until his recovery, finally resigning on March 14. Many bitter things were spoken of him. Once again he was accused of betraying his cause. But he had boldly brought forward his reforms, and his resignation followed upon their veto. Had he pressed his legislation, the king would have persisted inevitably in his opposition: moreover with the war going extremely ill it was not the moment to precipitate a domestic crisis. His promise to George never again to introduce the subject during the reign was sentimental, not necessary, and politically unwise. But he made it because the king had accused him of causing his illness and after all he might reasonably expect that the reign would be shortly finished. That Pitt intended to return to the fullest implications of his project is certain. But he himself had only five more years to live.

1801-1806

Retirement. — Henry Addington, who was called upon to lead the Government, had been universally praised as an expert speaker of the House of Commons; but he was no statesman. Pitt promised to do all he could to support Addington, and generously assisted in the conduct of negotiations for the Peace of Amiens. These terms which Grenville branded as "disgraceful and ruinous" appeared in general "highly satisfactory" to Pitt. Though he had long been anxious to conclude any peace which was at all reasonable, it is difficult to justify him in supporting a peace which recognized the failure of the coalitions to establish the independence of the Netherlands—which had been the ostensible *casus belli*. On the other hand there is evidence that Pitt was conscious of the unstable nature of the peace, and foresaw that a greater struggle was probable. The public supported the peace; and during the discussions a severe vote of censure upon Pitt was rejected, and a counter motion passed by 211 to 52 declaring that he had "rendered great and important services to his country, and deserves the thanks of the house." He retired now from parliament for the space of about a year, living largely at Walmer Castle, where as warden of the Cinque Ports he organized with great diligence and enthusiasm a local volunteer force. The brief interval gave an opportunity too for the examination of his debts. Pitt who had been so astute in public economy was careless of his own. He who had scornfully demanded an explanation of Lord North's expenditure of £340 of public money on whipcord, had himself to account for the grotesque item of £600 for hats. Both thoughtless and generous, Pitt was the victim of swindlers, and in 1800 already owed £45,000 despite the fact that he had received a salary of over £10,000 for many years. He nevertheless refused an offer of £100,000 from the citizens of London, and a gift of £30,000 from the king, though he accepted £11,700 as a loan from a committee of private friends; he was obliged to sell his house Hollowood.

Addington had won a great victory at the general election, but it was not long before his policy began to drift towards perilous courses. When it was clear that a rupture of the peace was imminent, Pitt was approached, but he no longer felt that Addington's policy could receive his honest support, and later negotiations provoked so wide and insistent divergencies of mind upon the personnel of a possible cabinet as to make agreement impossible and even to interrupt an ancient friendship. War broke out again on May 16, 1803. Against the insufficient programme of the ministry Pitt opposed a vigorous policy in a speech (May 23) which provoked the enthusiasm of all parties. But while the cleavage was growing plainer and plainer Pitt yet refused directly to oppose Addington, to whom he had promised his support. The situation was becoming increasingly serious. In the face of the

growing danger of invasion the measures of the Government were entirely inadequate, and early in 1804 Pitt was forced into stronger opposition. Complicated once again by a threatened relapse of the king, negotiations for a stronger administration were protracted. The ministry was doomed when a motion of Fox's for a committee of enquiry into the national defences was powerfully supported by Pitt, and after some days of negotiation he returned as chancellor of the exchequer and first lord of the treasury on May 10.

Second Ministry. — Pitt's second term of office was marked by no great enterprises of governance. The war alone absorbed his energies. The labour and the inspiration of the great European coalition again rested exclusively upon Pitt, and his health, now gravely undermined, was beginning to break beneath the strain when early in April 1805 he suffered the pain of witnessing the public disgrace of his old friend and colleague Dundas (Lord Melville, *q.v.*). The battle of Trafalgar (Oct. 21) destroyed the possibility of invasion; but the year closed in disaster. The capitulation of Ulm (Oct. 20) was succeeded by Austerlitz (Dec 2). At first Pitt was able to doubt the full implications of the news; but, gradually as despatches authenticated the reports he came to realize that the mighty coalition was hopelessly broken. England had saved herself by her exertions, he had remarked at the Lord Mayor's banquet in the previous November: she would save Europe by her example. And now Napoleon stood without a force to oppose him upon the whole continent; and Pitt, with prophetic accuracy, was brought to the bitter admission that the map of Europe would "not be wanted these ten years." On Jan. 23, 1806, he died, and if his last words were not "My country! How I leave my country!" his thoughts can have been none other.

Constitutional Importance. — The period of Pitt's government covered a supremely important moment of political transition. It was also a period of a not less important crystallization of British constitutional doctrine. It would be wrong-headed to attribute that growth too strongly to Pitt's political acumen. Both the length, and the critical instant, of his ministry made development natural and inevitable. He was placed in the position of leadership at precisely the tactical moment. The fruit was ripe: but it was the harvest of a century of other men's labours. Pitt was the first Hanoverian minister to appeal definitely from the vote of the House of Commons to the vote of the constituencies, and throughout his career his strength was derived from the public confidence. In his colleagues Pitt appeared to prefer industry to genius. If this was partly because of an exaggerated sense of his own authority, it must also be remembered that the choice was also one of necessity. Pitt did overshadow his colleagues—but it was no difficult task. The result contributed to his general theory that the independence of Government departments was impossible. They must rather be bound together with a corporate policy, responsible to the Crown under a common allegiance to the prime minister. Walpole, who is generally considered the first prime minister, denied the title, and was succeeded by Governments which could only exist under the leadership of duumvirates and triumvirates. Pitt not only claimed the title of prime minister but declared that the office was essential to sane government. In 1803, when negotiations were on foot for a ministry in which the authority should be shared by himself and Addington, he stated that it was "an absolute necessity that there should be an avowed and real minister, possessing the Chief Weight in the Council and the principal place in the confidence of the King; in that respect there can be no rivalry or division of power. It must rest in the person generally called *first minister*, who ought to be at the head of the finances." And if a difference of opinion arose "the sentiments of the minister must be understood to prevail." This view moreover was widely understood by contemporary commentators. In 1794 when Lord Fitzwilliam went to Ireland he was pledged to support the Government "considering Mr. Pitt as the *Prime Minister* without whom no material measure as to *Things or persons* is to be concerted or done" (*Carlisle Papers*); and the Glenbervie Diary (Dec. 30, 1798) corroborates this language. In everything Pitt laboured to assert the authority of the cabinet, and of the premier within the cabinet. He was the king's

minister; but not the minister of the king's policy. The theory was thrashed out over small details. Pitt claimed, for instance, that the Crown must follow his recommendations in the nominations of bishops, and when the king refused to concur declared that he would take it as a decisive mark of lack of confidence.

Cold, aloof, and sarcastic, supporting a reputation for an almost tiresome integrity, Pitt was not popular except, at a distance, with the people, who saw him as an inspired leader, or with his few intimates, who found him secretly gentle and affectionate. In perspective he has become a man of no little mystery and of unexpected inconsistencies. There seems no good enough reason adequately to explain his changed attitude towards Reform; his treatment of the Reform agitators; his cold indifference to social suffering in England; his support of the Addington ministry in spite of his patent disapproval of its conduct; the lack of a firmer policy during the Fitzwilliam fiasco in Ireland. He remains a statesman: indisputably supreme in debate and tactics and tireless in organization. Because of the failure of the allied cause in the war, it was once popular to assume that Pitt neglected the army and navy, depending solely upon his efforts as an international financier. The assumption is entirely unfair. British naval prestige was at a low ebb at the end of the American war, and it was largely owing to Pitt's interest and to his generous allocations of money that the administration was reformed, and the mastery of the sea re-captured. When Pitt entered office English credit was debased: restoration was effected by his regenerated understanding of finance. In 1783 England was practically outside the concert of Europe, yet in a few years she had become the director of an almost united European policy. A true perception of the future of the Empire was not to come before the 19th century. Yet Pitt's colonial interests were remarkably wide—covering not only the great administrative acts for India and Canada but also the colonization of Australia; the fortification of the West Indies; the defence of Nootka Sound. African settlements were considered, and the territories annexed during the war selected with remarkable discretion.

Actually and theoretically Pitt bridged the distance between the 18th and 19th centuries. He was the source of the emancipation of trade and finance from antiquated restrictions. He was the origin of modern financial theory. Yet, though he warmly supported the abolition of the slave trade, he did nothing to improve the condition of the worker, nothing to promote social emancipation at home. That is perhaps the measure of his position in history. He is revered but not loved.

Pitt was never married. He once professed a tender inclination towards the daughter of Lord Auckland; but the embarrassment of his debts prevented him from a formal declaration of his feelings. His real passion was for his work; and to that he gave his life.

Rose: *William Pitt and National Revival*, and *William Pitt and the Great War; Pitt and Napoleon*; and *A Short Life of William Pitt*. See also P. W. Wilson, *William Pitt, the Younger* (1930). (V. C. C.-B.)

PITTA, a genus of birds remarkable for their great beauty of coloration. For a long while the pittas were commonly supposed to be allied to the *Tzrridae*, but they form a separate family, *Pittidae* of the Passeres. There are about 50 species, divided into a number of genera, confined to the Old World, and ranging from India and North China to Australia, New Guinea and New Britain, with one species in West Africa, the greatest number being found in Borneo and Sumatra. Pittas vary in size from that of a jay to that of a lark, and have a strong bill, a thick-set form, which is mounted on rather high legs with scutellated "tarsi," and a very short tail. In many of the forms there is little external difference between the sexes.

PITTACUS, of Mytilene in Lesbos (650?–570 B.C.), one of the Seven Sages of Greece. About 611, with the assistance of the brothers of the poet Alcaeus, he overthrew Melanchrus, tyrant of Lesbos. In a war (606) between the Mytilenaeans and Athenians for the possession of Sigeum on the Hellespont he slew the

Athenian commander Phrynon in single combat. In 589 his fellow citizens entrusted Pittacus with despotic power (with the title of Aesymnetes) for the purpose of protecting them against the exiled nobles. He resigned the government after holding it for ten years. According to Diogenes Laertius, who credits him with an undoubtedly spurious letter to Croesus, Pittacus was a writer of elegiac poems, from which he quotes five lines.

See Herodotus v. 27, 94; Diog. Laët. i. 4; Lucian, *Macrobian*, 18; Strabo xiii, 600, 617–618; Aristotle, *Politics*, ii. 12, iii. 14; T. Bergk, *Poetae Lyrici graeci*.

PITTSOPORUM, the most numerous genus of the family Pittosporaceae, comprising about 100 species of evergreen trees and shrubs, native to tropical regions of the Old World, chiefly in the Southern Hemisphere.

Many species are grown as ornamentals in warm regions, as in Florida and California, and as house or greenhouse plants in cooler latitudes. *P. tobira* (Japanese pittosporum) and *P. viridiflorum* (Cape pittosporum) are attractive winter-blooming shrubs; *P. rhombifolium* (Queensland pittosporum) is often planted for avenues; *P. undulatum* (Victorian box), of Australia, is suitable for pruned hedges; *P. eugenioides* (tarata), of New Zealand, is useful in shrubberies; and *P. crassifolium* (karo) is planted for seaside windbreaks.

PITT-RIVERS, AUGUSTUS HENRY LAME-FOX (1827–1900), English soldier and archaeologist, son of W. A. Lane-Fox, was born on April 14, 1827. He entered the army, served in the Crimean War, and was one of the founders of the Hythe School of Musketry. General Pitt-Rivers made a collection of weapons and other things which was presented in 1883 to the University of Oxford. When, in 1880, General Pitt-Rivers obtained possession of his great-uncle's estates—practically untouched by the excavator since they had been the battleground of the West Saxons, the Romans and the Britons—he devoted himself to exploring them. His excavations round Rushmore resulted in valuable "finds"; he founded a local museum and published several illustrated volumes. As a scientific archaeologist he attained high rank. He received various honours, including the F.R.S. He married, in 1853, Alice Margaret, daughter of the second Lord Stanley of Alderley, and was the father of a large family; his second daughter became in 1884 the wife of Sir John Lubbock (Lord Avebury). He died at Rushmore on May 4, 1900.

PITTSBURG, a city of Contra Costa county, California, U.S.A., served by the Santa Fe, the Southern Pacific, the Western Pacific railways and by steamship lines. Pop. 9,520 (1940), 35% foreign-born white. It has fisheries, salmon and sardine canneries, the largest steel works west of Chicago, planing mills and asbestos, shipyards, rubber, firebrick and chemical factories. It was founded in 1835. Coal was discovered in 1863, and the town was incorporated under the name of Black Diamond. In 1911 it was chartered as a city and the present name was adopted because of its industrial development and importance. The annual industrial pay roll is \$8,000,000. Since 1918 it has had a city-manager form of government.

PITTSBURG, a city of Crawford county, Kansas, U.S.A., on federal highways 69 and 160, near the southeast corner of the state. It is served by the Frisco, the Kansas City Southern, the Missouri Pacific, the Santa Fe, and electric railways. Pop. 18,052 in 1920 (92% native white); 17,571 in 1940. It is in a great bituminous coal field, where 3,000,000 tons or more are mined annually, and is near oil and gas fields and the lead and zinc region of Kansas and Missouri. The main shops of the Kansas City Southern railway are there, and there are iron foundries, large pottery, sewer pipe works, and other manufacturing industries, with an aggregate output in 1939 valued at \$3,378,000. Bank clearings for 1940 amounted to \$46,388,000. The Kansas State Teachers college of Pittsburg (established 1903) has an annual enrolment of over 5,000. The city was settled about 1876 and chartered in 1880, when the population was 624. Between 1880 and 1890 it increased more than tenfold.

PITTSBURGH (sometimes, but erroneously, spelled Pittsburg), the second largest city of Pennsylvania, U.S.A., and the county seat of Allegheny county, on the Allegheny, Monongahela

and Ohio rivers, 440 mi. by rail W. by S. of New York city, 348.5 mi. W. by N. of Philadelphia, 368 mi. N.W. of Washington and 468 mi. E. by S. of Chicago. Pop. (1910, after annexation of Allegheny) 533,905; (1920) 588,343; (1930) 669,817; (1940) 671,659. In previous census years, the population was as follows: (1800), 1,565; (1820), 7,248; (1840), 21,115; (1860), 49,221; (1880), 156,389; (1890), 238,617; (1900), 321,616. After the

THE CARNEGIE STEEL WORKS, ONE OF THE MANY STEEL PLANTS IN PITTSBURGH: SEEN FROM TROY HILL, ON THE NORTH SIDE

1920 census was taken, and up to 1927, parts of Chartiers, Reserve and Lower St. Clair townships, Frick Woods and St. Clair, Carrick, Knoxville and Westwood boroughs, with a population of 30,000 were annexed.

The land area of the city is 52.1 square miles. The chief business area, called the golden triangle, covers 974.3 ac. or 1.52 sq. mi. The population of Allegheny county in 1940 was 1,411,539.

As a city Pittsburgh ranks tenth in the United States. The sesquicentennial anniversary (1758-1908) of the city was observed in 1908.

In the city, illiteracy is 2.6% compared with state average 3.1% but the illiteracy of native white is 0.3 compared with state average 0.5. The nonwhite population (1940) was 63,051 or 9.4%; orientals are few. Of the 109,072 (1930) foreign-born, 6,293 were natives of England, 3,130 of Scotland, 11,246 of Ireland, 1,117 of Wales, 986 of Sweden, 14,409 of Germany, 15,251 of Poland, 9,224 of Russia, 3,937 of Austria, 2,235 of Hungary, 6,670 of Czechoslovakia, 4,132 of Yugoslavia, 3,258 of Lithuania, 18,154 of Italy, 1,683 of Canada and 7,347 miscellaneous. Pittsburgh is served by the Pennsylvania, the Baltimore and Ohio, the New York Central (Pittsburgh and Lake Erie), the Buffalo, Rochester and Pittsburgh, the Bessemer and Lake Erie, and the Pittsburgh and West Virginia railways, and by boats on the Ohio, Monongahela and Allegheny rivers.

Picturesque rolling plateaus, the three-rivers and narrow valleys from which rise high hills or precipitous bluffs, are the principal natural features of the district over which the city extends. Retail houses, wholesale houses, banks, tall office buildings, hotels, theatres and railway terminals are crowded into the angle, or "The Point," formed at the confluence of the Allegheny and Monongahela rivers, with Fifth avenue as the principal thoroughfare, especially for the retail houses, and Fourth avenue as the great banking thoroughfare. Factories extend for several miles along the banks of all three rivers into the tributary valleys, and are the cause of Pittsburgh's former nickname, "The Smoky City." With the practical elimination of smoke through the use of natural gas, a more recent nickname is the "Steel City" or "Electric City." The more attractive residential districts are on the plateau in the eastern portion of the district between the Allegheny and Monongahela rivers and on the undulating hills overlooking the Allegheny river from the north. Overlooking the Monongahela river is Schenley park (about 422 ac.), the first city park, of which about 400 ac. were given to the city in 1890 by Mrs. Mary E. Schenley. About 2 mi. to the north, overlooking the

Allegheny river, is Highland park (about 366 ac.), which contains the city reservoirs and a picturesque lake. Not far from Schenley park are Homewood and Calvary cemeteries; and Frick park (470 ac.), on land donated by the late Henry C. Frick; and not far from Highland park is Allegheny cemetery, also overlooking the Allegheny river. Across the Allegheny river, in the Allegheny district, are the beautiful Riverview park (350 ac.) in which is the Allegheny observatory, and West park (about 110 ac.). In 1927 the county acquired the North and South parks (each 1,200 ac.). There are more than 200 bridges within the city limits. The county in 1923 completed twin tunnels—each tube 25 ft. wide and 5,889 ft. long—at a cost of \$6,000,000, under Mt. Washington, to connect the southern hill with the city by a high-level bridge over the Monongahela.

Public Buildings and Institutions.—The city has some fine public buildings, office buildings and churches. The Allegheny county courthouse (1884-88) is one of H. H. Richardson's masterpieces. The Nixon theatre is also notable architecturally. The high Frick office building has exterior walls of white granite; in its main hall is a stained-glass window by John La Farge representing Fortune and her wheel. A government building of sandstone and marble contains the post office and the customs offices. Other buildings are the City-County, Union Trust, Koppers, Gulf, Grant and a dozen others, equally imposing, together with several hotels. St. Paul's cathedral (Roman Catholic, 1903-06) is largely of Indiana limestone. The city is the see of a Roman Catholic and a Protestant Episcopal bishop, and the residence of a bishop of the Methodist Episcopal church. Other fine churches are Calvary, Sacred Heart, First Baptist and First Presbyterian. At the entrance to Schenley park is a great civic, educational, art and social centre, including the University of Pittsburgh with its 42-story Cathedral of Learning and other buildings; Carnegie Institute and School of Technology, the Twentieth Century, University, Athletic, Knights of Columbus, Y.M.H.A. clubs, Soldiers' and Sailors' Memorial hall, Masonic temple, Syria mosque, armory, Schenley hotel, Forbes field (1903), and University stadium.

In Schenley park is the Carnegie institute (established by a gift of \$10,000,000 from Andrew Carnegie, who made further contributions for its maintenance, its endowment in 1939 being \$9,465,836 and that of the school \$17,464,419 with provision for an addition to the latter of \$12,000,000 by 1946) with a main building containing a library, a department of fine arts, a museum and a music hall, and separate buildings for the School of Technology which had (1940) 388 teachers and 5,788 students. The main building, dedicated in April 1907, is 600 ft. long and 400 ft. wide; in its great entrance hall is a series of mural decorations by John White Alexander, a native of the city. The library, in which the institution had its beginning in 1895, contained (1940) 1,063,519 volumes and had 14 branches. The art department maintains the only international exhibition of modern paintings in the United States. The Phipps conservatory was presented to the city in 1903 by Henry Phipps (1839-1930), a steel manufacturer associated with Andrew Carnegie. It is the finest in America, and, with its Hall of Botany, which is utilized in instructing school children in botany, is situated in Schenley park. There is a zoological garden in Highland park.

In December 1907 it was decided that the several departments of the Western University of Pennsylvania, then situated in different parts of the city, should be brought together on a new campus of 43 ac., increased to 77 ac. (1941), near the Carnegie institute. In July 1908 the name was changed to the University of Pittsburgh, in which were (1940) 1,177 professors and 14,549 students. The institution had its beginning in the Pittsburgh academy, which was opened perhaps as early as 1780 and was incorporated in 1787. It was incorporated as the Western University of Pennsylvania in 1819.

The Pennsylvania College for Women (Presbyterian; chartered in 1869), has collegiate and musical departments, and in 1940 had 37 teachers and 341 students. Overlooking the golden triangle is Duquesne university (Roman Catholic) with its schools of liberal arts, commerce, pharmacy and law and its 201

THE "CIVIC CENTRE" OF PITTSBURGH

In the left centre is the University of Pittsburgh's 42-story Gothic "cathedral of learning," with the Stephen C. Foster memorial immediately in front. To the right of the "cathedral" is the Heinz Memorial chapel and the Mellon institute (with colonnade). At the upper left is the university's "upper campus," including Pitt stadium, the medical centre and the professional schools. In the lower left is the Carnegie library and museum

teachers and 3,010 students (1940). In the Allegheny district are the Allegheny Theological seminary (United Presbyterian, 1825), the Western Theological seminary (Presbyterian, opened 1827), and the Reformed Presbyterian Theological seminary (1810). Under the new school code (1911) a board of education consisting of 12 members appointed by the judges of the common pleas courts controls the public schools. There were (1940) 21 high schools, with 1,259 teachers and 39,400 pupils, one teachers' training school, six special schools, 114 elementary schools, with 1,393 teachers and 56,623 pupils and evening schools with 31,123 pupils. The parochial schools had 25 high schools, 246 teachers and 5,087 pupils and 80 grade schools, 918 teachers and 35,063 pupils; and there are many private schools and academies, among them Shadyside academy. The Henry C. Frick Education commission has an endowment of several millions for the improvement of teaching in the public schools.

The *Pittsburgh Casette* (1786) was probably the oldest newspaper west of the Allegheny mountains and was (1906) consolidated with the *Times* (1879) under the name of *Gazette-Times* and later (1927) consolidated with the *Post* (Sunday, 1792; daily, 1842) under the name *Post-Gazette*, the only morning paper.

The evening papers are *Sun-Telegraph* and the *Pittsburgh Press* which purchased and discontinued (1923) the *Dispatch* (1846) and the *Leader* (Sunday 1864, daily 1870). A German daily, weeklies in Slovak, Italian, Polish and nine other languages, and iron, steel, building, coal, glass, agriculture and other trade journals are published in the city. In Pittsburgh are published the *United Presbyterian*, the *Christian Advocate*, the *Catholic Observer*, the *Pittsburgh Catholic* and other weeklies.

The oldest hospital was the Reineman (1893), for maternity cases, made the University maternity hospital (1893) and transferred to Magee hospital (1910), the latter with the Children's, Eye and Ear, Presbyterian, Woman's, Psychiatric and Municipal, forming the new medical centre of the University of Pittsburgh. Other hospitals are: Tuberculosis, Shadyside, Montefiore, Passavant, Roselia Maternity, St. Johns, St. Josephs, St. Margaret Memorial, South Side, West Penn, Allegheny General, Columbia, in charge of United Presbyterian Women's association, and the Sisters of Mercy, Mercy hospital. Sisters of St. Francis, St. Francis hospital, and the Sisters of Charity, Pittsburgh hospital. The Western Pennsylvania schools for the deaf and for the blind, are located in Pittsburgh and many of the hospitals, schools, homes and charitable institutions, nonsectarian, are in part maintained by the state.

The Y.M.C.A. had 17 branches and the Y.W.C.A. (metropolitan) had three branches (1940), and there were over 550 churches, 14 all-year playgrounds, 24 public swimming pools, 20 parks and over 400 social and welfare agencies.

Industry and Commerce.—Pittsburgh is in the midst of the most productive coal fields in the country; the region is also rich in petroleum and natural gas. The city is on one of the main lines of communication between the east and the west, is the centre of a vast railway system, and has freight yards in and outside the city with a total capacity for more than 60,000 cars. Its harbour has a total length on the three rivers of 27.2 mi., and an average width of about 1,000 ft., and has been deepened by the construction (in 1877-85) of the Davis Island dam, by dredging, under a federal project of 1899. This dam has been superseded by the Emsworth fixed dam. Slack water navigation has been secured on the Allegheny by locks and dams (1890, 1896 *et seq.*) at an expense up to July 1909 of \$1,658,804; and up to that time \$263,625 had been spent for open-channel work. By 1941 there was a total of eight dams on the Allegheny river. The Monongahela from Pittsburgh to the West Virginia State line (91.5 mi.) was improved in 1836 *et seq.*, by a private company which built seven locks and dams; this property was condemned and bought for \$3,761,615 by the United States government in 1897, and, under the project of 1899 for rebuilding three of the locks and enlarging another, and that of 1907 for a new lock and dam and for other improvements, \$2,675,692 was spent up to July 1909. Since then six of these have been entirely rebuilt and changed to

two chamber locks and eight more locks have extended the facilities to Fairmont, 131 miles away. Coal is brought to the city from the coal fields by boats on the Allegheny and Monongahela rivers as well as by rail, and great fleets of barges carry coal and other heavy freight, such as steel rails, cotton ties, sheet iron, wire and nails, down the Ohio in the winter and spring. A ship canal to provide water communication between Pittsburgh and Lake Erie has been projected and is awaiting the approval of the army engineers. The railways have a heavy tonnage of coal, coke and iron and steel products, and a large portion of the iron ore that is produced in the Lake Superior region is brought to Pittsburgh. In 1938 the river traffic amounted to 19,734,725 tons valued at \$140,864,241. Most of the exports are carried on barges down the Ohio. Pittsburgh is also a port of entry; its 1938 imports amounting to \$4,165,000. According to the ninth industrial directory of Pennsylvania, the factories, 1,906 in number, situated within Allegheny county, gave employment to 189,807 workers, paid in wages the total sum of \$1,746,908,000 and manufactured products valued at \$1,541,863,800 in 1937.

The leading industries in order of the value of their products in 1937 were: steel works and rolling-mill products, \$78,709,550; printing and publishing, newspapers and periodicals, books and job printing, \$26,353,760; bread and other bakery products, \$25,482,909; meat packing, \$21,415,296; electrical machinery, apparatus and supplies, \$19,048,357; machine-shop products, \$9,777,580; nonferrous metal alloys, nonferrous metal products, except aluminium, \$7,629,184. Other manufactures included machinery; ice cream; confectionery; heating and cooking apparatus; paints, pigments and varnishes; structural and ornamental metal work; foundry products.

In finance Pittsburgh occupied sixth place in bank clearings with \$6,118,971,448 in 1939 and (Dec. 31, 1940) had national bank deposits \$722,879,505, state bank deposits \$127,310,335 and trust and savings deposits \$576,964,549. In Pittsburgh or the immediate vicinity are the more important plants of the United States Steel corporation, including that of the Carnegie company, and the Jones and Laughlin Steel corporation, one of the largest independent steel companies in the United States. Here, too, are the plants of the Westinghouse company for the manufacture of electrical apparatus, of air-brakes invented by George Westinghouse (1846-1914), and of devices for railway signals which he also invented. In the Allegheny district the H. J. Heinz company with its 57 varieties has its main food-preserving plant, the largest establishment of the kind in the country.

Government.—The Pittsburgh charter of 1816 vested the more important powers of the city government in a common council of 15 members and a select council of nine members, and until 1834 the mayor was appointed annually by these city councils from their own number. By the Wallace act of the state legislature in 1874 a form of government was provided for cities of three classes, and Pittsburgh became a city of the second class (population between 100,000 and 300,000); under the act of 1895 a new classification was made, under which Pittsburgh remains in the second class. An act of 1887 had amended the provisions of the Wallace act in regard to second class cities by changing the terms of select councilmen from two to four years and of common councilmen from one to two years. In 1901 a new act was passed for the government of cities of the second class. It provided that the executive be a "city recorder"; this provision was repealed in 1903, when the title of mayor again came into use. By act of legislature (1911) the former common and select councils were superseded by a small council of nine members, elected by general vote of the entire city. The mayor, elected by the people for a term of four years, continued to appoint the heads of departments (public safety, public works, assessors, treasurer, law, welfare, health, supplies, etc.), and the comptroller also continued to be elected by popular vote. By a two-thirds vote the council may pass resolutions or ordinances over the mayor's veto. The department of public safety controls the bureaus of police, fire, building inspection, electricity and general office; the department of public works controls the bureaus of water, highway and sewers, property, parks, recrea-

tions, tests, lights, deed registry, bridges and construction. The mayor appoints the members of the civil service commission. Through a city-planning commission, recommending zoning ordinances and through a board of adjustment, the height and character of all buildings are controlled. A bureau of traffic relief and a traffic commission were created in 1924, and in 1925 a department of city transit, charged with the regulation of traffic conditions and with the matter of recommending subways and a comprehensive system of rapid-transit lines for the entire city. In 1940 the taxable valuation was \$1,047,023,860 for land and buildings and the tax rate was 23 mills on land, 11.5 on buildings and 11.75 for schools. The water supply of Pittsburgh is taken from the Allegheny river and pumped into reservoirs, the highest of which in Highland park is 367 ft. above the river; the supply is filtered.

For the history of Pittsburgh, see PENNSYLVANIA.

PITTSFIELD, a city of western Massachusetts, U.S.A., the county seat of Berkshire county; on federal highways 7 and 20, and served by the Boston and Albany and the New York, New Haven and Hartford railways. Pop. (1920) 41,763 (20% foreign-born white); 1940 federal census 49,634. It occupies 40.9 sq.mi., at an altitude of 1,000 ft., in the midst of the Berkshire hills. Three branches of the Housatonic river wind through the city, uniting about a mile from the central green. Within its limits are the whole or parts of five lakes (Pontoosuc, Onota, Morewood, Silver and Richmond). It is a well built city, with dignified public buildings, substantial business blocks, modern schools, shaded residential streets and on the outskirts large manufacturing plants. The assessed valuation for 1940 was \$59,231,540. Pittsfield is a touring centre and a resort for winter sports. Its manufacturing industries are large and distinctive, with an output in 1938 valued at \$38,608,557. They include the world's largest electric transformer and plastic plants of the General Electric company; and the mill that makes all the paper used for the U.S. bank notes and government bonds. The oldest industry (still one of the most important) is textile manufacturing, chiefly woollen goods. Fine stationery, paper-mill equipment, machine tools, spool silks and silk braids are other leading products. The first settlement within the present boundaries of Pittsfield (Boston Plantation or Pontoosuc), made in 1743, was soon abandoned because of trouble with the Indians. It was revived in 1749, and in 1761 was incorporated as the town of Pittsfield, named in honour of the elder William Pitt. The town was chartered as a city in 1891. Shaker Village was settled (by Shakers) about 1790. Elkanah Watson (1758-1842), while living (1807-16) at what is now the country club, introduced the merino sheep. When he exhibited on the village green his sheep along with the livestock and produce of other farms, he became the father of the agricultural fair.

PITTSSTON, a city of Luzerne county, Pennsylvania, U.S.A., on the Susquehanna river, about midway between Scranton and Wilkes-Barre. It is served by the Central of New Jersey, the Delaware and Hudson, the Erie, the Lackawanna, the Lackawanna and Wyoming Valley and the Lehigh Valley railways. The population in 1920 was 18,497 (26% foreign-born white), in 1930 it was 18,246, and in 1940 it was 17,828 by the federal census. Within a 2.5 mi. radius from the city hall is a population of over 70,000.

Pittston is the centre of the anthracite coal region. The city also has foundries, machine shops, textile mills, dress factories, paper mills, a perforated metals plant, a cracker and cookie factory, mine and railroad machine shops. It was one of the five towns founded in the Wyoming valley by the Susquehanna company of Connecticut, and was named after the elder Pitt. It was founded about 1768, incorporated as a borough in 1803 and chartered as a city in 1894.

PITUITARY EXTRACT or **PITUITRIN**: see ANIMAL EXTRACTS.

PITYRIASIS VERSICOLOR, a skin disease, consisting of patches of brown discoloration, mostly on the front of the body, and often attended with itching, especially after exercise. The epidermis is scaly over the patch, and among the *débris* there may

be seen minute oval spores of a vegetable parasite, the *Microsporon furfur*. The disease is mostly one of adults, found all over the world, and not associated in any special way with poor general health. The treatment consists of rubbing in an ointment of potassium sulphide or one of the mercurial ointments, or using sulphur-soap habitually.

PIURA, a coast department of northern Peru, with area 15,235 sq.mi.; pop. (1940) 431,457. The department includes mountainous areas in the north (Cerros de Amatope) and east (cordilleran sierra) and a great desert (Sechura) in the south. The chief rivers are the Chira, a permanent stream, and the Piura. Crops are grown with the aid of irrigation as there is rainfall only at intervals of years. Cotton-growing is the leading industry in the irrigated valleys, stock-raising in the sierra. The cultivation of *aspero* (full-rough cotton) is peculiar to this department, the product of a large bush, and is known as vegetable wool (see PERU: Agriculture). There are gins and factories for making cotton-seed oil and cake; also a crushing-mill for castor-beans which produces about 20,000 gal. of castor-oil annually. Other crops include rice, sugar, tobacco, maize, potatoes, yuca, beans, cacao and fruits, all of which are consumed locally. *Sierran* cattle are fattened in the upper valleys. Goats are raised extensively. Charcoal is made from the wood of the algaroba tree. Though mineral deposits are widespread, petroleum is the only one exploited. It now heads the list of Peruvian exports and the only producing oil fields in the republic are in the department of Piura and the adjoining province of Tumbes. They lie along the north-western coast, a narrow belt about 60 m. in length. The two chief operating companies are in Piura; the International Petroleum Corporation, a subsidiary of the Standard Oil Company, whose chief field is Negritos, 40 mi. northwest of Paita, with a modern refinery at Talara, and the Lobitos oilfields, 10 mi. north of Talara, owned by an English company. In 1940, Peru exported more than 288,000 tons of gasoline, 716,000 tons of crude oil, and 57,000 tons of kerosene. The International Petroleum corporation normally produces about 80% of the national output. A standard gauge railway runs from Paita (*g.v.*) to Piura (58 mi.) by way of Sullana, a distributing centre for southern Ecuador, and narrow gauge railways connect the oil-fields with Talara. Roads are under active construction and sections of the coast highway and of the road across the Andes from Paita to the Amazon are finished.

Piura, capital of the department, population (1940) 20,093, is on the Piura river, 164 ft. above sea-level. It was founded by Pizarro in 1532 on a slightly different site. It has electric lights, telephone and telegraph, banks, theatres, superior court, secondary schools and an excellent hospital. Catacaos, 6 mi. south of the capital, is the centre of the Panama hat industry. Hats are woven from leaves of the *toquilla* palm (*Carludovica palmata*).

PIUS I., pope from about 141 to 154. He was the brother of Hermas, author of the Shepherd.

PIUS II. (Aeneas Silvio de Piccolomini, known in literature as Aeneas Silvius), pope from 1458 to 1464, was born on Oct. 18, 1405, at Corsignano (later called Pienza after him) near Siena. His family claimed to trace descent from Romulus. The eldest of 18 children, he worked on the farm with his father until a priest enabled him, at the age of 18, to go as a poor student to Siena, where he divided his time between severe humanistic studies and sensual pleasure. He was attracted to Florence by the teaching of Filelfo. He became secretary to Domenico Capranica, bishop of Fermo, and went with him to the Council of Basle, where he stayed several years (1431-35), changing masters whenever he could improve his position. He was engaged on various errands, some of them dangerous; they included a long journey to England and Scotland on secret diplomatic business. In 1436 he was back at Basle, and, although a layman, obtained a seat in the council and exercised considerable influence. Aeneas took an active part in the council after it was transferred to Florence, and though he still declined to take orders, he was given a position on the conciliar conclave which elected Amadeus of Savoy as pope under the title of Felix V. In return for his

services Felix made Aeneas papal secretary.

A new period of his career opened in 1442, when he was sent by the council to take part in the diet of Frankfurt-on-Main. Here he met Frederick III. of Germany, who made him poet laureate and his private secretary. He ingratiated himself with the chancellor, Kasper Schlick, at Vienna, one of whose adventures he celebrated in *Lucretia and Eurialus*, a novel in the style of Boccaccio. At this period he also wrote his witty but immoral play, *Chrisis*. In 1446 he took orders as subdeacon, and wrote that he meant to reform, "forsaking Venus for Bacchus." Aeneas was useful to Frederick as a diplomatist, and managed to give all parties the impression that he was the devoted advocate of each. He took an important part in the diet of Nuremberg (1444), and in 1445 made his peace with Eugenius. At the diet of Frankfurt (Sept. 1446) Aeneas modified the hostility of the electors to pope and emperor. The new pope, Nicholas V., made him bishop of Siena, and for his services in negotiating the concordat of Aschaffenburg in 1448 he was made prince of the empire and cardinal.

The death of Calixtus III. (who succeeded Nicholas V.) occurred on Aug 5, 1458. After a hot fight in the conclave, Aeneas was elected and took the title Pius II., with a reminiscence of Virgil's "pius Aeneas." The humanists hailed his election with joy, and flocked around to secure a share of the good things, but they were bitterly disappointed, as Pius did not prove himself the liberal and indiscriminating patron they hoped. The fall of Constantinople in 1453 made a deep impression upon Pius, and he never ceased to preach the crusade against the Turk. In Sept. 1459 he opened a congress at Mantua to promote the crusade, but both the French and the Germans were annoyed with him for different reasons, and he received little support. He believed that the decline in the papal influence was due to the usurpation of power by the councils, and he now issued (Jan. 1460) the bull *Execrabilis et in pristinis temporibus inauditus*, in which he condemned as heretical the doctrine that the councils were superior to the popes, and proclaimed the anathema against any one who should dare to appeal to one.

While Pius was at Mantua war broke out between the French and Spanish in southern Italy, and a rising of the barons devastated the Campagna. Hurrying back to Rome, Pius succeeded in quelling the disorders. This measure still further alienated the pope from the French, with whom he was at that time negotiating for the abrogation of the Pragmatic Sanction. When Louis XI. came to the throne (Nov. 1461), he sent to Pius saying that he had abolished the Pragmatic Sanction, hoping in return to get the kingdom of Naples, for his countryman, René of Anjou. As Pius continued to support Ferdinand, Louis retaliated by reasserting the ancient liberties of the Gallican Church. At the same time a serious quarrel with the Germans prevented anything being done towards a crusade. George Podiebrad, king of Bohemia, was plotting to depose the emperor Frederick III., who was supported by Pius. Diether, archbishop of Mainz, took the side of Podiebrad, and replied to Pius's measures by appealing to a general council. He was declared deposed by the pope, but kept his seat, and in 1464 compelled the pope to recognize him again. The quarrel with Podiebrad, who was accused of supporting the Utraquist heresy, continued with increasing bitterness, but without any decisive result, until the death of Pius. In the meantime the pope did what he could to further the cause of the crusade. The discovery of alum mines at Tolfa gave him an unexpected pecuniary resource, and to stimulate the zeal of Christendom, Pius took the cross on June 18, 1464. He set out for Venice, where he intended to sail for the East, but he was attacked with a fever, and on Aug. 14, 1464, he died.

Pius II. was a voluminous author. Besides poems, a novel and a play, he wrote a number of orations, which were considered models of eloquence in their day. The tale of *Euryalus and Lucretia* was translated into many languages (Eng., 1560), and his Latin poems, *Miseriae curialium* (Rome, 1473), were read throughout Europe. Alexander Barclay translated some of them in *Certaine Eglogues . . .* (1548?) repr. by Spenser Society (1885). His most valuable work, however, is his *Pii II. Com-*

mentarii rerum memorabilium quae temporibus suis contigerunt, a history of his times, told in an interesting and rational manner. Also, there is the *Cosmographia in Asiae et Europae . . . descriptione*, of which a complete edition was published at Venice in 1503, and *Historia Bohemica* (Cologne, 1532).

BIBLIOGRAPHY.—The letters of Pius II. are in process of publication by R. Wolkan, *Der Briefwechsel des Aeneas Silvius Piccolomini* (Vienna, 1909-), in *Fontes rerum Austriacarum*. The Commentaries were published in 1584, as begun by Pius himself, and completed by J. Gobellinus. His other works are found in *Aeneas Silvii opera omnia*, edit. M. Hopperus (Basle, 1551). See also Herzog-Hauck, *Realencyklopädie* (1904), vol. xv., where a full bibliography will be found; Voigt, *Pius II.* (1856-63); L. Pastor, *History of the Popes from the Close of the Middle Ages* (Eng. trans., 1896, vol. ii.); M. Creighton, *History of the Papacy during the Reformation*, vol. ii. (1882); W. Boulting, *Aeneas Silvius* (1908); C. M. Ady, *Pius II.: the Humanist Pope* (1913); C. Lucius, *Pius II. und Ludwig XI. von Frankreich, 1461-62* (1913).

PIUS III. (Francesco Nanni-Todeschini-Piccolomini), pope from Sept 22 to Oct 18, 1503, was born at Siena on May 9, 1439. When only 22 years of age he was made archbishop of Siena and cardinal-deacon of St. Eustachio by his uncle Pius II, who permitted him to assume the name and arms of the Piccolomini. He was employed by subsequent popes in several important legations, as by Paul II. at the diet of Regensburg, and by Sixtus IV. to secure the restoration of the ecclesiastical authority in Umbria. He opposed the policy of Alexander VI., and was elected pope, amid the disturbances consequent upon the death of the latter, through the influence of Cardinal della Rovere, afterward Julius II. Pius was a man of blameless life, and would doubtless have accomplished much had he lived. His successor was Julius II.

Gregorovius, *Rome in the Middle Ages*, vol. viii., trans. by Mrs. G. W. Hamilton (London, 1900-1902); Piccolomini, "Il Pontificato di Pio III.," in *Archivio stor. ital.*, vol. v. (Firenze, 1903).

PIUS IV. (Giovanni Angelo Medici, or "Medighino"), pope from 1559 to 1565, was born at Milan on March 31, 1499. He began his career as a lawyer, but later entered the service of Paul III., who made him a cardinal in 1549. In the protracted conclave that followed the death of Paul IV. the election of Pius (Dec. 25, 1559) was due to a compromise between the Spanish and French. In temperament Pius was affable, vivacious, convivial. He was, moreover, astute, diplomatic and experienced in affairs. He allowed the reform movement initiated by Paul IV. free course, but tried to repair certain injustices of Paul IV., and mitigated some of his extreme decrees. But to the nephews of Paul he showed no mercy: they were charged with various crimes, condemned, upon testimony of suspicious validity, and executed on March 5, 1561. With England lost to the papacy, Germany overwhelmingly Protestant, and France on the verge of civil war, Pius realized how fatuous was the anti-Spanish policy of his predecessor. He therefore recognized Ferdinand as emperor, and conciliated Philip II. with extensive ecclesiastical privileges. But subsequently, antagonized by Philip's arrogance, he assisted France with troops and money for use against the Huguenots.

After a suspension of ten years the council of Trent reconvened on Jan. 18, 1562. Among the demands presented by the various nations were the recognition of the equality of the episcopate, communion in both kinds, clerical marriage and the use of the vernacular in Church services. It required all the pope's diplomacy to avoid compliance on the one hand, and a breach with the powers on the other. Thanks to Morone and Borromeo, however, he achieved his end. The council was dissolved on Dec. 4, 1563, and its decrees and definitions confirmed by the pope (Jan. 26, 1564), who reserved to himself the sole right of interpretation, and took various measures for enforcing its decisions.

After the termination of the council Pius indulged his desire for ease and pleasure, to the great offence of the rigorists. Pius fortified Rome, and contributed much to the embellishment of the city—among other works, the church of Sta. Maria degli Angeli in the Baths of Diocletian; the Porte Pia; the Villa Pia in the

Vatican Gardens; and the Palace of the Conservatori. He died on Dec. 9, 1565, and was succeeded by Pius V.

Müller, *Das Konklave Pius IV.* (Gotha, 1889; more comprehensive than the title suggests); Ranke, *Popes* (Eng. trans., Austin), i. 323 seq., 358 seq., and v. Reumont, *Gesch. der Stadt Rom.* iii. 2, 534 seq., 730 seq.

PIUS V. (Michele Ghislieri), pope from 1566 to 1572, was born on Jan. 17, 1504, in the Milanese. At the age of fourteen he became a Dominican monk. He was appointed inquisitor in Como, where his zeal provoked such opposition as to compel his recall (1550). The chief inquisitor, Caraffa, convinced of his value, straightway sent him upon a mission to Lombardy, and in 1551 appointed him commissary-general of the Holy Office. When Caraffa became pope, Ghislieri was made bishop of Nepi and Sutri, cardinal (1557), and finally grand inquisitor. In this office he was continued by Pius IV., whom, however, he antagonized by his censoriousness and obstinacy. But after the death of Pius IV., the rigorists, led by Borromeo, had no difficulty in making him pope (Jan. 7, 1566). Retaining his ascetic mode of life, Pius immediately began the work of reform. Decrees and ordinances were rapidly issued; the papal court became a model of sobriety; prostitutes were driven from the city, or confined to a certain quarter; penalties were attached to Sunday desecration, profanity and animal baiting; clerical residence was enforced; conventuals were compelled to live in strict seclusion according to their vows; satechetical instruction was enjoined. A new catechism appeared in 1566, followed by an improved breviary (1568), and an improved missal (1570). The use of indulgences and dispensations was restricted, and the penitential system reformed.

Pius was the avowed enemy of nepotism. One nephew, it is true, he made cardinal, but allowed him no influence: the rest of his relatives he kept at a distance. By the constitution *Admonet nos* (March 29, 1567), he forbade the reinvestiture of fiefs that should revert to the Holy See, and bound the cardinals by oath to observe it. In March 1569 Pius ordered the expulsion of the Jews from the States of the Church. For commercial reasons they were allowed to remain in Rome and Ancona, but only upon humiliating conditions. In February 1571, the Urnilati, a degenerate monastic order of Milan, was suppressed on account of an attempt upon the life of the archbishop, Carlo Borromeo.

The rules governing the Holy Office were sharpened; old charges, long suspended, were revived; rank offered no protection, but rather exposed its possessor to fiercer attack; none were pursued more relentlessly than the cultured, among whom many of the Protestant doctrines had found acceptance; princes and states withdrew their protection, and courted the favour of the Holy See by surrendering distinguished offenders. Cosimo de' Medici handed over Pietro Carnesecchi (and two years later received in reward the title of grand duke, Sept. 1569); Venice delivered Guido Zanetti; Philip II., Bartolomé de Carranza, the archbishop of Toledo. In March 1571 the Congregation of the Index was established, and hundreds of printers took flight to Switzerland and Germany. The regret of Pius was that he had sometimes been too lenient. He spurred Philip II. on in the Netherlands, and commanded the utter extermination (*ad internecionem usque*) of the Huguenots; he protested against the tolerance shown by the emperor. One of his cherished schemes was the dethronement of Elizabeth, whom he excommunicated and declared a usurper (Feb. 25, 1570); but he had to content himself with abetting plots and rebellions. He effected an alliance with Spain and Venice against the Turks, and contributed to the victory of Lepanto (Oct. 6, 1571). Pius died on May 1, 1572; and was canonized by Clement XI. in 1712.

See Ciaconius, *Vitae et res gestae summorum pontiff. rom.* (Rome, 1601-02; a contemporary of Pius); *Acta sanctorum, maij*, tom. i. pp. 616 seq., containing the life by Gabuzio (1605), based upon an earlier one by Catena (1586); Falloux, *Hist. de St. Pie V.* (3rd ed., Paris, 1858), eulogistic; Mendham, *Life and Pontificate of St. Pius V.* (London, 1832), a bitter polemic. The life of Pius has also been written by Fuenmayor (Madrid, 1595), Paolo Alessandro Maffei (Rome, 1712), and by T. M. Granello (Bologna, 1877). His letters have been edited by Catena (*vide supra*), Goubau (Antwerp, 1640), and a select number in a French translation, by de Potter (Paris, 1826).

PIUS VI. (Giovanni Angelo Braschi), pope from 1775 to 1799, was born at Cesena, on Dec. 27, 1717. After taking the degree of doctor of laws he went to Ferrara and became the private secretary of Cardinal Ruffo, in whose bishopric of Ostia and Velletri he held the post of *uditore* until 1753. His skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV., who appointed him one of his secretaries and canon of St. Peter's. In 1758 he was raised to the prelature, and in 1766 to the treasurership of the apostolic chamber by Clement XIII., and in 1773 he became cardinal-priest of San Onofrio. In the four months' conclave which followed the death of Clement XIV., Spain, France and Portugal at length dropped their objection to Braschi, and he was elected to the vacant see on Feb. 15, 1775.

Pius had received the support of the ministers of the Crowns and the anti-Jesuit party upon a tacit understanding that he would continue the action of Clement, by whose brief *Do-minus ac redemptor* (1773) the dissolution of the Society of Jesus had been pronounced. On the other hand the *zelanti*, who believed him secretly inclined towards Jesuitism, expected from him some reparation for the alleged wrongs of the previous reign. The half-measures adopted by Pius gave little satisfaction to either party. It is perhaps largely due to him that the order was able to escape shipwreck in White Russia and Silesia; in 1792 he considered its re-establishment as a bulwark against revolutionary ideas.

The authority of the papacy was threatened in Austria by the social and ecclesiastical reforms undertaken by Joseph II. and, in the hope of staying them, Pius adopted the exceptional course of visiting Vienna in person. His mission proved a fiasco; he was, however, able a few years later to curb those German archbishops who, in 1786 at the Congress at Ems, had shown a tendency towards independence. Difficulties also arose in Naples and in Tuscany. At the outbreak of the French Revolution Pius saw the old Gallican Church suppressed, the pontifical and ecclesiastical possessions in France confiscated and an effigy of himself burnt by the populace at the Palais Royal. The murder of the republican agent, Hugo Basseville, in the streets of Rome (January 1793) gave new ground of offence; the papal court was charged with complicity by the French Convention; and Pius threw in his lot with the league against France. In 1796 Napoleon invaded Italy, defeated the papal troops and occupied Ancona and Loreto. Pius sued for peace, which was granted at Tolentino on Feb. 19, 1797; but on Dec. 28 of that year, in a riot created by some Italian and French revolutionists, General Duphot of the French embassy was killed and a new pretext furnished for invasion. General Berthier marched to Rome, entered it unopposed on Feb. 13, 1798, and, proclaiming a republic, demanded of the pope the renunciation of his temporal authority. Upon his refusal he was taken prisoner, and on Feb. 20 was escorted from the Vatican to Siena, and thence to the Certosa near Florence. The French declaration of war against Tuscany led to his removal by way of Parma, Piacenza, Turin and Grenoble to the citadel of Valence, where he died six weeks later, on Aug. 29, 1799. Pius VII. succeeded him.

See Zopffel and Benrath, "Pius VI.," in Herzog-Hauck, *Realencyklopädie*, 3rd ed., vol. xv., pp. 441-451 (Leipzig, 1904, with elaborate bibliography); F. Nielsen, *History of the Papacy in the 18th Century*, vol. i. chap. vii. (London, 1906); J. Gendry, *Pie VI. sa vie, son pontificat, d'après les archives vaticanes et de nombreux documents inédits* (2 vols., 1907).

PIUS VII. (Luigi Barnaba Chiaramonti), pope from 1800 to 1823, the son of Count Scipione Chiaramonti and the deeply religious Countess Ghini, was born at Cesena on Aug. 14, 1740 (not 1742). He entered the Benedictine monastery of St. Mary at Cesena, and held various teaching appointments in the colleges of his order at Parma and at Rome. He was created an abbot of his order by his relative Pius VI., who also appointed him bishop of Tivoli in 1782, and raised him to the cardinalate and the see of Imola in 1785. He became pope on March 14, 1800.

His attention was at once directed to the ecclesiastical anarchy of France, and he negotiated the celebrated concordat of 1801.

(See CONCORDAT.) The importance of this agreement was, however, considerably lessened by the "articles organiques" appended to it by the French government on April 8, 1802. In 1804 Napoleon opened negotiations to secure at the pope's hands his formal consecration as emperor. After some hesitation Pius was induced to perform the ceremony at Notre Dame and to extend his visit to Paris for four months; but in return for these favours he was able to obtain from Napoleon merely one or two minor concessions. Napoleon soon began to disregard the Italian concordat of 1803, and himself decreed the dissolution of the marriage of his brother Jerome with Miss Patterson of Baltimore. The irritation between France and the Vatican increased so rapidly that on Feb. 2, 1808 Rome was occupied by General Miollis; a month later the provinces of Ancona, Macerata, Fermo and Urbino were united to the kingdom of Italy, and diplomatic relations between Napoleon and Rome were broken off; finally, by a decree issued from Schonbrunn on May 17, 1809, the emperor united the Papal States to France. Pius retaliated by a bull excommunicating the invaders; and, to prevent insurrection, Miollis—either on his own responsibility, as Napoleon afterwards asserted, or by order of the latter—employed General Radet to take possession of the pope's person. On July 5 Pius was made prisoner; he was taken to Grenoble, and then to Savona, where he steadfastly refused canonical institution to the bishops nominated by Napoleon. In 1812 the aged and sick pontiff was removed to Fontainebleau, where he was lodged in a suite of regal magnificence to await the return of the emperor from Moscow. When Napoleon arrived, he entered into personal negotiations with the pope, who on Jan. 25, 1813 assented to a concordat so degrading that his conscience found no relief until, on the advice of the cardinal Pacca and Consalvi, he abrogated it (March 24); and on the 9th of May he defied the emperor by declaring invalid all the official acts of the new French bishops. Napoleon sent him back to Savona for safe keeping; but the course of events in 1814 forced him to liberate the pope and give back the States of the Church. On the 19th of March Pius left Savona, and was received with rejoicing at Rome on May 24. Reaction set in at Rome; the Jesuits were restored; the French legislation, much of which was of great social value, was repealed; the Index and the Inquisition were revived. On his return from the congress of Vienna Consalvi conducted a more enlightened and highly centralized administration, based largely on the famous *Motu proprio* of 1816; nevertheless the finances were in a desperate condition. Discontent centred perhaps in the *Carbonari*, a Liberal secret society condemned by the pope in 1821. Consalvi negotiated a series of valuable concordats with all the Roman Catholic powers save Austria. In the latter years of Pius's life royalty often came to Rome; the pope was very gracious to exiled kings and showed notable magnanimity toward the family of Napoleon. He attracted many artists to the city, including the greatest sculptors of the time, one of whom, the Protestant Thorwaldsen, prepared the tomb in which repose the remains of the gentle and courageous pontiff, who passed into rest on Aug. 20, 1823. His successor was Leo XII.

Both these last have good bibliographies.

PIUS VIII. (Francesco Xaviero Castiglioni), pope from 1829 to 1830, was born at Cingoli on Nov. 20, 1761. He studied canon law at Rome, became vicar-general at Anagni and later at Fano; in 1800 was appointed bishop of Montalto and in 1816 of Cesena.

In 1821 he was made cardinal-bishop of Frascati, also grand penitentiary; and later he became prefect of the Congregation of the Index. In the conclave which followed the death of Leo XII., Castiglioni, the candidate of France, was elected pope on March 31, 1829. He abandoned the system of espionage employed by his predecessor, and published an encyclical condemning Bible societies and secret associations. He exhibited a pacific spirit in dealing with the problem of mixed marriages in Germany. He died on Dec. 1, 1830. His successor was Gregory XVI.

See Zöpfel and Benrath, "Pius VIII.," in Herzog-Hauck, *Realencyklopädie*, xv. 458 seq. (Leipzig, 1904, with bibliography); F. Nielsen, *A History of the Papacy in the 19th Century*, ii. 31-50 (1906); P. B. Gams, *Series episcoporum ecclesiae catholicae* (Regensburg, 1873).

PIUS IX. (Giovanni Maria Mastai-Ferretti), pope from 1846 to 1878, was born on May 13, 1792 at Sinigaglia, the fourth son of Count Jerome and Countess Catherine Vollazi; the family of Mastai was of ancient descent, and the title of count came to it in the 17th century, while later the elder branch, allied by marriage with the Ferretti family, took that name in addition. He spent some time at the College of Piarists in Volaterra, and prepared to enter the pontifical guard as an officer but was refused on the ground that he suffered from epilepsy. The maiady, however, was surmounted; and in 1819 he was ordained priest. After ministering for some time in his native town, he accompanied Cardinal Muzzi to Chile (1823). On his return he was entrusted by Leo XII. with the direction of the Roman hospital of San Michele; in 1830 he received the archbishopric of Spoleto, in 1832 the bishopric of Imola, and in 1840 Gregory XVI. created him a cardinal, with the title Santi Pietro e Marcellino.

On the death of Gregory XVI. (June 1, 1846) the College of Cardinals met in conclave on June 14, and on June 16 Mastai-Ferretti obtained the requisite two-thirds majority, and ascended the papal chair under the title of Pius IX. In his various capacities he had gained much popularity: he had shown himself to be of a kindly disposition and a zealous churchman, and his reputation for piety and tact stood high; he possessed, too, a winning personality and a handsome presence.

Papal Reforms.—The reign of Pius IX. began at an extremely critical time. The problem of the government of the Papal States, transmitted to him by his predecessor, stood in urgent need of solution, for the conditions were intolerable. Dissatisfaction found vent in revolts which could only be quelled by the intervention of foreign powers; and the ferment in the dominions of the Church was accentuated by the revolutionary disturbances throughout ascendant in all the states of Europe. The proclamation of a general political amnesty made an excellent impression; and Pius at once instituted preparations for a reform of the administration, the judicature and the financial system. The regulations affecting the censorship were mitigated, and a breath of political liberalism vitalized the whole government. Pius at once acquired the reputation of a reforming pope. But two demands were urged with ever increasing energy—a share in the government and a national Italian policy. The problem of popular representation was one of peculiar difficulty in the Papal States. It was not simply a question of adjusting the claims of monarch and subject: it was necessary to oust the clergy—who, till then, had held all the more important offices—from their dominant position, or at least to limit their privileges. That the clerical character of the administration could not be indefinitely retained was plain to any clear-thinking statesman: for, since the restoration of the Papal State in 1814, the pernicious effects of this confusion of the spiritual and the secular power could no longer be denied. But Pius IX. lacked the courage and perspicacity to draw the inevitable conclusions from these premises; and the higher clergy at Rome were naturally opposed to any change which would deprive them of power and privileges. In the course of the year 1847 the pope by a series of decrees gave a reorganized municipal council to Rome and instituted a state council, and a responsible ministry, but these reforms were hedged in with reservations which made them unacceptable to the people. In March 1848 the pope promulgated a constitution, with a parliament consisting of two chambers.

Revolution of 1848.—The utility of this constitution was

never tested; for the demand for an extension of popular rights was now eclipsed by a still more passionate aspiration towards the national unity of Italy. This nationalist movement at once took head against Austria. On March 18 the revolution broke out in Milan, and King Albert of Sardinia undertook the conduct of the war against the emperor. The populace was swept by a whirlwind of enthusiasm: the Austrian embassy was mobbed; the imperial arms, surmounting the main gate of the palace, were torn down; and great troops of volunteers clamoured to be led against Austria. Pius seemed, after his proclamation of March 30, on the point of conferring his blessing upon the war against Austria. But on April 29, in his allocution to the cardinals, he proclaimed the papal neutrality; and the storm broke. Mamiani, Fabbri and Rossi, in successive ministries, sought to restore order. On Nov. 15 Rossi was assassinated as he was about to open the session of the chambers. The pope then assented to the formation of a radically democratic ministry under Galetti. The Swiss, who composed the papal guard, were disbanded; and the protection of the pontiff was transferred to the civil militia; in other words, Pius IX. was a prisoner. On Nov. 24 he fled, with the aid of the French and Bavarian ambassadors—the duc d'Harcourt and Count Spaur—to Gaeta in the kingdom of Naples. On Feb. 9, 1849 the constituent assembly decreed, by 142 votes to 23, the erection of a Roman republic. Pius answered by a protest dated Feb. 14. He had already appealed to the European Powers for assistance. For the intervention of France and Austria see ITALY. On July 14 Oudinot proclaimed the restoration of the pontifical dominion; and, three days later, Pius IX. issued a manifesto entrusting the government to a commission appointed by himself.

Loss of the Temporal Power.—On April 12, 1850 Pius returned to Rome, supported by foreign arms, embittered, and hostile henceforward to every form of political liberalism or national sentiment. In Gaeta he had mentally cut himself loose from all ideas of progress, and had thrown himself into the arms of the Jesuits. His subsequent policy was stamped by reaction. Whether it might have been possible to avoid the catastrophe of 1870, in which the remnant of the Papal States was lost, is a difficult question. But undoubtedly the policy which Pius now inaugurated, of restoring the old pre-revolutionary conditions, sealed the fate of the temporal dominion of the papacy. He made no attempt to regain the estranged affections of the populace, and took no measures to liberate himself and his subjects from the incubus of the last few years. The system of precautionary arrest, as it was termed, rendered it possible for any man to be thrown into prison, without trial and without verdict, simply on the ground that he lay under suspicion of plotting against the Government. The priests, who usurped the judicial function, displayed such cruelty on several occasions that officers of the Austrian army were compelled to record a protest. The consequence of these methods was that every victim—innocent or guilty—ranked as a martyr in the estimation of his fellow-citizens. Brigandage revived, corruption was rampant, and the financial administration under Cardinal Antonelli (*q.v.*) was disastrous.

The mismanagement which obtained in the papal dominions could not escape the observation of the other powers. As early as the Congress of Paris in 1856 the English ambassador, Lord Clarendon, had directed an annihilating criticism against the government of the pontiff; and a convincing proof of the justice of his verdict was given by Pius himself, in his treatment of the famous Mortara case (see MORTARA, EDGAR), which gave rise to diplomatic representations from France and England. The sequel to this mode of government was that the growing embitterment of the subjects of the Church came to be sympathized with outside the bounds of Italy, and the question whether the secular authority of the papacy could be allowed to continue became a much-debated problem. The continued existence of the Papal States as such, depended in fact on the maintenance of the understanding between the two powers protecting the papal state—France and Austria.

But Napoleon came to an agreement with Cavour against Austria, and one of the results of the war of 1859 was that the pope forfeited two-thirds of his dominions. After the war of

1866 (see ITALY: History), the States of the Church formed the last remaining obstacle to complete national unity. The news of the fall of the French empire in 1870 produced an electrical effect in Italy. The French troops had evacuated Rome in 1869, and the Italian parliament now called on the king to occupy Rome; on Sept. 8 Victor Emmanuel crossed the borders; and on Sept. 20 the green-white-and-red of the tricolour floated over the Capitol. The protests of Pius IX. remained unheeded, and his attempts to secure another foreign intervention met with no success. On Oct. 2 Victor Emmanuel instituted a *plébiscite* in Rome and the possessions of the Church to decide the question of annexation. The result of the suffrage was that 153,681 votes were given in favour of union with Italy, and 1,507 against the proposed incorporation: that is to say only the direct dependants of the Vatican were opposed to the change. The papal state was now merged in the kingdom of Italy, which proceeded to define its diplomatic relations with the Holy See by the law of May 13, 1871. (See ITALY: History.)

Ultramontanism.—In his capacity as head of the Church, Pius IX. adhered to the principles of the Ultramontanist party, and contributed materially to the victory of that cause. The political reaction which followed the revolutionary era in most quarters of Europe offered a favourite soil for his efforts; and in several countries he found it possible to regulate the relations between Church and state from the standpoint of the curia. In 1851 he concluded a concordat with Queen Isabella II. of Spain, proclaiming Roman Catholicism the sole religion of the Spanish people, to the exclusion of every other creed (art. 1); and we find the same provision in another concordat with the South American republic of Ecuador (1862). A third concordat, negotiated with the emperor Francis Joseph I. of Austria (1855), entrusted the supervision of schools and the censorship of literature to the clergy, recognized the canon law, and repealed all secular legislation conflicting with it. France came into line with the wishes of the pope in every respect, as Napoleon needed clerical support in his political designs. Even in Germany he found no resistance; on the contrary, he was able to secure advantageous compacts from individual states (Hesse, 1854; Wiirtemberg, 1857).

Among the most important acts of Pius IX. must be counted his proclamation of the dogma of the Immaculate Conception of the Virgin Mary, by the bull *Ineffabilis Deus*, on Dec. 8, 1854. In this bull the preservation of Mary from every stain of hereditary sin, in the first moment of her conception, was declared to be a divinely revealed truth, which consequently demanded universal acceptance. (See IMMACULATE CONCEPTION.) By this means a view, which till then had been no more than a pious belief, was elevated into a dogma to be held *de fide*; though grave doubts on the subject had always been entertained, even in the midst of the Church itself. For the inner life of that Church this solution of the controversy was of great significance, and created a desire for further dogmatic decisions on the Virgin Mary—her resurrection and ascension.

As reigning sovereign of the Papal States Pius IX. had passed through a "liberal period": as head of the Church, he had never been liable to attacks of liberalism. Nevertheless, his return from exile left its mark on his spiritual administration. For from this period onwards he set his face against the influence of modernism on ecclesiastical life; showed his displeasure at and distrust of the scientific theology and philosophy which marked a moderate advance (Giinther, Frohschammer and Dollinger); and, entrenched in the stronghold of mediæval ideals, combated the transformations of the new order of society, and the changes in the relationship between Church and state, which obtained in most countries of Europe since the French Revolution. After long and careful consultation, the adverse criticisms which he had expressed on various occasions were published on Dec. 8, 1864, together with the encyclical *Quanta cura*, under the title *Syllabus complectens præcipuos nostræ ætatis errores*. (See SYLLABUS.) In this Pius claimed for the Church the control of all culture and all science, and of the whole educational system. He rejected the liberty of faith, conscience and worship enjoyed by other creeds; and

bade an easy farewell to the idea of tolerance. He claimed the complete independence of the Church from state control; upheld the necessity of a continuance of the temporal power of the Roman See; and finally, in the last clause, declared that "the pontiff neither can be nor ought to be reconciled with progress, liberalism and modern civilization."

The publication of this syllabus created a profound impression: for it declared war on modern society, and committed the papacy to the principles of Ultramontanism (*q.v.*). But, as any attempt to translate its precepts into practice would entail a disastrous conflict with the existing regime as established by law, Roman Catholic circles have frequently shown a tendency to belittle the significance of the manifesto and to deny that its rules are absolutely binding. But these well-meant explanations, however comprehensible, are refuted by the unequivocal pronouncements of Pius IX., Leo XIII., and many recognized ecclesiastical authorities—*e.g.*, Cardinal Manning, archbishop of Westminster, who described the syllabus as an emanation from the highest doctrinal authority in the Church.

Infallibility.—The zenith of Pius's pontificate was attained on July 18, 1870, when the Vatican council proclaimed the infallibility of the pope and the universality of his episcopate, thus elevating him to a pinnacle which none of his predecessors had reached and at the same time fulfilling his dearest wish. That, personally, he laid great stress on the acceptance of the dogma, was a fact which he did not attempt to conceal during the long preliminary deliberations of the council; and his attitude was a not inconsiderable factor in determining its final resolutions. But the loss of the Papal States, immediately afterwards, was a blow from which he never recovered. Whenever he brought himself to speak of the subject—and it was not rarely—he repeated his protest in the bitterest terms, and, to the end of his days, refused to be reconciled with the "sacrilegious" king of Italy. When, in Germany, the situation created by the Vatican council led to the outbreak of the *Kulturkampf*, Pius IX. failed to display the tact peculiar to his successor. For, in the encyclical *Quod nunquam* (Feb. 5, 1875), he took the rash step of declaring invalid the Prussian laws regulating the relationship between Church and state—the only result being that the feud was still further embittered.

In these later years the dark days of his "captivity" were amply compensated by the proofs of reverence displayed by Roman Catholic Christianity, which accorded him magnificent ovations as his period of jubilee began to fall due. The twenty-fifth anniversary of his pontificate was celebrated with great splendour on June 16, 1871; for he was the first pope who had thus reached the traditional "years of Peter." In 1872 his 80th birthday gave occasion for new demonstrations; and 1875 was a so-called "year of jubilee." Finally, in 1877, the fifty years of his priesthood were completed: an event which brought him innumerable expressions of loyalty and led to a great manifestation of devotion to the Holy See from all the Roman Catholic world. He will be remembered as the pope who re-established the hierarchy in England. On Feb. 7, 1878 Pius IX. died. His successor was Leo XIII. (C. M.; X.)

PIUS X. (Giuseppe Sarto), pope from Aug. 4, 1903, to Aug. 20, 1914, was born of humble parents on June 2, 1835, at Riese in the province of Treviso, Italy, and studied at the episcopal seminaries of Treviso and Padua, being ordained priest in 1858. For 17 years he acted as parish priest at various places in Venetia

until his appointment in 1875 as canon of the cathedral and superior of the seminary at Treviso. In 1880 he refused the bishopric of Treviso, but accepted that of Mantua in 1884, at the command of Leo XIII. On June 12, 1893, he was created a cardinal and three days later was nominated patriarch of Venice, where his piety, simplicity and readiness to act in harmony with the Italian Government made him very popular. He succeeded Leo XIII. in his election to the papal chair on Aug. 4, 1903.

During his pontificate, in the defence of the faith, his condemnation of the 65 propositions of Modernism in 1907 will rank as a parallel to the condemnation of the 68 propositions of Molinism by Innocent XI. in 1637 or the 101 propositions of Jansenism condemned by Clement XI. in 1713.

Reforms of the first importance were undertaken—the codification of canon law; the protection of the liberty of the conclave by the abolition of the *exclusiva*; the simplification and security of the conditions of marriage by the *ne temere* legislation; the restoration of the Rota as the supreme court of appeal; the regulation of the triennial or quinquennial visits of bishops to Rome; the legislation as to church music; and the decree as to first communion, and the encouragement of international eucharistic congresses; the reform of the Roman breviary; the founding of the biblical institute for the work of Scriptural research; the regulation of studies in the seminaries; the creation of the commission for the great work of editing the true text of the Vulgate; the reconstruction of the official machinery of the Roman curia; the transfer of the English-speaking countries from the propaganda or missionary régime to the normal government of the Church. To these may be added in the domain of discipline the unflinching vindication by Pius X. of the Church's right to depose delinquent bishops, carried out even at the cost of rupture of diplomatic relations with France; an apostolic visitation rigorously carried out through the dioceses of Italy, resulting in four bishops being made to resign on account of neglect or inefficiency; a further regulation by which no one can be proposed for a bishopric unless his promotion receives the visa of the Holy Office, which means that his past life has been free from ecclesiastical censure or reproach.

The well-known personal characteristics of Pius X. were his piety, charity, deep humility, simplicity, pastoral zeal, combined with great charm of manner to all who approached him. For war he had nothing but horror and it was the shock of the outbreak of the World War that hastened his death, which took place in Rome on Aug. 20, 1914. It is said that one of his last acts was to refuse the request of the Austrian emperor to bless his cause, saying: "I do not bless war: I bless peace."

PIUS XI. (1857–1939), pope from 1922 to 1939, was born on May 31, 1857, at Desio, north of Monza, in the environs of Milan, on the road to Como, and was named Ambrose Damien Achille. His father was Francesco Ratti, the manager of one of the great silk factories of Desio, and partner in the firm of Gadda. Achille was educated at the seminaries of San Pietro Martire and of Monza, and at the college of St. Charles at Milan, where he graduated. Feeling that he was called to the priesthood, he studied for two years in the greater seminary. His life at this time was profoundly influenced by his spending his vacation months with his uncle, Don Rodolpho, the venerable and exemplary parish priest and provost of Asso, a village in the promontory of the Bellgio. From his windows he could see Lake Como and the Alps, of which later on he was so strongly to feel the lure. It was also here that he came under the personal notice of the archbishop of Milan, Mgr. Nazario di Calebiana, who was staying as the guest of Count de Herra and was a frequent visitor at his uncle's presbytery. The archbishop was much struck by the future pope's earnestness and maturity of judgment, and was wont to call him his "young old man." Ever afterwards he took a deep interest in his career. He sent him to the college of St. Martin and then to Rome to study at the Lombard college and attend the lectures at the Gregorian university. Here Achille Ratti took with distinction the degrees of doctor of philosophy, of theology and canon law. He was ordained priest on Dec. 20, 1879.

At the Lombard college his fellow student and closest friend

was Alessandro Lualdi, later cardinal archbishop of Palermo. These two were mentioned to the pope by Professor Liberatore as the most brilliant of his students. They were the first to win the doctorate at the Angelico, the new Thomistic college founded by Leo XIII. at Rome. The pope sent for the two students and while passing through the Clementine Hall, from his chair in which he was being carried to the Vatican gardens he delivered to them an impressive lecture upon the vital importance of a sound philosophy and of their mission in promoting it in the years which lay before them. In 1882 Dr. Ratti returned to Milan and was appointed for a period of some months to a curacy at the village of Barni.

Following up the intentions of Leo XIII., the archbishop transferred him to the Great Seminary, where he filled for five years the post of professor of dogmatic theology. In 1888 he was admitted as a member of the college of doctors at the great Ambrosian Library. This appointment gave a new direction to his scholarship. In this task, Dr. Ratti found a congenial field of labour under the guidance of the prefect of the college, the learned Abbate Cerriani. He became an expert, especially in Latin palaeography and published several studies, and contributed numerous articles to the learned reviews. In 1907 he succeeded Cerriani as prefect of the library. He was made domestic prelate by Pius X. During 1905-07 he undertook and carried out a reclassification of the library upon modern methods so as to facilitate the work of consultation and research. His success in this enterprise was recognized by the king of Italy, who bestowed on him the knighthood of the Order of Saints Maurice and Lazarus.

From 1888 onwards he was chaplain and director to the nuns of the Cenacle, an order specially devoted to the work of arranging spiritual retreats or conferences for all classes of women. At their convent he was brought into contact with all that was most distinguished and zealous among the laity of Milan and became an active organiser of their manifold works of charity. At the same time, he spent the hours that he could spare from his library in teaching the catechism to numbers of poor children, including the little chimney sweeps that annually come down from Tirol. He clung to this work during the 30 years that he remained in Milan.

He more than once visited England. In June 1900 he stayed for a time with his intimate friend, Bishop Casartelli, at Manchester. He studied at the Bodleian in Oxford and at the British Museum and said Mass in Westminster cathedral. In his summer vacations it was his custom to make climbing excursions in the Alps. The *Bolletino* of the Italian Alpine Club relates how, in 1889, he discovered a new way of ascent by the eastern slope to Monte Rosa, and how on one occasion by his courage and promptitude he saved the life of his guide. The ascent is commemorated by a monument erected by the club at Macugnaga. In 1908 during the riots at Milan, he was active in pacifying the turbulent elements and intervened successfully to save the Capucine convent from destruction during the bombardment.

Cardinal Ferrari had made him his trusted counsellor in the government of the diocese and in 1909 appointed him to a canonry in the cathedral. In 1912 Pius X. called him to Rome, made him vice-prefect of the Vatican library (where he served under Cardinal Gasquet) and at the same time promoted him to a canonry of St. Peter's. On the succession of Benedict XV. he became the familiar friend of the new pope, who, with a keen appreciation of his qualities singled him out for the diplomatic service and entrusted him with the delicate mission of apostolic visitor to the new republic of Poland. Here his clear judgment and tact and his fluent knowledge of German and Polish enabled him to achieve a marked success in dealing with the complicated claims along the Russian-Polish frontier.

In June 1919 Ratti was made nuncio apostolic in Poland and titular archbishop of Lepanto and on July 3 was consecrated in Warsaw by the archbishop, Mgr. Kakowski. It was a mark of the confidence reposed in him by all classes that he was chosen by the Interallied Commission to act as high ecclesiastical commissioner for the plebiscite of Upper Silesia by agreement of both the Polish and German Governments. During the Bolshevik inva-

sion, when most of the embassies withdrew from Warsaw, the nuncio remained and carried on his work of conciliation and of succour for the poor in devastated regions. Pope Benedict XV. sent him the pallium, the Polish Government decorated him with the Order of the White Eagle and the university enrolled him amongst its doctors. On the death of Cardinal Ferrari, Benedict XV., in June, 1921, appointed him archbishop of Milan, and made him a cardinal under the title of S.S. Silvestro and Martino ai Monti. On Sept. 2 he returned from a pilgrimage to Lourdes and on the following day was solemnly enthroned.

Pope Benedict XV. died on Jan. 22, 1922. On Feb. 2 the cardinals entered into conclave and on Feb. 6 Cardinal Ratti was elected pope. He chose the name of Pius XI., and was proclaimed from the balcony of St. Peter's. He received the triple obedience of the cardinals and on Feb. 11 was crowned in the presence of an enormous concourse in the Basilica. Subsequently the life of Pius XI. may be summed up as one of constant activity, in which his encouragement of all high ideals and good works was marked by staunchness in all matters of principle and the spirit of pacification and conciliation in administration. During 1925, the year of the jubilee, he was brought, perhaps more than any other pontiff, into personal contact with his spiritual subjects by receiving more than 1,250,000 pilgrims from all parts of the Catholic world. By all he was revered for his learning, his charity, piety and width of sympathy, his courtesy, tact and charm of deportment and, most of all, for his untiring devotion to the duties of his exalted pastorate. (J. Ms.)

Pope Pius XI. will go down in history as the supreme pontiff who, with the cordial co-operation of Mussolini—and their respective advisers—closed the breach between Church and State, known as the Roman Question. (See PAPACY.) The pontiff was said to have devoted over two-and-a-half years of patient and persistent study to the problems that were involved. Examination of the *communiqués* that were available at the time of the signing of the treaties between the Holy See and Italy shows that all bore the stamp of the august humility which had always characterized Pius XI.'s utterances. He is reported to have said, on the day the treaties were signed (Feb. 11, 1929), that he had asked for the least possible indemnity because he regarded himself as a father negotiating with his children, and, therefore, he had wished to make agreement as easy as possible. Five months later the Vatican concluded an agreement with Mexico which permitted the church to resume religious services in that country.

Until his death Pius XI. was an uncompromising opponent of communism, which he condemned as the common enemy of all Christians. It was principally his stand on communism, plus the anti-clerical opinions of certain sectors in the Spanish Republican Government, that led him to espouse the cause of the Insurgents under Franco.

Shortly after Hitler became chancellor, the Vatican signed a concordat with Germany intended to protect the property and rights of the church under the Nazi régime. The peace was short-lived, however, and Pius repeatedly voiced his displeasure at the neopaganism of the Nazis and their failure to observe the letter of the agreement. Pius' relationships with the Italian Fascist State, on the contrary, were friendly in the main until 1938, when Mussolini announced his new anti-Semitic policy. Pius thereupon assailed all racial theories as anti-Christian. Practically all the messages of the last year of his reign were pleas for the preservation of peace. He died at Vatican city on Feb. 10, 1939, and was buried four days later in the crypt of St. Peter's.

BIBLIOGRAPHY.—He published *Climbs on Alpine Peaks*, trans. by J. E. C. Eaton, with introd. by Bishop L. C. Casartelli and a foreword by Douglas W. Freshfield. See also *Annuaire Catholique* (1923), ed. by Mgr. A. Baudrillart; *Acta Apostolicæ Sedis. Commentarium Officiæ* (1919-25); and *Documentation Catholique* (1922-26).

PIUS XII (1876—) was elected pope on his 63rd birthday, March 2, 1939, and was crowned on March 12. He was born in the Palazzo Pediconi, via degli Orsini, in Rome. The second of the four children of Filippo Pacelli, he was given the baptismal name of Eugenio. His family was noted for its traditional loyalty to the Vatican. Filippo, his father, was dean of the Consistorial Advocates of the Vatican, and was a municipal councillor of Rome.

His grandfather, Marcantonio, was under-secretary of the Interior, Papal States, from 1851 till the absorption of the Papal territory by Italy in 1870. His great-grandfather was a minister of finance under Gregory XVI. Donna Virginia Graziosi, his mother, was descended from a noble family of Acquapendente, near Viterbo, equally well known as the Pacelli family for its closeness to and service of the Vatican.

Eugenio Pacelli attended the State primary schools of Rome and finished his secondary studies, with honours, at the famous Visconti Institute. Instead of following the legal tradition of his family, as he had early intended, he decided to enter the priesthood. Since his health, at that time frail, did not permit him to live the trying routine of the seminary, he was permitted to attend the courses of philosophy and theology as a day student at the Capranica seminary, the Gregorian university, and the Pontifical Institute of the Apollinare. He was ordained priest on April 2, 1899. For two years more he engaged in post-graduate studies in the theology, specializing in civil and canon law.

Because of his brilliant record as an ecclesiastical student he was offered, in 1901, occupation in the papal secretariate of State, first as apprentice (*apprendista*), and then as a minor official (*minutante*). His immediate superior was Msgr. Giacomo della Chiesa (Benedict XV), Cardinal Rampolla being then secretary of State and Leo XIII being pope. During these same early years, he devoted his energies to the care of souls, delivering lectures and conferences, conducting spiritual retreats, acting as a chaplain to religious communities. He was also attached to the faculty of the Apollinare as professor of canon law, as well as to that of the Academy of Noble Ecclesiastics, as professor of diplomacy and international law.

In 1904, the then Archbishop Gasparri was appointed by Pius X to undertake the momentous task of the codification of canon law, a work that was finally issued in 1917. Young Father Pacelli was drafted as an assistant and, in due time, became the valued co-worker of Gasparri, who persuaded him, about 1909, to relinquish his professorial duties in favour of his work in the secretariate of State. He was attached to the Department of Extraordinary Affairs, that section of the secretariate which prepares all matters concerning civil law, international law, concordats, etc., for the Sacred Congregation for Extraordinary Ecclesiastical Affairs. Under Cardinal Merry del Val and Pius X, he was named under-secretary of the department in 1912, and a short time later pro-secretary. In 1914, when Cardinal Gasparri became secretary of State, under Benedict XV, Msgr. Pacelli was appointed his successor as secretary of the Department of Extraordinary Affairs.

When the World War convulsed Europe in 1914, Msgr. Pacelli drew up, at the direction of Cardinal Gasparri, a series of notes to various Governments for the exchange and repatriation of prisoners of war. He actively engaged, also, in spiritual ministrations to the German, Austrian, and Italian soldiers. In 1917, the post of apostolic nuncio at Munich was vacant. This nunciature offered the only diplomatic contact between the German Empire and the Holy See. No one more competent than Msgr. Pacelli could have been found for this most delicate and vastly important diplomatic mission. Accordingly, on April 20, Benedict XV designated him as apostolic nuncio to Bavaria and, three days later, raised him to the episcopacy, as titular archbishop of Sardes. The pope himself consecrated him on May 13, in the Sistine Chapel.

Toward the end of May, Archbishop Pacelli arrived in Bavaria, with definite instructions to institute negotiations looking toward peace. He immediately opened conversations with Chancellor Bethmann von Hollweg, and in July interviewed Kaiser Wilhelm, at his field headquarters near Kreutznach. Both of them expressed a desire to consider peace proposals. Accordingly, Archbishop Pacelli advised Benedict XV to issue his *Nota per la pace*. This seven-point peace plan was sent on Aug. 1, 1917, to the heads of all the warring nations. It was then the task of Archbishop Pacelli to bring about acceptance of the plan by the Central Governments. Though the Kaiser and chancellor had previously expressed keen interest in the papal efforts, though the Reichstag had already adopted the Erzberger peace resolutions, both the Kaiser and the military leaders refused to accept the mediation of the

Holy See. Nevertheless, Archbishop Pacelli continued his representations through August and later, with the new chancellor, Georg Michaelis. His efforts were as unavailing as those of the other representatives who dealt with the Allies. And yet, the plan of Benedict was basic to the fourteen points of President Wilson, adopted after the German collapse.

When the war concluded, Germany became a land of conflict and chaos. Parties of the extreme Left and the Communists gained the ascendancy. Revolution, with all its attendant horrors of bloodshed, rioting and public executions unrolled before the eyes of Archbishop Pacelli. Early in 1919, during the Spartacist outbreak, the papal nunciature in Munich was sprayed with machine-gun fire, and the nuncio himself was threatened with a pistol at his heart. On this occasion, as on others, he betrayed not the slightest fear and conceded not a single demand of his attackers. By Aug. 1919, Germany had become partially pacified through the establishment of the confederated Republic and the adoption of the Constitution of Weimar. The Holy See was eager to establish relations with all of Germany and to transfer the apostolic nunciature to Berlin. Despite German political and religious opposition, Archbishop Pacelli secured authorization for the move, and was appointed the first papal nuncio to Berlin, June 22, 1920. He continued to reside in Munich, however, for he was engaged in negotiating the concordat between the Holy See and Bavaria. This important document was signed on March 20, 1924, and was ratified the following year.

Transferring his residence to Berlin, June 24, 1925, he opened a wider sphere, through all of Germany, for his diplomatic duties. Because of priority of appointment, he became the dean and spokesman of the diplomatic corps. As an orator and preacher he was much in demand, for he spoke German fluently and even wrote a book in exquisite German style. He had always been a favourite in Germany because of his war work and because of his balanced attitude toward the conflicting political parties. In Berlin, his culture, his affability and graciousness, his supreme tact, his sincerity and priestly charity won him the friendship and confidence of all classes, whatever their religious or political affiliations. He was negotiating during these years a concordat to settle the relation of the Vatican and the German Republic. This was opposed bitterly by the National Socialists, the Communists, and other Leftist parties. He succeeded in his endeavour, nevertheless. On July 9, 1929, the Prussian Landtag, though predominantly Protestant, approved of the concordat with the Holy See, and authorized the signature five days later. At the same time, Archbishop Pacelli was preparing further concordats with Baden and Wurttemberg. In Nov. 1929, he was recalled to Rome. His departure occasioned universal regret throughout Germany and, in Berlin, was marked with extraordinary testimonials of respect.

His summons to Rome was by way of reward for his eleven years of brilliant success in Germany as the papal representative. On Dec. 16, 1929, Pius XI elevated him to the cardinalate, as priest with the title of Saints John and Paul. This was in immediate preparation for his appointment as secretary of State for the Vatican City State on Feb. 7, 1930. As once before, he assumed the office vacated by his patron and friend, Pietro Cardinal Gasparri, then near to his 80th year. Despite his protests of unworthiness, he took his place beside Pius XI, the friend whom he revered and loved and with whom he was destined to govern the Universal Church in the most perfect and complete accord for nearly a decade. The biography of the future Pius XII, then, coalesces with that of the closing years of Pius XI.

One of the immediate problems of the new secretary was that of executing the terms of the Lateran Treaty between the Holy See and Italy, signed by Cardinal Gasparri and Mussolini on Feb. 11, 1929. Marquis Francesco Pacelli, his brother, as chief consistorial advocate of the Vatican, had played a leading part in negotiating the Lateran Treaty. Together, the brothers collaborated in the further applications and interpretations of the treaty that were summarized in the so-called "Reconciliations," signed in the summer of 1931.

Another problem of momentous international relations reared up in Germany. European pressure on the Reich and, as a result,

the failure of the democratic system, prepared the way for Adolf Hitler. By Jan. 1933, the National Socialists (Nazis) obtained such a majority that President von Hindenburg was left no alternative but that of inviting Hitler to form a cabinet. By March 23, the Weimar Constitution was scrapped and the dictatorship entered its first stages. In the national reorganization, it was deemed advisable to draw up a revised concordat between the Vatican and the Third Reich. Cardinal Pacelli, under direction of Pius XI, and Franz von Papen, the Catholic vice-chancellor under Hitler, drew up the terms of the agreement. The concordat was pushed through for signature by July 8, 1933. Within two years, the German bishops Cardinal Pacelli, and Pius XI were charging the Nazi Government of Hitler with violations of the concordat and were condemning the pagan and totalitarian ideology of the Nazi leaders.

Against atheistic communism, which he experienced personally in Germany, which he studied so minutely in Soviet Russia, with which he had to deal in Mexico, and most of all in Spain, Cardinal Pacelli, as secretary of State, threw the full force of his opposition. In this, he was one with Pius XI. He has been fearlessly outspoken against every governmental régime and every ideology that destroys the individual and social rights of man and that invades the spiritual supremacy of the Church. With all other nations and peoples, on the contrary, his policy has been that of conciliation and agreement. Through concordats and understandings he has consistently striven to create the status of peace between Church and State.

Without abandoning the security that comes from tradition and conservatism, Cardinal Pacelli proved himself one of the most progressive churchmen of all times. He was not deterred by precedent, if the flux of a rapidly changing world required readjustments. Thus, he avails himself of, and quickly adopts, the latest inventions of our mechanized world. Even when aviation was in the experimental stages, he was an ardent flyer, and travelled by air whenever possible. He recognized the value of communication through radio. He did not adhere to the tradition that the secretary of State should not travel abroad officially and be credited as papal legate. In 1934, against all custom, he attended, as legate, the 32nd International Eucharistic Congress at Buenos Aires, Argentina. The following year, again as legate, he closed the Holy Year Celebration at Lourdes, his visit being the first instance in a century of a secretary of State in his official capacity visiting France. In 1937, he represented Pius XI at the dedication of the Basilica of Lisieux, France. The year following, as papal legate, he took part in the 34th International Eucharistic Congress held at Budapest, Hungary.

His most exceptional and amazing tour was that to the United States. He was the first ever elected to the papacy to visit the United States, and the second ever to have crossed the Atlantic. His arrival in New York on Oct. 8, 1936, in the midst of a presidential election campaign, occasioned the most wide-spread speculation. Cardinal Pacelli simply stated that he came solely for a vacation and a desire to see America. After visiting the principal cities of the East, he followed the northern aeroplane route to San Francisco, with stops along the way, and returned from Los Angeles to New York across the southern lane, likewise dropping out of the air at the points of interest. He lunched with President Roosevelt at Hyde Park, N.Y., on November 5, the day following the President's re-election. On November 7, he sailed from New York, having travelled, it is estimated, some 8,000 miles, mostly by aeroplane; having visited 12 of the 16 ecclesiastical provinces; having conferred with 79 bishops; and having met an uncounted number of Americans.

As a young man, he had attended the 19th International Eucharistic Congress in London, in 1908, and returned to England in 1911 in the suite of Cardinal Granito Pignatelli di Belmonte, papal envoy at the coronation of George V. Then, as in his maturer life, he impressed everyone as a cultured gentleman, as a polished diplomat, as a statesman of deep sincerity, but most of all, as a saintly churchman.

Appointed papal chamberlain (camerlengo) in April 1935, he became automatically the administrator of the Church in the event

of an inter-regnum. It had become evident that Pope Pius XI was failing. Then, on Feb. 10, 1939, a little after 5:31 in the morning, his duty required that he solemnly pronounce his dearest friend, Pius XI, to be dead, in the 81st year of his age. On Cardinal Pacelli, thereupon, devolved the responsibility of taking charge of the arrangements for the burial of the late pontiff, and of superintending the election of the new pope.

The date set for the conclave was March 1. As papal chamberlain, Cardinal Pacelli superintended the enclosure of the 62 cardinal electors in the Vatican. He was freely spoken of as the best possible choice. His personal and priestly piety, his sincerity and rectitude, his humility and lack of selfish ambition, his sound judgement proved through forty years, his vast knowledge of dogmatic and moral theology, canon law, ecclesiastical procedure and diplomacy, his intimate experience with the international problems, his affable spirit of conciliation united with his terrific courage, his oratory, his fluent speaking of seven languages and his understanding of others, his whole deportment and personality and career—all seemed to constitute him the inevitable choice. Nevertheless, his election was doubted.

On the first day of voting, March 2, Cardinal Pacelli was elected on the third ballot. Having accepted, he took the name of Pius, stating that he did so because of his affection and veneration for the tenth and eleventh of that name. He was solemnly crowned with the triple tiara on March 12, on the outer portico of St. Peter's overlooking the vast square that was crowded with approximately 200,000 spectators.

The choice of the cardinal electors was unanimously and enthusiastically endorsed by bishops, priests, religious, and lay Catholics throughout the world. Nations and Governments, likewise, joined officially in the jubilation. The election of Cardinal Pacelli meant undeviating adherence to the policies of Pius XI. Certain curiosities attached to it. He was the first Roman, as against Italian, elected pope since Innocent XIII (1721-1724). He was the first secretary of State to follow his predecessor since Clement IX (1667-1669). He was the first to assume his predecessor's name since Pius VII (1800-1823). He was the first publicly crowned in St. Peter's square since 1846. Outside of Leo XIII, who received a majority on the third scrutiny, he was chosen on fewer ballots than any other pope since the early Middle Ages.

In appearance, Pius XII is somewhat above the average height, thin both in an ascetic and athletic way, carrying himself with the bearing of a true aristocrat yet with no trace of arrogance, marked in his face and whole appearance as a man of sincerity and religious ideals, one who is instinctively respected and trusted and loved. No one, in this modern world, according to the universal judgement of men of all races and all nations, was better fitted to be raised to the lofty responsibility of the 262nd Supreme Pastor of the Universal Church and Vicar of Christ on earth.

As he assumed the pontificate, he pledged himself to adhere to the policy of Pius XI in the promotion of Catholic Action and in the spiritual regeneration of society, as well as in the promotion of peace between nations and in the condemnation of atheistic and pagan totalitarianism. It would not be wholly true to claim that his election was a victory for democracy. His position in modern-world affairs cannot be expressed in terms of political ideologies. It must be formulated solely in moral and spiritual concepts. His first address to the world, as pope, was a fervent appeal for peace. His second world-wide address on Easter Sunday, April 9, was a vigorous demand that nations and classes should practise the principle of peace.

The final history of his pontificate will, undoubtedly, be summed up in the legend adopted on his coat of arms as cardinal: *Opus justitiae pax*, Peace is the Work of Justice, and in the word from which his family name is derived, *pace*. (F. X. T.)

PIZARRO, FRANCISCO (c. 1471 or 1475-1541), discoverer and conqueror of Peru, was born at Trujillo in Estremadura, Spain, about 1471 (or 1475). He was an illegitimate son of Gonzalo Pizarro. Of Pizarro's early years hardly anything is known; but he appears to have been poorly cared for, and his education was neglected. Shortly after the news of the discovery of the New World had reached Spain he was in Seville, and thence

found his way across the Atlantic. There he is heard of in 1510 as having taken part in an expedition from Hispaniola to Urabá under Alonzo de Ojeda, by whom he was entrusted with the charge of the unfortunate settlement at San Sebastian. He accompanied Balboa (whom he afterwards helped to bring to the block) in the discovery of the Pacific.

In 1522 he entered into a partnership with a priest named Hernando de Luque, and a soldier named Diego de Almagro, for purposes of exploration and conquest towards the south. Explorations were then undertaken down the west coast of South America, in which Pizarro was left for months with but 13 followers on the island of Gallo, without ship or stores. There it was that Pizarro, displayed the courage which has made famous the story of himself and his companions. (Some authorities, among them Xeres, Pizarro's secretary, give the number of his companions as 16. Herrera states the names of 13; Garcilaso supplies the remaining three.) But Pizarro persisted till he had coasted as far as about 9° south and obtained distinct accounts of the Peruvian empire. The governor of Panama showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panama for Spain, accompanied by Pedro de Candia, in the spring of 1528, reaching Seville in early summer. Charles V. was won over. Pizarro was decorated with the order of Santiago, was granted a coat-of-arms and 13 of his heroic companions were ennobled by name.

On July 26, 1529, was executed at Toledo the famous *capitulación*, by which Pizarro was upon certain conditions made governor and captain general of the province of New Castile for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a viceroy, his associates being left in wholly secondary positions. One of the conditions of the grant was that within six months Pizarro should raise a sufficiently equipped force of men, of whom 100 might be drawn from the colonies; as he could not make up his due complement he sailed clandestinely from San Lucar in Jan. 1530. He was afterwards joined by his brother Hernando with the remaining vessels, and when the expedition left Panama in January of the following year it numbered three ships, 180 men and 27 horses. The subsequent movements of Pizarro belong to the history of Peru (*q.v.*). After the final effort of the Incas to recover Cuzco from 1536 to 1537 had been defeated by Diego de Almagro, a dispute occurred between him and Pizarro respecting the limits of their jurisdiction. This led to battle; Almagro was defeated (1538) and executed; but his supporters conspired, and assassinated Pizarro on June 26, 1541.

Prescott, *History of the Conquest of Peru* (1847); A. Helps, *Life of Pizarro* (1869); Justin Winsor, *Narrative and Critical History of America*, vol. ii. (1886).

PIZARRO, GONZALO (?1505-1548), explorer, half-brother of Francisco Pizarro, was born at Trujillo in 1505 or 1506. He accompanied the Peruvian expedition in 1531, and received for his services extensive grants in the Potosí mines. In 1539 he was made governor of Quito, and in 1541-42 he led an expedition east of Quito in the course of which Francisco de Orellan explored the Amazon. Two years later he defeated Vela, the new viceroy, and was declared governor of Peru, but in 1548 he was himself defeated by a Spanish force under Pedro de la Casco, was compelled to surrender and was executed on April 10, 1548.

PIZZICATO, a musical term indicating that a given passage for a stringed instrument is to be plucked by the fingers instead of played by the bow.

PLACARD, a bill or poster pasted or affixed to a wall or in any prominent position. (See **POSTER**.)

PLACE, FRANCIS (1771-1854), radical reformer, was born on Nov. 3, 1771, and later apprenticed to a leather-breeches maker. He suffered great hardships owing to the decline of this trade, and in 1793 organized an unsuccessful strike of London breeches-makers. He acted as secretary to other trade clubs and from 1794-97 was prominent in the London Corresponding

Society. He used his frequent enforced leisure for self-education, especially in political economy, and became a great admirer of Bentham. In 1799 he and a partner opened a tailoring shop in Charing Cross road, and the next year he went into business alone, rapidly becoming so successful that in one year he made £3,000. He was already known as a Radical politician when in 1814 he took up seriously a campaign to secure the repeal of the Combination Acts forbidding trade unions. For some years he met with little success, but in 1824, acting through Joseph Hume, M.P., he secured a parliamentary committee "on artisans and machinery" which reported in favour of the abolition of the acts. Bills to this effect were carried, amid general indifference; the premier, indeed, afterwards assured the House of Commons that he had no idea of the contents of the bills when he recommended them. The immediate effect of the repeal was a sudden increase in the number and activity of trade unions, and next year the Government attempted to restore the prohibition. The public excitement and the interest of the working-men were such that after a parliamentary struggle of an unusual stiffness, Place secured the passing of an act which scarcely altered the position.

His skilled political organization made the Westminster elections from 1807-32 events of national importance in the struggle for parliamentary reform. In 1831 and 1832 he greatly assisted behind the scenes in the preparations for military revolt should the Lords remain obstinate. Together with Joseph Parkes of Birmingham he framed the placard "TO STOP THE DUKE, GO FOR GOLD" which produced the run on the banks that drove Wellington from office and carried the Reform bill without violence. He also disorganized the "Rotundanist" reformers, who wished the extension of the franchise to the working class, by the organization of a "tame" working class union at the height of the struggle. He died at the age of 83, having been for many years out of politics.

See Graham Wallas, *Francis Place* (1918). Place's mss. and guard-books, an incomparable source of political information from 1790 to 1850, are in the British Museum. (R. W. P.)

PLACE-NAMES. Ancient historians often speculated upon the meaning of place-names, inventing persons who are presumed to have been the first founders of the country and to have left their mark on its nomenclature. But it is only within the last half-century that attempts have been made to lay the foundations of a science of place-names. Förstemann in Germany, Rygh in Norway, Noreen in Sweden, Skeat in England, Longnon in France, are perhaps the best-known pioneers in this work. The main foundations upon which they built were the recognition (1) that no place-name can be interpreted in the light of its present-day form alone, but must be traced back to its earliest recorded form, (2) that no explanation of a place-name, however convincing as philology, can hold good if inconsistent with the known history and topography of the site, and, conversely that no explanation based upon legend or topography, is of value if inconsistent with philology.

Processes of Change.—The ordinary word is to some extent controlled by the written or printed book. But the transmission of most place names is still very largely oral, and as the name is merely a name, and rarely has any significance in itself, at least to its modern user, there is little or nothing to check the process of change. The natural result is that the modern form of the name is often misleading. *Cenwulfesleah* has become Knowsley, *Tidwulfestreo* has become Elstree; and Cholmondeley, *Cirences-ter*, *Auchinleck*, and *Wymondham*, while in spelling they retain something like their original form, in pronunciation have been reduced to *Chumley*, *Sissiter*, *Afleck* and *Wyndham*. (It should be noted that the spread of the printed word and universal primary education are now tending to reverse the process and to substitute spelling-pronunciations for the genuine local ones.) The lack of stress upon the final element together with certain common sound-assimilations have obscured the history of many names. Thus Embleton really should end in don, "hill," Hallington is really "holy dene" (the site of the battle of "Heavenfield"), Warden-on-Tyne is a "watch don" or "hill" at the junction of north and south Tyne. So, also, nearly all the place-names in *-hall*, such as *Willen-*

hall, really end in *hale*, "nook" or "corner of land." The proximity of some similar sounding name may lead to its ultimate substitution as when *Combe-in-Teignhead* replaces *Combe-in-Tenhide* because the place stands on a headland at the mouth of the *Teign*.

Folk-Etymology. — When we come across a name which in itself conveys no meaning we are apt to turn it into something which conveys some sort of meaning, however inapposite. Thus all the places once called *Fivehide* have now become *Fivelzead* or *Fyfield*, since we are no longer aware what a "hide" of land is. *Highenovre* (lit. "high bank") becomes *High and Over*. Folk-etymology has led to the formation of a series of "ghost" place-names, commonly spoken of as "back-formations." *Cambridge* is assumed to be the "bridge over the Cam" and the river is henceforward so called, though in reality *Cambridge* is an Anglo-Norman corruption of an earlier *Grantabrycg* and the correct name of the river is *Granta*. This process is specially common with river-names. The Sussex *Arun* and *Rother* are back-formations from *Arundel* and *Rotherfield*, while the *Adur* is a back-formation from the false identification of *Portus Adurni* with Shoreham. The old names for the rivers, in this case *Tarrant*, *Limen*, *Bramber*, were early lost and new names had to be found.

Early forms of certain names may be recorded by early geographers, historians or chroniclers but for most we have to turn elsewhere, to national surveys such as *Domesday Book* or the Danish Landbook of King Valdemar, to ancient charters, which often give not only the name of the land granted but also the names of the land-marks on its boundaries, royal and episcopal documents of every kind and, in later days, surveys, extents, terriers, maps. Here fresh difficulties arise. We find a large number of faulty and fantastic spellings, as when *Knighton* (O.E. *cnihataun*) commonly appears in *Domesday* as *Chenistestone*, or *Gilling* (O.E. *Gillingas*) is disguised as *Gwyllingues*. Such forms, if they appeared repeatedly in official documents, might actually be recognized as the correct names even locally. Thus the *Ciren-* of *Cirencester* is the Norman-French spelling for the native English *Churn*, the river on which that town stands, and *Durham* is the result of the Norman's attempt to pronounce *Dunholm*, in which the sound-combinations *nh* and *lm* proved too difficult for him.

Interpretation. — In the interpretation of early forms, we have, first, words descriptive of the actual topography and secondly personal names belonging to those who have been owners or occupiers of the site. Most of the descriptive words can readily be recognized but a goodly number furnish difficulties. Our knowledge of the vocabulary of our forefathers is derived chiefly from works of religious or homiletic character and there are extensive gaps in our knowledge of their secular vocabulary, especially in its earliest stages. These lost words may be found in place-names. Thus in *Herne* (Beds) and *Harome* (Yorks) we have an otherwise unknown O.E. *har*, "a stony place, heap, hill," found in various cognate languages. So also a word in common use in early days may have passed completely out of use in our language and still survive in place-names. O.E. *hearg*, "heathen grove" only survives in such place-names as *Harrow*, *Harrowden* and *Arrow Hill*. And similar difficulties arise with regard to the personal names found in place-names. Often when a personal name has been assumed the very name itself turns up later in some newly discovered document. Thus a personal name *Blücc* with a diminutive *Blüccel* was assumed to explain *Blüccing* and then later the name was found in a 12th century cartulary.

In, most countries we have to deal not with one people or language alone but with successive settlements by peoples using different languages. If the new race is only a powerful minority, as for example the Normans in England or the English in Ireland, its influence on place-names may be very small. In the case of the Romans in Celtic Britain it was almost negligible. If the invasion or settlement was a mass one, there may be very extensive renaming of the places, as was the case with the English in most parts of England, the Vikings in certain parts of the Danelaw and in Normandy, and the Celtic refugees who settled in Brittany. In England the dominant race and speech since the beginning of the 6th century has been English and, ex-

cept in Cornwall, Monmouthshire and Herefordshire, the nomenclature of the counties of England is predominantly English or Scandinavian. The only exception to this general statement is to be found in a good number of the names of natural features, such as rivers and mountains. Here, and in other countries also, the old names were usually kept. The rivers ran through wide tracts of country and were not the property of any single settler, while the mountains had no attractions for settlers in search of good pasture or arable land. Thus it is that *Wear*, *Tyne*, *Avon*, *Cheviot*, *Eildon*, *Malvern*, *Mendip*, are Celtic names, though English ones are not entirely wanting, as, for example, *Blyth*, *Loud*, *Clent*. Many river and hill-names cannot be explained even upon a Celtic basis and may have been taken over by the Celts from still earlier peoples. We must also note that some names which now look convincingly English may really be folk-etymological perversions of earlier Celtic names. The Celtic name has in a few cases survived to prove it, as in the case of O.E. in *Eoforwic*, *Searoburh* our *York* and *Salisbury*, which mean in Old English "board-dwelling" and "trickery-fort" respectively but are really anglicisings of the old Romano-Celtic names *Eburacum* and *Sorbiodunum*. How many similar cases there may be in which the evidence for it has not chanced to survive it is impossible to say.

The Romans seldom renamed the British towns, and beyond one or two somewhat doubtful examples, such as *Speen* and *Chester* (earlier *Lega-ceaster*) and *Lincoln* from the Latin *spinae*, (*urbs*) *legionis* and *Lindum colonia*, they left little to be handed on to the English. The latter had picked up a certain number of Latin words both in their old Continental homes and in England through the channels of war and trade and Christianity, such as *castra*, (*via*) *strata*, *monasterium*. These became *ceaster*, *Strat* and *mynster* in their own language and have given rise to groups of names in *-chester*, *-cester*, *-caster*, in *Street-*, *Stret-*, *Strat-*, *Streat-* and in *-minster*. The first of these elements is very commonly found in the names of the old Romano-British fortified towns, but it should be noted that the first element in such names (e.g., *Gloucester*, *Cirencester*, *Wroxeter*, *Exeter*) is Celtic and not Roman, the old names being *Glevum*, *Corinium*, *Uriconium* and *Isca*.

The English Conquest involved widespread renaming of the countryside. The comparative frequency of place-names in *-ing* and *-ingham* in the eastern and south-eastern counties and their comparative rarity elsewhere suggests the importance of the great leader and his followers in the early stages of the invasion, for in O.E. the suffix *ing(as)* was added to a personal name to denote that man and his family, followers, etc. Thus *Basing* denotes the "followers of Basa" and *Whittingham* is the "home of the followers of Hwita." The elements *ham* and *stede*, "site," "place," later *ste(a)d*, were freely used in the early days of the invasion. The suffix *ton*, from O.E. *tun* "enclosure" becomes relatively much more frequent as we travel westwards to the districts latest conquered and this suffix remained a living one till long after the Norman Conquest. *Worth*, *worthy* and *wardine* all denote small enclosures but the first soon ceased to be a living suffix. *Port* was used for a town (a loan-word from Lat. *porta*), and *burh* (dat. sing. *byrig*) is the source of many names in *bury* and a few in *borough*, *burgh*. It denotes a fortified place, of whatever age, and has none of the constitutional associations of the common word *borough*. Large areas of land were still covered with forest; as these were brought under cultivation names in *-ley* and *-field* arose, from the O.E. words *leah*, "clearing in woodland," and *feld*, "open country." Land dedicated to the service of religion was often called *stow*, hence *Halstow*, "holy place," *Bridstow*, "St. Bride's land," corresponding to the Welsh *Llan san Bregit*. Many other elements of a purely topographical character are found in place-names. Here and in other countries we find early peoples very sensitive to slight differences of terrain and a place might be called a *cliff*, e.g., *Egglescliffe*, or *hangra* (i.e., "hanging wood," as in *Shelfanger*), where we should only note a slight slope. The personal names found in these place-names, especially in eastern and south-eastern England, are often of an exceedingly archaic type, suggesting that soon after the settlement there were rapid changes in the nomenclature among our forefathers.

The Scandinavian settlement of certain districts of England

affected the place-nomenclature as deeply as the earlier English settlements, but its intensity varied a good deal from area to area and as the speech of the Vikings was closely allied it is not always easy to differentiate native and Scandinavian names. Changes were brought about in various ways. The commonest was entirely to re-name the place, as when O.E. *Nor-worig* became *Derby*. There was also a good deal of Scandinavianizing of names, as when O.E. *Eofor-wic* became *Jor-vik* (and so *Yorick* and *York*) or places which had once ended in *-bury* were given the Scandinavian suffix *-by*, so that in the middle of the 10th century *Badby* (Northants.) is called indifferently *Baddanby* and *Baddanburh*. How deep the influence of Scandinavian speech went is shown by more than one place-name which retains Scandinavian inflexional forms (e.g., *Beckermeth*, "meeting of the stream," which contains the gen. sing. *bekkjar* of O.Norse *bekkr*, and still more by a name like *Osmotherley* in which the English personal name *Osmund* was given a Scandinavian gen. sing. in *ar* even before an English second element). In some counties, where raids were extensive but where there was no organized dividing up of the land among the new settlers (e.g., Northumberland and a good part of Durham), the number of Scandinavian names is small but in others (e.g., the North and East Ridings of Yorkshire and in Lindsey), where the land was parcelled out among the Danes, we have a dominantly Scandinavian nomenclature. Danes for the most part settled in eastern England, Norsemen in north-western England. That there were some colonies of Norsemen amid a prevailing Danish population is shown by the *Normanbys* and *Normantons* in the east and the Midlands, all settlements of Norsemen and not of Normans. In the North Riding there were enough Norsemen for certain villages to have to be distinguished as *Danby*, "villages of the Danes." Where the English were almost entirely ousted we have a few *Znglebys*, isolated villages of the English surviving, while the *Denbys* and *Denaby* of Derbyshire and the West Riding suggest Danish settlements amid a prevalent English population. Those Vikings, chiefly Norsemen, who had previously been raiding in Ireland were commonly known as the "Irishmen" and gave their name to certain *Irbys*, *Zrebys* and *Iretons*. When they had been to Wales they were nicknamed *Brettar* and so we get *Bretby* and two or three *Birkbys*, which were earlier *Brettaby*. The commonest suffixes denoting various kinds of settlement are as follows: *by*, denoting variously farm, hamlet and village, *thorpe*, "a village," especially an "offshoot from a larger one" (carefully to be distinguished from the native *thorp*, *throp*, often found in the South Midlands, as in *Eythrope*, *Thrupp*, *Sedrup*, *Colstrophe*), *thwaite*, "clearing," "paddock," *toft*, "piece of ground," "message," "homestead." To the Vikings also we owe the *ridings* of Yorkshire and Lincolnshire, from O.Norse *thrithungr*, "third part" and the *wapentakes* of Scandinavian England generally, from O. Norse *vapna-tak*, "taking of weapons." They had their own topographical terms, some of the commonest being found in the suffixes *scoe*, *skew* "wood," *with*, "wood," *force*, "waterfall," *fell*, "mountain," Norse *breck* and Danish *brink* "slope," *wath*, "ford," Norse *slack*, "shallow valley." Personal names are very common as first elements in their place-names while in a few we have post-position of the personal name (e.g., *Aspatria*, lit. ash-Patrick), showing that the Norsemen when in Ireland must have learned the old Gaelic method of putting the personal name after the significant element. This name and others, such as *Commondale*, earlier *Colmandale*, containing the O.Ir. name *Colman* show how common Gaelic names were among these Vikings who had intermarried with the Celts. In gauging Scandinavian influence on the basis of place-names it should be borne in mind that many Scandinavian words (e.g., *biggin*, *fell*) soon became part of the English speech and that certain Scandinavian names such as *Harold* soon came to be borne by persons of English descent, so that the presence of such elements in place-names is no certain proof of their Scandinavian origin.

The main sphere of Norman-French influence on place-names has already been indicated, viz., its importance in changing the spelling and pronunciation of many of the older names. Such influence was specially common in the neighbourhood of the great castles and monasteries. They themselves often bore French, or

at least Gallicised names, such as *Richmond*, *Devizes*, *Belvoir*, *Rievaulx*, *Jervaulx*. The traditional pronunciations of these names are Anglo-French in character and thus it is that we have *Bewley* for *Beaulieu*, *Beaver* for *Belvoir*, *Rivers* for *Rievaulx*, and *Beaumont* commonly pronounced as *Beaumont* or *Bewmont*. Knowledge of modern French is gradually ousting these in favour of pseudo-educated ones. Norman-French feudalism led to the distinguishing of one manor from another by the suffixing (or occasional prefixing) of the name of its feudal holder, whence such names as *Stanstead Mountfitchet*, *Buckland Sororum* (i.e., of the nuns), *Bishop's Tawton*.

The more one studies the history of place-names the more one finds what a large proportion of them are really early in their origin. There are however two types which are definitely late. The type whereby a place came to be called *Poynatts*, *Chequers*, and the like, from the family names, *Poynatt*, *Chequer*, dates from the 14th century onwards. Place-names formed from phrases, often of a humorous character, such as *Glororum* (glower o'er 'em), *Make 'em Rich*, *Bo-peep* come even later, belonging as a rule to the 17th century or later.

BIBLIOGRAPHY—England: The English Place-name Society, with the help of the British Academy, is carrying through a survey of English place-names and has published volumes on Bucks., Beds., Hunts, Worcs., the North Riding of Yorks. and Sussex, together with an Introductory volume and one on the *Chief Elements* (1924-. In progress). Skeat has volumes on Cambs., Beds., Hunts., Herts., Suffolk, Berks. (1901-13), Moorman on the West Riding (1910), Stenton on Berks. (1911), Duignan on Staffs., Worcs., Warw. (1905-12), Baddeley on Gloucs., Bannister on Heref. (1913), Goodall on S.W. Yorks., Walker on Derbys. (1914), Alexander on Oxon. (1912), Ekblom on Wilts. (1917), Sedgefield on Cumberland and Westmorland (1911), Mawer on Northumberland and Durham (1920), Ekwall on Lancs., Gover on Middlesex (1922). Monographs on particular subjects are Ekwall on *Place-names in -ing* (1923) and on *River-namer of England* (1928), Lindkvist on *Middle English Place-names of Scandinavian Origin* (1912), Zachrisson, *Anglo-Norman Influence on English Place-names* (1909). Wales: No systematic work but Johnston, *Place-names of England and Wales* (1914) includes a good many. Scotland: Johnston, *Place-names of Scotland* (1903), and Watson, *The Celtic Place-names of Scotland* (1927). Ireland: Joyce, *Origin and History of Irish names of places* (1875-1901). Isle of Man: Kneen, *Place-names of the Isle of Man* (1926-28).

France: Longnon, *Les noms de lieu de la France* (1920-23), incomplete.

Germany: Forstemann-Jellinghaus, *Altdeutsches Namenbuch, Ortsnamen* (1913-16), including many Teutonic place-names from other Continental countries.

Norway: *Norske Gaardnavne* (1897-1919), *Norske Elvenavne* (1904), *Indledning* (1898) by Rygh, Olsen and others. Sweden: *Sverges Ortnamn* (1909-. In progress), *Ortnamen i Goteborgs och Bohus Lan* (1923-. In progress), Lindroth, *Våra ortnamn* (1923). Denmark: *Danmarks Stednavne* (1922-. In progress), Steenstrup, *Indledende Studier* (1909), *De Danske Stednavne* (1919).

Holland: *Nomina Geographica Neerlandica* (1892-1901). Flanders: *Woordenboek der Toponymie* (1914-. In progress), Mansion, *Oud-Gentsche Naamkunde* (1924).

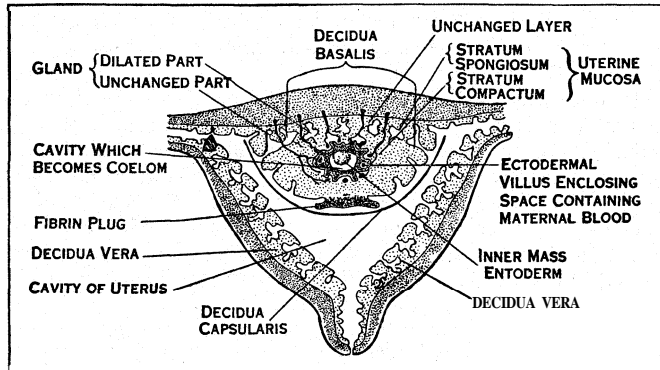

The periodicals *Namn och Bygd* (1913-) and *Zeitschrift für Ortsnamenforschung* (1926-) cover the chief European countries.

(A. M.)

PLACENTA, the organ by which the embryo is nourished within the womb of its mother. When the young one is born the placenta and membranes come away as the "afterbirth." The human placenta is a circular disk about 7 or 8 in. in diameter and $1\frac{1}{4}$ in. in thickness at its centre, while at its margin it is very thin and is continuous with the foetal membranes. It weighs about a pound.

Mode of Formation.—Before each menstrual period, during the child-bearing age of a woman, the mucous membrane of the uterus hypertrophies, and, at the period, is cast off, but if a fertilized ovum reaches the uterus the casting off is postponed until the birth of the child. From the fact that the thickened mucous membrane lining the interior of the uterus is cast off sooner or later, it is spoken of as the "decidua." The fertilized ovum, on reaching the uterus, embeds itself in the already prepared decidua, and, as it enlarges, there is one part of the decidua lying between it and the uterine wall ("decidua serotina" or "basalis"), one part stretched over the surface of the enlarging ovum ("decidua reflexa" or "capsularis") and one part lining the rest of the uterus ("decidua vera") (see fig. 1). It is the decidua

basalis which is specially concerned in formation of the placenta. That part which is nearest the ovum is called the "stratum compactum," but farther away the uterine glands dilate and give a spongy appearance to the mucous membrane (stratum spongiosum). Processes from the surface of the ovum penetrate the stratum compactum and push their way into the enlarged maternal blood sinuses; these are the "chorionic villi." Later,

FROM A. H. YOUNG AND A. ROBINSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 1.—DIAGRAM REPRESENTING A VERY YOUNG HUMAN OVUM ALMOST IMMEDIATELY AFTER ITS ENTRANCE INTO THE DECIDUA. THE PLACE OF ENTRANCE STILL BEING COVERED WITH A PLUG OF FIBRIN

the "allantoic" or "abdominal stalk" grows from the mesoderm of the hind end of the embryo into the chorionic villi which enter the decidua basalis, and in this blood-vessels push their way into the maternal blood sinuses. Eventually the original walls of these sinuses and the false amnion, disappear, and nothing separates the maternal from the foetal blood except the delicate walls of the foetal vessels covered by undifferentiated, nucleated tissue (*syncytium*), derived from the chorionic epithelium, so that the embryo is able to take its supply of oxygen and materials for growth from the blood of its mother and to give up carbonic acid and excretory matters. It is the gradual enlargement of the chorionic villi in the decidua basalis together with the intervillous maternal blood sinuses that forms the placenta; the decidua capsularis and vera become pressed together as the embryo enlarges, and atrophy. The allantoic stalk elongates enormously, and in its later stages contains two arteries (umbilical) and one vein embedded in loose connective tissue known as "Wharton's jelly." At first the stalk of the yolk-sac is quite distinct from this, but later the two structures become bound together (*see fig. 2*), as the "umbilical cord." A distinction must be made between the allantoic stalk and the allantois; the latter is an entodermal outgrowth from the hind end of the mesodaeum or primitive alimentary canal, which in the human subject only reaches a little way toward the placenta. The allantoic stalk is the mass of mesoderm containing blood-vessels which is pushed in front of the allantois and, as has been shown, reaches and blends with the decidua basalis to form the placenta.

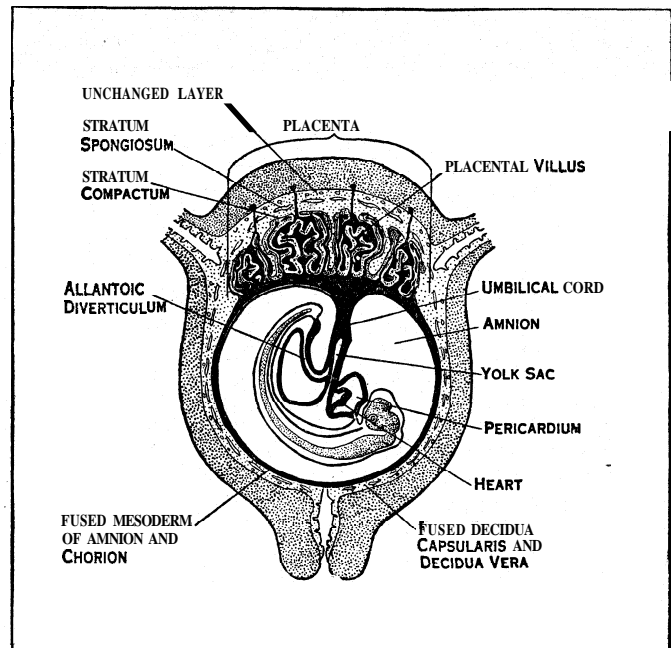

For further details *see* Quain's *Anatomy*, vol. i. (London, 1908); and, for literature, O. Hertwig's *Handbuch der Entwicklungslehre* (Jena).

Comparative Anatomy.—If the placenta is to be regarded as a close union between the vascular system of the parent and embryo, the condition may be found scattered throughout the phylum of the Chordata. In so lowly a member as *Salpa*, a placenta is formed, and the embryo is nourished within the body of its parent. In some of the viviparous sharks, *e.g.*, the blue shark (*Cacharias*), the yolk-sac has ridges which fit into grooves in the wall of the oviduct and allow interchange between maternal and foetal blood. This is an example of an "umbilical placenta." In the viviparous blennies (*Zoarces viviparus*), among the teleostean fishes, 200 or 300 young are nourished in the hollow ovary, which develops villi secreting nutritive material.

The mammals are divided into Placentalia and Aplacentalia; in the latter group, to which the monotremes and most marsupials belong, the ova have a great deal of yolk, and the young, born in

a very immature condition, finish their development in their mother's pouch; but although these mammals have no allantoic placenta there is an intimate connection between the walls of the yolk-sac and the uterine mucous membrane, and so an umbilical placenta exists. The name Aplacentalia therefore only means that they have no allantoic placenta. Among the Placentalia the umbilical and allantoic placentae sometimes coexist for some time, as in the hedgehog, bandicoot and mouse.

In the Carnivora, elephant, procavia (Hyrax) and aard vark (*Orycteropus*), there is a "zonary-placenta" which forms a girde round the embryo. In sloths and lemurs the placenta is dome-shaped, while in rodents, insectivores and bats, it is a ventral disk or closely applied pair of disks, thus differing from the dorsal disk of the ant-eater, armadillo and higher Primates, which is known as a "metadiscal placenta." Thus the form of the placenta is not an altogether trustworthy indication of the systemic position of its owner. In the diffuse and cotyledonous placentae the villi do not penetrate very deeply into the decidua, and at

FIG. 2.—DIAGRAM OF THE LATER STAGE IN THE DEVELOPMENT OF THE PLACENTA. SHOWING THE RELATIONS OF THE FOETAL VILLI TO THE PLACENTAL SINUSES, FUSION OF THE AMNION WITH THE INNER SURFACE OF THE CHORION, AND THE THINNING OF THE FUSED DECIDUAE

birth are simply withdrawn, the decidua being left behind in the uterus, so that these placentae are spoken of as non-deciduate while other kinds are deciduate.

PLACERS, the common name given to the alluvial deposits in which gold frequently occurs. They consist of sand and gravel deposited by existing or former streams of water carrying de-

tritus of gold-bearing rocks. Other metals, e.g., tin, are similarly deposited. The gold of the placers consists of grains called "gold-dust" and larger pieces, rounded by attrition, called "nuggets." The placer of an ancient stream may be deep-lying because covered since its formation with other deposits or even lava. (See GOLD: *Mining and Metallurgy*.)

PLAGIARISM, an appropriation or copying from the work of another, in literature or art, and the passing off of the same as original. The Lat. *plagiarius* meant a kidnapper, stealer or abductor of a slave or child, though it is also used in the modern sense by Martial (I. 53, 9). (See COPYRIGHT.)

PLAGIOCLASE, an important group of rock-forming minerals constituting an isomorphous series between albite feldspar and anorthite feldspar. The intermediate members are soda-lime feldspar which in their crystallographical, optical and other physical properties vary progressively between the two extremes, albite (Ab) $\text{NaAlSi}_3\text{O}_8$, and anorthite (An) $\text{CaAl}_2\text{Si}_2\text{O}_8$. The name plagioclase is derived from the Gr. *πλάγιος*, "oblique," and *κλάν*, "to break," in allusion to the oblique angle between the cleavages. Names are applied to members of the plagioclase group falling between certain arbitrary composition limits, those now commonly adopted being albite ($\text{Ab}_{100}\text{-Ab}_{90}$), oligoclase ($\text{Ab}_{90}\text{-Ab}_{80}$), andesine ($\text{Ab}_{70}\text{-Ab}_{50}$), labradorite ($\text{Ab}_{50}\text{-Ab}_{30}$), bytownite ($\text{Ab}_{30}\text{-Ab}_{10}$), anorthite ($\text{Ab}_{10}\text{-An}_{100}$). The pure end members are practically unknown in nature. All the plagioclases crystallize in the triclinic system, and as members of an isomorphous series show closely similar crystallographic constants. They possess a perfect cleavage parallel to the basal pinacoid (001) and a less pronounced cleavage parallel to the pinacoid (010), the angle between the two cleavages varying progressively from $86^\circ 24'$ in albite to $85^\circ 50'$ in anorthite. The molecular volumes are closely similar ($\text{Ab } 100.1$) ($\text{An } 101.5$). The habit of well-formed crystals is usually tabular on the plane 010, sometimes flattened parallel to 001 or, as in microlitic plagioclases of volcanic rocks, elongated in the direction of the edge 001:010. Twinning is a very important character of the plagioclases, being almost invariably present and affording a ready means of distinguishing them from other feldspars. The chief twin laws are the Carlsbad, albite and pericline; the latter two, being commonly polysynthetic, give rise to numerous thin lamellae, which are the cause of the fine striations seen on cleavage planes, and of the banded character visible in thin sections of the minerals examined in polarized light.

With the exception of the sodic end member (albite), which, owing to the high viscosity of its melts, is with difficulty crystallized, the plagioclases are readily prepared from dry melts of the component oxides. They show a continuous melting curve, the intermediate members exhibiting a melting interval. The temperatures of beginning of melting (solidus) have been determined in the laboratory for compositions ranging from pure An to Ab_3An_1 , and of completion of melting (liquidus) for a range An to Ab_8An_1 . These data are shown below.

Composition	Temperature of beginning of melting (solidus)	Temperature of completion of melting (liquidus)
Albite ($\text{Ab}_{98}\text{An}_2$)	1,100°C	—
Oligoclase (Ab_8An_1)	1,175°C	1,362°C
Andesine (Ab_2An_1)	1,205°C	1,394°C
Andesine-Labradorite (Ab_1An_1)	1,287°C	1,450°C
Labradorite (Ab_1An_2)	1,372°C	1,490°C
Bytownite (Ab_1An_3)	1,465°C	1,521°C
Anorthite (An_{100})	1,550°C	1,550°C

The density and mean refractive index of the plagioclase feldspars vary progressively, the extremes being albite, $D = 2.605, \mu = 1.530$; anorthite. $D = 2.765, \mu = 1.587$.

Since the plagioclases are of great importance in petrology much detailed study of their optical properties has been undertaken, so that it is now possible to determine by simple examination of thin slices of these minerals the exact chemical composition and crystallographic orientation of the selected section. For this purpose, the chief determinations are the refractive indices, and the optical extinctions of oriented sections, principally on

cleavage flakes (001 and 010), sections cut perpendicular to the optic axes and bisectrices, and especially those perpendicular to the plane of albite twinning (010) in multiple-twinned crystals. Other optical determinations are available for discriminating the various members of the group.

BIBLIOGRAPHY.—For a detailed summary of the optical characters, and their employment in the recognition of the quantitative composition of the feldspars, the following should be consulted: H. Rosenbusch, *Mikroskopische Physiographie der Mineralien und Gesteine* (Band i., Zweite Hälfte, 5 Auflage, revised by O. Mügge, 1927); L. Duparc and M. Reinhard, "La Détermination des Plagioclases" (Mem. Soc. Phys. Hist. Nat. Genève, xl., 1924, fasc. 1.); A. N. Winchell, *Elements of Optical Mineralogy* (pt. 2, 1927, pp. 277-341). For a recent preliminary X-ray study of the plagioclase feldspars, reference may also be made to E. Schiebold, *Fortschritte der Mineralogie, Kristallographie und Petrographie* (Band xii., 1927, pp. 78-82). A more detailed account of the occurrence of the various members is given under ALBITE, OLIGOCLASE, ANDESINE, LABRADORITE, BYTOWNITE, ANORTHITE. See also FELDSPAR. (C. E. T.)

PLAGUE, in medicine, a term formerly given to any epidemic disease causing a great mortality, but now confined to a specific infectious fever caused by *B. pestis*.

History to 1880.—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the Collections of *Oribasius*¹. Rufus speaks of the buboes called pestilential as being specially fatal and as being found chiefly in Libya, Egypt and Syria. This passage shows the antiquity of the plague in northern Africa, which for centuries was considered as its home. It is not till the 6th century of our era, that we find bubonic plague in Europe, as a part of the great cycle of pestilence, which lasted fifty years, and spread over the whole Roman world, beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were the plague cannot now be said; but it is possible the pestilences in England chronicled by Bede in the years 664, 672, 679 and 683 may have been of this disease, especially as in 690 *pestis inguinalis* is again recorded in Rome.

In the great cycle of epidemics in the 14th century known as the Black Death, some at least were bubonic plague. The mortality of the black death was, as is well known, enormous. It is estimated in various parts of Europe at two-thirds or three-fourths of the population in the first pestilence, in England even higher; but some countries were much less severely affected. Hecker calculates that one-fourth of the population of Europe, or 25 millions of persons, died in the whole of the epidemics.

The Great Plague of London.—The great plague of 1664-1665 must not be regarded as an isolated phenomenon. Plague had recurred frequently in all parts of Europe in the 13th, 16th and 17th centuries. Nevertheless in London the preceding years had been unusually free from plague, and it was not mentioned in the bills of mortality till in the autumn of 1664 (Nov. 2) a few isolated cases were observed in Westminster and a few occurred in the following winter, which was very severe. About May 1665 the disease again became noticeable and spread, but somewhat slowly. Boghurst, a contemporary doctor, notices that it crept down Holborn and took six months to travel from the western suburbs to the eastern through the city. The mortality rapidly rose from 43 in May to 590 in June, 6,137 in July, 17,036 in August, 31,159 in September, after which it began to decline. The total number of deaths from plague in that year, according to the bills of mortality, was 68,596, in a population estimated at 460,000, out of whom two-thirds are supposed to have fled to escape the contagion. This number is likely to be underestimated, since of the 6,432 recorded deaths from spotted fever many were probably really from plague, though not declared so to avoid painful restrictions. In December there was a sudden fall in the mortality which continued through the winter; but in 1666 nearly 2,000 deaths are recorded.

According to some authorities, the plague was imported into London by bales of merchandise from Holland, which came originally from the Levant; according to others it was introduced

¹ Lib. xlv. cap. 17—Oeuvres de Oribase, ed. Bussemaker and Daremberg (Paris, 1851), iii. 607.

by Dutch prisoners of war. From London the disease spread widely over England.

After 1666 there was no epidemic of plague in London or any part of England, though sporadic cases appear in bills of mortality up to 1679; and a column filled up with "o" was left till 1703, when it finally disappeared. The disappearance of plague in London was attributed to the Great Fire, but no such cause existed in other cities. It has also been ascribed to quarantine, but no effective quarantine was established till 1720, so that the cessation of plague in England must be regarded as spontaneous.

But this was no isolated fact. A similar cessation of plague was noted soon after in the greater part of western Europe. In 1666 a severe plague raged in Cologne and on the Rhine, which was prolonged till 1670 in the district. In the Netherlands there was plague in 1667-1669, but there are no definite notices of it after 1672. France saw the last plague epidemic in 1668, till it reappeared in 1720. In the years 1675-1684 a new plague epidemic appeared in North Africa, Turkey, Poland, Hungary, Austria and Germany, progressing generally northward. Malta lost 11,000 persons in 1675. The plague of Vienna in 1679 was very severe, causing 76,000 or probably more deaths. Prague in 1681 lost 83,000 by plague. Dresden was affected in 1680, Magdeburg and Halle in 1682—in the latter town with a mortality of 4,397 out of a population of about 10,000. Many North German cities suffered about the same time; but in 1683 the plague disappeared from Germany till the epidemic of 1707. In Spain it ceased about 1681; in Italy certain cities were attacked till the end of the century, but not later (Hirsch).

The plague-epidemics in Egypt between 1833 and 1845 are very important in the history of plague, since the disease was almost for the first time scientifically studied in its home by skilled European physicians, chiefly French. The disease was found to be less contagious than reported to be by popular tradition, and most of the French school went so far as to deny the contagiousness of the disease altogether.

An outbreak of plague in 1878-1879 on the banks of the Volga caused a panic throughout Europe and most European governments sent special commissions to the spot. The British commissioners were Surgeon-Major Colvill and Dr. J. F. Payne, who, like all the foreign commissioners, arrived when the epidemic was over. In the opinion of Dr. Payne the real beginning of the disease was in the year 1877, in the vicinity of Astrakhan, and the sudden development of the malignant out of a mild form of the disease was no more than had been observed in other places.

Plague in India.—It used to be held as a maxim that plague never appeared east of the Indus; nevertheless it was observed during the 19th century in more than one distinct centre in India. So long ago as 1815 the disease appeared in Guzerat, Kattywar and Cutch, "after three years of severe famine." It reappeared early next year, in the same locality, when it extended to Sind as far as Hyderabad, and in another direction south-east as far as Ahmedabad and Dhollerah. But it disappeared from these parts in 1820 or early in 1821, and was not heard of again till July 1836, when a disease broke out into violence at the town of Pali in Marwar in Rajputana. It spread from Pali to the province of Meywar, but died out spontaneously in the hot season of 1837.

In 1823 (though not officially known till later) an epidemic broke out at Kedarnath in Garhwal, a sub-district of Kumaon on the south-west of the Himalayas, on a high situation. In 1834 and 1836 other epidemics occurred, which at last attracted the attention of the government. In 1849-1850, and again in 1852, the disease raged very severely and spread southward. In 1853 Dr. Francis and Dr. Pearson were appointed a commission to inquire into the malady. In 1876-1877 another outbreak occurred. The symptoms of this disease, called *maha murree* or *mahamari* by the natives, were precisely those of oriental plague. The feature of blood-spitting, to which much importance had been attached, appeared to be not a common one. A very remarkable circumstance was the death of animals (rats, and more rarely snakes) at the outbreak of an epidemic. The rats brought up blood, and the body of one examined after death by Dr. Francis showed an affection of the lungs.

History Since 1880.—In 1880 plague existed or had existed within ten years, in the following parts of the world: (1) Beng-hazi, Africa; (2) Persian Kurdistan; (3) Irak, on the Tigris and Euphrates; (4) the Asir country, western Arabia; (5) on the lower Volga, Russia; (6) northern Persia and the shores of the Caspian; (7) Kumaon and Garhwal, India; (8) Yunnan and Pakhoi, China.

The most striking feature of the early history of plague is the gradual retrocession of plague from the west, after a series of exceedingly destructive outbreaks extending over several centuries, and its disappearance from Europe. Western countries were the first to be freed from its presence, namely, England, Portugal and Spain. From all these it finally disappeared about 1680, at the close of a period of pandemic prevalence. Northern and central Europe became free about 1714, and the south of France in 1722. The last outbreak in northern Russia occurred in 1770. After this plague only appeared in the south-east of Europe, where in turn it gradually died away during the first half of the 19th century. In 1841 its long reign on this continent came to an end with an isolated outbreak in Turkey. From that time until quite recently it remained extinct, except in the East. The province of Astrakhan, where a very small and limited outbreak occurred in 1878, is politically in Europe, but geographically it belongs rather to Asia. And even in the East plague was confined to more or less clearly localized epidemics; it showed no power of pandemic diffusion. In short, if we regard the history of this disease as a whole, it appears to have lost such power from the time of the Great Plague of London in 1665, which was part of a pandemic wave, until the present day. There was not merely a gradual withdrawal eastwards lasting nearly two hundred years, but the outbreaks which occurred during that period, violent as some of them were, showed a constantly diminishing power of diffusion and an increasing tendency to localization. The sudden reversal of that long process is therefore a very remarkable occurrence. Emerging from the remote endemic centres to which it had retreated, plague has once more taken its place among the zymotic diseases with which modern science has to reckon.

Diffusion.—Visitations of cholera can be traced definitely to a point of origin often in India. (See CHOLERA.) Similarly, though not with equal precision, a wave of influenza was shown to have started from central Asia in the spring of 1889, to have travelled through Europe from east to west, to have been carried thence across the sea to America and the Antipodes, until it eventually invaded every inhabited part of the globe (see INFLUENZA). In both cases no doubt remains that the all-important means of dissemination is human intercourse. The movements of plague cannot be followed in the same way. With regard to origin, several endemic centres are now recognized in Asia and Africa, namely, (1) the district of Assyr in Arabia, on the eastern shore of the Red Sea; (2) parts of Mesopotamia and Persia; (3) the district of Garhwal and Kumaon in the North-West Provinces of India; (4) Yunnan in China; (5) East and Central Africa. The last was discovered by Dr. Koch.

The following is a list of countries in which plague is known to have been present in each year (see Local Government Board's Reports): 1880, Mesopotamia; 1881, Mesopotamia, Persia and China; 1882, Persia and China; 1883, China; 1884, China and India (as *mahamari*); 1885, Persia; 1886, 1887, 1888, India (as *mahamari*); 1889, Arabia, Persia and China; 1890, Arabia, Persia and China; 1891, Arabia, China and India (as *mahamari*); 1892, Mesopotamia, Persia, China, Russia (in central Asia); 1893, Arabia, Persia, China, Japan, Russia, East Africa, Madagascar and China and India (as *mahamari*); 1895, Arabia and China; 1896, Arabia, Asia Minor, China, Japan, Russia and India (Bombay); 1897, Arabia, China, Japan, India, Russia and East Africa; 1898, Arabia, Persia, China, Japan, Russia, East Africa, Madagascar and Vienna; 1899, Arabia, Persia, China, Japan, Mesopotamia, East Africa, West Africa, Philippine Islands, Straits Settlements, Madagascar, Mauritius, Réunion, Egypt, European Russia, Portugal, Sandwich Islands, New Caledonia, Paraguay, Argentine, Brazil; 1900, to the foregoing should be added Turkey, Australia, California, Mexico and Glasgow; in 1901, South Africa

and in 1902 Russia, chiefly at Odessa.

In 1896 plague appeared in the city of Bombay; the infection spread gradually and slowly at first, but during the first three months of 1897 not only was the town of Bombay severely affected, but district after district in the presidency was attacked, notably Poona, Karachi, Cutch Mandvi, Bhiwandi and Daman. The following figures give the mortality for Bombay and Bengal, as well as the total mortality in India.

In 1900, there was an outbreak of plague in Australia. The total number of cases reported in Queensland was only 123, with 53 deaths. In Sydney there were 303 cases, with 103 deaths, a case mortality of 34%. The infection is supposed to have been brought from Noumea, in New Caledonia, where it was present at the end of 1899. Plague in Glasgow was on a still smaller scale. It began, so far as could be ascertained, in August 1900, and during the two months it lasted there were 34 cases and 15 deaths. Once more the disease was not at first recognized, and its origin could not be traced. In 1901 plague invaded South Africa, and obtained a distinct footing both at Cape Town and Port Elizabeth. The total number of cases down to July was 760, with 362 deaths; the number of Europeans attacked was 196, with 68 deaths, the rest being natives, Malays, Indians, Chinese and negroes. With regard to Great Britain, a few ship-borne cases had to be dealt with at the ports.

Causation.—Plague is a specific infectious fever, caused by the *bacillus pestis*, which was identified in 1894 by Kitasato, and subsequently, but independently, by Yersin (see BACTERIA and DISEASE). It is found in the buboes in ordinary cases, in the blood in the so-called "septicaemic" cases, and in the sputum of pneumonic cases. It may also be present in the urine. *Post mortem* it is found in great abundance in the spleen and liver. Nothing is known of its natural history outside the body, but on cultivation it is apt to undergo numerous involution forms. Its presence in a patient is regarded as positive diagnostic proof of plague; but failure to find or to identify it does not possess an equal negative value, and should not be too readily accepted. It is quite clear, from the extreme variations in the severity of the illness, that the resisting power of individuals varies greatly. According to the Plague Research Committee of Bombay, the predisposing causes are "those leading to a lower state of vitality," of which insufficient food is probably the most important. There is no evidence that age, sex or race exercises a distinct predisposing influence. The largest incidence in Bombay was on young adults; but then they are more numerous and more exposed to infection, because they go about more than the younger and the older. Similarly, the comparative immunity of Europeans in the East may be explained by their different conditions of life. It is doubtful whether the distinction drawn between *pestis minor* and *pestis major* has a real aetiological basis. Very mild cases occurring in the course of an outbreak of typical plague may be explained by greater power of resistance in individuals, but the epidemic prevalence of a mild illness preceding the appearance of undoubted plague suggests some difference or modification of the exciting cause. Of course plague does not stand alone in this respect. Epidemic outbreaks of other diseases—for instance, cholera, diphtheria and typhoid fever—are often preceded and followed by the prevalence of mild illness of an allied type.

Clinical Characters—One of the results of recent observation

is the classification of plague cases under the three heads: (1) bubonic; (2) pneumonic, (3) septicaemic. This classification is a clinical one, and the second and third varieties are just as much plague as the first. It is necessary to say this, because a misleading use of the word "bubonic" has given rise to the erroneous idea that true plague is necessarily bubonic, and that non-bubonic types are a different disease altogether.

The illness varies within the widest limits, and exhibits all gradations of severity, from a mere indisposition, which may pass almost unnoticed, to an extreme violence, only equalled by the most violent forms of cholera. The mild cases are always bubonic; the other varieties are invariably severe, and almost always fatal. Incubation is generally from four to six days, but it has been observed as short as thirty-six hours and as long as ten days (Bombay Research Committee). As a rule the onset is sudden and well marked.

(1) Bubonic cases usually constitute three-fourths of the whole, and the symptoms may therefore be called typical. In a well-marked case there is usually an initial rigor—in children convulsions—followed by a rise of temperature, with vomiting, headache, giddiness, intolerance to light; pain in epigastrium, back and limbs; sleeplessness, apathy or delirium. The headache is described as splitting; delirium is of the busy type, like delirium tremens. The temperature varies greatly; it is not usually high on the first day—from 101° to 103°—and may even be normal, but sometimes it rises rapidly to 104° or 105° or even 107° F; a fall of two or three degrees on the second or third day has frequently been observed. The eyes are red and inflamed; the tongue is somewhat swollen, and at first covered with a thin white fur, except at the tip and edges, but later it is dry, and the fur yellow or brownish. Prostration is marked. Constipation is the rule at first, but diarrhoea may be present, and is a bad sign. A characteristic symptom in severe cases is that the patient appears dazed and stupid, is thick in speech, and staggers. The condition has often been mistaken for intoxication. There is nothing, however, in all these symptoms positively distinctive of plague, unless it is already prevalent. The really pathognomonic sign is the appearance of buboes or inflamed glands, which happens early in the illness, usually on the second day; sometimes they are present from the outset, sometimes they cannot be detected before the third day, or even later. The commonest seat is the groin, and next to that the axilla; the cervical, submaxillary and femoral glands are less frequently affected. Sometimes the buboes are multiple and on both sides, but more commonly they are unilateral. The pain is described as lancinating. If left, they usually suppurate and open outwards by sloughing of the skin, but they may subside spontaneously, or remain hard and indurated. Petechiae occur over buboes or on the abdomen, but they are not very common, except in fatal cases, when they appear shortly before death. Boils and carbuncles are rare.

(2) Pneumonic plague was observed and described in many of the old epidemics, but its precise significance was first recognized by Childe in Bombay. He demonstrated the presence of the bacilli in the sputa, and showed that the inflammation in the lungs was set up by primary plague infection. The pneumonia is usually lobular, the onset marked by rigors, with difficult and hurried breathing, cough and expectoration. The prostration is great and the course of the illness rapid. The breathing becomes very hurried—forty to sixty respirations in the minute—and the face dusky. The expectoration soon becomes watery and profuse, with little whitish specks, which contain great quantities of bacilli. The temperature is high and irregular. The physical signs are those of broncho-pneumonia; oedema of the lungs soon supervenes, and death occurs in three or four days.

(3) In septicaemic cases the symptoms are those of the bubonic type, but more severe and without buboes. Prostration and cerebral symptoms are particularly marked; the temperature rises rapidly and very high. The patient may die comatose within twenty-four hours, but more commonly death occurs on the second or third day. Recovery is very rare.

The case mortality of plague still remains exceedingly high. The lowest recorded is 34% in Sydney, and the highest 95% at

Hong Kong in 1899. During the first few weeks in Bombay it was calculated by Dr. Viegas to be as high as 99%. It is very much higher among Orientals than among Europeans. In the Bombay hospitals it was about 70% among the former, and between 30% and 40% among the latter, which was much the same as in Oporto, Sydney and Cape Town. It appears, therefore, that plague is less fatal to Europeans than cholera. The average duration of fatal cases is five or six days; in the House of Correction at Byculla, where the exact period could be well observed, it was five and a half days. Patients who survive the tenth or twelfth day have a good chance of recovery. Convalescence is usually prolonged. Second attacks are rare, but not unknown.

Diagnosis.—When plague is prevalent in a locality, the diagnosis is easy in fairly well-marked cases of the bubonic type, but less so in the other varieties. When it is not prevalent the diagnosis is never easy, and in pneumonic and septicæmic cases it is impossible without bacteriological assistance. The earliest cases have hardly ever been even suspected at the time in any outbreak in a fresh locality. It may be taken at first for almost any fever, particularly typhoid, or for venereal disease or lymphangitis. In plague countries the diseases with which it is most liable to be confounded are malaria, relapsing fever and typhus, or bronchopneumonia in pneumonic cases.

Dissemination.—The investigations of the Indian plague commission working in conjunction with the advisory committee showed that bubonic and septicæmic plague are transmitted by the agency of fleas. Highly susceptible animals are not infected by their plague-stricken fellows so long as fleas are excluded from the cages, but with the introduction of these ectoparasites the disease forthwith spreads from the sick to the healthy. Subsequent experience has confirmed the main findings of the commission, and outbreaks of human plague are unquestionably mere extensions of preceding or concurrent plague affecting animals. Rats (*Rattus rattus*) are of outstanding importance as reservoirs of infection through their close association with man, but marmots (*Arctomys bobac*), gerbilles (*Tatera lovengulæ*) and ground squirrels (*Citellus beecheyi*) have been responsible for epidemic outbreaks in China, South Africa and California respectively.

The plague commission concluded that the disease can be transmitted by the faeces of infected fleas, but did not state that this is the usual method of spread. Bacot and Martin later demonstrated that the entrance to the flea's stomach becomes obstructed by a mass of plague bacilli. Such fleas in their persistent efforts to feed merely succeed in distending the gullet with blood, which, now contaminated, regurgitates on to the skin of the host. The organisms then enter the body either through the flea's bite or through some abrasion of the skin.

The flea most commonly incriminated as a plague-vector is *Xenopsylla cheopis*, but several other species of rat fleas (*Ceratophyllus fasciatus*, *Stivalius ahalæ*), the common mouse flea (*Lep-topsylla musculi*), the dog flea (*Ctenocephalus canis*), a marmot flea (*Ceratophyllus silantievi*) and the human flea (*Pulex irritans*), amongst others, are proven carriers of plague.

Epidemiology.—Laborious studies on the biology of fleas have added to our knowledge of the epidemiology of plague. These insects cannot withstand desiccation, and their survival apart from their host is proportional to the rate at which they lose moisture. Bacot and Martin (1924) found the water content of fleas to be 80% of their weight, and death occurred before the loss of water had reached 60% of their weight. This goes far to explain the observation that plague does not maintain itself in epidemic form when the temperature rises above 80° F, accompanied by a saturation deficiency of over .30 of an inch.

The seasonal variations in the spread of plague have been recognised for many centuries. In temperate countries epidemics attain their maximum in the summer months, whereas in tropical climates the onset of hot, dry weather brings an existing epidemic to an end. In each case, the peak of the plague curve coincides with meteorological conditions most favourable to the activity and longevity of fleas. In contradistinction to the foregoing, pneumonic plague, once established, spreads independently of animals and fleas. In outbreaks of ordinary plague, a secondary

involvement of the lungs supervenes in a small proportion of cases, and if atmospheric and environmental conditions favour the survival and transmission of the bacilli an epidemic of pneumonic plague may result, the virus being transmitted from the cougher to the victim up to a range of about three feet.

Treatment and Prophylaxis.—Unfortunately, there is no plague specific. Serum, to be really effective, must be given before the symptoms of the disease are manifest, an impossible procedure in most cases. Still, when available, serum should be administered intravenously in doses of 80–100 c.c.'s, and repeated. Some advocate injection of tincture of iodine (7–10 minims), or other antiseptics, intravenously, and also into the buboes. These measures are of doubtful benefit. Buboes showing signs of sup-puration should be incised. Otherwise, treatment is on general lines, and cardiac stimulants should be administered early.

So long as members of a community are content to live in association with rats and fleas correlative plague is a likely result. Meanwhile, plague prophylaxis consists mainly of warfare against rats, in the hope of ultimately banishing them from human habitations and from contact with man. Any general elimination of these pests over wide areas is a slow, costly and usually impracticable affair, and all that can be achieved in most cases is some degree of palliation by rat-proofing of grain stores, wharves and other places which serve as centres for the dissemination of plague. Destruction of rats by trapping and poisoning is a commendable procedure, but of itself will never eradicate endemic plague, for the losses in the rat population are quickly made good if survivors are provided with food and harbourage. An important measure of personal prophylaxis is inoculation with anti-plague vaccine, which affords a good degree of protection. Persons entering plague-infected houses should wear gaiters, and otherwise render their clothing as flea-proof as possible; if there is any suspicion of pneumonic plague, goggles, and masks made of several layers of fine gauze, should be worn without fail.

PLAICE (*Pleuronectes platessa*), a flat-fish that ranges from Iceland and northern Europe to south of Great Britain, and one of the most important commercial fishes of the North sea. Other species of somewhat similar form, with large eyes on the right side and with a small terminal mouth, are the dab and flounder; from these the plaice is easily distinguished by the red spots scattered over the body. The pharyngeal bones are strong and bear large blunt teeth, used for crushing the shells of the bivalves that are the principal food of this species. A length of more than 30 in. and a weight of 8 lb. may be attained, but nearly all the fish marketed are less than half that length.

PLAINFIELD, a city of Union county, New Jersey, U.S.A., 24 m. W. by S. of New York city; served by the Baltimore and Ohio, the Central of New Jersey and the Reading railways. Pop. (1930) 34,422; and 37,469 in 1940 by federal census. With the adjacent boroughs of North Plainfield and South Plainfield the population of "the Plainfields" was 53,434. At an altitude of 105 ft. near the Watchung hills, Plainfield is a residential suburb of New York. There are five golf courses in and near the city. A number of manufacturing plants had an aggregate output in 1940 valued at \$11,000,000. The city's assessed valuation for 1941 was \$59,028,340 and the total tax rate \$4.23 for each \$100 valuation. Settlement there dates from 1684 by colonists from Scotland. Around a gristmill built on Green brook in 1760 and a Quaker meetinghouse (still standing) removed from its ancient site

(1713) to its present location in 1788. there was formed a village named Milltown. Upon the opening of a U.S. post office in 1800 the name was officially changed to Plainfield which became an incorporated city in 1869. The free public school system in the state of New Jersey was started there in 1847.

PLAINS INDIANS. The tribes of the central portion of the North American continent, on the open plains and parkland prairies extending from Alberta and Saskatchewan to Texas and from the Rocky Mountains almost to the Mississippi river, formed a natural unit, both in environment and culture. Essentially, this territory is the habitat of the American bison (buffalo); and on this animal the Plains tribes primarily depended for food, shelter, clothing and many utensils, and to its habits many of their customs were adapted. The eastern tribes, in the prairies, seasonally combined bison hunting and maize farming; the western ones, in the plains proper, were wholly nomadic. Originally, they transported their tents and belongings on travois frames dragged by dogs. After the introduction of the horse by the Spaniards, beginning about 1650, this animal gradually replaced the dog, tribal movements became freer, while their numbers augmented and their culture elaborated. They camped in large circles of tepees, conical tents of bison skins supported by long poles leaning on a primary tripod (or four poles)—a highly specialized, convenient dwelling quickly pitched and struck. Cooking was by roasting, or with hot stones in bison rawhide containers; meat predominated heavily in the diet. Property and food were stored and transported in rawhide bags and "parfleches." Clothing was of deer (antelope, elk) skins, supplemented by bison robes, and was well tailored, ample, comfortable, and often highly ornamented with embroidery of porcupine quills, later beads. Social organization was simple: matrilinear clans, patrilinear clans, or non-exogamic bands, according to tribe. Warfare was constant, being carried on partly for profit (horse raiding) but chiefly for honour, a man's career depending directly on the prestige of his war exploits; hence arose the system of "counting coups," that is, publicly recounting blows struck on enemies. The best known ritual was the so-called Sun dance. Most other rites were conducted by societies, which among some tribes were age-graded. Supernatural power was sought in visions by most men, warriors as well as curers. There were sacred "bundles" for tribes, clans and societies; these were fetiches preserved for generations.

The Plains tribes are proud, brave, out-spoken and direct, and possess an unusual sense of individuality and personality. The physique is exceptionally tall, rangy and hardy. With their long braided hair, fringed costume, eagle feather war-bonnets, mounted on ponies, with tepees as a background, the Plains tribes have captured the imagination of recent generations of whites; and pass popularly as the most representative of Indians. The most typical Plains tribes are the Dakota, Assiniboine, Blackfeet, Gros Ventre, Arapaho, Cheyenne, Kiowa, Comanche; others are the Sarsi, Plains Cree, Plains Ojibwa, Wind River Shoshone, Mandan, Hidatsa, Arikara, Pawnee, Omaha, Ponca, Iowa, Oto, Missouri, Kansas, Osage, Wichita, Kiowa Apache; and, among the tribes in or across the Rocky mountains, the Kootenay, Flathead, Nez Percé, Bannock, Ute and Jicarilla Apache have been especially influenced by Plains culture. The preponderant stock is the Siouan; next, the Algonkin; Shoshonean, Athabaskan, Caddoan are also each represented by two or more tribes.

See C. Wissler, "Indians of the Plains" (*Am. Mus. Nat. Hist.*, 1912) for a general summary; and monographs or books by G. Catlin, W. P. Clark, E. H. Curtis, G. A. Dorsey, J. O. Dorsey, A. C. (A. L. K.)

PLAINSONG or **PLAIN CHANT.** A general term for a certain style of unisonal music, comprising chiefly the church-music called "Gregorian" which belongs to Rome, and that called "Ambrosian" which hails from Milan. But the other Western collections of church-music, much less well-known than these, and a good many groups of Eastern church-music could also quite properly be put under this heading.

Origin.—There are various factors in the genesis of music which determine its essential characteristics. Music intended for a

dance is necessarily regular in its rhythm; so also, though less tied, is music which is set to metrical verse. On the other hand music fitted to a prose text is not so regular. Thus there arise different kinds of rhythm in music, ranging from strict time to the freest of movement. Again some music arises from recitation and the need to declaim some words artistically and audibly; while other music aims at melody, that is to say a succession of sounds, which is pleasant for its own sake, and would be so independently of any words.

The ecclesiastical music which is called plainsong is so named because it is unmeasured music, not regular in rhythm, a *cantus planus* as contrasted with *cantus mensurabilis* or measured music. It is this feature that chiefly differentiates it from modern music; and at the same time allies it with such things as sea-chanties, counting-out rhymes, and the like. The Christian church, like other worshipping bodies, requires euphonious sounds for the recitation of its psalms, and for the reading of its scriptures in public. As these passages are not (for the most part) written in any strict metre, the music to be provided is essentially a "plain" chant; there are several classes of such plainsong.

Influence of the Psalter.—The chief influence in this evolution has been that of the Psalter. Hebrew poetry follows a metrical system, but this disappears in translation. There survives however, a more obvious feature of the original, viz., its parallelism. This consequently becomes a prominent characteristic of certain sorts of plainsong, so that the chants directly derived from the psalms take a binary form. The recitation demands a reciting note, on which the text can be freely recited in its own rhythm and shape. If this note alone is used, the effect soon becomes, in the strict sense of the word, monotonous. Therefore the music adopts the natural tendency of the voice to rise up to its reciting note at the beginning and to drop down from it at the end of the phrase. Thus arises the commonest chant-form of plainsong, consisting of (1) an intonation, (2) recitation, and (3) cadence, in each half-verse. The psalm-tones whether Gregorian or Ambrosian take this shape; and the form is capable of more or less elaboration for the psalms. The Gregorian tones are very simple; more elaborate forms of them are used for the Gospel-canticles; and still more developed forms for the Introits. A limit is naturally set to the amount of elaboration either (a) when whole psalms are to be sung at length, or (b) when they are to be sung by the whole congregation. When, however, select verses only are sung, and are sung by trained singers, there is far more scope for elaboration; and the developed responds used both at Mass and at the Choir-office exhibit this chant-form in a highly ornamental shape.

The chief development occurs in the Cadences. In its simplest form the musical cadence affects only the last syllable, e.g. there is the drop of a minor third. Next it concerns the last two syllables. These two simple cadences are familiar, even to those who do not know the Gregorian tones, from their being used in the Versicles and Responses of the Prayer Book. The more elaborate cadences naturally followed the "cursus" used by Latin prose-writers of the best, or at any rate, the most formal, style. In the responds a five-syllable cadence is constantly in use, and often in a highly decorated form.

All this music arises out of the recitation of psalms. For the purpose of declaiming the lessons of Scripture only the simpler inflexions were used; and the same is true of the prayers or collects, except a few which are of exceptional solemnity such as the "Preface" or the Lord's Prayer, as used in the consecration prayer at Mass; or the Hallowing of the Font at Baptism.

Antiphons.—Next to be considered is a totally different way of beautifying the recitation of psalms or other prose texts. Instead of elaborating the chant itself there was interpolated between the verses a suitable refrain. These refrains came to be known as "antiphons": and thus side by side with the older method, which came to be called "responsorial" from the responds which represented it at its fullest development, there arose the newer "antiphonal" method. The former music developed from recitation, and even in its most elaborate forms in more or less degree it hung round a reciting note. The antiphons were purely melodic and the method had its quality and meaning determined,

not by reference to a "dominant" reciting-note, but to the "final" note on which it ultimately came to rest.

Antiphonal music underwent modification and development just as the responsorial music did. Its relation to the psalm altered; the singing of the refrain after each verse survived mainly in processional use. In choir offices the refrain was dropped so that it was sung only at the beginning and end of the psalm, or else in a curtailed form at the beginning and in full only at the end. In the psalmody of the Mass the opposite form of abbreviation was adopted. For at the Introit and the Communion the psalm became restricted to only one or two verses, and at the Communion it ultimately disappeared altogether, leaving the Antiphon alone.

Some antiphons composed on a large scale arose independently of any connection with a psalm. These were used especially in processions. Others retained the idea of a psalm-verse, but utilized for such verses not the normal psalm-tones, but independent melodies, perhaps as elaborate as the psalm itself. Such antiphons especially prevailed at the Offertory in the Mass.

The greater part of the classical Gregorian plain-chant falls into one or other of these two classes. The amount of elaboration depended mainly upon two considerations (1) the importance of the occasion; and (2) the capacity of the singers. A great festival or a specially dignified part of the service demanded richer treatment: and the trained singers undertook more difficult music than the congregation, the soloists than the choir generally.

The Gregorian Music.—The *Cantilena Romana*, Gregorian chant proper, is thus a body of music, purely vocal and ecclesiastical, evolved by the Papal choir in the course of the fifth and sixth centuries. This was codified in the time of St. Gregory (c. 540–604) (*q.v.*) and it stands as the basis of all the Gregorian Music. The Milanese tradition was similar but less artistic. It is called "Ambrosian" (see ST. AMBROSE) but the term has no historical significance as the term Gregorian has. A comparison of these two families of plain-chant brings out clearly the comparative crudity of the Ambrosian tradition as distinct from the artistic balance and delicate finish of the classical Gregorian chant. The same is true also of such other specimens of Western ecclesiastical chant as are known. The Gregorian reform marks the close of a golden age of classical monody. The middle-ages subsequent to St. Gregory produced nothing so good; and the later part of them while producing only little and decadent plainsong depraved also the form of the classical tradition.

Something more must be said to describe the contents of the Gregorian *corpus* and also to explain the musical theory which lay behind it. The music covers the whole set of services of the Roman rite, but principally the Mass and the series of daily Choir Services. At the Mass some of the things sung are invariable, while others change according to the Sunday, or Festival, or occasion generally. The unchanging elements are chiefly the Kyrie, Credo, *Sanctus*, *Agnus dei*, and Gloria in *excelsis*. For these the old tradition provided little or no change of music; and what there was followed very simple lines suitable for congregational singing. The variable elements were principally the Introit-psalm, the Gradual-respond, the Offertory-antiphon and the Communion-antiphon. The Gradual was at times replaced or supplemented by an Alleluia with a Verse attached to it, or by a Tract. The Alleluia belonged specially to festive seasons and occasions, the Tract to penitential. Neither of these falls exactly into either of the two chief categories responsorial and antiphonal. The Tract is a very ancient but elaborate type of the developed psalmody; the Alleluia was an innovation which came in towards the end of the classical period, and extended beyond it into the "Silver Age" when little else was being composed.

For the choir-offices there was provided a large number of antiphons to go with the psalmody, and a considerable number of responds which mainly served as interludes between the lessons at Mattins. When hymnody began with St. Ambrose it was taken up and incorporated into the services by the monks; but Rome was for a long time too conservative to admit hymns. The plain-song hymn-tunes are, in the nature of the case, more definitely metrical than the other music: but they retain a considerable

freedom of movement, and are not "measured," like modern hymn-tunes.

Underlying Musical Theory.—The musical theory which lies behind this music is based on a series of eight scales or Modes. It uses the old diatonic scale of the Greek theorists (equivalent to the white notes of the pianoforte with the addition of B), but the modes themselves are different from the old Greek modes, and the use of the old Greek names only leads to confusion. The eight-mode system was probably the same as the *ὀκτώηχος* which underlies the Eastern church music; but the origins are obscure alike in East and West. The scheme seems to go back at least to St. John of Damascus (c. 750); but it is known in the West only in theoretical treatises derived through the Byzantine teachers at the court of Charlemagne at the end of the eighth century.

The eight modes are really four pairs, each pair being founded on the same note, the one scale (called Authentic Mode) being an octave ranging above the foundation or final note, the companion (called Plagal) being an octave ranging above and below it.

First	}	A BCD EF G a bc d
Second		
Third	}	BC D EF G a bc d e
Fourth		
Fifth	}	C D EF G a bc d ef
Sixth		
Seventh	}	D EF G a bc d ef g
Eighth		

Each of these pairs has a character or tonality of its own, dependent upon the position which the semitones have in the scale. None is similar to the major or minor key of modern music. It is this tonality which gives the special character to plain-song melody. Some theorists have reckoned twelve or even fourteen Modes; but this is unnecessary. So far as pitch goes, the range of two octaves covered by the eight modes is adequate; and so far as tonality is concerned, the new modes would be only the same as the first four or six over again with the Bb used instead of B. (For further discussion of the Modes see HARMONY.)

This modal theory does not fully account for all the procedure of the classical plain-chant (practice always surpasses theory): but these eight modes are clearly the foundation of this music, whether responsorial or antiphonal.

In the middle ages the *cantilena Romana* was handed on by tradition from St. Gregory's days; in the ninth century it was recorded in the notation reames. The notation on a staff which began a couple of centuries later, while it fixed accurately the pitch of each note, failed to reproduce the rhythmical delicacies which the earlier notation had recorded. Hence the recent renaissance of classical plain-song has been based on a return to the reames, as interpreted by the subsequent tradition.

The revived interest in music of the Carolingian era stimulated composition, which had been long in abeyance. Not only new music for new feasts arose, but fresh settings of the "Ordinary" (fixed elements) of the Mass. While the old music was preserved, it was padded out with new and inferior interpolations called by the generic name of "Tropes." These had their day and pervaded all the church music for a century or more; but then they went out of fashion, leaving only two considerable legacies, (a) a further series of settings of the "Ordinary," (b) the new form of rhythmical, or (later) metrical, poem called Sequences or Proses. These survived in considerable numbers down to the sixteenth century, but at the present time only a few are in use.

Modern Revival.—The rise of the art of harmony beginning from the eleventh century, diverted attention from the monody of plain-chant, and part-singing had the effect of "measuring" the music so that it fell into regular time and was no longer free or "plain." Under these influences the old plain-song was progressively debased and as harmonized music went up, plain chant went down. Not until the nineteenth century did this degradation cease. The efforts then made in various quarters to recover alike the true rhythm and tonality of the old music have culminated in the work of the Benedictines of Solesmes and their

followers, and in the revival which has produced the new Vatican Gradual and is producing by degrees a restored Antiphonal as well. With the recovery of the music has come a new insistence upon its use and study, as being the official music of the Roman church.

(W. H. F.)

PLAINTIFF: see PRACTICE AND PROCEDURE.

PLAINVIEW, a city of northwestern Texas, U.S.A., 270 mi. W. by N. of Fort Worth, on the south plains of the "Panhandle" at an altitude of 3,370 ft.; the county seat of Hale county. It is on federal highways 70 and 87, and is served by the Santa Fe and the Colorado and Southern railway systems. Pop. (1940) 8,263 by federal census. It is the trade centre of 5,000 sq.mi. of farming land, with over 1,500 irrigation wells in the territory, raising chiefly cotton, wheat and grain sorghums. The Texas Panhandle Plains dairy show is held there annually. The site for the city was surveyed in 1887. The settlement remained a trading post for the cattlemen who occupied the entire region until the railway reached it in 1907, and it was incorporated as a city. Farming began to displace ranching about 1915, and the cultivation of cotton began in 1918. Dairying and livestock feeding income amounts to more than \$2,250,000 annually in Hale county.

PLANCK, MAX (1858-), German physicist, was born at Kiel on April 23, 1858. He studied at the universities of Munich and Berlin, became an assistant in Munich University, and was subsequently appointed a professor in Kiel (1885) and in Berlin (1889). Planck devoted himself to the study of theoretical physics, and in particular to that of thermodynamics. His lectures on this subject appeared in book form and were translated into English, French and Russian. He gained international fame by his *Law of Radiation* (1901), which asserts that the energy of radiation is emitted and absorbed in integral multiples of certain indivisible "quanta" of energy, which depend on the frequency of oscillation of the electrons. In 1912 Planck extended this "quantum theory" (*q.v.*) to all kinds of energy and added the assumption that only emission proceeds discontinuously, in quanta, while absorption is continuous. On this assumption he was able to derive the distribution of energy in the spectrum of black-body radiation. The quantum theory has been developed and modified by him and many other physicists but the foundation was laid by Planck's work on black-body radiation. In 1918 he was awarded the Nobel Prize for physics. Planck became editor of the *Annalen der Physik*. He was elected a foreign member of the Royal Society in 1926.

Among his works are: *Die Entstehung und bisherige Entwicklung der Quantentheorie* (1920, Eng. trans. 1922); *Vorlesungen über die Theorie der Wärmestrahlung* (1921); *Physikalische Rundblicke* (1922, Eng. trans. 1925); *Einführung in die Theorie der Elektrizität und des Magnetismus* (1922); and *Die Ableitung des Strahlungsgesetzes* (1923).

PLANE. The simplest definition of plane given by the Greek geometers is that of Heron of Alexandria (*c.* 200):—a surface "such that if a straight line passes through two points on it, the line coincides wholly with it at every spot, all ways." Crelle (1834) defined it as the surface containing all the straight lines (throughout their entire lengths) passing through a fixed point and also intersecting a straight line in space. (For plane, a tool, see EDGE TOOLS.)

See H. Schotten, *Inhalt und Methode des planimetrischen Unterrichts* (Leipzig, 1890, 1893); Sir T. L. Heath, *The Thirteen Books of Euclid's Elements* (1926). (See also SURFACE.)

In botany, plane is the common name of a handsome tree known botanically as *Platanus orientalis* (family Platanaceae), a native of Greece and western Asia, a favourite shade-tree of the Greeks and Romans, introduced by the latter to southwest Europe. It is one of the most successful trees in London and other large industrial cities; the smooth face of the leaf is easily washed by rain; and the periodical peeling of the bark also serves to get rid of surface deposits of soot, etc. It is a large tree with widely spreading branches and alternate, palmately five-lobed leaves, resembling those of the sycamore maple in shape, but hairless and of a brighter green. The bud in the leaf axil is protected during its development by the hollow base of the leaf-stalk, which lifts off like an extinguisher when the leaf falls in autumn. The minute, unisexual flowers are borne in dense pendu-

lous heads, which contain either male or female flowers; the small one-seeded nutlets, each bearing a tuft of long silky hairs, are densely crowded in a ball, from which they gradually separate in drying, and are readily carried by the wind. A variety of forms are known in cultivation; var. *laciniata* has very deeply much divided leaves, and var. *variegata*, variegated foliage. The London plane, *P. acerifolia*, features three-lobed leaves. Several authori-

PLANE (*PLATANUS ORIENTALIS*), SHOWING BRANCH WITH FRUITS. A BRANCH WITH DROOPING FEMALE HEADS WHICH ARE WIND POLLINATED

ties regard this as a natural hybrid (*P. occidentalis* × *orientalis*) rather than as a distinct species. *Platanus occidentalis*, an allied species, is a native of the United States, being most abundant and growing to its largest size in the basin of the lower Ohio and the Mississippi rivers. It was introduced into England early in the 17th century, and is occasionally met with in western and central Europe; it is known in America as sycamore (*q.v.*) and buttonwood. It differs from *P. orientalis* in its less deeply lobed, more leathery pubescent leaves and in the usually solitary balls of fruit. Both the native sycamore and the London plane are extensively planted as ornamental trees in the eastern United States. The California sycamore (*P. racemosa*) and the Arizona sycamore (*P. wrightii*), of the extreme southwest, are much smaller than the eastern species.

PLANER: see MACHINE-TOOLS; WOOD-WORKING MACHINERY.

PLANET (Gr. *πλανήτης*, a wanderer). The term was applied in the ancient Ptolemaic or geocentric astronomy to the seven heavenly bodies which were observed to change their places as projected against the background of the so-called fixed stars. These bodies were the Sun, the Moon, Mercury, Venus, Mars, Jupiter and Saturn, all of which were supposed to revolve round the earth. In the modern or heliocentric astronomy (taught by Aristarchus of Samos in the third century B.C. but forgotten or neglected till revived by Copernicus in the 16th century of the Christian era) it is applied to all dark and opaque bodies in revolution round the sun, and the number of such bodies known has been greatly increased by successive discoveries. In 1781 William Herschel discovered Uranus. In 1801, on the first night of the new century,

Pluto	Reliable elements cannot yet be given. Distance at discovery about 41 units. Inclination about 17°. Period probably rather less than 300 years. Planet within Neptune's orbit at perihelion.											

*In mean solar days and tropical years.

Piazzi discovered Ceres, a small planet revolving between the orbits of Mars and Jupiter and the first of a great host of small bodies known as minor planets or asteroids; while in 1846 Neptune was added to the list of major planets following on the mathematical work on the unexplained irregularities in the motion of Uranus by Le Verrier and, independently, by Adams (see notes on Neptune). Recently (1930, Feb.) a yet more remote planet has been found at the Flagstaff Observatory near the position predicted by the late Professor Lowell. It has been named Pluto. Most of the major planets possess moons or satellites. So far as at present known, Neptune possesses one, Uranus four, Saturn nine, Jupiter nine, Mars two and the Earth one.

Distances of the Planets. — An empirical law expressing very closely the relative distances from the sun of the primary planets known to the ancients was discovered about the middle of the seventeenth century by Titius of Wittenburg, but it was later brought into notice by Bode and is generally known as Bode's law. If a series of 4's be written down, and 3 be added to the second, 6 to the third, 12 to the fourth and so on, each of the added numbers being double its predecessor, the sums of the first seven numbers are 4, 7, 10, 16, 28, 52, 100. These numbers divided by 10 were found to give with a surprising closeness the relative distances of the planets as far as Saturn, except that no planet was known to revolve in the orbit corresponding to 2.8 between the orbits of Mars and Jupiter. When Uranus was discovered and found to fit in well with the next number in the series (19.6) the conviction was strengthened that the gap between Mars and Jupiter must be occupied by some planet and a search for the missing body was organized. But before systematic work was actually begun the little planet Ceres was found. The discovery was soon followed by others, and at the present time considerably more than 1,000 of these minor planets are known. They are not, however, actually confined to the gap above mentioned. The little planet Eros discovered by Witt in 1898 comes at perihelion within 13,000,000 miles of the earth's orbit and hence it is of special value to astronomers for the determination of the solar parallax which fixes the scale of the planetary system. Hidalgo, discovered by Baade in 1922, in the most distant part of its orbit goes out as far as the orbit of Saturn and has a mean distance slightly greater than that of Jupiter. The actual distances of the greater planets from the sun in miles will be found in Table I.

Orbits and Phases of the Planets. — From the observations of Tycho Brahe, the great Danish observer, Kepler deduced the following three great laws of planetary motion:—

(1) The planets move in ellipses with the sun at one focus. Hitherto it had been believed that the circle being the most perfect geometrical figure celestial motions took place in circles.

(2) The straight line from the sun to a planet (radius vector) passes over equal areas in equal times. The importance of this law was that it involves a continually varying rate of motion, which was also contrary to accepted beliefs at the time. To maintain the equal description of areas in unit time a planet must travel faster in the neighbourhood of perihelion where the radius vector is at a minimum than near aphelion where it attains its maximum value.

(3) The squares of the periodic times (the times required for the orbital revolutions of the planets) are proportional to the cubes of the mean distances (the semi-major axes of their orbits). This is known as the harmonic law and defines the relationship between a planet's orbital motion and its distance from the sun.

From these laws of planetary motion Newton deduced his law of universal gravitation which has achieved such remarkable successes and prepared the way for Einstein's relativity theory.

The dimensions, form and aspect of a planet's orbit as well as the position of the planet in the orbit at any time are defined by what are known as its elements. These are:—

(1) Half the major axis, or mean distance (generally denoted by *a*). This defines the size of the orbit.

(2) The eccentricity (*e*) or the ratio of the distance of the sun from the centre of the orbit to the mean distance. This defines the shape of the orbit.

(3) The inclination (*i*) of the orbit plane to the ecliptic, *i.e.*, to the plane of the earth's orbit.

(4) The longitude of the ascending node (Ω), *i.e.*, the direction at the sun of the point on the orbit (measured from the vernal equinox or "first point of Aries") at which the planet crosses the ecliptic from its south to its north side. This defines the aspect of the orbit.

(5) The longitude of the perihelion ($\bar{\omega}$). This defines the direction of the major axis in the plane of the orbit.

(6) The period (*P*), *i.e.*, time the planet takes for a revolution.

(7) The longitude of the planet at the epoch (*L*) or time (*T*) of the planet's perihelion passage. These elements are given for the several planets in Table I.

Since the orbits of Mercury and Venus lie within that of the earth these two planets when observed telescopically will show phases similar to those presented by the moon. When on the far side of the sun, *i.e.*, near the time of superior conjunction, each of them will appear like a small full moon. As the angle earth-planet-sun increases a proportionally diminishing fraction of the illuminated surface will be presented to view, and when the angle reaches 90° the planet will appear half illuminated like the moon at first quarter. Following this a crescent form of steadily diminishing breadth will be assumed as the planet moves toward inferior conjunction, at which point it passes between the earth and the sun. Subsequently to this the phases described will be repeated in the reverse order up to superior conjunction when the planet will again be "full." The phases of a planet revolving outside the earth's orbit differ from those of Mercury and Venus in as much as the angle earth-planet-sun can never increase to 90°. Thus Mars, although at times presenting a markedly gibbous aspect like a nine or ten days' old moon, is always more than half illuminated. In the case of Jupiter the defect of illumination is so small as to be almost imperceptible, but during the occultation of a satellite the planet's dark limb is seen across the satellite's disk, and a narrow black space separates the latter from the bright part of the planet's surface. In the cases of the planets revolving outside Jupiter the phase is quite imperceptible even in powerful telescopes. The variations in apparent diameter and brightness will,

of course, also be small in the cases of the remoter planets.

Physical Condition and Atmospheres.— There* is a broad distinction between the two groups of the major planets on either side of the zone of the asteroids. The planets of the inner group are of relatively small mass and high density and possess solid surfaces. Those of the outer group, especially Jupiter and Saturn, are of much larger mass but of very low density. The density of Saturn is actually less than that of water. The masses of the planets possessing satellites are derived from the distances and periodic times of the satellites by an application of Kepler's third law. The masses of Mercury and Venus are deduced from their gravitational effect on other bodies.

There is for each of the planets a certain critical velocity determined by the force of gravity at its surface, and a particle of matter travelling at a speed in excess of this value will escape from the planet in question and revolve in an independent orbit round the sun. These critical values for the several planets are given in column 12 of Table II. Now according to the kinetic theory of gases every molecule of a gas is an independent particle and is in constant motion. Its velocity will depend on the atomic weight and the temperature and may attain to thousands of feet per second. A molecule with such a high speed in the upper part of a planet's atmosphere where it will be comparatively free from collision with other molecules cannot be retained by a body with low surface gravity but will escape into space. It might be expected, accordingly, that only the large and massive planets are enveloped in dense atmospheres, and that those of small mass and low surface gravity have atmospheres which are of greater rarity and tenuity. Observation shows that this is in general the case. The spectra of the planets of the outer group contain strongly marked absorption bands due to their atmospheres, while those of the inner group—Mars, Venus and Mercury—show but little deviation from the ordinary solar spectrum. It may be that the light received from Venus is almost entirely reflected from the upper part of the atmosphere, but in the cases of Mars and Mercury most of it has passed through the planetary atmosphere twice. As a matter of fact the atmosphere of Mercury seems to be almost negligible. It is known that the moon which is still smaller has none at all that is appreciable, and it cannot be supposed that an atmosphere exists on any of the minor planets, the largest of which (Ceres) has a mass only $\frac{1}{8,000}$ and a surface gravity only $\frac{1}{30}$ as great as the corresponding values for the earth.

The interpretation of the spectra of the outer planets, apart from the mere fact of considerable absorption, is puzzling. From the accompanying plate and Table III. it will be seen that there are one or two rather faint but broad bands in the spectrum of Jupiter which are seen to be much stronger in the spectra of Saturn, Uranus and Neptune. The two latter also contain a

number of additional bands. The origin of the bands was still unknown in 1927.

Temperatures of the Planets.— A matter of special interest in regard to the planets is that of the temperature of their surfaces. Speaking generally it may be said that the surface temperature of a planet which is without appreciable heat of its own and is warmed only by the solar radiation is determined by a number of factors of which the following may be specially mentioned:— (1) The distance of the planet from the sun, the intensity of solar radiation obeying the well-known inverse-square law. (2) The degree in which the planet's surface approaches that of a perfect radiator. (3) The presence or absence of an atmosphere and the nature of such atmosphere. (4) The planet's rotation. It can be shown that a black sphere without an atmosphere rotating with sufficient rapidity to be heated equally all round would have a mean surface temperature given by the formula $T = 277^\circ / \sqrt{R}$ where T is the temperature in degrees centigrade reckoned from the absolute zero and R is the distance of the body from the sun,

taking the earth's distance from the sun as unity. But should the periods of axial rotation and orbital revolution be equal, so that the body turns always the same face to the sun, the formula becomes for the point immediately under the sun $T = 392^\circ / \sqrt{R}$. This means, e.g., that on a perfectly radiating planet without an atmosphere at the distance of Mercury the point on the surface where the sun is overhead would have a temperature of 631° C (absolute). With a quick rotation the mean surface temperature would be about 445° C (absolute) or 342° F. The corresponding absolute temperatures at the distance of Mars come out 318° C

(113° F) and 224° C (−56° F), and at that of Neptune only 71° C (−332° F) and 51° C (−368° F). The actual temperatures will, of course, be affected to a large extent by the presence of an atmosphere which, while directly reflecting a large proportion of the solar rays, checks the escape by radiation of such as penetrate it and reach the planet's surface.

Until comparatively lately, however, the only available methods of estimating the surface temperatures of the planets were those based on general physical principles, and in view of the great uncertainty as to the conditions prevailing on the planets, and particularly as regards the nature of their atmospheres, the conclusions arrived at were necessarily of a highly speculative character. But in recent years great strides have been made in the development of radiometric apparatus, and by the use of thermo-couples in vacuum cells with extremely small receivers and sensitive galvanometers it has been found practicable to measure with considerable accuracy the radiations received from the planetary surfaces, and even, in some cases, from particular parts of those surfaces. In these measurements transmission screens of such materials as water, quartz, glass, fluorite, are interposed in the path of the rays which absorb the radiations in certain parts of the spectrum, and thus enable the total radiation to be resolved into a number of spectral components. For example, when a water cell is employed, the infra-red heat radiations are cut out, and the ratio of the transmitted to the total radiation of the planet provides data for determining the temperature of the planet's surface. It will be clear that if the ratio of transmission through the water cell is large the heat radiated by the planet is small, but that if the transmission ratio is small the proportion of heat rays is comparatively great. The matter is, of course, complicated somewhat by the presence of water vapour in the terrestrial and planetary atmospheres, but the necessary corrections can be estimated, and it is found that the reduction of the observations by various methods such as those based on (1) the distribution of energy in the spectrum, (2) the fourth power law and the measured water cell transmission, as worked out by Menzel and (3) a comparison with observations of the moon, all lead to satisfactorily accordant results.

The conclusions reached are of great interest. Measurements of the heat radiations from Mercury give values which support the conclusion that the planet's periods of rotation and orbital revolution are the same, and that its atmosphere is negligible or nearly so. In the case of Venus a considerable amount of heat is apparently emitted even by the unilluminated surface, which suggests a quick rotation. Observations of Mars at the Lowell observatory in 1922, 1924 and 1926, which are in fair agreement with those made at Mount Wilson, show that despite the planet's distance from the sun the temperature during the day rises well above the freezing point, and exceeds that value even at the polar regions during the summer; that the bright regions are cooler than the dark regions; that the summer hemisphere is warmer than the winter hemisphere; that afternoon temperatures are higher than those of the morning, and that low temperatures are recorded from what appear to be cloud surfaces which check the escape of heat from below. These radiometric results for Mars are consistent with telescopic observations of the surface features—particularly with the melting of the polar caps—and with terrestrial experiences of seasonal and diurnal temperature changes.

As regards Jupiter and Saturn the results obtained have given occasion for some surprise. Physical observations of the surface features of these planets, particularly the former, combined with the known low density, suggest very strong analogies with the sun, and apparently give evidence of considerable stores of heat. Yet the radiometric researches of Coblentz, Lampland and Menzel indicate a temperature of about 100° C for the visible surface of Jupiter and a value slightly higher for that of Saturn. Dr. H. Jeffreys, too, has concluded on theoretical grounds that the temperature of these planets is low. Observers, however, find it difficult to accept the position that the very large and violent disturbances and rapid changes exhibited by Jupiter can have their origin merely in solar radiation, and incline to the view that whatever the superficial temperature there must be a considerable dif-

ference between that at the centre and that of the external parts of the planet's mass. The difficulty might be removed if it can be supposed that the cloudy surfaces of Jupiter and Saturn are composed of substances which have a very low boiling point.

Habitability of the Planets.—It will be clear that the various points above referred to have an important bearing on the question of the suitability of the planets to be the abode of life. Apart from the question of temperature their low density rules out the large planets of the outer group as possible habitations for anything at all resembling human life. It is on the planets of the inner group with their solid surfaces and their proximity to the sun that the requisite conditions must be looked for. Of these planets Mercury, whose periods of axial rotation and orbital revolution are identical, with its scanty atmosphere, its extremely high temperature on the sunlit side and the intense cold of that which is in perpetual night cannot be habitable unless it be in the restricted region near the boundary of the light and dark hemispheres. Of Venus almost nothing is known apart from its resemblance to the earth in volume and mass and its possession of a seemingly cloud-laden atmosphere. About Mars much information has been gathered. Its transparent atmosphere has permitted a study in considerable detail of its surface markings and physical condition with the result that the planet is known despite its small dimensions to exhibit important resemblances to the earth. It may, accordingly, well support some form of animate life, though certain important differences in the conditions prevailing on its surface would seem to preclude its habitation by beings quite like man. More than this can hardly be said, but it may be held probable that on a planet where the required conditions are found life of some sort exists, and that at some period in such a planet's life evolutionary processes may bring its inhabitants to the status of intelligent beings.

See ASTRONOMY and articles under planetary names.

PLANETARIUM is the name given to an arrangement, made by Zeiss of Jena, for producing an artificial sky. By optical methods images of the sun, moon, planets and stars are projected on a large hemispherical dome and by mechanical and electrical means the apparatus can be revolved so as to show the principal motions. The name planetarium is apparently given because of the success with which the apparent motions of the planets amongst the stars can be shown; but the apparatus makes possible the representation of many other astronomical phenomena.

For several centuries orreries have been used to demonstrate the motion of the planets round the sun according to the Copernican system. Perhaps the best arrangement of this kind is in the German Museum at Munich where the observer can be carried in a cage which is moved in a path representing the earth's orbit. By means of a periscope he can look out on the motions of the other planets and at the stars of the zodiacal constellations shown on the wall by means of small electric bulbs. But it is impossible in a model of this nature to make the relative distances correct and thus to get the proper alignment of the various bodies. When this instrument was ordered from Zeiss in 1913 it was suggested that another astronomical model might be made depicting the heavens as actually seen from the earth and it was suggested that the heavenly bodies might be represented by electric bulbs fixed or moving on a rotating dome. This suggestion, however, was soon discarded in favour of another, due to Dr. Bauersfeld, in which the images of the bodies were projected optically on a fixed dome. The resulting apparatus has been a great success. It is found that when a dome soft or more in diameter is used, the appearance is extremely like that of the actual sky. For the stars it is merely necessary to have the projector mounted so that it can be rotated about an axis parallel to the earth's axis. For the sun, moon and planets small models, true to nature, are constructed. The angles between the orbit planes are allowed for and by the use of eccentric circular motion the elliptic motion is quite closely represented. For showing say the planet Venus, the model has pins representing Venus and the earth moving round the sun. A little projector is attached to the pin representing Venus and a linkage between the planets always directs the light away from the earth. Consequently, the image of the planet on the dome

is in the correct position amongst the stars. The gearing is so arranged that the mean motions are accurately represented and only comparatively slight periodic errors affect the positions of the sun, moon and planets. The phases of the moon are shown by an occulting device.

The planetarium can be operated at varying speeds corresponding to the phenomenon to be demonstrated so that even such a slow motion as that of the precession of the equinoxes is within its range. To show the rising and setting of the heavenly bodies a day is compressed into an interval of from 1 to 4 minutes; to show that of the planets the diurnal motion can be put out of gear and a year run off in intervals varying from 7 seconds to 4 minutes. The original model was made for one latitude only, but in later ones, by introducing an additional axis of rotation, the latitude can be altered at will. The stars are shown brighter than they appear in the sky—the eyes of the spectators coming from the daylight would otherwise take too long to be sensitive enough to see them. It is, of course, impossible to make the sun as bright as in nature but this has the advantage of enabling the stars to be seen in the sky along with the sun and thus demonstrate the motion of the sun amongst the stars.

With the planetarium the spectator can see in an hour or so motions which can only be seen in the heavens by years of watching. When a year is compressed into a minute or two the planets can be seen chasing one another about the sky, describing loops, advancing and retrograding, just as they do so slowly in nature. Great attention has been paid to details so as to make the apparatus as perfect as possible; *e.g.*, the brightness of the objects is dimmed as they approach the horizon and the light is practically cut off as the star actually reaches the horizon. The date corresponding to the configuration can be projected on the dome as well as the names of the constellations, and by means of a luminous pointer a lecturer can point out objects of interest. Planetaria have for some time engaged popular interest in a number of German towns. In the United States the first to be erected was the Adler Planetarium at Chicago, but others are now to be found in Los Angeles, Philadelphia, and New York, the last named of which was opened in 1935.

(J. J.N.)

PLANING-MACHINES rank in importance with the lathes and drilling-machines, and cut various kinds of plane surfaces in metal. The principle is that of attaching the metal to a long table which slides truly upon a massive bed, so that by holding a cutting tool in a slide overhead, the material becomes shaved off as the table moves. The width of surface is treated by giving the tool a cross-traverse. The slide moves on a horizontal rail for this purpose, and the rail is adjustable up and down two uprights flanking the bed. Tool-slides are often put on the faces of the uprights as well, so that the sides of the work may be planed. Planing-machines are of value both for big and small articles; they may take one of the former and deal with it singly, or a whole string of small objects can be clamped in line on the table and surfaced off. (See also WOOD-WORKING MACHINERY; MACHINE-TOOLS.)

PLANKTON is the name which is now given to the drifting (and usually microscopic) life contained in the waters of the seas, lakes, ponds and streams. Its study was begun, just prior to 1845, by the great German zoologist, Johannes Müller, in the sea round Heligoland. Associated with Müller, in 1845, were his pupils, Max Muller, Busch, Wilms, Wagener and others. Ernst Haeckel, as a student of 20 years of age, was with J. Müller, at Heligoland, in 1854, and began to study the plankton. "When," said Muller, "you have once entered this pelagic, magic world you will not easily leave it again." Rapid extension of plankton investigation followed, both in Germany and in Great Britain, and the great names associated with this branch of 19th century marine biology are Heinrich Müller, A. Kolliker, C. Gegenbaur, Leuckart, Carl Vogt, T. H. Huxley and McIntosh.

In 1873-76 the "Challenger" made her voyage of circumnavigation and great collections of plankton were made in all the seas of the world. Many other voyages have since been made but there

has been none that did so much work as was carried out during those three years under the direction of Wyville Thomson and John Murray. Another equally great landmark was the "Plankton Expedition" carried out by the "National." Victor Hensen, of the University of Kiel, led this expedition (which worked in the Atlantic ocean) and with him were associated Brandt, Schiitt, Fischer and Kriimmell. All subsequent work on the plankton has been dominated by the methods elaborated by these workers and by the extraordinarily fertile ideas of Hensen, and these methods, with their results, make up the modern science of hydrobiology.

The Plankton in General.—The passively drifting, pelagic life of the sea and of fresh waters consists mainly of microscopic organisms. There are some large plants and animals that are planktonic in their habits: such are the gulf-weed (Sargassum), medusae, siphonophores and other jelly-fishes; some molluscs like the pteropods ("whale-feed"), the pearly nautilus, etc. It is not usual, however, to consider these relatively large plants and animals when we are discussing the plankton: in practice we take the latter to mean the organisms which are, as a rule, invisible to the naked eye, because of their minute size and translucency. Even the most transparent sea water may contain very large numbers of these microscopic organisms and sometimes they are so abundant that the water may be coloured, or turbid, and they may even tint snow and ice. A practical distinction is made between the Macroplankton, which can be caught by filtering the water through very finely woven silk cloth, and the Microplankton, which are so small that they escape through the pores of the finest fabrics that can be employed. Later on we shall consider more fully the methods of collecting the plankton. A further practical distinction, in discussing distribution, is that between the Transitory Plankton and the Permanent Plankton. The former category includes all those organisms which have a brief, pelagic, drifting stage in their life history, after which they develop into actively swimming, large animals (the Nekton), or into rooted or sedentary plants and animals (the Benthos). The latter category includes a multitude of species of organisms which live throughout their lives as planktonic, passively drifting individuals. It is customary to distinguish between Oceanic and Neritic Plankton, the former inhabiting water which is far from land and the latter being practically restricted to the zone of shallow water near the Continental coasts. Then there are many plankton organisms that prefer to live near the surface of the sea and these we call the Epiplankton, while there are others that habitually live in the deeper layers of the ocean: these make up the Bathyp plankton. Finally the different oceans, seas, zones of latitudes, etc., tend to harbour characteristic plankton communities, so that a naturalist who is very familiar with plankton investigations can often say where an unknown sample has been collected.

After this general survey we may now consider the various kinds of organisms that occur in the plankton.

The Transitory Plankton.—A great number of marine organisms "spawn" in the general sense—that is, they discharge their spores, eggs and larvae into the sea, where these things simply drift about while they undergo development. After the latter process is complete the organisms leave the plankton communities, either to settle down on the sea-bottom or to roam about in the sea as freely-locomotory animals. Thus the eggs and larvae of innumerable marine species are transitorily planktonic organisms, finally becoming benthic or nektonic ones. Benthos includes all the organisms that live on or are attached to the sea bottom, while nekton includes those others that are actively locomotory in their habits. (See MARINE BIOLOGY.)

Thus most of the fishes spawn, emitting their eggs and spermatozoa into the sea water, where the processes of fertilization and embryonic development occur. When embryonic development ends the little fish is a larva, and as such it simply drifts about in the sea. Finally its development is completed by a metamorphosis and then it assumes the form and habits which are characteristic of its species. It leaves the plankton and becomes a nektonic animal. Most of the marine Crustacea reproduce in the same way, that is they may directly emit eggs into the sea,

or the parents may, for a time, carry these eggs attached to their bodies, but in most cases the embryos develop into larvae which are always small, practically non-migratory and which finish their development while drifting in the plankton. Many of the Mollusca lay their eggs (enclosed in cases, or cocoons) on the sea bottom, but others emit the eggs and sperms into the water. In all cases, however, the larvae drift about for a time. Just the same general life-history is displayed by most of the worms, the polyzoa and practically all the echinoderms, sponges and coelenterates. The rooted algae liberate their zoospores into the sea on the littoral and shallow-water zones and there these myriads of (even microscopically) tiny organisms drift about and perish.

The wealth of life that is so produced is incredibly great. Even one large cod will spawn annually several millions of eggs, all of which exist for a short time in the plankton, and some of which become larvae and small baby cod. So also with almost every kind of marine animal: its eggs that are spawned every year must generally be counted by the thousands or hundreds of thousands. Yet, on the average, of all the eggs produced by any marine animal only one or two can undergo development and growth up to full reproductive maturity. The remainder, destined to perish in the struggle for existence, have their life-phase for a few weeks or months in the hordes of transiently planktonic organisms.

The Permanent Plankton.—In all parts of the seas and oceans the plankton always contains great numbers of organisms that have this habitat throughout their whole lives. There are many large, permanently planktonic organisms—some algae; many medusae (which are sometimes so numerous as to make a visible, coloured carpet on the surface of the sea); many other coelenterates (such as the Siphonophores and the Ctenophores); some worms; some molluscs like the pearly nautilus, and the Heteropods and Pteropods (the latter may exist in great shoals and form the food of the whalebone whales). These large plankton animals and plants are, however, few and unimportant when compared with the multitudes of the microscopically small animals and plants which abound even in water that appears, to

the naked eye, to be perfectly clear and barren.

Among the Crustacea the little animals called Copepods, Schizopods, Ostracods, Cumacea, with some less abundant groups are always and everywhere present in the plankton and sometimes they are extraordinarily abundant. They live mainly in the upper layers of the sea, but many species are also found in very deep water. Their significance, even for human affairs, is very great for they are the food of such fishes as herrings, pilchards, sprats, hake and other kinds that are regularly caught by the fishermen. Many other marine animals, of course, eat them. They may be so very abundant that sufficiently large numbers to cook and eat may be taken by fine nets drawn through the sea.

Worms belonging to the groups called Polychaetes and Chaetognatha (these are the bristly jointed worms and the translucent "arrow-worms") abound. The only planktonic vertebrate (or rather "chordate") animals are some of the Tunicates, and one kind of these creatures—the salps—may at times be so very abundant in the sea as to clog and sink the drift nets set by the herring fishermen. The Heteropods and Pteropods are the only permanent plankton dwellers belonging to the Mollusca. There are no Echinoderms that are always planktonic but the beautiful larvae of these animals live for a time pelagically. The Coelenterates are, some of them, permanently planktonic (see above), but most of them (the zoophytes, sea anemones, corals, etc.) live on the sea bottom and their larvae appear for a short time only among the plankton. None of the sponges are permanent plankton denizens.

Great numbers of species of unicellular animals and plants are always planktonic: we shall notice the principal kinds very briefly, premising that their full description means writing great books on zoology and botany. Among the Protozoa are the Foraminifera and Radiolaria—the former characterized by their calcareous and the latter by their siliceous skeletons. These animals are microscopic in size (though sometimes big enough just to be discerned by the naked eye). They are found everywhere in the sea and they are so numerous that extensive regions of ocean-floor, at depths of about 2 to 3m., are covered with fine oozes made up almost entirely of the shells of Foraminifera and Radiolaria that

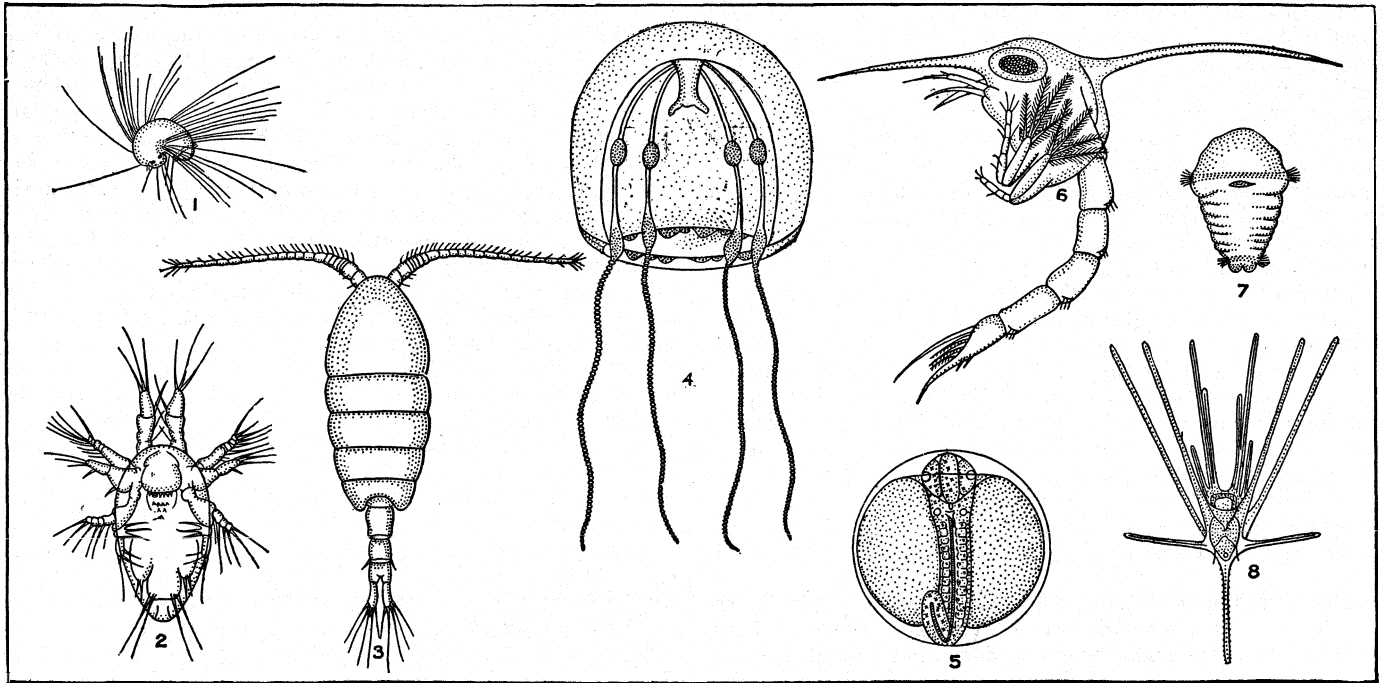

FIG. 2.— VARIOUS LARVAE OF MARINE ANIMALS (HIGHLY MAGNIFIED)

live and die in the upper layers of the ocean. These shells are beautiful and interesting objects when seen under the microscope. Very important from the human point of view are the Peridinians: these are unicellular organisms that can be regarded either as plants or animals and they are about as abundant as the Protozoa that we have already mentioned. They also have very elegant shells made of a kind of cellulose material which is impregnated with silica. Great numbers of Peridinians live in the sand and mud in the very shallow sea bottom near the land, but most of the species are pelagic—that is, they are permanently planktonic. The pelagic Peridinians are important food materials for some fishes—mainly the pilchard (when it is in the sardine stage). These organisms are interesting from another aspect—it is they that mainly cause the phosphorescence of the sea. Sometimes, when the sea is very fiery, an organism called *Noctiluca* is so abundant that the water may be visibly turbid and discoloured.

The Diatoms are to be regarded as unicellular, algal plants, and they are, on the whole, the most abundant of all the planktonic organisms. They have external, transparent, siliceous shells which are elegant in form and are often sculptured with beautiful patterns. They exist everywhere in water—in ponds, lakes, on the mud and sand of the foreshore and sea bottom, attached to weeds, etc.—the main restriction on their presence is the absence of light, for, being green plants, they cannot live except in the presence of solar radiation. There are innumerable species and they are so abundant in the ocean that millions of square miles of bottom, at about 2,000 fathoms in depth (and mainly in the Antarctic) are covered by the dead shells of Diatoms.

The Microplankton.— The above observations apply to the larger planktonic organisms, but there are numerous species which are not captured by using the ordinary "tow nets" (presently we refer to the methods that are employed by the planktologists). These smaller species (the Micro- or Nannoplankton) include many minute Diatoms, Peridinians, shelled and naked Protozoa, Flagellates, unicellular Algae and algal zoospores. There are, of course, hosts of marine bacteria, but these we do not consider in this connection. We shall see that, in point of numbers of individuals, the microplanktonic organisms far exceed the larger forms.

The Seasonal Variations in the Plankton.— Everywhere in the sea and in fresh waters the composition and abundance of the plankton change with the season. To some extent the nature

and sequences of these changes depend on the region which is being investigated and this is particularly the case when we consider the larvae, for the nature and abundance of these will depend on the nature of the local benthic and nektic faunas. If, however, we consider the North Atlantic region the following general descriptions will apply, to some extent, at all events, to most local regions.

The cold and dark months, December to February, are generally periods when the marine plankton is scarce and when the Diatoms and Peridinians, in particular, are relatively few in number. This is because of the feeble intensity of sunlight, which is necessary for the growth and reproduction of these organisms. But sometime about March or April there is a great outburst of life in the sea. Certain indispensable food materials (inorganic nitrogen compounds, silica and phosphate?) have been accumulating during the dark months; in the spring there is a rise in sea temperature and this acts as a stimulus to vital processes, but the main factor is the increase in the length of the day and the growing intensity of sunlight. The result of these changes is that all the vegetable plankton, but particularly the Diatoms, become stimulated to reproduce, so that there is almost an explosive outburst of life in the sea and great swarms of Diatoms invade the shallow sea areas. This is the great event of the year—the "vernal maximum" of vegetable life in the sea.

Immediately following it comes the reproduction of the nektic and benthic animals. Hosts of Fishes, Crustacea, Mollusca, Echinoderms and worms spawn their eggs into the water, or deposit them on the sea bottom. The eggs hatch out and the waters of the sea teem with larvae. The latter must feed and they utilize the vegetable plankton (Diatoms, algal spores, etc.). The production of animal larvae lasts into the early summer (or even later with some species), but while it goes on there is a diminution in the abundance of the Diatoms. Those indispensable food-stuffs which accumulated during the winter months are largely used up while the vernal maximum of vegetable plankton lasts. The extraordinary abundance of Diatoms therefore falls off during the months of June to August, but about then the Peridinians begin to increase. The summer months are characterized then by a relative scarcity of Diatoms, a great increase in the Peridinians, an abundance of larvae belonging to many groups of invertebrates and a great abundance in the Copepods.

In the autumn or early winter the Diatoms sometimes increase

again—there is an autumnal maximum. But this is a very brief phase and with the shortening of the day and the drop in sea temperature towards the annual minimum all kinds of planktonic life in the sea decrease. In this very summary account of the seasonal change stress has been laid on certain physical agencies—light, temperature and inorganic food substances—that are regarded as of importance, but we must never forget that intrinsic causes are also operative. Heredity has implanted, in the organizations of all marine organisms, a cyclical tendency so that the annual outbursts of reproductive activity are stimulated, or set off, so to speak, by the seasonal changes.

The Abundance of the Plankton.—There is no part of the seas and oceans where planktonic organisms do not occur. Even in the greatest depths of the ocean we suspect that certain microcrustacea exist. Under the ice, in polar regions, rich collections may be taken and there are abundant algal organisms in the pools that form in hollows on the surfaces of ice-floes in the summer. Snow and ice may actually be tinted with Diatoms and other organisms. The richest plankton in any part of the world-ocean is that found just on the borders of the polar seas, in the regions of melting ice. In general the temperate and cold seas are rich in plankton, while the tropical and warm waters are relatively poor.

What absolute quantities of plankton-organisms exist in the sea? There is so much variation with regions and seasons that it is difficult to give definite figures without going into great detail. A long series of experimental hauls made in the Irish sea gave a general average of one or two organisms in every cubic centimetre of water, while at the periods of greatest abundance each cubic centimetre contained about a dozen organisms. But this included only the larger planktonic individuals, and it is generally the case that the micro-forms are far more numerous. In some experiments made at Plymouth it was shown that there must have been at least several hundreds of individual organisms (macro- and micro-species) in every cubic centimetre of sea water.

These estimates refer to the numbers of organisms in the sea water at a particular moment, and we ought also to consider the rate at which they reproduce and grow. There is not the knowledge at present which would enable us to make such estimates, but some approximate idea of the total mass of living material that is produced in a sea area can be obtained by indirect methods. We must note, first, that all animal life in the sea depends on vegetable life: the animals can only subsist by eating other animals, or plants, but the plants can use as their source of food-stuff the carbonic acid that is dissolved in the water. Utilizing the energy of sunlight they can synthesize this carbonic acid into cellulose and other vegetable substance. Now it is mainly the Diatoms, Peridinians (and other plankton organisms that have the vegetable mode of nutrition) that do this, for the total mass of all the rooted algae must be very small in comparison with the mass of the vegetable plankton. It is possible, by routine chemical methods, to find out how much carbonic acid is removed from solution in a sea area, during the spring and summer seasons, and then converted into carbohydrate by the activity of the vegetable plankton. The result is very surprising: at least 300,000 kilog. of dry organic carbohydrate must be produced during a single season per square kilometre of sea surface. Or, expressed in more familiar terms, a spring and summer of organic production in the sea gives origin to about ten tons of moist vegetable substance per acre of sea. This is the marine harvest due to the activity of the vegetable plankton: at present man reaps only a very small fraction of it in the shape of the fishes and other edible animals that he catches.

Methods of Studying Plankton.—A veritable wonderland awaits the amateur naturalist who can spend a short time at the seaside during the spring months. He will require a student's microscope (magnifying 50 to 500 diameters) and some cheap, home-made apparatus. The net is simply a conical bag of the finest and strongest muslin obtainable: it is about 1 to 1½ ft. in diameter and about 4 ft. long. Its mouth consists of an iron ring, to which a selvage of strong canvas is laced. The net is sewn on to this canvas edging. It is towed in the sea behind a rowing

boat for about half an hour.

When the net is hauled it is drained of water and turned outside in. The pointed end is then rinsed in sea water contained in a 2 lb. glass jam jar. A small sieve is made by loosely tacking a piece of muslin on a square wooden frame about 4 in. along each side. The water containing the catch is then slowly poured through the central part of the sieve. Then the latter is turned upside down and the plankton is washed off into a little sea water in the bottom of a saucer. This will now be a thick, greenish turbid mass. A dipping tube is made (like a fountain pen filler, but with a wider opening) and some of the plankton is lifted with this and put into a watch glass, which is then examined under the microscope. Examined day by day the spring and summer plankton is full of the most beautiful things.

Nets contrived to fish quantitatively are also used. In such investigations fine miller's silk bolting cloth is used. This has meshes of over 100 to the inch. Heaps of organisms escape through this net. To catch the very minute plankton the water must be centrifuged, or cultures are made in an analogous way to those employed by bacteriologists. Elaborate methods have been evolved for counting organisms taken in a plankton catch.

BIBLIOGRAPHY.—There is a huge literature on plankton but many papers are cited, and their source stated, in *The Marine Plankton*, by Johnstone, Scott and Chadwick (Liverpool, 1924). (J. A. J.)

PLANTAGENET, a surname conveniently, but unhistorically, applied to the royal line descended from the union of Geoffrey, count of Anjou, with the empress Maud, who are now styled by historians the Angevin house. It was, historically, only a personal nickname of Geoffrey, as was "Curtmantel" of his son (Henry II), and was derived from his wearing in his cap a sprig of the broom (genet) plant. When the fashion of personal nicknames passed away, the members of the royal house were usually named from their birthplace, as Thomas "of Brotherton," Thomas "of Woodstock," and so forth. But Edward I and his younger brother, the founder of the house of Lancaster, had still nicknames respectively, as "Longshanks" and "Crouchback." In the later days of the dynasty the surname of Beaufort was adopted by the legitimated issue of John of Gaunt by Katherine Swynford, but that of Plantagenet was bestowed on Arthur, natural son of Edward IV, who was created Viscount L'Isle. It appears, however, to have been adopted as a surname by Richard duke of York (father of Edward IV) some 12 years before his death.

At the death of Geoffrey's grandson, Richard I, his younger brother John succeeded. John's younger son Richard, king of the Romans, left a son Edmund, earl of Cornwall, with whom his line ended; his elder son Henry III left two sons of whom the younger was created earl of Lancaster and was grandfather of Henry, earl of Lancaster, whose heiress married John of Gaunt (*i.e.*, Ghent). (*See* LANCASTER, HOUSE OF.) John of Gaunt's next brother, Edmund of Langley, founded the Yorkist line. (*See* YORK, HOUSE OF.) Although no other dynasty has reigned so long over England since the Norman Conquest, the whole legitimate male issue of Count Geoffrey Plantagenet became extinct in 1499. *See* Genealogical Tables, Vol. 8, p. 8.

PLANTAGINACEAE, a family of dicotyledonous herbs, the best known members of which are the plantains (*Plantago*), cosmopolitan weeds, of which five species occur in Great Britain and upwards of 30 in the United States. (*See* PLANTAIN.) The family contains three genera and about 260 species. The seeds of *Plantago psyllium* (Mediterranean) are used in silk and cotton manufacture. The flowers, usually hermaphrodite and inconspicuous, are wind-pollinated. For a monographic treatment see R. Pilger. "Plantaginaceae," *Pflanzenreich* 102 (iv, 269): 1-466, f. 1-44 (1937).

PLANTAIN, a name given to certain plants with broad leaves. This is the case with certain species of *Plantago*, *Alisma* and *Musa*, to all of which the term is popularly applied. The species of *Plantago* (family Plantaginaceae) are mostly weeds with a dense tuft of radical leaves and scapes bearing terminal spikes of small flowers; the long spikes of *P. major*, when in seed, are used for feeding cage-birds; *P. lanceolata*, so called from its narrow lanceolate 3-6-ribbed leaves, is popularly known as ribwort.

P. psyllium and *P. indica* produce leaves in whorls on branched stems; their mucilaginous seeds are used as demulcents under the name of Psyllium. *Alisma plantago-aquatica* (family Alismataceae) is the waterplantain. The tropical fruit known as plantain belongs to the genus *Musa*. (See BANANA.)

PLANTAIN-EATER: see TOURACOU.

PLANTATION, literally the placing of plants in the ground, hence a place planted or a collection of growing things, particularly used of ground planted with young trees. The term was early applied, in a figurative sense, to the settlement of people, and particularly to the colonization of North America in the early part of the 17th century and to the settlement of Scottish and English in the forfeited lands in Ireland. The practice of sending convicted criminals to serve on the plantations in the colonies became common in the 17th century (see DEPORTATION). For "plantation songs" see NEGRO, THE AMERICAN.

PLANT BREEDING. Modern scientific improvement of plants necessitates an understanding of the principles of genetics (science of heredity) and utilizes the integrated techniques of selection, hybridization, inbreeding and mutation. To this should be added the art of breeding, a combination of keen observational powers and the skill to deal wisely with immense numbers of experimental plants. Ordinarily the objectives of the breeder are improvements in yielding capacity, resistance to disease (bacterial, fungal, virus or insect), quality and uniformity of crop, lodging resistance, chemical characters (per cent protein, oil, carbohydrates, vitamins), nutritive values, hardiness, and season of maturity (earliness or lateness).

Techniques.— Selection of plants best adapted to the objective is a powerful tool. Two major forms are known as mass and pedigree selection. The former implies the continued selection of the better plants (seeds, fruits, ears) as progenitors in each generation. Seeds from the selections are bulked or massed and planted each season. Pedigree selection relies on the progeny of selected plants as a direct performance test, the progeny being grown in pedigreed rows or plots, each from a single mother plant. Hybridization, or the crossing of strains or varieties (rarely species or genera) is used to increase variability, particularly for new combinations of hereditary characters. Hybridization followed by selection is responsible for many varieties of plants. Inbreeding or self-fertilization methods serve to fix desirable hereditary qualities in distinct lines. Ordinarily, inbreeding leads to some deterioration, but this may be overcome by proper hybridization. Mutations or sports, both natural and artificial (induced by X-rays, radium, heat or chemicals), play an important role in some species. Mutations are changes in genes (hereditary units located in chromosomes) or in the number of chromosomes themselves. Superimposed on these four agents is a wise and proper use of field-plot techniques with adequate replication of the test strains to correct for soil heterogeneity and climatic variations. Proper statistical analysis is often essential for detecting the most efficient strains.

Mode of Reproduction.—The exact utilization of these techniques in plant improvement depends upon the type of natural reproduction, of which there are three main kinds: (1) Asexual or vegetative reproduction by tubers, cuttings, budding or grafting; (2) Self-fertilizing species, as wheat, barley, oats, rice, beans, tobacco, tomato; and (3) Cross-fertilizing species, as maize, rye, many grasses, sugar beets, certain clovers, hemp, hops, cucurbits.

Asexually Reproduced Species.—These are bred by a large scale selection of existing variations; sometimes by an enforced crossing to provide new combinations for future selection (sugar cane, potato and many garden flowers); and less frequently by use of bud-sports or mutations (citrus fruits, pineapple, potato, apple). Progeny of an asexually reproduced plant is termed a clone. Most older varieties of potatoes, apples and sugar cane arose from chance seedlings of hybrid origin possessing great hybrid vigour which reproduces itself in future clones. Modern potato improvement includes hybridization to obtain better stocks, resistant to virus, scab and late blight. Many apple varieties trace to bud mutations, largely towards an increase in red colour. Numerous commercial strains of the Delicious, Rome Beauty,

Winesap and McIntosh varieties arose as colour mutations. Variety crossing of apples to produce hardy, disease-resistant strains was responsible for many newly named varieties.

Similar techniques are successful with sugar cane. The "nobilitization" method used by the Dutch in Java consists of crossing and back-crossing hardy, inferior varieties by high-quality "noble" varieties to give a high sugar percentage combined with disease resistance, particularly to virus epidemics. Citrus varieties are produced from bud mutations, and interesting new forms by species crosses (tangelo = grapefruit X tangerine). Mutant strains of the Washington navel orange and Eureka and Lisbon lemons are grown commercially.

Self-Fertilizing Species.—Naturally self-fertilized species have been largely improved by pedigree or pure-line selection. Most of the older varieties of wheat, oats, barley, cotton, beans and tomatoes have so arisen. However, as the ceiling of remaining variation is reached by selection, hybridization of pure lines is resorted to for further improvement. The pure-line method of breeding is based on the genetic principle that the progeny of an individual plant selection in naturally self-pollinated species breeds true. The problem then is one of isolating the superior pure lines and increasing seed stocks of these. The varieties Kanred wheat, Fulghum oats, Atlas barley, Bison flax, Robust beans, Pima cotton and Manchu soybeans were all developed by this method. Examples of varieties developed by hybridization followed by pure-line selection are Federation, Marquis, Hope and Thatcher wheats, Wisconsin Pedigree 38 barley, Calady rice, Marglobe tomato, and Surprise pea.

Cross-Fertilizing Species.—Naturally cross-fertilized species are more difficult to handle, because any inbreeding necessary to fix desirable characters often leads to a decline in vigour. Accordingly two alternatives are possible. One is to use continuous mass selection broadly, avoiding inbreeding. This is a slow but sound method, similar to that used in livestock breeding. The second is the combination of inbreeding and controlled hybridization to utilize the phenomenon of hybrid vigour, technically known as heterosis. This approach revolutionized plant improvement in maize. It afforded an unusually striking example of the value of pure research to practical agriculture.

Hybrid Maize.—The hybrid corn industry in the U.S.A. traces to the scientific, genetical research of G. H. Shull and E. M. East, who reported their results of inbreeding followed by hybridization in 1907-10. But it was not until the 1920s that the real breeding program was underway. Phenomenal increases in uniformity, yield and resistance to lodging and disease, resulting in consistent increases in yield of 20-30% over those of the best varieties, with acre yields of 100-150 bu. of seed corn per acre, became possible. By 1933, only 0.4% of the corn acreage in the state of Iowa (U.S.A.) was devoted to hybrid corn, whereas in 1942 the percentage was 99 on the 10,000,000 corn acres. Average state yields in the decade 1933-42 rose from 39 to 52 bu. per acre. Certainly more than half of this remarkable increase may be attributed to the new breeding method.

The bases for hybrid corn are the self-pollinated or highly inbred lines. Usually 5 to 8 generations of inbreeding are necessary to isolate a true breeding line. Good lines with a high yield prepotency are very rare, not more than 60 having been isolated to 1940, despite the tremendous numbers tested. These inbreds are crossed, usually by detasseling the mother rows, in various combinations to make the (1) single cross, hybrid of two inbred lines, (2) three-way cross, hybrid of single cross by a third inbred (3) double cross, hybrid of two different single crosses ($[A \times B] \times [C \times D]$), (4) multiple or synthetic cross, hybrids of 5 or more inbreds, and (5) top cross or variety-inbred cross, hybrid of a variety by one prepotent inbred, usually as the sire. Most commercial field corn is produced from the double cross. Sweet corn growers favour the single cross because of its greater uniformity. Seed from the commercial crop is not saved by the grower for seed stock of the following year, but new seed is purchased each year from expert corn breeders. This necessitates some form of state control, certification and careful pedigree methods to insure purity of foundation stocks,

Trends in Plant Breedin%.—Modern developments of the decade 1932-42 may be illustrated by the following examples.

Forest tree breeding, largely by hybridization, for rapidity of tree growth (wood pulp, matchwood), for wood fibre length and for resistance to fungus and insect ravages, has shown encouraging prospects. Poplar hybrids have been developed which possess remarkable hybrid vigour. Improvements of nut-tree crops by hybridization in almond, filbert, hickory, pecan, walnut and tung species, and in the chestnut for resistance to chestnut blight, have been crowned with success.

Improvement of forage crops (alfalfa, red clover, sweetclover, lespedeza, vetch and hundreds of grass species) by modern breeding methods has received a powerful stimulus under the new agriculture based on a permanent soil conservation plan. With the newer techniques of hybridization and chromosome doubling, a renaissance in breeding of flowering and ornamental plants has emerged. Amateur as well as professional growers have been responsible for an exceedingly large array of rose, tulip, dahlia, iris, narcissus, gladiolus, peony, chrysanthemum, aster and sweet pea varieties.

Constant changes in international trade have necessitated more dependable domestic sources of certain crops like cotton. New approaches in cotton breeding for greater staple length, for new types adapted to mechanical harvesting methods and for increase in oil content of cottonseed, were afforded by successful hybridization of the Asiatic, 13-chromosome species by the American, 26-chromosome species in 1932. Varietal hybridization, however, has been responsible for the source of the best cotton varieties.

Breeding of bacteria and fungi for increased efficiency in fermentation processes has passed the experimental stage and has entered the industrial field. Bacterial strains of *Aerobacter aerogenes* differ greatly in ability to ferment sugars into 2, 3-butylene glycol, an intermediate stage in the production of synthetic rubber. Fungus strains of *Aspergillus niger* show striking differences in fermentation of citric acid from sugar or molasses. Improvements in fermentation efficiency of bacteria and fungi are based on the selection of mutations. Beginning in 1935 with work in Denmark, better strains of yeast were produced by hybridizing different species and varieties. Some of the resulting hybrids exhibited the well-known hybrid vigour effect and were successfully used in industry. Baking-yeast, beer-yeast, and wine-yeast became promising forms for such experimental procedures.

Artificial stimulation of mutations by X-ray, chemical or heat treatments, and artificial induction of polyploidy (increase in chromosome number) by colchicine to give giant, tetraploid (4n) forms are techniques which opened up new horizons in plant improvement. This is particularly true for species reproducing asexually, such as most fruits and many ornamental species.

Breeding for disease resistance against the attacks of old and new pathogens remains a major concern of the plant breeder. As more resistance is bred into varieties, more highly virulent forms of bacteria, fungi and viruses emerge which in turn must be combated.

Plant Breeding Institutes.—Some well-known centres for plant breeding are: Australia—department of agriculture, Sydney; Brazil—Instituto Agrônomico do Estado de São Paulo, Campinas; Canada—Dominion experimental farm, Ottawa; England—University of Cambridge, school of agriculture, Cambridge, and Welsh plant breeding station, Aberystwyth; Germany—Kaiser Wilhelm Institut für Züchtungsforschung, Müncheberg; India—Imperial institute of agricultural research, Delhi; U.S.S.R.—plant breeding experimental station, Moscow, and institute of applied botany, Leningrad; Sweden—Sveriges Utsädesforening, Svalof; United States—U.S. department of agriculture, Washington; regional laboratories at State College, Pa. and Charleston, S.C., and state experiment stations with well equipped laboratories and experimental plots (California, Connecticut, Illinois, Indiana, Iowa, Minnesota, Missouri, New York, Ohio, Wisconsin).

PLANTIN, CHRISTOPHE (1514-1589), French printer, was born in a village near Tours (probably Saint-Avertin). He learned bookbinding and bookselling at Caen, and, having married in that town, settled in 1549 as bookbinder in Antwerp, where he was soon known as the first in his profession. A bad wound in the arm seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was La *Institutione di una fanciulla nata nobilmente*, by J. M. Bruto, with a French translation, and this was soon followed by many other works in French and Latin, which in point of execution rivalled the best printing of his time, while the masters in the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562, Plantin himself being absent in Paris, his workmen printed an heretical pamphlet, which caused his movables to be seized and sold. It seems, however, that he recovered a great deal of the money, and in 1563 he associated himself with some friends to carry on his business. Among them were two grandnephews of Dan. Bomberg, who furnished him with the latter's fine Hebrew types. Christophe produced editions of the Bible in Hebrew, Latin and Dutch, a *Corpus juris* and Latin and Greek classics.

A much greater enterprise was planned by him in those years—the publication of a Biblia polyglotta, which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II king of Spain, who sent him the learned Benedictus Arias Montanus to superintend the work. It was finished in five years (1569-73, 8 vols. folio). Plantin earned little profit, but received the privilege of printing all liturgical books for the states of King Philip, and the office of "prototypographus regius." Though outwardly a faithful son of the church, he was till his death the partisan of a mystical sect of heretics.

Besides the polyglot Bible, Plantin published in those years editions of St. Augustine and St. Jerome, the botanical works of Dodonaeus, Clusius and Lobelius, the description of the Netherlands by Guicciardini, etc. In 1575 his printing-office reckoned more than 20 presses and 73 workmen, besides a similar number that worked for the office at home. But in Nov. 1576 the town was plundered and in part burned by the Spaniards, and Plantin had to pay an exorbitant ransom. He established a branch of his office in Paris; and when in 1583 the states of Holland sought a typographer for the newly erected university at Leyden, he left his much reduced business in Antwerp to his sons-in-law John Moerentorf (Moretus) and Francis van Ravelinghen (Raphelengius), and settled there. When in 1585 Antwerp was taken by the prince of Parma and affairs there became more settled, he left the office in Leyden to Raphelengius and returned to Antwerp, where he worked till his death on July 1, 1589. His son-in-law, John Moretus, and his descendants continued to print many works of note "in officina Plantiniana," but from the second half of the 17th century the house began to decline. It continued, however, in the possession of the Moretus family, which religiously left everything in the office untouched, and when in 1876 the town of Antwerp acquired the old buildings with all their contents, for 1,200,000 francs, the authorities created one of the most remarkable museums of its kind in existence, the Musée Plantin, opened Aug. 19, 1877.
