Measurement of Internal Dimensions.— The method of transference from external to internal measurement constituted a considerable difficulty, and the sizes of such objects as ring gauges, either plain or screwed, were usually estimated by the nature of their fit upon corresponding plug gauges. As the fit depends to a very marked extent upon the amount and nature of the lubricant used, considerable uncertainty existed as to the correct interpretation of the observed results. If well finished and liberally lubricated with thick grease, a cylindrical plug gauge will enter and pass through a ring gauge definitely smaller than itself without damage to either. Two instruments have now been produced for the measurement of internal diameters of either plain or screwed rings, which give results mutually consistent, if due care is taken, and the work being measured is sufficiently uniform in its dimensions, to the order of 0·00001 inch.

In the *chord contact* machine, due to G. A. Tomlinson, the diameter of the ring is deduced by calculation from the measured displacement, in a direction perpendicular to its length, of a double ball-ended distance piece of known length, which is allowed to make contact inside the ring, first on one side, and then on the other side of the diameter.

In the *displacement* type of internal measuring machine, due to J. E. Sears, the position of the ring is so adjusted that measurements are made exactly across the diameter. The ring is mounted on a carriage, which can be moved bodily in the direction of the diameter being measured by means of suitable micrometers. Contact is made first on one side of the ring, and then on the other, with a double-ended stylus attached to a sensitive indicating mechanism, and the micrometer readings are taken when the indicator reads zero. The same is done in turn with a standard plug substituted for the ring, provision being made for withdrawing the stylus temporarily as the plug passes across. If $x_1\ y_1\ x_2\ y_2$ are the four micrometer readings, the displacements d_1 and d_2 are equal to x_2-x_1 and y_1-y_2 respectively, and it is to be noticed that the pressure on the stylus is in the same direction when both x readings are taken, and also when both y readings are taken, so that any possible errors due to backlash or flexure in the indicating mechanism are eliminated. The transition from external to internal measurement is thus directly accomplished, and the final result is given by the equation

$$\mathrm{R}=d_1+d_2-\mathrm{P}=(x_2-x_1)+(y_1-y_2)-\mathrm{P}$$

where R and P are the diameters of the ring and plug, respectively.

MODERN PRACTICE

Scientific Principles. — The question of the general geometrical principles underlying the correct design of instruments intended to give the highest accuracy of measurement has received greater attention in recent years. Questions of the proper application of the theory of kinematic constraint to ensure definite and repeatable registration of parts, of eliminating backlash and friction effects, of preventing components of errors due to inevitable imperfections of workmanship (*e.g.*, in sliding ways) from becoming effective in the actual direction of measurement, of the design and relationing of parts so that elastic deformations due to changing distributions of load do not affect the results, and so on, are all involved here.

These various points have been fully considered in the travelling *microscope comparator* designed by J. E. Sears, jun., for the Metrology Department of the National Physical Laboratory. The long leg of an L-shaped carriage, which bears two microscopes, is supported on two wheels running in a V-guide along the upper side of the machine bed, so that whatever position is taken up by the carriage its form is undisturbed. The focal points of the two microscopes are arranged to lie in the extension of the axis of the micrometer screw, and the object to be measured is supported on an independent carriage which, by means of a small weight attached to a cord passing over a pulley, is held permanently in contact with a stud at the end of the screw abutment. Thus errors of straightness in the V-groove are non-effective, and so is any distortion of the base of the machine proper, due to the movement of the microscope carriage. Advantage is taken of the simple ratio 1 in. = 25·4 mm. (which is correct to within 2 parts in 1,000,000) to obtain simultaneous readings of equal accuracy in either British or the metric system, by means of suitable gearing in the compound micrometer head. The verniers read to 0·00001 in. and 0·0001 mm. respectively. The instrument can be used either with one microscope for making direct measurements against its own calibrated micrometer screw, or, using the two microscopes as a comparator, for determining the values of the sub-divisions of short scales.

Screw Gauges and Projection Gauges. — In the course of the War the necessity for rapid measurement of large numbers of screw gauges led to the development of special machines for the measurement of both pitch and effective diameter of screw threads. E. M. Eden, then of the National Physical Laboratory, was largely instrumental in this work and in the development of the optical projection method of examining profiles of gauges, both screws and flat templets. For the latter, he found lens combinations capable of giving an undistorted magnification of 50 times over a field of initial diameter approaching two inches. These combinations were incorporated in the now well-known "horizontal projector." For screw gauges the "vertical projector" was designed, in which the path of the light is vertical, and the image-forming rays are reflected back from an optically flat mirror overhead on to a specially prepared thread-form diagram placed on the table of the machine. The screw in this case is mounted in a carriage provided with two horizontal micrometer traverses in directions parallel and perpendicular to its axis, respectively, so that measurements of pitch and diameter can be made at the same time as the accuracy of the thread form is examined. Mention should also be made of the *Wilson* projection *gauge,* in which the optical system is duplicated, so that the two opposite sides of a screw can be projected simultaneously on to the screen, in such a manner that the two images of the thread intermesh, and if the screw is of direct form and size, and the apparatus correctly adjusted, exactly meet. If the screw is small a space is left between the images of its two sides; if large they overlap.

The projection method has naturally proved of great value in a number of other ways. In particular, it has been used in connection with the measurement of gear wheels and gear cutting hobs. Machines for this purpose have been designed by G. A. Tomlinson, and depend for their use on the accurate reproduction of the profiles of the teeth of the gear or hob, in the form of traces made on smoked glass, by a needle point attached to a specially designed pantograph. One of the machines is also fitted with a device for recording, in a similar manner, the relative velocities of rotation of two gear wheels when in mesh. In both cases the smoked glass, bearing the record, is put into the projection apparatus and magnified 50 times at the screen. It is found that the traces are quite sharp in the magnified image, and measurements can be made corresponding to an accuracy of about 0·0001 or 0·0002 inch on the original.

PREDESTINATION, as a theological term is used in three senses: (1) God's unchangeable decision from eternity of all that is to be; (2) God's destination of men to everlasting happiness or misery; (3) God's appointment unto life or "election" (the appointment unto death being called "reprobation." and the term "foreordination" being preferred to "predestination" in regard to it). In the first sense the conception is similar to that of fate; this assumes a moral character as nemesis, or the inevitable penalty of transgression. Sophocles represents man's life as woven with a "shuttle of adamant" (Antigone, 622–624). Stoicism formulated a doctrine of providence or necessity. Epicurus denied a divine superintendence of human affairs. A powerful influence in Scandinavian religion was exercised by the belief in "the *nornir*, or Fates, usually thought of as three sisters." In Brahmanic thought Karma, the consequences of action, necessitates rebirth in a lower or higher mode of existence, according to guilt or merit. With some modifications this conception is taken over by Buddhism. The Chinese tao, the order of heaven, which should be the order for earth as well, may also be compared. According to Josephus (Antiq. xviii. 1, 3, 4; xiii. 5, 9) the Sadducees denied fate altogether, and placed good and evil wholly in man's choice; the Pharisees, while recognizing man's freedom, laid emphasis on fate; the Essenes insisted on an absolute fate. This statement is exposed to the suspicion of attempting to assimilate the Jewish sects to the Greek schools. In Islam the orthodox theology teaches an absolute predestination, and yet some teachers hold men responsible for the moral character of their acts. The freethinking school of the Mo'tazilites insisted that the righteousness of God in rewarding or punishing men for their actions could be vindicated only by the recognition of human freedom.

The question of the relation of divine and human wiii has been the subject of two controversies in the Christian Church, the Augustinian-Pelagian and the Calvinistic-Arminian. Pelagius maintained the free-will of man and regarded grace as only an aid to freedom. Augustine held that God's grace alone is effectual and irresistible; He chooses whom He will have (election) and whom He will leave to perish (reprobation or praeterition).

At the Reformation the Augustinian position was accepted by both Luther and Calvin. Melanchthon modified his earlier view in the direction of synergism, the theory of a co-operation of divine grace and human freedom. Calvin wavered between the *supralapsarian* view that the fall was decreed in order to give effect to the previous decree of election and reprobation, and the *sublapsarian* of a "permissive decree—a volitive permission." This view repelled Arminius. According to Calvinism God's election unto salvation is absolute, determined by His own inscrutable will; according to Arminianism it is conditional, dependent on man's use of grace. The Synod of Dort (1618–1619) which affirmed the sublapsarian without excluding the supralapsarian form of Calvinism, condemned the views of Arminius and his followers, who were known as Remonstrants from the remonstrance "which in four articles repudiates supralapsarianism and infralapsarianism (which regarded the Fall as foreseen, but not decreed), and the doctrines of irresistibility of grace, and of the impossibility of the elect finally falling away from it, and boldly asserts the universality of grace."

In the Church of Rome the Dominicans favoured Augustinianism, the Jesuits Semi-Pelagianism; the work of Molina on the agreement of free-will with the gifts of grace provoked a controversy, which the Pope silenced without deciding; but it broke out again a generation later when Jansen tried to revive the decaying Augustinianism. The Church of England has passed through several disputes regarding the question whether the Thirty-Nine Articles are Calvinistic or not; while there is some ambigmty in the language, it seems to favour Calvinism. At the Evangelical Revival the old questions came up, as Wesley favoured Arminianism and George Whitefield Calvinism. In Scotland Calvinism was repudiated by James Morison, the founder of the Evangelical Union, who declared the three universalities, God's love for all, Christ's death for all, the Holy Spirit's working for all.

While retained in the creeds of several denominations, in the public teaching of the churches the doctrine of predestination is less emphasized. The problem is the reconciliation of human freedom with divine foreknowledge. It has been argued that, if God allows His activity to be limited by human freedom, He may also so limit His foreknowledge as to know free acts as possible and not as actual.

PREDICABLES, in logic, are the main types of predicates, or the principal ways in which the predicate of a proposition can be related to its subject. The oldest known doctrine of predicables is that of Aristotle, but the one that had, and still has, the greatest vogue is that of Porphyry, which is not essentially different from that of Aristotle. According to Porphyry there are five predicables, namely, genus, species, differentia, *proprium,* accident. These five predicables are obtained as follows. When a predicate is affirmed of a subject it must either express something that is essential to the subject (that is, something in the absence of which the subject would not be called by that name) or not. If the predicate is not essential to the subject it is described as an accident. *E.g.,* "Many Prime Ministers of England are Scotsmen" (or "Oxford men," or "wealthy," etc.); but they need not be. If the predicate is essential, then there are four possibilities. The predicate may state the including class in which the subject is included—*e.g.,* "Prime Ministers are Cabinet Ministers" (or "Rectangles are parallelograms," etc.). In this case the predicate is described as a genus of the subject; and the subject (if a class-name) is called a species of the predicate. The predicate is called a species in relation to the subject, if the subject is a singular term and the predicate represents this class (*e.g.,* "Mr. Kellogg is a statesman"), or if the subject is a class-name restricted by "Some" and the predicate denotes an included class (*e.g.,* "Some members of Parliament are Cabinet Ministers," or "Some rectangles are squares"). Again the predicate may assert of the subject some character, or group of characteristics, which distinguishes (or differentiates) one species of a genus from the other species (*e.g.,* "Squares are equilateral," whereas other rectangles are not). In this case the predicate is called a differentia (or "difference") of the subject term. Lastly, the predicate may assert of the subject something essential, but different from either its genus or *differentia,* though derivable from these (*e.g.,* "Equilateral triangles and equiangular"). In this case it is called a *proprium* (or "property") of the subject. The predicables are applicable readily enough to ideal objects like those of geometry, but cannot be applied very satisfactorily or usefully to empirical objects. Although they mark distinctions which are very important and useful in connection with many ordinary problems, they play no very important part in modern science, which needs more precise and more numerous distinctions than they mark. See LOGIC, HISTORY OF.

PREECE, SIR WILLIAM HENRY (1834–1913), British electrical engineer, was born in Wales on Feb. 15, 1834, and educated at King's College, London. He became a civil engineer, but in 1853 joined the Electric and International Telegraph Co. In 1869 he returned to the civil service, and in 1877 was appointed electrician to the Post Office, in 1899 engineer-in-chief, and, after his retirement, consulting engineer. He was a pioneer of wireless telegraphy (*see* TELEGRAPH; *Part II.,* Wireless Telegraphy). He died at Penrhos, Carnarvon, on Nov. 6, 1913.

PRE-ESTABLISHED HARMONY, in philosophy, denotes the relationship between body and mind as conceived by Leibnitz. According to the interaction theory body and mind act upon each other, so that the body does what the mind wants done, and the mind is affected by the condition of the body. Cartesian dualism excluded the possibility of such interaction, by its conception of an absolute difference and opposition between mental and material substances. To account for the appearance of such interaction some of the Cartesians introduced the theory of "occasionalism," namely, that the mind does not influence the body nor *vice versa,* but that on every occasion that anything happens to the one, God produces a certain change in the other. This implied God's constant interference with everything. Leibnitz suggested that body and mind have been harmonized by God once for all, so that their changes correspond or synchronize without either influencing the other, and without needing God's incessant intervention. He compares the relation between body and mind to that between two clocks which have been synchronized once for all. and so keep step without mutual interaction and without the constant intervention of anybody. This is the theory of pre-established harmony, which Leibnitz applied to his system of monads. For Leibnitz reality consists of monads or spirits of different degrees of development. Their active side is their spiritual side, and matter is simply the appearance of their passivity or deficiency. As their activity is entirely immanent, the monads do not interact (they "have no windows"), but there is a pre-established harmony between them inasmuch as they all mirror the same universe, though each "from its own point of view." *See* LEIBNITZ.

PRE-EXISTENCE, DOCTRINE OF, in theology, the doctrine that Jesus Christ had a human soul which existed before the creation of the world — the first and most perfect of created things — and subsisted, prior to His human birth, in union with the Second Person of the Godhead. It was this human soul which suffered the pain and sorrow described in the Gospels. The chief exposition of this doctrine is that of Dr. Watts *(Works,* v. 274, etc.) ; it has received little support. In a wider form the doctrine has been applied to men in general — namely, that in the beginning of Creation God created the souls of all men, which were subsequently as a punishment for ill-doing incarnated in physical bodies till discipline should render them fit for spiritual existence. Supporters of this doctrine, the Pre-existants or Pre-existiani, are found as early as the 2nd century, among them being Justin Martyr and Origen (*q.v.*), and the idea not only belongs to metempsychosis and mysticism generally, but is widely prevalent in Oriental thought. It was condemned by the Council of Constantinople in 540, but has frequently reappeared in modern thought *(cf.* Wordsworth's *Intimations of Immortality)* being in fact the natural correlative of a belief in immortality.

PREFECT, in France, the title of a high official (*préfet*). The prefects of the department were created by a law of the 28th Pluviose in the year VIII. (Feb. 17, 1800). They were intended to be the chief officers of internal administration, and have, in fact, discharged this function, especially under the First and Second Empire, surviving, under the other forms of government which modern France has seen.

The prefect has a double character and two series of functions. First, he is the general representative of the Government, whose duty it is to ensure execution of the Government's decisions, the exercise of the law, and the regular working of all branches of the public service in the department. Thus far the rôle of the prefect is essentially political; he guarantees the direct and legal action of the Government in his department. He has the supervision of all the State services in his department, which procures the necessary uniformity in the working of the services, each of which is specialized within a narrow sphere. He serves as a local source of information to the Government, and transmits to it representations from those under his administration.

In the name of the State he exercises a certain administrative control over the local authorities, such as the *conseil ge'ne'ral,* the mayors, and the municipal councils. This control, though considerably restricted by the laws of Aug. 10, 1871, and April 5, 1884, still holds good in some important respects. The prefect can still annul certain decisions of the *conseil ge'ne'ral.* He can suspend for a month a municipal council, mayor, or deputy-mayor; certain decisions of the municipal councils require his approval; and he may annul such of their regulations as are *extra vires.* He can annul or suspend the *maire's* decrees and he has also considerable control over public institutions, charitable and otherwise. He may make regulations both on special points and for the general administration of the police.

Secondly, the prefect is not only the general representative of the Government, but the representative of the department in the management of its local interests. But his unfettered powers in this respect were reduced under the Third Republic, chiefly by the law of Aug. 10, 1871, which led to decentralization, by increasing the powers of the *conseils généraux.*

The *sous-préfets,* having very limited powers of deciding questions, serve as intermediaries between the prefect and the persons under his administration. This function was most useful in the year VIII., when communications were difficult, even within a department. At the present time their chief service to the administration lies in keeping up good relations with the *maires* of the communes in their *arrondissement,* and thus acquiring a certain amount of influence over them.

The National Assembly of 1871 proposed to suppress the *sous-préfets,* but the president, M. Thiers, persuaded them to reconsider their decision. The question has been raised from time to time, since that date, in the Chamber of Deputies, and finally, by the decree of Sept. 6, 1926, the *Conseils de Préfecture* were suppressed and the *Conseils de Préfecture interdépartementaux* created. The suppression of a certain number of the *sous-préfectures* was effected by the decree of Sept. 10, 1926.

See *Journal Officiel,* Sept. 9, 14, and 30, 1926, and June 3, 1927.

PREFERENCE, IMPERIAL: *see* IMPERIAL PREFERENCE.

PREFERENCE SHARES. In a joint-stock company, the name given to shares entitled to a dividend at a fixed rate before any dividend is paid on other shares. If the arrears of preference dividend have to be paid before any profits are divided amongst other shareholders, the shares are called "cumulative preference shares." Sometimes a company issues "first preference" and "second preference" shares, the latter ranking after the former. For further details *see* INVESTMENT.

PREFERRED STOCK, stock of a corporation which possesses the same rights and privileges as common stock and which has in addition certain more or less valuable and desirable preferences. Such stock may be *preferred as to assets,* or *preferred as to dividends,* or as to both. Being preferred as to assets means that in case of dissolution of the company, the holders of the stock will receive their portion of the proceeds before holders of other stock not preferred as to assets will participate. This preference is, of course, of no service to the stockholder as long as his company is prosperous and in no danger of dissolution, but in case of weak companies the preference tends to give his stock a higher market value than stock not so preferred. And in case of actual dissolution where the assets are not sufficient to satisfy all claims, the preference will prove most valuable.

The expression *preferred as to dividends* means that this stock is entitled to a specified rate of dividend out of the earnings before any dividend is given to the stock not so preferred. It does not mean that a certain dividend is guaranteed but merely that if any amount of the earnings is declared as a dividend, then the amount necessary to pay the specified rate of dividend on the preferred stock, or such part of such dividend as possible, must be used for this purpose before any is allocated to pay a dividend on non-preferred stock. If the entire amount declared as a dividend is absorbed by the dividend on the preferred stock, it means simply that the non-preferred or common stock gets nothing. In prosperous companies, however, it is usually possible to pay the stipulated rate to the preferred stock and still have sufficient money left to pay an equal or even larger rate to the comman stock. It is ordinarily only fair that the common stock should get more in view of the fact that it takes a risk by permitting the preferred stock to take out its share of dividend first. It is sometimes deemed advisable to have several issues of preferred stock, one taking precedence over the next, just as ordinary preferred stock takes precedence over common. These several issues are then usually classified as 1st preferred, and preferred, etc.; or sometimes as preferred A, preferred B, preferred C.

Preferred stock is also sometimes made participating. Participating preferred stock is that which is to receive first its preferential dividend at the stipulated rate and after that is to participate or share with the other stock in the remainder of the funds declared as dividend. This participation or sharing may be done in one of a number of ways, but regardless of the manner of participation, if the preferred stock shares in any way in the dividend over and above its stipulated rate it is participating stock. Dividends on preferred stock may be either cumulative or non-cumulative. (J. H B.)

PREHNITE, a mineral of the composition $H_2Ca_2Al_2Si_3O_{12}$, but containing also small amounts of Fe_2O_3, and traces of Mn, Mg and alkalis; so called after Col. Prehn, who first brought it to Europe from Cradock, in Cape Colony. It crystallizes in the hemimorphic class of the rhombic system, but the hemimorphic character is often obscured by twinning. Crystals are pyroelectric. The habit is that of flat tables on 001 or elongated along the crystallographic axis *a*. Crystals, however, rarely occur singly, most frequently being aggregated together in divergent groups to form fan-shaped, or globular masses. Prehnite has a dominant 001 cleavage and is usually white or pale green. Though often classed with the zeolites, the contained water is only expelled at a red heat. Optical anomalies are not uncommon, this characteristic being ascribed to twinning on a fine scale. The hardness is 6–6.5 and specific gravity 2·80–2·95. Prehnite occurs in association with zeolites in amygdales of basic igneous rocks such as basalt and dolerite, as well as a purely secondary mineral in veins. In contact-altered limestones the mineral is not uncommon. Here it appears to represent a late hydrothermal stage of alteration, being found in veins and replacing such minerals as labradorite, vesuvianite and scapolite. In the crystalline schists it is sparingly developed in amphibolites, and metamorphosed carbonate sediments. (C. E. T.)

PREJUDICE. In law "without prejudice," means without detriment to a person's rights or claims. When two parties are negotiating for the settlement of an existing dispute, statements or admissions made by or on behalf of either, with a stipulation, expressed or implied, that the statements are made "without prejudice" to the party's claims in the dispute, cannot be put in evidence in litigation to settle the dispute. But a letter which by its nature may prejudice the person to whom it is written may be put in evidence, *e.g.,* if it contain threats. *(See* EVIDENCE.)

PREL, KARL, FREIHERR VON (1839–1899), German philosopher, was born at Landshut on April 3, 1839, and died on Aug. 4, 1899. After studying at the University of Munich he served in the Bavarian army from 1859 to 1872, when he retired with the rank of captain. He then gave himself up to philosophical work, especially in connection with the phenomena of hypnotism and occultism from the modern psychological standpoint. He attempted to deduce the existence of spirit, apart from, and yet entering from time to time into connection with, the phenomena of the senses, by an examination of the relation between the ego of thought and the age of sensible experience as understood by Kant. In *Der Kampf ums Dasein am Himmel* (1874), republished in 1882 under the title *Entwickelungsgeschichte des Weltalls.* Prel endeavoured to apply the Darwinian doctrine of organic evolution not only to the sphere of consciousness but also even more widely as the philosophical principle of the world. He was one of a large number of German thinkers who during the latter half of the 19th century endeavoured to treat the mind as a mechanism. *See* EVOLUTION; *in Philosophy.*

PRELATE, ecclesiastical dignitary of high rank. In the early middle ages the title *prelate* was applied to secular persons in high positions and thence it passed to persons having ecclesiastical authority. The *De prelatis* of Valerian is concerned with secular princes, and even as late as the 14th century the title was occasionally applied to secular magistrates. In mediaeval ecclesiastical usage the term might be applied to almost any person having ecclesiastical authority. The term occurs very frequently in the Rule of St. Benedict and other early monastic rules.

In more modern usage in the Roman Catholic Church prelates, properly so-called, are those who have jurisdiction *in foro externo,* but a liberal interpretation has given the title a more general significance. Prelacy is defined by the canonists as "pre-eminence with jurisdiction" and the idea supposes an episcopal or quasi-episcopal jurisdiction. But gradually the title was extended to ecclesiastical persons having a prominent office even without jurisdiction, and later still it has come to be applied to ecclesiastical persons marked by some special honour though without any definite office or jurisdiction.

We may therefore distinguish "true" from "titular" prelates. The true prelacy is composed of the persons who constitute the ecclesiastical hierarchy; jurisdiction is inherent in their office and gives pre-eminence, as with patriarchs, archbishops and bishops. The true, no less than the titular, prelates have their various ranks, differing as regards title, precedence, clothing and other insignia. The distinguishing colour of a prelate's clothing is violet; the form, like the greater or less use of violet, depends on the rank of the prelate. Four classes may be distinguished: (1) Great prelates, *e.g.,* cardinals, archbishops and bishops. (2) Exempt prelates, *i.e.,* abbots and religious superiors, who are withdrawn from the ordinary diocesan jurisdiction and themselves possess episcopal jurisdiction. (3) Roman prelates, *(a)* active and *(b)* honorary. The title is applied to numerous ecclesiastics attached by some dignity, active or honorary, to the Roman court *(see* CURIA ROMANA).

In the Reformed churches the title was retained in England, Sweden, Denmark and Germany. The cathedral chapter of Brandenburg consists of two prelates, the dean and the senior, besides eight other members. The chapter of Merseburg contains five prelates, viz., the dean, senior, provost, custos and scholasticus. In Baden the general synod is presided over by the prelate (*prelat*), *i.e.,* the principal "superintendent." In the Church of England the term prelate has been since the Reformation applied only to archbishops and bishops.

PRELLER, LUDWIG (1809–1861), German philologist and antiquarian, was born at Hamburg on Sept. 15, 1809. He taught at Dorpat and Jena, and was head librarian at Weimar, where he died on June 21, 1861. His chief works are: *Demeter u. Persephone* (1837) ; *Griechische Mythologie* (1854–55); and *Romische Mythologie* (1858); with H. Ritter he produced the valuable *Historia philosophiae graecae et romanae ex fontium locis contexta* (1838). He contributed to Ersch and Gruber's *Allgemeine Encyklopadie* and Pauly's *Realencyklopadie der classischen Altertumswissenschaft.* A complete list of his works will be found in *Ausgewahlte Aufsätze aus dem Gebiete der klassischen Altertumswissenschaft* (ed. R. Kohler, 1864).

See G. T. Stichling, *Ludwig Preller. Eine Gedächtnissrede (1863).*

PREMONITION, an impression relating to a future event. In modern times the best attested premonitions are those relating to events about to occur in the subject's own organism. The power of prediction possessed by the subject in such cases may be explained in two ways: (1) As due to an abnormal power of perception possessed by certain persons, when in the hypnotic trance, of the working of their own pathological processes; or (2) more probably, as the result of self-suggestion.

Apart from these cases there are two types of alleged premonitions. (1) The future event may be foreshadowed by a symbol. Amongst the best known of these symbolic impressions are banshees, corpse lights, phantom funeral processions, ominous animals or sounds and symbolic dreams (*e.g.,* of teeth falling out). Of all such cases it is enough to say that it is impossible for the serious inquirer to establish any causal connection between the omen and the event which it is presumed to foreshadow. (2) There are many instances, recorded by educated witnesses, of dreams, visions, warning voices, etc., giving precise information as to coming events. In some of these cases, where the dream, etc., has been put on record before its "fulfilment" is known, chance is sufficient to explain the coincidence, as in the recorded cases of dreams foretelling the winner of the Derby or the death of a crowned head. In cases where such an explanation is precluded by the nature of the details foreshadowed, contemporaneous documentary evidence is usually lacking. The persistent belief on the part of the narrators in the genuineness of their previsions indicates that in some cases there may be a hallucination of memory, analogous to the well known feeling of "false recognition."

PREMONSTRATENSIANS, also called Norbertines, and in England White Canons, from the colour of the habit: an order of Augustinian Canons founded in 1120 by St. Norbert, afterwards archbishop of Magdeburg. He had made various efforts to introduce a strict form of canonical life in various communities of canons in Germany; in 1120 he was working in the diocese of Laon, and there in a desert place, called Prémontré, in Aisne, he and thirteen companions established a monastery to be the cradle of a new order. They were canons regular and followed the so-called Rule of St. Augustine (see AUGUSTINIANS), but with supplementary statutes that made the life one of great austerity. St. Norbert was a friend of St. Bernard of Clairvaux—and he was largely influenced by the Cistercian ideals as to both the manner of life and the government of his order. But as the Premonstratensians were not monks but canons regular, their work was preaching and the exercise of the pastoral office, and they served a large number of parishes incorporated in their monasteries. The strength of the order now lies in Belgium, where at Tongerloo is a great Premonstratensian abbey that still maintains a semblance of its mediaeval state.

PŘEMYSL, the reputed ancestor of the line of dukes and kings which ruled in Bohemia from 873 or earlier until the murder of Wenceslaus III. in 1306, and which was known as the Pfemyslide dynasty. According to legend Pfemysl was a peasant of Staditz who attracted the notice of Libussa, daughter of a certain Krok, who ruled over a large part of Bohemia, and is said to have been descended from Samo. Přemysl married Libussa, the traditional foundress of Prague, and during the 8th century became prince of the Bohemian Czechs. His family became extinct when Wenceslaus III. died, but through females the title to Bohemia passed from the Přemyslides to the house of Luxembourg and later to the house of Habsburg.

See F. Palacky, Geschichte von *Böhmen,* Bd. I. (Prague, 1844).

PRENZLAU or **PRENZLOW,** a town in the Prussian province of Brandenburg, Germany, on the lower Ucker See, 30 mi. W. by S. of Stettin by rail. Pop. (1939) 26,562. Prenzlau is first mentioned at the close of the 12th century, and received its municipal charter in 1235. As the capital of the old Uckermark it was a frequent object of dispute between Pomerania and Brandenburg until incorporated with the latter about 1480. The Gothic church of St. Mary dates from 1340, and the remains of the town gates, walls and towers are also interesting. The industries include machine building, iron-founding, brewing and sugar-refining. Tobacco is grown in the neighbourhood, and cigars, margarine and leather are manufactured in the town.

PREPARATORY SCHOOLS form part of what is known as the public school system. (In the United States the term is used for those schools which prepare for higher education, and they are discussed in articles SECONDARY EDUCATION and EDUCATION, *United* States sections.) In Great Britain before Thomas Arnold, in the 'thirties of last century, excluded boys of under twelve years of age from Rugby, there were exceedingly few of these schools, but they now number some 700. It has for many years been exceptional for a boy to enter a public school otherwise than from a preparatory school. These schools are privately owned and are free of Government control; the majority are, however, linked together by membership in an incorporated association. They cater, for the most part, for boys between the ages of six and fourteen years, and, outside the large towns and cities, the great bulk of the pupils are boarders, with only a few day scholars.

BIBLIOGRAPHY.—*See* The Board of Education Report on Preparatory *Schools,* ed. Michael Sadler (1900); The Preparatory *Schools'* Review issued by the Incorporated Association of Preparatory Schools; S. S. Harris, The Master and his Boys; J. Alan Rannie, The Schools of England (1928).

PREROGATIVE, in English law, means the powers, privileges and immunities peculiar to the King. In the early Middle Ages the word occurs as an adjective meaning "exceptional," as in the sentence "The King is prerogative."

A distinction has to be made at the outset between prerogatives peculiar to the King in his "natural" capacity and confined to him, such as the rule that he is personally exempt from all jurisdiction, criminal or civil, and cannot be sued for debt, and prerogatives which belong to his "politic" capacity and as such extend to the whole Government carried on in his name, such as the immunity of "the Crown" from being sued by ordinary civil process. (See PETITION OF RIGHT.) English law has, however, never clearly distinguished between the two capacities; indeed Coke declared it "a damned and damnable opinion" to attempt such a distinction. The whole history of "constructive treason" is a witness to this dualism, as when the judge held that "every rebellion intendeth as its natural consequence the death of the King." In other words, a subject indicted for attempting to compel the King to change his counsellors was not allowed to plead that his "overt acts" were not directed against the life of the King but merely against his Government. The result was that the King was completely identified with the State and even to-day our constitutional law knows no such term as "The State." The State is the King. All writs run in his name. All indictable offences are offences "against the peace of our Lord the King, his Crown and dignity." All "public" property is legally vested in the King—"his" are the ships of war, the Government buildings; the courts of justice and all other governmental agencies.

All statutory powers conferred upon the Government are declared to be conferred on "His Majesty in Council." All money voted by Parliament is voted to "the King," even though it be appropriated by statute to public services from which the King is powerless to divert it. This identification of the State with the King is nothing but a survival of mediaeval times when the King was, indeed, "every inch a King," when he governed largely by his own will, did justice in person and chose his own servants.

The Crown.—The term "Crown" is occasionally used to mark the distinction between the King's Government and the King's person, but its use is intermittent and, strictly speaking, the Crown is, as has been prettily said, nothing but "a chattel in the Tower which has been entailed upon the Hanoverian dynasty." The common law, apart from statute, makes no distinction, for example, between debts due to the King's household and debts due to the Crown, so that, at common law, debts due to the King personally and taxes due to his Government enjoy, indifferently, the prerogative of priority over all other claims against the estate of a debtor, a bankrupt or a deceased person. In the same way a royal palace and a Post Office are equally exempt from the payment of rates, for it is one of the "prerogatives" that "the King" is not bound, in the absence of express words, by a taxing statute. We see the same identification of the "natural" King and the "politic" King in the rule that the King's Government can never, in any circumstances, be sued for wrongful, *i.e.,* tortious, acts. The immunity of the latter is based, historically, on the rule that the "King can do no wrong" which did not mean originally, *e.g.,* in the time of Bracton, the perfectibility of the King but the simple feudal fact that the King could not be tried or sued in his own courts any more than any other feudal lord in the court of that lord's jurisdiction.

As the King was, and is, the "Government," the rule found a new application in the principle that no governmental acts or defaults could be the subject of legal proceedings. Had this application been carried to its logical conclusion, it would have resulted in the immunity of all the King's officers from being sued for their wrongful acts. But English law was, and is, too practical a science to be logical and a consequence so disastrous to the rights of the subject was avoided by the evolution of the principle, laid down by the judges, that no servant of the Crown could be allowed to plead the command of the King, even where such a command had actually been issued, as a defence for an unlawful act, for to admit such a plea would, they held, be to impute wrong to the King. This theory reaches its triumphant climax in the dictum of Blackstone that the King not only can "do" no wrong but cannot even "think a wrong." The failure of the law to make any distinction between the natural and political capacity of the King led to some desperate fictions, of which the supreme example is the legal maxim that "the King never dies." This fiction, in the absence of such a distinction, was necessary because otherwise the death of the King would have dissolved the State in the interregnum between the decease of one King and the coronation of his successor. Indeed, this was actually the situation before the invention of the fiction.

A mediaeval chronicler records that on the death of one of the earlier Kings "every man did what was right in his own eyes." The King was dead, his "peace" died with him and, for the time being, offences ceased to be "crimes" for the legal essence of a crime, as we have seen, is an offence "against the King's peace." Here is the mystical doctrine, so mystically expressed by Allen when he says "When the King dies his politic body escapes from his natural body and by a sort of legal metempsychosis enters into the natural body of his successor; but whilst he is alive the two bodies are indissolubly united and consolidated into one." But the conquest of this fiction was not complete. Right down to 1867 the death of the King operated to dissolve Parliament; the King was, and is, a constitutional element in Parliament and the summons of a Parliament was regarded as an act so personal to him that when he died his Parliament died with him. It was reserved for the Demise of the Crown Act of 1867 to provide that the death of the King should not involve a dissolution. On the other hand the death of the King still operates to dissolve the whole Privy Council from the date of his death until his successor re-appoints the members.

Modern Kingly **Prerogative.**—The prerogative powers of the King, *i.e.,* powers original and inherent in the Kingship, as distinct from powers conferred on him by statute, have all of them one feature in common which is that they can no longer be exercised by the King in person but only on the advice of Ministers or, what amounts to the same thing, in particular forms and by the use of particular instruments. Long before "responsible government" made its appearance in England and at a time when the Commons even repudiated responsibility for the government of the country, Parliament, guided by a sound instinct, insisted that the royal prerogative in certain matters could only be exercised by the use of certain seals, notably the Great Seal and the Privy Seal, which were in the custody of certain great officers of State. There are innumerable mediaeval statutes to this effect. For the use or misuse of these seals their custodians could be brought to book by *impeachment* (*q.v.*) in Parliament. As early as the 16th century the judges held in Mildmay's Case that the King's order to issue "treasure" could only be executed by a warrant under the Great or Privy Seal—a principle now embodied in the Exchequer and Audit Act of 1866 which requires that the sign-manual, *i.e.,* the King's personal signature, must always be countersigned by two Lords of the Treasury before money can issue out of the national exchequer. In the same way the common law courts themselves laid down the rule, at the beginning of the 17th century, that, even in the Court of King's Bench, held *coram* rege and in which mediaeval Kings had presided in person, the King could no longer administer justice in person—"the King cannot speak by word of mouth but only by record." There still remained, it is true, the residuary jurisdiction of the King in Council which could be, and was, exercised by him in person, but with the abolition of the Star Chamber in 1641 this jurisdiction disappeared. By the same statute the King's personal command, *i.e.,* a warrant issued under his hand, was no longer, of itself, to be a decisive answer to an application for a writ of Habeas Corpus by a person arrested under such a warrant. (See WARRANT and HABEAS CORPUS.)

So long as it was in the power of the King to remove the judges for decisions adverse to the exercise of his personal will or to dismiss ministers who refused to carry out his wishes, he could, of course, bend them to exercise his prerogatives according to his pleasure, even when their exercise was subject to the formal rules described above. Parliament, however, gradually stopped up every earth in this respect. It refused to accept the King's command as a defence to the impeachment of one of his ministers, as in Danby's Case (1679), while by the Act of Settlement (section 3) it enacted that the King's prerogative of pardon under the Great Seal should not be pleadable to an impeachment. So long, however, as the King was not dependent on supplies for the ordinary expenses of the Government he could neglect to summon a Parliament for as many years as he pleased and impeachment was thereby made impossible. What was really decisive in securing the exercise of the King's prerogative by ministers in accordance with popular will was not so much the development of Cabinet Government as the transfer, principally as the result of Burke's reforms, of all governmental expenses from being a charge on the hereditary revenues of the Crown, or the Civil list, to the annual Estimates. In strict law the King can still appoint and dismiss ministers as he pleases, nor is he under any statutory obligation to summon Parliament. But if he did the one and omitted the other, he and his ministers would be without money to carry on the Government. Taxes might still be imposed, for much of our taxation is voted under permanent Acts, but none of the proceeds could be expended. Only the annual Appropriation Act can authorize the expenditure of the public money.

Decreasing Powers.—As with the King's ministers, so with "his" judges. In virtue of the Act of Settlement the King can no longer dismiss judges at his pleasure; they are removable only on an address by both Houses of Parliament. Even their appointment, although technically the act of the King, is the act of a minister, namely the Lord Chancellor who issues, in each case, a "patent" of appointment.

The prerogatives are thus no longer an instrument of arbitrary government. They have, constitutionally speaking, passed into the hands of the Cabinet. Hence Dicey's epigram that "the prerogatives of the Crown have become the principles of the people." Like all epigrams, this statement is, however, more pointed than true. Cabinets may be as arbitrary as Kings, and Prime Ministers as arbitrary as Cabinets. The prerogative of dissolution, for example, now operates, in virtue of the modern convention that the King is constitutionally bound to grant a dissolution to a Prime Minister, even when he has been defeated in the House of Commons, to make the former the master of the latter. So too a Government, faced by a hostile House of Lords, can in certain cases avail itself of the prerogative where it cannot be sure of getting its way by statute. Furthermore the prerogative interposes a shield between a Government department and a subject whose rights it has invaded. (See PETITION OF RIGHT.)

Pre-Cabinet Government.—Before the development of Cabinet Government, in other words while the exercise of the prerogative was exclusively in the hands of the King himself, or of ministers subservient to him, the efforts of Parliament were directed to depriving, subjugating or abolishing the prerogative The chief example is afforded by statutes such as the Petition of Right, the Bill of Rights and the Act for the Abolition of the Star Chamber, statutes abolishing respectively the prerogative of the King in taxation to supply his needs, in raising and keeping a standing army to enforce his will, and in exercising a jurisdiction to punish his opponents. Here Parliament went further than the courts were prepared to go. The courts did, indeed, in the famous "Case of Proclamations" lay down the important principle that "the King hath no prerogative except that which the law allows him," But the law itself, *i.e.,* the common law, was disposed, as in Bate's Case, 2 State Trials 371 (1606), and in the Ship Money Case, 3 State Trials 1090 (1638), to recognize an arbitrary power in the King by distinguishing an "absolute" prerogative in cases of emergency, of which the King must be the sole judge, and from the exercise of which no King, not even by statute, would contract himself out—at any rate so as to bind his successors. The answer to this doctrine was the pertinent challenge of Mr. Hakewill in the Commons debates, "Who then shall decide what is an emergency?". It was the Revolution of 1689 that really decided the issue by settling that the King has no power above and beyond the law and that the real sovereign is not the King but the King in Parliament.

Summary.—The chief prerogative powers may be summarised as follows:

(1) In foreign relations the King has the exclusive power of making war and of declaring peace. The power is usually exercised by a Proclamation and an Order in Council and, as such, it is binding on the courts who cannot go behind it but must accord it the same "judicial notice" as an Act of Parliament, *Esposito* v. *Bowden* 7 E. and B. 765. In practice, of course, the power is never exercised except with the approval of Parliament. The treaty-making power may be regarded as an exercise of the

same prerogative. The King can make what treaties he pleases, provided they do not impose a tax on the subject or derogate from common law rights. Whether he can, by the negotiation of such a treaty, cede British territory is more doubtful and has been much disputed; no King, in other words no English ministry, has ventured to exercise such a prerogative since 1894 without seeking the consent of Parliament in the form of a statute and it may be regarded as now settled usage that, as in the case of the Treaty of Versailles, the Crown will always, in the case of a Treaty of Peace involving cession or annexation, seek statutory powers, *ex magna cautela,* to do all such things as may be necessary to carry such a treaty into effect. The Crown has, however, often, as in the case of certain African Protectorates, annexed "foreign" territories by mere prerogative in the form of an Order in Council. Furthermore it rests with the Crown, and the Crown alone, to "recognize" the foreign Governments as *de jure* Governments: a recent case in point is the recognition of the Bolshevik Republic (see *Luther* v. *Sagor* [1921] 3 K.B. 533). Such recognition is binding on the courts and, by a logical sequence, so is a declaration by the Crown that a particular person is entitled to the status of a foreign sovereign and as such is immune from the jurisdiction of the courts—cf. *Mighell* v. *Sultan of Johore* (1880) *L.R.* 5 P.D. 197. So too with the status of an ambassador and the diplomatic immunity of himself and his "suite"—it has now been held that the courts cannot, in the presence of a Foreign Office certificate, even traverse that certificate in order to decide whether the person, in favour of whom diplomatic immunity from their jurisdiction is claimed, is, as a matter of fact, a member of the embassy or not—*Mussman* v. *Engelke* (1928) A.C.

(2) Defence.—The King is head of the naval and military forces of the country and can alone recruit them. It is a statutory offence for any other person to "recruit." The Bill of Rights has limited the exercise of this prerogative by making the raising and maintaining of a standing *army* in *time of peace* illegal. The words italicized are important; they do not prohibit the exercise of the power in time of war and they leave the prerogative unaffected as regards the navy. "The Crown is *not* precluded from raising a standing navy in time of peace nor from imposing a permanent discipline" and in time of war the King can impress sailors and ships by virtue of royal prerogative, R. v. *Broadfoot* (Foster, *Crown Cases* p. 154). There is considerable authority for the proposition that in time of war the King can conscript civilians for the defence of the realm although he cannot compel them to serve abroad. So, too, with certain limitations, he can requisition the subject's property and enter on the subject's land in time of war although this prerogative is now entirely regulated by statute *(see* the *De Keyser Case* below). The necessity of an annual statute to put in force the code of discipline known as the Army Act has, as it has been well said, made of the army "a statutory not a prerogative force." The fact also that all Army expenditure is subject to the annual vote of the Army Estimates has the same effect. And it is, in fact, impossible for the King to "make war," as distinct from declaring it, without the consent of Parliament. Not only would a vote of special supplies be necessary. but by the Reserve Forces Act of 1882, mobilization itself is subject to Parliamentary consent inasmuch as the Army Reserve cannot be called up for permanent service unless Parliament is summoned within 10 days. The same condition is attached to the embodiment of the Territorial Force. *(See* also MARTIAL LAW and MILITARY LAW.)

(3) Legislation.—The requirement of the King's assent to a bill passed by both Houses of Parliament before it can be "enacted" may be regarded as an aspect of the royal prerogative in that the King may, in law, withhold his assent. This prerogative is not dead—"time never runs against the King" so as to make a prerogative wholly obsolete by desuetude—but it has not been exercised since the reign of Queen Anne. But the King may legislate by prerogative, *i.e.,* by Proclamation or by Order in Council, as distinct from statute. But it was long ago laid down by Coke that the King cannot, by his prerogative, alter the common law or create a new offence. In the case of colonies acquired by conquest or cession the prerogative is, however, as absolute as in the time of the earlier statutes. In such cases the King may make what laws he pleases *(Campbell* v. *Hall,* 20 St. Tr. 239). And in the case of all colonies, even the self-governing Dominions, the King can "disallow" an Act to which his local representative, the Governor or Governor-General, has assented. This power is recognized in the constitution of the self-governing Dominions themselves, but it is therein made subject to a period of limitation, usually one or two years.

(4) Parliament.—It is the sole prerogative of the King to summon, prorogue and dissolve Parliament. This may properly be regarded as an executive, not a legislative, act and it is, of course, performed on the advice of ministers. As has been said above, it may be regarded as an accepted convention, at any rate since 1924, that the King cannot, under any circumstances, refuse to dissolve Parliament when a request to that effect is preferred by a Prime Minister. But he might still dissolve Parliament *ex proprio motu* and against the wishes of his Prime Minister under certain circumstances, as, for example, when a Prime Minister having been defeated on a direct Vote of Confidence in the Commons refused either to resign or to ask for a dissolution. Such a state of affairs is not likely nor would it, in any case, be durable, but it is not inconceivable.

(5) Executive.—The theory of the law is that the Government of the country is still entirely a matter of prerogative, although, of course, many, if not most, of the powers now exercised by the Crown have been conferred upon it by statute—in particular the power of making Statutory Rules and Orders *(q.v.)* to carry a statute into effect. All ministers are appointed by the King—on the nomination of the Prime Minister—and "Kiss hands" or, as in the case of Secretaries of State, receive their seals from the King himself. In law there is no such office as that of "Prime Minister." In the choice of a Prime Minister the King has, both in law and in fact, a discretion and he sends for whom he will, when the outgoing Prime Minister has resigned, but his choice is usually limited to the leader of the Opposition. All military and naval officers are appointed by a "commission" from the King. So too with the Governors of the Colonies. And as he appoints, so he dismisses. Every office under the Crown, except that of the judges and the Comptroller and Auditor General, is held "during pleasure." This doctrine has important legal consequences in that the King's ministers, exercising the prerogative, can terminate any commission or contract of service whenever they please and the servant of the Crown, civil or military, has no remedy. English law "imports into every agreement" for service with the Crown the term "that the Crown has power to dismiss at pleasure" and even that any term of agreement purporting to exclude this power would be void (Lord Watson in *De Dohse* v. *the King* quoted in *Dunn* v. *the Queen* [1896] 1 *Q.B.* at p. 118). This is a striking example of how the prerogative may operate to invest ministers with arbitrary power. No servant of the Crown has any legally enforceable right to pay, pension or security of tenure.

(6) General.—The less important prerogatives of the Crown may be dealt with generally. The King is the supreme landowner, a relic of feudal doctrines, which is only important in the case of a man dying intestate and without heirs in which case his land "escheats" to the Crown. The King also is the depositary of the prerogative of mercy, in other words he can pardon those who offend against his "peace"; the prerogative is now exercised exclusively on the advice of the Home Secretary. He is the "fountain of honour" and as such is the sole grantor of titles such as peerages, baronetcies and knighthoods; his power in this respect is subject to no limitations except those contained in peerage law but "honours" are rarely conferred by him except on the advice of Ministers. He is the "supreme governor" of the Church in virtue of the Acts of Supremacy and Uniformity. The prerogatives of the Crown in the courts are dealt with in the article on PETITION OF RIGHT.

Effect of Statutes on the Prerogative.—As has been seen Parliament has frequently intervened to abolish some particular prerogative, deemed to be oppressive, and since the Revolution of 1689 it has never been doubted that such a statute will bind not only the King who actually assented to it but all his successors. It has, however, until recently, been a matter of considerable doubt and speculation whether a statute can curtail a prerogative in the absence of express words to that effect. In a book of considerable authority in its day, Chitty (The Prerogative of the *Crown* [1820] p. 383) laid down that "Acts of Parliament which would divest or abridge the King of his prerogative, his interests or his remedies in the slightest degree do not in general extend to bind the King unless there be express words to that effect." This view was expressed more widely by a judge, Hobart, C. J., in 1624 in the quaint words "Everything [in a statute] for the benefit of the King shall he taken largely [*i.e.*, liberally], as everything against the King shall be taken strictly" —Sir Edward Coke's Case (1624), Godbee's Reports, p. 289. Thus it has been successfully contended that the Crown is not bound by the Statute of Limitations and it has obtained judgment in proceedings against a subject, by Information of Debt, on a claim thirty years old (*Brummell* v. *M'Pherson* 7 L.J. [O.W. Series] Ch. 1.). But the presumption in favour of the Crown, in the interpretation of a statute, is no longer as strong as it was. In this respect the great case of *Attorney-General* v. *De Keyser's* Hotel [1920] A.C. is decisive to the extent that when Parliament has by statute regulated "the whole field of the prerogative," that particular prerogative can be exercised in no other way than that prescribed by the statute. In that case the Defence Act of 1842 had laid down regulations for the payment of compensation by the Crown for lands taken for the purpose of national defence, and it was held that, though that Act had not expressly abolished the prerogative of taking land or premises in time of war, the prerogative itself could only be exercised in accordance with the terms laid down by the Act, namely the payment of compensation duly assessed by a jury. The Crown's contention that, as there was no direct mention of the prerogative in the Act of 1842, that prerogative was unaffected and unimpaired, was decisively rejected by the courts. The same principle has been followed by the courts in the more recent case of Food *Controller* v. Cork (1923) A.C. 647. (See also articles on ATTORNEY-GENERAL, COMMON LAW, CONSTITUTIONAL LAW, PETITION OF RIGHT.)

PREROGATIVE COURTS, the name given to the English provincial courts of Canterbury and York, as far as regarded their jurisdiction over the estates of deceased persons. They had jurisdiction to grant probate or administration where the diocesan courts could not entertain the case owing to the deceased having died possessed of goods above the value of £5 (bona notabilia) in each of two or more dioceses. The jurisdiction of the prerogative courts was transferred to the court of probate in 1857 by the Probate Court Act, and is now vested in the probate, divorce and admiralty division of the High Court of Justice by the Judicature Act 1875. In the State of New Jersey, United States, the court having jurisdiction over probate matters is called the prerogative court.

PRESBYTER, the title borne from very early times by certain officers or ministers of the Christian Church intermediate between "bishops" and "deacons." The word is the original form of priest (*q.v.*). The word is not found in pre-Christian writing: except in the Septuagint, though as Deissmann has shown it is found on the Papyri as an official title for the village magistrates of Egypt and the members of the γερουσία, or senate, of many towns in Asia Minor. The office is, however, closely analogous to, and perhaps founded on, a similar office in the Jewish synagogue organization among the officials of which were the *zekenim*, or elders, sometimes identified with the archi-synagogues. In the New Testament the Greek word is used both for the ancient Jewish official and for the Christian elder.

The history of presbyteral government as opposed to episcopacy and pure congregationalism is not known in detail. After the Reformation, however, it was adopted by Calvin and his followers, who created that system which has ever since been known as Presbyterianism (*q.v.*). During the last quarter of the 1st century, a threefold organization is found in the Church: (a) a spiritual organization composed of "apostles, prophets and teachers who had been awakened by the spirit and by the spirit endowed"; (b) an administrative organization, "For the care of the poor, for worship, for correspondence, the congregation needed controlling officials. These were the bishop and the deacons, the former for higher, the latter for inferior services"; (c) a patriarchal organization based upon the natural deference of the younger to the older members of the Church. The senior members of the community, by virtue of their age and experience, watched over the conduct and guided the action of the younger and less experienced portion of the Church, though they held no official position and were not appointed for any particular work like the bishops and deacons. In the and century the patriarchal element in the organization was merged in the administrative, and the presbyters became a definite order in the ministry. The time at which the change occurred cannot be definitely fixed. Although presbyters are not mentioned in the genuine Epistles of St. Paul, there are hints that similar officers existed in some of the churches founded by the apostle. There is a reference in 1 Thess. v. 12 to "those who rule over you" (προϊστάμενοι), and the same word occurs in Rom. xii. 8. The term "governments" (κυβερνήσεις) in 1 Cor. xii. 28 obviously refers to men who discharged the same functions as presbyters. If too, as seems most probable, bishops and presbyters were practically identical, there is of course a specific reference to them in Phil. i. 1. The "leaders" who are mentioned three times in Hebrews xiii. were also probably "presbyters" under another name. If the Church at Jerusalem had any officials, it is highly probable that those officials bore the name and took over the functions of the elders of the synagogue. The statement in Acts xiv. 23, that Paul and Barnabas appointed elders in the churches of South Galatia, is more open to objection perhaps, owing to the silence of the Epistle to the Galatians.

The conclusions which we seem to reach are as follows: (1) In the earliest stage (between 30 and 60) there is no uniform organization in the Christian Church. Presbyters are found in Jerusalem from primitive times. In the Pauline churches the name is not found except at Ephesus and possibly in south Galatia, though there are traces of the office, at any rate in germ, under different titles in other churches. (2) In the second stage (between 60 and 100) there is an increasing tendency towards uniformity. The office is found definitely mentioned in connection with the churches of Asia Minor (1 Pet. v. 1), Corinth (Epistle of Clement) and Crete (Titus). The officials were called by two names, "elders" and "bishops," the former denoting the office, the latter the function (exercising the oversight). The substantial identity of the two titles cannot be doubted in the light of such passages as Acts xx. 17, 28; 1 Pet. v. 1, 2; 1 Tim. iii. 1–7, v. 17–19 and Titus i. 5–7.

There is far less controversy with regard to the later history of the presbyters. The third stage of the development of the office is marked by the rise of the single *episcopus* as the head of the individual church (see BISHOP; EPISCOPACY). The first trace of this is to be found in the Epistles of Ignatius which prove that by the year 115 "the three orders" as they were afterwards called—bishops, presbyters and deacons—already existed, not indeed universally, but in a large proportion of the churches. The presbyters occupied an intermediate position between the bishop and the deacons. They constituted "the council of the bishop." It was some time before the threefold ministry became universal. The *Didache* knows nothing of the presbyters; bishops and deacons are mentioned, but there is no reference to the second order. The Shepherd of Hermas knows nothing of the single bishop; the churches are under the control of a body of presbyter-bishops. Before the close of the 2nd century however the three orders were established almost everywhere. The sources of the Apostolic Canons (which date between 140–180) lay down the rule that even the smallest community of Christians, though it contain only twelve members, must have its bishop and its presbyters. The original equality of bishops and presbyters was still however theoretically maintained. The presbyters formed the governing body of the church. It was their duty to maintain order, exercise discipline, and superintend the affairs of the Church. At the beginning of the 3rd century, if we are to believe Tertullian, they had no spiritual authority of their own, at any rate as far as the sacraments are concerned. The right to baptize and celebrate the communion was delegated to them by the bishop.

In the fourth stage we find the presbyters, like the bishops, becoming endowed with special sacerdotal powers and functions. It was not till the middle of the 3rd century that the priesthood was restricted to the clergy. Cyprian is largely responsible for the change, though traces of it are found during the previous half century. Cyprian bestows the highest sacerdotal terms upon the bishops of course, but his references to the priestly character of the office of presbyter are also most definite. Henceforth presbyters are recognized as the *secundum sacerdotium* in the Church.

With the rise of the diocesan bishops the position of the presbyters became more important. The charge of the individual church was entrusted to them and gradually they took the place of the local bishops of earlier days, so that in the 5th and 6th centuries an organization was reached which approximated in general outline to the system which prevails in the Anglican Church to-day.

Bib.*

PRESBYTERIANISM, one of the three principal systems of church polity known to the Christian (Protestant) Church, and occupying an intermediate position between episcopacy and congregationalism.

I. THE SYSTEM DESCRIBED

As compared with the Church of England (Episcopal) in which there are three orders of clergy—bishops, priests and deacons, Presbyterianism recognizes but one spiritual order, viz., presbyters. These are ecclesiastically of equal rank, though differentiated, according to their duties, as ministers who preach and administer the sacraments, and as elders who are associated with the ministers in the oversight of the people. There are deacons, in Presbyterianism inferior in rank to presbyters, their duties being regarded as non-spiritual. The membership of a Presbyterian Church consists of all who are enrolled as communicants, together with their children. Others who worship regularly without becoming communicants are called adherents. Only communicants exercise the rights of membership. They elect the minister and other office-bearers. But, in contrast with Congregationalism, when they elect and "call" a minister their action has to be sustained by the presbytery, which judges of his fitness for that particular sphere, of the measure of the congregation's unanimity, and of the adequacy of financial support. When satisfied, the presbytery proceeds with the ordination and induction. The ordination and induction of ministers is always the act of a presbytery. The ordination and induction of elders in some branches of the Church is the act of the session; in others it is the act of the presbytery.

Church **Courts.**—(i.) The *session* is the first of a series of councils or church courts which are an essential feature of Presbyterianism. It consists of the ministers and ruling elders. The minister is *ex officio* president or moderator. Without his presence or the presence of his duly-appointed deputy the meeting would not be in order nor its proceedings valid. The moderator has not a deliberative, but only a casting vote. (This is true of the moderator in all the church courts.) Neither the session nor the congregation has jurisdiction over the minister. He holds his office *ad vitam aut culpam;* he cannot demit it or be deprived of it without consent of the presbytery. In this way his independence among the people to whom he ministers is to a large extent secured. The session has oversight of the congregation in regard to such matters as the hours of public worship, the arrangements for administration of the sacraments, the admission of new members and the exercise of church discipline. New members are either catechumens or members transferred from other churches. The former are received after special instruction and profession of faith; the latter on presenting a certificate of church membership from the church which they have left. Though the admission of new members is, strictly speaking, the act of the session, this duty usually devolves upon the minister, who reports his procedure to the session for approval and confirmation. Matters about which there is any doubt or difficulty, or division of opinion in the session, may be carried for settlement to the next higher court, the presbytery.

(ii.) The *presbytery* consists of all the ministers and a selection of the ruling elders from the congregations within a prescribed area. The presbytery chooses its moderator periodically from among its ministerial members. His duty is to see that business is transacted according to Presbyterian principle and procedure. The moderator has no special power or supremacy over his brethren, but is honoured and obeyed as *primus inter pares.* The work of the presbytery is episcopal. It has oversight of all the congregations within its bounds; hears references from kirk-sessions or appeals from individual members; sanctions the formation of new congregations; superintends the education of students for the ministry; stimulates and guides pastoral and evangelistic work; and exercises discipline over all within its bounds, including the ministers. Appeals and complaints may be taken from the presbytery to the synod.

(iii.) The *synod* is a provincial council which consists of the ministers and representative elders from all the congregations within a specified number of presbyteries, in the same way as the presbytery is representative of a specified number of congregations. Though higher in rank and larger than most presbyteries it is practically of less importance, not being, like the presbytery, a court of first instance, nor yet, like the general assembly, a court of final appeal. The synod hears appeals and references from presbyteries; and by its discussions and decisions business of various kinds, if not settled, is ripened for consideration and final settlement by the general assembly, the supreme court of the Church.

(iv.) The *general assembly* is representative of the whole Church, either, as in the Irish General Assembly, by a minister and elder sent direct to it from every congregation, or, as in the Scottish General Assemblies, by a proportion of delegates, ministers and elders from every presbytery. The general assembly annually at its first meeting chooses one of its ministerial members as moderator. He takes precedence, *primus inter pares,* of all themembers, and is recognized as the official head of the Church during his term of office. His position is one of great honour and influence, but he remains a simple presbyter, without any special rule or jurisdiction. The general assembly reviews all the work of the Church; settles controversies; makes administrative laws; directs and stimulates missionary and other spiritual work; appoints professors of theology; admits to the ministry applicants from other churches; hears and decides complaints, references and appeals which have come up through the inferior courts; and takes cognizance of all matters connected with the Church's interests or with the general welfare of the people. As a judicatory it is the final court of appeal; and by it alone can the graver censures of church discipline be reviewed and removed. The general assembly meets once a year at the time and place agreed upon and appointed by its predecessor.

The weak point in the system is that episcopal superintendence being exercised in every case by a plurality of individuals there is no one, moderator or senior member, whose special duty it is to take initial action when the unpleasant work of judicial investigation or ecclesiastical discipline becomes necessary. This has led in some quarters to a desire that the moderator should be clothed with greater responsibility and have his period of office prolonged;

should be made, in fact, more of a bishop in the Anglican sense of the word.

Divergent Views.—Though Presbyterians are unanimous in adopting the general system of church polity as here outlined, and in claiming New Testament authority for it, there are certain differences of view in regard to details which may be noticed. (See Lightfoot's exhaustive essay in his volume on the Epistle to the Philippians.) There is no doubt that considerable indefiniteness in regard to the precise status and rank of the "ruling elder" has prevailed. When ministers and elders are associated in the membership of a church court their equality is admitted; no such idea as voting by orders is ever entertained. Yet even in a church court a certain disparity is apparent between a minister and his elders. Practically the minister is regarded as of higher standing. The duty of teaching and of administering the sacraments and of always presiding in church courts being strictly reserved to him invests his office with a dignity and influence greater than that of the elder. The practice which is most characteristic of Presbyterianism is that which recognizes one order of presbyters but in this order two degrees or classes, known as teaching elders or "ministers" and ruling elders. In teaching, in dispensing the sacraments, in presiding over public worship, and in the private functions by which he ministers to the comfort, the instruction and the improvement of the people committed to his care, a pastor acts within his parish (or congregation) according to his own discretion; and for the discharge of all the duties of the pastoral office he is accountable only to the presbytery from whom he received the charge of the parish (or congregation). But in everything which concerns what is called discipline—the exercise of that jurisdiction over the people with which the office-bearers of the church are conceived to be invested, he is assisted by lay-elders. They are laymen in that they have no right to teach or to dispense the sacraments, and on this account they fill an office in the Presbyterian Church inferior in rank and power to that of the pastors. Their peculiar business is expressed by the term "ruling elders."

In the initial stages of the Apostolic Church it was no doubt sufficient to have a plurality of presbyters with absolutely similar duties and powers At first, indeed, this may have been the only possible course. But apparently it soon became desirable and perhaps necessary to specialize the work of teaching by setting apart for that duty one presbyter who should withdraw from secular occupation and devote his whole time to the work of the ministry. There seems to be evidence of this in the later writings of the New Testament. It is now held by all Presbyterian churches that one presbyter in every congregation should have specially committed to him the work of teaching, administering the sacraments, visiting the flock pastorally, and taking oversight, with his fellow elders, of all the interests of the church.

Another subject upon which there is a difference of opinion in the Presbyterian churches is the question of Church Establishments. The view, originally held by all Presbyterian churches in Great Britain and on the Continent, that union with and support by the civil government are not only lawful but also desirable, is now held only by a minority, and is practically exemplified among English-speaking Presbyterians only in the Church of Scotland (see SCOTLAND, CHURCH OF). The lawfulness of Church Establishments with due qualifications is perhaps generally recognized in theory, but there is a growing tendency to regard connection with the state as inexpedient, if not actually contrary to sound Presbyterian principle.

Those who favour state connection and those who oppose it agree in claiming spiritual independence as a fundamental principle of Presbyterianism. All Presbyterians admit the supremacy of the state in things secular, and they claim supremacy for the Church in things spiritual. Those who favour a Church Establishment hold that Church and state should each be supreme in its own sphere, and that on these terms a union between them is not only lawful but is the highest exemplification of Christian statesmanship. So long as these two spheres are at all points clearly distinct, and so long as there is a desire on the part of each to recognize the supremacy of the other, there is little danger of friction or collision. But when spiritual and secular interests come into unfriendly contact and entanglement; when controversy in regard to them becomes inevitable; from which sphere, the spiritual or the civil, is the final decision to come? Before the Reformation the Church would have had the last word; since that event the right and the duty of the civil power have been generally recognized.

Origin.—The origin of Presbyterianism is a question of historical interest. By most students of the subject it is regarded as of later Jewish origin, and as having come into existence in its present form simultaneously with the formation of the Christian Church. The last is Bishop Lightfoot's view. He connects the Christian ministry, not with the worship of the Temple, in which were priests and sacrificial ritual, but with that of the synagogue, which was a local institution providing spiritual edification by the reading and exposition of Scripture. The first Christians were regarded, even by themselves, as a Jewish sect. They were spoken of as "the way." They took with them, into the new communities which they formed, the Jewish polity or rule and oversight by elders. The appointment of these would be regarded as a matter of course, and would not seem to call for any special notice in such a narrative as the Acts of the Apostles.

But Presbyterianism was associated in the and century with a kind of episcopacy. This episcopacy was at first rather congregational than diocesan; but the tendency of its growth was undoubtedly towards the latter. Hence for proof that their church polity is apostolic Presbyterians are accustomed to appeal to the New Testament and to the time when the apostles were still living; and for proof of the apostolicity of prelacy Episcopalians appeal rather to the early Church fathers and to a time when the last of the Apostles had just passed away. (See Lightfoot's essay in his *Commentary* on the Epistle to *the* Philippians.) It is generally admitted that distinct traces of Presbyterian polity are to be found in unexpected quarters (*e.g.*, Ireland, Iona, the Culdees, etc.) from the early centuries of church history and throughout the mediaeval ages down to the Reformation of the 16th century. Only in a very modified sense, therefore, can it be correctly said to date from the Reformation.

At the Reformation the Bible was for the great mass of both priests and people a new discovery. The study of it shed floods of light upon all church questions. The leaders of the Reformation searched the New Testament not only for doctrinal truth but also to ascertain the polity of the primitive Church. This was specially true of the Reformers in Switzerland, France, Scotland, Holland and in some parts of Germany. Luther gave little attention to New Testament polity, though he believed in and clung passionately to the universal priesthood of all true Christians, and rejected the idea of a sacerdotal caste. He had no dream or vision of the Church's spiritual independence and prerogative. He was content that ecclesiastical supremacy should be with the civil power, and he believed that the work of the Reformation would in that way be best preserved and furthered. In no sense can his "consistorial" system of church government be regarded as Presbyterian.

It was different with the Reformers outside Germany. While Luther studied the Scriptures in search of true doctrine and Christian life and was indifferent to forms of church polity, they studied the New Testament not only in search of primitive church doctrine but also of primitive church polity. One is struck by the unanimity with which, working individually and often in lands far apart, they reached the same conclusions. They did not get their ideas of church polity from one another, but drew it directly from the New Testament. They were unanimous in rejecting the episcopacy of the Church of Rome, the sanctity of celibacy, the sacerdotal character of the ministry, the confessional, the propitiatory nature of the mass. They were unanimous in adopting the idea of a church in which all the members were priests under the Lord Jesus, the One High Priest and Ruler; the officers of which were not mediators between men and God, but preachers of One Mediator, Christ Jesus; not lords over God's heritage, but examples to the flock and ministers to render service. They were unanimous in regarding ministerial service as mainly pastoral;

preaching, administering the sacraments and visiting from house to house; and, further, in perceiving that Christian ministers must be also spiritual rulers, not in virtue of any magical influence transmitted from the Apostles, but in virtue of their election by the Church and of their appointment in the name of the Lord Jesus. When the conclusions thus reached by many independent investigators were at length reduced to a system by Calvin, in his famous Znstitutio, it became the definite ideal of church government for all the Reformed, in contradistinction to the Lutheran, churches.

Yet we do not find that the leaders of the Reformed Church succeeded in establishing at once a fully-developed Presbyterian polity. Powerful influences hindered them from realizing their ideal. In the first place, the people generally dreaded the recurrence of ecclesiastical tyranny. A second powerful influence was of a different kind, viz. municipal jealousy of church power. The municipal authority in those times claimed the right to exercise a censorship over the citizens' private life. Any attempt on the part of the Church to exercise discipline was resented as an intrusion. Hence friction, at times, between the Reformers and civic authorities friendly to the Reformation; not as to whether there should be "discipline" (that was never doubted) but as to whether it should be ecclesiastical or municipal. Even, therefore, where people desired the Reformation there were powerful influences opposed to the setting up of church government and to the exercise of church discipline after the manner of the Apostolic Church; and one ceases to wonder at the absence of complete Presbyterianism in the countries which were forward to embrace and adopt the Reformation. Indeed the more favourable the secular authorities were to the Reformation the less need was there to discriminate between civil and ecclesiastical power, and to define strictly how the latter should be exercised. We look in vain, therefore, for much more than the germs and principles of Presbyterianism in the churches of the first Reformers. Its evolution and the thorough application of its principles to actual church life came later, not in Saxony or Switzerland, but in France and Scotland; and through Scotland it has passed to all English-speaking lands.

Presbyterian Worship.—The form of worship associated with Presbyterianism has been marked by extreme simplicity. It consists of reading of Holy Scripture, psalmody, non-liturgical prayer and preaching. There is nothing in the standards of the Presbyterian Church against liturgical worship. In some of the early books of order a few forms of prayer were given, but their use was not compulsory. On the whole, the preponderating preference has always been in favour of so-called extemporaneous, or free prayer; and the Westminster Directory of Public Worship has to a large extent stereotyped the form and order of the service in most Presbyterian churches. Within certain broad outlines much, perhaps too much, is left to the choice of individual congregations. It used to be customary among Presbyterians to stand during public prayer, and to remain seated during the acts of praise, but this peculiarity is no longer maintained. The psalms rendered into metre were formerly the only vehicle of the Church's public praise, but hymns are now also used in most Presbyterian churches. Rous's version of the Psalms is the best known and most widely used. It is an English work. Somewhat reluctantly it was accepted by Scottish Presbyterianism as a substitute for an older version with a greater variety of metre and music. "Old Hundred" and "Old 124th" mean the 100th and 124th Psalms in that old book. Organs used to be regarded as contrary to New Testament example, but their use is now all but universal. The public praise used to be led by an individual called the "precentor," who occupied a box in front of, and a little lower than, the pulpit. Choirs of male and female voices now lead the church praise.

Presbyterianism has two sacraments, baptism and the Lord's Supper. Baptism is administered both to infants and adults by pouring or sprinkling, but the mode is considered immaterial. The Lord's Supper, as generally observed throughout the various Presbyterian churches, is a close imitation of the New Testament practice; and where it is not marred by undue prolixity commends itself to most Christian people as a solemn and impressive service. The old plan of coming out and taking one's place at the communion table in the body of the church is unhappily seen no more; communicants now receive the sacred elements seated in their pews. The dispensing of this rite is strictly reserved to an ordained minister, who is assisted by elders in handing the bread and the cup to the people. The administration of private communion to the sick and dying is extremely rare in Presbyterian churches, but there is less objection to it than formerly, and in some churches it is even encouraged.

Discipline.—Presbyterian discipline is now entirely confined to exclusion from membership or from office. Though it is the duty of a minister to warn against irreverent or profane participation in the Lord's Supper, he himself has no right to exclude any one from communion; that can only be done as the act of himself and the elders duly assembled in session. A code of instructions for the guidance of church courts when engaged in cases of discipline is in general use, and bears witness to the extreme care taken not only to have things done decently and in order, but also to prevent hasty, impulsive and illogical procedure in the investigation of charges of heresy or immorality. Cases of discipline are now comparatively rare, and, when they do occur, are not characterized by the bigoted severity which prevailed in former times and was rightly denounced as unchristian.

The extent to which the Presbyterian form of church government prevails throughout the world has been made more manifest in recent years by the formation of the "General Council of the Alliance of Reformed Churches holding the Presbyterian System," the object of which is to promote unity and fellowship among the numerous branches of Presbyterianism throughout the world. Since 1910 the Presbyterian churches have encountered, in common with others, the obstacles and the impetus created by the World War. The gains have outweighed the losses upon the whole: Numerically, to judge from the statistics presented to the general council held at Cardiff in July 1925 the total membership of the Presbyterian churches had increased between 1913 and that date by well over 2,000,000. The precise figures are, for 100 organised churches which it has been possible to reach, 8,670,500 souls; so that, on the usual scale of estimating people under the direct influence of a Church, there are over 40,000,000 who are Presbyterians.

II. HISTORY IN DIFFERENT COUNTRIES

From this general outline of Presbyterianism we now turn to consider its evolution and history in some of the countries with which it is or has been specially associated. We omit, however, one of the most important, viz., Scotland, as the history is fully covered under the separate headings of SCOTLAND, CHURCH OF, and allied articles.

Switzerland.—The Swiss, owing to their peculiar geographical position and to certain political circumstances, early manifested independence in ecclesiastical matters, and became accustomed to the management of their church affairs. The work of Zwingli as a Reformer, important and thorough though it was, did not concern itself mainly with church polity. Ecclesiastical affairs were, as a matter of course, wholly under the management of the cantonal and municipal authorities, and Zwingli was content that it should be so. The work of Farel, previous to his coming to Geneva, was almost entirely evangelistic, and his first work in Geneva was of a similar character. It was the town council which made arrangements for religious disputations, and provided for the housing and maintenance of the preacher. When Calvin, at Farel's invitation, settled in Geneva (1536) the work of reformation became more constructive. "The need of the hour was organization and familiar instruction, and Calvin set himself to work at once." The first reforms he wished to see introduced concerned the Lord's Supper, church praise, religious instruction of youth and the regulation of marriage. In connection with the first he desired that the discipline de l'excommunication should be exercised. His plan was partly Presbyterian and partly consistorial. Owing to certain circumstances in its past history, Geneva was notoriously immoral. "The rule of dissolute bishops, and the example of a turbulent and immoral clergy, had poisoned the morals of the city. Even the nuns of Geneva were notorious for their conduct." Calvin suggested that men of known worth should be appointed in different quarters of the city to report to the ministers those persons in their district who lived in open sin; that the ministers should then warn such persons not to come to the communion; and that, if their warnings were unheeded, discipline should be enforced. It was on this subject of keeping pure the Lord's Table that the controversy arose between the ministers and the town councillors which ended in the banishment of Calvin, Farel and Conrad from Geneva. In 1538 the ministers took upon themselves to refuse to administer the Lord's Supper in Geneva because the city, as represented by its council, declined to submit to church discipline. The storm then broke out, and the ministers were banished.

Calvin's refusal to administer the sacrament, for which he was banished from Geneva, is important as a matter of ecclesiastical history, because it is the essence of the whole system which he subsequently introduced. It rests on the principles that the Church has the right to exclude those who are unworthy, and that she is in no way subject to the civil power in spiritual matters. During the three years of his banishment Calvin was at Strassburg, where he had been carrying out his ideas. His recall was greatly to his honour. The town had become a prey to anarchy. One party threatened to return to Romanism; another threatened to sacrifice the independence of Geneva and submit to Berne. It was felt to be a *political* necessity that he should return, and in 1541, somewhat reluctantly, he returned on his own terms. These were the recognition of the Church's spiritual independence, the division of the town into parishes, and the appointment (by the municipal authority) of a consistory or council of elders in each parish for the exercise of discipline. The arrangement was, however, a compromise. The state retained control of the ecclesiastical organization, and Calvin secured his much-needed system of discipline. Fourteen years of friction and struggle followed, and if there came after them a period of comparative triumph and repose for the great reformer it must still be remembered that he was never able to have his ideal ecclesiastical organization fully realized in the city of his adoption.

The early Presbyterianism of Switzerland was defective in the following respects: (1) It started from a wrong definition of the Church, which, instead of being conceived as an organized community of believers in the Lord Jesus Christ, was made to depend upon the preaching of the gospel and the administration of the sacraments. As these implied a duly appointed minister, the existence of the Church was made to depend upon an organized ministry rather than an organized membership. It calls to mind the Romish formula: *"Ubi episcopus ibi ecclesia."* (2) It did not maintain the scriptural right of the people to choose their minister and other office-bearers. (3) Its independence of civil control was very imperfect. (4) And it did not by means of church courts provide for the manifestation of the Church's unity and for the concentration of the Church's influence.

"Calvin," says Principal Lindsay, "did three things for Geneva all of which went far beyond its walls. He gave its Church a trained ministry, its homes an educated people who could give a reason for their faith, and the whole city an heroic soul which enabled the little town to stand forth as the citadel and city of refuge for the oppressed Protestants of Europe."

France. — It is pathetic and yet inspiring to study the development of Presbyterianism in France; pathetic because it was in a time of fierce persecution that the French Protestants organized themselves into churches, and inspiring, because it showed the power which scriptural organization gave them to withstand incessant, unrelenting hostility. It would be difficult to exaggerate the influence of Calvin upon French Protestanism. His *Christianae religionis institutio* became a standard round which his countrymen rallied in the work and battle of the Reformation. Though under thirty years of age, he became all over Europe, and in an exceptional degree in France, the leader, organizer and consolidator of the Reformation. The work which the young Frenchman did for his countrymen was immense.

The year 1555 may be taken as the date when French Protestantism began to be organized. A few churches had been organized earlier, at Meaux in 1546 and at Nimes in 1547, but their members had been dispersed by persecution. Prior to 1555 the Protestants of France had been for the most part solitary Bible students or little companies meeting together for worship without any organization. The first organized church was formed in that year in Paris; and from that date they began to spring up in all parts of the country.

In 1558 a further stage in the development of Presbyterian church polity was reached. Some doctrinal differences having arisen in the church at Poitiers, a synod was convened to meet in Paris the following year (1559). It was the first general synod of the French Protestant Church, and consisted of representatives from, some say sixty-six, others, twelve churches. It adopted a confession of faith and a book of order or discipline. The confession consisted of forty articles. It was based on a short confession drafted by Calvin in 1557, and may still be regarded, though once or twice revised, as the confession of the French Protestant Church. The book of order, *Discipline ecclésiastique des e'glises réformées de France*, regulated the organization and procedure of the churches. It contains this fundamental statement of Presbyterian parity, "Aucune église ne pourra prétendre primauté ni domination sur l'autre; ni pareillement, les ministres d'une église les uns sur les autres; ni les anciens ou diacres, les uns sur les autres"; and it explains various church courts, familiar to us now as Presbyterian. "It is interesting to see how in a country whose civil rule was becoming gradually more absolutist, this 'Church under the cross' framed for itself a government which reconciled, more thoroughly perhaps than has ever been done since, the two principles of popular rights and supreme control. Its constitution has spread to Holland, Scotland (Ireland, England), and to the great American (and Colonial) churches. Their ecclesiastical polity came much more from Paris than from Geneva."

To trace the history of Presbyterianism in France for the next thirty years would be to write the history of France itself during that period. We should have to tell of the great and rapid increase of the Church; of its powerful influence among the nobles and the *bourgeoisie;* of its direful persecutions; of its St. Bartholomew massacre with 70,000 victims; of its regrettable though perhaps inevitable entanglements in politics and war; and finally of its attaining not only tolerance but also honourable recognition and protection when Henry IV. in 1598 signed the famous Edict of Nantes. This secured complete liberty of conscience everywhere within the realm and the free right of public worship in all places in which it existed during the years 1596 and 1597, or where it had been granted by the edict of Poitiers (1577) interpreted by the convention of Nérac (1578) and the treaty of Fleix (1580)—in all some two hundred towns; in two places in every *bailliage* 'and *sénéchaussée*; in the castles of Protestant *seigneurs hauts justiciers* (some three thousand); and in the houses of lesser nobles, provided the audience did not consist of more than thirty persons over and above relations of the family. Protestants were granted full civil rights and protection, and were permitted to hold their ecclesiastical assemblies. Under the protection of the edict the Huguenot Church of France flourished. Theological colleges were established at Sedan, Montauban and Saumur, and French theology became a counterpoise to the narrow Reformed scholastic of Switzerland and Holland. The history of the Church from the passing of the edict of Nantes till its revocation in 1685 cannot be given here. That event was the climax of a long series of horrors. Under the persecution, a large number were killed and between four and five millions of Protestants left the country. From 1760 owing to the gradual spread of the sceptical spirit and the teaching of Voltaire more tolerant views prevailed. In 1787 the Edict of Tolerance was published. In 1789 all citizens were made equal before the law, and the position of Presbyterianism improved till 1791. In 1801 and 1802 Napoleon took into his own hands the independence of both Catholic and Protestant Churches, the national synod was abolished, and all active religious propaganda was rigorously forbidden. In 1848 an assembly representative of the *e'glises consistoriales* met at Paris. When it refused to discuss points of doctrine a secession took place under the name of the *Union des églises évangéliques de France.* This society held a synod at which a confession of faith and a book of order were drawn up. Meanwhile the national Protestant Church set itself to the work of reconstruction; and in 1852 a change took place in its constitution. The *églises consistoriales* were abolished, and in each parish a presbyterial council was appointed, the minister being president, with four to seven elders chosen by the people. In the large towns there were consistories composed of all the ministers and of delegates from the various parishes. Over all was the central provincial council consisting of the two senior ministers and fifteen members nominated by the state in the first instance. The vigour shown by the two groups of Presbyterian churches in France (whose members number nearly half the Protestant population) in the work of reorganization since the Great War, has helped to vitalize French Presbyterianism.

The Netherlands.— From the geographical position of the Netherlands, Presbyterianism there took its tone from France. In 1562 the *Confessio belgica* was publicly acknowledged, and in 1563 the church order was arranged. In 1574 the first provincial synod of Holland and Zealand was held, but William of Orange would not allow any action to be taken independently of the state. The Reformed churches had established themselves in independence of the state when that state was Catholic; when the government became Protestant the Church had protection and at the same time became dependent. It was a state church, and could not shake off the civil power in connection with the choice of church officers. Thus, although the congregations were Presbyterian, the civil government retained overwhelming influence. The Leiden magistrates said in 1581: "If we accept everything determined upon in the synod, we shall end by being vassals of the synod. We will not open to churchmen a door for a new mastership over government and subjects, wife and child." From 1618 a modified Presbyterian polity predominated. In 1795, of course, everything was upset, and it was not until after the restoration of the Netherland States that a new organization was formed in 1816. Its main features were strictly Presbyterian, but the minister was greatly superior to the elder, and the state had wide powers especially in the nomination of higher officers. In 1851 the system now in force was adopted. The congregation chooses all the officers, and these form a church council.

England.— Presbyterian principles and ideas were entertained by many of the leading ecclesiastics in England during the reign of Edward VI. Even the archbishop of Canterbury favoured a modification of episcopacy, and an approach to Presbyterian polity and discipline; but attention was mainly directed to the settlement of doctrine and worship. Cranmer wrote that bishops and priests were not different but the same in the beginning of Christ's religion. Thirteen bishops subscribed to the proposition that in the New Testament there is no mention made of any distinctions or degrees in orders but only deacons and "priests or bishops." As an indication of sympathy with Presbyterianism, it may be noted that Cranmer favoured a proposal for the formation of a council of presbyters in each diocese, and for provincial synods.

During 1567 and 1568 the persecutions in France and Holland drove thousands of Protestants, mostly Presbyterians, to England. In 1570 Presbyterian views found a distinguished exponent in Dr. Thomas Cartwright at Cambridge. In 1572 a formal manifesto was published, entitled an *Admonition to Parliament,* the leading ideas in which were: parity of ministers, appointment of elders and deacons; election of ministers by the congregation; objection to prescribed prayer and antiphonal chanting; preaching, the chief duty of a minister; and the power of the magistrates to root out superstition and idolatry. On the 20th of November 1572 the authors of the "Admonition" set up at Wandsworth what has been called the first presbytery in England. They adopted a purely Presbyterian system which was published as the *Orders of Wandsworth.* Similar associations or presbyteries were formed in London and in the midland and eastern counties; but the privy council was hostile. The temper of Parliament was shown by the introduction of bills to reduce the position of a bishop to well-nigh that of *primus inter pares;* to place the power of veto in the congregation; to abolish the canon law and to establish a presbytery in every parish. These proposals were rendered abortive by the unflinching use of the queen's prerogative.

In 1640 Henderson, Baillie, Blair and Gillespie came to London as commissioners from the General Assembly in Scotland, in response to a request from ministers in London who desired to see the Church of England more closely modelled after the Reformed type. They were able men, whose preaching drew great crowds, and increased the desire for the establishment of Presbyterianism. In 1642 the Long Parliament abolished Episcopacy (the act to come into force on the 5th of November 1643); and summoned an assembly of divines to meet at Westminster in June 1643 to advise parliament as to the new form of Church government. The Westminster Assembly, through its *Confession, Directory* and *Catechism,* has become so associated with the Presbyterian Church that it is difficult to realize that it was not a church court at all, much less a creation of Presbyterianism.

It was a council created by parliament to give advice in church matters at a great crisis in the nation's history; but its acts, though from the high character and great learning of its members worthy of deepest respect, did not *per se* bind parliament or indeed anyone. It was, in a very real sense, representative of the whole country, as two members were chosen by parliament from each county. The number summoned was 151, viz., ten lords, twenty members of the House of Commons, and one hundred and twenty-one ministers. The ministers were mostly Puritans; by their ordination, etc., Episcopalian; and for the most part strongly impressed with the desirability of nearer agreement with the Church of Scotland, and other branches of the Reformed Church on the Continent. About one-half of the members attended regularly. Those who were out-and-out Episcopalians did not attend at all. Apart from these, there were three well-defined parties: (1) those with Presbyterian ideas and sympathies, a great majority; (2) Erastians, ably represented and led by Selden, Lightfoot and Coleman; (3) Independents, ten or eleven in number, led by Philip Nye, and assured of Cromwell's support. Then there were the Scottish commissioners who, though without votes, took a leading part in the proceedings. Judged by the objects for which it was summoned the Westminster Assembly was a failure, a remarkable failure. Episcopacy, Erastianism and Independency, though of little account in the assembly, were to bulk largely in England's future; while the church polity which the assembly favoured and recommended was to be almost unknown. Judged in other ways, however, the influence of the assembly's labours has been very great. *The Confession of Faith* and the *Larger* and *Shorter Catechisms* are recognized and venerated standards in all the lands where British Presbyterianism, with its sturdy characteristics, has taken root. And the *Directory of Public Worship* has shaped and coloured, perhaps too thoroughly, the ritual and atmosphere of every group of Protestant Anglo-Saxon worshippers throughout the world, except Episcopalians.

In June 1646 the ordinance establishing presbyteries was ratified by both houses of parliament, and a few days afterwards it was ordered to be put into execution. But the system never took root. Not only were there well-known adverse influences, but the soil seems to have been uncongenial. During the Commonwealth Independency gained ground. Then with the Restoration came Episcopacy, and the persecution of all who were not Episcopalians; and the dream and vision of a truly Reformed English Church practically passed away. From the beginning of the 18th century the greater number of the Presbyterian congregations became practically independent in polity and Unitarian in doctrine. Indigenous Presbyterianism became almost unknown. The Presbyterianism now visible in England is of Scottish origin and Scottish type, and beyond the fact of embracing a few congregations which date from, or before, the Act of Uniformity and the Five Mile Act, has little in common with the Presbyterianism which was for a brief period by law established. In 1876 the union of the Presbyterian Church in England with the English congregations of the United Presbyterian Church of Scotland gathered all English Presbyterians (with some exceptions) into one church, "The Presbyterian Church of England." Following the lead of the Independents, who set up Mansfield College at Oxford, the Presbyterian Church has founded Westminster College at Cambridge as a substitute for its Theological Hall in London. It was opened in 1899 with the view of securing a home-bred ministry more conversant with English academic life and thought.

Ireland.—Presbyterianism in Ireland, in modern times at least, dates from the plantation of Ulster in the reign of James I. The infusion of a considerable Scottish element into the population necessitated the formation of a congenial church. The immigrants from England took with them, in like manner, their attachment to the Episcopal Church. But these two sections of Protestantism, in their common exile and in presence of the preponderating Roman Catholicism of the country, seemed at first inclined to draw closer together than had been thought possible in Great Britain. A confession of faith, drawn up by Archbishop Usher at the Convocation of 1615, implicitly admitted the validity of Presbyterian ordination, and denied the distinction between bishop and presbyter. Within the Episcopal Church and supported by its endowments, Robert Blair, John Livingstone and other ministers maintained a Scottish Presbyterian communion.

From 1625 to 1638 the history of Irish Presbyterians is one of bare existence. Their ministers, silenced by Wentworth, after an ineffectual attempt to reach New England, fled to Scotland, and there took a leading part in the great movement of 1638. After the Irish rebellion of 1641 the Protestant interest for a time was ruined. A majority of the Ulster Protestants were Presbyterians, and in a great religious revival which took place the ministers of the Scottish regiments stationed in Ireland took a leading part. Kirk-sessions were formed in four regiments, and the first regular presbytery was held at Carrickfergus on the 10th of June 1642, attended by five ministers and by ruling elders from the regimental sessions. This presbytery supplied ministers to as many congregations as possible; and for the remainder ministers were sent from Scotland. By the end of 1643 the Ulster Church was fairly established. Notwithstanding intervening reverses there were by 1647 nearly thirty ordained ministers in fixed charges in Ulster besides the chaplains of the Scottish regiments. After the Restoration the determination of the government to put down Presbyterianism was speedily felt in Ireland. In 1661 the lords justices forbade all unlawful assemblies, and in these they included meetings of presbytery as exercising ecclesiastical jurisdiction not warranted by the law. Bishop Jeremy Taylor was forward in this work of persecution. The ministers refused tb take the Oath of Supremacy without the qualifications suggested by Usher. Their parishes were declared vacant, and episcopal clergy appointed to them. The ejected ministers were forbidden to preach or administer the sacraments. Under Ormonde, in 1665, ministers were again permitted to revive Presbyterian worship and discipline, and for several years the Church prospered not only in Ulster but also in the south and west. In 1672 she received a yearly grant from Charles II. of £600 (*regium* donum), and under William III. the amount was considerably increased. Trouble arose again over the policy of James II., to which the Irish Presbyterians were opposed, though they had benefited by his Declaration of Indulgence, and they were the first to congratulate the Prince of Orange on his arrival in England. The defence of Londonderry owed much to them, as they were a majority of the population, and some of their ministers rendered conspicuous service. There were then in Ireland about a hundred congregations, seventy-five with settled ministers, under five presbyteries.

The Presbyterian Church in Ireland is the most conservative of the great Presbyterian churches in the United Kingdom. Her attitude is one of sturdy adherence to the old paths of evangelical doctrine and Presbyterian polity. She has been a zealous supporter of Irish national education, which is theoretically "united secular and separate religious instruction." The Church Act of 1869 which disestablished and disendowed the Irish Episcopal Church took away the Presbyterian *regium* donum. The ministers, with all but absolute unanimity, decided to commute their life-interest and form therewith a great fund for the support of the Church. The commutation fund thus formed is a permanent memorial of a generous and disinterested act on the part of her ministry. The interest accruing from it is added to the yearly sustentation contributions, and forms a central fund for ministerial support. Since the state endowment ceased the average income of ministers from their congregations has considerably increased.

Wales.—The Presbyterian Church of Wales, commonly known as the "Calvinistic Methodist," had its origin in the great evangelical revival of the 18th century. Its polity has been of gradual growth, and still retains some features peculiar to itself. In 1811 its preachers were first presbyterially ordained and authorized to administer the sacraments. In 1823 a Confession of Faith was adopted. In 1864 the two associations or synods of North and South Wales were united in a general assembly. Great attention is given to the education of the ministry, a considerable number of whom, in recent years, have taken arts degrees at Oxford and Cambridge. As far as the difference in language will permit, there is cordial fellowship and co-operation with the Presbyterian Church of England. The appetite of the Welsh people for sermons is enormous, and the preachers are characterized by an exceptionally high order of pulpit power.

Other European Countries.—In Germany the disestablishment of the churches, which followed the Revolution, has moved the Reformed section of the Church, tlie "Reformierte Bund," to stress its distinctively Presbyterian principles, and as its membership numbers over 600,000 souls, it is destined to exercise a powerful influence in the future reorganisation of the Evangelical churches in that country. The rise of the new state of *Czechoslovakia* in 1918 led to an extraordinary break-away from the Roman Church; the united Evangelical Church of Czech Brethren now numbers over 250,000 adherents, one of its members being President Masaryk. A similar movement is reported from Ukrainia, further east, where over 1,000,000 inhabitants have left the Roman and the Orthodox churches, and are being consolidated in a Presbyterian Church, largely under the mission work of Ukrainians who came back from Canada to carry on the movement. In Transylvania, on the other hand, the Presbyterians, like the rest of the religious minorities have suffered and are still suffering under oppressive legislation at the hands of the Rumanian Government. The Magyar Reformed Church, with 800 ministers and about 720,000 souls under its charge, has to encounter the Rumanian prejudice against Magyars and the Greek Orthodox dislike of Protestants. The rights guaranteed by the Peace Treaty of 1918 to religious minorities are imperfectly observed by the Rumanian Govt. and no remonstrances from outside have yet availed to check the persecution of the Church. Hungarian Presbyterians in Transylvania thus suffer heavy damage by the War-settlement which brought relief and advance to their Bohemian brethren. In Hungary, although the partition of the country brought about untoward religious results, the Reformed Church is still powerful both in numbers and in prestige, with over 1,000 congregations and 1,500,000 adherents. The Magyar racial problem emerges again in the position of the Magyar Reformed Church in Czechoslovakia, where about 40,000 members still keep apart from the larger Church of the country, and in the Reformed Church of Yugoslavia, where the members, two-thirds of whom (in all, about 23,000) are Magyars, lie exposed to hardships like those of their brethren in Transylvania. Possibly the racial prejudices and religious rivalries which make the situation in Transylvania and Yugoslavia so bitter at present may die down in the course of years; meantime the redeeming feature is the tenacity with which the oppressed Presbyterians maintain their faith amid a struggle in which, unfortunately, their outside brethren are unable to afford them very much practical sympathy. The four Presbyterian churches in Switzerland have formed a Federation of Evangelical Churches, representing 2,250,000 souls. Switzerland has felt, like most other countries, the call to re-union in organised religion, and the rise of this Federation is a first proof of the Swiss interest in unity. Since 1919 efforts have been made to bring together the Evangelical Church of Neuchatel and the mother church from which it broke away under Godet in 1873, but the local difficulties are still insurmountable. In Belgium the two small Presbyterian churches, the Union of Reformed Churches and the Missionary Church in Belgium. suffered heavily during the War. Together they now number 50 congregations, with 22,000 members. An even smaller group is the Reformed Helvetic Church in *Austria,* with its centre at Vienna, which numbers 25,000 souls, out of a total Protestant population of 260,000. The Waldensian Evangelical Church in *Italy* numbers only 22,633 members in 112 congregations, but its sturdy spirit is unabated; indeed since the War it has asserted itself more definitely than ever in Italian life, actually holding an Evangelical Congress at Rome itself, in 1920. Its theological college is now transferred from Florence to Rome. The *Spanish* Evangelical Church has but 1,000 members, a tenth of the total Protestant population in Spain, with 26 ministers and 32 congregations. Still fewer, though for no such reasons as in Italy and Spain and Belgium, are the Presbyterians in *Denmark and Sweden,* with three congregations between them and barely 400 communicants. The History of these countries seems to have marked the Lutheran form of organisation as native to their genius, as is the case with Norway. In *Russia* the Bolshevik persecution has reduced the Reformed Church from 25 to two congregations, which still survive in Moscow and Odessa. In *Poland* the Reformed Synod of Warsaw is now reduced to seven congregations, with barely 11,000 people; however, the transfer of Galicia from Austria has added a Reformed Church of three congregations and 7,000 souls. In *Lithuania,* which was mangled by the Peace settlement, the ancient Reformed Church numbers only nine congregations, with 17,527 members, but the land is politically free, and, though it is still predominantly Roman Catholic, the first national Cabinet was half Protestant in its membership.

Canada, Australia, Africa.—The United Church of Canada came formally into existence at Toronto on June 10, 1925. This remarkable union of Congregationalists, Methodists and Presbyterians is the outcome of negotiations which have been proceeding since 1908, in order to cope effectively with the religious needs of the Dominion, where (especially in the west) the ecclesiastical divisions were felt to be a serious weakness. The legislation required to make the union effective was carried through the Canadian Parliament in 1924. The polity of the united church is admittedly Presbyterian. A minority of the Presbyterian Churches (714 out of 4,531 congregations) declined to follow the lead. In *Australia* a movement for re-union similar to the Canadian enterprise has been wrecked in the meantime. Both in Australia and in New Zealand the shortage of ministers is being acutely felt, in face of the increasing number of immigrants and the scattered population. Australasia reckons 127,305 communicants (including the Missionary Synod of Tahiti, New Hebrides, etc.) with 967 ministers, but the latter are insufficient for the needs of the situation. Another failure of Presbyterianism to unite with other branches of the Church has to be chronicled in *South Africa.* In 1917 the Presbyterian Church inaugurated a movement for union with the Congregationalists, but the project had to be abandoned in 1921, partly on account of the colour question. Within the Presbyterian Church herself the colour question has had to be solved by the creation of the Bantu Presbyterian Church, composed of purely African natives, independent but allied. On the other hand, the Church of Central Africa came into being on Sept. 17, 1924, a very fine example of union between the Church of Scotland's Blantyre Presbytery, the United Free Church's Livingstonia Presbytery and the Dutch Reformed Church's Nyassaland (Mission) Presbytery. The Dutch Reformed Church in South Africa with a membership embracing 840,000 white adherents, brings up the total of Presbyterians in Africa at present to a large number, proportionately; there are in all 1,768 congregations, including the various missions and 532,085 communicants. A growing spirit of co-operation is also manifest.

Asia.—In *India* the South United Church was formed of Presbyterians and Congregationalists in 1908; the community numbers over 240,000, and proposals have even been made for union between this Church and the Southern Indian section of the Church of England. The North United Church, also on a Presbyterian basis, arose in Dec. 1924, from the Presbyterian Church, which had received 53,000 Welsh Calvinistic Methodists from Assam in 1921, and the local Congregationalists. On a smaller scale the genesis of the United Church of Christ in *China* resembles that of the Indian and the Canadian communities. It arose in 1921 from the Presbyterians and the Congregationalists, the former numbering 87,332 members, the latter 29,000. This had been rendered possible by a previous reunion among the Presbyterians themselves; in 1918, after 11 years' negotiations, 10 different missions came together to form the Presbyterian Church in China. The combined community is now the largest Protestant Church in China. In *Korea* the Church, originally founded by American missionaries, has prospered rapidly, and displays a true missionary spirit; it numbers 1,266 congregations, with a Christian community of over 200,000. (W. Y.; J. MoF.; X.)

UNITED STATES

Presbyterianism in the United States is a reproduction and further development of Presbyterianism in Europe. Excluding the "Reformed" Churches—which also maintain, with minor modifications, the Presbyterian form of church government (*see* REFORMED CHURCH IN THE UNITED STATES and REFORMED CHURCH IN AMERICA), there are some ten Presbyterian denominations in the United States. In what follows, attention will be devoted mainly, but not exclusively, to the largest and most influential of these bodies—the Presbyterian Church in the United States of America. The narrative naturally falls into three periods.

I. The Colonial Period.—The earliest Presbyterian emigration from Europe to America was that of French Huguenots who, under the auspices of Admiral Coligny, were led by Jean Ribaut to Port Royal, S.C., in 1562, and to Florida (near the present St. Augustine) by Laudonniere, in 1564. In the latter half of the 17th century there were Huguenot churches at Boston, New York city, New Rochelle, N.Y., and Charleston, S.C.

English Puritanism under the auspices of the Virginia Company established itself in the Bermuda islands as early as 1612; and in 1617 a Presbyterian church, governed by ministers and four elders, was organized by the Rev. Lewis Hughes, who used the liturgy of the isles of Guernsey and Jersey. A considerable number of the Puritans who settled in Massachusetts were Presbyterians, and their churches in Connecticut were commonly spoken of as Presbyterian. The early New England churches have been aptly described as representing, in general, "a Congregationalized Presbyterianism, or a Presbyterianized Congregationalism." Later the Congregational elements predominated in these regions, and in the main only those Puritans who drifted west and south of New England became a permanent part of the Presbyterian Church. In New York city, Francis Doughty preached to Puritan Presbyterians in 1643, though there was no organized Presbyterian church there before 1717. In 1650 he was succeeded by Richard Denton, who returned to England in 1659. The oldest church on Long Island—of those now under the care of the General Assembly of the Presbyterian Church in the U.S.A.—is that of Southold, established in 1640 by the Rev. John Young. The first Presbyterian churches in North and South Jersey—Newark (1667), Elizabeth (1668), Woodbridge (1680) and Fairfield (1692)—were due to Puritan migrations from Connecticut and Long Island.

After leaving New York, Francis Doughty laboured in Virginia and Maryland from 1650 to 1659, becoming the pioneer of British Presbyterianism in the Middle Colonies. Likewise, other Presbyterian ministers, chiefly from Great Britain and Ireland, began to labour in the Middle Colonies and in the Carolinas during the latter half of the 17th century—Matthew Hill, William Trail, Joseph Lord and Archibald Stobo.

The tap-root of American Presbyterianism is to be found in Maryland, the chief field of the apostolic labours of Francis Makemie, the foremost representative of the Irish Presbyterians and the virtual founder of the American Presbyterian Church. He was born in Ireland, educated in Scotland, ordained and commissioned by the Presbytery of Laggan, in Ireland, to be a missionary to the Barbadoes and other American colonies. He organized several churches in Maryland, including those at Snow Hill and Rehoboth, the latter probably as early as 1683. He itinerated from New York to the Carolinas, preaching and establishing churches. He did much to encourage that notable immigration of Presbyterians from Scotland and Ireland who, to escape the prelatic oppressions under the Stuarts, crossed the sea and ere iong made Presbyterianism the dominant religious force in New Jersey, eastern Pennsylvania and Delaware. In 1706, he secured the establishment of the first presbytery. popularly known, from its customary place of meeting, as the Presbytery of Philadelphia. He was chosen to be its first moderator. Of the eight ministers composing the judicatory at the close of that year, all were foreign-born excepting Jedediah Andrews, a native of Massachusetts and a graduate of Harvard college. He began his ministry in Philadelphia in 1698, and in 1701 was ordained and installed in what is now the First Church. All but two of the eight were ordained in Scotland or Ireland.

In 1716 the presbytery had 17 ministers on the roll, the number having more than doubled in a single decade. In view of the difficulties of travel and the wide territory represented, the presbytery resolved in that year to transform itself into a synod, with four presbyteries under its jurisdiction (Philadelphia, New Castle, Snow Hill and Long Island). The first meeting of the synod was held on Sept. 17, 1717. In 1729 the synod passed what is called the Adopting act, by which it was agreed that "all the ministers of this synod, or that shall hereafter be admitted into this synod, shall declare their agreement in, and approbation of, the Confession of Faith, with the Larger and Shorter Catechisms of the Assembly of Divines at Westminster, as being in all essential and necessary articles good forms of sound words and systems of Christian doctrine." The act allowed scruples about "articles not essential and necessary in doctrine, worship, or government," the court, not the individual, being the judge of the issue raised.

The religious revival known as the Great Awakening profoundly affected most of the Protestant Churches, stimulating their evangelistic, missionary and educational enterprises, and proving itself a decisive factor even in the political sphere by breaking down some of the barriers of sectarian isolation, and promoting the sense of the growing national unity. But the revival also brought discord. The zealous evangelists severely criticized all who questioned the wisdom and propriety of their methods. Gilbert Tennent was especially censorious, and his sermon on "An Unconverted Ministry" was aimed at the opponents of the revival. He and his three brothers—sons of the William Tennent who in 1727 established the celebrated "Log College" at Neshaminy, Pa,, as a training school for the ministry—were prominent leaders of the "new side," while Robert Cross and Jedediah Andrews were foremost in charging the Tennents with heresy and disorder. The consequence was the first division of the Church (1741). The synod of Philadelphia represented the "old side"; and the synod of New York, the "new side." The latter body was the more enterprising and prosperous, making provision for the training of its ministers by the establishment at Elizabeth, in 1747, of the College of New Jersey, subsequently removed to Newark, and in 1756 to Princeton (now known as Princeton university). In 1758 a reunion of the two Synods was effected under the name of the "synod of New York and Philadelphia," upon the basis of the same Westminster standards of doctrine, polity and worship which both sides had maintained after their separation.

The Presbyterians from the Scots established Church, when they came to the Colonies, commonly joined the main body of American Presbyterians; but the seceding Churches of Scotland organized independent bodies. The Reformed Presbyterian Church (Covenanters) sent the Rev. John Cuthbertson in 1751. After labouring alone for many years in the interests of his denomination, with the aid of two fellow labourers from Scotland, Rev. Matthew Lind and Rev. Alexander Dobbin, he organized in 1774 the Reformed Presbytery of America. The Anti-Burgher Synod of Scotland sent two ministers, Alexander Gellatly and Andrew Arnot, to represent their cause, and thus were organized the Associate Presbytery of Pennsylvania (1753) and that of New York (1776). These two presbyteries joined with the Covenanters in 1780 and 1782 to make the Associate Reformed Church of America; but opposing minorities in both presbyteries kept up the separate denominations.

During the American Revolution the Presbyterian churches throughout the Colonies suffered severely. The devotion of their members, especially the Scotch-Irish, to the cause of national independence was equalled by that of no other denomination. No racial or religious group was superior to them in intelligence, love of freedom, moral firmness and capacity for political achievement. At the time of the Revolutionary War almost 2,000,000 of the 3,000,000 inhabitants of the 13 Colonies were of Calvinistic stock. The form of government of our nation is practically the form of government of the Presbyterian Church with such modifications as the civil sphere requires. The public-school system of America has grown out of the parish schools established in a multitude of Presbyterian parishes by their pastors. Many of the ministers served as chaplains or combatants. John Witherspoon, president of the College of New Jersey, was the only clerical member of the Continental Congress in 1776, and in many lines of activity, civil and military, he rendered distinguished service to his adopted country. John Murray, of the Presbytery at the Eastward, had as high a price set on his head by the Tories as did Samuel Adams or John Hancock. The testimony of the historian Bancroft to the patriotic fidelity of the Presbyterians is too familiar to be quoted. At the close of the war, the Synod of New York and Philadelphia, sharing in the general movement towards organization of nation-wide churches, soon made good the losses sustained during the struggle for independence, and in 1788 took steps to divide itself into four synods, with a General Assembly, consisting of representative delegates, both ministers and laymen, to serve as the supreme legislative, judicial and executive agency of the whole church. The Synod adopted as the constitution for the re-organized church the Westminster Confession of Faith, amended in Chapter xxiii., in regard to the relation of the civil power to the church; the Larger Catechism, with an amendment as to the toleration; the Shorter Catechism; the Directory of Worship, much revised; and the Form of Government and the Book of Discipline, with many alterations. It was also provided that thereafter the standards could be amended only by a two-thirds vote of the presbyteries, and subsequent enactment by the Assembly.

In 1801 this body entered into a Plan of Union with the General Association of Connecticut, for the purpose of a more efficient joint performance of their home missionary duties. This scheme, did, indeed, promote aggressive missionary work, and in the next half-century most of the existing theological seminaries of the Presbyterian Church were established to furnish ministers for the ever-expanding task: Princeton, 1811; Auburn, 1818; Union at Hampden-Sidney, later at Richmond, Va., 1824; Allegheny, 1827; Columbia, S.C., 1828; Lane, at Cincinnati, 1829; McCormick at Chicago, 1830; Union at New York, 1836; Dubuque, Ia., 1856. But while most of the Puritan migration from New England to the west was identified with the Presbyterian Church, these great gains in number were to a large extent offset by troublesome irregularities in polity, laxity in discipline and novelties in theology, all of which presently led to another division of the main Presbyterian body. To increase the embarrassments that grew out of the plan of union, there was the administrative question as to the best method of conducting the general benevolent and missionary work of the church. The supporters of the old order ("Old School"), deeply alarmed, charged their opponents ("New School") with doctrinal aberrations in 16 counts; with errors in church order in ten; and with mistakes in discipline in four.

After several years of bitter controversy, culminating in repeated but vain efforts to remove offending ministers by due process of law, the Old School Assembly of 1837, realizing that it once more had a majority—only the second time in seven years—abrogated the Plan of Union and then exscinded the Synod of Western Reserve in Ohio, and the Synods of Utica, Geneva and Genesee, in New York. The New School met in convention at Auburn, N.Y., in Aug., 1837, and adopted a "Declaration" setting forth the "True Doctrines" of their party as against the "Errors" charged on them by their opponents. When the Assembly met in 1838, the New School commissioners were denied legal standing in the court; whereupon they withdrew, organized their own Assembly, with the same title as the other body, and brought suits in the civil courts of Pennsylvania to determine the property issues involved. The first decision favoured the New School (1839); but the court en *banc* set aside this verdict on grounds that made another trial useless. After the division was completed the New School embraced about four-ninths of the ministry and membership of the Church, but in spite of its being almost as large as the other body, its growth was slow. It continued to co-operate with the Congregationalists for some time, but in 1852 it decided, in view of the ever-increasing doctrinal defection among the Congregationalists, to accept the proposal of the latter for the abolition of the Plan of Union. In the course of a few years, moreover, the strong anti-slavery sentiment among New School leaders led to the voluntary withdrawal of nearly all the Southern churches connected with this Assembly and to their organization as the United Synod of tht Presbyterian Church. The Old School Assembly also was rent asunder during the Civil War. The occasion was the adoption of the "Spring Resolutions" (1861), which declared it the duty of the church "to promote and perpetuate . . . the integrity of the United States, and to strengthen, uphold and encourage the Federal Government in the exercise of all its functions. . . ." During the summer of 1861, 47 Southern presbyteries of the Old School renounced their General Assembly and formed the Presbyterian Church in the Confederate States of America.

Another important division in the main body of Presbyterians during this period was that of the Cumberland Presbyterians. Kentucky and Tennessee, at the beginning of the 19th century, were particularly affected by the revival of religion which spread over most of the Eastern States. To accommodate the large crowds that wanted to hear the Gospel, "camp meetings" were much used in these frontier regions. The religious excitement became intense. Even children again and again preached with powerful effect. The demand for ministers far exceeded the supply. Under these circumstances the Presbytery of Transylvania, and then the Cumberland Presbytery—set off from the former in 1802—began ordaining a number of zealous young men who, in the judgment of the Synod of Kentucky, had not had an adequate training for the office and were unsound in doctrine. The Synod, in 1806, dissolved the Cumberland Presbytery, which in a few years organized itself into a new denomination (1810). It grew rapidly in numbers, as well as in its respect for, and its insistence upon, an educated ministry. The Synod of Cumberland, established in 1813, adopted as its standard the Westminster Confession, but in revised form, the alterations being designed to eliminate what was called the "fatalism" of this symbol. In 1829 a General Assembly was formed.

In 1822, under the influence of John M. Mason, the Associate Reformed Synod undertook a union with the General Assembly of the Presbyterian Church, but most of the ministers opposed the project and organized three independent presbyteries. In 1858 the Associate Synod and the General Synod of the Associate Reformed Church effected a union under the style of the "United Presbyterian Church." the basis being the Westminster Confession (slightly altered) and a "Testimony" in 18 articles, the last of which declared that "it is the will of God that the songs contained in the Book of Psalms be sung in His worship, both public and private, to the end of the world; and that in singing God's praise, these songs should be employed to the exclusion of the devotional compositions of uninspired men"—a requirement now left to the discretion of the individual church.

In 1833 the Reformed Presbyterian Church divided into New and Old Lights on the question as to whether their members may properly exercise the rights of citizenship under the U.S. Constitution.

III. The Modern Period (Since the Civil War).—Several important church unions mark this period. In the South, under the stress of the Civil War, the two branches that had seceded from the Old and the New School Assemblies, namely, the Presbyterian Church in the Confederate States of America and the United Synod of the Presbyterian Church, united in 1865, and at the close of the war adopted the name of the Presbyterian Church in the United States. In the North also, after several years of friendly negotiations, the Old School and the New School united in 1869 on the basis of "the standards pure and simple," and commemorated the happy event by raising a memorial fund of over $7,000,000. In 1906 the Presbyterian Church in the U.S.A. united with the Cumberland Presbyterian Church, and in 1920 with the Welsh Calvinistic Methodists.

In 1902 the General Assembly of the Presbyterian Church in the U.S.A. adopted a "Brief Statement of the Reformed Faith," not as an addition to its standards, but rather for popular use as an interpretation of its Confession, and the next year it made several amendments to this Confession, adopted a "Declaratory Statement" as to Chapters iii. and x., and added two new chapters, entitled "Of the Holy Spirit" and "Of the Love of God and Missions."

The Presbyterian Church in the U.S.A. administers its national and international affairs, other than those committed by its General Assembly to its four benevolent boards, to which reference will be made below, through the office of the General Assembly (five departments—administration, vacancy and supply, publicity, church co-operation and union, and historical) which has as its permanent executive head the stated clerk of the General Assembly; and through the General Council (23 members) of which the moderator of the General Assembly is, ex-officio, chairman (one year term) and the stated clerk secretary by election.

The Presbyterian Church in the U.S.A. has, under the supervision of the board of foreign missions, important missions in Africa, Mesopotamia, Persia, Syria, India, Siam, China, Japan, Chosen, Laos, Latin America and the Philippine Islands. Besides this board, it has, since the consolidations (1923) of its many agencies, three other boards, those for national missions (six divisions), Christian education (eight departments), and ministerial pensions ($15,000,000 fund raised, 1927), each of which boards carries on a work comparable in importance with that conducted by the board of foreign missions.

The Presbyterian Church in the U.S. (Southern) unlike the Presbyterian Church in the U.S.A., works not through "boards," but through executive committees, which were formerly more loosely organized, and which left to the presbyteries the more direct control of their activities, but which now differ little from the boards of the Presbyterian Church in the U.S.A. The Presbyterian Church in the U.S. has executive committees on foreign missions, home missions, publication and Sabbath school work, Christian education and ministerial relief, men's work, advisory committee on education, Protestant relief in Europe, Bible cause, reformation day and a permanent judicial committee, which report to the General Assembly annually.

The United Presbyterian Church of North America has a board of foreign missions, a board of home missions, a board of publication and Bible school work, a board of education and a board of ministerial pensions and relief, and a woman's guild and missionary society.

In 1928 the Presbyterian bodies, nine in number, reported 2,800,000 communicant members while other closely related bodies reported 550,000 additional communicants. The Presbyterian

Church in the United States of America, the largest of the Presbyterian bodies, reported 1,962,838 communicant members; 9,432 churches; 10,013 ministers; 1,614,013 Sabbath school members; total benevolences $15,642,508; total congregational expenses $48,956,022. The next largest body, the Presbyterian Church in the United States (Southern), reported 444,657 communicant members; 3,596 churches; 2,342 ministers; 431,065 Sabbath school members; total benevolences $5,520,285; congregational expenses $10,306,188. The United Presbyterian Church of North America reported 238,240 communicant members; 898 churches; 927 ministers; 182,304 Sabbath schoolmembers; $1,683,212 total benevolences; $4,254,717 congregational expenses.

PRESBYTERY, in architecture, that portion of the choir of a church in which the high altar is placed, and which is generally raised a few steps above the rest of the church. It is reserved for the priests and differs from the choir, the stalls in which are occasionally occupied by the laity. In Westminster Abbey the space east of the transept is the presbytery, and the same arrangement is found in Canterbury cathedral. In S. Clemente at Rome the presbytery is enclosed with a marble balustrade or screen. For the use of the word in Church government *see* PRESBYTER and PRESBYTERIANISM.

PRESCOT, urban district, Lancashire, England, 8 mi. E. of Liverpool by the L.M.S.R. Pop. (est. 1938) 11,510. Area 1.4 sq.mi. It is of considerable antiquity and received a grant for a market and fair by Edward III. A church existed in the 13th century. The present church of St. Mary is in various styles, with a lofty tower and spire and carved timber roof. Since John Miller brought the industry from Yorkshire (1730) the town has been famed for watches, watch movements and tools. Electric cables are also manufactured. To the north is Knowsley Park, seat of the earls of Derby, containing a fine collection of pictures.

PRESCOTT, WILLIAM HICKLING (1796–1859), American historian, was born in Salem (Mass.), on May 4, 1796, his grandfather being Colonel William Prescott (1726–95), who commanded at the battle of Bunker Hill, and his father, a well known lawyer. Although he was blinded in one eye by a crust of bread flung in the Harvard Commons, he graduated with honour in 1814 and entered his father's office. The verdict of physicians abroad, however, that the injured eye was hopelessly paralysed, and that the preservation of the sight of the other depended upon the maintenance of his general health, caused him to abandon further pursuit of the legal profession and to devote his life to literature. A review of Byron's *Letters on Pope* in 1821 constituted his first contribution to the *North American Review,* to which he continued for many years to send the results of his slighter researches.

Although his early essays were distinctly literary, history had always been a favourite study with him, and Mably's *Observations sur l'histoire* appears to have influenced him. After prolonged hesitation, he recorded in Jan. 1826 his decision "to embrace the gift of the Spanish subject." The choice was certainly a bold one, but he was happy in the possession of ample means and admirable friends. His method of work is an excellent illustration of his resourcefulness and perseverance. Seated in a darkened study, he kept his writing apparatus (a noctograph) before him, and his ivory stylus in his hand to jot down notes as his assistant read aloud. These notes were in turn read over to him until he had completely mastered them, when they were worked up in his memory to their final shape. So proficient did he become that he was able to retain the equivalent of 60 pages of printed matter in his memory, turning and returning them as he walked or drove. On Oct. 6, 1829 he began the actual work of composition of his *History of the Reign of Ferdinand and Zsabella,* the concluding note being written June 25, 1836. Another year, during which his essay on *Cervantes* appeared, was spent in the final revision of the *History* for the press. Its success was immediate. From the position of an obscure reviewer Prescott suddenly found himself elevated to the first rank of contemporary historians.

After coquetting for a short time with the project of a life of Molière he decided to follow in the track of his first work with a *History of the Conquest of Mexico.* Washington Irving, who had already made preparations to occupy the same field, generously withdrew in his favour. Prescott's five years of labour on this second book were broken by the composition of various reviews and by the preparation of an abridgment of his *Ferdinand and Zsabella.* In Dec. 1843 the *Conquest of Mexico* was published with a success proportionate to the wide reputation he had won. The careful methods of work which he had adopted from the outset had borne admirable fruit. While the consultation of authorities had been no less thorough, his style had become more free and less self-conscious; and the epic qualities of the theme were such as to call forth in the highest degree his powers of picturesque narration. It was only a step from his great work on Mexico to that on Peru, and scarcely three months elapsed before he began to break ground on the latter subject. In Feb. 1845 he received the announcement of his election as corresponding member of the French Institute in place of the Spanish historian Navarrete, and also of the Royal Society of Berlin. The winter found him arranging for the publication in England of his *Critical and Historical Essays* (New York ed., *Biographical and Critical Miscellanies*). *The Conquest of Peru* was completed in Nov. 1846 and published in the following March. His misgivings as to its reception were at once set at rest, and it was speedily issued in translations into French, Spanish, German and Dutch, in addition to the English editions of New York, London and Paris. Prescott was now over 50 and his sight showed serious symptoms of enfeeblement. He had been for many years collecting materials for a history of Philip II., but he hesitated to attempt a work of such magnitude. Nevertheless in March 1848 he set himself with characteristic courage to its accomplishment. Through the aid of Don Pascual de Gayangos, then professor of Arabic literature at Madrid, he was enabled to obtain material not only from the public archives of Spain but from the muniment rooms of the great Spanish families. With an exceptional range of information thus afforded him, he wrote the opening of his history in July 1849; but, finding himself still unsettled in his work, he decided in the spring of the following year to carry out a long projected visit to England, where he was received with great honour. In Nov. 1855 the first two volumes of his uncompleted *History of Philip II.,* were issued from the press, their sale eclipsing that of any of his earlier books. This was his last great undertaking; but a year later he published in revised form Robertson's *Charles V.* A slight attack of apoplexy on Feb. 4, 1858 foretold the end, though he persevered with the preparation of the third volume of *Philip II.* for the press, and with the emendation and annotation of his *Conquest of Mexico.* On the morning of Jan. 28, 1859, a second attack occurred, and he died in the afternoon of the same day. Prescott's power lies chiefly in the clear grasp of fact, in selection and synthesis, in the vivid narration of incident. For extended analysis he had small liking and faculty; his critical insight was limited in range, and he confined himself almost wholly to the concrete elements of history. Moreover, the authorities on whom he relied have had to be corrected since in many points of detail in the light of later archaeological research. Few historians have had in a higher degree, however, that artistic feeling in the broad arrangement of materials which ensures popular interest.

BIBLIOGRAPHY.—The definitive or Montezuma ed. of Prescott's works was ed. by W. H. Munro (1904). His Life was written by George Ticknor (1864; rev. 1875). There are later lives by R. Ogden (1904) and H. T. Peck (1905). See also the chapters on Prescott and Motley in J. S. Bassett, The Middle Group of American *Historians* (1917) and The Cambridge History of American Literature (vol. 2, 1918); and sketch by M. A. D. Howe in American *Bookmen* (1898).

PRESCOTT, a city of central Arizona, U.S.A., on Federal highway 89 and the Santa Fe railway, at an altitude of 5,320 ft.; the county-seat of Yavapai county. Pop. (1920) 5,010 (82% native white); 6,018 in 1940 by the Federal census. It lies between the two divisions of the Prescott National Forest of 1,164,829 ac. in a region rich in mineral resources, flocks and herds, picturesque life (of Indians and ranchers), and natural beauty. The mines of the county produce copper, gold, silver, lead and zinc. Prescott is called "the cowboy capital" and the place "where the West remains."

It has held a Frontier Days' celebration annually since 1888, and the Smoki People of Prescott have since 1921 presented some of their ceremonial dances in an annual pageant of primitive Indian life. There are several "guest ranches" in the vicinity. Prescott was founded in 1864, to be the capital (1864–67) of the newly organized Territory of Arizona.

PRESCRIPTION, in the broadest sense, the acquisition or extinction of rights by lapse of time. The term is derived from the *praescriptio* of Roman law, originally a matter of procedure. It seems to have been introduced by the praetor to meet cases affecting aliens or lands out of Italy where the *usucapio* of the civil law (the original means of curing a defect of title by lapse of time) could not apply. The prescription of Roman law (and of modern systems based upon it) is both acquisitive and extinctive. It looks either to the length of time during which the defendant has been in possession, or to the length of time during which the plaintiff has been out of possession.

In English law prescription is used in a comparatively narrow sense. It is acquisitive only, and is very limited in its application. A title by prescription can be made only to incorporeal hereditaments—*i.e.,* in legal language, hereditaments that are or have been appendant or appurtenant to corporeal hereditaments — and to certain exemptions and privileges. The rights claimable by prescription for the most part consist of rights in alieno solo. The most important are advowsons, tithes, commons, ways, watercourses, lights, offices, dignities, franchises, pensions, annuities and rents. Land or movables cannot be claimed by prescription. The foundation of prescription is the presumption of law that a person found in undisturbed enjoyment of a right did not come into possession by an unlawful act. In the English courts this presumption was, perhaps still is, based upon the fiction of a lost grant. The enjoyment of the right must have been from a time whereof the memory of man runneth not to the contrary. After one or two previous enactments the date was finally fixed by the Statute of Westminster the First (3 Edw. I. c. 39) at the reign of Richard I., which was interpreted to mean the first year of the reign of Richard I. (1189). This is still the law with respect to claims not falling within the Prescription Act, 1832. By that act (extended to Ireland in 1858, but not to Scotland) claims to rights of common and other profits *à prendre* are not to be defeated after 30 years' enjoyment by any person claiming right thereto without interruption for 30 years by showing only the commencement of the right, and after 60 years' enjoyment the right is absolute and indefeasible unless had by consent or agreement by deed or writing (s. 1). In claims of rights of way or other easements the periods are 20 years and 40 years respectively (s. 2). The beforementioned periods are to be deemed those next before suits, and nothing is to be deemed to be an interruption unless acquiesced in for one year (s. 4). The time during which a person otherwise capable of resisting a claim is an infant, idiot, non *compos mentis,* feme covert or tenant for life, or during which an action or suit has been pending until abated by the death of a party, is to be excluded in the computation of the periods unless where the right or claim is declared to be absolute and indefeasible (s. 7). An act to define the period of prescription for a *modus decimandi,* or an exemption from tithes by composition, was passed the same year. The claim under the statute must be one which may be lawfully made at common law. The principal rules upon the subject are these: (1) The title is founded upon actual usage. The amount of actual usage and the evidence necessary to prove it vary according to the kind of claim. (2) The enjoyment must (except in the case of light) be as of right — that is to say, peaceable, openly used, and not by licence. (3) The prescription must be certain and reasonable. Inhabitants cannot, however, claim by prescription, as they are an uncertain and fluctuating body, unless under a grant from the Crown, which constitutes them a corporation for the purposes of the grant. (4) The prescription must be alleged in a *que* estate or in a man and his ancestors. Prescription in a que estate lies at common law by reason of continuous and immemorial enjoyment by the claimant, a person seised in fee, and all those whose estate he had. Prescription in a man and his ancestors is not of ordinary occurrence in practice. Corporations, however, occasionally claim by a prescription analogous to this, viz. in the corporation and its predecessors. Such claims by either a person or a corporation are not within the Prescription Act, which applies only where there are dominant and servient tenements. By 32 Hen. VIII. *c.* 2 (1540) no person can make any prescription by the seisin or possession of his ancestor unless such seisin or possession had been within three score years next before such prescription made. (5) A prescription cannot lie for a thing which cannot be granted, as it rests upon the presumption of a lost grant.

Prescription must be carefully distinguished from custom. Some rights may be claimed by custom which cannot be claimed by prescription, *e.g.,* a right of inhabitants to dance on a village green, for such a right is not connected with the enjoyment of land.

International Law uses the term "prescription" in its wider or Roman sense. "The general consent of mankind has established the principle that long and uninterrupted possession by one nation excludes the claim of every other" (Wheaton, *Int.* Law, s. 165). Historic instances of rights which were at one time claimed and exercised by prescription as against other nations are the sovereignty of Venice over the Adriatic and of Great Britain over the Narrow seas, and the right to the Sound dues long exacted by Denmark. But such claims were rejected by the highest authorities on international law (*e.g.,* Grotius), on the ground that they were defective both in *justus titulus* and in de facto possession. In private international law prescription is treated as part of the lex fori or law of procedure. (J. WIL.; X.)

Scotland. — In the law of Scotland "prescription" is a term of wider meaning than in England, being used as including both prescription and limitation of English law. In its most general sense it may be described as the effect which the law attaches to the lapse of time, and it involves the idea of possession held by one person adverse to the rights of another. Though having its basis in the common law, its operation was early defined by statute, and it is now in all respects statutory. Prescription in Scots law may be regarded (1) as a mode of acquiring rights — the positive prescription; (2) as a mode of extinguishing rights — the negative prescription; (3) as a mode of limiting rights of action — the shorter prescriptions. It must, however, be observed with reference to this division that the distinction between (1) and (2) is rather an accidental (due to a loose interpretation of the language of the act of 1617, c. 12) than a logically accurate one. It is, moreover, strictly confined to heritable rights, having no application in the case of movable property.

Positive Prescription. — The positive prescription was introduced by the Act of 1617, c. 12, which regulated the prescription of land rights till 1874. The provisions of the Act of 1874 are repealed as from Jan. 1, 1930, by the Conveyancing Act, 1924 (s. 16). As from that date the prescription will be 20 years without allowance for legal disability. The Acts of 1874 and 1924 provide that possession for 20 years upon "an ex facie valid irredeemable title recorded in the appropriate register of sasines" should in future give the same right as 40 years' possession upon charter and sasine under the earlier laws. These Acts also provide that the 20 years' prescription is not to apply to servitudes, rights of way and public rights generally.

Negative *Prescription.*—This prescription was introduced by the Act of 1469, c. 28, and was substantially re-enacted by the Act of 1474, c. 55. The negative prescription accordingly extinguishes *in toto* the right to demand performance of an obligation after 40 years, the years being reckoned from the day on which fulfilment of the obligation can be first demanded. Such a lapse of this period of time creates a conclusive presumption—one incapable of being reargued—that the debt or obligation has been paid or fulfilled. But it must be kept in view that the negative prescription does not per se—without the operation of the positive--establish a right to heritable property (Erskine, *Inst.* bk. iii. tit. 7. s. 8). The negative prescription of heritable debts (Act of 1617) is reduced to 20 years without allowance for legal disability as from Jan. 1, 1930, by the Conveyancing Act 1924 (s. 17). This reduction of period does not apply to the prescription of servitudes and public rights.

United States.—Prescription in the United States though often used synonymously with adverse possession is technically confined as at common law to the acquisition of rights to incorporeal hereditaments, chiefly easements. The common law doctrine of presuming a lost grant after a certain period of undisturbed enjoyment of the right prevailed in the States. Upon an analogy to the period of limitations prescribed by the Statute of James I., undisturbed enjoyment of the right for 20 years was deemed to raise the presumption of a lost grant. Some differences of opinion have prevailed as to whether the presumption is a matter only of fact and hence rebuttable or is conclusive as a matter of law, the latter view being the majority rule: Thus prescription has in many States been assimilated to the acquisition of title to land by adverse possession. Statutes have commonly dealt with prescription, abolishing the lost grant presumption and substituting the doctrine of acquisition of title through adverse possession. As at English common law the adverse use must be open and notorious and not under licence of the owner; it must be uninterrupted for the statutory period, and the right acquired is limited to the extent of the use and the enjoyment of it during the period of prescription: No easement can be acquired save as appendant to an absolute estate in land. No right to maintain a nuisance can be acquired by prescription nor can a right of user be acquired by prescription against the State.

PRESERVING AND BOTTLING, terms used for methods of saving perishable foods from moulds, yeasts and bacteria. (See FOOD PRESERVATION.) In the United States the term "canning," instead of "bottling," is used for the preservation of food in containers, whether of glass or tin, and the word "preserves" implies that sugar is added to the food material.

The application of heat in some form is one of the commonest means of destroying bacteria, yeasts and moulds, and is utilized in jam-making (see JAMS AND JELLIES), bottling, canning, pickle-making, drying and crystallizing. Pickle-making is a method of preserving in which heat, vinegar, sugar or salt, or both, are used to destroy the micro-organisms contained in fruit and vegetables. The acetic acid in the vinegar acts as an antiseptic and prevents further growth of bacteria, moulds or yeasts. Chutneys, pickles, catchups and sauces are examples of foods preserved with vinegar.

BOTTLING FRUIT

The aim when bottling is to sterilize the contents of the bottle, and having done so to prevent any germs from entering by sealing it. Bottling is one of the simplest, but most useful methods of preserving fruit and vegetables, for their character and flavour is unaltered, whereas in jam and pickle-making both taste and appearance are changed. Provided attention be paid to a few important points success is assured, and a lavish supply of peas, beans, cherries, currants, etc., is available for winter use at little cost beyond the initial expense of buying a supply of vacuum jars. These are not essential, however, for ordinary jam jars can be used, although special care and precautions must be taken to obtain an airtight seal. When bottling is done regularly it is advisable to purchase a supply of vacuum jars and a sterilizer.

Vacuum jars or bottles consist of (a) a glass container with wide neck. It should be without flaws and it is important that the rim should not be chipped; (b) a metal or glass lid; (c) a rubber band, which acts as a washer between the bottle and lid; (d) a metal screw band or clip. When bottling is carried out on a large scale special sterilizers are employed, but in the home a large zinc bath, fish kettle, bath or even a large clothes boiler or copper, can be used. As bottles are liable to crack if they are placed in immediate contact with the heated bottom of the pan some good non-conductor of heat must come between them. A simple slatted wood board to fit the copper, bath or fish kettle makes an excellent false bottom.

Selecting and Preparing the Fruit.—(I) Select sound fruit which is very slightly under-ripe, with the exception of pears, which are better bottled when fully ripe. (2) Wash to remove dust, grade according to degree of ripeness and pack neatly and firmly, using a smooth piece of wood or bone spatula. The bottle should be shaken from time to time to ensure a tight pack. Loose packing is responsible for the fruit rising when sterilized, leaving a space of one to two inches at the bottom of the jar. (3) Fill each jar with cold water and pour away. This is to rinse the fruit as it is handled during the packing process. (4) Fill the jars with syrup or water, taking care that the fruit is completely covered. The flavour is improved when syrup is used, but if sugar is scarce or unavailable water can be used. (5) Put the rubber rings, lids and screw bands or clips in position. When screw bands are used, they should be screwed down tightly and then unscrewed for rather less than a half turn to allow the steam and air to escape. (6) Stand the bottles in the sterilizer or bath, which should contain sufficient cold water to cover the bottles completely, and apply gentle heat until the correct temperature is reached. This varies according to the variety of fruit from 125° F for small soft fruit, such as raspberries and blackberries, to 185° F for fruit salad, plums, cherries and pears. The process must not be hurried and approximately $1\frac{1}{2}$ hours should be taken in bringing the water to the correct temperature. (7) Allow the bottles to remain at this temperature for from 10 to 30 minutes Most soft fruit requires about 15 minutes and pears and apples about 30 minutes. (8) When sterilizing is completed remove the bottles from the boiler, stand on a wooden table or some other good non-conductor, tighten the screw bands and leave until cold. (9) Next day examine the bottles to see if they are airtight. To do this, remove the screw bands and clips, hold the bottles by the lid and raise them. If the lid is firm and secure the seal is perfect. Should the lid show the slightest signs of movement or come off the seal is imperfect, and the bottle should be re-sterilized

To Make *the Syrup.*—Dissolve four to six pounds of sugar in a gallon of water—according to the sweetness of the fruit being bottled—bring to the boil and when cool fill the bottles.

BOTTLING VEGETABLES

Vegetables require rather more severe treatment than fruit, particularly peas and beans, as they contain nitrogen, which renders them favourable to the growth of certain micro-organisms Prepare brine of a suitable strength by dissolving 24 oz. salt in one gallon of water and adding 5 fluid oz. or $\frac{1}{4}$ pint lemon juice, when preserving peas and beans. Boil the water, add the salt and the exact quantity of lemon juice. When cold it is ready for use.

Peas must be cleaned thoroughly by washing, and as a precaution it is advisable to soak them for 15 minutes in a weak solution of permanganate of potash. Sufficient crystals should be added to the water to produce a deep magenta colour. Remove the pods and shell the peas. Put them loosely in muslin and dip in a saucepan of boiling water for 1–$1\frac{1}{2}$ minutes Then place in cold running water for about 10 minutes. Pack into the bottles and fill with acidified brine.

French and Runner Beans.—Wash the beans thoroughly, using a nail brush if necessary to remove soil from the pods; string (the runner beans will also require slicing); pack lengthways in the jars. After packing, rinse out the jars with water, cover with acidified brine and place the rubber ring, glass lid and screw band in position. (See detailed instructions for fruit bottling.) Put in the sterilizer or boiler, bring very slowly to the boil and boil for $1\frac{1}{2}$ hours. If, after the bottles have been boiling the brine has boiled away, remove the jars and fill up with boiling brine. Replace the rings and complete the cooking. Next day examine and test the seal as when fruit bottling.

CANNING

The same principles and methods are used in canning as bottling, the chief difference being that metal, and not glass, containers are used, and the method of sealing is therefore different.

Canning has the advantage that it occupies less time than bottling and less care is necessary as there is no risk of breakage. It has not been widely practised by housewives, chiefly owing to the fact that until recently soldering was necessary, a process which the majority of women found difficult. This drawback no longer exists, for a small hand sealing machine is now available which eliminates soldering. Numerous tests with the machine have been carried out and the results are invariably extremely satisfactory and reliable. In conjunction with the hand sealer, special straight sided sanitary cans with open ends must be used. The cans may be either plain or lacquered. The latter are preferable, as they prevent the acid fruit coming in contact with the tin. The outer rim of the lid has a groove which is treated with rubber solution and which acts in the same way as the flat rubber band used when fruit bottling.

Method of Canning.——(I) Wash the cans thoroughly in hot water before ase. Pack with prepared fruit or vegetables, and cover entirely with boiling syrup or brine. *(2)* Put the lids in position and with the aid of the sealing machine close the can. As the escape of steam exhausts the air it is important to seal the can whilst very hot; therefore only two or three should be filled with boiling syrup at one time, otherwise they cool down before there is time to seal them. (3) When all the cans have been sealed, place them in any large container, such as a clothes boiler, large pan or zinc bath containing sufficient boiling water to cover them completely. (4) Bring to the boil and boil gently for 15–40 minutes, according to the fruit. Small soft fruit requires 15 minutes only, and pears from 35 to 40 minutes. The time must be calculated from the moment the water boils again after all the cans have been put in. Small bubbles rising from the can whilst it is in the water indicates that it is not airtight, and has been sealed imperfectly. The contents must be removed, put into a new can and resealed. (5) When sterilizing is complete, cool the cans quickly by placing them in a bath or sink of cold water. When cold, dry and label. *(See* also Food Preservation.)

(D. D. C. T.)

In the United States processing is the term applied to the heating of the material to a temperature and for a length of time that will kill bacteria producing spoilage, and the following methods are used: (A) Water-bath canner, in which the containers are set far enough apart to allow free circulation of the water. This must be boiling when the sealed containers are set in (glass jars being preheated to avoid breakage) and must come over the top of the containers. (B) Steam-pressure canner, in which only enough water is put to come almost to the rack on which the containers are set.

The hot-pack method of canning is recommended by the United States Department of Agriculture. The food material is first heated to boiling point in a minimum of water, is packed while boiling hot into the containers, then processed. In the cold-pack method the material is packed cold into the container (often after first being blanched), then processed. (I. E. L.)

PRESIDENCY, an administrative unit of the Indian empire. The word is derived from the title of president or chief of the council of a principal factory under the East India Company—a title which lasted until governors were appointed under act of parliament in 1784. It thence came to be applied to the three original provinces of Bengal, Madras and Bombay. It is now restricted to Madras and' Bombay, in distinction to the lieutenant-governorships. In Anglo-Indian usage, "presidency" was also applied to the capital city as opposed to the country beyond, termed the "mofussil"; and this usage lingers in such phrases as "presidency town," and "presidency magistrate."

PRESIDENT, a style of title of one who presides. In classical Latin the title *praeses,* or president, was given to all governors of provinces, but was confined in the time of Diocletian to the procurators who, as lieutenants of the emperor, governed the smaller provinces. In this sense it survived in the middle ages. Du Cange gives instances from the capitularies of Charlemagne of the style *praeses provinciae* as applied to the count; and later examples of *praeses,* or *praesidens,* as used of royal seneschals and other officials having jurisdiction under the Crown.

In England the word survived late in this sense of royal lieutenant. Thus, John Cowell, in his *Interpreter of Words* (1607) defines "president" as "used in common law for the king's lieutenant in any province or function; as president of Wales, of York, of Berwick, president of the king's council." In some of the British North American colonies (New Hampshire, Pennsylvania, South Carolina) there was a president of the council, usually elected by the council; and when Pennsylvania and New Hampshire became States, one member of the executive council was called president. The chief (and single) executive head in Delaware, South Carolina and New Hampshire (1784–92) was called president.

During the revolutionary struggle in America from 1774 onwards, the presiding officer of the continental congress was styled "president" and when the present constitution of the United States was framed in 1787 (in effect 1789) the title of president was transferred to the head of the Federal Government. "President" thus became the accepted style for the elected chief of a modern republic.

In the simple sense of "one who presides" the word "president" preserved its meaning alongside the technical use implying royal delegation. In ecclesiastical terminology *praesidens* was sometimes used for the head of cathedral chapters, instead of dean or provost; and it was sometimes the title given to the principal visitor of monasteries. In Great Britain the heads of many colleges are styled "president," the title being of considerable antiquity in the case of one college at Cambridge (Queens', founded in 1448) and four at Oxford (St. John's, Magdalen, Corpus Christi, Trinity). At five Cambridge colleges (Pembroke, Gonville and Caius, St. Catherine's, St. John's, Magdalene) the title "president" is borne by the *second* in authority, being the equivalent of "vice-master." In the United States "president" is the usual style of the head of a college and also of a university wherever this has developed out of a single college. "President" is also the style of persons elected to preside over the meetings of learned, scientific, literary and artistic academies and societies, *e.g.,* the president of the Royal Academy (P.R.A.) in London; the title of the president of the Royal Society (P.R.S.) dates from its foundation in 1660. In the United States the style "president" is also given to the person who presides over the proceedings of financial, commercial and industrial corporations (banks, railways, etc.), in Great Britain usually styled "chairman," but in the Bank of England and certain other banks "governor."

In France, besides the president of the republic, there are presidents of the senate and of the chamber of deputies. In Germany the word *Priisident* is used in most of the English senses of "president," *e.g.,* of a corporation, assembly or political body.

PRESLAV, a village of Bulgaria, situated on the north edge of the Balkans, south of Shumen *(q.v.)*. Preslav was the second capital of the mediaeval Bulgarian tsars, and was raised to great splendour by Tsar Symeon (893–927). It was then compared to Constantinople, and described as "full of high palaces and churches, with countless stones, woods and paintings, so adorned with marble and copper, silver and gold, that the visitor knows not wherewith he shall compare it." It fell into decay on the fall of the first Bulgarian Empire, and was later plundered to adorn the new capital of Trnovo *(q.v.)*. It is now a heap of ruins.

PREŠOV, a town in eastern Slovakia, 25 m. north of Košice. Situated on the left bank of the river Tarcza, a tributary of the Theiss, it is a very old town but has been almost entirely rebuilt since a great fire in 1887. Following the foundation of the town by German colonists in the 12th century its history has been much affected by the nodal character of its site; today it is the seat of the District authorities, the centre of a Greek Catholic diocese and an important railway junction for the Carpathians and Poland. In the neighbourhood of the town is an opal mine and mineral springs, but importance rests on its administrative functions supplemented by small manufactures. Pop. (1930) 21,870.

PRESS. For the history of the liberty or freedom of the press see PRESS LAWS; also NEWSPAPERS and PERIODICALS. For the punishment of "pressirig" *see* PEINE FORTE *ET* DURE. For the "press gang" *see* IMPRESSMENT.

PRESS ASSOCIATION, THE, the oldest and largest news agency operating exclusively in Britain, was founded by provincial newspapers on a co-operative basis in 1868, and began active work on February 5, 1870, when the post office took over the private telegraph companies which had previously supplied the provincial papers with news. For 50 years the P.A. transmitted news by press telegrams, but in 1920 it leased private telegraph wires from the post office. Its private wire system embraces over 3,000 miles of telegraph circuits radiating from London and serving either direct or through centres at Birmingham, Bristol, Manchester, Leeds, and Glasgow, about 120 provincial morning and evening newspapers. It also operates a direct printer system to offices in London. The P.A. has always had the exclusive right to supply in the provinces Reuters' (*q.v.*) imperial and foreign news services. The two agencies are closely associated. With the Exchange Telegraph Company, the P.A. operates in the provinces a joint telephonic service for the rapid collection and distribution of racing results, etc., and cricket and football scores

The P.A. is governed by a board of seven directors. One new director is elected annually by the shareholders (the provincial newspapers). The Association's new headquarters' building, which it occupied in July, 1939, is at 85, Fleet Street, London. From this building it supplies news to all the London daily and Sunday newspapers, provincial newspapers, and trade journals and other periodicals. (H C. RO., X.)

PRESSBURG: see BRATISLAVA.

PRESSED METAL, a broad term which includes that class of merchandise made by the process of bending, shaping and forming sheets, strips, plates or bars of metal in either hydraulic or mechanically-driven presses. Steel so treated is referred to as "pressed steel" or "stampings." While brass, aluminium, zinc and various alloys are all formed in substantially the same manner as steel and with similar equipment, this article will be largely confined to pressed steel.

The greater portion of the work is done cold and pressed steel is generally assumed to mean the cold forming of sheet steel in power-driven presses. Castings and forgings constitute the classes of material that are most generally replaced by pressed steel. Pressed steel is different from both castings and forgings in that, while either a casting or a forging may have a solid section of varying degrees of thicknesses, except in rare cases, pressed steel is a flat or hollow form. such as a shell, the walls of which are of equal thickness throughout. While by special processes and by specially constructed tools it is possible to make a wall of varying thickness, it generally follows that if the sheet of steel which is used as raw material is $\frac{1}{8}$ in. thick, the walls of the finished pressed steel form will also be substantially $\frac{1}{8}$ in. thick. Cold forming of steel first became industrially important through its adoption by bicycle manufacturers. When bicycles became popular, pressed steel replaced forgings and castings because of the need of producing a lighter vehicle at a lower cost.

The next great advance in the use of pressed steel was by the automobile manufacturer. In 1929, apart from units such as the engine, front axle and a few minor parts, most automobiles were made almost entirely of pressed steel. (See MOTOR CAR BODIES.) Other manufacturers, perceiving the advantages of pressed metal over castings and forgings, changed their methods so that pressed steel now goes into many manufactured products. It is impossible here to give a complete list but a few of the better known products are beds, alarm clocks, cooking utensils, gas and electric ranges, lighting fixtures, electrical conduits, switch boxes, push button plates, office furniture, filing cabinets, concrete forms, car wheels, hot water heaters, gasolene pumps, washing machines and typewriters. Wherever a large number of individual units are demanded for mass production, pressed metal has, in the majority of cases, been utilized.

The equipment used for the manufacture of pressed steel carries the general term of presses. There are two general classes known as hydraulic and mechanically-driven. The majority, however, are belt-driven power presses of varying size. The press furnishes the power and the means of holding the "tools" or punches and dies that do the actual forming of the metal. These "tools" consist of an upper or male section, which is known as a punch, and the lower or female section, which is known as a die. A piece of steel is held over the lower section (the die) and the upper section (the punch) is brought down on this by the power press, thus cold forming the steel into the desired shape. The majority of pressed steel parts are made by several successive operations. A certain shape of flat blank receives the first operation in one set of tools, it is then passed along to a second press carrying a second set of tools and is further formed or drawn, and so on through various stages.

It is usually necessary to heat-treat the steel between these various operations as cold pressing makes steel harder and tougher and without heat-treating the steel would not withstand the strain to which it is subjected. Soft, well-annealed steel is ductile, while steel that has been worked in the tools is tough and hard. The tensile strength of a piece of steel can be increased as much as 30% by a single drawing operation. Holes are punched and edges trimmed smooth and round by specially designed tools. While forgings are heavy and castings are both brittle and heavy, a pressed steel part, when properly manufactured, is both lighter and stronger, has a smoother surface and requires less finishing or machining. It has replaced wood in many cases.

PRESSENSÉ, FRANCIS DE (1853–1914), French politician and man of letters, was born in Paris on Sept. 30, 1853, being the son of Edmond de Pressensé, and was educated at the Lycée Bonaparte. He served on General Chanzy's staff in the war of 1870, and was taken prisoner at Le Mans, but after the war entered the public service. After a short period at the ministry of public instruction he entered the diplomatic service, and was appointed first secretary at Washington. In 1882 he returned to France and took up journalism, becoming in 1888, foreign editor of the Temps. At the time of the Dreyfus case (1895) de Pressensé identified himself with the cause of the prisoner. He wrote in support of General Picquart, and in consequence of his advocacy of Émile Zola's cause was struck off the roll of the Legion of Honour. This led to his resignation from the Temps, and he came forward as a socialist politician, being in 1902 elected socialist deputy for the Rhône. He took part in the debates on the question of the separation of church and state, and a bill brought in by him formed the basis of the one finally carried by Briand. He died in Paris on Jan. 19, 1914.

His works include *Le Cardinal Manning* (1896), and *L'Irlande et l'Angleterre depuis l'acte d'union jusqu'à nos jours, 1800–1888* (1889), besides many articles in the *Temps*, the *Revue des Deux Mondes, Aurore* and *Humanité*.

PRESSES AND PRESSWORK. The method of converting ingots of steel into forgings depends upon the size of the completed pieces and the number of these required. Hammer heads are formed in dies under a drop hammer. (*See* DROP FORGING.) Locomotive connecting rods would probably be forged under a steam hammer (*q.v.*). Ingots larger than 3 ft. in diameter, however, would usually be forged under a hydraulic press. The present article will confine itself to the latter type, although many hydraulic presses are used for the manufacture of seamless tubes, shells or flasks, and adapted to many forming operations in trades other than metal working. Machines for forming cold sheet metal and thin plate (*see* PRESSED METAL) are also called presses, although the dies are opened and closed by cam or eccentric-driven levers.

In a forging press the hot metal rests on a stationary anvil and is squeezed by a pallet forced downward by a hydraulic ram. Four heavy round columns act as tension members with both ends fixed into massive rectangular slabs called entablatures; the lower entablature rests directly on the foundation and supports the anvil; the upper entablature or cap carries the hydraulic cylinder. Fluid pressure in this cylinder forces a closely fitting ram downward; to the bottom of the ram is attached a cross head guided by four bushings sliding over the columns, and to this cross head is secured the upper working tool or pallet. Auxiliary cylinders are provided for lifting the cross head after the force has been exerted, and to move the ram up to its work. High pressure in the ram cylinder may be built up directly from a pump, from an accumulator *(see* STEAM ACCUMULATORS) or by a steam intensifier. .Frequently more than one pressure is available so that work of various sizes can be handled. Reliable valves and packing at all sliding joints are essential. The capacity of a press is rated by the total squeeze it can exert. The smaller sizes, which compete with steam hammers, are designed for rapid operation and economy of power and water; in the bigger ones these considerations are subordinated to the necessity for complete reliability.

So much improvement has been made in the art of casting and heat treating alloy steels that the large expense of forging is now justified only when the utmost of uniformity, soundness and toughness is essential. Castings and ingots are made up of interlocked fern-like crystals of metal, whose size depends upon the slowness of solidification. Long continued heat treatment may be able to refine this structure into an aggregate of microscopic crystals, but it is much more amenable to heat treatment if the hot ingot has been squeezed and the coarse crystals more or less broken up mechanically. Accidental internal cavities may also be closed up and welded shut. This kneading of metal, to be effective, should obviously extend to the very centre of the section. Hence large ingots need the slow, deliberate, irresistible squeeze of a hydraulic press. The sharp blow of the biggest hammer is cushioned by the outer layers of metal and fails to reach the centre of the slab. American railroad practice in 1929 calls for a 5 to 1 reduction from the ingot and a 4 to 1 from rolled billets. Recent investigations have shown, however, that fine grain can be obtained with even less than 3 to 1 reduction if proper precautions are taken. The irregularities caused by segregation (see IRON AND STEEL) can more than counteract the advantages of large reduction under the press. The carbon is lower in the bottom and sides of the ingot and higher in the centre and top; to counteract this in big ingots requiring the full capacity of several furnaces, metal containing less and less carbon is poured in the successive heats.

It is impossible to make absolutely clean steel. Tiny nonmetallic inclusions will be caught between the crystals throughout the ingot; soluble impurities like phosphorus will concentrate in the metal locked within the crystal branches. Forging tends to arrange these impurities into planes parallel to the pallet faces; the more the reduction the more pronounced would these "flow lines" become. Thus if tensile test pieces are cut from a thick forged slab in three directions (a) parallel to the main extension, (b) crosswise and (c) from front to back, the ultimate strength of all might be fairly close. However, the first or longitudinal piece would have satisfactory contraction of area and impact toughness; the second or tangential test piece would have markedly less toughness; the third, or transverse test piece would be the most brittle. Such "transverse weakness," as it is called, is a great danger to cylindrical objects which must withstand bursting pressure, because the greatest stress is in a tangential direction. Transverse weakness may be minimized by making ingots of cleanest steel, and also doing no more work in forging than is necessary. Hence the modern method of minimizing the size of ingots and degree of forging avoids undue trouble from segregation and transverse weakness. Tensile properties taken from representative large forgings are as follows:

Article	Steel	Size	Ultimate strength	Yield point	Elongation in 2 in.	Reduction in area
Hydraulic press column . . .	Kickel-chromium . .	24 in. dia. by 36 ft.	115,000	8j,000	21	55
40,000 lb. Intensifier	Nickel-chromium . .	18 in. dia.	148,500	110,000	15 (tangential)	50
47,000 lb. Extrusion press . . .	Chromium-vanadium .	32 in. dia.	..	110,000	..	..
Boiler drum	0·26% Carbon. . .	63 in. dia.	64,000	29,000 min.	2j in 3 in.	45

(See IRON AND STEEL.)

(E.E.T.)

PRESS GANG. The Press Gang was the name given to the naval parties who, until the beginning of the 19th century, were used forcibly to take or "impress" men for service in the British fleet. From mediaeval times the Crown claimed the power to impress able-bodied subjects for the defence of the realm, and as early as the time of Edward III. complaints are recorded in Parliament of the excessive use of this power. From the earliest time, England depended upon her professional seamen, the merchantmen, to man her fighting ships: but it was not until the end of the 16th century that fishermen, watermen and mariners were exempted by law from being "pressed" as soldiers: they remained liable to impressment for service in the Navy. The needs of Elizabeth's fighting fleet became so large that the Vagrancy Act was passed, rendering all "disreputable persons" liable for impressment for service in the fleet: the sheriffs and mayors being bound, upon the production of the warrant of the "takers" or "press gang," to produce the number of men required. This naturally led to jail clearance; the law remaining unaltered, throughout the 17th and 18th centuries there were constant complaints from naval officers of the quality of men supplied. In the 18th century certain exemptions were made, in the case of apprentices, a proportion of fishermen, seamen employed in the coastwise coal trade, but even at the height of Britain's maritime power, from 1780 to 1815, the press gang was the chief means of recruiting the fleet.

The action of English cruisers in pressing men from the merchant ships of the American colonies was one of the causes that led to the War of Independence. A favourite means of completing the complement of warships was by stopping homeward bound merchantmen and removing some of their seamen. Service became so unpopular that in 1795 the press gangs and the jails failed to provide sufficient men. An Act was passed directing each county to provide a "quota" of men, with the result that the authorities of each district handed all malcontents and agitators over to the press gangs, by whom they were taken to the guard ships stationed round the coast for drafting into the fleet. The introduction of this bad element into the Navy was one of the causes of the mutiny of 1797 which nearly brought disaster to the country. The insistence of the right to press British subjects in America was one of the chief causes of the war between Great Britain and the United States in 1812.

The press gangs were not used after the close of the Napoleonic Wars in 1815, although it is lawful to this day to impress men for service in the navy, though not in the army. By an Act of 1835 a "pressed" man is exempt after five years' service and seamen in the Merchant Service, fishermen and certain other persons are exempted from impressment. With the introduction of the long service system in 1853 all need for impressment disappeared and since that date there have always been more volunteers than could be accepted for service in the Royal Navy. (S. T. H. W.)

PRESSING: *see* PEINE FORTE ET DURE.

PRESS LAWS, the laws affecting the products of the printing-press and newspapers in particular. (See NEWSPAPERS.) In English-speaking countries the liberty of the press is nowadays taken for granted. It was not always so, but in 1784 Lord

Mansfield made the following pronouncement in *R.* v. Dean of St. Asaph (3 T.R. 431 n): "The liberty of the press consists in printing without any previous licence, subject to the consequences of the law." This liberty was a plant of slow growth in England, and in some Continental countries the State still exercises an authority over the newspaper press which in Anglo-American spheres would be considered intolerable in time of peace. (*See* also CENSORSHIP.)

In the middle ages the church kept a firm hand on the free expression of opinion, spoken or written, and when printing was discovered co-operated with the secular authority in keeping an even tighter hand on the printed word. The principle of the censorship over the products of the press, which is still maintained by the Roman Catholic Church (see INDEX LIBRORUM PROHIBITORUM), was initiated by a bull issued by Pope Alexander VI. in 1501 against unlicensed printing. In 1535 Francis I. issued an edict prescribing the death penalty for the unauthorized printing of books, and soon afterwards the Sorbonne became the licensing authority and remained so until the French Revolution.

England. — In England after the Reformation in Henry VIII.'s reign most of the rights of censorship passed from the ecclesiastical authorities to the Crown, which began to grant by letters patent the privilege of printing or selling books as a monopoly. Under Queen Mary the right of printing was limited to 97 members of the Stationers' company, founded by royal charter in 1556, and their successors by apprenticeship. Under Queen Elizabeth the Star Chamber limited the number of printers and presses, and ordained that printing should be carried on only in London, Oxford and Cambridge. In view of the increase in unlicensed printing-presses, the Star Chamber in 1637 decreed that all printed books must be submitted for licence and registered by the Stationers' company before publication, with the penalty of forfeiture of all presses belonging to disobedient printers, who were disabled thereafter from carrying on their trade. The old formula *imprimatur* (let it be printed) thenceforward denoted the authority to print the book. Law books had to be licensed by one of the chief justices or the chief baron of the Exchequer, certain other classes of books by special dignitaries, but most of the licensing devolved on the archbishop of Canterbury and his coadjutors and the chancellors or vice-chancellors of the universities. It was a similar ordinance made by the Long Parliament, after the Star Chamber had been abolished, that called forth John Milton's unlicensed essay, Areopagitica, a Speech for the Liberty of Unlicensed Printing. Under the Licensing Act of 1662 (in effect reproducing the Star Chamber order of 1637), practically the newspaper press was reduced to the London Gazette. In 1695 the Licensing Act lapsed and, to quote Macaulay, "English literature was emancipated for ever from the control of the Government." Lord Chief Justice Russell (of Killowen) said in R. v. Gray 1900, 2 Q.B. at p. 40: "The liberty of the press is no greater and no less than the liberty of every subject of the queen." (See CONTEMPT OF COURT.)

One effect of unlicensed printing was to lay authors open to the attacks of literary piracy, and in 1709 the first Copyright Act (8 Anne c. 19) was enacted for their protection. The old power of a secretary of State to issue a warrant, general or special, for the purpose of searching for and seizing the author of a libel, or seizing the libellous papers themselves, was not finally declared illegal until the case of *Entick* v. Carrington in 1765 (St Tr. xix. 1030). In 1776 the House of Commons passed a resolution in accordance with this decision. The compulsory stamp duty on newspapers was abandoned in 1855 (18 Vict. c. 27), the duty on paper in 1861 (24 Vict. c. 20), the optional duty on newspapers in 1870 (33 and 34 Vict. c. 38).

A declaration in favour of the liberty of the press is usually a prominent feature in the written constitutions of foreign States, but in England it rests upon a constitutional rather than a legal foundation. (Dicey's Introduction to the Law of the Constitution, 7th edition, chap. 6.)

The last relic of the censorship before publication is to be found in the licensing of stage plays. (See THEATRES, LAW RELATING TO.) The last relic of the monopoly of printing formerly granted to licensees of the Crown is found in the exclusive right of the king's printer and the universities of Oxford and Cambridge to print the Bible and the Book of Common Prayer, and of the king's printer to print Acts of parliament, statutory rules, and other State documents. This monopoly, so far as the Bible is concerned, extends only to the Authorized Version, and not to any accompanied by annotations or new marginal readings. In the case of re Red Letter New Testament (Authorized Version) in 1900, on the application of the queen's printers an order was made by a chancery judge expunging from the register of copyrights of the Stationers' company an entry whereby an American was registered as the owner of the copyright in that book (17 T. L.R. 1). The rights of the king's printers are protected by 8 and 9 Vict, c. 113 and 45 Vict. c. 9; the rights of the printers of the journals of either house of parliament are protected by 8 and 9 Vict. c. 113.

By 32 and 33 Vict. c. 24 the printer of any paper or book for profit is required under penalties to print thereon his name and address or the name of a university press, and is to keep a copy of everything printed, with a few exceptions. Penalties must be sued for within three months, and no proceeding for penalties can be begun uniess in the name of the attorney-general or solicitor-general of England or the lord advocate of Scotland.

Under the Copyright Acts a newspaper is a book, and the obligation imposed by the 1842 Act still remains of delivering (without request) to the British Museum a copy of any work published within the United Kingdom, and of delivering (on request) copies for the use of the university libraries at Oxford and Cambridge, the library of the faculty of advocates at Edinburgh, the library of Trinity college, Dublin, and the national library of Wales (1 and 2 Geo. V. c. 46, s. 15; see COPYRIGHT).

In the High Court a request by a judge that certain details be not published is equivalent to a command. By the Judicial Proceedings (Regulations of Reports) Act 1926 there is a declaration of the common law as to the offence of publishing indecent matter in reports of judicial proceedings and a special proviso limiting the reports of matrimonial causes. (See DIVORCE.) By the Children Act 1906 (8 Edw. VII. c. 67) reporters cannot be excluded from children's courts, subject to any powers that a police magistrate has of hearing proceedings in camera, but the normal practice is not to report the names and addresses of child offenders. By the Criminal Justice Act 1925 no photographs or sketches may be taken in court, or, if they are taken contrary to the law, published. Seditions, blasphemous, or obscene words in a newspaper may be punished as treason, treason felony, seditious libel, or misdemeanor. (W. LA.)

United States. — There is no body of law in America which with strict accuracy may be called "the law of the press." Except for a few statutes and peculiar rules of common law, journalists are not singled out for special legal favours or restrictions. Naturally, however, the press comes into more direct and frequent contact with certain branches of law than with others. These branches, touching content and distribution of newspapers, may, for convenience, be grouped under the above title.

The sources of press law are found in the Federal and State Constitutions, statutes and in decisions of Federal and State courts interpreting constitutional and statutory provisions and declaring the common law. Some branches are restrictive, others protective. Nearly all are relatively modern and all are in process of development, chiefly toward enlarged freedom for ethical journalism.

The restrictive laws are those thought necessary by legislatures or courts to serve three purposes: protection of Government and its processes, including judicial action, from violent disruption and unlawfully created disrespect; protection of individuals in good name, business reputation and right of privacy; and protection of the morals of the public and of its right not to be defrauded or deceived.

The chief instances of restriction for governmental protection are the statutes condemning publications constituting contempt of court, sedition (*e.g.,* the war-time Espionage Acts of Congress), criminal anarchy and syndicalism. Acts of Congress and State statutes generally deal with contempt of court and courts have repeatedly held certain publications to be contemptuous. Federal statutes prohibiting various forms of seditious publications have been common in war time, but ordinarily have been repealed on restoration of peace. Their constitutionality has been upheld with great uniformity. Many State statutes condemn criminal anarchy and syndicalism. The New York Criminal Anarchy statute (Penal Law, Sect. 160–161) is typical. These statutes are directed against advocacy of overthrow of Government and of destruction of property (sabotage) by violence or other unlawful means.

The chief instances of restriction for protection of individuals are the libel law and the prohibition of unauthorized publication of photographs and names of individuals for purposes of advertising or trade. This prohibition is statutory in two States (New York and California) and exists by judicial decision in others. It is destined to become general, if not universal.

Every State has libel law, usually expressed partly in statutes and partly in court decisions declaring common law rules. This is by far the most important phase of press law. It has its origin in the common law and many of its fundamental rules were laid down when the art and practice of printing were in their infancy. Even now the law for the most part is found, not in statutes or codes, but in court decisions. In general, the judicial tendency has been to abandon or relax common law rules thought too harsh for conditions of modern journalism. In the main, at least from the standpoint of importance, the statutes are relaxations of former harsh common law rules; in some instances the legislatures have codified liberal court decisions and in others they have advanced beyond the courts in enlarging the freedom of decent journalism.

Fundamentally, the libel law in the various States is 'substantially the same, though naturally there are variations in details, some of which are important, and in the application of underlying rules. Published matter is libellous if its natural tendency, in the opinion of a substantial number of right-thinking persons, is to induce an ill opinion of an individual or is to affect injuriously a person's standing in his business, profession or office or is to impugn the management or credit of a corporation in such manner as to be calculated to cause pecuniary loss. Libellous publications may be the subject of civil suits and criminal prosecutions but may not be restrained by injunction.

The generally recognized complete defences are that the published matter was true, that it was a fair and true report of legislative, judicial or other public and official proceedings published without malice, that it was fair comment or criticism concerning a matter of public interest, that it was published in good faith in defence of some attack upon the publisher or that it was published with the consent of the person named. Partial defences—those which mitigate or reduce damages—are also allowed. They consist generally of proof concerning the publisher's good faith and the reasons why he believed his publication to be true or otherwise justifiable.

The chief instances of restriction for the protection of public welfare are the statutes prohibiting publication of obscene matter; advertisements of such matter as lotteries, betting odds and other data useful in gambling; intoxicating liquor, abortifacient drugs and instruments, cures for venereal disease, procuration of divorce; false statements of circulation and false and misleading merchandise advertisements. Federal and some State statutes require that reading matter which is in fact paid advertising shall be plainly marked as advertising. A few States, in varying forms of phraseology, prohibit the publication and sale of newspapers "devoted to" or "principally made up" of stories of bloodshed, lust or crime.

The protective branches of newspaper law consist mainly of constitutional guaranties of freedom of the press, the copyright law and trade-mark law. Comment upon the latter two branches, each of which is a special body of law not peculiar to newspapers, is beyond the scope of this discussion, except to say that newspapers enjoy the same rights and privileges thereunder as do citizens generally.

The U.S. Constitution (1st amendment) provides that Congress shall pass no law abridging the freedom of the press and the State Constitutions, in varying phraseology, declare that citizens may freely speak, write and publish their sentiments on all subjects, being responsible for the abuse of that right, and that no law shall be passed to restrain or abridge the liberty of the press. Controversy concerning the proper interpretation of these guaranties rages endlessly and even now the subject is in doubt. Those favouring a narrow interpretation contend that the guaranties mean merely that there shall be no restraint in advance of publication or prevention of future publication, that Congress and the State legislatures are free to provide for punishment after the event for the publication of any sort of matter that they think objectionable and that the legislative conclusion of objectionableness is not subject to judicial scrutiny. Those favouring a broad construction contend—and sometimes with more emotion than logic—that the guaranties, properly interpreted, prevent any form of legal responsibility for any publications except those which are seditious, obscene or libellous. That contention has been rejected in a number of decisions of appellate courts. The truth lies, it is believed, between the two extremes. These guarantees do not protect a publisher from the consequences of a crime committed by the act of publication. They mean, however, more than that there shall be no restraint of future publications. They imply not only liberty to publish but complete immunity from legal punishment for the publication so long as it is not harmful in its character when tested by such standards as the law affords.

(H. L. Cr.)

The British Empire.—In the British dominions and possessions overseas the press is, generally speaking, as free as in England. In India the press laws are contained in a series of Acts of which the last and most important is No. XIV. of 1922, known as the Press Law Repeal and Amendment Act. The governor-general is given wide powers with regard to preventing a seditious use of newspapers, whether printed in English or in the vernacular, and there are elaborate provisions for the registration of printers and publishers, for the seizure and confiscation of seditious matter and for preventing its importation or circulation, and for the punishment of those responsible for its publication or distribution. Every copy of a newspaper must bear the name of the responsible editor.

Other Countries.—The press law in Austria is contained in the federal law of April 1922, which guarantees the freedom of the press subject to limitations set out in 51 articles. In Hungary the press law of 1914 (Act XIV.) is an elaborate set of regulations containing 64 articles, the first of which says: "It is open to every one to communicate and propagate his ideas by means of the press." Art. 14 of the Argentine Constitution provides that any inhabitant may publish his ideas in the press without any previous censorship. The only restrictions of the liberty of the press are contained in the penal code and social defence law dealing with defamation and other offences. By the Belgian Constitution of 1831 the liberty of the press is declared. In Bulgaria the press law of 1921 deals mainly with questions of responsibility and procedure, press offences being set out in the penal code. By the Constitution of Chile the liberty of the press is guaranteed, subject to ordinary restrictions. In China newspapers are governed by the press law of 1914, which follows the model of most European countries in its general outline, except for the important difference that in theory all leading articles have to be passed before publication by the police. The Czechoslovakian press law of May 1924 consists of 42 articles which amplify previous laws relating to the press passed when this country was part of the Austro-Hungarian empire. In the main the 1924 law deals with questions of procedure and responsibility and does not enact new offences. In Denmark press laws date from 1851, subject to amendments in the general civil penal law of 1866. As one of the new independent post-War States, Finland's press law dates from Jan. 1919.

In France the press is controlled by the law of July 1881, which declares the liberty of the press, subject to the prohibition of abuses. Is Germany, by the Constitution of Aug. 1919, Art, 118, "every German has the right, within the limits of the common law, to express his opinion by word of mouth, in writing, in print, or in any other way. A censorship will not be established, but certain regulations will be laid down dealing with cinematograph exhibitions. Legal measures are permissible for the prevention of immoral literature." For the rest the press is subject to the press law of May 1874.

Liberty of the press is provided in the Constitutions of Greece and Holland. In Holland it actually exists as in England, but the troublous political developments in Greece during and since the World War have resulted in a considerable limitation.

In Italy the press has become under Signor Mussolini's régime almost entirely, on its political side, an exponent of the Fascist idea. Nearly all professional journalists perforce belong to an organization under Government control, and by a decree of July 1924 the responsible editor of a newspaper must be approved by the prefect of the province. A prefect may warn the newspaper editor or manager who publishes false or tendencious news calculated to embarrass the country with foreign Governments, or to damage the national credit, or in any way to disturb public order, and may rcvokc his rccognition of the editor who has been so warned twice in a year. An appeal lies, not to a judicial tribunal, but to the minister of the interior. For breaches of these rules newspapers may be confiscated. In practice the Fascist press laws have, at any rate for the present, done away with the nominal liberty of the press expressed in the royal edict of 1848.

The press law of May 1901 in the main governs the activities of newspapers in Japan, other forms of print being dealt with in an earlier law of 1893. The various press laws under which partitioned Poland lived are being replaced by a uniform law based on the principle of freedom of opinion. In Portugal, Yugoslavia and Rumania there is a theoretical liberty for the press, liable to be waived during not infrequent periods of unrest. In other respects the press is subject to the usual restrictions against abuse of the printed word. In Russia by a decree of 1921 the Government of the Republic of Soviets has practically brought the newspaper press and all printed publications under State control, and there is no independent press. Unauthorized printing results in confiscation and the trial of those responsible. In Spain, since the abolition of parliamentary government, which was superseded by the régime of the Marques de Estella, the press has been in a political sense subject to Government control, but in other respects it is governed by laws passed since 1883 which are more or less in common with the press laws of other Roman Catholic countries. In Norway and Sweden there are voluminous press laws in operation, but they follow the usual order of things, freedom of opinion being allowed. The same applies to Switzerland. (W. La.)

PRESSURE CHEMISTRY. The influence of pressure on chemical transformations has long been recognized, but it is only within the 20th century that high pressures have been applied to industrial chemical processes. Haber's process for the direct synthesis of ammonia from its elements, which has been developed in Germany by the Badische Anilin und Soda Fabrik, has not only solved the problem of the world's supply of fixed nitrogen but has produced a technique in dealing with gases under conditions of high pressure and temperature, which is now being applied in the field of organic chemistry. Bergius's process for the production of oil from coal involves treatment of the latter with hydrogen at high temperatures and pressures. This process, after over 20 years' sustained research, has been placed on a manufacturing basis, and affords a solution of one of the greatest European problems, namely, the creation of an adequate oil supply.

Pressure and Chemical **Action.**—Le Chatelier's principle states, in effect, that if a system in equilibrium be subjected to a constraint, a change will take place in the system which is in opposition to the constraint. An increase of pressure favours the system formed with a decrease in volume, while a reduction of pressures favours the system formed with an increase in volume. Pressure may consequently be employed in gaseous reactions, which proceed with diminution in volume, to change the equilibrium in favour of the product desired. The attainment of this equilibrium or a close approach to it is brought about by the use of a catalyst, which may be defined as a substance which can accelerate a chemical change without itself undergoing permanent alteration. The development of ammonia synthesis has shown that a catalyst may be specially sensitive to the presence of certain substances which may either inhibit or enhance its activity. For example, the activity of iron as an ammonia catalyst is partially or totally destroyed by the presence of traces of sulphur, selenium, tellurium and other elements which act as poisons. Catalyst masses must consequently be prepared with great care, and the reacting gases need special purification. In contrast to the poisoning action of the elements mentioned above, the presence of a small proportion of certain substances called promoters, as for example the oxides of the alkalis and alkaline earths, greatly enhances the activity of the iron catalyst. Lowering the temperatures of reaction has the same effect on the ammonia equilibrium as raising the pressure. Haber has calculated that if the temperature of reaction could be reduced to 300° C, satisfactory yields of ammonia would result at ordinary pressures. No catalyst is known which will bring about reaction at so low a temperature, therefore the industrial procedure is to obtain a catalyst highly reactive at as low a temperature as possible, and to raise the pressure till adequate yields of ammonia result.

Synthetic Ammonia Processes.—Nitrogen and hydrogen subjected to high temperatures and pressures in the presence of a suitable catalyst unite to form ammonia, in accordance with the equation $N_2+3H_2\rightleftharpoons 2NH_3$. Variations in the different industrial processes lie principally in the pressures employed, the special form of catalyst, and in the method of preparing the nitrogen hydrogen mixture. The Haber-Rosch, Casale, and Claude processes operate at pressures of about 200, 800 and 900 atmospheres respectively. The first two processes employ circulatory forms of plant (figs. 1 and 2), where the nitrogen-hydrogen mixture is passed over the catalyst at a temperature of 500°–600° C. The partial pressure of ammonia in the gases leaving the converter amounts to about 12 atmospheres in the Haber-Bosch, and 160 atmospheres in the Casale process. Ammonia is removed in the former process by solution in water, and in the latter by condensation at ordinary temperatures. Unchanged gas is circulated by a pump over the catalyst together with fresh gas mixture added to maintain the pressure. A flow-through form of plant is employed in the Claude process. The catalyst is held in a battery of six converter tubes, one of which is shown in fig. 3. In the first of these, which contains the old catalyst, any carbon monoxide in the gas is converted to methane. The next two tubes are arranged in parallel to prevent overheating due to excessive reaction, while the last three tubes are in series. The partial pressure of ammonia in the gases leaving each converter tube is about 250 atmospheres. Ammonia is removed by simple condensation after each contact with the catalyst. In all, 85% of gas is converted to ammonia. The residual gas after reduction to atmospheric pressure is used for other purposes.

FIG. 1.— DIAGRAMMATIC PLAN OF CASALE SYNTHETIC AMMONIA PLANT

In the three processes provision is made for heat interchange betw-een gas entering and leaving the converter, either inside the converter itself or in a separate heat interchanger, so that the heat of reaction maintains the temperature of the catalyst. Nitrogen and hydrogen are prepared as a mixture in the Haber-

Bosch process from producer gas (a mixture of nitrogen and carbon monoxide) and water gas (a mixture of hydrogen and carbon monoxide). Water gas and producer gas in suitable proportions are passed with steam over an iron oxide catalyst kept at a correct temperature, when nearly all the carbon monoxide reacts with steam to give a mixture of hydrogen and carbon dioxide; the latter gas is removed by solution in water under high pressure, while any unchanged carbon monoxide is absorbed by a solution of a cuprous salt (*e.g.,* ammoniacal cuprous formate). In the Casale process hydrogen is produced electrolytically, and in the Claude process the gas is obtained from coke-oven gas by a process in which other constituents are removed by liquefaction. In both processes the nitrogen-hydrogen mixture is produced by burning a calculated amount of air in the hydrogen.

Alcohol Synthesis.—G. Patart has shown that methyl alcohol (methanol) is produced by the interaction of carbon monoxide and hydrogen, under conditions of high temperature and pressure, in the presence of zinc oxide. The activity of zinc oxide as a methanol catalyst is increased by the addition of certain acidic oxides (*e.g.,* oxides of chromium, manganese and uranium). A most efficient catalyst is produced by the reduction of a basic zinc chromate ($3ZnO \cdot CrO_3$). Two litres of methyl alcohol per hour can he produced for each litre of space occupied by catalyst when a mixture of hydrogen (two parts by volume) and carbon monoxide (one part) is passed under a pressure of 200 atmospheres over the catalyst kept at 400° C, at a rate corresponding to 20,000 litres per hour (measured at N.T.P.) of gas mixture.

Audibert has found that copper prepared by regulated reduction of cuprous or cupric oxide acts as a methanol-forming catalyst; both the activity and stability of this catalyst may be increased by the addition of small amounts of oxides of various metals (zinc, manganese, beryllium or cerium) which act as promoters. A catalyst containing 0·01 atoms of cerium for each atom of copper is stated to be highly reactive at so low a temperature as 300° C.

Experience in high-pressure practice gained through the development of ammonia syntheses enabled the Badische Anilin und Soda Fabrik to place the methanol synthesis on a manufacturing basis, and in 1925 to export 500,000 gallons of synthetic methanol to the United States.

The possible number of reactions that can be effected between a mixture of carbon monoxide and hydrogen is theoretically almost unlimited, and the course of reaction is largely dependent on the nature of catalyst employed. A catalyst made from zinc chromate leads to the production of substantially pure methanol from a mixture of carbon monoxide and hydrogen under conditions detailed above, but if the catalyst is made alkaline by the addition of, e g., potassium carbonate or chromate, the product contains beside methanol, n-propyl, isobutyl and higher alcohols, together with acids, free or combined as esters. The proportion of the various constituents depends on the rate of passage of the carbon monoxide-hydrogen mixture over the catalyst.

Addition of metallic cobalt to zinc chromate produces a catalyst which brings about the formation of methyl, ethyl, *n*-propyl, isobutyl, n-butyl and higher primary alcohols; small amounts of aldehydes can also be isolated, but the product contains no acids free or combined.

Production of Oil from Coal.—Bergius's process for conversion of coal into oil consists in heating powdered coal, preferably in a liquid medium, to a temperature of 450°–470° C, in the presence of hydrogen under a pressure of about 250 atmospheres The introduction of 5% of hydrated ferric oxide (bog-iron ore) assists the process by combining with sulphur contained in the coal; the oxide possibly functions also as a catalyst. A large amount of heat is produced by the hydrogenation which may result in rise of temperature and the consequent formation of coke.

The oil-coal mixture has a much better thermal conductivity than powdered coal alone, and it is possible with the assistance of a stirrer to keep the reacting mass within the necessary limits of temperature.

The liquefaction of coal is regarded by Bergius as proceeding in two stages: (1) hydrogen addition, and (2) a splitting up of large molecules into smaller ones, with subsequent further addition of hydrogen. Bergius's liquefaction process is applicable to all types of coal, including lignites, except the anthracites and coals which consist chiefly of fusain. A continuously acting plant is usually employed on the works scale. The coal-oil mixture is forced in at one end of a long, cylindrical iron converter down which it is propelled by a mechanically driven stirrer. Hydrogen is circulated through the converter which is partially immersed in a gas-heated lead bath. The products from 100 parts of bituminous coal are as follows: gas (methane and ethane), 20 parts; oil boiling up to 230° C, 20 parts; oil boiling at 230°–330° C, 10 parts; and oil boiling above 330° C, including pitch, 20 parts. The remaining products are ammonia, 0·5 parts; water, 8 parts; and ash, 10 parts. The oily products consist of members of the aliphatic, aromatic and hydroaromatic series. Compounds of a phenolic character, chiefly cresols, are also included. Motor spirit obtained from the products (about 15%) is very rich in aromatic and hydroaromatic hydrocarbons, and may be blended with petrol to give a mixture with good anti-knocking qualities.

The process of heating materials with hydrogen under pressure is termed berginisation and has been applied to asphalts, coke-oven tars, and heavy distillate oils for the production of light-boiling oil suitable for use as motor spirit.

High-pressure Plant.—Gases used in high-pressure processes are usually stored at atmospheric pressure in ordinary inverted bell-type, water-sealed gas holders. Gas from the holders is then compressed and passed into the high-pressure system as required. Multiple-stage compressors should be specially designed for the particular gas mixture, since gases vary in their deviation from Boyle's law. The design of the compressor should also guard against leakage of gas to atmosphere and the possibility of air being drawn into the plant.

FIG. 3.— CLAUDE BOMB TUBE

A large factor of safety must be employed in the construction of high-pressure vessels, owing to the possibility of blow holes and other structural faults. Vessels for use at ordinary temperatures are usually constructed of mild steel. When the vessel is to be subjected to both high pressure and high temperature, mild steel can no longer be used since its tensile strength begins to decrease very appreciably at about 300° C. If the reacting gases contain hydrogen, the metal may also suffer serious deterioration in strength owing to the removal of carbon by the action of hydrogen at the elevated temperature. In practice, a complex form of vessel is constructed in which the outer pressure-resisting shell, made of mild steel, is kept cool and away from the action of the hot gases (compare fig. 2); or else some special steel or alloy is used which retains a high tensile strength at the temperature to which it is subjected, and which suffers little deterioration through contact with gases employed in the process. (*See* fig. 3) Steels containing chromium and nickel have been found to be best suited to this purpose.

The construction of plant for chemical processes, involving the use of gases at high pressures and temperatures, has presented many difficulties, for example the making of pressure-tight enclosures, glands and valves, but the advantages which arise from the reduction in gas volumes and possible efficient heat recovery make such processes in many ways preferable to normal pressure systems.

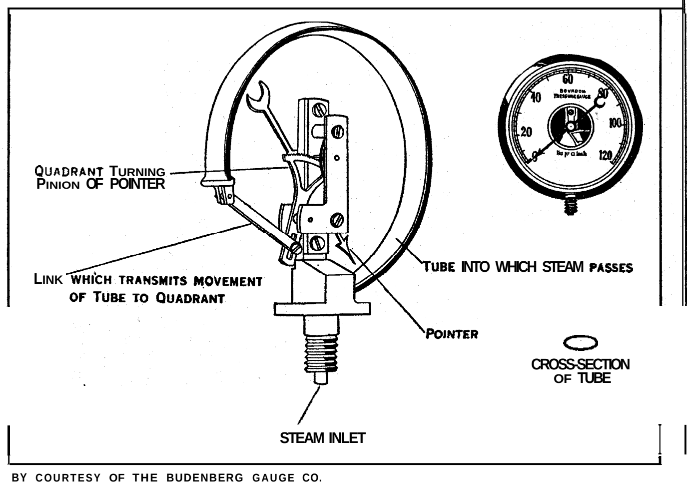
PRESSURE GAUGE, a term commonly applied to an instrument for measuring pressure, as distinct from a barometer, a manometer (*qq.v.*), or a gauge employed in vacuum practice. The following article deals with the type of gauge which registers pressure by the distortion of a metal tube or diaphragm, and which may be used to indicate the pressure of steam, gas, ammonia, water, brine, petrol, or oil. The lowest pressure requirements are those for blast pressures, or gas or air, working up to about 2 lb. per sq.in., and the highest the hydraulic gauges up to 12 tons per square inch. For very low pressures a diaphragm arrangement is employed. In the Schaffer gauges a corrugated diaphragm is acted upon by the pressure and its deflection communicates the movement through a link and toothed quadrant to the pinion, which turns the pointer around the gauge dial. Such gauges will withstand rough usage, as on road vehicles and portable engines.

The Bourdon type has a bronze tube of elliptical cross-section bent into circular form. One end is soldered to a central block through which the fluid enters (see fig.) and the other end is sealed, and coupled by a link to a pivoted quadrant with teeth meshing with those of a pinion on the pointer spindle. Backlash between the teeth is absorbed by a hair-spring exerting constant



BY COURTESY OF THE BUDENBERG GAUGE CO.

THE BOURDON GAUGE, SHOWING FLATTENED TUBE, WHICH UNCOILS WHEN PRESSURE IS ADMITTED AND AFFECTS THE POSITION OF THE POINTER AROUND THE DIAL

pressure on the pinion. Pressure within the tube tends to change its cross-section from elliptical to circular, and the tube consequently uncoils to a slight degree, so turning the pointer.

In a vacuum gauge the reduction of pressure has an opposite effect, and the mechanism must be arranged in reverse fashion to cause the pointer to move clockwise. In a *compound* gauge, reading for both pressure and vacuum, the latter figures are placed to the left of the pressure figures. For high pressures a steel tube is fitted instead of bronze, being more elastic and less affected by high temperatures. Special construction or some suitable safeguard is necessary in dealing with some gases, such as oxygen, or where corrosive action is set up.

Special types include the differential pressure gauge for registering the difference only in pressure at any two points. There are two inlet tubes and two hands, and if the pressures are equal there is no reading on the dial. The electric alarm gauge possesses electric contact devices to ring a bell at a definite minimum or maximum pressure. The electric control gauge closes a circuit at a definite pressure, and operates a relay in the circuit of an electric motor; *e.g.*, an electrically-driven air-compressor may be started and stopped automatically in accordance with the demands for air. The self-recording pressure-gauge traces a permanent record of varying pressures upon a chart. See also VACUUM and VACUUM-PUMP.

PRESTEIGN, urban district, Radnorshire, Wales, on the Lugg, which here forms the boundary between Wales and England. Pop. (1938) 1,102. Area. 4.2 sqmi. It has a G.W.R. station. The village was in the lordship of Moelynaidd until the 14th century, when Bishop David Martin of St. David's (1296–1328) conferred valuable market privileges upon his native place. In 1542 Presteign was named as the meeting-place of the county sessions for Radnorshire in conjunction with New Radnor. It has the fine parish church of St. Andrew, daring chiefly from the 15th century but with traces of Norman work. Presteign is the most easterly spot on the Welsh border; hence the expression "from St. David's to Presteign" to mark the breadth of Wales.

PRESTER JOHN, a fabulous mediaeval Christian monarch of Asia. The history of Prester John no doubt originally gathered round some nucleus of fact, though what that was is extremely difficult to determine. Before Prester John appears upon the scene we find the way prepared for his appearance by a kindred fable, which entwined itself with the legends about him. This is the story of the appearance at Rome (1122), in the pontificate of Calixtus II., of a certain Oriental ecclesiastic, whom one account styles "John, the patriarch of the Indians," and another "an archbishop of India." This ecclesiastic related wonderful stories of the shrine of St. Thomas in India, and of the miracles wrought there by the body of the apostle, including the distribution of the sacramental wafer by his hand.

Nearly a quarter of a century later Prester John appears upon the scene, in the character of a Christian conqueror and potentate who combined the characters of priest and king, and ruled over vast dominions in the Far East. This idea was universal in Europe from about the middle of the 12th century to the end of the 13th or beginning of the 14th. The Asiatic story then died away, but the name remained, and the royal presbyter was now assigned a locus in Ethiopia. Indeed, it is not improbable that from a very early date the title was assigned to the Abyssinian king, though for a time this identification was overshadowed by the prevalence of the Asiatic legend. At the bottom of the double allocation there was, no doubt, that confusion of Ethiopia with India which is as old as Virgil and perhaps older.

The first mention of Prester John occurs in the chronicle of Otto, bishop of Freisingen. This writer states that when at the papal court in 1145 he met with the bishop of Gabala (Jibal in Syria), who related how "not many years before one John, king and priest (rex et sacerdos), who dwelt in the extreme Orient beyond Persia and Armenia, and was, with his people, a Christian but a Nestorian, had made war against the brother kings of the Persians and Medes, who were called Samiards (or Sanjards), and captured Ecbatana their capital. After this victory Presbyter *John* —for so he was wont to be styled—advanced to fight for the Church at Jerusalem; but when he arrived at the Tigris and found no means of transport for his army, he turned northward, as he had heard that the river in that quarter was frozen over in wintertime. After halting on its banks for some years in expectation of a frost he was obliged to return home." About 1165, a letter was circulated purporting to be addressed by Prester John to the emperor Manuel. This letter, professing to come from "Presbyter Joannes, by the power and virtue of God and of the Lord Jesus Christ, Lord of Lords," claimed that he was the greatest monarch under heaven, as well as a devout Christian. The letter dealt at length with the wonders of his empire. It was his desire to visit the Holy Sepulchre with a great host, and to subdue the enemies of the Cross. Seventy-two kings, reigning over as many kingdoms, were his tributaries. His empire extended over the three Indies, including that Farther India, where lay the body of St. Thomas, to the sun-rising, and back again down the slope to the ruins of Babylon and the tower of Babel. In war thirteen great crosses made of gold and jewels were carried in wagons before him as his standards, and each was followed by 10,000 knights and 100,000 footmen. There were no poor in his dominions, no thief or robber, no flatterer or miser, no dissensions, no lies, and no vices. His palace was built after the plan of that which St. Thomas erected for the Indian king Gondopharus. Before it was a marvellous mirror erected on a many-storeyed pedestal; in this speculum he could discern everything that went on throughout his dominions, and detect conspiracies. He was waited on by 7 kings at a time, by 60 dukes and 365 counts; 12 archbishops sat on his right hand, and 20 bishops on his left, besides the patriarch of St. Thomas's the protopope of the Sarmagantians (Samarcand?), and the archprotopope of Susa, where the royal residence was. Should it be asked why, with all this power and splendour, he calls' himself merely "presbyter," this is because of his humility, and because it was not fitting for one whose chamberlain was a bishop and king, and whose chief cook was an abbot and king, to be called by such titles as these.

How great was the popularity and diffusion of this letter may he judged in some degree from the fact that Zarncke in his treatise on Prester John gives a list of close on 100 mss. of it. Of these there are 8 in the British Museum, 10 at Vienna, 13 in the great Paris library, 15 at Munich. There are also several renderings in old German verse.

The only other surviving document of the 12th century bearing on this subject is a letter of which ms. copies are preserved in the Cambridge and Paris libraries, and which is also included in mediaeval chronicles. It is a letter purporting to be written by Pope Alexander III. on Sept. 22, 1177, to *carissimo in Christo filio Johanni, illustro et magnifico indorum regi,* of whom he had heard from his physician Philip.

There is no express mention of the title "Prester John" in what seem the more genuine copies of this letter. But the address and a warning against a boastful spirit appear to indicate that the pope supposed himself to be addressing the author of the letter of 1165. In 1221 a rumour came out of the East that a great Christian conqueror was taking the hated Muslims in reverse and sweeping away their power. The name ascribed to the conqueror was David, and some called him the son or the grandson of Prester John of India The conqueror was in fact the famous Jenghiz Khan: but the delusion was dissipated slowly.

European travellers in Asia looked for a prince to whom the legend of Prester John could be attached. Carpini (1248) makes him the king of the Christians of India the Greater; Rubruquis (1253) gives the title of "King John" to Kushluk, king of the Naimans, and makes him a brother of Ung Khan (d. 1203), the ally of Jenghiz. In Marco Polo's narrative "Unc Khan," alias Prester John, is the lord of the Tatars up to the advent of Jenghiz Khan. This story is repeated by other writers. Both Marco Polo and Friar John of Montecorvino speak of the descendants of Prester John as holding territory in the plain of Kuku-Khotan (about 300 miles north-west of Peking). Friar Odoric gives a circumstantial account of this kingdom, and with this Prester John disappears from Asia to figure in African legend.

It is indeed probable that, however vague may have been the ideas of Pope Alexander III. respecting the geographical position of the potentate whom he addressed from Venice in 1177, the only real person to whom the letter can have been sent was the king of Abyssinia. The "honourable persons of the monarch's kingdom" whom the leech Philip had met with in the East must have been the representatives of some real power, and not of a phantom It must have been a real king who professed to desire reconciliation with the Catholic Church and the assignation of a church at Rome and of an altar at Jerusalem. Moreover, we know that the Ethiopic Church did long possess a chapel and altar in the Church of the Holy Sepulchre, and, though we have been unable to find travellers' testimony to this older than about 1497, it is quite possible that the appropriation may have originated much earlier. We know from Marco Polo that about a century after the date of Pope Alexander's epistle a mission was sent by the king of Abyssinia to Jerusalem to make offerings on his part at the Church of the Sepulchre; and it is extremely likely that the princes of the "Christian families" who had got possession of the throne of northern Abyssinia should have wished to strengthen themselves by a connection with European Christendom, and to establish relations with Jerusalem, then in Christian hands.

From the 14th century onwards Prester John had found his seat in Abyssinia. It is there that Fra Mauro's great map (1459) presents a fine city with the rubric, "Qui il Preste Janni fa residentia principal." When, nearer the end of the century (1481–1495), King John II. of Portugal was prosecuting inquiries regarding access to India his first object was to open communication with "Prester John of the Indies," who was understood to be a Christian potentate in Africa. And when Vasco da Gama went on his voyage from Mozambique northwards he began to hear of "Preste Joham" as reigning in the interior—or rather, probably, by the light of his preconceptions of the existence of that personage in East Africa he thus interpreted what was told him. More than twenty years later, when the first book on Abyssinia was composed—that of Alvarez—the title designating the king of Abyssinia is "Prester John," or simply "the Preste."

BIBLIOGRAPHY.—For the older aspects of the subject, *see* Ludolf's *Historia Aethiopica* and its *Commentary,* passim. The excellent remarks of M. d'Avezac, comprising a conspectus of almost the whole essence of the subject, are in the *Recueil de voyages et de mémoires* published by the Société de Géographie, iv. 547–564 (Paris, 1839). Two German works of importance which have been used in this article are the interesting and suggestive *Der Presbyter Johannes in Sage und Geschichte,* by Dr. Gustav Oppert (2nd ed., Berlin, 1870), and, most important of all in its learned, careful and critical collection and discussion of all the passages bearing on the subject, *Der Priester Johannes, by* Friedrich Zarncke of Leipzig (1876–79). *See* also Sir H. Yule's *Cathay and the Way Thither,* p. 173 *seq.,* and in *Marco Polo* (2nd ed.), i. 229–233, ii. 539–543.

PRESTIDIGITATION: *see* CONJURING.

PRESTON, municipal, county, and parliamentary borough and port, Lancashire, England, on the river Ribble, 209 mi. N.W. from London by the L.M.S.R. Pop. (1938) 113,200; area 9 sq.mi. The site consists of a ridge rising from the north bank of the river, nhile the surrounding country, especially to the west about the estuary, is flat. Among the numerous parish churches that of St. John, built in Decorated style in 1855, occupies a site which has carried a church from early times. Among several Roman Catholic churches, that of St. Walpurgis (1854) is a handsome building of Early Decorated character. Of public buildings the most noteworthy is the large town hall, with lofty tower and spire, in Early English style, built in 1867 from designs by Sir Gilbert Scott. The free public library and museum were established by the trustees of E. R. Harris in 1879, and a new building opened in 1893. This contains Dr. Shepherd's library and the Newsham collection of pictures. In addition, the same trustees endowed the Harris institute, a science and art school, in 1849, with £40,000. The grammar school, founded in 1550, mas housed in a building of Tudor style in 1841, but was purchased by the corporation in 1860. A bluecoat school was founded in 1jor. The Victoria Jubilee technical school was established in 1897 by the Harris trustees. There is also a deaf and dumb school. Preston is well supplied with public parks, there being Avenham park, Miller park, Moor park, the Marsh and the Deepdale grounds with an observatory. In early days Preston, owing to its geographical position, became an important trade centre with an agricultural market. Its importance progressively increased after the advent of the cotton industry, and in addition there are iron and brass foundries, engineering, cotton machinery, chemical and soap works, boiler works and shipbuilding and ship repairing works. Preston became an independent port in 1843, and after that time was progressive in increasing the depth of the seaward channel and building and improving the docks and quays. The main wet dock is 3,240 ft. long and 600 ft. wide. There is a total quayage of 8,500 ft. and the depth of the channel is 19 ft. at ordinary spring tide. A chamber of commerce was formed in 1916. A canal connects Preston with

Lancaster and Kendal. The parliamentary borough returns two members. The county borough was created in 1889.

History. — Preston, otherwise Prestune, was near the Roman station at Walton-le-Dale: and the great Roman road running from Warrington passed through it. It is mentioned in Domesday Book as one of Earl Tostig's possessions which had fallen to Roger of Poictou, and on his defection it was forfeited to the Crown. Henry II. (about 1179) granted the burgesses a charter — the first of 14 royal charters which have been granted to Preston. Elizabeth (1566) granted the town its great charter which ratified and extended all previous grants. Charles II. (1662 and 1685) granted charters, by which an additional weekly market on Wednesday was conceded and a three days' fair, beginning on March 16. The most important industry used to be woollen weaving. Other early industries were glove-making and linen weaving. The first cotton-spinning mill was built in 1777 in Moor Lane, and in 1791 John Horrocks built the Yellow factory. In 1835 there were 40 factories, chiefly spinning, yielding 70,000 lb. of cotton yarn weekly.

A gild existed perhaps in Saxon times, but the grant of a gild merchant dates from Henry II.'s charter, about 1179. The first gild of which there was any record was celebrated in 1328, at which it was decided to hold a gild every 20 years. Zip to 1542, however, they do not appear to have been regularly celebrated, but since that year they have been and still are held at intervals of 20 years. A special gild mayor is appointed on each occasion. The first mention of a procession at the gild is in 1500. One of the most important items of business was the enrolling of freemen, and the gild rolls are records of the population. The statement that Preston was burnt in 1322 by the Scots is probably false. The town suffered severely from the Black Death (1349–50), and again from pestilence in the year Nov. 1630 to Nov. 1631. During the Civil War Preston became the Lancashire Royalist headquarters. In February 1643 a Parliamentary force marched from Manchester and successfully assaulted it, but in March the earl of Derby recaptured the town. The Royalists did not garrison it, but after demolishing the greater part of the works left it unfortified. After the battle of Marston Moor Prince Rupert marched through Preston in September 1644 and carried the mayor and bailiffs prisoners to Skipton castle. On Aug. 17, 1648 the Royalist forces under the duke of Hamilton and Gen. Langdale were defeated at Preston by Cromwell. During the Rebellion of 1715 the rebel forces entered Preston Nov. 9, and after proclaiming the chevalier de St. George king, remained here for some days, during which the government forces advanced. The town was assaulted, and on Nov. 14, Gen. Forster surrendered his army to the king's forces. In 1745 Prince Charles Edward marched through on the way south and north.

The borough returned two members from 1295 to 1331, then ceased to exercise the privilege till 1529, but since that date (except in 1653) it has always sent two representatives to parliament. In the 18th century Preston had a high reputation as a centre of fashionable society, and earned the epithet still familiarly associated with it, "proud."

See H. Fishwick. *History of the Parish of Preston* (1900); W. F. Fitzgerald, "The Ribble Basin," *Journ., Manchester Geog. Soc.* (1927).

PRESTONPANS, police burgh, burgh of barony, parish and watering-place of East Lothian, Scotland, on the Firth of Forth, 9½ m. E. of Edinburgh by the L.N.E R. Pop. (1931), 2,426. A mile to the east of the village is the site of the battle of 1745, in which Prince Charles Edward and his highlanders gained a complete victory over the royal forces under Sir John Cope.

The salt trade, formerly flourishing, has declined. There are manufactures of fire-bricks, tiles and pottery, besides brewing and soap-making, and rich collieries at Tranent, 1 m. S.E, and elsewhere in the neighbourhood. Fisheries are less important than formerly. There are harbours at Morrison's haven to the west and at Cockenzie and Port Seton to the north-east, which form one burgh with a population of 2,526.

PRESTWICH, SIR JOSEPH (1812–1896), English geologist, was born at Clapham, Surrey, on March 12, 1812. He was educated in Paris, Reading and at University College, London. He was a wine merchant in London, and devoted his leisure more especially to the study of the Thames basin. In 1853 he was elected F.R.S. He published in 1851 *A Geological Inquiry respecting the Water-bearkg Strata of the Country around London,* which became a standard authority. With Dr. Hugh Falconer and Sir John Evans, Prestwich examined the implements discovered by Boucher de Ferthes in the gravels of the Somme valley; their investigations proved that man existed contemporaneously with the Pleistocene mammalia *(Phil. Trans.* 1861 and 1864). In 1874 Prestwich was appointed to the chair of geology at Oxford. During his professorship he wrote his great work, *Geology: Chemical, Physical and Stratigraphical* (vol. i., 1886; vol. ii., 1888). He died on June 23, 1896, at Shoreham.

See *Life* and *Letters of Sir Joseph Prestwich,* ed. by his wife (1899).

PRESTWICH, a municipal borough in the Middleton and Prestaich parliamentary division, Lancashire, England, 5 mi. N.W. of Manchester, on the L.M.S.R. Pop. (1938) 32,410. Area 3.8 sq.mi. It has cotton factories and is a suburb of Manchester, with which (and Salford) it is contiguous. It was incorporated 1939.

BRETE, CARLO DEL (1897–1928), Italian aviator, served in World War I as a submarine officer at the age of 17. After the war. he acted for a time as observer for naval seaplanes. In 1926 he obtained his pilot's certificate for the air service, and acted as second pilot to Commander De Pinedo on his Atlantic flight. His flight with Captain Ferrarin on June 2, 1928, lasting 58 hours 37 minutes, was at the time a record of endurance; a month later (July 3–4), again with Captain Ferrarin, he exceeded the longest non-stop flight which had ever been achieved, flying from Rome to Brazil (over 4,500 miles). Del Prete died on Aug. 16, 1928, as the result of an accident while inspecting an aeroplane.

PRETORIA, administrative capital of the Union of South Africa. Pop. (1921) 24,794 natives, 1,757 Asiatics, 2,140 coloured and 45,361 whites, the latter increasing by 1931 to 47,322. The city is built in a hollow, about the Aapies river, a tributary of the Limpopo. Pretoria is laid out in rectangular blocks. At the centre is Church square, on the south side of which are the Provincial Council buildings and other public offices, erected in 1892 in the Renaissance style. On the north side are the law courts and on the west the post office. The Union Government building built 1910–13 on Meintje's kop cost £1,800,000 and overlooks the city. It accommodates the governor-general and more than 1,000 officials. The lower slopes of the hill are laid out in beautiful terraced gardens. The city has several parks and sports grounds, including Burger park, and the zoological gardens. Signal hill rises 400 ft. above the plain, west of Burger park. The plateau at its foot is now occupied by the central railway station and workshops. There is an Anglican cathedral, several high schools, a normal training college, and the Transvaal university college, which includes an agricultural faculty and an experimental farm. Cement and iron are produced locally.

Pretoria was founded in 185j and was made the centre of a new district created at the same time. By treaty between the South African Republic (then comprising the districts of Potchefstroom. Rustenburg, Pretoria and Zoutpansberg) and the Republic of Lydenburg. concluded at Pretoria in 1860, the two republics were united and Pretoria was chosen as the capital of the whole State In September of that year the *Volksraad* held its first meeting in the new capital. Until 1864, however, when the civil war in the Transvaal ended, Potchefstroom remained the virtual capital of the country. From that year the seat of government has always been Pretoria. As revenue flowed in from the gold mines on the Rand, many buildings were erected in the capital, which was linked by railway with Cape Town in 1893 and with Lorenço Marques and Durban in 1895. In May, 1900, Kruger fled from the town, which surrendered in June to Lord Roberts. On May 31, 1902, the articles of peace, whereby the Boer leaders recognized British sovereignty, were signed at Pretoria, and five years later there assembled here the first parliament of the Transvaal, as a self-governing State of the British empire. On the establishment of the Union of South Africa in 1910, Pretoria became its administrative capital.

PRETORIUS, the family name of two of the early leaders of the "Trek" Boers--Andries Wilhelmus Jacobus Pretorius and

Marthinius Wessels Pretorius, father and son.

1. ANDRIES PRETORIUS (1799–1853), a Dutch farmer of Graaff-Reinet, Cape Colony, and a descendant from one of the earliest Dutch settlers in South Africa, left his home in the Great Trek, and by way of what is now the Orange Free State crossed the Drakensberg into Natal, where he arrived in Nov. 1838, at a time when the emigrants there were without a recognized leader. Pretorius was at once chosen commandant-general and speedily collected a force to avenge the massacre of Piet Retief and his party, who had been treacherously killed by the Zulu king Dingaan the previous February. Pretorius's force was attacked on Dec. 16 ("Dingaan's Day") by over 10,000 Zulus, who were beaten off with a loss of 3,000 men. In Jan. 1840 Pretorius with a commando of 400 burghers helped Mpande in his revolt against his brother Dingaan and was the leader of the Natal Boers in their opposition to the British. In 1842 he besieged the small British garrison at Durban, but retreated to Maritzburg on the arrival of reinforcements under Colonel (subsequently Sir) Josias Cloete and afterwards exerted his influence with the Boers in favour of coming to terms with the British.

He remained in Natal as a British subject, and in 1847 was chosen by the Dutch farmers there to lay before the governor of Cape Colony the grievances under which they laboured owing to the constant immigration of natives, to whom locations were assigned to the detriment of Boer claims. Pretorius went to Grahamstown, where Sir Henry Pottinger (the governor) then was; but Sir Henry refused to see him or receive any communication from him. Pretorius returned to Natal determined to abandon his farm and once more trek beyond the British dominions. With a considerable following he was preparing to cross the Drakensberg when Sir Harry Smith, newly appointed governor of the Cape, reached the emigrants' camp on the Tugela (Jan. 1848). Smith promised the farmers protection from the natives, and persuaded many of the party to remain, but Pretorius departed, and on the proclamation of British sovereignty up to the Vaal fixed his residence in the Magalisberg, north of that river. He was chosen by the burghers living on both banks of the Vaal as their commandant-general.

At the request of the Boers at Winburg Pretorius crossed the Vaal in July and led the anti-British party in their "war of freedom," occupying Bloemfontein on July 20. In August he was defeated at Boomplaats by Smith, and thereupon retreated north of the Vaal, where he became leader of one of the largest of the parties into which the Transvaal Boers were divided, and commandant-general of Potchefstroom and Rustenburg, his principal rival being Commandant-General A. H. Potgieter. In 1851 he was asked by the Boer malcontents in the Orange River Sovereignty and by the Basuto chief Moshesh to come to their aid, and he announced his intention of crossing the Vaal to "restore order" in the Sovereignty. His object, however, was rather to obtain from the British an acknowledgement of the independence of the Transvaal Boers. The British cabinet having decided on a policy of abandonment, the proposal of Pretorius was entertained. A reward of £2,000 which had been offered for his apprehension after the Boomplaats fight, was withdrawn.

Pretorius then met the British commissioners at a farm near the Sand river, and concluded the Sand river convention (Jan. 17, 1852) by which the independence of the Transvaal Boers was recognized by Great Britain. Pretorius recrossed the Vaal, and at Rustenburg on March 16 was reconciled to Potgieter, the followers of both leaders approving the convention, though the Potgieter party was not represented at the Sand river.

Pretorius died at his home at Magalisberg on July 23, 1853. In 1855 a new district and a new town were formed out of the Potchefstroom and Rustenburg districts and named Pretoria in honour of the late commandant-general.

2. MARTHINIUS PRETORIUS (1819–1901), the eldest son of Andries, was appointed in Aug. 1853 to succeed his father as commandant-general of Potchefstroom and Rustenburg, two of the districts into which the Transvaal was then divided. In 1854 he led his burghers against a chief named Makapan, who had murdered a party of 23 Boers, including ten women and children. The natives were blockaded in a great cave in the Zoutpansberg, and about 3,000 were starved to death or shot as they emerged.

Having thus chastised Makapan's clan, Pretorius created a strong central Government, and from 1856 onward set to work to form one Boer State to include the Orange River burghers. In Dec. 1856 representatives of the districts of Potchefstroom, Rustenburg and Pretoria met and drew up a constitution, and on Jan. 6, the "South African republic" was formally constituted, Pretorius having been elected president on the previous day. Though the Boers of the Lydenburg, Utrecht and Zoutpansberg districts refused to acknowledge the new republic, Pretorius, with the active co-operation of Paul Kruger (*q.v.*), endeavoured (1857) to unite the Orange Free State and the Transvaal, and a commando crossed the Vaal to support Pretorius. The attempt at coercion failed, but in Dec. 1859 Pretorius was elected president of the Free State. Pretorius had just effected a reconciliation of the Lydenburg Boers with those of the other districts of the Transvaal, and he assumed office at Bloemfontein in Feb. 1860. But the anarchy in the Transvaal effectually weaned the Free State burghers from any thought of immediate amalgamation with their northern neighbours. Pretorius, however, continued to intervene in the affairs of the Transvaal and at length (April 15, 1863) resigned his Free State presidency. Acting as mediator between the various Transvaal parties Pretorius in Jan. 1864 ended the civil strife, and in May following once more became president of the South African republic—now for the first time a united community.

To Pretorius more than any other man was due the welding of the Transvaal Boers into one nation. Pretorius contemplated indefinite expansion of the Transvaal State north, east and west. In April 1868, on the report of gold discoveries at Tati, he issued a proclamation annexing to the Transvaal on the west the whole of Bechuanaland and on the east territory up to and including part of Delagoa Bay. Portugal at once protested, and in 1869 its right to the bay was acknowledged by Pretorius, who in the same year was re-elected president. The Boer claim to the whole of Bechuanaland was not pressed by Pretorius in the face of British opposition, but in 1870, when the discovery of diamonds along the lower Vaal had led to the establishment of many diggers' camps, an attempt was made to enforce the claims of the Transvaal to that district.

Pretorius held repeated conferences with the Bechuana chiefs, but failed to persuade them to join the Transvaal to "save" their territory from the British. Finally, without consulting his colleagues, he agreed to refer the question of the boundary to the arbitration of R. W. Keate, then lieutenant-governor of Natal. The award, given on Oct. 17, 1871, was against the Boer claims. Pretorius loyally accepted the decision, but it aroused a storm of indignation in the Transvaal. The Volksraad refused to ratify the award and thereupon Pretorius resigned the presidency (Nov. 1871).

Pretorius then temporarily retired from politics, but after the first annexation of the State by Great Britain he acted (1878) as chairman of the committee of Boer leaders who were seeking the restoration of their independence. He was arrested in Jan. 1880 by order of Sir Garnet Wolseley on a charge of treason. (*See* the Blue Book [C. 2584] of 1880 for details of this charge.) He was admitted to bail, and shortly afterwards urged by Wolseley to accept a seat, which he declined, on the executive council. In December of the same year he was appointed, with Paul Kruger and P. Joubert, to carry on the government on the part of the insurgent Boers. He was one of the signatories to the Pretoria convention, and acted as a member of the triumvirate until the election of Kruger as president in May 1883. He then withdrew from public life; but lived to see the country re-annexed to Great Britain, dying at Potchefstroom on May 19, 1901. Within four months of his death he had visited Louis Botha and Schalk Burger, on behalf of Lord Kitchener, with the object of ending the war.

For the elder Pretorius *see* G. M. Theal, *Compendium of the History and Geography of South Africa* (3rd ed. 1878), and *History of South Africa,* vol. iv. [1834–54] (1893). For the younger Pretorius *see* vol. v. of the same series.

PREVENTIVE MEDICINE. The prevention of disease is the true ideal of medicine. Its application is twofold—the preventive medicine of the community which is generally termed Public Health or State Medicine, and the prevention of disease or its sequelae in the individual.

HISTORICAL DEVELOPMENT

Ancient Origins.—The practice of preventive medicine had its origin in the ancient world. Hippocrates classified the causes of disease into those concerned with seasons, climates and external conditions, and those more personal causes such as irregular food, exercise and habits of the individual. Through the Middle Ages the principles of preventive medicine were ignored, in spite of the scourges of leprosy and plague. Then with the Renaissance came the new learning on the nature both of health and disease, which revolutionised the whole content of medicine and gave it a fresh centre of gravity and a new outlook. Leonardo da Vinci—whose genius suggested some of the great discoveries of modern science—and Vesalius of Padua, were followed in the 17th century by Galileo, Harvey—who discovered the circulation of the blood—Helmont and the experimentalists. and Sydenham and the great practitioners who with their contemporaries observed the relation of the seasons, of telluric conditions, and the contagion in relation to the incidence of disease. This was quickly followed by new knowledge of anatomy, physiology and pathology. At the end of the first half of the 19th century a beginning had been made in the discovery of specific organisms in diseased tissues and by the end of the century the literature on Bacteriology and Parasitology (*see* BACTERIA AND DISEASE; PARASITIC DISEASES) had become enormous.

Practical Needs.—Concurrently with the growth of medical knowledge there was an empirical movement of practical prevention. Long before the days of Hippocrates men had sought to stem the tides of disease which threatened to overwhelm them. Even in Britain it was the ravages of pestilence in the Middle Ages—of leprosy from the 12th century, of the Black Death from the 14th, of sweating sickness in the 16th, and of cholera and smallpox subsequently—which compelled attention to the conditions which seemed responsible for these scourges. The great monastic orders and some of the historical cities—Rome, Venice and London—provided comfort, refuge and sustenance for the victims, and in 1388 was passed the first Sanitary Act in England, directed to the removal of nuisances. In 1443 came the first plague order recommending quarantine and cleansing; in 1518 were made the first rough attempts at notification of epidemic disease and of isolation of the patient; under Queen Elizabeth scavenging became more stringent; and as time passed men began to see that environment was one of the principal factors in the origin and spread of disease.

Experimental Method.—At first the new applications of medicine were suggested by medical practitioners. Three centuries ago Harvey indicated for us the true experimental method; he placed the blood in the forefront of physical life, and gave it a new chemical and physiological meaning, and by his demonstration of the circulation he provided a new conception of the method by which the blood carried its nourishment to all parts of the body. Fifty years later, Thomas Sydenham, another practitioner, living in a "generation of the strongest and most active intellects that England has produced," laid the basis of epidemiology by his observation of cases, his power of analysis and comparison, his deduction of laws of prevalence, and his suggestive hypothesis of "epidemic constitutions."

Richard Mead, a successful English practitioner in the first half of the 18th century, left behind him published works on poisons, on the plague and the methods of its prevention, on smallpox, measles and scurvy. Bradley and Rogers deduced from their general practice some of the principles of epidemiology, Fothergill described "putrid sore throat," and Haberman chickenpox. Huxham, of Totnes, became an authority on the treatment of fevers, recommended vegetable dietary in cases of scurvy and defined Devonshire colic, which his medical neighbour, Sir George Baker, traced to lead in the vats and cider presses. Willan made a systematic study of the health conditions of London. Withering, of Shropshire, contributed to our knowledge of the incidence of scarlet fever, analysed water, was a climatologist and used digitalis. Edward Jenner, a practitioner in Gloucestershire, introduced vaccination. James Lind issued the first treatise on scurvy and the health of seamen. Thackrah, who practised in Leeds, explored industrial health problems and described dust diseases and brassfounders' ague, and Michael Taylor of Penrith was the first to elucidate milk-borne epidemics. Indeed, the 18th and 19th centuries furnish a remarkable record of clinical discoveries which prepared the ground for the study of causation and the influence of external environment in relation to communal disease.

BRITISH PRACTICE

Legislative Action.—The applications of state medicine, in the 19th century, found their inspiration in England in two sources, and their expression in legislation. The twofold inspiration came from the recurrent outbreaks of cholera and consequent commissions of inquiry, and from popular demand for reform, which was realised after each of the four extensions of the franchise (1832–1918). The Legislature placed on the statute honk a wonderful series of enactments. The alarm caused by the ravages of cholera in 1831 led to the first steps in administrative sanitary reform; in 1849 there was a second visitation of cholera, and in 1854 a third. These cholera epidemics led to a new appreciation of the unsanitary condition of the country as a whole, to an understanding of the nature of the disease and its epidemicity, to the establishment of "cholera dispensary stations" and to the Infectious Diseases Prevention Act 1855.

Concurrently with and following upon these epidemics there were various commissions of investigation. In 1838–9 the Poor Law Commissioners drew attention to the prevalence of epidemic disease and its relation to poverty. The reports by Neil Arnott, Kay, Southwood Smith and Chadwick were the predecessors of another famous series of investigations in 1859–65 by Greenhow and his colleagues under the Privy Council into epidemic diarrhoea, pulmonary disease, infant mortality and ague; and also into the four "elementary requisites of popular healthiness," viz., adequate food supply, sufficient house accommodation, healthy physical surroundings and wholesome industrial circumstances. They led the way to the new application of medicine for the removal of nuisances, the prevention of contagion and infection and industrial hygiene and welfare.

In 1843 Sir Robert Peel, at the instigation of Edwin Chadwick, advised appointing a Royal Commission to inquire into the outbreaks of disease in large towns and the best means of improving the public health, the report of which led to the passing of the comprehensive sanitary measure in 1848, the establishment of the General Board of Health and the appointment of medical officers of health. In 1869 was appointed the Royal Sanitary Commission, on which sat Thomas Watson, James Paget, Henry Acland, Robert Christison and William Stokes, and before which Simon, Budd and Farr gave evidence. Speaking broadly, the 1843 commission found the existence of a serious national evil of insanitation and ill-health, and recommended a legislative remedy, whereas the 1869 commission found that the remedy had proved ineffective and recommended that "the present fragmentary and confused sanitary legislation should be consolidated." They proposed, in fact, for the first time, a Ministry of Health, and though the case miscarried, and the Local Government Board was created in 1871, a comprehensive Ministry of Health was at last established in 1919. The commission's summary of the national sanitary minimum of "What is necessary for civilized social life" provided the grand inventory of that period (1871) and was as follows:—

1. The supply of wholesome and sufficient water for drinking and washing.
2. The prevention of the pollution of water.
3. The provision of sewerage and utilisation of sewage.
4. The regulation of streets, highways and new buildings.
5. The healthiness of dwellings.
6. The removal of nuisances and refuse, and consumption of smoke.
7. The inspection of food.

8. The suppression of causes of diseases, and regulations in cases of epidemics.

9. The provision for the burial of the dead without injury to the living.

10. The regulation of markets, etc., public lighting of towns.

Registration of Death and Sickness.—The programme of 1875 represented the most enlightened thought of the time regarding the sphere and scope of preventive medicine. Even now it is almost a complete summary of the elements of a sanitary environment. The commission also showed how it could be worked out in practice by laying down the general principles to be followed and by drafting a new statute. They diagnosed with unfailing accuracy the causes of imperfect sanitary administration—(a) the variety and confusion of authorities concerned in the public health, (b) the want of sufficient motive power in the central authority, (c) the non-coincidence of areas of various kinds in local sanitary government, (d) the number and complexity of enactments, (e) the needless separation of subjects, (f) the leaving some general Acts to voluntary adoption and the permissive character of other Acts and (g) the incompleteness of the law. Finally, the commissioners lent all the power and prestige of their position and experience in unreserved support of the great principle of local self-government.

Public Health Act, **1875.**—The Public Health Act of 1875, which emerged from the labours of the Royal Sanitary Commission, may be regarded as marking a great advance in the development of sanitary administration. Before that time sanitation was interpreted in large measure as a negative policy—in a word, the removal of nuisances; after that time sanitation received a new connotation, positive, constructive, remedial. That is the reason why this Act forms the great line of division, the watershed in the progress of modern preventive medicine, on its environmental side. The report of Sir Robert Peel's Commission, in 1845, contains a significant suggestion in its recommendation that each local governing body should have a medical officer whose duty it should be "to ascertain the true causes of disease and death, more especially of epidemics increasing the rates of mortality, and the circumstances which originate and maintain such diseases, and injuriously affect the public health." No one can read the preamble of the report of the commission of 1869 on the history of the sanitary laws enacted up to that date without being impressed with their character. They dealt, almost monotonously with nuisances and their removal, sewerage and drains, sewage utilisation, the paving, lighting and cleansing of streets, common lodging-houses, the supervision of artisans' dwellings, smoke nuisances, local government and the burial of the dead. The only group of laws directly concerned with disease were the Vaccination Acts. Then came the Public Health Act of 1875, which in conception and working led for 20 years to enactments on the prevention of river pollution, the protection of water supplies, the provision of housing accommodation and isolation hospitals, and the notification and prevention of infectious disease. The elementary Education Act of 1870, and the Public Health Act of 1875, were forms of germinative legislation bearing fruit in a single generation.

The Practitioner's Aid.—Whilst the state was thus calling into being various public medical services, the practitioner in medicine and surgery was finding ways and means of preventing disease met with in his practice, both infectious and non-infectious. Abortion, miscarriage, still-birth are preventable conditions. Children's disorders such as ophthalmia, rickets, dental decay and malnutrition are preventable, and the same may be said of many diseases of the skin, the eye, ear, nose and throat. The examination of recruits and of insurance patients shows that much physical impairment is due to the effects of rheumatism, dyspepsia, constipation, bronchitis, anaemia, debility, neurasthenia, heart disease, dental decay, mental disease or disorders of metabolism. Some of these conditions are due to factors such as infection (fevers, rheumatism, tuberculosis, venereal disease, etc.), or degenerative processes, like arteriosclerosis and nephritis, or fatigue and unhygienic living; others are more obscure, but the great bulk of them are in large degree preventable. Midwifery alone provides many opportunities for preventive medicine.

Surgical Aid.—Surgical conditions seem at first sight to be less directly preventable, and curative only. Yet the task of the surgeon is to serve and assist nature by placing the human body and its organs at her service, by removing obstructions from her path, by supplementing and aiding her processes and by fortifying the body defences against infection or accident. All this is of the essence of preventive medicine. It is an alliance with nature against disruptive forces. Surgery finds its preventive expression in a great variety of ways. The fundamental principles of aseptic surgery are the elimination of sepsis and its practice is repair, the removal of hurtful tissues and the avoidance of disablement. Preventive surgery may be illustrated in a general way as follows:—

(a) Surgery in children's conditions—enlarged tonsils and adenoids, phimosis, hernia, ophthalmia.

(*b*) Surgery in deformities—rickets, tuberculosis, scoliosis, talipes, flat-foot, hammer-toe, fractures.

(*c*) General surgery—sepsis, tuberculosis, varicose veins, hernia, venereal disease, malignant disease, turnours, thoracic conditions, abdominal and genito-urinary surgery, gynaecology, dental caries.

(*d*) Industrial surgery—wounds, fractures, injuries, poisons, fumes, anthrax, tetanus, etc.

The first generation of the 20th century (1900–24) witnessed a continued development in sanitary environment, which indeed must always remain the foundation of preventive medicine, and in various new departures dependent upon the principles which had been established by the Public Health Act 1875, and by the growth of medical knowledge. The public health service expanded to include particular measures against tuberculosis and venereal disease, the provision of municipal midwives, and a remarkable extension of the supervision of maternity and child welfare. Indeed, the characteristic of this period was the progress made in personal hygiene as distinct from environmental hygiene. Its centre is the person rather than the premises. The School Medical Service was organized in 1907, systematic provision was made for the care of infancy in 1914, the National Health Insurance Act was passed in 1911 and medical research has been organized on a large scale.

Concurrently with these great movements increased attention was given to industrial welfare and the health of the factory worker. Time alone can show the effect on the public health of the wide extensions and applications of the public health principles of 1875. It cannot be doubted that an improved midwifery service, the care of the newborn infant, the systematic health supervision of every school child, improved hygiene in the workshop and factory and a system of health insurance by which medical aid is promptly available for 14,000,000 insured persons must exert in the course of time a profound effect upon the national health. That such an effect has already been produced is shown by the vital statistics. The following table gives the birth-rate, population, number of deaths, average annual death-rate and infant mortality from 1871 to 1920:—

Period	Average annual birth-rate per 1,000 living	Average estimated population	Average estimated number of deaths registered	Average annual death-rate per 1,000	Average annual infant mortality, *i.e.*, deaths of children under one year of age per 1,000 births
1871–1880	35·4	24,225,271	517,831	21·4	149
1881–1890	32·4	27,384,934	524,477	19·1	142
1891–1900	29·9	30,643,316	557,538	18·2	153
1901–1910	27·2	34,180,052	524,877	15·4	128
1911–1920	21·8	35,750,765*	518,805	14·3†	100

*Including civilian population only from 1915–18.
†Including civilian mortality only from 1915–18.

In 1927 the birth-rate had fallen to 16.7, the crude death-rate to 12.3 and the infant mortality rate to 69 per 1,000 born. The decline in the infant mortality rate from 153 per 1,000 born in 1891–1900 to less than 80 for 1920–4 and less than 70 for 1927 is one of the most significant and sensitive indications of the improvement of the public health. Perhaps an even more valuable indication is the expectation of life at birth. In 1871–80 the expectation of life at birth in London was for males 38 years, and for females 42. By 1920–2 these figures had risen to approximately 54 years for males and to 59 for females, a rise of 16 and 17 years respectively in two generations.

Since 1900 there have been various collateral developments in medicine which cannot fail to exert powerful influence on the prevention of disease. The use of X-ray (*q.v.*), of radium (*q.v.*), and of the ultra-violet rays has been conducive not only to greater accuracy of diagnosis, but also to steady improvement in the treatment of tuberculosis (*q.v.*) and cancer (*q.v.*). Heliotherapy (*q.v.*) and open-air treatment are likewise finding many applications. The perfection of the Wassermann-Bordet test and the discovery by Ehrlich of Salvarsan (the 606th preparation tried for syphilis) have advanced the diagnosis and treatment of this disease, now carried out in England and Wales in 186 (1927) specia! clinics receiving state subsidy (see VENEREAL DISEASES). The Widal reaction for typhoid and various tests for tuberculosis have been followed by the Schick and Dick immunizing tests for diphtheria and scarlet fever, and these have opened up new opportunities for the control of these diseases (see INFECTIOUS FEVERS.)

The dispensary and sanatorium treatment for tuberculosis has been greatly developed, and this has led to the arrest or retardation of the disease in many individuals. The disease has been steadily declining in Great Britain since about 1875. The new knowledge of filter-passing viruses has already created far-reaching possibilities, and that of the physiology of internal secretion has led to the introduction for therapeutic purposes of artificially prepared extracts, such as insulin (for diabetes), thyroxin (for myxoedema) and pituitrin (for acromegaly). (See ENDOCRINOLOGY.) There has also been an enormous development in the use of antitoxins, vaccines and serums (see IMMUNITY; SERUM THERAPY; VACCINE THERAPY)—the harvest of the epoch-making work of Louis Pasteur.

These advances are finding their way into various forms and degrees of State enactment, the most recent example of which is the Local Government Act of 1929, which inter alia made available for the whole community upwards of 100,000 hospital beds formerly allocated to the Poor Law.

Lastly, the creation of the League of Nations has facilitated considerable development in the international study of hygiene, and there has thus been opened a new sphere for the application of preventive medicine to international health problems and the control of the tropics for the white man. Plague, yellow fever, malaria and sleeping sickness have now, under favourable circumstances, come under man's dominion.

See J. G. Fitzgerald, P. Gillespie and H. M. Lancaster: *An Introduction to the Practice of Preventive Medicine* (1923). (*G.* N.)

THE UNITED STATES

Notable Advances.—The rapid growth of America was associated with primitive sanitary conditions, so that epidemics of typhoid fever, cholera, yellow fever, typhus fever and other preventable plagues marred the development of the country. In many instances the water supplies were contaminated and sewage and wastes were disposed of by ready methods that were unsanitary and unsatisfactory. The reforms along these lines in recent years have worked hygienic marvels.

In 1893 Theobald Smith demonstrated that Texas fever of cattle was transmitted by the bite of an infected tick, thus proving for the first time the great principle of insect-borne transmission of infection. Shortly afterwards the mosquito was shown to be the factor in the spread of malaria and then of yellow fever. Following this, other insects were found to be responsible for a long and growing list of infections. In 1900 Carter discovered the extrinsic period of incubation of yellow fever. In 1882 Carlos Finlay of Cuba implicated the responsible mosquito, but it remained for the United States Army Medical Commission, consisting of Reed, Carroll, Lazear and Agramonte, to prove the fact by a convincing demonstration in 1900. This discovery was soon put to practical use by White in New Orleans during 1905 when, for the first time, an epidemic of yellow fever was stamped out before the advent of frost. The work of Gorgas which made the building of the Panama Canal possible was a dramatic demonstration in preventive medicine.

The cause and modes of spread of tularaemia, another insect-borne disease, primarily of rabbits and secondarily of man, were discovered by McCoy and Francis, scientists of the Hygienic Laboratory of the U.S. Public Health Service. Ricketts lost his life from typhus fever in Mexico City while unravelling the mysteries of that disease, and McClintock was a martyr to Rocky Mountain spotted fever while studying that tick-borne infection which has been revealed by American investigators. A triumph was achieved by the Dicks of Chicago who demonstrated the cause of scarlet fever and developed an antitoxic serum for its cure, a toxin for its prevention and a skin test (the Dick test) by which it is possible to determine who are susceptible and who immune. Stiles pointed out the importance of hookworm disease and discovered an American species of this parasite. Trudeau founded at Saranac Lake, New York, the sanitorium for tuberculosis which now bears his name; Theobald Smith discovered the bovine tubercle bacillus; and Noguchi's brilliant achievements have placed some obscure problems on a secure scientific basis. In the field of nutrition, Atwater and Benedict, Osborne and Mendel, and Lusk and McCollum have enriched the important subject of dietetics, which is one of the most fundamental factors in health. Among other outstanding contributions should be mentioned the work of Goldberger on pellagra and Strong on trench fever. Oliver Wendell Holmes, as early as 1843, pointed out the contagiousness of puerperal fever. The blessings of anaesthesia (*q.v.*) were among America's first contributions to preventive medicine.

Administrative Measures.—The United States was a pioneer in recognizing the importance of clean, safe milk supplies. In Jan. 1908 the United States Public Health Service published a Bulletin of the Hygienic Laboratory entitled "Milk and Its Relation to the Public Health," which favourably influenced the milk supplies in the United States and elsewhere. Pasteurization was advocated and is now generally applied to all large milk supplies throughout the land. While the United States was somewhat tardy in supplying clean and safe water to its large cities, it developed the method of rapid (or mechanical) sand filtration for muddy waters and has been quick to seize the advantage of chlorination. The recent reduction of typhoid fever in the United States is one of the dramatic demonstrations of preventive medicine.

The United States was early in the field to develop special schools for public health education. A School of Public Health was established by Harvard University and The Massachusetts Institute of Technology in Boston in 1913 (Rosenau, Sedgwick and Whipple). Other universities have participated in this movement, especially the University of Pennsylvania (Abbott), Johns Hopkins University (Welch) and the University of Michigan (Vaughan). Names especially associated with public health administration are Biggs, Chapin, Shattuck, Wiley and Wyman.

Health administration in the United States is part of the police power of the several states. The Federal Government has no constitutional power for local administration of health codes. It has, however, full powers with reference to maritime quarantine and interstate quarantine; it acts in emergencies and it promotes public health through demonstrations, co-operation and investigation. Federal health activities are centred in the United States Public Health Service, which is a bureau of the Treasury Department. Each state has a health organization, and all the large cities and some of the smaller ones also have well organized health services. The county district is the weakest link in the sanitary chain, but in 1925, 280 of the 2,850 rural counties of the United States had full-time health officers. Many other agencies are active in preventive medicine throughout the country—for example, the International Health Board of the Rockefeller Foundation; the Rockefeller Institute for Medical Research; the

McCormick Institute for Infectious Diseases; the Society for the Study and Prevention of Tuberculosis; the National Health Council; the Metropolitan Life Insurance Company, as well as universities, health centres, etc. (M. J. Ro.)

PREVEZA or PREVESA, seaport, southern Epirus, in Greece; at the entrance to the Gulf of Arta, an inlet of the Ionian sea. Pop. (1928, last census before World War II) 8,659. The town is surrounded by dense olive groves. The harbour is small, and closed to large vessels by a bar of sand. Preveza exports dairy produce, valonia, hides and wool, olives and olive oil. About 3 mi. N. are the ruins of Nicopolis (*q.v.*).

It was seized by Ali Pasha in 1798 and recovered by Greece in 1912 during the first Balkan War. In April 1941 it was occupied by Italy.

PREVOST, ANTOINE FRANÇOIS (1697–1763), French author and novelist, was born at Hesdin, Artois, on April 1, 1697. He was educated at the Jesuit school of Hesdin, and in 1713 became a novice of the order in Paris, pursuing his studies at the same time at the college of La Flèche. At the end of 1716 he left the Jesuits to join the army, but he soon tired of life in barracks, and returned to Paris in 1719 with the idea, apparently, of resuming his novitiate. He is said to have travelled in Holland about this time; in any case, however, he returned to the army, this time with a commission. He joined in 1719–20 the learned community of the Benedictines of St. Maur, with whom he found refuge, he himself says, after the unlucky termination of a love affair. He took the vows at Jumièges in 1721 after a year's novitiate, and received in 1726 priest's orders at St. Germer de Flaix. He resided for seven years in various houses of the order, teaching, preaching and studying. In 1728 he was at the abbey of St. Germain-des-Prés, Paris, where he was engaged on the *Gallia christiana,* the learned work undertaken by the monks in continuation of the works of Denys de Sainte-Marthe, who had been a member of their order. His restless spirit made him seek from the Pope a transfer to the easier rule of Cluny; but without waiting for the brief, he left the abbey without leave (1728), and, learning that his superiors had obtained a *lettre de cachet* against him, fled to England.

In London he acquired considerable knowledge of English history and literature, traceable throughout his writings, and he has left an interesting account of English life in his famous memoirs. Before leaving the Benedictines Prévost had begun his most famous romance, *Me'moires et aventures d'un homme de qualité qui s'est retire' du monde,* the first four volumes of which were published in Paris in 1728, and two years later at Amsterdam. In 1729 he left England for Holland, where he began to publish (Utrecht, 1730) a romance, the material of which, at least, had been gathered in London—Le *Philosophe anglois, ou Histoire de Monsieur Cleveland, fils naturel de Cromwell, écrite par lui-mesme, et traduite de l'anglois* (Paris 1731–39, 8 vols., but most of the existing sets are partly Paris and partly Utrecht). Meanwhile during his residence at The Hague, he translated the *Historia* of De Thou, and, relying on the popularity of his first book, published at Amsterdam a *Suite* in three volumes, forming volumes v., vi. and vii. of the original *Me'moires et aventures d'un homme de qualité.* The seventh volume contained the famous *Manon Lescaut,* separately published in Paris in 1731 as *Les Aventures du chevalier des Grieux et de Manon Lescaut, par Monsieur D. . . .* The book was eagerly read, chiefly in pirated copies, as it was forbidden in France. In 1733 he left The Hague for London, and Miss M. Robertson gives an entry showing that he was in prison in London in December on a charge of fraud.

In the autumn of 1734 Prévost was reconciled with the Benedictines, and, returning to France, passed through a new, though brief, novitiate. In 1735 he was dispensed from residence in a monastery by becoming almoner to the prince de Conti, and in 1754 obtained the priory of St. Georges de Gesnes. He continued to produce novels and translations from the English, and, with the exception of a brief exile (1741–1742) spent in Brussels and Frankfort, he resided for the most part at Chantilly until his death on Dec. 23, 1763.

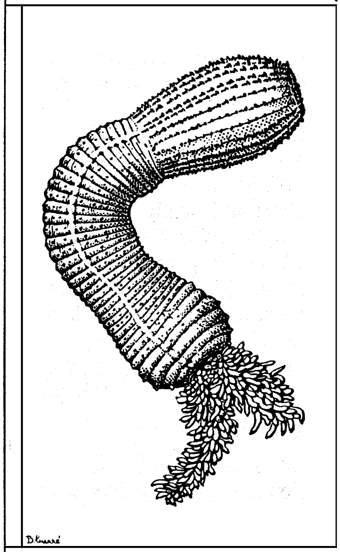
For the bibliography of Prévost's works, which presents many complications, and for documentary evidence of the facts of his life *see* H Harrisse, *L'Abbé Privost* (1896); also a thesis (1898) by V. Schroeder. A critical edition by M. Robertson of the 5th vol. of the *Mémoires et Aventures* dealing with Prévost's adventures in London, was published in 1927.

PRÉVOST, EUGENE MARCEL (1862–1941), French novelist, was born in Paris on May 1, 1862. He was educated at Jesuit schools in Bordeaux and Paris, entering the École Polytechnique in 1882. He published a story in the *Clairon* as early as 1881, but for some years after the completion of his studies he applied his technical knowledge to the manufacture of tobacco. He published in succession, *Le Scorpion* (1887), *Chonchette* (1888), *Mademoiselle Jauffre* (1889), *Cousine Laura* (1890), *La Confession d'un amant* (1891), *Lettres de femmes* (1892), *L'Automne d'une femme* (1893), and in 1894 he made a great sensation by an exaggerated study of the results of Parisian education and Parisian society on young girls, *Les Demi-vierges,* which was dramatized and produced with great success at the Gymnase on May 21, 1895. *Le Jardin secret* appeared in 1897; and in 1900 *Les Vierges fortes,* and a study of the question of women's education and independence in two novels, *Frédérique* and *Léa L'Heureux ménage* (1901), *Les Lettres à Françoise* (1902), *La Princesse d'Erminge* (1904), *L'Accordeur aveugle* (1905) and *Lettres à Frangoise Marie'e* (1908) were among his later novels. In 1904 *La Plus faible* was successfully produced at the Comédie Française In 1909 he was elected to the Academy.

PRIAM, in Greek legend, the last king of Troy (*q.v.*), son of Laomedon. According to Homer *(Iliad,* iii. 184) in his youth he fought on the side of the Phrygians against the Amazons. He had fifty sons and twelve daughters, and immense wealth. He was slain by Neoptolemus, son of Achilles, during the sack of Troy.

PRIAPEIA, a collection of poems (all together about 80 in number) in various metres on the subject of Priapus. It was compiled from literary works and inscriptions on images of the god by an unknown editor, who composed the introductory epigram.

BIBLIOGRAPHY—*See* F. Biicheler's *Petronius* (1904), L. Miiller's *Catullus* (1870), and *E.* Bahren, *Poetae latini minores,* i. (1879).



FROM THEEL, 'NORTHERN AND ARCTIC INVERTEBRATES

PRIAPULUS BICAUDATUS, A WORM-LIKE MARINE ANIMAL OF THE ARCTIC AND NORTH ATLANTIC SEAS

PRIAPULOIDEA, a small group of vermiform marine animals inhabiting the cold seas of both hemispheres; they were formerly placed near the Gephyrea, but their positionis uncertain, and it is doubtful if they are to be regarded as coelomate animals. Their early development is unrecorded, but O. D. Hammersten who studied the late larva of *Halicryptus* claims that it bears a strong resemblance to the Kinorhyncha (*q.v*), and accordingly suggests that the priapuloids are related to this group.

The Priapuloidea are cylindrical worm-like animals with a median anterior mouth devoid of tentacles. The body is covered with a thick cuticle which is shed in its entirety at least once during growth. The anterior end forms the invaginable introvert and is covered with longitudinal rows of small spines continued into the pharynx as powerful hooks: the body is ringed and dotted with small papillae: mouth and anus are terminal and the alimentary canal is straight; behind the anus there occur in *Priapulus* one or two hollow caudal appendages, probably respiratory in function. The nervous system, composed of a ring and a ventral cord, retains its primitive connection with the ectoderm: there are no specialized sense organs and no vascular system. There is a wide body cavity of doubtful homology. The sexes are separate and the organs of sex are one with the excretory organs. According to Schauinsland these organs are separately developed from the same pair of urogenital ducts that open to the exterior on either side of the anus. This author states that from this pair of blindly ending tubes there first arise branching tufts ending in flame-cells similar to those found in the Platyhelminths; these are the excretory organs, and, as sexual maturity approaches, from the walls of the ducts are formed pouches from which the sexual cells are developed. These pass out through the ducts.

There are two genera, *Priapulus* and *Halicryptus,* separated on the presence in *Priapulus* of the caudal appendages. They live in burrows in the mud, which they eat, in comparatively shallow waters up to 50 fathoms. The secretion of the circumanal glands serves to cement the walls of their burrows.

BIBLIOGRAPHY.—O. D. Hammersten, "Zur Entwicklungsgeschichte von *Halicryptus spinulosus* (von Siebold)," *Z. Wiss. Zool.* 112, (2) (1915), contains a discussion of the morphology and relationships of the Priapuloidea and a bibliography. (C. C. A. M.)

PRIAPUS (prē-ah′poōs, anglicized prī-ā′pus), a god of fertility, personification of the fruitfulness of nature, chief deity of Lampsacus on the Hellespont (Dardanelles). He was represented as a man, usually grotesquely ugly, with an enormous and erect sexual organ. Locally, he was thought to be the son of Dionysus and Aphrodite. His cult reached Greece somewhat late in the classical epoch, not becoming really important until Alexandrian times. Later still, it penetrated to Italy. Various legends, all of them late, bring him into connection with the gods of the Greek pantheon, particularly Aphrodite, often represented as his mother, Hermes, Dionysus, and other deities connected with fertility. In Bithynia he is a warlike god, associated with Ares. He absorbed, or was closely identified with, a number of minor rustic deities of similar type; *e.g.,* Phales, Conisalus, Tychon, etc.

He is perhaps best known as a god of gardens, where his image was commonly erected, both to give supernatural protection against thieves and for practical use as a scarecrow' (see, *e.g.,* Horace, *Sat.,* I., 8, 3, et seq.). But as the phallus is a common luck-bringing object, he was worshipped by persons in need of luck, such as hunters and fishermen, and also was frequently employed to keep off the evil eye (numerous examples are found in and outside of houses at Pompeii).

See Jessen in Roscher's *Lexikon, s.v.;* Herter, *De dis Atticis Priapi similibus* (Bonn, 1926).

PRIBILOF ISLANDS (often called the Fur Seal islands), a group of four islands, part of Alaska, lying in Bering sea in 56° 50′ N. and 170° W., about 180 m. north of Unalaska and 200 m. S.W. of Cape Newenham, the nearest point on the mainland. The principal islands are St. Paul (about 35 sq.m.; 13 m. long. from north-east to south-west; maximum width about six miles; named from St. Peter and St. Paul's day, on which it was discovered) and St. George (about 27 sq.m.; 10 m. long, maximum width, 4 m.; probably named after Pribilof's ship) about 30 m. south-east.

The native population in 1940 was 482. The white population act as supervisors. Only agents of the United States or Aleut natives are permitted as residents on the islands. The natives are employed in the sealing industry during the hunting season but in reality they are chiefly dependent on the U.S. Government for food, clothes, schools and medical attention. They maintain their own church on each island (the Russian-Greek Church).

The islands are hilly and of volcanic origin, without harbours, and have a mean annual temperature of about 35·7° F, and a rainfall of about 35 inches. There are only two seasons—rainy summers lasting from May to October, and dry winters from November to April. The flora is restricted to ferns, mosses and grasses, though there are a number of creeping willows and small shrubs.

Fur Industry.—The seals which visit the Pribilof islands from April until November are a distinct species *(Callorhinus ursinus)* with much better fur than that of any other. The sealing operations during the year 1937 resulted in a take of 55,000 skins, valued at approximately $250,000. The valuable herd of seals was rapidly being killed off in 1911, when the U.S. bureau of fisheries took over control. At that time the herd numbered about 125,000; by 1926 a census showed that it had increased to 761,281, and in 1937 it had increased further to almost 1,850,000.

Besides the fur seal there are blue and white foxes (more on St. George than on St. Paul). The natives trap foxes during the winter, when there are no sealing operations, and take about 1,000 pelts during the season. On St. George island and the two islets there are great bird rookeries, which are the breeding places of immense numbers of gulls, sea-parrots, auks and cormorants.

The islands were first sighted in 1767 by Joan Synd, and were visited in 1786 by Gerasim Pribilof, who discovered the fur seal rookeries for which they became famous. From Russia the islands passed with Alaska to the United States in 1867. From 1870 to 1890 the U.S. Government leased the islands to the Alaska Commercial Company. In 1890–1910 the North American Commercial Company held the monopoly, but in the meantime the industry shrank considerably owing to pelagic sealing. The islands were taken over by the U.S. bureau of fisheries in 1910 and since that time sealing operations have been administered directly by its representatives.

PRIBRAM, ALFRED FRANCIS (1859–), Austrian historian, was born in London Sept. 1, 1859. He studied in London and Vienna, and in 1894 became professor of modern history at the University of Vienna, being also elected a member of the Viennese Akademie der Wissenschaften. His main works are: *Oesterreich und Brandenburg* (2 vols., 1884–85); *Der Rheinbund* (1888); *Franz von Lisola und die Politik seiner Zeit* (1894); *Das bohmische Commerzcollegium* (1898); *Die niederoesterreichische Stande* (1898); *Oest. Staatsvertriige* (England) (2 vols., 1907–13); *Geschichte der Juden Wiens* (2 vols., 1918); *The Secret Treaties of Austria-Hungary 1879–1914* (English, German and French ed., 1919–23); *Austria-Hungary's foreign policy 1908–1918* (1923). Professor Pribram also finished and issued vols. 2 and 3 of Friedjung's ambitious work *Das Zeitalter des Imperialismus.* He was a contributor on a large scale to the 11th, 12th, 13th and 14th editions of the *Encyclopædia Britannica.* Pribram's output was comparatively small, owing to his cautious and conscientious methods of working. Truth was his principal preoccupation, and he sought it among documents. His *Secret Treaties* threw much light on modern history in 1929.

PŘIBRAM, a town of Bohemia, lies in the upper valley of the Litavka, near the edge of the Brdy Wald highlands. In its vicinity are some of the deepest silver and lead mines in the world, several centuries old, but now zinc, antimony and bismuth are the chief ores raised. There is a home glove industry. Beside the town rises the Heiliger Berg (1,889 ft.) with a church containing a miracle-working image of the Virgin, the principal place of pilgrimage in Bohemia. Pop. (1930) 10,468. Příbram was occupied by Germany in March 1939.

PRICE, RICHARD (1723–1791), English moral and political philosopher, son of a dissenting minister, was born on Feb. 23, 1723, at Tynton, Glamorganshire. He was chaplain and companion to a Mr. Streatfield at Stoke Newington, London, and by his death and that of an uncle in 1756 his circumstances were improved. In 1757 he married Sarah Blundell.

After publishing several sermons, philosophical papers, and the *Appeal to the Public on the Subject of the National Debt* (1771) he turned his attention to the question of the American colonies, and in 1776 he published a pamphlet entitled *Observations on Civil Liberty and the Justice and Policy of the War with America.* A second pamphlet on the war with America, the debts of Great Britain, and kindred topics followed in the spring of 1777. His name thus became identified with the cause of American independence. He was the intimate friend of Franklin; he corresponded with Turgot.

Price was an intimate friend of Priestley, in spite of the fact that they took the most opposite views on morals and metaphysics. In a published correspondence between them (1778) on the subjects of materialism and necessity, Price maintained, in opposition to Priestley, the free agency of man and the unity and immateriality of the human soul. The pamphlets on the

American War made Price famous. He preached to crowded congregations, and, when Lord Shelburne acceded to power, was offered the post of private secretary to the premier. In 1786 Mrs. Price died, and the remainder of his life appears to have been clouded by solitude and dejection. The progress of the French Revolution alone cheered him. On April 10, 1791, he died, worn out with suffering and disease. His philosophical importance is in the region of ethics. The *Review of the Principal Questions in Morals* (1757, 3rd ed. revised 1787) is professedly a refutation of Hutcheson, but is rather constructive than polemical. The theory he propounds is closely allied to that of Cudworth, but is interesting mainly in comparison with the subsequent theories of Kant.

Besides the above-mentioned, Price wrote an *Essay on the Population of England* (2nd ed., 1780); two Fast-day Sermons, published respectively in 1779 and 1781; and *Observations on the importance of the American Revolution and the means of rendering it a benefit to the World* (1784). A complete list of his works is given as an appendix to Dr. Priestley's *Funeral Sermon*. His views on the French Revolution are denounced by Burke in his *Reflections on the Revolution in France*. Notices of Price's ethical system occur in Mackintosh's *Progress of Ethical Philosophy*, Jouffroy's *Introduction to Ethics*, Whewell's *History of Moral Philosophy in England;* Bain's *Mental and Moral Sciences*. *See* also ETHICS, and T. Fowler's monograph on Shaftesbury and Hutcheson. For Price's life *see* memoir by his nephew, William Morgan.

PRICE, STERLING (1809–1867), American general, was born in Prince Edward county, Virginia, on Sept. 14, 1809. He was educated at Hampden Sidney college and afterwards studied law. In 1830 he removed to Missouri and from 1840 to 1844 served in the Missouri State legislature as speaker of the house of representatives. He was elected a U.S. representative in 1844 but resigned in 1846 to raise and lead the 2nd Missouri Cavalry Regiment in the Mexican War. In 1847 he was commissioned brigadier-general of volunteers and made military governor of Chihuahua. He was governor of Missouri, 1853–57, and State bank commissioner, 1857–61. In 1861 he was appointed major-general of the State militia. Upon the outbreak of the Civil War Price gathered 9,000 Confederate troops at Carthage, Mo., and defeated a small force of Union troops under Franz Sigel. Joined by other troops from Arkansas, Price fought the battle of Wilson's Creek, defeating the Union forces under Gen. Lyons. In the battle of Lexington, shortly afterward, Price captured over 3,000 Union troops, but he was forced to retreat before Gen. Frémont. In March 1862, he was commissioned major-general in the Confederate forces. He commanded under Van Dorn at the battle of Pea Ridge, Ark., on March 7, 1862, and in several engagements around Corinth, Miss. On July 4, 1863, he fought a sharp battle at Helena, Ark., and later prevented Steele's advance to the Red river. In Sept. 1864 he invaded Missouri and advanced to the environs of both St. Louis and Jefferson City, but was repulsed in his attacks at these places. After the war Price went to Mexico in the interest of a colonization project but he returned to Missouri and died at St. Louis on Sept. 29, 1867.

PRICE, THOMAS (1852–1909), Australian statesman, was born at Brymbo, North Wales, on Jan. 19, 1852. He was educated at a penny school in Liverpool, and became a stonecutter. He went to Australia for his health in 1883, where after a time he again found employment as a stonecutter, working on the parliament buildings in Adelaide. We was secretary for two years (1891–93) of the Masons' and Bricklayers' Society of South Australia, and then obtained a seat as Labour member in the House of Assembly. In 1900 he was made secretary of the Labour Party, and in 1901 became its parliamentary leader. He held office as prime minister of South Australia from 1905 until his death on May 31, 1909, at Hawthorn, near Adelaide.

PRICE. What prices are and what price, as a general conception, means would seem to be obvious enough. Yet economists, dealing with the relations of prices to different forms of economic activity and with their own interrelations find that they must take pains if they are to keep their conceptions of price clearly defined and consistent. Thus one may speak of the whole amount of money paid for a quantum of goods as their price, or—if the goods are of a homogeneous or standardized kind, sold by measure, weight, or tale—the amount of money given for each unit of the goods may be regarded as the price. Alternatively, price may be defined, not as a quantity of money but as a ratio between a quantity of money and a quantity of goods. This is generally the more useful conception, but the prices of unique goods, such as works of art, cannot be said to be ratios of quantities. The price ratio is usually stated as so many monetary units (shillings, pounds, dollars) per unit of commodity (ton, yard, bushel). In some markets, however, the ratio is expressed inversely, as so many ounces or yards per shilling, pound, or dollar. This would be a negligible difference if it were not that, as the makers of index numbers have found, where prices or percentage changes in prices are averaged or otherwise combined, precautions must be taken if the results are not to be affected by the particular form in which the price ratios are expressed.

A distinction may also be made between the conceptions of price as a ratio of quantities and as a ratio of values. If ten units of money are required to purchase one unit of a commodity, it may be inferred that a unit of the commodity is ten times as valuable as a unit of money and that the price ratio merely gives expression to that fact. That price is "value expressed in terms of money" is a standard definition. This should not be taken to mean that the values of goods are determined independently of or prior to the determination of their prices, or that the values of goods and of money are determined separately. The factors which determine the values both of goods and of money operate through the processes of exchange, and the values which are thus determined appear in the guise of money prices. It is probable, indeed, that the abstract notion of exchange value is nothing more than a generalization of the simpler idea of price. When we say that price is a ratio of values or that price is value expressed in terms of money, we logically imply, not that value is antecedent to price, but either that in respect of each particular transaction the limits within which the ratio of exchange can vary are established by the general state of the market, or that in analysing the factors which determine the price of any one commodity, the value or general purchasing power of money, may often, without too large an error, be assumed to be constant. The conception of the value of money, in turn, rests upon nothing more tangible than a broad view of all the various prices of different goods and services, but it is nevertheless a useful conception.

The Problems of Price.—The economic theory of price has two principal divisions. One division has to do with the interrelations of the prices of different goods and services, and with the way in which changes in production, consumption, and trade operate directly upon some prices and indirectly upon others. This division of price theory includes that important part of economics sometimes called the theory of value and distribution (or sometimes simply the theory of price-making) and also parts of other fields, such as the theory of international trade. It is concerned both with the tendencies which continually make for a coherent and consistent system of prices and with the subversive forces which make continuously for change. The other division of the theory of prices has to do with the causes of general movements of prices to a higher or lower level—movement which may continue gradually through a long period of years, but which may be broken by shorter movements, convulsive or cyclical in nature. The study of the long-continued general trends of price, and, in considerable measure, of their shorter movements as well, is commonly made a part of the general theory of money. The reason is not that general changes of prices are always attributable to the action of monetary factors alone, but that they are reflected in and in fact are changes of the value of money. They can be studied most conveniently and effectively by enquiring into the changing relations between the supply of money and credit and the volume of production and trade. In recent years especial attention has been given to what might be called the distortions of the whole interrelated structure of prices which accompany changes in their general level. The movements of certain classes of prices, for example, generally lag behind the movements of other classes of prices in a more or less systematic way.

Commodity prices are not the only prices with which economists are concerned. Securities such as bonds or debentures, stocks or shares and bills or notes, have their prices. Railway rates are prices. Foreign exchange rates express the price of current funds in one market in terms of current funds in another market. Wages, of course, may be regarded as the price of labour, rent as the price of the use of land or of other durable goods, and interest as the price of advances of money. Profits, however, are not prices, for they are not proportioned in any definite way to the amounts of goods or services supplied, but are contingent upon the success of particular undertakings. Nor are taxes prices, for the governmental services for which taxes pay are diffused, and not apportioned to different taxpayers in accordance with their respective contributions. Not even the fees which are paid to Government offices for licences or for particular services are in all respects like prices, for the amount of the fee is usually proportioned very loosely, if at all, either to the value of the service to the recipient or to its cost to the Government. But the charges which Governments make for supplying such things as water, gas, electricity and transport may be governed more or less completely, according to the circumstances of the particular case, by the principles in accordance with which prices are determined.

Equilibrium Price. — This is a price at which supply and demand are equal. A distinction has to be made between a temporary equilibrium, such as would express a balancing of the immediate factors which are operative in the market at any given time, and such an equilibrium as would be reached eventually if the particular factors now known to be at work could have their full effects. Equilibrium, then, is always relative to time. All economic equilibria are unstable, but it is convenient in analysis to take separate account of the factors which, if they were neither impeded nor deflected, might finally lead to a stable equilibrium. Market price is the price which will be found in a given market at a given time. It may be regarded as the limiting form of short-time or temporary equilibrium price. Normal price is a price just high enough to cover the expenses of production, including whatever profits are necessary to induce men to undertake the risks of productive enterprise. Because some firms produce at smaller expense than others, because the expense per unit of production often varies, directly or inversely, with the volume of output, and because of the difference, at any given time, between the average expense incurred per unit of product in a given establishment and the expense of producing an additional unit, the conception of normal price is attended with serious, though not altogether insuperable difficulties.

Competitive Price. — This is the price which results from the activities of many buyers and sellers, each of whom can affect the outcome only by buying or selling larger or smaller quantities according as the price is at one point or another. Monopoly price is a price fixed with a view to his or their own advantage by a single (exclusive) seller or buyer, or by a combination of sellers or buyers acting as a unit. Class price (or differential or discriminatory price) is possible only when a monopolist seller is able to deal separately with different classes of buyers or to manage in some other way to sell his goods in what are virtually separate markets. A speculative price is a present price which is influenced by estimates of what the price of the same commodity or security will be in the future. A contract price, or what is sometimes called in speculative markets a "future," is the present price for an exchange which is to be completed by delivery or by taking delivery in the future. Mint price is the price of gold in terms of money at a Government's mint or at a bank which acts as agent for the mint. Gold price is the rather misleading name sometimes given to the result obtained by dividing a price which is quoted in terms of some depreciated paper currency by the price, in terms of the same currency, either of gold or of funds payable in some other country where a gold monetary standard is at the time effective.

Demand Price. — This is the price at which some specified quantity of a given commodity will find purchasers. A schedule of demand prices or demand schedule, exhibits the general relation between the price of a commodity and the amount of it which will be purchased. Supply price, similarly, is the price at which a specified quantity of a given commodity will be offered in the market. The form of the supply schedule depends upon the conditions under which the particular commodity is produced and also upon the period of time which is taken into account. Thus a sudden general increase in demand (in the sense of a general upward movement of a schedule of demand prices) would have the effect of increasing the price at which a specified quantum of a given commodity would be offered for sale. But if the commodity is produced under conditions of increasing returns (*i.e.*, if the output can be increased without a proportionate increase of costs), an increase of demand, continued over a period of years, will have an opposite effect upon its supply price. Indeed, the gradual lowering of the supply prices of commodities produced under conditions of increasing returns need not wait upon a general increase of demand. It is necessary only that demand should be elastic, *i.e.*, that the demand price of successively larger quantities should not fall off too rapidly.' It follows that when an adequate period of time is taken into account, a schedule of supply prices may show that larger quantities will be supplied at lower instead of higher prices. A corresponding schedule of supply prices for a commodity produced under conditions of diminishing returns (*i.e.*, with increased output procurable only at a more than proportionate increase of costs) would, of course, like a schedule of short-period or "instantaneous" supply prices, show higher prices associated with larger quantums of supply. (See: also ECONOMICS, SUPPLY AND DEMAND, and VALUE.) **(A. YO.)**

For bibliography see PRICES, STATISTICS OF.

PRICE-CUTTING, the term used to indicate the practice of selling standard merchandise at a price below that advertised by the manufacturers. With many trade-marked articles the manufacturer attempts to maintain the price at which his products are sold to consumers. The idea is that both wholesalers and retailers should make a profit on his merchandise; otherwise they might refuse to handle it. When an article becomes so well known that it is widely accepted as a standard, it is a common practice, for retailers having similar gocds that they sell under the store label to reduce the price of the trade-marked article and use it in their advertising as a special attraction. Their clerks are instructed to try to sell the substitute bearing the store label instead of the trade-marked article requested. This practice is disadvantageous to the manufacturers inasmuch as the cut-price often makes the article unprofitable for other retailers and they also attempt to substitute other brands for the one advertised. When the distributor departs from the usual practice and sells for cash where most stores would extend credit, and when he refuses to deliver goods and requires the customers to carry their own purchases, he is expected to sell at a lower price because he gives less service. The reduced price of the "cash and carry" stores is not usually included in the term price-cutting. In most countries price-cutting is prevented by contract between the manufacturer and distributors. That form of contract has not been legal in the U.S. until the recent passage of "fair trade" laws by the separate States. Price maintenance is still illegal, by contract, excepting in States having these enactments. (H. E. A.)

PRICE MAINTENANCE. The subject of price maintenance, or, more specifically, resale price maintenance, is one that demands special consideration among the various types of price fixing, both from the legal and the economic aspects. Other forms of price fixing are treated elsewhere. For agreements and understandings as to prices among competing manufacturers, wholesalers or retail dealers, see ASSOCIATIONS, INDUSTRIAL, and also POOLS, IN INDUSTRY and CARTEL; for concentrations of industry in monopolistic, or quasi-monopolistic, forms, see TRUSTS; for price fixing by legal monopolies, such as railroads and other privately owned public utilities, see PUBLIC UTILITIES. All of these forms are found both in the United States and in the United Kingdom. The following discussion relates to resale price maintenance exclusively.

Resale price maintenance is the term applied to various devices by which individual manufacturers or distributors of particular trade-marked, branded, or otherwise identified articles fix minimum resale prices. The most widespread and important manifestation of resale price control is seen where the manufacturer of an article, by contract, fixes a price below which retailers shall not sell it to the public.

The practice has been fostered in the United States by manufacturers who sell trade-marked and well advertised commodities such as breakfast foods, toilet goods, proprietary medicines, books and musical instruments, and has been supported by trade associations of manufacturers and dealers in various lines of products. Supporting dealer organizations have the further objective of inducing the fixing of minimum prices high enough to insure a margin satisfactory to the dealer. In Great Britain there exists an association, known as the Proprietary Articles Trade Association, whose main object is to encourage and enforce this system. A similar association was founded in Canada in 1925 but was later disbanded when it was adjudged to be a combination in restraint of trade.

It is contended by the advocates of resale price maintenance that the maker of an article which bears a trade-mark that he has made valuable by extensive advertising should be entitled to stipulate the price at which it shall be sold by dealers to the public. It is claimed that the manufacturer cannot adequately protect his intangible property—the good will attaching to his trade-mark or brand—unless he restrains dealers who sell his products at a lower price than he suggests, sometimes less than cost, as a "leader" or a "draw" to customers. This use of "leaders," it is maintained, sometimes causes competing retailers to refuse to handle the goods because they can neither make a profit by meeting the low prices, nor sell at the manufacturers' higher resale prices, thus destroying good will of the dealer and reducing the number of dealer outlets.

In England, the legal status of resale price maintenance is based largely upon court application of common law rules respecting freedom of contract and the reasonableness of agreements in restraint of trade. The courts interpret the right of contract broadly and permit manufacturers to make resale price maintenance agreements among themselves and with their distributors provided undue restraint of trade is not shown. Resale price maintenance was considered by official committees in 1920 and again in 1931. The report of 1931 neither condemned, nor did it give unqualified approval to the practice.

Canadian policy follows quite closely that of England but is somewhat more restricted. In certain cases resale price maintenance has been declared to be against public policy, but the practice itself has not been passed upon. Resale price control by a combination of manufacturers, jobbers, and retailers of drugs was condemned in 1927, and a similar combination to control prices of tobacco products was likewise condemned as a combine within the meaning of the Canadian Combines Investigation Act.

In the United States prior to 1936, in cases coming before the U.S. Supreme Court, resale price maintenance was permitted in cases of goods distributed through bonafide agents rather than independent dealers, but otherwise goods sold under a trade name or mark were not exempted from the common law and statutory provisions against monopolies and restraints of trade. As early as 1907 the courts held that a system of contracts entered into by the manufacturer of a proprietary medicine with a large part of the wholesale and retail druggists stipulating the resale price of the product was unlawful and unenforceable on the grounds that it restrained trade (*Park and Sons* v. *Hartman,* 153 Fed. 24), and in 1911 the U.S. Supreme Court rendered a similar decision in the Dr. Miles case (*Dr. Miles Medical Co.* v. *Park and Sons Co.,* 220 U.S. 373). Patented and copyrighted articles have also been held to be within the scope of the Dr. Miles case, and agreements to maintain resale prices thereon declared unlawful.

In 1915, the Federal courts refused to issue an injunction restraining the manufacturer of a breakfast food from carrying out the policy of refusing to sell to those dealers unwilling to maintain resale prices. In 1922, the U.S. Supreme Court held that a corporation may have and announce a policy of refusing to sell to cut-rate dealers and withhold its goods but may not consistently go beyond this act and by contracts or combinations, express or implied, unduly hinder or obstruct the free and natural flow of commerce (*F.T.C.* v. *Beech-Nut Packing Co.,* 257 U.S. 441).

Throughout the period from the Dr. Miles decision in 1911 to the enactment of the National Industrial Recovery Act in June 1933 (48 Stat. 195), bills to legalize resale price maintenance in interstate commerce in the United States were continually presented to the Congress, but all failed of passage. In 1931, however, the State of California enacted a law legalizing resale price maintenance by contract between manufacturers or distributors and retail dealers within the State of California. With the setting up of the National Recovery Administration under the National Industrial Recovery Act, interest in the enactment of further State laws waned due to the fact that numerous codes contained price control provisions and a number provided for some form of resale price maintenance. Following the decision of the U.S. Supreme Court in the Schechter case (*Schechter Poultry Corp.* v. *U.S.,* 295 U.S. 495) which declared portions of the National Recovery Act unconstitutional, the movement to enact State resale price maintenance laws again gained momentum. By the end of 1935, ten States had enacted such laws, generally similar to the 1931 California act. Late in 1936, the U.S. Supreme Court declared the State laws of California and Illinois to be constitutional (Old *Dearborn Distributing Co.* v. *Seagram Distillers Corp.,* 299 U.S. 183, and *The Pep Boys, Manny, Moe & Jack of California, Inc.* v. *Pyroil Sales Co., Inc.,* 299 U.S. 198). These decisions provided such a stimulus that by 1939 44 of the States had legalized resale price maintenance, by laws commonly designated as Fair Trade Acts.

In 1937, the Tydings-Miller Act amended the Sherman Antitrust Act by exempting from the application of that act, "contracts or agreements prescribing minimum prices for resale of a commodity which bears, or the label or container of which bears the trade mark, brand, or name of the producer of such commodity, and which is in fair and open competition with commodities of the same general class produced or distributed by others when contracts or agreements of that description are lawful as applied to intrastate transactions, under any statute, law, or public policy now or hereafter in effect in any State, Territory, or the District of Columbia," and further declared that the making of such contracts "shall not be an unfair method of competition under the Federal Trade Commission Act." This exemption, however, is specifically stated in the act not to make lawful "horizontal" agreements or understanding on prices between competitors, whether they be manufacturers or distributors, and such "horizontal" agreements are still a violation of law when in restraint of trade or commerce among the States.

While resale price maintenance appears presently to find legal sanction in the United States and in the United Kingdom, consumer organizations and economists generally are opposed to the practice from the standpoint of its effects on the public, and many in the United States advocate returning to former policies on the ground that the evils inherent in a system of fixed retail prices outweigh the benefits of resale price maintenance to manufacturers of some lines of merchandise and a segment of the retail trade.

PRICES, STATISTICS OF. The following article deals with the movement of wholesale prices, (A) since 1782 in the United Kingdom; (B) since 1913 in the United States and other countries; (C) the wholesale prices of selected commodities; (D) the movement of retail prices of food in the United Kingdom.

These general movements are measured by index numbers (*see* INDEX NUMBERS), which are averages, computed in various ways, of the changes of prices of selected commodities. The relative importance given to the various classes of commodities in the principal index numbers for the United Kingdom are indicated in

**These numbers are approximate. Jevons's tabulation mas not clear.

the table at the left.

During the very rapid and diverse price movements from 1914 to 1922 the results obtained by the three methods diverged (see table IV.): that of the Board of Trade is on the broadest and most scientific basis.

A. The United Kingdom.—Table I. and fig. 1 exhibit the general movement of wholesale prices, so far as it can be measured, for nearly 150 years. With the outbreak of the French wars in 1793 prices rose, and after some fluctuations, especially at the date of the Peace of Amiens in 1802, reached in 1810 a level nearly twice as high as in 1790. A considerable fall took place immediately after the battle of Waterloo, and, again with fluctuations, prices tended downwards to a minimum about 1850, when they were 25% lower than in 1790. In consequence of the Californian and Australian gold discoveries in 1847 and 1851 prices moved upwards on the whole till 1873. With renewed demand for gold in consequence of the demonetization of silver on the Continent, a considerable fall in prices followed and the minimum of the 150 years under review occurred in 1895–97. With the development of the South African gold mines prices then rose till the outbreak of the World War, and in 1913 reached

approximately the same level as in 1844 and 1881.

This general view is of course based on the average of the movements of prices of many commodities and eliminates the effects of the variations in supply and demand on the prices of particular goods. The only complete record at all easily obtainable for one nearly unchanged commodity is that of the prices of British wheat, which are shown in Table II. and fig. 1. The

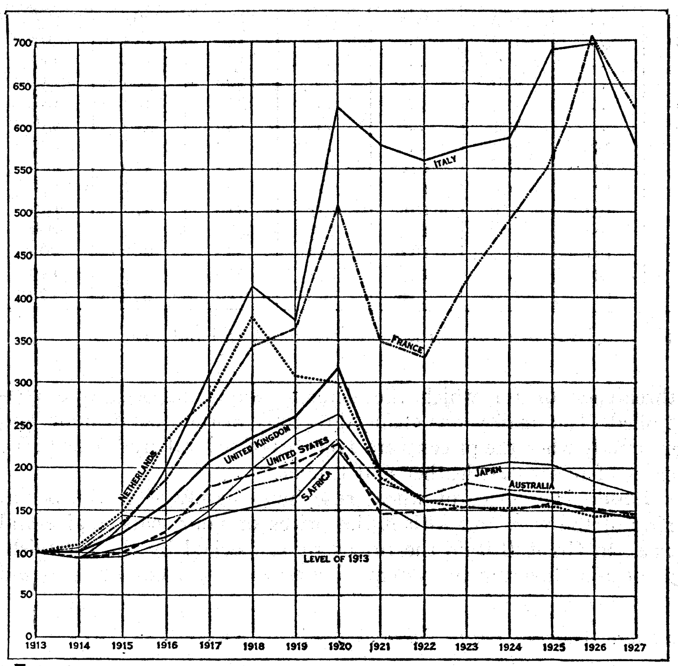

FIG. 2.—RISE AND FALL OF WHOLESALE PRICES IN EIGHT COUNTRIES FROM THE YEARS 1913–1927 INCLUSIVE

fluctuations in the price of wheat were extreme over the whole period 1782 to 1878; after the latter of these dates the increased availability of the American and other distant sources of supply partially steadied the price, which no longer was dependent on the English harvest as in the Napoleonic wars. On a broad view it is seen that the price of wheat has moved with the prices of things in general—both the general index-number and the price of wheat had in 1927 returned nearly to their levels of 1783—but the rise of wheat prices was much the greater of the two in the Napoleonic wars and much the less in the World War, while its fall was delayed in the decades following 1820. A detailed study of the diagram would show the sharp rise in prices during the Crimean War, 1854–55 (especially on wheat prices), the American Civil War, 1861–63, the Franco-Prussian War, 1870–71, and the South African War, especially in 1899–1900, as well as in the two great movements in 1790–1815 and 1913–21. Also the dates of the well-known commercial crises are marked by sudden drops of price, *e.g.* in 1825, 1836, 1839, 1847, 1857, 1873, 1880, 1891 and 1907.

It is interesting also to study the only record of retail prices that is available throughout the century, namely the price of bread in London (Table III.). It will be found on examination that there is a fairly constant relationship between the prices shown in tables II. and III. expressed by the formula:—price of the 4-lb. loaf in pence= 2·06+(number of pence per quarter of wheat÷98).

Immediately after the declaration of war in 1914 prices began to rise, and with certain interruptions continued to mount up till the spring of 1920, when the index numbers reached their maximum (Statist 323, end of April; Economist 326, end of March; Board of Trade 357, average of July). Till Oct. 1917 the increases showed a remarkable regularity, averaging 2% monthly, equivalent cumulatively to 27% per annum; on this scale the index in the successive Octobers would reach 106 in 1914, 135 in 1915, 171 in 1916, 217 in 1917 and 258 in 1918, numbers which (except the last) are in close agreement with those shown in Table IV. There was, however, a definite seasonal movement superimposed on this regularity; in the first three or four months of each year prices moved up with special rapidity, while in the summer the increase was slackened and in some cases was replaced by a fall. The check in the increase in the summer of 1917, following a specially rapid rist, is attributable to the control of prices which by that date was general. From Aug. 1917 prices continued to rise in spite of control till Sept. 1918, but the rise in these 13 months aggregated to only 13% (239 against 213).

After the armistice prices fell slowly for five months, during the season in which in previous years the increase had been specially rapid, but expectations of a permanent fall were not realized; in the year beginning April 1919, the index rose from 224 to 323, or 44%. The reaction began in the early summer of 1920, and the fall was very rapid in the following winter and continued till the end of 1921, when prices were 60% above the pre-war level, and only half those at the maximum of April 1920 by the Statist account. During the subsequent four years the movement was relatively slight, but there was a definite fall and rise in the middle of 1923, and a further rise in the latter part of 1924. The gold basis was restored in May 1925, and both in anticipation of this and after it there was a fall amounting to 10% in the whole year, till prices were 58% above 1913; equilibrium with the United States price index was reached in the latter part of 1925. In 1926 and 1927 the tendency was downwards, and in the winter 1927–28 prices were less than 50% higher than at the outbreak of war.

B. Other Countries.—The world movement of prices is best indicated by the United States index number, since in that country alone the gold basis has been maintained throughout the period 1913 to 1925. In the United States prices rose rapidly, from the year 1916 to a maximum in 1920—in April the index was 273—and then fell rapidly till the spring of 1921; after slight variations, there was a rise from June 1924 to Feb. 1925, and during the subsequent six months the number remained close to 160. The index then fell till April 1927 (144) and rose to 149 in the winter of 1927–28. In all the countries included in Table V. there was a rise from 1915 to 1920, greater or smaller according to the amount of paper money issued. In Germany and Austria the increase was so great that the numbers reached were almost incredible. After 1920 there was a fall in all the index numbers in the table; by the end of 1925 Canada, Australia, South Africa, Sweden, the Netherlands, Switzerland and Germany had returned to the gold basis, and in Canada and Europe there was a close approximation to the American index. There was a general slight fall in 1926–27. In Belgium, France and Italy depreciation recommenced in 1922, and in France and Italy prices had in 1925 passed the 1920 average. In 1936 Belgium reconstituted her currency, and in 1927 Italy and in 1928 France stabilized the exchange of lire and francs respectively. At the end of 1925 Japan was taking steps to stabilize her currency.

C. Selected Commodities.—When commodities are taken separately, the measurements can be made more exactly, subject to the two following qualifications: (1) during the war period the ordinary sources of supply were so disturbed that pre-war kinds and qualities were no longer in the market (in the Economist index number 25 out of the 44 quotations included were subject to some modification of quality); and (2) a statement of prices is generally taken as meaning the price at which a purchaser can obtain the goods he desires, and at which a merchant is willing to sell, but in the time of control and rationing these conditions did not obtain, and the price was fixed by other conditions than those which influence a free market.

Table VI. is based on the prices tabulated annually, in the *Journal* of the Royal Statistical Society, by the editor of the Statist. The index numbers have been recast, the average price in 1913 being taken as 100 for each commodity; the totals have been obtained by grouping together the separate entries on the same plan as in the original, but the change in the base year affects the results, which thus differ from those given in Table IV. in the same way as if the weights had been changed.

It is at once evident that the various prices have not followed the same course; the extremes in 1920 were house coal, whose price rose only 49% in seven years, and Java sugar, where the price is 587%. This wide divergence of itself shows that the general

"Converting the new currency into the old at the ratio 1 to 5. †Average 1914 = 100 for Switzerland and Belgium.

index number cannot have great precision. The prices as recorded are the resultants of at least five forces, viz., the general inflation of prices, the conditions of supply and demand for the separate commodities, the control of supply, the control of prices, the change of quality. In 1915–16 the principal increases may be traced to the diminution or difficulty of supply (cereals, sugar, flax), to acuteness of demand (wool) or to both (timber). In 1917–18 the prices of nearly all commodities whose supply was threatened or for which the demand was increased were controlled. The quality was changed directly in the case of flour, and indirectly when the prices were averages of several grades, as in the cases of meat, flax, leather and timber.

Food.—The price of wheat rose immediately after the beginning of the war, and with it the prices of flour, oats, maize and rice. In Great Britain the prices were checked by the establishment of a Government system of purchase at the end of 1916 and

*The entries in these cases of similar commodities are averaged before conclusion in the index numbers. †These commodities are not included in the index numbers. ‡Wallsend Hetton in 1913. ¶Livonian Z. K. from 1921. §Common New Style from 1921. ‖Average price January-April, 1926.

by the control of the prices of home-grown cereals, in 1917; with this system, flour of mixed materials was substituted for wheat-flour and the product sold at a price kept constant and relatively low by the help of a subsidy, beginning in the autumn of 1917. In the case of wheat and flour the subsidy and control continued till the beginning of 1921, but the prices rose; the prices of other cereals increased very rapidly from the autumn of 1919. An attempt was made to control the consumption of oats in 1917–18, otherwise cereals were not rationed. The wholesale price of potatoes was fixed from time to time, the Government undertaking to make good growers' losses, but the price was changed so frequently that the control had little effect. After the general fall of prices in 1920–21, the fluctuations were principally due to rather abnormal harvest vicissitudes.

During the war the price of meat increased somewhat less than that of commodities in general. Prices were fixed in Great Britain in Aug. 1917 and consumption was rationed early in 1918; after the armistice, control was gradually released, but prices of beef and mutton changed very little during the two years after the first fixing of them. After the great drop in prices in 1921–22, wholesale prices of beef and pork remained relatively low, and those of mutton high during the period 1922–25. Sugar was controlled till

the beginning of 1921, at which date the world's supply had been adjusted to the new conditions, but the supply of beet sugar did not recover, and prices were relatively high till 1925.

Materials.—The prices of coal, iron and steel were subject to great fluctuations. Iron and steel were controlled during the war, and from Nov. 1917 till early in 1919 a subsidy was given to producers. On its removal prices rose very considerably in consequence of the great demand for construction and repairs. Subsequently there was the general collapse in prices, marked by the coal strike of 1921, partly due to the gradual return to normal conditions of the Continental coal mines and steel works. Some stimulus was given to prices by the French occupation of the Ruhr district in 1923, but by the end of 1924, it was evident that the world's capacity for coal and steel production was in excess of requirements, and prices fell to an unremunerative level. The prices of copper and tin and, in some years, of lead fell relatively to general prices.

The prices of cotton and wool reached great heights in the boom of 1920, followed by a complete collapse in 1921. During the period 1922–25 a world shortage of supply (as compared with normal requirements) kept prices on a high level, while continued fluctuations of price hampered manufacture. The extraordinary rise in the price of flax was due to the cutting off of the Polish-Russian supply, which had not recovered by the end of 1925. Space does not permit any analysis of the price movements of

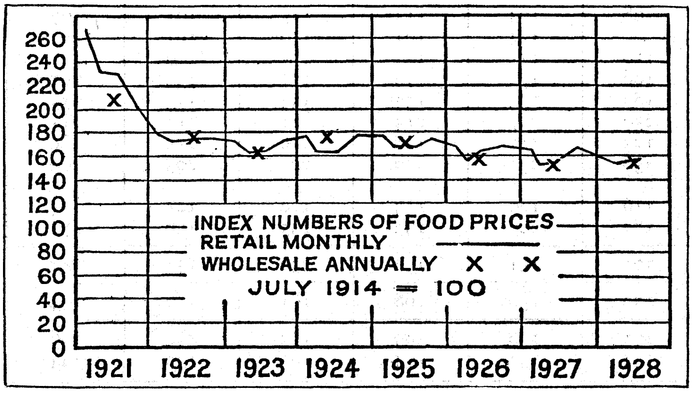

FIG. 3 — SEASONAL MOVEMENT OF PRICES OF FOOD. AND COMPARISON OF WHOLESALE AND RETAIL PRICES

miscellaneous materials, or of that of rubber, not included in the Statist list.

D. Retail Prices of Food in the United Kingdom.—Table VII. shows the movement of the Ministry of Labour's index of retail food prices. This measures the relative cost of purchasing each month exactly the same quantities and as nearly as possible the same kind of food as in a standard budget of working-class expenditure; this budget is based on an investigation made in 1904 and was modified slightly in 1914. During the period of control, 1917–19, the index is to some extent fictitious, since the quantities of the goods included could not be purchased, and generally no allowance is made for modifications of purchases when prices are changing unequally; but there is good reason to believe that these considerations are of little importance after 1920. There is a seasonal fall in the spring and rise in the autumn, owing to the inclusion of dairy produce, and in particular to the supposition that the same number of eggs are bought in January and April; but not improbably this reflects a real change in the cost of nourishment. Though the number is based on an average of prices all over the country, it is nearly applicable to all districts, since in recent years there has been increasing uniformity in prices.

The *Statist* wholesale food index is repeated (on the basis of July 1914) for comparison, though the range of commodities and their relative importance are not the same in the two numbers. The rise up to 1920 is considerably smaller in the retail index, while the concurrence since 1921 is very striking, as shown in fig. 3. Retail prices in 1921 did not fall, however, so rapidly as wholesale, and it is to be expected that their movements will be later and of a smaller amplitude than those of wholesale prices.

(A. L. B.)

United States.—The course of wholesale prices in the United States between 1890 and 1913, as measured by weighted index numbers (*see* INDEX NUMBERS) of the U.S. Bureau of Labor Statistics, is shown in Table I. below, and changes in wholesale and other prices between 1913 and 1938 are shown in Table II.

Table I. shows the drop of wholesale prices to a low point in 1896–97, following the long decline which began in 1865, and the subsequent rise, with occasional interruptions, to the beginning of the World War. Between 1896 and 1913 wholesale prices in the United States rose at an average annual rate of 2·3%. Table II. continues the story, with additional material concerning prices in other markets. In all price fields we find sharp war-time advances, drastic declines in 1920–21, moderate changes during the era of post-war prosperity from 1922 to 1929, and violent recessions during the business decline of 1929–33. Price fluctuations in the two major post-war trade cycles were greatest among wholesale prices and farm prices. In 1932–33 indexes for these groups were below the levels prevailing in 1913. Net changes during the period 1913–38 brought about wide price disparities. Living costs and the composite index of wage rates, security

†Weighted index of U.S. Bureau of Agricultural Economics, based on farm prices (*i.e.*, prices received by producers) of 47 agricultural products.

‡Weighted index of U.S. Bureau of Labor Statistics, based on the prices, at retail, of 84 articles of food in 51 cities. (The index numbers for the years 1913–18 are based on the prices of 22 articles of food, those for the years 1919–34 on the prices of 42 articles of food)

§Weighted index of U.S. Bureau of Labor Statistics, based on the cost of food, clothing, rent, fuel and lighting, house-furnishings and certain miscellaneous items.

¶Index constructed by the Federal Reserve Bank of New York. It is a weighted composite of index numbers of industrial commodity prices, equipment and machinery prices, hardware prices, automobile prices, farm prices, retail food prices, rents, other cost of living items, transportation costs, realty values, security prices and wages.

prices and commodity prices were some 50% higher than in 1913; retail food prices 25% higher; wholesale prices 13% higher; and farm prices 6% lower. These shifts reflect major changes in the internal organization of the national economy.

Details of the movements of wholesale prices in recent years are most accurately measured by the revised index of the Bureau of Labor Statistics. constructed on the 1926 base (Table III).

*109 commodities; †93 commodities; $582 commodities; §618 commodities. (These numbers relate to the period 1926–38.)

Group movements of prices in wholesale markets are in Table IV. Farm and textile products suffered most severely in the business recession of 1929–32, while metals and house-furnishings showed the smallest declines. In general, as is shown in the classification based on degree of fabrication, the prices of raw materials fell most sharply, while those of finished goods showed the smallest declines. The subsequent record is one of general improvement, though farm products and raw materials generally remained at relatively low price levels and metal products, building materials and finished goods, particularly products of the heavy industries, remained high in price. This sharp discrepancy, which means at once low purchasing power on the part of agricultural producers and high costs in the markets for building materials and new investment generally, constitutes one of the persistent obstacles to enduring economic recovery.

The most comprehensive collection of price quotations on individual commodities is that compiled by the United States Bureau of Labor Statistics, and available in monthly releases of that agency. Quotations on important individual commodities are published in numerous trade papers and commercial journals.

PRICHARD, JAMES COWLES (1786–1848), English physician and ethnologist, was born on Feb. 11, 1786, at Ross, Herefordshire. He adopted medicine as a profession mainly because of the facilities it offered for anthropological investigations. He took his M.D. at Edinburgh, afterwards reading for a year at Trinity College, Cambridge, whence, joining the Church of England, he migrated to St. John's College, Oxford, afterwards entering as a gentleman commoner at Trinity College, Oxford, but taking no degree in either university. In 1810 he settled at Bristol as a physician, and in 1813 published his *Researches into the Physical History of Man*. The central principle of the book is the primitive unity of the human species, acted upon by causes which have since divided it into permanent varieties or races.

In 1843 was published his *Natural History of Man.* Prichard may fairly be called the founder of the English branch of the sciences of anthropology and ethnology. In 1811 he was appointed physician to St. Peter's hospital, Bristol, and in 1814 to the Bristol infirmary. In 1822 he published a *Treatise on Diseases of the Nervous System*, and in 1835 a *Treatise on Insanity and other Disorders affecting the Mind*, in which he advanced the theory of the existence of a distinct mental disease, "moral insanity." In 1842, following up this suggestion, he published *On the different forms of Insanity in relation to Jurisprudence designed for the use of Persons concerned in Legal Questions regarding Unsoundness of Mind*. In 1845 he was made a commissioner in lunacy, and removed to London. He died there on Dec. 23, 1848. At the time of his death he was president of the Ethnological Society and a fellow of the Royal Society.

See Memoir by Dr. Thomas Hodgkin (1798–1866) in the *Journal of the Ethnological Society* (Feb. 1849); Memoir read before the Bath and Bristol branch of the Provincial Medical and Surgical Association (March 1849) by Dr. J. A. Symonds *Journ. Eth. Soc.*, (1850); *Prichard and Symonds in Special Relation to Mental Science*, by Dr. Hack Tuke (1891).

PRICKLY ASH (*Zanthoxylum americanum*), a North American shrub or small tree of the rue family (Rutaceae), called also toothache tree, found in woods and thickets from Quebec to Minnesota and southward to Virginia and Missouri. While usually a shrub, it sometimes attains a height of 2j ft. and a trunk diameter of 6 inches. It bears alternate, pinnate leaves, composed of from 5 to 11 ovate, dark green, somewhat pointed leaflets, with the twigs and leaf-stalks usually prickly. The small greenish flowers, which appear before the leaves in early spring, are borne in short axillary clusters; the fruit is a black ellipsoid capsule about $\frac{1}{6}$ in. long, containing one or two seeds.

The similar but larger Herculesclub (*Z. clavaherculis*), known also as sea ash and pepperwood, occurs along streams from southern Virginia to Florida west to Kansas and Texas.

PRICKLY LETTUCE (*Lactuca scariola*), an annual or biennial herb of the family Compositae, closely allied to the garden lettuce (*q.v.*), native to Europe and widely distributed in temperate regions as a naturalized weed. It is a whitish green, usually smooth plant, with a stiff, erect stem, 2 to 7 ft. high, bearing oblong, more or less toothed or cut leaves, with spiny midribs and edges, usually clasping the stem by a more or less eared or heart-shaped base. The very numerous heads of yellow flowers are borne in a large open panicle.

The plant is noteworthy in that the leaves exhibit a marked tendency to become vertical. Moreover, when growing in open places, equally exposed to the sun during either half of the day, the vertical leaves often assume a north and south direction. Because of this characteristic the designation compass-plant is sometimes applied to this species of lettuce, as it also is to various other plants of similar habit.

PRICKLY PEAR, the name given to cacti of the genus *Opuntia,* from the appearance of their fruit. There are about 250 species, all originally American, but several have been introduced elsewhere and, in some places (*e.g.,* Australia), have overrun the countryside. Most species have flattened, jointed stems, and the flowers are white or red. The prickly pear proper is *O. vulgaris; O. Ficus-indica* is Indian fig. The fruit of both of these forms is edible. *O. subulata* is remarkable in that the leaves are large and functional. From *O. tuna,* the tuna hedges are grown in the West Indies, where it is also used as a food plant for the cochineal insect (*Coccus cacti*). (*See* CACTUS)

PRIDE, THOMAS (d. 1658), Parliamentarian general in the English Civil War, is stated to have been brought up by the parish of St. Bride's, London. Subsequently he was a drayman and a brewer. At the beginning of the Civil War he served as a captain under the earl of Essex, and was gradually promoted to the rank of colonel. He distinguished himself at the battle of Preston, and with his regiment took part in the military occupation of London in December 1648, which was the first step towards bringing the king to trial. Pride is chiefly remembered for the expulsion (Dec. 6, 1648) of the Presbyterian and Royalist elements in the House of Commons. This, resolved by the army council and ordered by the lord general, Fairfax, was carried out by Colonel Pride's regiment. Taking his stand at the entrance of the House of Commons with a written list in his hand, he caused the arrest or exclusion of the obnoxious members, who were pointed out to him. After about a hundred members had been thus dealt with ("Pride's Purge"), the mutilated House of Commons proceeded to bring the king to trial. Pride was one of the judges of the king and signed his death-warrant, appending to his signature a seal showing a coat of arms. He commanded an infantry brigade under Cromwell at Dunbar and Worcester. He took no conspicuous part in Commonwealth politics, except in opposing the proposal to confer the kingly dignity on Cromwell. He was knighted by the Protector in 1656, and was also chosen a member of the new House of Lords. He died at Nonsuch House, Surrey, on Oct. 23, 1658. After the Restoration his body was ordered to be dug up and suspended on the gallows at Tyburn along with those of Cromwell, Ireton and Bradshaw, though it is said that the execution of this sentence was evaded.

See Noble, *Lives of the Regicides;* Bate, *Lives of the Prime Actors and Principal Contrivers of the Murder of Charles I.;* Carlyle, *Cromwell's Letters and Speeches.*

PRIDEAUX, HUMPHREY (1648–1724), English divine and Oriental scholar, born at Place, Cornwall, on May 3, 1648, was educated at Westminster School and Christ Church, Oxford. His account of the famous Arundel marbles just given to the university, *Marmora Oxoniensia* (1676), won for him the favour of Heneage Finch, who secured his rapid preferment. Prideaux held several livings, was Hebrew lecturer at Christ Church (1679–86), and dean of Norwich (1702–24). He died on Nov. 1, 1724.

Prideaux's most important work was The Old and New Testament connected in the History of the Jews (1716), which not only displayed but stimulated research.

A volume of his letters to John Ellis, some time under-secretary of state, was edited by E. M. Thompson for the Camden Society in 1875; they contain a vivid picture of Oxford life after the Restoration. For a complete list of his printed and ms. work see Bibliotheca *Cornubiensis* (ii., 527–533 and iii. 1319).

PRIDE OF CALIFORNIA (Latkyrus *splendens*), a name given to a North American plant of the pea family (Leguminosae), native to the mountains of southern California, called also campo pea. It is closely allied to the sweet pea of the gardens, and bears showy clusters of brilliant red flowers.

PRIENE (mod. *Samsun* kale), an ancient city of Ionia on the foot-hills of Mycale, about 6 m. N. of the Maeander. It was formerly on the sea coast, but now lies some miles inland. It is said to have been founded by Ionians under Aegyptus, a son of Neleus. Sacked by Ardys of Lydia, it revived and attained great prosperity under its "sage," Bias, in the middle of the 6th century. Cyrus captured it in 545; but it was able to send twelve ships to join the Ionian revolt (500–494). Disputes with Samos, and the troubles after Alexander's death, brought Priene low, and Rome had to save it from the kings of Pergamum and Cappadocia in 155. Orophernes, the rebellious brother of the Cappadocian king, who had deposited a treasure there and recovered it by Roman intervention, restored the temple of Athena as a thank-offering. Under Roman and Byzantine dominion Priene had a prosperous history. It passed into Muslim hands late in the 13th century. The ruins, which lie on successive terraces, were excavated mainly in the late 19th century. The city, as rebuilt in the 4th and 3rd centuries, was laid out on a rectangular scheme. It faced south, its acropolis rising nearly 700 ft. behind it. The whole area was enclosed by a wall 7 ft. thick with towers at intervals and three principal gates. On the lower slopes of the acropolis was a shrine of Demeter. The town had six main streets, about 20 ft. wide, running east and west and fifteen streets about 10 ft. wide crossing at right angles, all being evenly spaced; and it was thus divided into about So *insulae*. Private houses were apportioned four to an *insula*. The systems of water-supply and drainage can easily be discerned. The houses present many analogies with the earliest Pompeian. In the western half of the city, on a high terrace north of the main street and approached by a fine stairway, was the temple of Athena Polias, a hexastyle peripteral Ionic structure built by Pythias, the architect of the Mausoleum. Under the basis of the statue of Athena were found in 1870 silver tetradrachms of Orophernes, and some jewellery, probably deposited at the time of the Cappadocian restoration. Fronting the main street is a series of halls, and on the other side is the fine market place. The municipal buildings, Roman gymnasium, and well preserved theatre lie to the north, but, like all the other public structures, in the centre of the plan. Temples of Isis and Asclepius have been excavated. At the lowest point on the south, within the walls, was the large stadium, connected with a gymnasium of Hellenistic times.

See Society of Dilettanti, Ionian Antiquities (1821), vol. ii.; Th. Wiegand and H. Schrader, *Priene* (1904); on inscriptions (360) see Hiller von Gartringen, Znschriften von *Priene* (Berlin, 1907), with collection of ancient references to the city.

PRIEST, the contracted form of "presbyter" (*πρεσβύτερος*, "elder"; see PRESBYTER), a name of office in the early Christian Church, already mentioned in the New Testament. But in the English bible the presbyters of the New Testament are called "elders," not "priests"; the latter name is reserved for ministers of pre-Christian religions. The reason of this will appear more clearly in the sequel; it is enough to observe at present that, before our English word was formed, the original idea of a presbyter had been overlaid with others derived from pre-Christian priesthoods, so that it is from these and not from the etymological force of the word that we must start in considering historically what a priest is. The theologians of the Greek and Latin churches expressly found the conception of a Christian priesthood on the hierarchy of the Jewish temple, while the names by which the sacerdotal character is expressed—*ἱερεύς*, sacerdos—originally designated the ministers of sacred things in Greek and Roman heathenism, and then came to be used as translations into Greek and Latin of the Hebrew *kōhēn*. *Kōhēn*, *ἱερεύς*, sacerdos, are, in fact, fair translations of one another; they all denote a minister whose stated business was to perform, on behalf of the community, certain public ritual acts, particularly sacrifices, directed Godwards. Such ministers or priests existed in all the great religions of ancient civilization.

Early Priesthoods.—Among the Babylonians and Assyrians magic and soothsaying were intertwined with priestly functions, as was the case in early Hebrew pre-exilian days with the *Kōhēn*. The bark (from bark to see, inspect) was a soothsaying priest who was consulted whenever any important undertaking was proposed, and addressed his inquiries to Samaš the sun god (or Adad) as *bêl* biri or lord of the oracle (accompanied by the sacrifice of lambs). (See OMEN and DIVINATION.)

As contrasted with the bark or soothsaying priest we have the *ašipu,* who was the priest-magician who dealt in conjurations (*šiptu*), whereby diseases were removed, spells broken, or in expiations whereby sins were expiated. Now, as the conjurations were addressed to the deity, *ašipu,* according to the definition given above, comes more reasonably under the category of priest. In Babylonia priesthoods were endowed with great wealth and power, and even the king stood in awe of them. (See Johns, Babylonian and Assyrian Laws, Contracts *and* Letters, p. 212 sqq.) These powerfully-organized priesthoods, as well as the elaborate nature of their ritual and apparatus of worship, must have deeply and permanently impressed the exiled Jewish community. Thus arose the more developed system of Ezekiel's scheme (xl.–xlviii.) and of the Priestly code and the high dignity which became attached to the person of the High Priest (reflected in the narrative of Uzziah's leprosy in 2 Chron. xxvi. 16–20).

Among the ancient Egyptians the local god was the protector and lord of the district. Consequently it was the interest and duty of the inhabitants to maintain the cultus of the patron-deity of their city who dwelt in their midst. Moreover, in the earlier times we find the prince of the nome acting as the High Priest of the local god, but in course of time the state. represented by the king, began to an ever-increasing degree to take oversight over the more important local cults. Thus we find that the Egyptian monarch was empowered to exercise priestly functions before all the gods. We constantly see him in the wall-paintings, portrayed as a priest in the conventional attitudes before the images of the gods. In the chief sanctuaries the chief priests possessed special privileges, and it is probable that those in the immediate entourage of the king were elected to these positions. The highest nobility in the nome sought the honour of priesthood in the service of the local deity. One special class called kher *heb* was charged with reciting the divine formulae. which were popularly held to possess magical virtue. In the middle empire (VIIth to XIIth Dynasties) the lay element maintains its position in religious cultus despite its complexity. But under the new empire (Dynasties XVIIIth and following) the professional priest had attained to ominous power. Priests increased in number and were divided into ranks; temples possessed larger estates and became more wealthy.

Ancient Greece.—Homer speaks of special priests who preside over ritual acts in the temples to which they are attached; but his kings also do sacrifice on behalf of their people. The king, in fact, both in Greece and in Rome, was the acting head of the state religion, and when the regal power came to an end his sacred functions were not transferred to the ordinary priests, but either they were distributed among high officers of state, as archons and prytanes, or the title of "king" was still preserved as that of a religious functionary, as in the case of the rex *sacrorum* at Rome and the *archon basileus* at Athens. In the domestic circle the union of priesthood and natural headship was never disturbed; the Roman paterfamilias sacrificed for the whole family. On the other hand, gentes and *phratriae,* which had no natural head, had special priests chosen from their members; for every circle of ancient society, from the family up to the state, was a religious as well as a civil unity, and had its own gods and sacred rites. We cannot speak of priestly power and hardly even of a distinct priestly class.

In Greece the priest, so far as he is an independent functionary and not one of the magistrates, is simply the elected or hereditary minister of a temple charged with "those things which are ordained to be done towards the gods" (see Aristotle, Pol. vi. 8), and remunerated from the revenues of the temple, or by the gifts of worshippers and sacrificial dues. The position was often lucrative and always honourable, and the priests were under the special protection of the gods they served. But their purely ritual functions gave them no means of establishing a considerable influence on the minds of men, and the technical knowledge which they possessed as to the way in which the gods could be acceptably approached was neither so intricate nor so mysterious as to give the class a special importance. There was, indeed, one sacred function of great importance in the ancient world in which the Greek priests had a share. As man approached the gods in sacrifice and prayers, so too the gods declared themselves to men by divers signs and tokens, which it was possible to read by the art of Divination (*q.v.*). In many nations divination and priesthood have always gone hand in hand; at Rome, for example, the augurs and the XV. viri *sacrorum,* who interpreted the Sibylline books, were priestly colleges. In Greece, on the other hand, divination was not generally a priestly function, but it did belong to the priests of the Oracles. (See ORACLE.) The great oracles, however, were of Panhellenic celebrity and did not serve each a particular state, and so in this direction also the risk of an independent priestly power within the state was avoided.

In Rome, again, where the functions of the priesthood were politically much more weighty, where the technicalities of religion were more complicated, where priests interpreted the will of the gods, and where the pontiffs had a most important jurisdiction in sacred things, the state was much too strong to suffer these powers to escape from its own immediate control: the old monarchy of the king in sacred things descended to the inheritors of his temporal power; the highest civil and religious functions met in the same persons (cf. Cic. De dom. i. 1); and every priest was subject to the state exactly as the magistrates were, referring all weighty matters to state decision and then executing what the one supreme power decreed. And it is instructive to observe that when the plebeians extorted their full share of political power they also demanded and obtained admission to every priestly college of political importance, to those, namely, of the pontiffs, the augurs, and the XV. viri *sacrorum.* The Romans, it need hardly be said, had no hereditary priests.

Aryan Religions.—In historical times the priesthood in India is rigidly confined to members of the Brahman caste. But at an earlier date the warrior caste often became priests. The power of the priesthood began with the delegation by the king of his sacrificial duties to an appointed official. This power grew with the growing importance of the sacrifice and the complication of its ceremonial. In the post-Vedic period "right" or "wrong" simply meant the exact performance or the neglect, whether intentional or unintentional-of all the details of a prescribed ritual, the centre of which was the sacrifice. At this period the priestly caste gained its unbounded power over the minds of men. For further details as to the development of the priestly caste and wisdom in India the reader must refer to BRAHMANISM.

Among the Zoroastrian Iranians, as among the Indian Aryans, the aid of a priest to recite the sacrificial liturgy was necessary at every offering (Herod. i. 132), and the Iranian priests (âthravans, later **Magi)** claimed, like the Brahmans, to be the highest order of society; but they did not acquire the powers of the Indian priesthood; in particular, the priesthood, as it was not based on family tradition, did not form a strict hereditary caste. Nevertheless, it formed a compact hierarchy not inferior in influence to the clergy of the Christian middle ages, had great power in the state, and were often irksome even to the great king. But the monarchs had one strong hold on the clergy by retaining the patronage of great ecclesiastical places.

The Persian religion throughout all its multitude of purifications, observances and expiations was a constant warfare against impurity, death and the devil. Amid all the ceremonialism of its priesthood there were also high ideals set forth in Zoroastrian religion of what a priest should be. Thus we read in Vendidâd xviii., "Many there be, noble Zarathustra, who bear the mouth bandage, who have yet not girded their loins with the law. If such a one says 'I am an Athravan' he lies, call him not Athravan, noble Zarathustra, said Ahura Mazda; but thou shouldst call him priest, noble Zarathustra, who sits awake the whole night through and yearns for holy wisdom that enables man to stand on death's bridge fearless and with happy heart, the wisdom whereby he attains the holy and glorious world of paradise."

Semitic Races.—Among the nomadic Semites there was no developed priesthood. Religion partook of the general simplicity of desert life; apart from the private worship of household gods and the oblations and salutations offered at the graves of departed kinsmen, the ritual observances of the ancient Arabs were visits to the tribal sanctuary to salute the god with a gift of first-fruits or the like (see NAZARITE and PASSOVER), and an occasional pilgrimage to discharge a vow at the annual feast and fair of one of the more distant holy places. (See MECCA.) These acts required no priestly aid; each man slew his own victim and divided the sacrifice in his own circle; the share of the god was the blood which was smeared upon or poured out beside the stone set up as an altar or perhaps as a symbol of the deity. We find therefore no trace of a sacrificial priesthood, but each temple had one or more doorkeepers, whose office was usually hereditary and who had the charge of the Temple and its treasures.

The sacrifices and offerings were acknowledgments of divine bounty and means used to ensure its continuance; the Arab was the "slave" of his god and paid him tribute, as slaves used to do to their masters, or subjects to their lords; and the free Bedouin, trained in the solitude of the desert to habits of absolute self-reliance, knew no master except his god. The decision of the god might be uttered in omens which the skilled could read, or conveyed in the inspired rhymes of soothsayers, but frequently it was sought in the oracle of the sanctuary, where the sacred lot was administkred for a fee by the *sādin.* The sanctuary thus became a seat of judgment, and here, too, compacts were sealed by oaths and sacrificial ceremonies. These institutions, though known to us only from sources belonging to an age when the old faith was falling to pieces, are certainly very ancient. The fundamental type of the Arabic sanctuary can be traced through all the Semitic lands, and so appears to be older than the Semitic dispersion.

With the beginning of a settled state the sanctuaries rose in importance and all the functions of revelation gathered round them. A sacrificial priesthood arose as the worship became more complex (especially as sacrifice in antiquity is a common preliminary to the consultation of an oracle), but the public ritual remained closely associated with oracle or divination, and the priest was, above all things, a revealer. That this was what actually happened may be inferred from the fact that the Canaanite and Phoenician name for a priest (*kōhēn*) is identical with the Arabic *kāhin,* a "soothsayer." Soothsaying was no modern importation in Arabia; its characteristic form—a monotonous croon of short rhyming clauses—is the same as was practised by the Hebrew "wizards who peeped and muttered" in the days of Isaiah. The *kāhin,* therefore, is not a degraded priest but such a soothsayer as is found in most primitive societies, and the Canaanite priests grew out of these early revealers. In point of fact some form of revelation or oracle appears to have existed in every great shrine of Canaan and Syria, and at Hierapolis it was the charge of the chief priest, just as in the Levitical legislation.

The Hebrews, who made the language of Canaan their own, took also the Canaanite name for a priest. But the earliest forms of Hebrew priesthood are not Canaanite in character; the priest, as he appears in the older records of the time of the Judges, Eli at Shiloh, Jonathan in the private temple of Micah and at Dan, is more like the *sādin* than the *kāhin*. The whole structure of Hebrew society at the time of the conquest was almost precisely that of a federation of Arab tribes, and the religious ordinances are scarcely distinguishable from those of Arabia, save only that the great deliverance of the Exodus and the period when Moses, sitting in judgment at the sanctuary of Kadesh, had for a whole generation impressed the sovereignty of Jehovah on all the tribes, had created an idea of unity between the scattered settlements in Canaan such as the Arabs before Mohammed never had. But neither in civil nor in religious life was this ideal unity expressed in fixed institutions, the old individualism of the Semitic nomad still held its ground. Thus the firstlings, first-fruits and vows are still the free gift of the individual which no human authority exacts, and which every householder presents and consumes with his circle in a sacrificial feast without priestly aid.

As in Arabia, the ordinary sanctuary is still a sacred stone set up under the open heaven, and here the blood of the victim is poured out as an offering to God. (See especially 1 Sam. xiv. 34, and cf. 2 Sam. xxiii. 16, 17.) The priest has no place in this ritual: he is not the minister of an altar; but the guardian of a temple, such as was already found here, and there in the land for the custody of sacred images or other consecrated things (the ark at Shiloh, 1 Sam. iii. 3; images in Micah's temple, Judges xvii. 5; Goliath's sword lying behind the "ephod" or plated image at Nob, 1 Sam, xxi. g; no doubt also money, as in the Canaanite temple at Shechem, Judges ix. 4). Such treasures required a guardian; but, above all, wherever there was a temple there was an oracle, a kind of sacred lot, just as in Arabia (1 Sam. xiv. 41, lxx.), which could only be drawn where there was an "ephod" and a priest (1 Sam. xiv. 18, Sept., and xxiii. 6 seq.). The Hebrews had already possessed a tent-temple and oracle of this kind in the wilderness (Exod. xxxiii. 7 seq.), and ever since that time the judgment of God through the priest at the sanctuary had a greater weight than the word of a seer, and was the ultimate solution of every controversy and claim (1 Sam, ii. 25; Exod. xxi. 6, xxii. 8, g, where for "judge," "judges," of A.V. read "God" with R.V.).

The temple at Shiloh, where the ark was preserved, was the lineal descendant of the Mosaic sanctuary and its priests claimed kin with Moses himself. In the divided state of the nation, indeed, this sanctuary was hardly visited from beyond Mt. Ephraim; and every man or tribe that cared to provide the necessary apparatus (ephod, teraphim, etc.) and hire a priest might have a temple and oracle of his own at which to consult Jehovah (Judges xvii., xviii.); but there was hardly another sanctuary of equal dignity. The priest of Shiloh is a much greater person than Micah's priest Jonathan; at the great feasts he sits enthroned by the doorway, preserving decorum among the worshippers; he has certain legal dues, and, if he is disposed to exact more, no one ventures to resist (1 Sam. ii. 12 *seq.*, where the text needs a slight correction). The priestly position of the family survived the fall of Shiloh and the capture of the ark, and it was members of this house who consulted Jehovah for the early kings until Solomon deposed Abiathar.

Ultimately, indeed, as sanctuaries were multiplied and the priests all over the land came to form one well-marked class, "Levite" and legitimate priest became equivalent expressions, as is explained in the article LEVITES. But between the priesthood of Eli at Shiloh or of Jonathan at Dan and the priesthood of the Levites as described in Deut. xxxiii. 8 seq. there lies a period of the inner history of which we know almost nothing. It is plain that the various priestly colleges regarded themselves as one order, that they had common traditions of law and ritual which were traced back to Moses, and common interests which had not been vindicated without a struggle. The kingship had not deprived them of their functions as fountains of divine judgment (cf. Deut. xvii. 8 seq.); on the contrary, the decisions of the sanctuary had grown up into a body of sacred law, which the priests administered according to a traditional precedent. According to Semitic ideas the declaration of law is quite a distinct function from the enforcing of it, and the royal executive came into no collision with the purely declaratory functions of the priests. The invective of Hos. iv. equally with the eulogium of Deut. xxxiii. proves that the position which the later priests abused had been won by ancestors who earned the respect of the nation as worthy representatives of a divine Torah.

The ritual functions of the priesthood still appear in Deut. xxxiii. as secondary to that of declaring the sentence of God, but they were no longer insignificant. With the prosperity of the nation, and especially through the absorption of the Canaanites and of their holy places, ritual had become much more elaborate, and in royal sanctuaries at least there were regular public offerings maintained by the king and presented by the priests. (Cf. 2 Kings xvi. 15.) Private sacrifices, too, could hardly be offered without some priestly aid now that ritual was more complex; the provision of Deut. xviii. as to the priestly dues is certainly ancient, and shows that besides the tribute of first-fruits and the like the priests had a fee in kind for each sacrifice, as we find to have been the case among the Phoenicians according to the sacrificial tablet of Marseilles. Their judicial functions also brought profit to the priests, fines being exacted for certain offences and paid to them (2 Kings xii. 16: Hos. iv. 8: Amos ii. 8). The greater priestly offices were therefore in every respect very important places, and the priests of the royal sanctuaries were among the grandees of the realm (2 Sam. viii. 18; 2 Kings x. 11, xii. 2); but there is not the slightest trace of an hereditary hierarchy officiating by divine right, such as existed after the exile. The sons of Zadok, the priests of the royal chapel, were the king's servants as absolutely as any other great officers of state; they owed their place to the fiat of King Solomon, and the royal will was supreme in all matters of cultus (2 Kings xii., xvi. 10 seq.); indeed the monarchs of Judah, like those of other nations, did sacrifice in person when they chose down to the time of the captivity (1 Kings ix. 25; 2 Kings xvi. 12 seq.; Jer. xxx. 21).

The detailed steps which prepared the way for the post-exile hierarchy, the destruction of the northern sanctuaries and priesthoods by the Assyrians, the polemic of the spiritual prophets against the corruptions of popular worship, which issued in the reformation of Josiah, the suppression of the provincial shrines of Judah and the transference of their ministers to Jerusalem, the successful resistance of the sons of Zadok to the proposal to share the sanctuary on equal terms with these new-comers, and the theoretical justification of the degradation of the latter to the position of mere servants in the Temple supplied by Ezekiel soon after the captivity, need not here be dealt with. Already in the time of Josiah altar service and not the judicial or "teaching" function had become the essential thing in priesthood (Deut. x. 8, xviii. 7); the latter, indeed, was not forgotten (Jer. ii. 8, xviii. 18), but by the time of Ezekiel it also has mainly to do with ritual, with the distinction between holy and profane, clean and unclean, with the statutory observances at festivals and the like (Ezek. xliv. 23 seq.). What the priestly Torah was at the time of the exile can be seen from the collection of laws in Lev. xvii.–xxvi., which includes many moral precepts, but regards them equally with ritual precepts from the point of view of the maintenance of national holiness. The holiness of Israel centres in the sanctuary, and round the sanctuary stand the priests, who alone can approach the most holy things without profanation, and who are the guardians of Israel's sanctity, partly by protecting the one meeting-place of God and man from profane contact, and partly as the mediators of the continual atoning rites by which breaches of holiness are expiated. In the old kingdom the priests had shared the place of the prophets as the religious leaders of the nation; under the second Temple they represented the unprogressive traditional side of religion, and the leaders of thought were the psalmists and the scribes, who spoke much more directly to the piety of the nation.

But, on the other hand, the material influence of the priests was greater than it had ever been before; the Temple was the only visible centre of national life in the ages of servitude to foreign power, and the priests were the only great national functionaries, who drew to themselves all the sacred dues as a matter of right and even appropriated the tithes paid of old to the king. When the High Priest stood at the altar in all his princely state, when he poured out the libation amidst the blare of trumpets, and the singers lifted up their voices and all the people fell prostrate in prayer till he descended and raised his hands in blessing, the slaves of the Greek or the Persian forgot for a moment their bondage and knew that the day of their redemption was near (Ecclus. l.). The High Priest at such a moment seemed to embody all the glory of the nation, as the kings had done of old, and when the time came to strike a successful blow for freedom it was a priestly house that led the nation to the victory which united in one person the functions of High Priest and prince. From the foundation of the Hasmonean state to the time of Herod the history of the high-priesthood merges in the political history of the nation; from Herod onward the priestly aristocracy of the Sadducees lost its chief hold over the nation and expired in vain controversy with the Pharisees.

The influence of the Hebrew priesthood on the thought and organization of Christendom was the influence not of a living institution, for it hardly began till after the fall of the Temple, but of the theory embodied in the Priestly Code of the Pentateuch. Two points in this theory were laid hold of—the doctrine of priestly mediation and the system of priestly hierarchy. The first forms the text of the principal argument in the Epistle to the Hebrews, in which the author demonstrates the inadequacy of the mediation and atoning rites of the Old Testament, and builds upon this demonstration the doctrine of the effectual high-priesthood of Christ, who, in His sacrifice of Himself, truly "led His people to God," not leaving them outside as He entered the heavenly sanctuary, but taking them with Him into spiritual nearness to the throne of grace.

The idea that presbyters and bishops are the successors of the Old Testament priesthood first appears in full force in the writings of Cyprian. The further development of the notion of Christian priesthood was connected with the view that the Eucharist (*q.v.*) is a propitiatory sacrifice which only a consecrated priest can perform. It is sufficient to remark here that the presentation of the sacrifice of the mass came to be viewed as the essential priestly office, so that the Christian presbyter really was a *sacerdos* in the ancient sense. Protestants, in rejecting the sacrifice of the mass, deny also that there is a Christian priesthood "like the Levitical," and have either dropped the name of "priest" in reference to any specific office, or use it in a quite emasculated sense.

BIBLIOGRAPHY.—For non-Christian religions, *see* articles under heading "Priest" in Hastings, *Encyclopaedia of Religion and Ethics*, vol. x., by various writers, where many references are given under each division of the subject; and with special reference to Christianity, *see ibid.* vol. viii., article "Ministry" by A. J. Maclean, and the art. CHRISTIANITY. For an official statement from the Roman Catholic point of view, *see* article "Priest" and related topics in the *Catholic Encyclopedia.* The literature of the subject, both theological and historical, is very extensive; only a limited number of typical references can be given here: J. G. Frazer, *The Golden Bough,* third edition (esp. part i. "The Magic Art and the Evolution of Kings"); M. Jastrow, *Die Religion Babyloniens* u. *Assyriens* (1905–12); H. Hackmann, *Buddhism as* a *Religion* (Eng. tr. 1910); R. F. Johnson, *Buddhist China* (1913); J. H. Breasted, *A History of Egypt* (1906); J. E. Harrison, *Themis* (1912); W. Moulton, *Early Zoroastrianism* (1913); W. W. Fowler, *The Religious Experience of the Roman People* (1911). The work of W. Robertson Smith and J. G. Frazer is epoch-making and fundamental for all further study.

PRIESTLEY, JOSEPH (1733–1804), English chemist and Nonconformist minister, was born on March 13, 1733, at Fieldhead, a hamlet in the West Riding of Yorkshire. His father, Jonas Priestley, a woollen-cloth dresser of moderate means, was a Nonconformist. At the age of 12 the son was sent to a neighbouring grammar school, but later Kirkby, a minister at Heckmondwike, took entire charge of his education. From the age of 16 to nearly 20 he worked at Chaldee and Syriac, began to read Arabic, and mastered 'S Gravesande's *Natural Philosophy,* together with various textbooks of logic and metaphysics. He also learned French, German and Italian. In 1752 he went to Daventry to attend the Nonconformist academy there.

In 1755 he was appointed to a small congregation at Needham Market, in Suffolk. In 1758 he obtained a more congenial congregation at Nantwich, where he opened a school at which the elementary lessons were varied with experiments in natural philosophy. Three years later he removed to Warrington as classical tutor in a new academy, and there he attended lectures on chemistry by Dr. M. Turner of Liverpool and pursued the studies in electricity which gained him the fellowship of the Royal Society in 1766 and supplied him with material for his *History of Electricity.* In 1767 he was appointed to the charge of Mill Hill Chapel at Leeds, where he wrote many political tracts attacking the Government policy towards the American colonies. He also began his researches into "different kinds of airs," getting a plentiful supply of "fixed air" from a brewery next door to his house.

In 1772, the year in which he was chosen a foreign associate of the French academy of sciences, Priestley accepted the position of librarian and literary companion to Lord Shelburne (afterwards 1st Marquess of Lansdowne) at Calne, with a salary of £250 a year and a house. He travelled with his patron on the Continent and in Oct. 1774 he met Lavoisier and his friends in Paris and gave them an account of the experiment by which on the previous Aug. 1 he had prepared "dephlogisticated air" (oxygen). In 1780 he left Lord Shelburne, who allowed him an annuity of £150 for life, and settling at Birmingham was appointed junior minister of the New Meeting Society. There he found friends in Matthew Boulton, James Keir, James Watt and Erasmus Darwin. On July 14, 1791 the Constitutional Society of Birmingham arranged a dinner to celebrate the anniversary of the fall of the Bastille. Priestley, according to his own account, "had little to do with it." But his predilections in favour of the revolutionists were notorious, and the mob seized the occasion to burn his chapel and sack his house at Fairhill. He and his family escaped, but his possessions were destroyed and the labour of years annihilated. He retreated to London, where he felt safe, though he continued to be an object of "troublesome attention," and even the fellows of the Royal Society shunned him. He received an invitation to become morning preacher at Gravel Pit Chapel, Hackney, and there he remained until 1794, when he determined to emigrate to America. Settling at Northumberland, Pennsylvania, he lived there for nearly ten years, until his death on Feb. 6, 1804.

Priestley made very important contributions to pneumatic chemistry—the study of gases—and was the inventor of the "pneumatic trough" which allowed gases to be collectkd and examined. By heating spirits of salt he obtained "marine acid air" (hydrochloric acid gas), and he was able to collect it because he happened to use mercury, instead of water, in his pneumatic trough. Then he treated oil of vitriol in the same way, but got nothing until by accident he dropped some mercury into the liquid, when "vitriolic acid air" (sulphur dioxide) was evolved. Again he heated fluorspar with oil of vitriol, as K. W. Scheele had done, and because he was employing a glass vessel he got "fluor acid air" (silicon fluoride). Heating spirits of hartshorn, he was able to collect "alkaline air" (ammonia), again because he was using mercury in his pneumatic trough; then, trying what would happen if he passed electric sparks through the gas, he decomposed it into nitrogen and hydrogen, and "having a notion" that mixed with hydrochloric acid gas it would produce a "neutral air," perhaps much the same as common air, he synthetized sal ammoniac. Dephlogisticated air (oxygen) he prepared in Aug. 1774 by heating red oxide of mercury with a burning-glass, and he found that in it a candle burnt with a remarkably vigorous flame and mice lived longer than in an equal volume of ordinary air. He concluded that it was not common air, but the substance "in much greater perfection," that rendered common air respirable and a supporter of combustion. Of the analogy between combustion and respiration—both true phlogistic processes in his view—he had convinced himself three years before, and his paper, "On Different Kinds of Air" (*Phil. Trans.*, 1772) described experiments which showed that growing plants are able to "restore" air which has been vitiated, whether by being breathed or by having candles burnt in it. He noted that when hydrogen and oxygen were exploded together a mist or dew coated the inside of the vessel, but it was Cavendish who showed that the dew consisted of water.

Priestley had an unusual gift, as well as a passion, for experimenting, although he had received no scientific education; probably for this reason he supported the doctrine of phlogiston to the very last in spite of the fact that his own researches had probably given Lavoisier (*q.v.*) the clue to the oxygen theory of combustion. But although his theoretical knowledge was weak his observations and experiments had a profound influence on the development of chemistry.

Priestley was a most voluminous writer, and his works (excluding his scientific writings) as collected and edited by his friend J. T. Rutt in 1817–32 fill 25 octavo volumes. His chief theological and philosophical works were *Institutes of Natural and Revealed Religion* (3 vols., 1772–74); *History of the Corruption of Christianity* (2 vols., 1782); *General History of the Christian Church to the Fall of the Western Empire,* vols. i. and ii. (1790), vols. iii. and iv. (1802–03); and *Disquisitions relating to Matter and Spirit* (1777).

His chief books on chemistry were six volumes of *Experiments and Observations on different Kinds of Air,* published between 1774 and 1786; *Experiments on the Generation of Air from Water* (1793); *Experiments and Observations relating to the Analysis of Atmospheric Air,* and *Considerations on the Doctrine of Phlogiston established and that of the Composition of Water refuted* (1800). He also published (1767) a treatise on the *History and Present State of Electricity,* which embodies some original work, and (1772) a *History of Discoveries relating to Vision, Light and Colours,* which is a mere compilation.

PRIEUR, PIERRE (c. 1626–*c.* 1676), French enamel painter. He married Marie (1610–1677), sister of Jean Petitot, as her second husband. In 1669 he was in England, painting a miniature of Charles II. and another of Lady Castlemaine, both after Cooper, for the king of Denmark. In 1670 he was in Poland, painting for the Danish monarch a portrait of King Michael, and in the following year was in Denmark executing a remarkable series of portraits of the children of Frederick III. All these, with some beautiful enamel badges for the Order of the Elephant, are in the Danish royal collection. By Christian V. he is said to have been sent to Spain and Russia, where several examples of his work, dated 1676, are to be seen in the Hermitage, Leningrad. He died in Denmark, in 1676. He was a Huguenot, and was said to possess secret colours in enamel, especially a blue, which were not known to his Petitot relations. His work in England is of great rarity; Lord Dartrey possesses the finest example, and there are two remarkable works in the Pierpont Morgan collection and one at Windsor Castle. (G. C. W.)

PRIEUR DE LA MARNE [PIERRE LOUIS PRIEUR] (1756–1827), French politician, was born at Sommesous (Marne) on Aug. 1, 1756. He practised as a lawyer at Chblons-sur-Marne until 1789, when he was elected to the states-general. He became secretary to the Assembly, and the violence of his attacks on the ancien *régime* won him the nickname of "Crieur de la Marne." In 1791 he became vice-president of the criminal tribunal of Paris and in May 1796 president of the Convention, hiding from May 1795 until the amnesty proclaimed in the autumn of that year. In 1816 he was banished as a regicide. He died in Brussels on May 31, 1827.

See Pierre Bliard, *Le Conventionnel Prieur de la Marne en mission dans l'ouest 1793–1794 d'après* des documents ine'dits (1906).

PRIEUR-DUVERNOIS, CLAUDE ANTOINE, COMTE (1763–1832), French politician, was born at Auxonne on Dec. 2, 1763, and was known as Prieur de la Côte d'Or. He was a member of the legislative assembly and of the Convention. In 1793 he was employed in breaking up the Federalist movement in Normandy, but he was arrested by the Federalist authorities of Caen, and only released in July 1793 after the defeat of their forces at Vernon. On Aug. 14, 1793, he became a member of the committee of public safety, allying himself with Carnot in the organization of national defence. Under the Directory he sat in the Council of the Five Hundred, retiring after the coup *d'e'tat* of 18 Brumaire (Nov. 9, 1799). In 1808 he was created a count of the empire, and in 1811 retired from the army with the grade of chef *de* brigade. He was one of the founders of the École Polytechnique, and shared in the establishment of the Institute of France; the adoption of the metric system and the foundation of the bureau of longitude were also due to his efforts. Prieur died at Dijon on Aug. 11, 1832.

See J. Gros, *Le Comité de salut public* (1893); and E. Charavay, *Correspondance de Carnot,* vol. i., which includes some documents drawn up by Prieur.

PRILEP, a town in southern Serbia, Yugoslavia. Pop. (1931) 21,405. The town owes its chief importance to a large annual fair. The town is famous in Serbian history as the birthplace and capital of Marko Kralyevich, one of the favourite national heroes, who held his kingdom, after the fall of Serbia in 1389, as a vassal of the Turks. Legend says that before his death he buried his sword deep in the rocks of Prilep and left his magic horse Sharatz to nibble the moss near by, with the promise of reappearing in his country's hour of need. In the Balkan Wars (1912–13) the Serbs successfully stormed the heights, reputed to be impregnable. In 1941 the town was occupied by Bulgaria.

PRIM, JUAN, MARQUIS DE LOS CASTILLEJOS, COUNT DE REUS (1814–1870), Spanish soldier and statesman, was born at Reus, Catalonia, on Dec. 12, 1814. He served in the volunteers of Isabella II. in 1834, becoming lieutenant-colonel during the Carlist War In 1839, as a progressist opposed to the dictatorship of Espartero, he was exiled. Elected deputy for Tarragona in 1843, he defeated Espartero at Bruch and entered Madrid in triumph with Serrano. The regent Maria Christina made him major-general and count of Reus. Narvaez, the prime minister, who did not understand what constitutional freedom meant, sentenced Prim to six years' imprisonment in the Philippine islands; the sentence was not executed, and until the amnesty of 1847 Prim remained an exile in England and France. On his return he was made captain-general of Porto Rico and military representative with the sultan during the Crimean War. Elected to the Cortes in 1854, he supported O'Donnell, who promoted him lieutenant-general in 1856. He was made marquis de los Castillejos and a grandee of Spain for his valuable services in Morocco (1860). A member of the opposition against Narvaez, at his death (1868) Prim and Serrano raised the standard of revolt at Cadiz. with Admiral Topete commanding the fleet. In July 1869 Serrano was elected regent, and Prim became president of the council and was made a marshal. He was shot by unknown assassins on leaving the chamber of the Cortes on Dec. 28, 1870.

Blairet, *Le Général Prim et la situation actuelle de l'Espagne* (1867); Guillaumot, *Juan Prim et l'Espagne* (1870); H. Leonardon, *Prim* (1901, bibl.); F. González Llanos, *Biografiá política y militar del . . . general . . . Prim . . .* (1860).

PRIMARIES, a term applied to preliminary elections in which delegates to conventions or candidates for office are nominated directly by the voters, instead of being chosen by political conventions as was formerly the universal custom in the United States. The primary election is by ballot, is accompanied by the same election machinery, regulations and safeguards, and is fully as "official" as the final election. The first use of the direct primary in the United States so far as known, was in Crawford county, Pa., in 1868, from whence it spread to other counties of that State and of States in the Middle West, South and West. It was not until the opening of the 20th century, when a wide-spread distrust of political conventions had grown up, that the method was adopted by an entire State. In 1903, Wisconsin, under the leadership of Governor Robert M. La Follette, passed a mandatory primary law. Oregon passed a similar law the following year. By 1915 the direct primary for some purposes had been adopted by nearly every State in the Union, although its scope and administrative details varied widely from State to State. In 1928 it was mandatory in all but five States. Utah permitted primaries if desired by a political party but did not require them. Connecticut, Delaware, New Mexico and Rhode Island had no primary law.

In several States the primary law applies to all political parties, but in most States minor parties which do not poll a fixed minimum vote, or a certain percentage of votes cast at the previous election, are allowed to nominate their candidate by convention if they prefer. Likewise, primaries may be held to nominate candidates for all or for only certain offices. In most of the Western States the law applies to almost all elective officers from the governor down to and including local officials. In New York, however, a State convention is held for the nomination of State officials and the application of the direct primary is for local officers only. In six States in 1928 presidential electors were nominated through primaries.

Methods by which aspirants for nomination have their names placed upon the primary ballot vary widely. The most commonly used is that by petition, wherein a fixed number of signatures, or signatures totalling a certain percentage of the voters must be secured by the candidate. A second method is to allow any one to have his name entered upon the payment of a certain fee, which varies in amount according to the importance of the office. A third method is to allow party committees to designate "official" aspirants for nomination—with the reservation that others may place their names on the ballot by petition. In Colorado conventions are held previous to the primary and all names placed in nomination before the convention and receiving 10% or more of that body's vote are placed on the ballot. A similar system exists in South Dakota with the provision there that other names may be added by petition.

Primaries may be either open or closed. In the first case the voter has a choice of the ballot of any party regardless of his regular party affiliations. The open primary was used in only three States, Colorado, Montana and Wisconsin in 1928. The voter was given the ballots of all parties as he entered the booth, and upon his exit he placed the one he had marked in one box and the others in a discard box. The advantage of this procedure is that the voter is able to keep his party affiliation a secret. The most commonly used closed primary procedure is that of enrolment in a political party at the time of registration previous to election. In a few States the voter does not declare his party until he steps up to receive his ballot. In neither of these procedures, however, as in the open primary, is there any guarantee that the voter will vote for the nominees of the same party in the final election as in the primary. In this respect the primary so far as party government is concerned is defective, in that it allows the voter to interfere with the selection of candidates in a party to which he does not belong. Where the final race is likely to be close he may vote for a candidate of the opposing party whom his own candidate can more easily defeat, or, if his own party has little chance, he may vote for his favourite among the candidates of the other party, in which case the minority party sinks to an ineffective position. In Wisconsin, for example, the Democratic candidates often receive too few votes in the primary to give them a place on the final ballot, in which case they are forced to run as independents or discontinue the race. Some States require a voter, if challenged, to swear that he has supported for a certain time the party in which he enrols. Others require a promise to vote for the same party's nominees in the final election, while a few States require a promise of support for a longer period, in Illinois, for example, for two years.

There is also a wide variation among States in the vote necessary at a primary to constitute a choice. Where more than two candidates are usually on the ballot it is evident that the leading one may not always have a majority. Most of the primary laws of the United States provide merely that the candidate with the highest number of votes is nominated. This method, however, may allow a minority candidate to win in case several majority candidates divide the majority vote between them. It also may keep good majority men out of the race for fear of creating a split that would give an undesired candidate the nomination. To obviate this defect a number of States, especially in the South, where a victory in the primary usually means a victory in the election, require an absolute majority to win, and, if no candidate has this, a "run-off primary" between the two highest candidates is held a few weeks after the regular primary. Two States in 1928, Alabama and Florida, used a system of preferential voting, the voter designating second choices as well as first. If a candidate had a majority of first choices, the election was thereby decided, but if no majority appeared, all but the two highest candidates were dropped and the second choices were then added, the candidate having the highest number of both winning. Indiana, Louisiana and Minnesota at one time had preferential voting but abandoned it. In Indiana if no candidate received a majority in the primary, the nominee was chosen by a regularly constituted State convention. In Iowa the same procedure takes place if no candidate receives 35% of the votes in the primary. Just as under the convention system a defeated candidate may start an independent movement, so in most States a candidate defeated in the primaries may seek election as an independent. In Wisconsin, where the real contest is between factions of the Republican Party, this is often done. Maryland, Oregon and California do not permit it while several other States permit it only under certain restrictions.

Non-partisan primaries are held for some offices in which the candidates are nominated without regard to party lines. Twice the number are nominated as there are offices to be filled at the election. Non-partisan primaries originated in municipal elections where national and State party lines have less significance. In 1928 North Dakota and Wisconsin had non-partisan primaries for all cities, Minnesota and Utah for cities of the first and second class, and certain other States for cities under home rule charters, or under the commission or city-manager forms of government. County officers in three States are elected by non-partisan primaries, and Minnesota, since 1913, has chosen its members of the legislature this way. In 12 States in 1928 judges were chosen by non-partisan primaries, a practice in line with the growing movement to take the judiciary out of politics. Non-partisan primaries do not, however, do away entirely with party politics for parties generally openly endorse their favoured candidates. On the other hand, where the local vote is non-partisan national parties have difficulty in maintaining effective local organization.

PRIMATE, a title applied during the 4th and 5th centuries A.D. to both secular and ecclesiastical officials. The Theodosian Code mentions primates of towns, districts and fortified places *(Primates urbium, vicorum, castellorum)*. The Pragmatic Sanction of Justinian also mentions primates governing a district, *primates regionis;* and in this sense the title survived, under Turkish rule, in Greece until the 19th century. An official called "primate of the palace" is mentioned in the laws of the Visigoths. Primas also seems to have been used loosely during the middle ages for "head" or "chief." Du Cange cites *primas castri.* The title, however, has been more generally used to denote a bishop with special privileges and powers. It was first employed almost synonymously with *metropolitan* to denote the chief bishop of a province having his see in the capital and certain rights of superintendence over the whole province. At the Council of Nicaea (A.D. 325) the metropolitan constitution was assumed as universal, and after this the terms "metropolitan," and "primate," to denote the chief bishop of a province, came into general use. The title of primate was used more generally in Africa, while elsewhere metropolitan was more generally employed.

At a later date "primate" became the official title of certain metropolitans who obtained from the pope a position of episcopal authority over several other metropolitans and who were, at the same time, appointed vicars of the Holy See. This was done in the case of the bishops of Arles and Thessalonica as early as the 5th century. The archbishop of Reims received the title of *primas inter primates.* By the False Decretals an attempt was made to establish such a primacy as a permanent institution, but the attempt was not successful and the dignity of primate became more or less honorary. The overlapping of the title is illustrated by the case of England, where the archbishop of York still bears the title of primate of England and the archbishop of Canterbury that of primate of all England.

BIBLIOGRAPHY.—See Du Cange, Glossarium; Hinschiue, *Kirchenrecht* (Berlin, 1869); Moeller, History of the Christian *Church,* translated from the German by Andrew Rutherford (1902); Bingham, Origines *ecclesiasticae* (1840).

PRIMATES, an order of mammals, including man, the apes, monkeys, tarsiers and lemurs. The name, meaning "chiefs," was given by Linnaeus in 1758. Linnaeus also included the bats, assigned to a separate order by modern zoologists.

Structure and Habits.—Primates are primarily arboreal animals with hands and feet adapted for climbing. The fingers and toes are provided with nails (rarely compressed as claws). The great toe of the hind-foot is usually more or less divergent and the foot functions as a grasping organ, branches of trees being seized between the great toe and the four outer toes. The hands serve both for climbing and for manipulating food. The limbs are relatively long and slender, with free movements of rotation and supination. The lower primates (lemurs) are practically quadrupeds that run and leap in the trees but in the more advanced monkeys and apes there is an increasing tendency to climb with the arms extended above the head and the weight of the body suspended beneath the branches (brachiation). On the other hand, in the baboons the limbs plainly show secondary adaptation for running on the ground, both in their somewhat dog-like proportions and in the reduction of the great toe.

In the stem type of arboreal monkeys, vision is dominant over smell, whereas in typical ground-dwelling mammals the reverse is the case. Hence the occipital poles of the brain, which are connected with vision, are much enlarged. The adjustments for balancing in such actively climbing animals are extremely various and rapid; this requires a correspondingly complex development of the cerebellum and of the cerebral areas of the brain concerned with the movements of the limbs and body. As intelligence increases the prefrontal lobes of the brain develop. Thus the brain of monkeys is proportionately larger and more complexly convoluted than in ordinary ground-living animals. As a whole the brain of the Old World monkeys presents the ground-plan of the human brain without the special developments and complications connected with man's superior mentality.

The bony braincase closely follows the shape of the brain, except in front, where the large eye sockets jut forward, thus enabling the achievement of binocular, stereoscopic vision. Owing to the forward growth of the temporal lobes of the brain the greater wings of the sphenoid are moved forward to form the back-wall of the orbits, which are thus separated by a bony partition from the temporal fossae.

Hearing is acute and the temporal lobes are large. A thin bony shell, the auditory bulla, on the under-side of the braincase behind the socket for the lower jaw, covers the lower side of the cavity of the middle ear and is connected by a bony tube with the root of the external ear; the latter resembles that of man but usually has a point on its upper rim and lacks a lobule below.

In the more primitive primates, *e.g.* lemurs, the jaws are long and slender and the muzzle pointed. In typical monkeys, however, the jaw is shortened and deepened and the muzzle broad, the nose and lips assuming more or less the human aspect. The opposite halves of the lower jaw are fused in front even in young animals. The dentition is adapted for a mixed diet, with fruits or vegetation prevailing. The teeth in an adult Old World monkey number 32, as in man. The incisors are cutting teeth, the lower ones slightly inclined forward. There are two pairs in both upper and lower jaw. The canines are sharp and adapted for biting; the upper premolars are bicuspid, *i.e.,* with single, outer and inner cusps; and the low-crowned molars are surmounted by low cusps.

The female reproductive organs are fundamentally as in man (except in details) and there is likewise only a single pair of breasts in the female. The placenta is disc-shaped and intimately attached to the wall of the uterus.

Thus a typical monkey differs from an ordinary mammal such as a dog in its thorough adaptation to arboreal life, in the greater activity of the visual as compared with the olfactory powers, in its more advanced type of brain, and in its much greater likeness to man in the entire ground-plan of its anatomy.

Such a monkey is structurally connected on the one hand with lower primates (including New World monkeys, tarsiers and lemurs) and on the other hand with the higher primates, the anthropoid apes and man. Even the still existing species of primates form a fairly gradual transition from the tree-shrews at the base to highly specialized forms like the spider-monkey, the orang-utan and man, which stand far out on widely divergent branches.

LOWER PRIMATES

The Tree-Shrews.—The tree-shrews (Tupaiidae) are generally classed as Insectivora (*q.v.*) but they are related to Primates in many anatomical details. The pen-tailed tree-shrew (*Ptilocercus*) of Borneo is a mouse-like arboreal animal. Its hands and feet are five-toed and provided with claws, the thumb and great toe somewhat divergent. The food includes insects and fruit; the upper molar teeth are tritubercular, the lower molars tuberculo-sectorial (see MAMMALIA). The skull is lemur-like, especially in the ring-shaped orbit and inflated auditory bulla, which completely encloses the ring-like tympanic bone and ear-drum. The brain is primitive in having relatively unreduced olfactory parts and very feebly-developed neopallium or higher part of the brain. *Tupaia* and related genera of India and the Malayan region are in many ways more advanced toward the lemur type.

Imperfect fossil jaws and teeth, apparently of tree-shrews not greatly different from modern forms, have been found in Lo er Eocene deposits in Wyoming.

The **Tarsioids.**—Of equal antiquity are the oldest known forerunners of the true primates, represented by fossil jaws and teeth from the Lower Eocene of Wyoming and New Mexico and apparently belonging respectively to the tarsioid and lemuroid division of the order. Even at this early date a breaking up of the groups into different genera was in progress. In some of the tarsioid genera the incisors were already enlarging and the molars acquiring round, blunt cusps instead of the sharp-edged V-shaped cusps of their Cretaceous insectivorous ancestors. Probably from some of the less specialized of these Lower Eocene tarsioids sprang the line leading to *Pseudoloris* of the European Eocene. This genus in turn had already progressed far toward the modern *Tarsius.* The most famous Lower Eocene tarsioid was the little skull *Anaptomorphus* (*Tetonius*) *homunculus,* at one time, though erroneously, supposed to be in the direct line of human descent. That strange-looking animal, the spectral tarsier, survives today in the forests of the larger Malay islands. About as large as a good-sized rat, it has long jerboa-like hind legs, with which it can make extraordinary leaps, presumably to capture insects. Both the hands and feet have long spreading digits tipped with flattened discs for grasping the branches of the trees in which it lives. The lower part of the heel-bone and navicular are lengthened into long narrow rods to increase the leaping power. The huge eyes are brought forward so that their inner borders almost meet across the nose, which is small and resembles the platyrrhine type. The ears are very large. The brain, although large, is of remarkably low type for a primate. Accordingly the skull, which largely reflects the character of the brain and sense organs, reveals enormous circular orbits, a swollen braincase, expanded auditory bullae and a reduced, greatly constricted nasal-chamber. The jaws are slender and the teeth small, the upper molars being transversely widened with low, rounded cusps. *Tarsius* appears to be the rather specialized survivor of a very old primate stock structurally intermediate between the tree-shrews and lemurs below and the monkeys, apes and man above. Most of the known Eocene tarsioids are too specialized in their teeth to be the ancestors of the monkeys (with possible exceptions noted below). The foot structure of at least two of these forms already showed more or less of the characteristic elongation of the heel-bone and navicular.

The **Lemuroids.**—Along with the tarsioids in the Lower and Middle Eocene of North America occur the fossil teeth and jaws of another group of Primates, constituting the family Notharctidae, the members of which ranged in size from a chipmunk to a cat. During the Eocene, the first and second upper molar teeth gradually evolved from a three-cusped to a four-cusped stage. Apparently the entire family then became extinct, but some of them may possibly have given rise to the ancestral South Amencan monkeys. In *Notharctus* osborni from the Middle Eocene of Wyoming the hands and feet were of the grasping, climbing type, much like those of existing lemurs. The skull was far less specialized than that of contemporary tarsioids, both skull and dentition retaining the primitive features of lemurs on the one hand and monkeys on the other. Thus the dental formula of *Notharctus* $(I\frac{2}{2}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{3}{3})\times 2=40$ is the primitive one for all primates. The braincase is primitive with no great expansion of the brain and with an unreduced nasal-chamber. The orbits were protected behind by a rim of bone, not by a fully developed partition. The auditory region and base of the cranium, backbone, forearm, pelvis and hind-feet were like those of lemurs.

Structurally related to the Notharctidae was the European Eocene family Adapidae. The skull was more robust than that of Notharctus, with higher crests, more massive cheek-arches and more expanded lower jaws. On the other hand, the lower molars were relatively smaller, with sharper oblique cross-crests. In many skeletal features the Adapidae approached the modern Madagascan lemurs, to which they were either directly ancestral or closely related.

Madagascar has been the lemuroid headquarters for a long period. To-day it is the home of many species and genera of three families, while a number of recently extinct forms of widely different genera have also been found there. The central family is the Lemuridae, including the true lemurs, which range in size from the tiny mouse-lemur (*Microcebus*) to the extinct short-limbed *Megaladapis,* as large as a half-grown brown bear.

The typical lemur has a fully arboreal skeleton, with grasping hands and feet, although certain species live in rocky places. The animal is essentially an arboreal quadruped, which runs and leaps on top of the branches. The head is fox-like, but the eyes are very large and protrude from their sockets. The ears are usually large and movable. The food consists of msects, fruits and leaves. The lower incisors and much reduced canines are sharply inclined forward, compressed and pointed. With these the animals comb their fur and seize their food. The upper molars have a rounded inner cusp connected by a sharp small cross-crest with the front one of the two rounded outer cusps. The opposite halves of the lower jaw are not fused in front as in the higher primates. The skull varies in length from the extremely long skull of *Megaladapis* to the short sloth-like skull of *Myoxicebus.* The placenta is diffuse, with a large allantois, and is indeciduous; *i.e.,* is torn away from the uterine wall at birth.

The indrisine lemurs or sifakas, also peculiar to Madagascar, have more monkey-like faces. The central types have very long hind limbs and long hands and feet and are good climbers and leapers. The indris has a tall like that of a rabbit; the different species of *Propithecus* have brilliant areas of colour against a dark background. All are very conspicuous in a museum-case but as they are nocturnal animals their bizarre colouring may have a disruptive or concealing effect at night.

The skeleton could be derived directly from that of the Eocene lemuroids by emphasizing certain details almost to the point of caricature. These indrisine lemurs have a spiral colon, recalling that of other leaf-eating animals; the molar teeth also are adapted to cutting vegetation, the blades of each W-shaped lower molar fitting between corresponding V's of the upper molars. The area for the insertion of the masseter or outer jaw-muscle on the outer side of the lower jaw is greatly expanded and the bony cheek-arches are strengthened to support the powerful grinding muscles. The lower front teeth are reduced to a single pair. The detailed construction of the skull is obviously a modification of the primitive Eocene lemuroid type.

The extinct *Archaeolemur* (or *Nesopithecus*) resembled some of the South American monkeys in its upper and lower premolars and molars and in certain features of the skull, but in many other features (such as the middle ear region) it is connected with the indrisine lemurs. It seems probable that *Archaeolemur* illustrates one of the structural phases through which the ancestors of the New World monkeys may have passed in their descent from lemuroid ancestors. There is also a gradual transition in the form of the "braincast" and of the furrows on its surface between these lemuroids and the New World monkeys.

The last family of Madagascar lemuroids is that of the aye-aye (Daubentonia or Chiromys), one of the most extraordinary of all animals. Arboreal in habit, it has very large ears with which it listens for the sound of insect grubs boring beneath the bark. When it locates a grub it gnaws through the bark and into the wood with its rodent-like front teeth, which are large and compressed with sharp tips. Into the narrow slot thus opened it thrusts its very long, attenuated third finger, hooking the grub on the end of its curved nail. In accordance with its grub- and fruit-eating habits its molar teeth are much reduced. The general anatomy of the aye-aye agrees with that of other Madagascar lemuroids (especially the indris group). Fossil jaws with gnawing front teeth, much like those of the aye-aye, have been found in the French Eocene. These are more or less intermediate between the Eocene tree-shrews (Plesiadapidae) and the modern aye-aye. Probably the indrisine lemurs are a related off-shoot of the primitive tree-shrew-lemur stock.

The lemurs of southeastern Asia and of Africa differ in certain respects from the Madagascar lemurs, but agree with them in the curious comb-like arrangement of the lower front teeth. The lorises (Lorisidae) extend from tropical India southeastward through most of Malaya and are also represented in west Africa. The slender loris (*Loris gracilis*) is a large-eyed, small-nosed, nocturnal form with long and excessively slender bent limbs and no tail. It clings to the branches and feeds upon leaves and fruit, small birds, insects and mice. The awantibo (*Arctocebus*) and the potto (*Perodicticus*) of Africa have heavier skulls and blunter-cusped molats. The hands are extremely specialized for grasping and have very large thumbs and vestigial second fingers.

The galagos of Africa (Galaginidae), commonly known as "bush babies," are active arboreal leapers, catching insects on the wing. They have long, pointed muzzles and very large eyes and ears. They approach the tarsioids in these characters and in the elongation of the tarsal bones for leaping. But they differ in the lemur-like character of the lower front teeth, and the resemblances between the two families seem partly due to parallelism. Pronycticebus from the French Lower Oligocene is represented by a fossil skull structurally intermediate between the Eocene adapids and the modern lorisids.

NEW WORLD MONKEYS

The American monkeys are differentiated from those of the Old World by the widely separated nostrils facing laterally, whence the name "platyrrhine" (flat-nosed). The head is rounded with relatively small jaws and the ears lack the pointed tip common in Old World monkeys. The buttocks do not bear callosities and the thumb is never truly opposable to the other digits. The opposable great toe of the hind-foot bears a flattened nail, but the nails of the other digits of both hand and foot are frequently compressed laterally and in the marmosets become claws.

The American monkeys are all arboreal. The recent genera inhabit the tropical forests of South America, a few species extending northward into Central America, spider-monkeys and certain marmosets even to Mexico. Except from Ecuador northward, the Andes limit the western range of monkeys, though some howlers, spider-monkeys and sapajous reach an elevation in Guatemala of 6,000 to 7,000 feet. A fossil cebid Homunculus, found in lower Miocene formations in Patagonia, indicate the great antiquity and former wide range of the family.

Cebidae.—The recent Cebidae, which comprise all the platyrrhine monkeys except the marmosets, are divided into some ten quite distinct genera. Of these the most central or primitive type is probably Callzcebus, of which numerous species, known as titis or teetees inhabit the forests of Brazil and neighbouring countries. They feed on fruits, insects and small birds and are extremely vociferous. They are very small, with long, bushy, non-prehensile tails. Rather closely related to these are the dourocoulis (Aotus or *Nyctipithecus*), the only truly nocturnal monkeys. The huge,

LEMURS AND MONKEYS OF THE OLD AND NEW WORLDS

1. The ruffed lemur (Lemur *varius*) of the Malagasy region. It is coloured either black and white or reddish brown, and feeds on birds, reptiles, eggs, insects and fruit
2. The lemuroid potto (*Perodicticus potto*) or West African slow-lemur, an almost tailless primate somewhat larger than a squirrel
3. Bush baby (*Galago* alleni) of Africa, a small arboreal lemur with long pointed muzzle and very large eyes and ears
4. Woolly Saki (Pithecia *monachus*), a tropical American monkey characterized by a bushy tail and whiskers of long, loose fur
5. The common or white-eared marmoset (*Hapale* (*Callithrix*) *jacchus*), a diminutive American monkey that feeds on insects and fruit
6. An immature woolly monkey (*Lagothrix lagotricha*) of tropical America, distinguished by the naked, singularly human face and the powerful prehensile tail used for picking up objects as well as for climbing
7. Spider monkey (*Ateleus geoffroyi*) of tropical America, so designated because of its extremely slender limbs. The tail is very long and prehensile and the hand is thumbless. It is easily tamed
8. White faced capuchin monkey (*Cebus capucinus*), a vivacious American species that derives its name from the cowl-like form assumed by the hair on the crown of the head. It is common in captivity
9. Guereza (*Colobus abyssinicus*), an arboreal African monkey hunted for its fur which forms a black and white mantle on the sides and back

OLD WORLD MONKEYS AND APES

1. Celada Baboon (***Theropithecus gelada***), a large terrestrial monkey of southern Abyssinia. On the old males the hair develops into a mantle-like mane which covers the forequarters, leaving the chest bare
2. Chimpanzee (Pan ***calvus***), the smaller of the two great man-like apes inhabiting equatorial Africa. It seldom exceeds 4½ feet in height and is almost completely arboreal, sleeping in nests in trees
3. Guenon (Cercopithecus tantalus), a small arboreal monkey of the African forests. It subsists chiefly on fruits and leaves
4. Capped Langur female and young of the Malay Peninsula. In common with other members of the langur family, it has slender limbs and a very long tail, and feeds on leaves
5. Group of mountain gorillas (Gorilla ***beringei***), Belgian Congo, showing two males and two females, the standing male being in characteristic posture of thumping his chest. The male at the left is in the position generally assumed by the gorilla when moving about on the ground
6. Siamang (***Hylobates*** (***Symphalangus***) ***syndactylus***) Malay Peninsula and Sumatra; largest of the gibbon group with an average height of 3 feet. It is distinguished from other gibbons by a laryngeal air-sac
7. Orang-utan (***Simia satyrus***), "man of the forest," the least man-like of the three great anthropoid apes. It inhabits Borneo and Sumatra
8. The silvery gibbon (***Hylobates leuciscus***), one of the small arboreal apes of the Indo-Malay peninsula and East Indies

closely-approximated eyes and short face, surrounded by a ruff of pale fur, give these little animals a peculiarly owl-like expression. *Aotus* lives on fruits and insects which it hunts at night, remaining hidden during the day. Some species are reputed to have remarkable vocal powers, but in captivity they are often very silent. The nose is more prominent than in any other American monkey, the nostrils resembling those of catarrhine forms. This is probably correlated with the close approximation of the enlarged eyes. Its behaviour in captivity and the anatomy of the olfactory parts of the brain, indicate that smell is well-developed, perhaps more so than in the higher members of the family. This is probably of more service to nocturnal than to diurnal forms, but is nevertheless probably a primitive character. Both titis and dourocoulis use the hands in holding food but do not exhibit the manifold manipulations of these organs seen in the sapajous.

Two genera of small monkeys, placed in the sub-family *Pithecinae,* are *Pithecia,* the saki and *Brachyurus* or *Cacajao,* the uakari, both with several species. They are characterized by extremely procumbent incisors. The sakis have long, loose fur, that of the head often directed forward on the crown and forming a thick beard about the jaws. The tail is bushy and son-prehensile. The uakaris are the only short-tailed American monkeys. The face is naked and in one species is a brilliant vermilion; the body is covered with pale sandy or straw-coloured long hair.

The squirrel-monkeys (*Saimiri* or *Chrysothrix*), are extremely diminutive. The face is short and round and the back of the head projects markedly, its balance on the neck giving a particularly human appearance. The cerebrum, relatively very large, is slightly convoluted, but overhangs the cerebellum to a greater extent than in any other primate, even man. These monkeys are chiefly insectivorous, and associate in small groups. Some half-dozen species are known, ranging from the Amazonian forests to Costa Rica. They are richly coloured little animals often seen in captivity.

Cebus is aptly called by H. O. Forbes "the typical genus of the American monkeys." The common names sapajou and capuchin are applied to these familiar monkeys. They are vivacious and relatively hardy, individuals having been known to survive in captivity for 25 years in the north temperate zone. The thumb is well-developed, though not opposable and the hands are used in a great variety of manipulations. The tail is slightly prehensile and usually carried curved toward the underside. With the superior functional adaptation of the hands is correlated a large, highly-developed brain and an intelligence comparable to that of the Old World monkeys. Over 20 species have been described, some extending as far north as Nicaragua. In Colombia *Cebus apella* is found at nearly 7,000 feet.

A group of closely related monkeys comprises the woolly monkeys *Lagothrix*, the spider-monkeys *Ateleus* (or *Ateles)* and, intermediate between these, the woolly spider-monkey *Brachyteles.* These are fruit-eating monkeys, all considerably larger than *Cebus. Lagothrix* has particularly soft, woolly fur, greyish or brownish in colour, and a naked black peculiarly human face. The spider-monkeys have long hair and remarkably slender elongate limbs. But while woolly monkeys have the thumb well-developed, it is entirely absent externally in the spider-monkeys, though bony and muscular vestiges are present under the skin. The other fingers are elongated and form a highly serviceable hand for rapid progression in the treetops. Spider-monkeys in captivity frequently walk erect on their hind-legs for a few feet. *Brachyteles* forms a link between these two genera in certain respects. Its fur is woolly like that of *Lagothrix;* the thumb is intermediate, greatly reduced but usually still visible externally. In its attenuated limbs it approximates *Ateleus.* These three genera all have long and powerful prehensile tails, of which the extremity is naked on the under side and provided with friction-ridges like a finger. This organ is used not merely in climbing but also for picking up objects. These monkeys are easily tamed, affectionate and intelligent. The brain, especially in *Ateleus,* is exceptionally large and complex.

The last Cebid genus to be mentioned is *Alouatta (Mycetes),* the howler monkey, with several species. The group is notorious for its extraordinary vocal powers, their roars being audible for several miles. The howlers are gregarious, living on leaves and fruit and are the largest and heaviest American monkeys, though the limbs are shorter than those of the spider-monkey. The powerful prehensile tail is very similar to that of the monkeys last described but this may be an example of parallelism in view of numerous differences in other respects. The most noteworthy anatomical feature is the vocal apparatus. The hyoid bone is expanded into a great bony cup, the thyroid cartilage greatly dilated and the angle of the jaw enlarged to protect these structures. The intelligence of the howlers is low and the brain extremely small and poorly developed. Their relation to other genera is unsettled.

Callitrichidae.—The second family of the American monkeys is that of the marmosets, Callitrichidae or Hapalidae, including the diminutive, squirrel-like marmosets proper, *Callitrichus* or *Hapale,* and the closely related tamarins, *Midas.* Some zoologists have considered these the most primitive American monkeys, but they probably represent dwarfed descendants of primitive Cebidae. In addition to small size, they are characterized by reduction of the jaws with a correlated loss of the third molar, leaving but 32 teeth. The digits, except the hallux, Sear sharp curved claws in place of nails, forming, in such small creatures, highly efficient organs for arboreal locomotion. The hands are used for grasping food, but lack the varied functions of these members in larger monkeys, a fact which may be correlated with the inferior intelligence of marmosets. In the hind foot the great toe is relatively smaller and less opposable than in the Cebidae. The cerebrum, though very large, is almost devoid of convolutions. Marmosets are usually found in small groups and subsist on insects and fruit. They have occasionally bred in captivity, producing up to three young at a birth, instead of one as in monkeys in general. *Callimico,* a peculiar type previously assigned to the genus *Midas,* has most of the external features, including claws, like the Callitrichidae, but the skull, though essentially that of a marmoset, has certain likenesses to the Cebidae, the most important being the retention of the third molars. O. Thomas proposes a new subfamily, Callimiconinae, which he is inclined to place in the Cebidae, but its affinities seem to be with the marmosets.

Origin of the New World Monkeys.—The monkeys of South and Central America form an entirely different series from the monkeys of the Old World and in spite of their general similarity to the latter, they probably have been derived from a different ancestral stock.

In the first place the face in New World monkeys differs widely from that in Old World monkeys, especially in the fact that in the New World or platyrrhine series the nostrils are usually widely separated at the base and are directed laterally. Other external differences from the Old World monkeys have been noted above. The New World monkeys may also be at once distinguished by the fact that there are three bicuspid or premolar teeth on each side, both in the upper and in the lower jaws, whereas in Old World monkeys there are two. In the region of the middle ear, on the lower side of the skull, New World monkeys have a large ring-like tympanic bone, whereas in Old World monkeys the same element forms a bony gutter, completely covering the drum-membrane on the lower side of the skull. Moreover, the cheek-bone of New World monkeys has a broad contact with the parietal bone, which is never the case in Old World monkeys. The placenta in New World monkeys is disc-like, without the secondary placenta seen in Old World monkeys.

All known New World monkeys both living and fossil stand on a rather high plane of evolution and there are no "living fossils" to connect the group definitely with any older fossil family. It is also difficult to be sure which is the most primitive living genus, but after repeated analyses of the characters of the skull and teeth it seems probable that the most primitive are certain small monkeys of the family Cebidae, especially the owl monkey *(Aotus)* and *Callicebus.* As noted above, the olfactory region of *Aotus* is less reduced than in most Cebidae and marmosets. These little monkeys have large orbits, short deep lower jaws, short muzzles and unreduced molar teeth. They agree with certain North American Eocene tarsioids in their dental formula $(I\frac{2}{2}\,C\frac{1}{1}\,P\frac{3}{3}\,MI)\times 2=36$

and in the general form of the skull, but they differ from all known tarsioids in that the tarsal bones are not elongated. On the other hand, it is not impossible that the skeleton of the South American monkeys may have been derived from the type illustrated in the North American Eocene Notharctus, but in the present state of knowledge this inference is unsafe in view of the prevailing resemblances of the dentition and skull of *Aotus* to the tarsioids rather than to the notharctids. Finally there is the possibility that the New World monkeys may be derived from early extinct lemuroids resembling *Archaeolemur*.

Typical platyrrhine monkeys (Homunculus) in the Lower Miocene of Patagonia have been found in association with a peculiar mammalian fauna which for millions of years had its headquarters in South America; but some of the ancestral stocks of this fauna have been found in far earlier (Eocene) deposits of North America. In view of other available evidence, an ultimate North American origin for the New World primates seems quite possible. The monkeys now inhabiting Central America are closely related to those of Guiana and Brazil.

The New World monkeys as a whole exhibit a profound adaptation to arboreal life and probably originated in some heavily forested region such as they now occupy.

OLD WORLD MONKEYS

The Old World or Catarrhine division comprises three families: monkeys, apes and man. The first of these, the Cercopithecidae or tailed monkeys, distinguished from the American monkeys by the features mentioned above, are subdivided into two subfamilies, first, Cercopithecinae, including the macaques, baboons, mangabeys and guenons, and second, Semnopithecinae, comprising the langurs and the guerezas. In general the Old World monkeys are gregarious, living in small bands or large troops numbering hundreds.

The Cercopithecinae all have cheek-pouches for temporary storage of food. Of this group the macaques, probably the best-known of all monkeys, are widely distributed through India and the East Indies, extending northward to northern China and Japan, while one species, the Barbary ape, inhabits Morocco, Algeria and the Rock of Gibraltar. The macaques are among the most generally adaptable of monkeys and are hardy and long-lived in captivity. Though agile climbers, they are by no means exclusively arboreal and some are entirely terrestrial. They are usually omnivorous and the crab-eating macaque of India lives chiefly on Crustacea. They have fore and hind limbs of about equal length. The thumbs, though short, are opposable and the animals have considerable manual dexterity. There is a median air-sac connected with the larynx. The ischial callosities are well-developed. The tail may be long, short or practically absent, as in the Barbary ape, *Inuus ecaudatus*. Prominent examples are Macacus *rhesus*, the common rhesus monkey, M. *cynomolgus*, the crab-eating macaque, M. *sinicus*, the bonnet monkey, M. *silenus*, the lion-tailed macaque, all of India, and M. *speciosus*, the red-faced monkey of Japan.

The baboons constitute a group of large monkeys of terrestrial habit, closely related to the macques, but differing in the great elongation of the muzzle, which gives the head a dog-like form. The skeleton also reflects the terrestrial habits in the form and proportions of the limbs. The various species, mostly of the genus Papio, inhabit practically the whole African continent south of the Sahara, and one extends into Arabia. They live in large troops under the leadership of an old male and are omnivorous, feeding on roots, insects, fruits, etc., and often raiding plantations. One of the largest is the powerful chacma baboon of South Africa, Papio porcarius. The grey-mantled hamadryas, P. *hamadryas*, of Abyssinia and Arabia, is the sacred baboon of ancient Egypt. The most remarkable of all is the mandrill, P. sphinx of west Africa. This is one of the weirdest and most gorgeously-coloured of mammals. The nose is scarlet, the cheeks bear corrugated swellings of brilliant blue and the posterior part of the body exhibits various tints of violet and scarlet, while the fur shows great variety of colour on different parts of the body. An aberrant form placed in a separate genus is the gelada baboon of Abyssinia, *Theropithecus* gelada. In this animal the nasal region is concave, the nostrils somewhat short of the tip of the snout and the jaws shorter than in *Papio*. The baboons are a modified branch of the macaque group and in structural essentials the two types are quite similar. In captivity a hybrid offspring has been produced from a male rhesus macaque and a female mandrill.

The name mangabey is applied to a small group of arboreal fruit-eating monkeys of west Africa, which compose the genus Cercocebus. They are characterized by flesh-coloured or white upper eyelids and they lack laryngeal air sacs. Mangabeys are rather slender animals, with long limbs and tail and are intermediate between the macaques and the guenons of the genus *Lasiopyga* (or *Cercopithecus*). This genus, with several subgenera, comprises a vast number of species, more than any other genus of monkeys, scattered over almost the entire African continent, but each occupying a somewhat restricted area. The last lower molar tooth lacks the fifth cusp present in the other Old World monkeys thus far described. The fur is commonly "ticked," *i.e.*, the hairs ringed with light and dark colours, and many species exhibit brilliant tints. Whiskers and beards are common. The guenons are mostly rather small arboreal monkeys, inhabiting forests and subsisting on fruits and leaves. Their cheek-pouches are exceptionally capacious. Of the vast number of species a few of the more familiar forms, to give only the common names, are the green monkey, mona, diana, grivet, vervet, deBrazza monkey and moustached monkey. These, and many others, are common inhabitants of zoological gardens.

Semnopithecinae.—The second sub-family (Semnopithecinae) includes the genus *Semnopithecus*, which comprises the sacred monkeys of India, which with their relatives of Asia and the East Indies are commonly termed langurs. In the same sub-family are placed the guerezas of Africa. The most remarkable feature of these monkeys is the structure of the stomach which, in correlation with their leaf-eating habits, is greatly enlarged and divided into sacculated compartments. Cheek-pouches are absent in the langurs but are said to be present in some guerezas. *Semnopithecus* has the hind-legs rather longer than the arms and a very long tail. The jaws are relatively short, the thumb shorter than in Cercopithecinae. The hanuman monkey (*S. entellus*) of central and northern India is one of the best-known species. In the large snub-nosed monkeys (*Rhinopithecus*) of northwestern China and Tibet, the nose is concave with a protruding upturned point. The proboscis monkey or kehau of Borneo (*Nasalis* larvatus) has the most remarkable physiognomy of all monkeys. The nose is enormously elongated, in old males even hanging down over the mouth. Both the snub-nosed and proboscis monkeys have the sacculated stomach and are closely related to the true langurs.

The guerezas are found only in Africa, inhabiting the forests in small troops. They also feed largely on leaves. The most striking difference anatomically is the reduction of the thumb to a vestige, which, however, often bears a minute nail. This reduction parallels in a remarkable manner the condition in the American spider-monkeys. The guerezas are generally known generically as *Colobus*. In certain species of these monkeys, which are much hunted for their skins, the hair forms a long mantle on the sides and back. The white-tailed colobus (C. caudatus), black' in general with white mantle and tail, is a particularly beautiful species. The langurs and guerezas are difficult to keep in captivity and are not often seen in zoological collections.

Origin and Evolution. — The Old World or catarrhine monkeys are widely distributed, mostly in tropical Asia and Africa, a few outlying forms reaching as far north as Tibet, China and Japan, while the baboons extend southward to South Africa. A single species, the Barbary ape of North Africa inhabits the Rock of Gibraltar in Europe. In the Pliocene, however, fossil monkeys of various species have been recorded in England, Germany, France, Italy, Greece, north Africa and India. In the Miocene of Tuscany there was a large form (Oreopithecus), in which certain features of the molar teeth suggest remote relationship with the anthropoid apes. In the Lower Oligocene of Egypt was found a small lower jaw fragment, *Apidium*, the lower molars of which may be transitional from the tuberculo-sectorial or primitive mammalian type to the bilophodont form (with two cross-crests) of the Old World monkeys. The group seems to have originated somewhere either in Africa or in the European-Asiatic landmass and negative palaeontological evidence indicates their complete absence from America and the Australian region.

No known fossil forms definitely connect the Old World stock with the New World series, tarsioids, lemuroids or tree-shrews. The New World series, for reasons given above, seems entirely independent; while the known fossil tarsioids appear too peculiarly specialized to be direct ancestors of the Old World stock; yet such tarsioids as Necrolemur and *Microchoerus* are the only forms so far known that have even the appearance of evolving toward the catarrhine stage. This is broadly characterized as follows.

Nostrils, closely approximated and opening downward. tending to form a V; molars with two cross-crests; dental formula $I\frac{2}{2}\ C\frac{1}{1}\ P\frac{2}{2}\ M\frac{3}{3}$. Tympanic bone forming a gutter leading to the outer ear; stomach simple or (in *Semnopithecus*) highly complex; habits primarily arboreal, the animals climbing as pronograde quadrupeds, mostly on top of the branches. Hands and feet prehensile. Thumb opposable, more or less flattened nails on all digits Tail long, short or wanting, never prehensile. Cheek-pouches in most genera. Large callous areas on buttocks, with corresponding flattening on lower ends of pelvis. Placenta double, consisting of a primary and secondary discoidal area with smooth chorion between them.

Although we have not as yet been able to trace the direct fossil ancestors of the Old World group into formations older than at most Lower Oligocene, even the known living and extinct tree-shrews, lemuroids and tarsioids preserve the broad stages by which arboreal insectivorous mammals with a relatively low type of brain were transformed into monkeys with a relatively high type of brain, with binocular, stereoscopic vision and an advanced method of intra-uterine nourishment of the young.

ANTHROPOID APES

Among the Old World primates one group is distinguished from the rest by its far closer resemblance to man, a likeness recognized in the name anthropoid (man-like) apes. These include the gibbons, the orang, chimpanzee and gorilla (*qq.v.*). The anthropoids have usually been collectively grouped in a single family Simiidae, but this name is now frequently restricted to the orang, chimpanzee and gorilla, a second family, Hylobatidae ("tree-walkers"), comprising the much smaller gibbons.

Hylobatidae.—The range of this family is now restricted to southeastern Asia, especially the Malay peninsula, Borneo, Sumatra and some other East Indian islands, though in the Miocene gibbons extended into Europe and in the Pliocene as far north as central China. They are slender, long-limbed, monkey-like apes, the most striking feature being the enormously elongate arms, which reach the ground when the animal stands erect. Like other anthropoids, they are tailless. They differ widely from the tailed monkeys in their mode of progression, as they do not run on all fours, either in the trees or on the ground, but hang and swing from branches by their long arms and hook-like fingers, making almost incredibly long leaps in the manner of a trapeze gymnast. This mode of arboreal locomotion has been called "brachiation" by Sir Arthur Keith. While travelling thus by the hands, gibbons use the feet for prehension and carrying food. They sit upright and when on the ground run swiftly in an erect position, holding the arms out as balancers. Gibbons differ from most Old World monkeys in the absence of cheek-pouches and in the pattern of the molars, which is essentially that of the great apes and man. They also in common with these forms have a vermiform appendix and flattened sternum. They nevertheless retain some Old World monkey characters; for example, the small ischial callosities are present, and the central bone in the wrist is retained as a separate element. Air-sacs, formed as extensions of the laryngeal ventricles, well-developed in the Simiidae, are present only in the siamang.

About a dozen species of Hylobates have been described, a few well-defined, but most of them, based chiefly on hair colour (which is a variable character even in the same species), are of doubtful validity. Among the more distinctive may be mentioned H. hoolock which extends northwesterly as far as Bhutan, H. *lar* in Burma and Siam, and H. leuciscus in Java. The colours in general are black, fawn or grey, sometimes with white around the face or on the hands. The fur is soft and woolly. A considerably larger black gibbon, the siamang, found in Sumatra, is now separated as *Symphalangus,* the name referring to the fusion of the second and third digits of the foot. This animal has a better developed chin than any other anthropoid, but its most conspicuous character is the possession of a large laryngeal air-sac capable of inflation. The siamang when standing erect may exceed three feet in height. Forms closely related to the Sumatra siamang, S. *syn*-dactylus, occur in adjacent regions. The vocal ability of gibbons is most remarkable, their high-pitched cries being audible for a mile or more.

Simiidae.—The three genera of great apes constituting the family Simiidae, the orang-utan of Borneo and Sumatra and the chimpanzee and gorilla of the African forests, are by far the closest of all animals to man. Their divergences from man, striking though some of them are, are nearly all differences in degree rather than in kind, and these apes are nearer anatomically and physiologically to man than to any of the tailed monkeys. Their differences from man are largely correlated with habit. Man has become terrestrial, while the apes have retained their primary arboreal habit, and have even developed further arboreal adaptations in varying degrees. In the orang these have become greatly exaggerated, while in the gorilla, which has become partly terrestrial, they are less marked. The chimpanzee is intermediate. The arms have become long and the relatively short legs retain the opposable great toe. This disproportion of limbs results in a peculiar secondary type of quadrupedal progression on the ground, the hands resting on the knuckles and the fore-part of the body somewhat elevated. The spinal column has a suggestion of the curves seen in man, but the balance of the head on the neck, the weight of the long arms, form of pelvis and weak gluteal and calf muscles, collectively preclude an habitual erect bipedal gait, though the animals often stand erect. Divergence from the Old World monkeys and likeness to man is seen in the absence of ischial callosities and cheek-pouches and in the presence of the vermiform appendix. The development of laryngeal air-sacs, apparently a point of difference, is in reality a likeness, since man retains homologous vestiges of these in the laryngeal ventricles. In the chimpanzee and gorilla (but not in the orang) the central bone of the wrist becomes fused with the scaphoid during embryonic life, as in man. The menstrual cycle has the same phases as man and in the chimpanzee the interval is the same. In this animal the period of gestation is nine months and the placenta is essentially of the human type. The secondary placenta, present in Old World monkeys, is absent. Even the brain, though roughly only about one-third the size of that of man, is essentially a miniature of the human brain, no part or organ of one being absent in the other, but the differences being differences of proportion of certain parts. The susceptibility of anthropoids to many human diseases to which other animals are relatively immune, indicates the close chemical similarity, and the well-known precipitin tests by G. F. Nuttall show the blood of these apes to be essentially identical with that of man, while differing from that of Old World monkeys.

Of the three great apes, the least man-like is the orang-utan (Malay, "man of the forest") which inhabits swampy coastal forests of parts of Borneo and Sumatra. This animal is completely arboreal, rarely descending to the ground, and exhibits exaggerated brachiating adaptations. It is a large ape, over 4 ft. high, with heavy body and short feeble legs but very long arms extending to the ankles when the animal stands erect. The digits of both hands and feet are elongated and hook-like, except the relatively short thumb and great toe. Though the orang is rather deliberate in his motions and does not leap through the trees, as does the gibbon, the elongation of the arms permits an extended reach from branch to branch and enables it to progress with considerable rapidity. Among structural characters the following may be noted: there are but 12 pairs of ribs as in man; the cranium is rounded and lacks the prominent supraorbital crest of the

African anthropoids; the carpus retains the central bone as in monkeys and gibbons; the laryngeal air-sacs are enormously developed, extending far down under the arms and on the chest in adult animals; the hair is coarse and sparse but very long and bright red in colour; a feature frequently, but not always, present in old males is a pair of prominent ridges of connective tissue on the cheeks. The orang feeds on fruits, especially the durian. There is probably only one species, with several local varieties. It is usually known as *Simia satyrus* (or *Pongo pygmaeus*). A fossil jaw ascribed to *Simia,* in the Upper Pliocene of India, and a molar tooth *(Paleosimia)* from the Miocene indicate the ancient differentiation of the orang line.

The chimpanzee, variously known as *Anthropopithecus* and *Pan,* and the gorilla *(Gorilla)* both inhabit the great forests of central Africa, the chimpanzee having far the wider range. The latter is smaller, more agile and more completely arboreal in habit. The gorilla, probably owing to its great weight (males exceed 400 lb.), is largely terrestrial, though it climbs readily and in the west coast species the females and young are said to sleep in nests built in trees. Though the arms are somewhat longer than those of the chimpanzee, the hands have shorter fingers and are less adapted for brachiation; the feet show distinct secondary adaptation to walking on the ground. The foot of the mountain gorilla (G. *beringei)* of the eastern Congo presents the closest approach to the human foot found among primates. In both chimpanzee and gorilla the ribs number 13 pairs, one more than in man, but the total number of presacral vertebrae is the same, and a 13th rib in man is not uncommon. In both apes the hair is mainly black. In the chimpanzee the skin is usually light-coloured in early life, tending to become dusky later; in the gorilla the face is intensely black. In both animals a heavy brow-ridge overhangs the eyes and in the gorilla the cranial form in adult males becomes greatly altered by the development of huge crests for muscle-attachment. The gorilla has well-marked alae of the nose, separated from the cheeks by distinct grooves. *See* CHIMPANZEE, GORILLA.

Origin **and** Evolution.--Of the fossil gibbons the best known is *Pliopithecus antiquus* from the Miocene of middle Europe. This differs from the recent gibbons in the lesser specialization of the canines and front lower premolar. A fossil humerus and femur of *Pliohylobates eppelsheimensis* from Eppelsheim, Germany, are close to those of the recent gibbons.

The earliest known forerunner of the gibbons and possibly also of the great apes and man is the fossil lower jaw named *Propliopithecus haeckeli,* from the Lower Oligocene of Fayûm, Egypt. This little jaw, while no bigger than that of a small monkey, already shows the relatively great depth characteristic of all anthropoids and of early man; its molar teeth also have the five main cusps arranged substantially as in the higher forms. Many nominal species of fossil anthropoid apes of the genera *Dryopithecus, Sivapithecus* and others are known.

MAN

The origin and evolution of man is fully discussed in other articles (ANTHROPOLOGY; BRAIN; MAN, EVOLUTION OF, etc.).

PRIME MINISTER. Though a Wolsey or a Cecil might, in practice, achieve for a time a predominant position among the counsellors of the English Crown, the persistence of the doctrine that ministers were all equally royal servants, severally responsible to the sovereign for their respective departments, was for centuries fatal to the recognition of any such predominance in theory Thus Burnet describes Clarendon as "chief, or the only, minister," but the latter knew only too well that the style "first minister" was "a title so newly translated out of French into English that it was not enough understood to be liked, and every man would detest it for the burden it was attended with." Even in the 18th century it is more usual to find partnerships of two or three individuals, such as Marlborough and Godolphin, Harley and St. John, Stanhope and Sunderland, Townshend and Walpole, Newcastle, Henry Pelham and Hardwicke, sharing the principal burden of government. But the place vacated by the sovereign when, from 1717 onwards, he ceased to attend cabinet meetings, had necessarily to be filled by a single individual, and this presiding officer developed naturally, almost inevitably, into a prime minister. Walpole, though he "unequivocally denied" the title, is usually reckoned the first of the line, and certainly during his last spell of office (1720–42) he developed many of the attributes of premiership. He was master of his cabinet; he insisted on a general subscription by his colleagues to the Whig principles; he dismissed his opponents; he dispensed the royal patronage; and, with reservations, he may be described as commanding a majority in the House of Commons. How novel, how dangerously unpopular, such a position still was may be gathered from the proceedings of both houses in 1741. "According to our Constitution," said Sandys, "we can have no sole and prime minister . . every . . . officer has his own proper department; and no officer ought to meddle in the affairs belonging to the department of another." And the minority in the House of Lords was, if possible, even more downright. "We are persuaded," they protested, "that a sole, or even a first minister, is an officer unknown to the law of Britain, inconsistent with the Constitution of the country and destructive of liberty in any Government whatsoever."

On the fall of Walpole the further development of the office was checked, firstly, by the group system and consequent group Coalition Governments of the latter half of George II.'s reign, and later, by the interference of George III., who aspired to be himself "the only element of coherence in a ministry." Thus Grenville (1763–65) thought that "Prime Minister is an odious title," and North (1770–82) would not countenance it even from his own family. It was the younger Pitt who, on the fall of personal government, consolidated the work of his predecessors and by his long tenure of power (1783–1801) accustomed the nation to the office, if not to the name. The extent of his achievement can be measured by the terms of his famous interview with Lord Melville in 1803. They are axiomatic. He "stated not less pointedly and decidedly his sentiments with regard to the absolute necessity there is in the conduct of the affairs of this country, that there should be an avowed and real minister, possessing the chief weight in the council, and the principal place in the confidence of the king. In that respect there can be no rivalry or division of power. That power must rest in the person generally called the first minister, and that minister ought, he thinks, to be the person at the head of the finances. . . ." Nevertheless, old prejudices die hard. In 1806 it could still be said in parliament that "the Constitution abhors the idea of a prime minister," and in 1829 that "nothing could be more mischievous or unconstitutional than to recognize by act of parliament the existence of such an office." Such recognition was not granted until 1905, and even now the prime minister is known to the law merely as someone who has precedence next after the archbishop of York.

The prime minister is appointed by the sovereign. "I offered," said Sir Robert Peel (1834–35, 1841–46) on his resignation of office, "no opinion as to the choice of a successor. That is almost the only act which is the personal act of the sovereign; it is for the sovereign to determine in whom her confidence shall be placed." And, as late as 1894, Queen Victoria could call Lord Rosebery (1894–95) without consulting the retiring prime minister, Gladstone (1868–74, 1880–85, 1886, 1892–94), or the wishes of the parliamentary majority. Nevertheless, the Crown's freedom of choice is narrowly circumscribed. The "economic" reforms of Rockingham's administration (1782), by reducing the royal patronage, made it less easy for the sovereign to put ready-made majorities at the disposal of whatever minister he might fancy, and the Reform bills of the 19th century made the ministry dependent on parliament and the electorate rather than on the royal favour. The prime minister is normally the acknowledged head of the party commanding a majority in the House of Commons, and it is only, therefore, on occasions when no party commands an absolute majority of the House, or when the majority party has no acknowledged head, that there is room for the exercise of the royal discretion.

It will be obvious from what has been said above that the prime minister has no salary as such. He merely draws the emoluments of whatever office he may happen to hold. At the close of the 17th century the lord treasurer was already regarded as the most important Government official, and since the Treasury came to be put into commission, the leading minister has normally held the office of first commissioner, or first lord (until the middle of the 18th century he was usually chancellor of the Exchequer as well). But Chatham (1766–67) was lord privy seal; Salisbury (1885–86, 1886–92, 1895–1902), successively secretary of State and lord privy seal; and Ramsay Macdonald (1924) simultaneously first lord of the Treasury and secretary of State. In addition, the prime minister is usually leader of the house of which he is a member. D. Lloyd George (1916–22), however, finding his duties too onerous, transferred this burden to other shoulders. In the 18th century, when cabinets were almost exclusively composed of peers, the leading minister, curiously enough, was recruited most of the time from the Commons; in the 19th century, when commoners came to form the bulk of the cabinet, the prime minister was, more often than not, a peer. As a result, however, of the passage of the Parliament Act of 1911, truncating the powers of the Lords, and of the rise of a Labour Party with few adherents in the upper house, the Commons have, for the time being, at any rate, achieved a practical monopoly of the office. Thus, for instance, Lord Curzon's claims to the premiership were passed over, in 1923, in favour of those of Stanley Baldwin.

"As the cabinet stands between the sovereign and parliament," wrote Gladstone, "so the prime minister stands between the sovereign and the cabinet." He it is who, with the king's consent, appoints his fellow ministers to their respective posts. Originally, of course, the sovereign exercised an unfettered choice. Even so old and faithful a servant as Cecil never knew whom the queen would appoint to her council. Even in Anne's reign it required the united and persistent pressure of a ministry to get a Harley out or a Sunderland in. Even Pitt, at the close of the 18th century, had to put up with Thurlow, "the king's chancellor," and, at the dawn of the 19th century, to do without Fox, the king's *bête noire*. So even to-day, when the prime minister's choice is theoretically as free as was originally the Crown's, the pressure of party, the claims of talent and the prescriptive rights of previous office-holders render that freedom largely nugatory. With the right of appointment is bound up the right of dismissal, but the responsibility of the cabinet to the prime minister and the remaining functions of the latter belong properly to the history of the cabinet (*q.v.*). For lists of the prime ministers and other principal Government officials see MINISTRY.

BIBLIOGRAPHY.—Such books as ***The Prime Ministers of Britain*** (4th ed., 1924) by the Hon. Clive Bigbam, give certain dates and facts, but the history and functions of the office can only be authoritatively studied in the memoirs and biographies of the statesmen themselves and in the party, ministerial and cabinet history of the last two centuries. (F. L. B.)

PRIMITIVE METHODISTS, a community of nonconformists, formed in consequence of the belief that Methodism as founded by the Wesleys tended, after the first generation, to depart from the enthusiasm that had marked its inception and to settle down to the task of self-organization. There were some ardent spirits who continued to work along the old lines and whose watchword was revivalism; and out of their efforts came the Bible Christian, the Independent Methodist and the Primitive Methodist denominations. One of the zealous evangelists to whom Primitive Methodism owes its existence was Hugh Bourne (1772–1852), a millwright of Stoke-upon-Trent. He joined a Methodist society at Burslem, but, business taking him at the close of 1800 to the colliery district of Harrisehead and Kidsgrove, he was so impressed by the prevailing ignorance and debasement that he began a religious revival of the district. His open-air preaching was accompanied by prayer and singing, a departure from Wesley's practice and the forerunner of the well-known "camp meeting." One of the after-fruits of this revival was the conversion (Jan. 1805) of the joint founder of Primitive Methodism, William Clowes (1780–1851), of Burslem, who threw his house open for love-feasts and prayer-meetings, and did a great deal of itinerant evangelization among the cottages of the countryside. The first "camp meeting" was held on Mow Cop, since regarded as the Mecca of Primitive Methodism. It lasted from 6 A.M. to 8 P.M., and Bourne and his friends determined to continue the experiment as a counterblast to the parish wakes of the time, which were little better than local saturnalia; but serious difficulties were presented by the antagonism of the Wesleyan Methodist circuit authorities. But Bourne and his friends persisted against both Conference and the local superintendent, who issued bills declaring that no camp-meeting would be held at Norton in August 1807. The meeting was held and ten months later Bourne was expelled by the Burslem Quarterly Meeting. Camp-meetings went steadily on, and in 1810, the methods of the meetings organized by Bourne and Clowes were found to be incompatible with those of Wesleyan Methodism. A chapel was built at Tunstall, which became the nucleus of a circuit. Clowes and James Crawfoot, an ex-Wesleyan local preacher, were set apart as preachers to "live by the gospel," and in February 1812 the name "Primitive Methodist" was formally adopted.

The period 1811–43 was a time of rapid expansion for the new sect. Enthusiasts pressed forward through the "Adam Bede" country to Derby (which became the 2nd circuit in 1816), Nottingham, where a great camp-meeting on Whit Sunday 1816 was attended by 12,000 people, Leicestershire, where Loughborough became the 3rd circuit, with extensions into Rutland, Lincolnshire and Norfolk, and ultimately to Hull, which became the 4th circuit, and where a meeting which deserves to be called the First Conference was held in June 1819. The Hull circuit during the next five years, through its Yorkshire, Western, North-Western and Northern Missions, carried on a vigorous campaign with great success, especially among the then semi-savage colliers of Durham and Northumberland. Simultaneously Tunstall circuit, having thrown off its lethargy, was carrying on an aggressive evangelism. Work in the Black Country was extended to Liverpool and Manchester on the one side and South Shropshire on the other; and thence to Herefordshire, Glamorganshire and Wiltshire. Thenceforward, while the Oxford Movement was awakening one section of the people of England the Primitive Methodists were making themselves felt among other classes of the population. The early Primitive Methodists had to meet mob violence that often amounted to sheer ruffianism, especially in Wessex and the home-counties. On the other hand there was legal persecution all over the country, and the preachers suffered many things from the hands of rural clergy and county magistrates. There are a score of cases of serious imprisonment, and a countless number of arrests and temporary detention. Local preachers received notice to quit their holdings, labourers were discharged, those who opened their cottages for meetings were evicted, and to show any hospitality to a travelling preacher was to risk the loss of home and employment.

The years 1842–53 mark a transition period in the history of

Primitive Methodism. From being a loosely jointed home missionary organization, the movement developed on the lines of a real connectionalism. One of the first steps was to move the Book Room and the meeting place of the executive committee to London. Soon after came the gradual process by which the circuits handed over their mission-work to a central Connexional Committee. The removal to London was proof that the leaders were alive to the necessity of grappling with the rapid growth of towns and cities, and that the Connexion, at first mainly a rural movement, had also urban work to accomplish. The period 1853–85 finds Primitive Methodism as a connection of ten federated districts, a unity which may be described as mechanical rather than organic. Conference—the supreme assembly—was a very jealously guarded preserve, being attainable only to preachers who had travelled 18 and superintended 12 years, and to laymen who had been members 12 and officials 10 years. This exclusiveness naturally strengthened the popularity and power of the districts, where energy and talent found a scope elsewhere denied. Thus Hull district inaugurated a bold policy of chapel-buildings; Norwich that of a foreign mission; Sunderland and Manchester the ideal of a better-educated ministry; Nottingham district founded a middle-class school; Leeds promoted a union of Sunday-schools, and the placing of chapel property on a better financial footing. The period as a whole had some anxious moments; emigration to the gold-fields and the strife which afflicted Wesleyan Methodism brought loss and confusion between 1853 and 1860. Yet when Conference met at Tunstall in the latter year to celebrate its jubilee it could report 675 ministers and 11,384 local preachers, 132,114 members, 2,267 chapels, 167,533 scholars and 30,988 teachers.

Work in Australia and New Zealand prospered, and the former country finally contributed over 11,000 members to the formation of the United Methodist Church of Australia, New Zealand with its 2,600 members preferring to remain connected with the home country. In the United States there had been a quiet but steady growth since the first agents went out in 1829. There are now three Conferences—the Eastern, Pennsylvania and Western, with about 70 ministers, 100 churches and 7,000 members. The Canadian churches had a good record, consummated in 1884 when they contributed 8,000 members and 100 ministers to the United Methodist Church of the Dominion. In January 1870 the first piece of real foreign missionary work was begun at Fernando Po, followed in December of the same year by a mission on the Orange River in South Africa. This station is the centre of a polyglot circuit or district and carries on an efficient institution for training teachers, evangelists and artisans. In 1899 another South African mission was started, and a few years later work was begun in Southern Nigeria.

Since 1885 Primitive Methodism has been developing from a "Connexion" into a "Church," the designation employed since 1902. At home a Union for Social Service was formed in 1906, the natural outcome of Thomas Jackson's efforts for the hungry and distressed in Clapton and Whitechapel, and of similar work at St. George's Hall, Southwark. Other significant episodes have been the Unification of the Funds, the Equalization of Districts and the reconstruction of Conference on a broader basis, the Ministers' Sustentation Fund and the Church Extension Fund, and the enlargement and reorganization of the college at Manchester. This undertaking owes much to the liberality of Sir William P. Hartley, whose name the college, which is affiliated to the Victoria University of Manchester, now bears. The Christian Endeavour movement in Great Britain derives, perhaps, its greatest force from its Primitive Methodist members; and the appointment of central missions, connectional 'evangelists and mission-vans, which tour the more sparsely populated rural districts, witness to a continuance of the original spirit of the denomination, while the more cultured side is fostered by the Hartley lecture. In 1932 the Primitive Methodists combined with the Wesleyan Methodists and the United Methodist Church to form the Methodist Church.

For recent statistics *see* art. METISODISM. On the history see H. B. Kendall, *The Origin* and *History of the Primitive Methodist Church* (2 vols., 1906); and *What* hath *God wrought? A Centenary Memorial of the P.M. Church* (1908). (A. J. G.; X.)

PRIMO DE RIVERA, MIGUEL (1870–1930), Spanish soldier and statesman, known as the Marquis de Estella, was born at Jerez de la Frontera Jan. 8, 1870, and studied at the Madrid military academy. After four years in Toledo he was ordered to Morocco in 1893 as lieutenant of the Infantry Regiment of Extremadura, and in Oct. of the same year was promoted to the grade of captain for extraordinary personal bravery. In 1895 he was adjutant to Gen. Martinez Campos in Cuba, and rose to be major commanding the infantry battalion of Zamora.

He served in the Philippines in 1897, and negotiated the Treaty of Biagnabato (Biacabato) on Dec. 12, 1897. He then held commands at Barcelona, on the general staff and at Algeciras. In 191j he was appointed governor of Cadiz, and spent a month at the French front during the World War. His speech to the Hispano-American Academy advocating the exchange of Gibraltar for Ceuta or other North African territory, and corrosively criticising the Government's policy in Morocco, resulted in his being relieved from the governorship of Cadiz. His exceptional military talents, his brilliant exploits, his unaffected simplicity and straightforwardness, his sympathy with the feelings and interests of the army and the nation, had won for him the confidence of the King, the general staff and the public, so that despite his outspokenness in the academy, he was soon afterwards promoted to be general and chief of the First Infantry Division in Madrid.

In 1921 Estella was elected senator for Cadiz, and in a powerful speech urged the necessity of relieving the nation of the Moroccan burden. Whereupon Primo once again lost his post. But the effects of his courage and patriotism prevailed once more over considerations of petty discipline, and he was entreated to undertake the most difficult and dangerous post in Spain—that of captain-general of Catalonia—with a view to ending the reign of terror there, of which the central Government was content to remain a listless onlooker. The new captain-general soon reaped a measure of success fully proportionate to his chivalrous character, his personal influence and his limited legal powers.

Easy and generous to the point of familiarity in his private life, Estella was punctilious and exacting in matters affecting the nation, the army and the monarch, and his integrity was proverbial. He soon recognized the chaos in Catalonia as one of the indirect consequences of the breakdown of the parliamentary regime. This was also responsible for the mismanagement of the Morocco campaign, as well as for the ferment in the army brought about by the niggardliness, the favouritism and criminal recklessness of the central Government. Although the evil had long been diagnosed nobody had had the courage to uproot it, until the dauntless Marquis de Estella issued the manifesto dated Sept. 12, 1923, suspending the constitution and proclaiming in its place a directorate consisting of military and naval officers. He announced that this arrangement was but a bridge leading to a future system of government better suited to Spain's needs than that which he abolished. This military coup d'état was carried out without bloodshed.

The methods of the directorate were prompt and radical. (See SPAIN: *History*.) Primo called into being under the name la *Unión Patriótica*, a fellowship of "citizens of goodwill" to work for the realization of ethical ideals in public life, and hinder a return to the venal system just swept away. This innovation was welcomed with marked enthusiasm, and within a few months the members numbered over 1,250,000. Mindful of the undertaking he had given at the outset, Primo dissolved the directorate on Dec. 3, 192j, and substituted a government composed of civil as well as military ministers—mostly young men—as a preparatory step towards a new regime. The dictator became premier, and his policy was pursued for a considerable period. He resigned on Jan. 28, 1930, and died in Paris on March 16, 1930.

PRIMOGENITURE, a term used to signify the preference in inheritance which is given by law, custom or usage, to the eldest son and his issue. or in exceptional cases to the line of the eldest daughter. The history of primogeniture is given in the article LAW OF SUCCESSION. See also INHERTTANCE; INTESTACY.

BIBLIOGRAPHY.—H. Maine, Ancient Law (1861), Early History of Institutions (1875); K. E. Digby, History of the Law of Real Property (1875); C. S. Kenny, *Law of Primogeniture* in England (1878); F Pollock and F. W. Maitland, History of English Law (1895); E. Cecil, Primogeniture (1895).

PRIMROSE. The genus *Primula* contains about goo species distributed throughout the cooler parts of Europe and Asia, and found also on the mountains of Abyssinia and Java; a few are American. They are herbaceous perennials, with a permanent stock from which are emitted tufts of leaves and flower-stems which die down in winter; the new growths formed in autumn remain in a bud-like condition ready to develop in spring. They form the typical genus of Primulaceae (*q.v.*), the floral conformation of which is very interesting on several accounts independently of the beauty of the flowers.

The variation in the length of the stamens and of the style in the flowers of *Primula* has attracted much greater attention since Charles Darwin investigated them. Some of the flowers have short stamens and a long style, while others have long stamens, or stamens inserted so high up that the anthers protrude beyond the corolla tube, and a short style. Gardeners and florists had for centuries been familiar with these varrations, calling the flowers from which the anthers protruded "thrum-eyed" and those in which the stigma appeared in the mouth of the tube "pin-eyed."

Darwin showed by experiment that the most perfect degree of fertility, as shown by the greatest number of seeds and the healthiest seedlings, was attained when the pollen from a short-stamened flower was transferred to the stigma of a short-styled flower, or when the pollen from the long stamens was applied to the long style. As in any given flower the stamens are short (or low down in the floner-tube) and the style long, or conversely, it follows that to ensure a high degree of fertility cross fertilization must occur, and this is effected by the transfer of the pollen from one flower to another by insects. Incomplete fertility arises when the stigma is impregnated by the pollen from the same flower. The size of the pollen-grains and the texture of the stigma are different in the two forms of flower.

Among species found in Britain may be mentioned the common primrose (P. vulgaris); the cowslip (P. *veris*); and the oxlip (P. elatior), a rare plant found only in the eastern counties. In addition to these, two other species occur in Britain, namely, the Eurasian P. farinosa, bird's eye primrose, found in Wales, the north of England and southern Scotland, and P. scotica, which occurs in Orkney and Caithness. These two species are found also in high arctic latitudes, and P. *farinosa,* or a very closely allied form, exists in Fuegia. About 15 species occur in North America, chiefly in the western and northwestern parts of the continent.

The auricula (*q.v.*) of the gardens is derived from P. *auricula,* a yellow-flowered species, a native of the Swiss mountains. The Himalayas are rich in species of primrose, often very difficult of determination or limitation, certain forms being peculiar to particular valleys. Of these P. denticulata, *stuarti, sikkimmensis, nivalis, floribunda,* may be mentioned as frequently cultivated, as well as the lovely rose-coloured species P. rosea. The royal cowslip (P. *imperialis*) resembles P. *japonica* but has leaves measuring 18 in. long by 5 in. wide. It grows at an elevation of 9,000 ft. in Java and has deep yellow or orange flowers.

The primrose is to be had in cultivation in a considerable variety of shades of colour, ranging from the palest yellow to deep crimson and blue. Since the varieties do not reproduce quite true from seed, it is necessary to increase special kinds by division. The primrose is at its best in heavy soils in slight shade, and with plenty of moisture during the summer. One of the most popular of winter and early spring decorative plants is the Chinese primrose, *Primula* sinensis, of which some superb strains have been obtained. *P. japonica,* a bold-growing and very beautiful Japanese plant, is hardy in sheltered positions in England but must be grown in the cool greenhouse over most of the U.S. P. cortusoides of Siberia and P. sieboldi of Japan, of which there are many lovely forms, is suitable for outdoor culture and under glass. There are several small-growing hardy species which should be accommodated on the best positions on rockeries, where they are secure from excessive dampness during winter; excess of moisture at that season is the worst enemy of the choice Alpine varieties. They are propagated by seed and by division of the crowns after flowering. P. forresti is an orange-yellow flowered species from China, as is also P. bulleyana. They are hardy in favoured spots in the rock garden.

Evening primrose belongs to the genus Oenothera (*q.v.*) (family Onagraceae).

The Cape primrose comprises hybrid forms of Streptocarpus, a South African genus belonging to the family Gesneriaceae. The Arabian primrose is Arnebia *cornuta* of the family Boraginaceae, a garden annual.

PRIMULACEAE, a family of gamopetalous dicotyledons belonging to the order Primulales and containing 22 genera with about 600 species. It is cosmopolitan in distribution, but the majority of the species are confined to the temperate and colder parts of the northern hemisphere and many are arctic or alpine. Nine genera are represented in the British flora.

The plants are herbs, sometimes annual as in pimpernel (*Anagallis arvensis*), but generally perennial as in *Primula,* where the plant persists by means of a sympodial rhizome, or in Cyclamen by means of a tuber formed from the swollen hypocotyl. The leaves form a radical rosette as in *Primula* (primrose, cowslip, etc.), or there is a \\ell-developed aerial stein which is erect, as in species of *Lysimachia,* or creeping, as in Lysimachia *nummularia* (creeping jenny or moneywort). Hottonia (water violet) is a floating water plant with submerged'leaves cut into fine linear segments. The leaves are generally simple, often with a toothed margin; their arrangement is alternate, opposite or whorled. The flowers are solitary in the leaf-axils as in pimpernel, moneywort, etc., or umbelled as in primrose, where the umbel is sessile, and cowslip, where it is stalked, or in racemes or spikes as in species of Lysimachia. Each flower is subtended by a bract, but there are no bracteoles, and corresponding with the absence of the latter the two first developed sepals stand right and left. The flowers are hermaphrodite and regular with parts in fives (pentamerous) throughout, though exceptions from the pentamerous arrangement occur. The sepals are leafy and persistent; the corolla is generally divided into a longer or shorter tube and a limb which is spreading, as in primrose, or reflexed, as in Cyclamen; in *Soldanella* it is bell-shaped; in Lysimachia the tube is often very short, the petals appearing almost free; in Glaux the petals are absent. The five stamens spring from the corolla-tube and are opposite to its lobes; this anomalous position is generally explained by assuming that an outer whorl of stamens opposite the sepals has disappeared, though sometimes represented by scales as in Samolus and Soldanella. The superior ovary—half-inferior in *Samolus*—bears a simple style ending in a capitate entire stigma, and contains a free-central placenta bearing generally a large number of ovules, which are exceptional in the group Sympetalae in having two integuments. The fruit is a capsule dehiscing by five, sometimes ten, teeth or valves, or sometimes transversely (a pyxidium) as in Anagallis.

Cross pollination is often favoured by dimorphism of the flower, as shown in species of Primula. The two forms have long and short styles respectively, the stamens occupying corresponding positions half-way down or at the mouth of the corolla-tube; the long-styled flowers have smaller pollen-grains, which correspond with smaller stigmatic papillae on the short styles (see PRIMROSE).

The family is divided into five tribes by characters based on the presence or absence of tubers, the regularity of the flower, the aestivation of the corolla, etc. The ovules are generally semianatropous so that the seed is peltate with the hilum in the centre on one side (or ventral), but sometimes, as in Hottonia and Samolus, anatropous with the hilum basal—together with the method of dehiscence of the capsule and the relative position of the ovary.

The chief British genera are Primula; and the Lysimachia, loosestrife, including L. *Nummularia,* moneywort; Anagallis, pimpernel; and Hottonia, water violet. The most familiar American genera are Primula (primrose), Samolus (water pimpernels and brookweeds), Lysimachia (loosestrife), and Dodecatheon (shooting stars or American cowslips).

See F. Pax and R. Knuth, "Primulaceae," *Pflanzenreich* 22 (iv, 237): 1–386, fig. 1–75 (1905).

PRINA, GIUSEPPE (1768–1814), Italian statesman. He was an adherent of Napoleon Bonaparte, and when Eugene Beauharnais became viceroy of Italy, was appointed minister of finance. His skill in devising fresh taxes to meet the enormous demands of Napoleon's government made him the best-hated man in Lombardy. After the emperor's forced abdication in 1814 Prina's party moved in the senate that delegates should go to Vienna to request that Eugène Beauharnais be raised to the throne of a free Italian kingdom. This provoked the formidable riot in which Prina was dragged about the town for four hours, until almost torn to pieces, he received his death-blow.

PRINCE, MORTON (1854–1929), U.S. psychologist, was born in Boston, Mass., Dec. 21, 1854, and was educated at Harvard university (B.A., 1875; M.D., 1879). His particular interest lay in the study of abnormal psychology, a field in which he taught for many years. He was founder (1906) and editor (1906–29) of the *Journal of Abnormal Psychology.* His books include *The Nature of Mind and Human Automatism* (1885); *Dissociation of a Personality* (1906); *The Unconscious* (1913); *The Psychology of the Kaiser* (1915); and *Clinical and Experimental Studies in Personality* (1929). He died Aug. 31, 1929.

PRINCE, a title implying either political power or social rank. The Latin word *princeps* originally signified merely "the first." As an honorary title it was applied in the Roman republic to the *princeps senatus, i.e.,* the senator who stood first on the censor's list, and the *princeps juventutis, i.e.,* the first on the roll of the equestrian order. The assumption of the style of *princeps senatus* by Augustus (*q.v.*) first associated the word with the idea of sovereignty and dominion, but throughout the period of the empire it is still used as a title of certain civil or military officials; while in the middle ages it is applied vaguely in charters to the magnates of the State or the high officials of the palace, *principes* being treated as the equivalent of *proceres, optimates* or *seniores.* In the Visigothic and Lombard codes *princeps* is the equivalent of *rex* or *imperator.*

From Italy the use of the title spread—first, with the crusaders, to the Holy Land, where Bohemund, son of Tancred, took the style of prince of Antioch; next, with the Latin conquerors, into the East Roman empire, where in 1205 William de Champlette, a cadet of the House of Champagne, founded the principality of Achaea and the Morea. This example was followed by lesser magnates, who styled themselves loosely, or were so styled by the chroniclers, "princes." From the East the fashion was carried back to France; but there the erection of certain fiefs into "principalities," which became common in the 15th and 16th centuries, certainly implied no independent sovereignty, and the title of "prince" ranked below that of "duke," being sometimes borne by cadet branches of ducal houses. On the other hand, the title of "prince" was borne from the time of Charles VII. or Louis XI. by the sons of the royal house, so-called "princes of the blood," who took precedence in due order after the king. To these were added, from the time of Louis XIV., the *princes légitimés,* recognized bastards of the sovereign.

In Germany, Austria and other countries formerly embraced in the Holy Roman empire the title of "prince" had a somewhat different history. During the first period of the empire, the "princes" were the whole body of the *optimates* who took rank next to the emperor. In the 11th century, with the growth of feudalism, all feudatories holding in fief of the Crown ranked as "princes." Towards the end of the 12th century, however, the order of princes *(Furstenstand)* was narrowed to the more important spiritual and temporal feudatories who had a right to a seat in the diet of the empire in the "college of princes" (*Fürstenbank*). Finally, in the 13th century, seven of the most powerful of these separated themselves into a college which obtained the sole right of electing the emperor. These were called "prince electors" (*Kurfürsten*), and formed the highest rank of the German princes *(see* ELECTORS). The formal designation of "prince" (*Fürst*) was, however, extremely rare in Germany in the middle ages; but in the 17th and 18th centuries the number of principalities was increased.

Thus, in Germany, with the decay of the empire the title "prince" received a sovereign connotation, though it ranked, as in France, below that of "duke." There were, however, in the countries formerly embraced in the Holy Roman empire other classes of "princes." Some of these inherited titles, sovereign under the old empire, but "mediatized" during the years of its collapse at the beginning of the 19th century; others received the title of "prince" at the end of the empire as "compensation" for ceded territories. There were also in Austria and Germany "princes," created by the various German sovereigns, and some dating from the period of the old empire, who took a lower rank, as not being "princes of the Holy Roman empire" nor entitled to any royal privileges. Some of these titles were bestowed to give rank to the morganatic wives and children of royal princes; others as a reward for distinguished service, *e.g.,* Hardenberg, Bliicher, Bismarck. In this latter case the rule of primogeniture was usual, the younger sons taking the title of "count" *(Graf).* All these princes were styled *Fürst,* having the predicate "Serene Highness" (*Durchlaucht*). The word *Prinz,* actually synonymous with *Fürst,* was reserved as the title of the non-reigning members of sovereign houses and, with certain exceptions (*e.g.,* Bavaria), for the cadets of mediatized ducal and princely families. The heir to a throne was "crown prince" (*Kronprinz*), "hereditary grand duke" (*Erbgrossherzog)* or "hereditary prince" (*Erbprinz*). The heir to the crown of Prussia, when not the son of the monarch, had the title of "prince of Prussia" (*Prinz von Preussen).*

In Italy the title "prince" (*principe*) is also of very unequal value. The heads of great families sometimes bear the title of "prince," sometimes that of "duke." The title of "prince of Naples" is attached to the eldest son of the king of Italy.

"Prince" is also the translation of the Russian title *knyaz.* In general, though the title "prince" implies descent from one or other of the ruling dynasties of Russia, it is in itself of little account owing to its being borne by every member of the family.

The title of "prince" is also borne by the descendants of those Greek Phanariot families *(see* PHANARIOTES), who formerly supplied hospodars to the Turkish principalities on the Danube. The only instance in Europe of "prince" as a completely sovereign title is that of the prince of Monaco, the formal style having been adopted by the Grimaldi lords in 1641.

Great Britain.—In Great Britain "prince" and "princess" as titles are confined to members of the royal family, though nonroyal dukes are so described in their formal style *(see* DUKE). Nor is this use of great antiquity; the custom of giving the courtesy title of "prince" to all male descendants of the sovereign to the third and fourth generation being foreign to English traditions. It was not till the reign of Henry VII. that the king's sons began to be styled "princes"; and as late as the time of Charles II., the daughters of the duke of York, both of whom became queens regnant, were called simply the Lady Mary and the Lady Anne. The title of "princess royal," bestowed on the eldest daughter of the sovereign was borrowed by King George II. from Prussia. Until recent years the title "prince" was never conferred on anybody except the heir-apparent to the Crown, and his principality is a peerage. Since the reign of Edward III. the eldest sons of the kings and queens of England have always been dukes of Cornwall by birth, and, with a few exceptions, princes of Wales by creation, Before that Edward I. had conferred the principality on his eldest son, afterwards Edward II., who was summoned to and sat in parliament as prince of Wales. But Edward the Black Prince was the original grantee of the principality as well as of the dukedom, under the special limitations which have continued in force to the present day. The entail of the former was "to him and his heirs the kings of England" and of the latter "to him and his heirs the first-begotten sons of the kings of England." Hence when a prince of Wales and duke of Cornwall succeeds to the throne the principality in all cases merges at once in the Crown, and can have no separate existence again except under a fresh creation, while the dukedom, if he has a son, descends immediately to him, or remains in abeyance until he has a son born. If, however, a prince of Wales and duke of Cornwall should die in the lifetime of the sovereign, leaving a son and heir, both dignities are extinguished, because his son, although he is his heir, is neither a king of England nor the first-begotten son of a king of England. But, if instead of a son he should leave a brother his heir, then —as was decided in the reign of James I on the death of Henry, prince of Wales, whose heir was his brother Charles, duke of York—the dukedom of Cornwall would pass to him as the first-begotten son of the king of England then alive, the principality of Wales alone becoming merged in the crown.

But even now the children of the sovereign other than his eldest son, though by courtesy "princes" and "princesses," need a royal warrant to raise them de *jure* above the common herd; and even then they remain "commoners" till raised to the peerage. In 1905 King Edward VII established what appears to be a new precedent, by conferring the titles of "princess" and "highness" upon the daughters of the princess Louise, duchess of Fife, created "princess royal."

PRINCE EDWARD ISLAND, the smallest province of the dominion of Canada, lies between 45° 58′ and 47° 7′ N. and 62° and 64° 27′ W. The island lies in a great semi-circular bay of the Gulf of St. Lawrence, which extends from Point Miscou in New Brunswick to Cape North in Cape Breton. From the mainland it is separated by Northumberland strait, which varies from 9 to 30 mi. in width. Structurally, however, it is a continuation of northern plain of Kew Brunswick and on the island the red rocks again appear (Permian with Triassic outliers). The island is extremely irregular in shape; deep inlets and tidal streams almost divide it into three approximately equal parts; from the head of Hillsborough river on the south to Savage Harbour on the north is only one and a half miles, while at high tide the distance between the heads of the streams which fall into Bedeque and Richmond bays is even less. North of Summerside the land nowhere rises more than 175 ft. above sea level; but between Summerside and Charlottetown, especially near north Wiltshire, is a ridge of hills, running from north to south and rising to a height of nearly 500 ft. From Charlottetown eastwards the land is low and level. Beds of peat, dunes of drifted sand, alluvial clays and mussel mud occur in and near the creeks and bays. The north shore, facing the gulf, is a long series of beaches of fine sand, and is a favourite resort in summer. On the south low cliffs of crumbling red sandstone face the strait. The oceanic influences make the climate of the province milder than that of the neighbouring mainland. The mean January temperature is 16° and the mean for July a little over 65°. The winter and summer rainfall is about the same—between 3 and 5 in. in January and July respectively. Fogs are much less common than in either New Brunswick or Nova Scotia.

Area and Population.—The greatest length of the island is 145 mi., its greatest breadth 34 mi., its total area 2,184 sq.mi. The population stood at 94,021 in 1871, just before the union with Canada in 1873, and slowly increased to 109,078 (1891); then it declined till it reached 88,038 (1931), and rose again to 95,047 in 1941. On the other hand urban movement brought a slow but continuous increase of town people; Charlottetown 7,872 (1871); 14,821 (1941). As with all the maritime provinces, there was long a steady migration to the Canadian west and to the United States. The population is mainly of British descent, census returns showing 84% British, in part the descendants of American Loyalists; 14.5% French, original settlers and refugees from Nova Scotia. A few Indians of the Micmac tribe remain.

Government.—The government of the province rests upon the (Imperial) British North America act of 1867, and its amendments, together with all pre-union laws and institutions not altered or abolished by these acts, including the British common law and the constitutional conventions of British government. Prince Edward Island was united with the dominion of Canada (July 1, 1873) by an Imperial Order in Council (June 26, 1873) under the B.N.A. Act of 1867. This act provided for representation in the parliament of Canada, by senators and a number of members of the commons in proportion to its population as compared with that of Quebec (65 members). A later B N.A. act (1915) set a minimum in the commons at the existing number of senators, notwithstanding any decline in population.

The provincial government at Charlottetown consists of a lieutenant-governor, appointed and paid by the dominion, a ministry on the constitutional model, and a legislative assembly of 30 members, elected for five years unless sooner dissolved. Each of the 15 electoral districts in the province has two representatives, a councillor and an assemblyman.

Finance.—The revenue of the province in 1871 was $385,000; in 1940, $2,030,000. Large items are gasoline, corporation and succession taxes. The province, unlike all the others, is under prohibition and draws no revenue from liquor control.

Education.—Education in Prince Edward Island is compulsory and free and is almost entirely conducted by the state. Of a total school and college population of 19,689, 18,308 were enrolled in free public elementary, 756 in privately controlled (including denominational) schools, and 610 in courses of college standing in 1943. There are two colleges, Prince of Wales college, and St. Dunstan's, a Roman Catholic institution, both in Charlottetown.

Agriculture.—All the staple crops are grown, especially oats, potatoes and turnips. Wheat is raised only for local consumption. The total area of field crops was 494,100 ac. in 1941. Of this 218,353 acres represented hay, and 125,264 acres oats. The acreage under potatoes (39,856) produced 2,840,000 tons in 1941. In 1941 there were 44,000 milk cows; 46,000 sheep; 54,000 swine. Total production of butter (1941) was 3,569,400 lb., total production of cheese (1941) 684,300 lb. Fruit is raised less extensively than in Nova Scotia.

Fisheries.—Lobsters are an important catch (49 lobster canneries in 1940; more than in any other province), together with smelts, herring, cod and mackerel. The total value of the fisheries in 1940 was $714,870. Experiments begun in 1929 by the dominion department of fisheries led to the successful establishment of commercial oyster farming.

Other Industries.—The island has natural forests of birch, beech, maple, pine, spruce, cedar and other woods. Forested land (1940) covered 725 sq.mi. There were 1,088 employees in industry in 1939, of whom about 300 were engaged in fish processing, chiefly carried on at Charlottetown. Fox farming in Canada began with experiments made in Prince Edward Island in 1894. In 1938–39, 70,420 pelts (worth $20 to $70 per pelt) were produced (about 22% of total Canadian production).

Communications.—A railroad runs from end to end of the island (Tignish to Elmira) with branches to Georgetown, Murray Harbour, Charlottetown and Cape Traverse. The railway, originally built by the province, became a part of the Canadian National railway system in 1919. A wide gauge branch from Charlottetown to Borden connects by car ferry with the mainland at Tormentine, N.B. Ice impedes winter navigation in Northumberland strait and at Charlottetown from mid-December to early April. But after 1917–18 powerful ice-breaking ferry boats plied the ferry passage all winter. Total railway mileage in 1941 was 286 mi. Statistics of civil aviation in the province (1940) showed 1,207 passengers; freight 6,251 lb.; mail 73,217 lb.

History.—Jacques Cartier sighted Prince Edward Island in June 1534. Later it was called Ile St. Jean until renamed after the Duke of Kent in 1799. Under the French little attention was paid to the island prior to the peace of Utrecht, when they began to make efforts to colonize it; and the creation of a feudal proprietorship gave to the French settlers a precarious existence. In 1758 the island, with its capital at Port La Joie (Charlottetown), was occupied by a British force under Lord Rollo, and a partial expulsion of the French inhabitants took place, comparable with that of the Acadians from the mainland of Nova Scotia. Ceded finally to England in 1763, it became a separate government ten years later. At this period an unfortunate system of large land grants to a group of proprietors blocked settlement and created claims that had ultimately to be bought out. Meantime, in 1803–04, Thomas Douglas, Earl of Selkirk (*q.v.*), brought out with great success an emigrant settlement of dispossessed Highland tenantry. In the period from the close of war in 1815 until the middle '60s, the island had an uneventful but happy history, its economy based on agriculture, fishing and shipbuilding with open and profitable trade with Great Britain, the West Indies and the United States. The passing of free trade, the abolition of the navigation laws (1849) and the abrogation of American reciprocity greatly altered the outlook, and seemed to demand a change. The people of the province favoured maritime union as proposed at Charlottetown in 1864, but refused confederation in 1867. They were persuaded to enter in 1873 largely by the offer of the dominion to assume the island railway. Economic hardship after confederation led to a decline of immigration, a slackening in the growth of population, and later (1901 to 1931) an actual decline. Politics in Prince Edward Island in the 20th century turned on these relations. In spite of discontent, however, the government remained in the hands of the orthodox Liberal and Conservative parties.

BIBLIOGRAPHY.—See *Canadian Census; Canada Year Book* (annual); *Handbook of Prince Edward Island,* Department of the Interior, Ottawa; D. Campbell, *History* of *Prince Edward Island.* (S. LEA.)

PRINCE RUPERT, port, British Columbia, Canada, situated over 480 mi. N.W. of Vancouver. Pop. (1941) 6,714. The city is built on an island, connected by a steel bridge with the mainland and is a western terminus of the Canadian National railways (previously that of the Grand Trunk Pacific). There is a fine natural harbour, sheltered by Digby island and a promontory of the Tsimpsean peninsula with a government dry dock and a shipbuilding yard. Steamers run regularly to Vancouver, Anyox, Stewart, Seattle, etc. Fish, largely halibut and cod, form the chief article of trade, and there are refrigerating plants and fish-fertilizer works, and lumber and shingle mills. Mining and lumbering are carried on in the neighbourhood. It took its name from the nephew of Charles I of England, who was first governor of the Hudson's Bay company.

PRINCES' ISLANDS, a cluster of nine islands in the Sea of Marmora, forming a caza of the prefecture of Constantinople. They figure in Byzantine history chiefly as places of banishment. A convent in Prinkipo (now a mass of ruins at the spot called Kamares) was a place of exile for the empresses Irene, Euphrosyne, Zoe and Anna Dalassena. Antigone was the prison of the patriarch Methodius, and its chapel is said to have been built by the empress Theodora. In Khalki the monastery of the Theotokos (originally of St. John), which since 1831 has been a Greek commercial school, was probably founded by John VI or VII. Palaeologus was rebuilt about 1680, and again in the 18th century by Alexander Ypsilanti, hospodar of Moldavia. Close beside it is the tomb of Edward Barton, second English ambassador to the Porte. Hagia Trias (a school of theology since 1844) was rebuilt by the patriarch Metrophanes. On Prote were the monasteries to which Bardanes (Philippicus), Michael I. Rhangabes, Romanus I (Lecapenus) and Romanus IV (Diogenes) were banished.

See G. Schlumberger, *Les Îles des Princes* (Paris, 1884); A. Grisebach, *Rumelien und Brussa* (Gottingen, *1839).*

PRINCETON, a city of Illinois, U.S.A., 105 mi. W.S.W. of Chicago; the county seat of Bureau county. It is on federal highways 32 and 6, and is served by the Burlington route, as well as by many truck and bus lines. Pop. 4,762 in 1930; in 1940 it was 5,224.

It is the trading centre of a very productive corn farming region and hybrid seed corn processing plants and other smaller manufacturing industries.

PRINCETON, a city of southwestern Indiana, U.S.A., on federal highway 41, 27 mi. N. of Evansville; county seat of Gibson county. It is served by the Chicago and Eastern Illinois and the Southern railways. Pop. (1930) 7,505; in 1940 it was 7,786. It is the trade centre for an agricultural region, and there are coal mines and gas and oil wells. The city was founded in 1814 and chartered in 1884.

PRINCETON, a borough of Mercer county, New Jersey, U.S.A., on the Lincoln highway about equally distant (50 mi.) from New York and Philadelphia; served by the Pennsylvania railroad. Pop. 1930 federal census 6,992; 1940 census 7,719 (13% Negroes and 5% foreign-born white). During the school year this is increased by some 3,000 students and teachers, and at commencement or on the occasion of a big ball game there are frequently 50,000 visitors. Princeton is on high land (210 ft. above sea level) surrounded on three sides by Stony brook. Lake Carnegie (3.5 mi. long and 800 ft. wide), the gift of Andrew Carnegie, was constructed in 1905–06. The borough is a beautiful academic and residential community, with no factories. It is the seat of Princeton university (*q.v.*), Princeton Theological seminary (Presbyterian), St. Joseph's college (Roman Catholic, 1914), Westminster Choir college (founded 1926 in Dayton, Ohio; moved to Princeton 1932), Institute for Advanced Study (1930) and several preparatory schools for boys and for girls. The Lawrenceville school for boys (1810) is 5 mi. west. Princeton Theological seminary, established by the general assembly of the Presbyterian Church in 1812, has had many theologians among its professors and presidents and has trained more than 7,000 men for the ministry. At times there have been as many as 30 denominations represented in the student body. It is well endowed and has a fine campus near the university. On the eastern shore of Carnegie lake, in the township of West Windsor, are the laboratories of the department of animal pathology of the Rockefeller institute. There are many beautiful modern estates, and a number of colonial buildings still stand. The Quaker meeting-house adjoining the battlefield and replacing one built in 1726 dates from 1760. "Morven," the homestead of the Stocktons, built between 1701 and 1709, has entertained many presidents and other prominent persons. "Rockingham," at Rocky Hill, a village 3 mi. north, was occupied by Washington for three months in the autumn of 1783, and it was there that he wrote his farewell orders to the army. It is now maintained as a historical museum.

Settlement there began in 1696 and the name was adopted in 1724. Princeton was incorporated as a town in 1813 and as a borough in 1873. Among the early settlers was Richard Stockton, grandfather of the signer of the Declaration of Independence who bore the same name, and John Olden, great-grandfather of New Jersey's Civil War governor. The College of New Jersey (now Princeton university) moved there from Newark in 1756. On Aug. 27, 1776, the first legislature of New Jersey met in Princeton. On Jan. 3, 1777, near Stony brook about a mile west of Princeton, Washington won an important victory over part of Cornwallis' troops, both sides losing many brilliant officers. A battle monument by MacMonnies, which has as the central figure an equestrian statue of Washington, was dedicated in 1922. In old Nassau hall, the largest building in the Colonies when it was erected in 1754–56, the Continental Congress sat from June 30 to Nov. 4, 1783, receiving there on Oct. 31 the news that peace had been signed.

PRINCETON, a city in the mountains of southern West Virginia, U.S.A., the county seat of Mercer county; on the Virginian railway and federal highways 19 and 21, 10 mi. N.E. of Bluefield. Pop. 6,224 in 1920 (93% native white); 7,426 in 1940 by the federal census. Coal mining and lumbering are the principal industries, and there are several textile and garment factories. The city was founded in 1826 and incorporated in 1862.

PRINCETON UNIVERSITY, a privately-endowed nonsectarian institution of higher learning for men, at Princeton, N.J., until 1896 called officially the College of New Jersey. Its buildings, about 80 in number, are grouped in the central portion of a campus of 800 acres which is one of the most beautiful in the country.

Nassau hall, the oldest and historically the most interesting building on the campus, was at the time of its completion in 1756 the largest academic building in the American colonies. It was designed by Robert Smith, architect of Independence hall in Philadelphia and named in honour of William of Nassau, William III of England. There in 1783 General Washington received the formal thanks of the American congress for his conduct of the Revolutionary War.

Characteristic of life at Princeton, in addition to the university's rural location and consequently its active outdoor interests, are the residential dormitory system (in 1936 there were 25 campus dormitories housing the majority of the students), the system of elective upper-class eating clubs and the form of student self-government illustrated particularly by the student council, by the "honor system" and by undergraduate participation in the administration of university discipline.

The university offers (1936) undergraduate courses in the liberal arts and sciences leading to the degree of A.B., many graduate courses in the same fields leading to the degrees of A.M., M.F.A. and Ph.D., and technical courses in engineering leading to the degree of B.S. in engineering and ordinarily after one year of graduate study to the degrees of C.E., E.E., M.E. and Ch.E. A field artillery unit, maintained and staffed by the War Department, offers a course extending through four years and two summers, at the satisfactory completion of which, provided he also gains his university degree, the candidate receives from the President of the United States a commission in the Officers Reserve Corps.

In all admissions, regard is given to character, personality and promise as well as to scholarly attainment. Enrolment is limited in the undergraduate department to approximately 2,300 and in the graduate school to 250. Under the Princeton plan an upperclassman concentrates upon a definite subject within one of the 15 departments of the university, and prepares himself for what are known as "comprehensive examinations" at the end of each year, the final examination covering the work of the two previous years. In order to receive his degree he must attain a standing of better than average grade.

A feature of instruction is the preceptorial method, introduced in 1905, by which large classes are broken into small groups or informal conferences with "preceptors" on prescribed reading, especially in the departments of philosophy, history, politics, art, English and the languages. Princeton has no professional schools for utilitarian ends, except the school of engineering and possibly the school of architecture, although both of these are so strongly humanistic in their curricula and methods that they are in marked contrast in this respect with the usual American engineering and architectural schools. The school of architecture is developed directly out of the department of art and archaeology, and on successful conclusion of the course the degree of Master of Fine Arts is conferred.

In assuming the university title in 1896, it was definitely concluded that Princeton's future did not lie in developing professional schools but in upholding pure learning and in devoting herself "to the liberal aspects of those studies which underlie and broaden professional and technical education." The university therefore is not a congeries of professional schools overshadowing an undergraduate department, but consists of a large, homogeneous and well organized body of undergraduate students, with a small and carefully selected graduate school, devoted to the liberal arts and sciences.

There are a large number of scholarships and fellowships, both graduate and undergraduate, and a particularly well developed system whereby undergraduates of limited means are enabled to earn part or all of their expenses. During the year 1935–36 over 700 undergraduates were thus assisted.

The university is governed by a board of trustees, not less than 23 nor more than 40 in number, of which the Governor of the State of New Jersey (and in his absence the chairman of the board) is presiding officer. Eight of the trustees are elected, two each year, by the alumni of the university; the others are elected by the board.

History. — The university owes its origin to a movement set on foot by the Synod of Philadelphia in 1739 to establish in the Middle Colonies a college to rank with Harvard and Yale in New England and William and Mary in Virginia. Owing to dissension in the Church, no progress was made until 1746, when the plan was again broached by the Synod of New York, formed by the secession of the presbytery of New York and the presbytery of New Brunswick, radical (New School) presbyteries of the Synod of Philadelphia. Most of the leaders of the presbytery of New Brunswick had been educated at Log college, a school with restricted curriculum about 20 m. from Philadelphia, founded in 1726 but recently closed. The opportunity was taken by the Synod of New York to found a larger institution of higher learning, broader in scope and training, and to transfer to the new project the Log college interests. On Oct. 22, 1746, John Hamilton, acting governor of New Jersey, granted a charter for erecting a college in New Jersey, which was opened in May, 1747, at Elizabeth, N.J. A second charter was granted by Gov. Jonathan Belcher who on his arrival in the province in 1747 had at once taken the college under his patronage. The college was removed to Newark where the first graduation exercises were held in 1748; but the situation was unsuitable, and in 1752 the trustees voted to remove the college to Princeton. While additional funds were being collected in Great Britain, work was begun in Princeton in 1754 on the first college building, Nassau hall.

John Witherspoon, president during the Revolutionary period, influenced the college strongly by his personality and political prominence, and graduates of his training became leaders in public affairs. The history of the college during the first half of the 19th century was uneventful. Because of its large Southern clientèle, it suffered in the Civil War a blow from which it recovered only under the energetic administration of President James McCosh (1868–88). The undergraduate enrolment was nearly trebled, gifts amounting to more than $2,000,000 were contributed, only half of which sum was for endowment, 14 new buildings were erected, and important changes in the curriculum were put into effect. Fellowships were established in 1869, the elective system was introduced in 1870, the John C. Green school of science was erected in 1873, the graduate department was systematized in 1877 and the faculty grew from 17 to 40 and the number of volumes in the library from 25.000 to 65,000.

Under President Francis L. Patton (1888–1902) a school of electrical engineering was established, the "honor system" was instituted and the plan of electing alumni trustees adopted, 17 buildings were erected, the student body was doubled and the faculty increased to 100, while the endowment reached two and a half million dollars. In 1902 Professor Woodrow Wilson, of the Class of 1879, was elected president. In his administration the undergraduate curriculum was again revised, the departmental system was organized, an extensive building programme was completed. To obtain the necessary funds a committee of 50 alumni was formed, later changed into a Graduate Council. Through their agency in the eight years of President Wilson's administration the University received over four and one-half million dollars, the faculty was greatly strengthened and the library increased to 271,000 volumes. A plan for grouping the University into small self-contained units was prematurely proposed by the president in 1907 and was withdrawn by the trustees. The Princeton plan of a residential building for graduate students had been successfully tested on a small scale and a bequest in 1908, although inadequate for the full project which included professorships and fellowships, gave the plan its first semblance of permanent realization. Additional funds being conditionally offered in 1909, controversy developed as to the site for the building and finally as to the plan itself, the president no longer favouring it. A further bequest of about two millions for the project brought matters to a head and the president recommended acceptance of the legacy. In September 1910, having received the democratic nomination for Governor of New Jersey, he resigned the presidency.

Prof. John Grier Hibben, of the class of 1882, professor of philosophy in the university, was the fourteenth president of Princeton, Jan. 1912 to June 1932. His administration was marked by extended administrative reorganization, by very large additions to the endowment and by extensive expansion along material and scholastic lines. Faculty autonomy was made complete: a joint committee of trustees and faculty considers all matters of educational policy and administration; the faculty has voice in forming its committees and initiates appointments, promotions and increases of salary; the rights of the individual in cases of dismissal are safeguarded; faculty retiring allowances and insurance have been arranged. In the World War over 5,000 Princeton men saw service, 150 of them losing their lives; university laboratories were occupied by government bureaux of research.

The Honourable Edward Dickinson Duffield of the class of 1892 and a Trustee of the University served as acting president until the election of Harold Willis Dodds, Professor of Politics, as fifteenth president in June, 1933.

In 1913 the erection of the residential graduate college rendered permanent what had been an experimental feature of the Princeton graduate school. The school of architecture was opened in 1920. The school of engineering was in 1921 reorganized. Continuing the Princeton tradition for scientific research, the sum of $3,000,000 was secured in 1927, one-third being a grant from the General Education Board. The school of public affairs, designed to give its students a broad background for an understanding of and active participation in local, state, national and international affairs, was founded in 1930. Among the 29 buildings erected since 1912 are the psychological, engineering and chemical laboratories. a hall of mathematics, headquarters for the school of architecture, a new infirmary, a new chapel, the university dining halls, a university theatre, and ten dormitories. Plans have been developed for a new library building.

In 1936 the endowment was $27,068,388.58, operating income $2,820,241.64 (of which $1,164,586 was income from investments and $1,180,442 from student fees) and disbursements $2,757,-911.89. The library contained 740,000 volumes exclusive of pamphlets, etc.; the teaching staff numbered 334 and the student enrolment was 2,586, of which 2,302 were under-graduates, and 284 graduate students.

PRINCIPAL AND AGENT. In law an agent is a person authorized to do some act or acts on behalf of another, who is called his principal. The law regulating the relations of principal and agent is almost alike throughout the whole British empire, and differs only slightly from the law of the rest of Europe.

In a general view of the law of agency it is necessary to have regard to the rights and duties of the principal, the agent, and third persons with whom the agent deals. The agent should not do what he has no authority for; yet as between the principal and those with whom the agent deals, the test of the principal's responsibility for what is done by the agent on his behalf, but in excess of his actual authority, is his ostensible authority.

Agents are of different kinds, according to the extent of their implied powers. The main restraint in the powers of an agent is in the old maxim, delegatus *non* potest delegare, designed to check the complexity that might be created by enquiries into repeatedly-deputed responsibility. As a general rule an agent cannot delegate his authority or put another in his place; but this rule is sometimes modified, for it may arise from the nature of his employment or the necessity of the case that he has to employ other persons for the accomplishment of certain objects.

In the general case agency is constituted by the acceptance of the mandate or authority to act for the principal, and the evidence of this may be either verbal or in writing. But an agent who has to execute a deed in the absence of the principal must be appointed by deed for that purpose. As a corporation aggregate can in general act only by deed its agent must be so appointed, except in the case of trading corporations and joint stock companies, to which this rule has no application. Agency is often constituted, at the same time that its extent is defined, by mere appointment to some known and recognized function—as where one is appointed agent for a banking establishment, factor for a merchant, broker, or traveller. In these cases usage defines the powers granted to the agent; and the employer will not readily be subjected to obligations going beyond the usual functions of the office; nor will third persons dealing with the agent be bound by private instructions inconsistent with its usual character. While, however, third persons, ignorant of such secret limitations, are not bound to respect them, the agent himself is liable for the consequences of transgressing them. Agency may also be either created or enlarged by implication. What the agent has done with his principal's consent the person with whom he has dealt is justified in believing him to be authorized to continue doing.

In questions of this kind the distinction between a general and a special agent is important. A general agent is one employed to transact all his principal's business of a particular kind; as a factor to buy and sell; a broker to negotiate contracts of a particular kind; a solicitor to transact his legal business; a shipmaster to do all things relating to the employment of a ship. Such an agent's power to do everything usual in the line of business in which he is employed is not limited by any private restriction or order unknown to the party with whom he is dealing. On the other hand, it is incumbent on the party dealing with a particular agent, *i.e.,* one specially employed in a single transaction, to ascertain the extent of his authority. As to a mercantile agent, see FACTOR.

The obligations of the principal to the agent are: to pay the agent's remuneration, or, as it is often called, commission, the amount of which may be fixed by contract or usage; to repay all advances made by the agent in the regular course of his employment; to honour the obligations lawfully undertaken for him; and to indemnify the agent against all liabilities incurred by him in the proper execution of his mandate. The agent is bound to exercise proper skill and use the proper means for carrying out the functions which he undertakes. He must devote to the interests of his principal such care and attention as a man of ordinary prudence does on his own. He must observe the strictest good faith; and must not enter into transactions in which his interests are in conflict with the interests of his principal. Thus, when he is employed to buy, he must not be the seller; when he is employed to sell, he must not be the buyer. A mercantile agent who guarantees the performance by persons with whom he deals of the obligations contracted by them is said to hold a del credere commission.

In the United States courts have often been somewhat more liberal in interpreting an agent's powers than in England, a fact probably attributable to the absence on the part of third parties dealing with agents, of the degree of caution characteristic of an older business community. On the other hand, statutes in some American states forbid certain types of agents, notably real estate brokers, from recovering their commissions at law unless their contract of employment was written and signed. It should be noted further that modern American merchandizing practice works out into many situations deemed by business men "agencies," which may however be dealt with by the law as "sales"; a situation which makes reliance on any general statements of law quite unsafe. Finally, especially in the United States, much of the law as to a master's responsibility for the acts of his servant (see MASTER AND SERVANT) has been carried over to make a principal responsible for wrongs committed by his agent in the course of his employment.

PRINCIPE ISLAND, a Portuguese island in the Gulf of Guinea, of volcanic origin, 90 m. N.E. of St. Thomas with an area of 42 sq.m. The highest point is Pico-Papagaio, nearly 3,000 feet Pop. 4,938 (169 Europeans). The tsetse fly (which is not found in St. Thomas) infests the wooded part of the island, and through it sleeping sickness has been spread. The chief settlement is S. Antonio. Cocoa is cultivated.

PRINCIPLE, in philosophy, means something ultimate (Latin *principium,* a beginning). The early Greek philosophers applied the term (or rather its Greek original ἀρχή) to whatever they regarded as the primal stuff of which things are made, the source of all things. The term was used in this sense even in the 17th century or later. The followers of Paracelsus and others described salt, sulphur and mercury as "principles," in the sense of ultimate elements; and Robert Boyle used "principles" and "elements" indifferently as synonymous terms. The term "principle" was naturally applied not only to the original stuff of reality but also to its fundamental laws. And now only the fundamental laws or assumptions of science and philosophy are usually called principles, the terms elements, energy, etc. being used instead of "principle" in the other application it once had. Popularly the term is often employed for any kind of general truth or guiding norm. Hence the pleonasm "first principles" to distinguish them from derivative truths or secondary norms, etc.

PRINGLE, SIR JOHN (1707–1782), British physician, was born on April 10, 1707, at Stitchel, Roxburghshire, and educated at St. Andrews, at Edinburgh, and at Leyden. He settled in

Edinburgh as a physician, but after 1734 also acted as professor of moral philosophy in the university. In 1742 he became physician to the earl of Stair, then commanding the British army in Flanders, and in 1744 was appointed physician-general to the forces in the Low Countries. In 1749, having settled in London, he was made physician in ordinary to the duke of Cumberland, and subsequently received other court appointments as physician, being made a baronet in 1766. In Nov. 1772 he was elected president of the Royal Society, but resigned his presidency in 1778. He died on Jan. 18, 1782. Pringle was the founder of modern military medicine. He remedied camp sanitation and the ventilation of hospitals, and laid down the principles for preventing dysentery and hospital fever, at the same time showing that the different forms of dysentery were varieties of one disease and that gaol fever was the same as hospital fever.

His chief works are: *Observations on the Nature and Cure of Hospital and Jayl Fevers* (1750); "Experiments on Septic and Antiseptic Substances" in the *Philosophical Transactions* of the Royal Society (1750), and especially the *Observations on the Diseases of the Army* (1752). His *Six Discourses* (1783), contains a biography by A. Kippis.

PRINGSHEIM, NATHANAEL (1823–1894), German botanist, was born at Wziesko in Silesia, on Nov. 30, 1823. He studied at the universities of Breslau, Leipzig, and Berlin, graduated in 1848 as doctor of philosophy with the thesis *De forma et incremento stratorum crassiorum in plantarum cellula,* and rapidly became a leader in the great botanical renaissance of the 19th century. His contributions to scientific algology were of striking interest. Pringsheim was among the very first to demonstrate the occurrence of a sexual process in this class of plants, and he drew from his observations weighty conclusions as to the nature of sexuality. Together with the French investigators G. Thuret and E. Bornet, Pringsheim ranks as the founder of our scientific knowledge of the algae. The conjugation of zoospores, regarded by Pringsheim, as the primitive form of sexual reproduction, was a discovery of fundamental importance. A work on the course of morphological differentiation in the Sphacelariaceae (1873), a family of marine algae, is of great interest, inasmuch as it treats of evolutionary questions; the author's point of view is that of Naegeli rather than Darwin. Closely connected with Pringsheim's algological work was his investigation of the Saprolegniaceae, a family of algoid fungi, some of which cause disease in fish. His career as a morphologist culminated in 1876 with the publication of a memoir on the alternation of generations in thallophytes and mosses.

From 1874 to the close of his life Pringsheim's activity was chiefly directed to plant physiology. He founded the *Jahrbuch für wissenschaftliche Botanik,* and the German Botanical Society. His work was for the most part carried on in his private laboratory in Berlin; he only held a teaching post of importance for four years, 1864–68, when he was professor at Jena. He died in Berlin on Oct. 6, 1894.

His works include memoirs on *Vaucheria* (1855); the Oedogoniaceae (1855–58); the Coleochaeteae (1860) *Hydrodictyon* (1861); and *Pandorina* (1869) The last mentioned bore the title *Beobachtungen uber die Paarung de Zoosporen.*

A fuller account of Pringsheim's career will be found in *Nature,* (1895) vol. li., and in the *Berichte der deutschen botanischen Gesellschaft* (1895), vol. xiii.

PRINSEP, VALENTINE CAMERON (1838–1904), English artist, was born on Feb. 14, 1838. His father, Henry Thoby Prinsep, who was for sixteen years a member of the Council of India, had settled at Little Holland House, which became a centre of artistic society. Val Prinsep first studied under G. F. Watts, and later in Paris in the *atelier* Gleyre. "Taffy," in his friend Du Maurier's novel *Trilby,* is said to have been sketched from him. He was an intimate friend of Millais and of Burne-Jones, with whom he travelled in Italy and he had a share with Rossetti and others in the decoration of the hall of the Oxford Union. He first exhibited at the Royal Academy in 1862 but the first picture to attract notice was a portrait (1866) of General Gordon in Chinese costume. He was elected A.R.A. in 1879 and R.A. in 1894. In 1877 he went to India where he painted a huge picture of the Delhi durbar, exhibited in 1880 and afterwards hung at Buckingham Palace. Prinsep wrote two plays, *Cousin Dick* and *Monsieur le Duc,* produced at the Court and the St. James's theatres respectively; two novels; and *Imperial India: an Artist's Journal* (1879). He was one of the founders of the Artists' Corps.

PRINTING. Letterpress printing is the art of producing impressions by means of pressing an inked relief surface on to paper or other material. The term "printing" can be applied to any process by which a print is obtained, but it usually refers to typography, or, as it is now generally termed, "letterpress printing," which includes not only printing from type, but the obtaining of impressions from wood cuts, line and half-tone blocks in monochrome and colour. It has been claimed that the craft of letterpress printing is the medium which turned the darkness of the middle ages into light; which secured to posterity the intellectual achievements of the past; and which furnished to civilization a means of recording all future progress.

The Chinese were the first printers. The oldest known printed book, printed from blocks, was discovered in the Chinese province of Kansu in 1900. It bears the statement, "Printed on May 11, 868. by Wang Chieh. for free general distribution. in order in deep reverence to perpetuate the memory of his parents." Printing from movable type was first done by Pi Shêng in China in the years 1041 to 1049. Both events are well authenticated. Because of the large number of characters in what in Chinese corresponds to an alphabet, the new method was not generally adopted.

History. — There is no certainty as to the actual date of the European invention of printing from movable type, which was independent of the discovery of the principle by the Chinese, but it is assumed that it took place about 1440. At an early date books were printed from engraved wood blocks, thus the term "block books" indicates that all the words on the page of a book have been cut by hand on to a solid block of wood. It is by no means certain, however, if these preceded the invention of movable types, for it is known that block books were produced after the invention of printing. In fact, no extant block book bears a date earlier than 1470. That prints were obtained from wood blocks previous to 1440 there is ample evidence, but these were of a pictorial character. In the John Rylands library, Manchester, England, there is a wood block print depicting St. Christopher, dated 1423. It is known that block prints were produced in Japan as early as A.D. 770.

Just as there is no actual certainty as to the date of the European invention of printing from movable types, so it is also doubted who the inventor really was and where the invention took place. Claims are made for Germany, Holland, France and Italy. One authority, however, sums up the position by stating: —

> Holland has books but no documents;
> France has documents but no books;
> Italy has neither books nor documents;
> Germany has both books and documents.

It is generally agreed that certain letters of indulgence are the first documents bearing a printed date, and these were printed from type cast in a mould and issued in 1454 and 1455 from a press at Mainz, and ascribed to Johann Gutenberg.

From the press at Mainz a Vulgate bible was published in 14j6. This was attributed to Gutenberg, the strongest claimant to the honour of the invention of printing. This book became known as the Mazarin bible, because a copy was found in the famous library of Cardinal Mazarin, or, as it is sometimes called, the 42-line bible, owing to the fact that the large majority of its pages are 42 lines to the column, of which there are two on a page. In 1457 the Mainz psalter was produced; it was the first book to bear the name of the printer and the place and date of its production. It was also the first attempt at colour printing. The printers were Johann Fust and Peter Schoeffer, the latter one of Gutenberg's workmen.

From Mainz the art of printing spread throughout the continent. In 1464 Sweynheym and Pannartz, two Germans, carried it into Italy, beginning at Subiaco near Rome. In 1469 Johann and Wendelin, of Speier, began in Venice. They were followed there by Nicolas Jenson, a Frenchman, who printed from 1470 to 1480. Jenson added lower case to the capital letters he found on the Roman monuments, and the type design thus created has since remained standard. Another famous printer in Venice was Aldus Manutius, who printed from 1495 to 1515. He was the originator of Italic lower case letters, to which were later added Italic capitals. Aldus, as he was generally known, contributed to the spread of learning by printing the classics in small inexpensive volumes. In 1470 printing was introduced into France by three men of German nationality, Krantz, Gering and Friburger, who in that year set up a printing establishment within the precincts of the Sorbonne in Paris.

Berthold Ruppel is usually credited with the introduction of printing into Switzerland, the date being possibly 1468. The most famous and learned printer in Swiss history was Joannes Froben (*q.v.*). With him was associated, as press corrector, the great Dutch scholar. Desiderius Erasmus. In the Low Countries (Holland and Belgium) printing was done at Utrecht as early as 1471, but the name of the printer is unknown. N. Ketelaer and G. de Leempt were the first Dutch printers to place their names in a printed book of their own production, the date being 1473.

Spain's first known printer was Lambert Palmart who began at Valencia in 1474. The best known name in the history of Spanish printing is that of Kromberger, Jacob and John (father and son), the elder having begun at Seville soon after the opening of the 16th century, the exact date being unknown.

William Caxton was England's first printer. He was a native of Kent. After serving an apprenticeship to a London mercer, he resided for a period of about 30 years in the Low Countries, where he eventually became governor of a company of English merchants known as the English Nation. He learned the art at Cologne and, with Colard Mansion, started business at Bruges, removing in 1476 to Westminster where he set up a press at "The Red Pale" in the Almonry. His first production in England was a papal indulgence, issued on Dec. 13, 1476. He continued there during an active period of 15 years, producing about 100 volumes. He died in 1491 and his press passed to his assistant, Wynkyn de Worde.

The introduction of printing into England was characterized by a number of innovations. In all other countries the pioneers were wandering German printers who began to print in Latin. England's first printer was an Englishman who used only his own language. Caxton wrote or translated much of the material he converted into books, and he printed with type faces of a design that was neither Gothic nor Roman.

The quality of printing began to deteriorate in the 16th century, owing somewhat to the fact that the ruling powers in church and State became alarmed because the new art seemed to be creating too much freedom of thought. Measures of repression were adopted and printing ceased to be an art and became merely a vehicle for the conveyance of information. Some great printing and publishing families, such as the Estiennes in France and Plantin and the Elzevirs in the Low Countries, carried on the traditions, but the general level of quality was low. A change came in England early in the 18th century. In 1720 William Caslon began to produce a Roman type face that was little more than a refinement of that designed by Nicolas Jenson, but it was accepted as a practically new design and has ever since borne Caslon's name. It exercised a profound influence upon 18th century typography. A generation later John Baskerville, after seven years of experimenting with type, ink and paper-making, began to print in Birmingham. Because of the high quality of his productions he, too, exercised a decided influence upon the printing of the time. Just before Baskerville's death in 1775, another printer of similar eminence was coming into notice in Italy. He was Giambattista Bodoni, who began at Parma in 1768 and continued until his death in 1813.

Printing began in the Western Hemisphere in Mexico City, probably in 1539, when a printer named Giovanni Paoli reached there with an equipment sent, at the request of the reigning archbishop, by John Kromberger, of Seville, Spain. In what is now the United States, the first press began at Cambridge, Mass., in 1638. The Rev. Jesse Glover had left England with it, but had died on the way over. It was set up by Stephen Day and his son Matthew, a lad of 18 years, who had some knowledge of printing. Their first work was called the "Freeman's Oath." The first book from the press, known as the Bay Psalm Book, was produced in 1640.

The deterioriation in the quality of printing, which began to manifest itself in the 16th century, continued with exceptions noted through the 17th, 18th and 19th centuries. A revival came in the last decade of the 19th century, led by William Morris at the Kelmscott Press in England. Morris' books were issued in limited editions and are prized by book-collectors. They cannot be said to be highly successful, however, as books; it was pictorial effect rather than legibility for which Morris strove. He had many imitators, but few successful followers.

The standard of book-making in the 20th century remained high. In England, apart from the few excellent private presses, good work was produced by the presses of the universities and many other commercial printing-houses. Bruce Rogers (1870–) in New York, and Daniel Berkeley Updike (1860–1941) at the Merrymount Press, in Boston, produced volumes that from all the points that go to make up good book-making were scarcely surpassed. Frederic W. Goudy (1865–) produced type designs that will give his name a permanent place in printing history.

The Printing Press.—The development of the printing press provides a remarkable history of achievement. Hand presses were for more than 100 years constructed of wood and operated on the screw principle. Willem Janszon Blaeu (1571–1638), of Holland, made the first improvements, but no radical change came until the end of the 18th century. Adam Ramage, of Philadelphia, and Charles, Earl of Stanhope, of London, working at about the same time, made further improvements, Stanhope's press, appearing in 1800, being the first to be constructed entirely of iron. George Clymer, beginning in Philadelphia and continuing in London from 1817 to 1834, was the first to abandon the screw entirely, his substitute being a series of compound levers. The hand-lever press, known as the Washington hand press, operated on the toggle-jointed bar principle, appeared about the same time and eventually superseded all others. John J. Wells, Peter Smith and Samuel Rust, of New York, all had a hand in its development.

In 1790, William Nicholson, an Englishman, took out a patent for a cylinder press, but this did not get beyond the drawing of plans. It was left for Frederick Koenig—a Saxon—to construct the first power-driven machine in 1811. This, however, proved but little more than the adaptation of power to the hand press, and it is assumed that only one of these machines was made and used for book printing. Soon after this, Koenig and a fellow-countryman, Andrew Bauer, constructed a flat-bed machine with a continually revolving cylinder. Two of these machines, called cylinder presses, were erected in The Times, London, and the issue dated Nov. 29, 1814, states that it "was printed by steam power." The machine produced 1,100 impressions per hour, thus quadrupling the output of a hand press. Later, a machine was constructed to print upon both sides of the sheet before delivery, and these machines were in operation until 1827.

Koenig returned to Germany in 1817, and Applegarth and Cowper, engineers of The Times, built a machine in 1827 for printing on one side of the sheet, and capable of giving 4,000 impressions an hour. This was in use until 1848, when Applegarth invented a new type of machine with cylinders in a vertical position and on which the type was secured by means of wedge-shaped column rules. Around the type cylinder were grouped eight impression cylinders, the sheets being delivered in a vertical position and taken off by hand. The output of this machine was 8,000 impressions per hour. There was only one of these machines made and it was ultimately replaced by the Hoe type revolving machine, which made way for the Walter rotary perfecting press in 1868.

In 1846, Robert Hoe, founder of the world-renowned American printing machinery manufacturing firm, built a new style of press. This was known as the Hoe type revolving machine. The type cylinder was placed in a horizontal position and the type secured in cast-iron beds by special locking up apparatus. Each bed repre-

PARABOLAS SALOMONIS

Incipit prologus sancti Jeronimi pb̄ri in parabolas salomonis.

Iungat epistola quos iungit sacerdotium: immo carta non dividat quos xp̄i nectit amor. Cōmentarios in osee. amos. zachariā malachiā. quoq; poscitis. Scripsissē: si licuisset pre valitudine. AFTER A FACSIMILE BY SCHWENKE OF THE PELPLIN COPY OF THE GUTENBERG BIBLE, BY COURTESY OF THE NEW YORK PUBLIC LIBRARY

ILLUMINATED PAGE FROM THE GUTENBERG BIBLE

The Gutenberg Bible, traditionally accepted as the first book printed from movable type, was issued at **Mainz,** Germany, about 1454. The illustration shows **page** one of the Proverbs of Solomon. The pages are illuminated to give the effect of a hand-copied manuscript, as desired by the printers, who did not wish their invention discovered. The book was probably printed in 10 sections on 6 Dresses workina simultaneously. **Of** nearly 300 copies, only 45 are known to be in existence to-day

sented one page of a newspaper. Grouped around the type cylinder were four, six or ten impression cylinders, each of which had feeders laying on sheets of paper. As the main cylinder rotated, the type was inked by a roller, the sheets as they were fed in being taken by grippers to receive the inked impression of the type. In this instance, the sheets were delivered by means of "mechanical flyers." This machine was capable of turning out 2,000 sheets per feeder per hour, *i.e.,* with a four-cylinder machine 8,000 impressions were obtained. The first machine was erected in London in 1856; it had six cylinders and was installed to print *Lloyd's Weekly Newspaper.*

An impetus was given to the production of newspapers by the invention of the papermaking machine by the brothers Fourdrinier, in 1803, while the knowledge of how to cast curved stereo plates also helped forward the development of newspaper production. In 1865, the first printing press to print from a continuous reel of paper was made by an American named William Bullock The machine consisted of four cylinders—two impression cylinders and two plate cylinders—but as the paper passed from the reel it had to be cut before printing. This led to many difficulties and the machine was soon discarded owing to its unreliability.

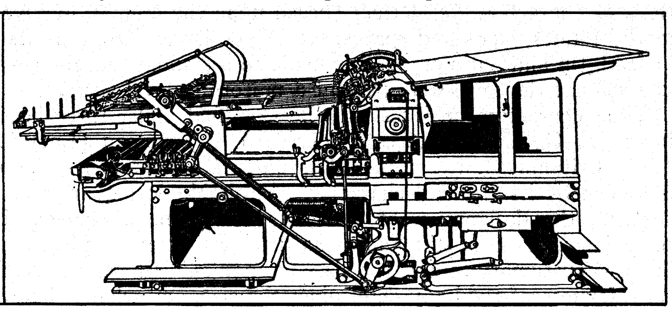
The proprietors of *The Times* were continually endeavouring to construct a rotary perfecting machine and in 1868 the famous Walter rotary perfecting press was built to print *The Times. A* reel of paper was used, both sides being printed from curved stereo plates and the sheets delivered flat. These were used until 1895, and were undoubtedly the models from which present-day newspaper rotaries have developed. One drawback to the speedy production of newspapers in the early days of the rotary machine was that they were delivered flat and had to be folded by hand. In 1870, the first folder attachment was invented by two English engineers, G. Duncan and W. A. Wilson, and since then the development of the rotary press has been rapid: the reason undoubtedly being the overcoming of the folding difficulty which in turn has enabled proprietors to produce newspapers in large numbers and at the nominal price at which they are now sold. Present-day newspaper presses are capable of printing simultaneously from as many as 1j reels and to produce over 300,000 copies per hour. Credit must be given to Sir Rowland Hill for the inception of the idea of printing on both sides of the paper from a reel, the suggestion having emanated from him in 1835.

In 1822, Daniel Treadwell of Boston applied power to a machine built on the "bed and platen" principle. The original machine of this type was improved upon by Adams, of Boston, and for many years this class of machine was used for printing fine books and woodcuts.

The next notable development of a printing machine was one worked by treadle and adaptable for the printing of small jobbing work such as cards, handbills, etc. The first machine of this character was made by S. P. Ruggles, of Boston, Mass., in 1830, and was known as the Ruggles card press. Just over a quarter of a century later (1856) George P. Gordon, an American, built a press which proved to be the forerunner of what are now known as light platen machines. This was constructed with the type bed in a vertical position, was named "the Franklin," and rapidly became in general use throughout the world.

Improvements on platen machines became necessary by the introduction of half-tone and colour printing. In 1869 Merritt Gally, of Rochester, N.Y., invented a new type of platen machine known as the Universal press which proved the pattern for heavy platen machines for colour printing. About 1850 a London printer named Main introduced a new type of flat-bed printing machine. Instead of a continuous rotary motion, as in the Koenig machine, the cylinder "rocked," making about three quarters of a revolution and then reversing, at the same time rising to allow the return of the bed. This machine was generally known as a "tumbler" and was the forerunner of what is now known in Great Britain as the Wharfedale stop-cylinder machine which was invented about 1860 by William Dawson and David Payne of Otley.

The modern type of flat-bed printing machine is known as the two-revolution press. It is so called because the cylinder, the rotary movement of which is continuous, makes two revolutions far every sheet printed. The second revolution occurs as the cylinder rises to permit the return of the bed carrying the forme. (This movement was a feature of the Napier machine built about 1830.) The most widely used form of this type of machine, and the one which has made it so popular, was invented in 1883 by Robert Miehle, a practical pressman, and the first



BY COURTESY OF LINOTYPE AND MACHINERY CO.
TWO-REVOLUTION PRINTING MACHINE

machine was installed in America in 1888. "The Miehle," as it is generally termed, has revolutionized the manufacture of printing machinery. It is to be found in most printing offices, producing not only commercial but the finest coloured work; machines of this type are made for every class of work, and are known as single-colour, two-colour and perfecting machines, respectively.

Mechanical Typesetting.— The first type composing machine was patented in England in 1822 by Dr. William Church of Boston. This machine set ordinary founder's type from channels previously filled by hand. Upon the depression of the respective keys, the type was released into a raceway, it being delivered in one continuous line and subsequently justified by hand. This was followed by numerous attempts, all more or less successful, to set and justify founder's type mechanically. All these efforts, however, still left the problem of distribution unmastered, the most successful attempt to achieve this being that of Joseph Thorne who, in 1880, brought out a combined typesetting and distributing machine.

In 1878 Ottmar Mergenthaler (1854–99), a German immigrant to America in 1872, constructed a "type impression" machine and in 1885 took out patents for a slug casting machine, the forerunner of the Linotype. In the following year, 1886, this machine was actually used in the United States, but was not introduced into Great Britain until 1890. The typograph, another slug casting machine, was the invention of John Raphael Rogers, who was a consulting engineer with the Mergenthaler Linotype Company. The first machine was built in Cleveland, but, as the U. S. courts found that Rogers infringed certain patents owned by the Mergenthaler Company, the use of the machine was prevented in the United States. Ultimately, the Mergenthaler Company purchased the U.S. rights of the typograph company. In 1890 this machine was being built in Canada and, on the expiration of the linotype agreement, its manufacture was commenced in Detroit, Mich. In 1893 the manufacture of the typograph was undertaken in Germany, the first typograph built in that country being put on the market in 1896. Germany is now the headquarters for the manufacture of this type of machine where it has achieved a remarkable success.

It was about the same time as Mergenthaler placed his invention for a slug casting machine on a successful basis that Tolbert Lanston, a clerk in the Pensions Office at Washington, developed and perfected a method of casting type by means of a perforated sheet on the Jacquard principle. He applied for his patent in 1885, this being granted two years later, the year in which the first machine was produced.

The Practice **of Printing.**—As in all processes of printing, there are two main operations in letterpress printing: (1) The setting up of the type, reading, making up the type and blocks into pages, imposition and locking up. This embraces the work of a compositor and is done in the composing room. (2) Printing, which includes the fixing of the forme on the machine, making ready (a process whereby irregularities of pressure are removed), getting position on the sheet, inking and the printing of the sheets. This work is done by the machine minder or the pressman, the latter being the American term.

Type.—The typefounder supplies type to the printer in founts which are of varying weights but made up in recognised proportions of characters, *i.e.,* letters (based upon the number of "A's" in the fount), signs and spaces, etc. Type is cast from an alloy of lead, tin and antimony and is made to a standard height (·918 in.) so that the faces may present a uniformly level surface.

Type characters or faces may be classified under three headings: (1) Gothic (Encyclopaedia Britannica), (2) Roman (Encyclopædia Britannica), (3) Italic (*Encyclopædia Britannica*). Type is known by its size and character. Within the last quarter of a century, the designation of sizes has undergone a change. In some instances it is still known as nonpareil, brevier, pica, etc., but it is customary to give the sizes in "points." In this the vertical thickness of the body determines the size, and what is known as the "point system" is now accepted as a standard measurement. There are 72 points to the inch. A point, therefore, is approximately ·0138 inch. The sizes are graduated by points up to 12-point; those above 18-point are multiples of 6-point. There are types from 3- to 5-point but these are not in general use, being too small for ordinary purposes. The $5\frac{1}{2}$-point is used considerably in American newspaper "want" advertisements.

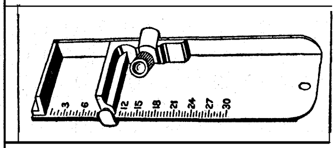
The following are a few of the approximate sizes of type in general use for printing books:—

Points	Old terms	Number of words to a square inch
6	Nonpareil	47
7	Minion	38
8	Brevier	32
9	Bourgeois	28
10	Long Primer . . .	21
11	Small Pica . . .	17
12	Pica	14
14	English	11
18	Great Primer . . .	7

The above table is set in 8 point: the body of this book is set in 9 point. In addition to these sizes there is a wide variety of display types, *i.e.,* types used for advertisement purposes which can be cast up to 144-point:—12 times the size of 12-point, or, to use an old term, 12-line pica. However, it is deemed inadvisable to cast in metal much above 72-point or 6-line pica. There is no accepted standard for naming type faces. Similar characters of design bear the distinctive names which the different type founding firms give it.

Composing.—The first work of a compositor when the type is received from the founder is to "lay" it in cases. A case may be described as a wooden tray about $32\frac{1}{2}$ in. long, $14\frac{1}{2}$ in. broad and about $1\frac{1}{3}$ in. deep. The case is divided by cross partitions into "boxes," each of which holds a different character. Generally, there are two kinds of cases, namely, the upper case (capitals) and the lower case (small letters). It is usual for the upper case to have 98 boxes, the capitals on one side and small capitals on the other, and the lower case 53. The divisions in the upper case are all of the same size while those in the lower case are of varying sizes according to the number of a particular letter contained in the fount. For instance, the box for the lower case "e" is about five times the size of that for the capital "E" in the upper case. The letters in the lower case are not placed in alphabetical order but in accordance with the frequency with which a particular letter is used in the English language, those most frequently used being nearest the hand of the compositor.

When the compositor is given "copy" to set up, he places it in front of him on the upper case, and memorizing as many words as he can he proceeds to pick up from the various boxes in the case the particular letters required. These letters he places in a "composing stick" which in reality is a narrow metal tray (usually about 10 in. long and 2 in. wide) with flanges on the back and the right hand side, and on the left an adjustable slide which can be fixed to the particular "measure" or length of line required for the work in hand. On each type there is a "nick" (or "nicks"), *i.e.,* a slight groove on the front of the "body" of the type, which is a guide to the correct placing of the type in the composing stick. At the completion of each word "a space" (a short piece of metal) is inserted, it being by this means that the words are separated. When the line is completed it is "justified" or made tight to the "measure" of the composing stick with spaces of varying widths, to make the lines of uniform length.



BY COURTESY OF STEPHENSON, BLAKE & CO.
COMPOSING "STICK"

The compositor proceeds to set up the matter line by line until the stick is full. He then carefully removes the type from the stick and places it upon a shallow tray with raised edges on three sides called a "galley." When a galley is full, proofs are taken and read in conjunction with the manuscript, the reader carefully marking in by recognized symbols the corrections necessary. This is returned to the compositor who makes the necessary alterations by lifting, where necessary, the line out of the galley and replacing it in the stick, the reason for this being to ensure that justification of the lines is uniform throughout during the process of correction. When the work is completed finished proofs are pulled, usually in galley form, and sent to the author for correction.

The next operation in the production of a book is to make the type up into pages, the depth and width of which are determined by the size of paper on which it is to be printed. It is usual to send the author another set of proofs for a final "revise." When the work is finally passed for press, the pages are placed in such a position that when the sheet is printed and folded they fall in correct sequence. This is called "imposition," and includes placing the pages within an iron frame called a "chase," which, when there are a number of pages to be printed together, has crossbars—one across the length of the chase, the other across the width. The determined space between the pages is filled up with what is called "furniture," which is made of either wood or metal, and about $\frac{1}{4}$ in. lower than type, so that it does not get inked during the process of printing. The whole is then locked up within the chase by means of a system of wedges, called "quoins," thus making the type and furniture portable. When this is accomplished it is known as a forme and is ready to be printed.

Composing Machines.—The setting of the type for newspapers, magazines and books is now almost entirely a question of mechanical composition and the machines used for this purpose can be divided into two classes:

(1) That which casts a "slug" (or line of type), such as the Linotype, Intertype, Typograph and Ludlow.

(2) That which produces justified lines of single types, and known as the Monotype.

Slug-Casting Machines.—Such machines as the Linotype and Intertype consist of a keyboard, magazines (containing matrices), casting apparatus and a distributing system. The compositor on these machines is called an "operator," and when he presses a key representing a particular character on the keyboard, it operates certain levers which allow a matrix, with the letter cut into its edge, to be released from the magazine. The matrix, dropping on to a revolving belt, is carried automatically to an assembly box. By touching another key, a double wedge spaceband is placed between the words. When the line is full a lever is depressed and causes the matrices and spacebands to be carried to a position in front of the mould, behind which is situated a pot of molten metal. While in this position, the line is justified by the pushing up of the spacebands from below, the line thus spreading out to the full measure. A plunger in the metal pot then descends and forces the molten metal into the mould and against the face of the matrices. The resultant metal bar or "slug" with the letters in relief is then automatically trimmed for height and thickness prior to its being ejected on to a receiving galley. The matrices from which the slug has been cast have meanwhile

SCENES IN VARIOUS DEPARTMENTS OF A PRINTING PLANT

1. Operator at the keyboard of a monotype composing machine. The keyboard action perforates a reel of paper, which, when fed into another machine, the "caster," causes to be delivered on to a tray a separate piece of type for each letter in the matter "set" on the keyboard

2. A battery of monotype keyboards, here assembled in a sound-proof room to prevent distraction of the operators from the "copy" by noise

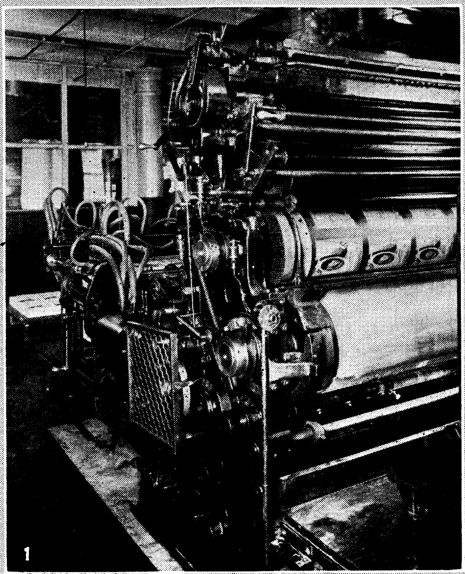
3. Setting type by hand. The larger, or "display," sizes of type are still set by hand. The composing room here shown is in the school of a large American plant

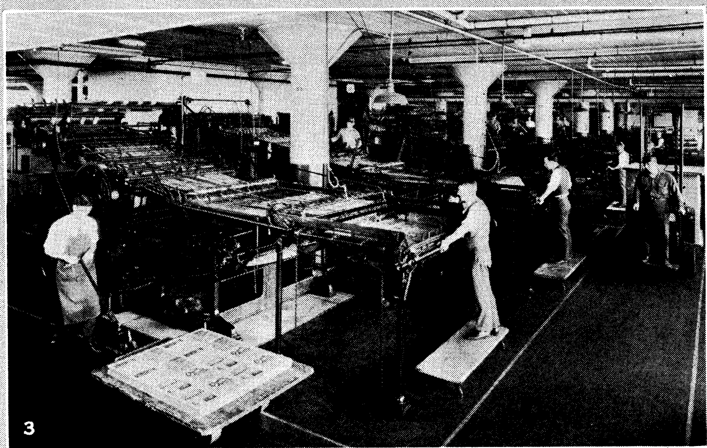
4. The proof-room, showing proof-readers seated at each of the glass enclosed desks. The readers compare printed proofs with author's manuscript. For some kinds of work copy-holders read author's manuscript aloud to readers

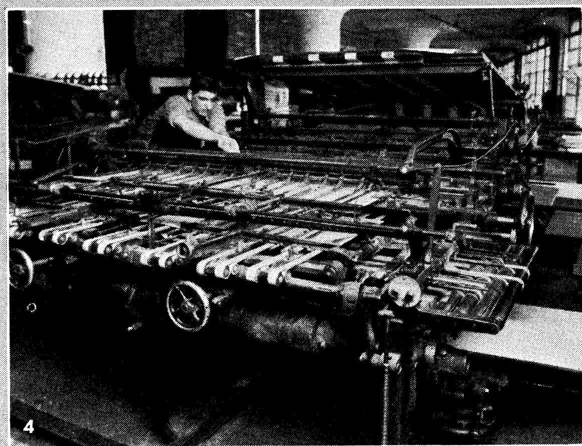
5. A "stone-hand" working on a 32-page forme. This is termed imposing. When ready, this forme will be locked up with metal wedges, called quoins, in the iron frame, or chase, which surrounds it and taken to the press for printing

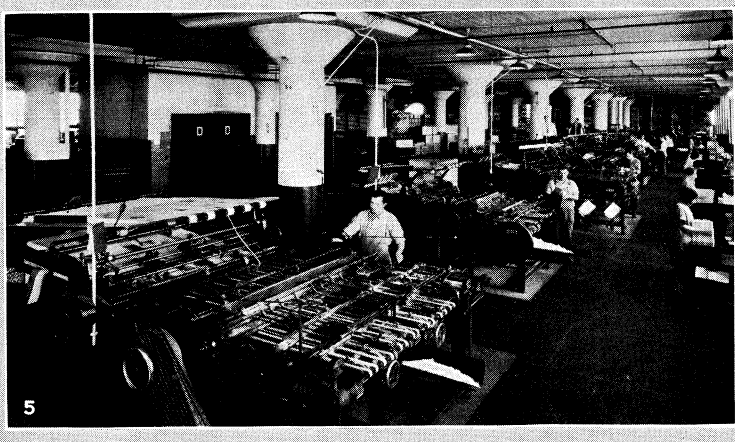
6. Handling rolls of paper in the pressroom. These rolls, or "reels" as they are called, weigh from 1,200 to 2,200 lb. according to the width and kind of paper. Mechanical handling, as here shown, is practically necessary.

PRINTING









BY COURTESY OF R. R. DONNELLEY AND SONS COMPANY

VIEWS OF PRESSES, FOLDERS AND TIPPING MACHINES

1. Side and back view of an offset press. Below the rollers at top is the printing plate fixed round a cylinder. The plate prints upon the rubber blanket on the cylinder below, which in turn prints upon the paper

2. Modern rotary or "web," press for commercial work. These presses print direct from curved plates, secured on a cylinder, onto the paper. The paper is automatically fed from the roll. After being printed the paper, as it reaches the "delivery end," is folded and cut. When presses print on both sides of the paper, they are called "perfecting presses"

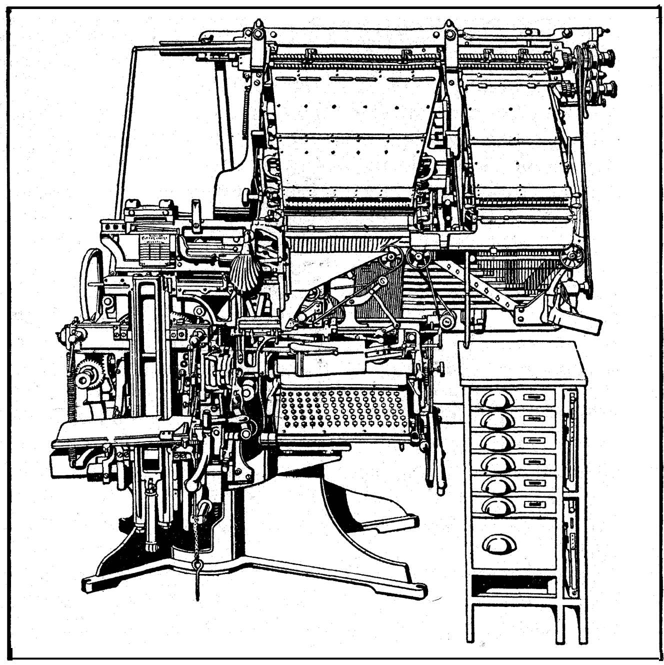
3. Flat-bed press equipped with an automatic feeder (left), which feeds the sheets of paper, and with extension delivery (right), which is automatically lowered to the floor as the printed sheets pile up after being printed. The piles of printed sheets when completed are transported by trucks (right) to the folding machines. Presses of this type are used extensively in colour-printing

4. Adjusting a folding machine. These folders are automatically fed and will fold printed sheets with any number of pages into "book form"

5. Battery of folding machines. The automatic feeder is on the left; the folded sheets (in this case book signatures of 32 pages each) may be seen in the "lay-boy" in the bottom right hand corner of the illustration

6. Girls working glueing machines used for "tipping" inserts onto book sections

been lifted by an arm to the top of the machine, and are caused to travel along a serrated distributor bar until the matrix finds its way into its correct channel in the magazine. Each matrix has on its top edge a double series of seven teeth, the arrangement of same varying with each matrix. The individual matrix travelling along the corresponding rail on the distributor bar eventually arrives at a break in the rail on which it has been hanging and



BY COURTESY OF LINOTYPE AND MACHINERY CO

MODERN LINOTYPE

has no alternative but to drop into its respective magazine channel.

All the operations are automatic and continuous, it being possible for three lines of matrices to be in circulation at the same time, one in course of assembly, another in the process of casting and a third in the stage of distribution.

The Typograph is a further and somewhat different expression of slug-casting machine. In this machine the matrices hang on a series of wires which converge fan-shape towards the point of assembly. As the operator touches the respective keys on the keyboard, the matrices slide by gravity down the wires to the point of assembly. The line is justified by means of circular space discs which expand as they are caused to revolve just prior to the casting. The slug cast by this machine does not require trimming to give either the height or the body width. The operation of distribution is performed automatically, the top frame of the machine tilting backwards and so reversing the angle of the wires when the matrices automatically slide back to their original postion.

The Ludlow Typograph is a class of slug-casting machine designed for the production of display lines. It does not, however, set up matrices, its function being to produce cast slugs from lines of matrices set up by hand in a special composing stick. As each line is set by the compositor the stick containing it is clamped into the machine which produces a solid line of type with the characters in slug form. This particular form of slug-casting machine is employed in the main for producing head-lines for use in newspaper and periodical work, advertisements and various similar purposes.

Monotype.—The Monotype is a system of mechanical composition that produces justified lines of single types. It comprises two distinct machines—a keyboard and a caster, The keyboard has the appearance of an elaborate typewriter. As the operator depresses each key, holes are punched into a strip of paper which automatically travels with each tap of the keys from one spool-holder to another, each letter being represented by its particular combination of perforations. At the end of each line a pointer indicates what special keys should be touched in order to ensure the justification of such line when eventually cast in metal.

When the spool is completed it is placed in position on the casting machine which contains a metal pot, a mould and a matrix holder called the "die case." The latter usually contains 225 matrices arranged in 15 rows of 15 in the compass of a 3-in. square. The perforated strip of paper controls the action of the mechanism which brings the respective matrices into position over the mould in the order-desired. When the matrix has been momentarily clamped into position, a jet of metal is forced into the mould and the type cast. The characters as cast are pushed along until, when the line is completed, they are automatically transferred on to a galley. The last line of the spool is the first to be cast, but when each galley is completed the lines will run in correct sequence as in the copy. There is an adaptation of the Monotype machine by which rules, ornaments, and a wide range of display type faces may be cast, and afterwards put into cases to be used by the hand compositor.

Machining.—When the forme is sent to press from the composing room the printer's work commences. The printer is called a machine-minder in Great Britain, and a pressman in America, and it mainly depends upon him as to whether the work bears the hall mark of "quality" (or otherwise), the printing of the sheets demanding the greatest of care in every stage.

The first operation is to prepare the impression surface (the platen or cylinder) by covering it with a number of sheets of a suitable paper. This is followed by locking the forme securely in the bed of the machine in a position necessary to the requirements of the particular work in hand. The quoins securing the work in the chase are loosened, and the type "planed down" with a planer, *i.e.,* a smooth flat piece of wood is placed on the type and carefully struck with a mallet to ensure that the "feet" of the type rest solidly on the bed; the quoins are then again tightened and an impression "pulled" on a sheet of paper. Invariably this first pull shows irregularities in the weight of pressure, some parts being so weak that they are unreadable and others so heavy as nearly to cut through the sheet of paper. It is in the rectification of these inequalities that the skill and experience of the machine-minder are exhibited, for unless this work is done with understanding, the printed sheets will appear "patchy" and difficult to read. When the printed sheet has been made "readable" the pages are "registered," *i.e.,* placed to print in the proper position on the sheet, and in printing book work, made to "back up" correctly. A well printed book, if the pages are of uniform size, should have the lines on both sides of the leaf printing exactly on the back of each other.

When a forme of type is registered, a sheet is sent to the reader for revision (in case of any letters having been broken off or a word "pied"). While this is taking place, the operation called "make-ready" is commenced, and it is not unusual for a large forme to take two or even three days to make ready. The desired results are obtained by cutting out on a sheet of thin paper the heavy parts with a sharp knife and "patching up" with paste on the sheet, varying thicknesses of paper on those parts that are weak. When the sheet is completed it is "stuck up" on the impression surface in a position corresponding exactly with that part of the forme which requires the particular treatment. Another impression is then pulled, and the work of cutting out and patching up is continued until the impressions seen on the back of the sheet present an even and regular appearance. The supply of ink has then to be adjusted so that the requisite amount will be transferred to the type in a uniform manner throughout the "run."

When printing half-tone work, "interlaying" is often done to ease the pressure on the high lights and to give greater resistance to the solids contained in the plate while printing. "Overlaying" is invariably used when printing illustrations either in monochrome or colour. It is a means of supplying the graduated pressure necessary to ensure that a clean sharp impression of the inked blocks will be made upon the sheet of paper.

There are various methods of making overlays, the usual being to pull three impressions from the block on thin, hard paper On the first sheet, which is the foundation sheet, all the high lights are cut out; on the next sheet all the solids are carefully cut out and pasted accurately in a corresponding position on to the first sheet. The third sheet has the high lights and intermediate tones cut out, leaving the three-quarter tones and solids; this is then pasted on to the foundation sheet on which the solids have already been fixed. When the overlay is completed and held up to the light "a picture" of the illustration in its various tones will be seen. The overlay is then pasted on to the impression surface in a position to correspond exactly with the block on the bed of the machine; thus the varying tones in the plate will receive graduated degrees of pressure, and by this means a true representation of the tones in the block is obtained when inked and impressed on to a sheet of paper.

There are mechanical means of making overlays. The most popular form is known as the "chalk" overlay. An inked impression of the illustration is taken on both sides of a piece of paper, which is treated with a chalk preparation. The ink, according to its density, acts as a resist when the prepared paper is immersed in a solution of chloride of lime, the result being that a graduated surface in hardened chalk is obtained in exact relation to the tones contained in the plate, the solids being highest and the other tones correspondingly lower. When the etching is completed the paper is allowed to dry and then pasted an to the impression surface. Another method (a photo-mechanical one) is that of a thin piece of zinc etched in relief, with the tones in correct relation to each other.

When printing newspapers there is no time for making ready and when blocks are printed they are prepared mechanically by putting the printing surface on different planes. This is generally called "bumping" and is done by making a metal "interlay" which is forced into the back of the plate, with the result that the tones in the plate are slightly raised in accordance with the pressure required to give a correct impression, the solids being highest and the high lights lowest. This method of obtaining regulated pressure is likewise frequently resorted to in magazine printing and in a particular method of colour printing.

Duplicate Plates.—To secure economical and expeditious production of large editions it is necessary to print at the same time a number of duplicate plates identical with the original page of type or blocks. This is done by two processes, known as stereotyping and electrotyping.

Stereotyping.—Stereotyping is a process whereby duplicate plates of pages of type and relief printing blocks are obtained. This is done by taking a mould of the forme in plaster of paris or papier mâché, placing it in a "casting box" and pouring molten metal into the box and over the face of the mould.

Like others of the crafts included in the printing industry, there is some obscurity about the date of the invention of this process, but it can be safely dated as about the beginning of the 18th century (1700–25). It is attributed to William Ged, an Edinburgh goldsmith. It is believed that he made a mould by pouring gypsum (plaster of paris) over a page of type, and allowing it to set. In 1730 it is known that he went to Cambridge and made plates for a bible for the university, but it is said that these plates were spoiled by the printers and the process abandoned. Ged returned to Edinburgh in 1733, where he died in 1749. About 1779, Tilloch and Foulis seemed to have "re-invented" the process of stereotyping, since they took out patents in April 1784 for a method of making plates for printing. Earl Stanhope is likewise credited with having reintroduced Ged's process early in the 19th century. In America, stereotyping was introduced by David Bruce (1813) who served his apprenticeship in Edinburgh. The first book stereotyped in the United States was the Westminster Catechism, printed by John Watts in 1813.

The Plaster Process.—This method of making stereotype moulds is not now in general use, but certain firms in England employ it for duplicating half-tone plates, the usual method being to spread on a sheet of stout paper a coating of about $\frac{1}{8}$ in. of fine plaster of paris which, when about to set, is placed in contact with a forme (the imposed type matter or blocks), and subjected to pressure. When the plaster is set, the mould is dried by heat.

The Paper Process.—A plate by the papier mâché method is obtained by making a "flong" composed of blotting and tissue papers pasted together. The particular method of making a flong is largely an individual opinion of the stereotyper, but generally it is made up of a sheet of strong, coarse blotting called a backing sheet. On this a fine sheet of blotting is pasted, followed by three sheets of tissue one on top of the other. It being necessary to keep the flongs damp, they are placed between damp blankets. The type from which stereotypes are to be made is placed within bevelled type-high bearers and locked up in a strong chase, the bearers serving the purpose of protecting the edges of the type and facilitating the moulding.

Moulding.—The face of the forme is then carefully brushed over with oil, the open spaces between the lines being packed with card or pieces of thin metal to prevent the cracking of the flong when moulding. A piece of the damp flong about an inch larger all round than the surrounding bearers is placed face-downwards (tissue side) on to the forme and, by means of a stiff brush with a long handle, is beaten by hand evenly into the type until a uniform depth is obtained. The "blanks" (depressions) on the back of the flong are then filled in with felt or card and covered with a strong sheet (usually brown paper). Both the forme and the flong are then placed into a drying press, being kept under pressure until the flong is baked dry. The flong is then carefully removed from the iorme and becomes known as a matrix, or, as the stereotyper calls it, a "mat." This is then trimmed, and a long piece of brown paper, called a "tail," is pasted on to one end. The latter acts as a guide to lead the molten metal on to the face of the matrix when the plate is being cast.

Casting.—The matrix is then placed in a casting box which consists of two flat surfaces, the top part being hinged so that it may be thrown back in a perpendicular position. When the matrix is placed in the box it is held in position by two steel gauges which not only determine the thickness of the plate but prevent the molten metal running out at the bottom and sides of the casting box. When the matrices and gauges are correctly positioned the top is lowered and clamped to the lower surface. It is then tightly secured by means of a screw, the whole of the box being tilted into a perpendicular position. The mouth of the box is bevelled to allow the molten metal to be easily poured in. This is done by means of a ladle. A few moments are allowed for the metal to set. When the box is opened the gauges are removed and the matrix relieved from the newly cast plate, the casting operations being repeated from the same mould according to the number of stereo plates required. The plate has then to go through a series of finishing operations to put it in a proper condition for printing. The plates are mounted on a block of wood to bring the printing surface to type height.

Newspaper and Periodical Printing.—It is in newspaper and magazine production that stereotyping has made the greatest progress. Speed is essential in these particular branches of printing, and instead of a wet flong a special manufacture of dry flong is used, the matrix being moulded either by cylindrical pressure, usually known as a "mangle," or by means of a special press on the platen principle. The matrix is then dried and when thoroughly free from moisture is placed in a casting box which is half cylindrical in form and conforms to the diameter of the cylinder of the printing machine on which the plate is to be printed. Metal is then pumped direct from the metal pot into the casting box. When the plate is cool it is removed from the box in a semi-circular shape.

Automatic Casting.—The ever-increasing demand for speed and accuracy in the production of newspapers has brought into general use an ingenious machine called "the Autoplate." This is an American invention, capable of producing two plates in a minute in place of the one plate in three minutes, which was the usual time taken to cast a plate when the work was done by hand. On the Autoplate the matrix is fixed into clips and carried to the casting box, which, when closed, is flooded with molten metal pumped from a large metal pot. After a short "dwell," the casting box is opened and the plate removed from the matrix, the former being cooled by a system of water circulation. The plate is then mechanically bored, routed and finished, ready for the printing press, every operation being automatically controlled.

A later development in the automatic casting of stereotype plates is the invention of a Swiss engineer and is known as "the Winkler." In this instance, a "perfect plate" is produced without resorting to the usual finishing operations. The metal pot is directly connected with the casting box and the weight of the metal in the pot provides the necessary pressure to cast a large sized plate without leaving surplus metal to be trimmed off. This machine produces two finished plates per minute.

Electrotyping. — Electrotyping is an electrolytic method of producing a duplicate printing plate. In this process a mould from the original is taken in wax or prepared lead, on which a coating of copper is electrolytically deposited.

When Volta invented the galvanic battery in 1799, the foundation of the process was laid. About 1839, two Englishmen (Thomas Spencer, of Liverpool, and C. J. Jordan, of London) and Prof. Jacobi, of St. Petersburg, were experimenting with the making of plates by the science of electrometallurgy. About the same time, J. A. Adams, a wood-engraver in New York, is credited with having made an electrotype, which was used for printing in 1841; this process he also used for duplicating illustrations for Harper's family bible, which was issued between 1842 and 1844. To obtain a mould he used a soft metal. About 1840 Smee's battery was introduced, making the deposition of copper a commercial proposition. About this date graphite was first used to make the surface of a mould made in beeswax conductive. A French cabinetmaker, M. Victor Morel, took a prominent part in improving the process for printing purposes. He was ultimately engaged to install a foundry in the establishment of Cassell (London). Electrotyping owes a debt to this publishing and printing house for the experiments they made at great cost, with a view to perfecting the electrotyping process. Beeswax as a moulding medium was first used by them.

Moulding.—The first operation in electrotyping is to run melted beeswax on to a perfectly level metal plate called a "case." This must be such that it will withstand the great pressure exerted on the moulding press. When the wax has had time to "set" the surplus is trimmed from the edges with a knife, the case then being put into a machine which shaves the surface of the wax down to a standard height, making it of uniform thickness. The wax is usually flared over with a gas flame to give it a smooth surface, the case having to be kept at a regular temperature until the moulder is ready to take a mould on the wax from the original. This is a most important operation. Before moulding, the case and the forme are brushed over with fine graphite, care being taken to have all the loose particles of black-lead removed before being placed in contact with each other. They are then put in a press and subjected to the necessary pressure. The presses are of great strength and are usually operated by hydraulic methods. When the mould is made the case is taken to a workman called a "builder" who trims the wax which has spread over the edges of the case with a knife, at the same time reducing to an even height the wax standing in high relief through being forced into the lower parts of the forme which do not have to print. The mould then goes to the "black shop" where it is carefully and thoroughly dusted and polished with graphite. This is done either by hand or machine, the purpose being to make the surface conductive, as otherwise the copper shell would not grow upon the mould. A thin piece of copper is now inserted into the wax at the top end of the case. In the copper there are two holes through which hooks are placed to enable the case to be hung on the negative rod in the depositing bath.

Previous to placing the mould in the bath "stopping out" takes place. This is done by running a hot iron over the surface of the wax to within about an inch of the actual moulding on three sides of the mould, thus removing the graphite, and rendering the surface non-conductive. If this is not done a waste of copper will be entailed, but care has to be taken that the copper connection inserted into the wax comes within the area of conductivity, since otherwise it would not be possible to obtain a shell. The mould is thoroughly washed over with a strong force of water to remove all foreign matter from the surface. The modern tendency is to obtain moulds by the lead process. A piece of specially prepared lead is pressed into the original forme by a press of great power, It is claimed that a greater degree of accuracy and a finer reproduction is obtained by this method because changes of temperature do not affect lead in the same way as wax.

Deposition.—The mould is now ready for the depositing bath, although it sometimes is previously prepared by covering it with a solution of copper sulphate into which fine iron filings are sprinkled and the whole stirred with a soft camel's-hair brush, thus precipitating a fine film of copper on the mould. Extreme care has to be taken to see that all connections are clean.

The depositing equipment consists of a bath or tank which is lead lined. This is filled to within about 6 in. of the top with water into which is placed copper sulphate and a percentage of sulphuric acid. When completed the solution should have a density of about 20° Beaumé. When working, the solution is agitated to keep the concentration uniform while a regular temperature has to be maintained. The electrical current necessary for depositing is obtained from a dynamo situated in close proximity to the bath. The current is carried from the dynamo through a resistance board to the bath by two copper rods which run along the length of the tank, one being connected to the positive pole and the other to the negative pole of the dynamo. Flaced on the long copper rods are shorter copper rods running across the bath. On the short rod connected with the positive pole and suspended by means of hooks into the solution is a copper plate called an anode. The prepared mould is suspended in a similar manner on the other short rod connected with the negative pole with its face towards the anode.

The copper sulphate when dissolved in the water and sulphuric acid breaks up into two portions: — (I) a copper portion which is electrically positive, (2) a sulphate portion which is electrically negative. The positive copper portion is attracted to the negative pole, *i.e.*, the wax mould and is there deposited while the negative sulphate portion travels to the anode (which is positive) and there combines with the copper to yield more copper sulphate so that the concentration of the bath is kept more or less constant. In this way the Shell is grown until a sufficient thickness is obtained.

Nickel is deposited in a similar manner, but the bath is composed of a solution of nickel sulphate and ammonium chloride. Electrotypes are sometimes faced with a deposition of nickel to increase their durability and also to prevent certain chemical actions taking place which may occur when printing with coloured inks from a copper surface. The deposition of chromium is at the moment receiving much attention, it being one of the hardest metals and of great durability.

Backing.—When the deposition is complete the mould is taken from the bath and the shell removed by pouring hot water over it until the wax melts, the wax removed being melted and used again. Tbe next operation is the backing up of the copper shell which when it is released from the wax is trimmed round the edges and prepared for receiving about ¼ in. of molten metal. As the metal (which is composed of lead, tin and antimony) will not adhere to copper, the back of the shell has to be "fluxed." This is done by brushing it over with a soldering fluid and covering it with "tin foil," heat being applied until the two fuse together. The shell is then placed face downwards on to a pan or tray with flanges, and molten metal poured over the back and allowed to solidify.

When the backing is completed it is removed from the pan and the face cleaned free from wax. It is then trimmed and passed through a series of finishing operations such as roughing and planing the back, routing the "blanks," bevelling the plate and mounting it on wood or metal, great care having to be exercised in every detail to ensure that the printing face is not damaged.

It is by the process of electrotyping that the duplication of the highest grade of printing plates is undertaken and that the reproduction of the finest half-tones and colour plates in accurate register and with fidelity to the original is made possible.

A Swiss inventor has made "shells" by spraying metal on to a mould, using a special tool, called a "pistol," through which metal in the form of wire is automatically fed. This is fused by gas and spread in a state of sub-divisions by means of compressed air on to a matrix. Should this invention prove successful, the whole method of the duplication of printing plates may become revolutionized.

PRINTING MACHINES

The different styles of printing machines are too numerous to detail. In America they are called "presses" and in Great Britain (with the exception of proving presses) they are called "machines." They may, however, be classified as platens, automatics, cylinders and rotaries. Many firms adopt standard makes of machines to suit their requirements. The larger number of machines in general use print on one side of the sheet at a'time, but in offices where magazines and books are produced "perfecting" machines are employed. These machines have two type beds and two impression cylinders, thus when one side of the sheet is printed, it is mechanically reversed and the other side receives an impression from another set of plates or type. In colour printing there are machines for printing a number of colours before delivery of the sheets. The usual method in multi-colour printing, is to print two colours before the sheet is delivered. There are two impression cylinders and two beds each with its respective forme of type or blocks. When the sheet receives its first impression it is transferred to another cylinder and the second colour is superimposed on the first. Thus, in reproducing pictures in four colours the sheets go through the machine twice before the work is completed.

Colour printing has been attempted by placing machines "tandem wise," *i.e.,* end on to each other, the sheets being carried from one machine to another by means of a travelling conveyor and automatically placing the sheets into the lays on the respective machines. Four colours have been printed by this method. The most effective multi-colour printing method, however, is that done on rotary presses, where a sheet is taken by means of grippers round a large impression cylinder and receives an impression from four sets of plates, each inked with a different colour.

The Hand Press.—The hand press is of the platen type, *i.e.,* an impression is taken from the whole forme at the same moment by means of a flat surface. The hand press is mainly used for proof-pulling. Photo-engravers usually pull the proofs of their plates on such a press, and it is invariably used by amateurs and those running private presses for printing small editions.

On the hand press the type bed runs on two rails and is propelled under the platen by means of a rounce consisting of a handle and a pulley to which belts are attached; the ends of the belts are secured to the ends of the bed, and by turning the handle the bed is moved to and fro as the belts wind and unwind round the pulley; while to obtain the necessary pressure the platen is depressed by means of a lever, which when pulled forward acts upon a toggle joint (inclined pieces of metal) bringing it into a perpendicular position. This forces the platen down and presses the sheet on to the inked forme. On the bar being released the platen is lifted to its normal position by springs. Attached to the end of the type bed a hinged frame is fixed and covered with parchment or fine linen; this is called the "tympan," and it is on this that the making ready is fixed and the sheet of paper secured by means of "lays" (pins being usually used). The paper is kept from being soiled by a "frisket" (another hinged frame fixed on to the top of the tympan and covered with paper with parts cut out corresponding to the area of the type which has to be printed). The portions of paper remaining on the frisket keep the sheet from being marked by the furniture or chase which is liable to become inked when rolling a forme by hand. Two hundred and fifty impressions an hour are considered a good production on this type of press.

Platens. — The platen machines now used are generally known as "light" and "heavy" types. The terms explain the class of work for which they are intended.

Light platens are fast-running machines suitable for general job work, and are invariably actuated by what is known as the "clam shell" movement, which brings the platen on which the packing and "making-ready" are fastened, and on which the sheet to be printed is placed to guides, into a position where the sheet can be pressed against the forme, which is held in a perpendicular position. The forme is automatically inked by two or three rollers passing over the surface, the ink being fed by a roller from a "duct" on to a rotating "disc," which assists in the distribution of the ink before the inking rollers take up a supply from the disc. The platen and the bed are brought together by means of rods working on eccentrics. By moving a lever acting upon the eccentric the platen is thrown back, thus preventing the forme from printing by keeping the platen from reaching the forme. This style of machine can be worked by treadle, although motive power is now usually employed. The feeder stands in front of the machine, lifts a sheet of paper with his right hand, places it on to lays on the platen which rises and prints the sheet. On the return motion of the platen the feeder removes the printed sheet with his left hand and places it on a table, at the same time placing another sheet on to the platen ready for printing. The average size of a sheet printed on these machines is 10 in. by 15 in. and the speed is approximately 1,500 impressions per hour.

Heavy platens are of exceptional strength built to meet the exacting demands of high grade printing. The frame is cast in one solid piece and the platen is placed on finished rails. The movement of the platen is known as the "rocking-sliding" action due to the platen having on its underside semi-circular rails which work on the rails on the frame and is controlled by a cam known as a "swan's neck." The platen is connected with the back of the frame by two arms, the ends on the platen side working in eccentrics. As the machine works the platen is brought into action with a rocking motion until it reaches a perpendicular position and is then pulled into contact with the forme by a "slide up" or parallel movement.

A cylindrical inking system is *a* feature of this class of machine. The ink from the duct is fed on to a series of rollers, and oscillating metal drum. This ensures a better distribution and also enables a graduated supply of ink to be conveyed to the forme by four inking rollers. It is on this style of machine that the best half-tone and colour work is printed. The machines are built for large sheets (the usual size being about 22 by 14), and are fed and operated in the same way as light platens. The average production from a heavy platen is approximately about 1,000 impressions per hour.

Cylinders. — The term "cylinder" is given to those machines where the impression is obtained by means of a cylinder pressing a sheet of paper on to the face of a forme which is secured on a flat horizontal bed. The cylinder runs in bearings held by brackets and rotates as the bed moves to and fro beneath it. There are three different styles, (a) the drum cylinder, (b) the stop cylinder, (c) the two-revolution cylinder.

The drum cylinder, the successor to Koenig's machine (1811), is now but little used. The cylinder, continually revolving, makes one revolution for each impression. One half of the cylinder is lower to allow for the return of the type bed which has a short travel. When the cylinder completes its travel the gripper automatically opens and the printed sheet is transferred to a delivery apparatus known as the "flyers." The sheets as they are delivered are placed one on top of the other on a board at the rear of the machine. The inking equipment is what is usually known as the "pyramidical system," the ink duct being placed in front of the cylinder and the ink transferred to the forme by a system of rollers. The sheets are fed in from the top or crown of the cylinder. These machines are made in various sizes, and a production of between 2,000 and 3,000 is a fair average.

The stop cylinder is essentially an English machine, and commonly known as a "Wharfedale." In this class there is a small cylinder, about three quarters of the circumference being used for impression. On both ends of the cylinder pinions are geared into corresponding racks on each side of the type bed One of the gears on the cylinder "runs loose" and the other is fixed with the teeth on the under portion cut away. This allows for the return of the bed after the sheet has been printed. The carriage is supported by "bowls" running on rails and receives its reciprocating motion by

FLAT-BED CYLINDER PRESSES IN OPERATION

1. A large flat-bed cylinder printing press showing automatic feeder at one end and extension delivery at the other. The cylinder grips a sheet of paper upon every alternate revolution. On the first revolution the paper is carried around the cylinder. Simultaneously the bed of the press, in which the type matter is secured, moves to and fro and the paper is printed. By the second revolution of the cylinder the printed sheet is released from the cylinder and travels down the tapes towards the delivery table. 2. View from the driving-side of the same type of press as in fig. 1. The printed sheets are seen coming down the tapes towards the delivery table. The tapes carrying the printed sheets do not move continuously but only when the bed is moving from the delivery towards the feeding end. Consequently the sheet's progress is retarded, permitting it a longer interval to dry before reaching the delivery table where it will lie upon the sheet printed immediately before it. As the pile of printed sheets on the delivery table increases, the delivery table is lowered automatically. Then the piles of printed sheets are removed by means of trucks. To hasten drying many presses are equipped with drying apparatus which may be either gas or electric, over which each sheet passes in its journey towards the delivery table

means of racks fixed on the underside of the carriage geared into large wheels running on bearers and in gears. These are connected by a rod to another set of gear wheels which obtain their motion from small pinions keyed on to the driving shaft.

The cylinder is rotated by means of racks fixed on the side of the bed. As the carriage is propelled to and fro the gears on the cylinder turn the cylinder and in this way the sheet is printed and is usually fed by hand to lays at the base of the cylinder. When printed it is automatically removed to the delivery board by means of "flyers."

The inking system includes an ink trough, or "duct," situated at the back of the machine. From the duct a supply of ink is fed by means of rollers and placed on to a "slab" fixed to the end of the carriage. As the carriage moves to and fro, the ink on the slab is distributed by a group of rollers. The inking rollers (held in brackets behind the cylinder) get their supply of ink from the slab as it passes under them and by this means inking the printing surface. This type of machine is made in a large number of sizes and can run at anything from 1,000 to 2,000 impressions an hour.

The Vertical Job Press.—This press is an adaptation of the stop-cylinder principle to a small printing machine with automatic feeding device. The movement of the bed is on a vertical plane with the cylinder rotating over the forme but in an opposite direction to the bed.

This machine has been likened to a cylinder machine placed on its end but with the cylinder on which the sheet is placed travelling over the inked forme. The cylinder stops to enable the grippers to take a sheet from the feedboard. The sheets are automatically fed into lays and, after printing, are delivered at the back of the machine. It is a high speed machine capable of printing a sheet 19 in. by $13\frac{1}{2}$ in. and producing about 3,000 copies per hour.

There are on the market two or three well known machines that are adaptations of the stop-cylinder principle to a small press with automatic feeding device.

The two-revolution machine is now generally accepted as the standard type of cylinder printing machine for general work. It derives its name from the fact that the cylinder makes two revolutions for each sheet printed. During one revolution the sheet is printed, after which the cylinder rises clear of the forme to allow the return of the carriage to deliver the sheet on to the flyers. In this type of machine the cylinder is not actuated by the bed. Both cylinder and bed are driven independently but in unison with each other.

The inking mechanism is on the slab principle and the sheets are fed from the crown of the cylinder, a feature being the method of delivery of the printed sheet which is done in such a way that the newly printed work does not come into contact with anything that would be likely to smear the wet ink. This style of machine is capable of producing an average of about 2,000 copies per hour. One well-known machine is an adaptation of the two-revolution principle to a small press with automatic feeding attachment. The two-revolution make of machine is made with two cylinders, either for "perfecting," *i.e.,* printing both sides of the sheet, or for printing two colours before the sheet is delivered. These machines have two type beds, each with separate inking equipment. The demands for fine work, coupled with the need for speed have brought this style of machine to an extremely high degree of efficiency and accuracy.

A large number of small cylinder machines are built with the object of giving a large output, but quality and speed do not usually go together. Hand feeding of printing machines is rapidly being superseded by automatic feeding. There are two distinct types of machines for this purpose. One is known as a "pile feeder" where a large stack of paper is placed in a contrivance which automatically rises as the sheets are removed from the top by means of suction, placed on the feed board, and carried to the lays on to the printing machine. In the event of the sheet not reaching the lays, the machine stops. The other type is known as the "continuous feeder." In this case the sheets are "put up" a few at a time and while the printing machine is running they are "combed out" and mechanically controlled until they reach the lays, and should they not do so, the machine automatically stops.

Rotaries.—In this class of machine the impression is obtained by means of two cylinders, one of which carries the plate and the other the necessary packing, the paper passing between the two. The plates have to be curved to suit the cylinders and are secured by means of clamps. Where only one size of plate is printed on the machine, as in newspapers, two clamps are fixtures and the other two are movable in order to provide for the secure locking up of the plates. Where plates of various sizes are printed the plate cylinder is spirally grooved, into which movable clamps are fitted to suit the size of the plates to be printed.

There are two types of rotary machine: one of which prints single sheets (on one side), and the other where the paper is fed from a reel, printed on both sides and folded before delivery.

The inking mechanism on a rotary consists of an ink duct, a distributing drum, and a series of rollers to carry the ink from the drum to the rollers which ink the plates. The speed of a sheet-fed rotary being beyond the capacity of hand-feeding, makes automatic feeding an essential. On the reel-fed, or, as it is sometimes called, the web-fed perfecting rotary press, the travel of the paper through the machine and the folding of the pages are entirely automatic. Both sheet-ied and reei-fed rotaries are used for fine colour printing from half-tone plates.

The most effective multi-colour printing machines are those which consist of a large impression cylinder with four separate plate cylinders each with its own mechanism for inking. The plate cylinders are half the circumference of the impression cylinders and two sheets may be printed (on one side) at each revolution of the cylinder. The sheet is taken from the feed board by means of grippers attached to the cylinder, is carried under the first plate cylinder (where a yellow impression is printed on the sheet), then under the second set of plates (where a red impression is made on the top of the yellow impression), the sheet passing on to the two remaining plate cylinders (where blue and black impressions respectively are superimposed on the top of the previous colours), and the sheet is delivered with the picture completed in its full range of colours and tints. Electrotype plates are used for printing, these having to be curved to suit the circumference of the plate cylinders, it being impossible to use "overlays" on the impression cylinder. The impressions from the four sets of plates take place on the same section of the cylinder. As each set of plates requires a different "make ready," the plates are "bumped" (the surface graded in height according to the tones in the plate).

In America this is accomplished by the McKee process, in which the plate is "made ready" and the make-ready impressed into its back through hydraulic pressure. The back of the plate is then shaved to proper thickness and the plate curved to fit the rotary cylinder.

The rapid printing of the McKee four-colour machines made it necessary to devise a method for quickly drying the sheets to prevent offset or smudge. This was at first accomplished by interleaving the freshly printed sheets with specially prepared manilla paper. The device known as travelling offset prevents offsetting upon the impression cylinders of wet perfecting rotaries. It winds and unwinds (working backward and forward) around a reel which engages the second impression cylinder. This has given way to other methods, such as the spraying of a coat of powdered paraffin over the printed surface, so thin as to be imperceptible, but sufficient to prevent offsetting of the sheets.

Special inks are required for printing wet colours on the top of each other. The results cannot be said to equal those obtained when sufficient time is allowed for each colour to "set" before printing the following colour.

In newspaper production the reel-fed rotary has been brought to a high degree of efficiency. Although a newspaper machine is of great size and seems highly complicated, really it is simple. It comprises a number of units, each of which "perfects" a number of pages. If the pages exceed the number of plates which can be printed on a single unit, another unit or units can be linked up together, and the printed "webs" come to a point in proper sequence where they are folded and cut before delivery.

There is usually a blank space left on one or more pages of a newspaper for the purpose of publishing news which has arrived after the paper has gone to press. This late news is printed into the blank spaces by a contrivance called a "fudge box" which is circular in form and into which are secured linotype slugs. The "fudge" is fastened on to an auxiliary cylinder equipped with inking mechanism. This works in unison with one of the main impression cylinders and as the paper is printed an impression of the lines in the fudge box is made in the space left for the purpose. The "edition seals" and lines printed in colour in newspapers are produced by the same means.

There is in practice a very wide limit in the planning of a newspaper machine. Units can be arranged in a straight line or placed one on top of the other. The capacity is determined by the number of folders which it is possible to fit on the machine. Each of these can turn out 45,000 folded copies per hour. Not infrequently the paper is run through the machine at an approximate rate of 54 m. per hour and it is possible to join up new reels and change the fudge box without stopping the machine. (See BOOK; PRINTING TYPE; COLOUR PRINTING; PHOTO-ENGRAVING; also LITHOGRAPHY.)

PRINTING TYPE. At the time of the invention of printing, European scripts were changing. The ideas of the artistic and literary movement of the 15th century, known as the Renaissance, were drawn from the classics of old Rome, and as many of the texts were preserved in the beautiful caroline hand, scribes learnt to copy the letters as well as the text of the original. The resulting "neo-caroline" hand was probably first seen at Florence, where Niccolò Niccoli, a celebrated humanist, directed a school of copyists about 1425 and trained scribes to write a very neat, round letter, which was in fact a revised and, in certain respects, more beautiful version of the old 9th century hand. The new letter won a great success in literary circles, and by the middle of the 15th century a company of scholars, artists and nobles, passionately interested in the culture of pre-Christian civilization, enthusiastically practised it. They thought the old heavy black-letter most objectionable, and invented for it the nickname "gothic" (*i.e.*, barbarous) by which it has been known ever since. Thus the neo-caroline letter, or "littera antiqua" as it was then called, became accepted for secular manuscripts. Moreover, just as there had been for centuries a formal and an informal "gothic," the modern-antique writing was upright for formal text and sloping for informal current use. These are the originals of our so-called "roman" and "italic" types.

By the time of Gutenberg, therefore, the scripts in use in Europe consisted of the old so-called "gothic," and the new so-called "humanistic." The former showed national peculiarities according as it was handled by German, French or English scribes, but the "humanistic" was for some time confined to Italy. This, then, was the calligraphic situation when in the north men were straining their ingenuity to invent some form of multiplying texts by means of impressions from movable types.

Leaving it for specialists to determine the priority of invention as between the Dutch "Costeriana" and productions of Johann Gutenberg of Mainz, we may note that printing type began with that pointed black-letter design to which the scribes, secular and monastic, had long accustomed the librarians and readers of Europe. There can be no doubt that Gutenberg's pointed text is a magnificent type, not perhaps as fine as others of later date, but well cut, harmonious and very pleasantly conscious of its discipline and integrity. His informal Italianate bookish type (of the Indulgence) is also successful.

The Churches and the Printer.—The current demand for ecclesiastical works produced a number of exceedingly handsome founts of formal pointed text. Inevitably the Church's permanent need of books made her the early printer's best customer, and the finest types were cut for use in mass-books, psalters, breviaries, rituals, etc.

The uncompromising joints of typical German black-letter are rounded in early Italian printing, and angles give place to curves. Rounded scripts were characteristic of Italian book-making in the two centuries preceding the introduction of printing into Italy by Conrad Sweynheim and Arnold Pannartz at the Benedictine monastery of Subiaco near Rome in 1464. These two Germans used a type based upon the common round bookhand neither "gothic" nor "humanistic." Other Germans migrated south, coming through what is now the Austrian Tyrol, followed the road to Venice, and printed in "gothic" letters of the rounded kind. Four years after the printing at Subiaco of Sweynheim and Pannartz' *Lactantius* in *fere humanistica* type there was cut in Venice a letter which may positively be described as a pure humanistic letter—or, in printers' language, a pure *roman*. The design was first used in Italian printing in 1469 by two Germans who had come to Venice from Speier in the Rhineland, and is so well made that it presents a modern appearance to our eyes. In fact, with Johann and Wendelin da Spira we come into contact with the modern book, although the title-page and other preliminaries have yet to develop. It must be noted, however, that a good roman was still earlier used in Germany by Adolph Rusch of Strassburg, in a *Durandus* issued not later than 1464. Had this example been followed, Germany might have followed. up the "gothic" triumphs of Gutenberg, Sensenschmidt and Stuchs with no less notable roman founts. But Rusch's isolated and barren achievement lay outside that main line of development which, beginning with the da Spira fount, held within it the promise of a brilliant future which was to place Venice above any other printing centre. The da Spira letter was surpassed the next year by the design of the Frenchman, Nicholas Jenson. This is an even more distinguished type, so elegant and readable that the authorities in typography have pronounced it to be the most perfect type ever cut. Jenson also used more than one gothic letter whose technique rivalled that of his famous roman, and which found great contemporary favour. His roman was much copied in Italy and 25 years passed before the appearance of any rival which might be regarded as having the slightest right to dispute its primacy.

The Aldine Press, 1495.—But in 1495 there was founded in Venice a press whose reputation for scholarship was destined to become unique. Aldus Manutius Romanus was both a scholar and a business man, but it does not appear that he took great interest in the technical problems of printing. His passion was for pure scholarship, and he devoted himself to the printing of inedited Greek and Latin texts. Some diversity of opinion exists with regard to Aldus's merit as a typographer. The late Robert Proctor says roundly that his founts "whether Greek, Roman or Italic are in each case lamentably devoid of any beauty of form other than that conferred on them by good cutting." Proctor was upset by Aldus's patronage of cursive Greek hands as type-models, so full of unnecessary flourishes and ligatures; and the unfortunate effect of Aldus's prestige was to perpetuate a sloped Greek calligraphic lower-case. But it is more than doubtful whether the romans of Aldus can reasonably be lumped in with the Greek and Italic as equally bad in design. The contention that such beauty as they have is that conferred upon them by good cutting is also a little wide of the mark, in view of the fact that none of the Aldine types possesses anything like the technical excellence of Jenson's. It may also be suggested that the design of one of the Aldine romans equals Jenson's in point of design, but a liberally linked page of Jenson's shows that the capitals are unnecessarily assortive.

The press began with an *Erotemata* which Constantinus Lascaris brought out in March, 1495, the capitals of which fount reappear later in the year in conjunction with a lower-case which is of prime historical importance. The complete fount first appears as a short tract, *De Aetna,* by one of the leading Italian humanists, Pietro Bembo, afterwards Cardinal. The *Erotemata* capitals, though well designed, are too roughly cut to combine agreeably with the very beautiful lower-case letters. The type of the *De Aetna* represents, as it were, only a "first state." Aldus retained it for the *Diario* of Alexander Benedictus in 1496. In June of the next year he issued the work of a local physician, Nicholaus Leonicenus, entitled *De Epidemia,* which was set in a letter of similar design but on a smaller body. In the famous *Hypnerotomachia Poliphili* the same face appears in a lighter, more graceful and more harmonious cutting. It is not claimed that the final form of this is perfect: at least the "L" is inferior in design to that of Jenson, and the "G" almost ugly, but the type does present a very distinguished appearance, which would have gained had a first-class pressman been entrusted with the printing.

The type of the *Polifilo* made another appearance in the next year (1500) in the preliminaries of a folio Politian of 500 or more pages composed in the type of the Bembo. In the preliminaries referred to, a commendatory epistle is composed in the "Bembo" lower-case, joined to a new and much larger series of capitals. The fact seems to be—not exactly as Proctor would have it, that Aldus was a "man of phenomenal bad taste for his time"—but that his interest was rather less in typography than in scholarship. Before passing to the Aldine Italic, we may point out that the type of Bembo's *De Aetna* is the origin of that style of letter known to English printers as "old face." We have only to compare the founts of Jenson, Aldus, Garamond and Caslon to see that the forms of our present letters derive immediately from Aldus through Garamond, and that the latter did not copy from Jenson.

Italic.—In 1500, Aldus' office was cutting the sloping character described by himself as *Chancery,* and which we have grown accustomed to call *italic.* It is not a very satisfactory letter from the point of view of design, or indeed in its suitability as type; no fewer than 68 ligatures have been counted in the early volumes of the library of classics for which Aldus specified this type. It was engraved by the same Francesco (Griffi) da Bologna who cut the type of the De *Aetna* and the *Polifilo.* Owing to the warm welcome that greeted the low prices and novelty of the Aldine classics, the type in which they were set made an undeserved reputation, with the result that, though Aldus did what he could to protect it, the design was copied in many other Italian printing centres and in England, the Netherlands and France. Its artistic merit is very slight, but it "takes in" extremely economically, a supreme quality in the series for which Aldus employed it. The calligraphic deficiencies of the Aldine italic are apparent when it is placed side by side with that designed in Rome by one of the scribes employed in the Vatican Chancery, Ludovico Arrighi, alias Vicentino, and cut by the goldsmith, Bartholomeo dei Rotelli of Perugia. The fame of the Aldine italic arises from priority in time, but Arrighi's is infinitely better in design, more graceful, more legible, and more permanent in its influence. The form of italic which we employ as a companion to our "old-faces," descends from Arrighi. The extent of the use of "Italic" types cut on the Arrighi model in Italy, prepares us for its utilization by the greatest printers of Paris, Robert Estienne and Simon de Colines. A comparison of Arrighi's italic with that of Colines' shows that the French fount is directly indebted to Arrighi's design.

"Old Face."—Garamond, obviously had before him the ***De Aetna*** or the *Polifilo* as models for his roman, and Arrighi for the italic; and craftsmen of his generation merged these two originally independent founts into two mutually dependent constituents. Thus for France and England *roman* and *italic* were twin halves of one fount. These French designs are the originals of our "old faces'—the design which came into English printing with John Day, and which, by the medium of Voskens, van Dyck, and Caslon, is characteristic of our work until the coming of Baskerville and the moderns. Whether or not the first "Garamond" letter was designed by himself or in association with Geoffrey Tory cannot be said, but it was certainly sponsored by very high authority. The fine folio Bible of Robert Estienne (1532), which must have taken some three or four years in going through the press, contains probably the finest use of this letter.

The "Garamond" type steadily acquired influence, and in a short time actively affected the typography of Venice and Florence. Indeed, by the middle of the 16th century the Garamond letter had succeeded in deposing the Venetian design which, as we have seen, was originated by the da Spiras and Jenson. It is not easy to account for the progress of the Garamond design in Italy. Guillaume Le BC, Garamond's pupil, was in Venice between 1546 and 1550, and doubtless supplied a certain quantity of French type to Venetian printers; but it remains curious that the merits of the Jenson design should have been overlooked in favour of the work of a newcomer. It was another Frenchman who cut punches for a new printing office attached to the Holy See: Robert Granjon went to Rome at the invitation of Gregory XIII., and remained there several years, cutting numerous orientals and romans on the Garamond model. The italic is generally of the flowing Arrighi design. Garamond made one experiment, and perhaps more, with types which deliberately reproduced the Aldine italic, and himself printed three or four books about 1545 in this face. It would appear that the taste of the day approved his effort.

Italic, in fact, from this time, tends to be reserved for preliminary matter, citation and emphasis. It should be observed, too, that by 1540 the upper case of italic founts is sloped, whereas Arrighi's and Estienne's texts were invariably worked with upright capitals.

From the middle until the end of the 16th century there was little change in type-design. The great successes in Italian printing were won between 1470 and 1520, and in French between 1525 and 1550 Christophe Plantin of Antwerp, working with types of Garamond and Granjon, produced a number of handsome works; and, though the artistry of this printer has perhaps been overrated, his Polyglot Bible is a notable achievement alike in scholarship and in typography. He contributed nothing to roman or italic type design. The range of type varieties characteristic of incunabula narrowed with the opening of the 16th century, typographical supremacy passed to Paris, and the Garamond design was stabilized for 150 years. The 17th century did little beyond reproducing these and Estienne's types, generally with some loss of beauty—an exception being the types of Christopher van Dyck, a freelance punch-cutter in Amsterdam who worked for several foundries, cutting types certainly less important to the historian than those of Gararnond, but obviously more beautiful—not the only instance of types designed after the model of a historic letter being superior in design to their prototype. Thus, Garamond's design was improved upon, first by Robert Granjon, and next by Christopher van Dyck.

The reputation of Dutch types is intimately connected with van Dyck, largely because his types were used by the Elzevirs. The editions of the famous Leyden firm have not the interest of the work of the preceding century, but their types are undeniably finer in design and technique. Other engravers, such as Bartholomew Voskens and his brother Dirck, contributed to the renown of Dutch typefounding, while English craftsmanship, owing to repressive legislation scarcely existed. Books were commended by advertising that they were printed in Dutch letter. Moxon thought van Dyck's the best of all, and made a fount of similar design. When in 1660 Bishop Fell took in hand the task of procuring types for the use of the press of Oxford university he immediately turned to Holland. His agent, Thomas Marshall, procured punches and matrices from the Voskens, but unfortunately he secured none of van Dyck's. The 18th century brings us to the types called "modern" of which Bodoni is the most notable protagonist. Giambattista Bodoni of Parma was an innovator, but he did not, as often assumed, create the "modern" serif, for the same thin, flat serif is found in codices written 300 years before Bodoni was born. Some of the letters modelled upon manuscripts of this time — those of da Lignamine — themselves possess flat, unbracketed serifs, though they are heavier in weight. The thin, flat serif is to be seen in the copybooks of several professional Venetian writing-masters; for instance, the *lettera antiqua tonda*, drawn by G. A. Tagliente, exhibits it; as do other Italian and French writing-books which we need not specify. The "modern" serif is, indeed, only a forgotten renaissance trick contemporary with the short, stubby and bracketed serif which we find in the Bembo type.

Romain du Roi.—When that most important printing institution, the Imprimerie Royale, was established in the Louvre by Richelieu in 1640, its sole types were cuttings and re-cuttings of the "old-face" originals of Garamond, Le BC, and Granjon. The next sovereign, however, Louis XIV., approved the creation of an entirely new set of roman and italic types to be absolutely reserved to the office of the Louvre. The project was sanctioned in 1692, and a commission of experts was appointed by the Académie Royale des Sciences to study the formation of perfect roman letter. The chairman of the commission, one Jaugeon, embodied the findings in a bulky report, and a set of elaborate geometric designs in which the traditional roman forms were once more disciplined by rule and compass. Jaugeon's letters were drawn upon a field subdivided into no fewer than 2,304 small squares. The royal road to a perfect roman letter was in theory a mathematical one, but when Philippe Grandjean came to cut the punches, he elected to work with a considerable degree of independence, preferring the guidance of his own trained eye. The *romain* du *roi Louis XIV.*, as the new letter was called, when compared with Garamond's roman shows a sharper contrast between its thick and thin strokes, it is more regular, and better in its justification. The most important general differences are in respect to a certain condensation of form and the novelty of serif. For the first time the thin, flat, unbracketed variety appears in a type-form. In the top of the roman lower-case 'b', 'd', 'i', 'j', 'k', 'l', and 'h' the new feature extended both sides.

An interesting feature of Grandjean's italic is his departure from the ancient old-face form of the lower-case 'b' which is derived, of course, from that modification of roman square capital writing known as uncial. It is, perhaps, not so generally realized that the hooped forms of Garamond's and Caslon's italic lower-case "h" go back to a fourth century original, while the other form is no older than Louis XIV.'s time.

The *romain du roi* inevitably exercised a considerable influence. The enterprise of trade type-founders, nevertheless, was obstructed by a decree forbidding any counterfeiting. Fournier-le-jeune's way out was to narrow the proportions of his letter and slightly to modify the serifs. His italic modifications can be seen in the fine oblong folio specimen published 1742. Though the crown monopoly of the *romain* du *roi* was safeguarded by the enactment of penalties against its reproduction by trade type-founders, the advantage of a narrow-bodied letter was quickly observed, and Grandjean's methods were followed by Dutch founders.

J. M. Fleischman cut a new series for the Enschedés at Haarlem, 1730–68; some 20 of his alphabets were of an elongated character, with thin hair lines and thin serifs. Fournier copied these, as he admits in his description "Goût Hollandois." When Bodoni commenced to print he used these and other of Fournier's letters and ornaments. Later he made copies of his own, and later still cut new varieties in which the contrast between the thicks and thins was accentuated. There is much to be learnt from Bodoni's careful presswork and sense of style in typography, and his influence was rightly considerable on the continent and in England towards the end of the 18th century. At the same time, François Ambroise Didot, the founder of the great dynasty of printers, publishers and paper-makers, was experimenting with types cut in the style of Grandjean and of Louis Luce, cutter at the Imprimerie Royale of the first of all condensed letters.

England, slow in following new fashions, was using the founts of Caslon and Baskerville. The types which William Caslon I. cut between 1720 and 1726 were, and are, very fine renderings of the "old-face" design which came down from Aldus. The sizes—english, pica and brevier — are brilliantly cut. Certain of the larger bodies cut by William Caslon II. are at least agreeable, though every size above two-line pica contains more than one ill-formed sort. Caslon undeniably made a very handsome letter out of the Dutch models, which he manifestly had before him; but credit for initiative must go to John Baskerville — his roman is an open, legible and expressive letter pcssessing a great deal of individuality though the wiry, thin and pinched italic which he drew for companion use is less successful.

The refinement and precision of the Baskerville type were not much valued in England during his lifetime. Bodoni and the Didots, however, admired his presswork and paper; later the influence of Baskerville's forms was considerable in Britain, as witness the types of Fry and Wilson. One of the Caslons, also, who split away from the parent firm, made a letter similar to Baskerville's. These types are round and, though sharing sharp contrasts as between their thicks and thins, remain in the "old-face" tradition. Nevertheless, their nicety and precision of cut reflect the "modern" invention of Grandjean. In making a comparison of the merits of Caslon and Baskerville, perhaps we may summarize by saying that while Baskerville shows greater originality and personality in design than does Caslon, the latter was undoubtedly a more expert engraver. Baskerville's "modernity" lay in his printing methods rather than in his typefounding technique.

The first of the Didots who took typography as a career was François Ambroise Didot (1730–1804) who directed the French national printing office for a time, and to whom the continent of Europe owes its authoritative point system. His light-faces were engraved by the punch-cutter Waflard and take the original design of Grandjean a step farther than Fournier or Bodoni. His sons and their successors drew and redrew upon the same models, first increasing their brittle and attenuated aspect, next fattening and condensing them.

English Designs. — English modern-faces are to be early found in the books of William Bulmer (1758–1830) of the Shakespeare Press. Here is to be found a close-set, narrow-bodied letter with fine hair-lines. It possesses the curly-tailed capital "R" which never occurs in the genuine old-faces and which Grandjean, Baskerville and Bodoni preferred. These types were well cut by William Martin, and after Bulmer came many other modern-faces, all possessing extremely thin hair-lines. Ever since the days of Caxton, England had depended upon foreign types, Netherlandish or French. The first original English design of any kind to make an impression abroad was Thorne's "fat grotesque" — produced during 1800–03. It was a distinct novelty, and was taken up with great enthusiasm in France, Germany and Holland. The Imprimerie Nationale itself in 1840 commissioned Thorne to cut a like face. Bodoni fattened his large sizes, and the Paris trade was supplied with a *gras* instead of a *maigre* Didot.

After Thorne (1803) came a heterogeneous swarm of fat and lean faces. The unexampled successes of English industrialism staggered the world, and the continent, while cursing British "hypocrisy," bought British machines and copied British types. Consequently from 1820 to 1860 all printing was in a sorry condition, though, by way of exception, the London publisher, William Pickering, and his printers, the Whittinghams, produced some comely books in "modern" and "old-face" types.

But the return to decent standards was slow. Abroad, the work of a scholar-printer and publisher at Lyons is to be noted. In 1846 Louis Perrin cut the first types designed since the Renaissance upon the model of Latin inscriptions — plentiful in an ancient Roman foundation, like Lyons (Lugdunum). The lower-case roman resembles Caslon's, but the italic, deriving from Grandjean and Fournier, gains elegance by reason of Perrin's inclusion of swash capitals. Perrin's handsome printing in these *Caractères Augus-*

taux, gave the types an important influence in France. They were copied by Beaudoire (Paris), who called them by the arbitrary and confusing name "Elzevir," since applied by continental convention to all "old-faces." Beaudoire's capitals, imported by the Chiswick Press in the 'sixties while that illustrious establishment was managed by Whittingham and Wilkins, are to-day in use at their printing works in Tooks Court under the name "Lyons capitals," a curious survival unfair to Perrin.

William Morris.—The Oxford Movement in the Church of England, and Scott's novels, mediaevalism and the pre-Raphaelites, opened the way for William Morris, poet and craftsman. He had secured the printing of his *Roots of the Mountains* (1889) in an old Chiswick Press type cut by William Howard in 1858, but he now created an entirely new formula of the printed book. 1891 saw the first Kelmscott book, *The Story of the Glittering Plain.* Morris, as a typographer at least, was a mediaevalist; he admired the early printing and, naturally, his types were archaistic; he thought Jenson's the finest roman and drew a fount therefrom, the *Golden* type. The *Troy* type and the *Chaucer* came later. There followed similar experiments by others: Mr. Charles Ricketts made the *Vale* with its individualistic 'g'. 'e', 'b', 'y'. and obtrusive capitals. The *King's* fount, also cut for the Vale Press, is a strongly personal design. Mr. Ashbee's *Endeavour* (1901) is perhaps the most extreme of these idiosyncratic founts. Mr. Lucien Pissaro's *Brook* type is less eccentric than sophisticated, but serves to throw into welcome relief the elegance and simplicity of the *Doves* type designed on the basis of Jenson by Cobden-Sanderson and Emery Walker. Another fine letter, but too closely following an ancient model, is Mr. C. H. St. John Hornby's *Ashendene* type (1902) which reproduces the *fere-kzcmanistica* of Sweynheim and Pannartz (Rome, 1465). Italian models were also followed by Herbert P. Horne, who cut three types between 1905 and 1909. The first, the *Montallegro,* was cut for Mr. Updike and first used in the *Life of Michelangelo Buonarroti* by Condivi (1905). The *Florence* type, cut for Chatto and Windus, came in 1909, as also the *Riccardi* for the Medici Society. All three types are agreeable and restful in composition. The capitals are better in design than the lower-case. In all the latter, the poor forms are the 'a', 'e', 'y', always difficult letters to draw. Not one of these experimenters made an italic, and an unbreakably conservative mood seems to have settled upon the English private presses after the insurgent individualism of the *Vale* and *Endeavour* types.

In the United States a similar reaction is to be noticed. Mr. Bruce Rogers, who made a new type for an edition of Montaigne's "Essays" published by Houghton, Mifflin of Boston (1903) succeeded in constructing a readable and dignified letter, though even here an unhappy lower-case 'e' may be detected. The capital 'R' varies from the Jenson model (accepted as the basis of the fount), and not for the better. There can be no two opinions, however, about the same artist's *Centaur* (1916), again based upon Jenson but improving at many points upon the Venetian model, notably in the capital 'M.'

German printing, mean and even horrible since the extinction of the Frankfurt school headed by Egenolff, improved with Unger. His quasi-Didot *frakturs,* however, depended for their effect upon better presswork than they ever received. The roman (antiqua) acquired influence when used by Karl Tauchnitz in 1825. Ever since then the *fraktur* and *schwabacher* types have been slowly undermined by the *antiqua* and *kursiv* until at the present time there is used perhaps more roman than *jraktur. A* number of the modern German roman types are excessively personal—witness the fount designed by the architect Eckmann for the Klingspor foundry. It is a fair example of the kind of type which the intelligent German put out before the introduction to Germany in 1905 of the teaching of the English calligrapher, Edward Johnston. The fine school of calligraphers which arose from this source greatly influenced all those- crafts in which lettering plays any part; and the German typefounders, led by the house of Klingspor, quickly applied the skill of several masters of the new calligraphy to the designing of new roman and gothic founts. Peter Behrens, Rudolf Koch and F. H. Ehmcke are perhaps the best-known of these artists. Their types have raised the typography of German private presses from a low to a very high place in the esteem of collectors; but for the bulk of German printed books, types drawn from older English and French models prevail, varied by the occasional use of the more conservative of the new founts. Unlike ourselves, the Germans less strenuously resist experiment in books: it is perhaps for this reason that the English typefounders have ignored the new calligraphical movement. Certain it is that the English dislike novelty in typography, and many years must elapse before any British design influences the continent of Europe. It was not always so. About 1802 certain Scottish printers originated the crisply cut modern face now known by the name of *Scotch Ronzan.* The type remains in constant employment in Great Britain, and to an even greater extent in the United States. In 1850 Miller and Richard evolved their *Revived old-style,* which is not a revival, but an insipid original design. It found immediate favour in England, and is widely used to-day at home, in Scandinavia, Germany and the United States. These two Scottish faces represent the most popular designs in the English-speaking world. They are book types. (S. Mo)

Advertising Type.—The rise of advertising gave a new opportunity to type designers, and it was to be expected that America. the home of advertising, would take full advantage of it. The most widely used face of the first quarter of the 20th century was the *Cheltenham* designed by Goodhue and Kimball in 1902. With its success, initiative in type design passed to the United States, and with the corps of fine designs made by the exceptionally able American designer, Mr. F. W. Goudy, and the justly appreciated *Cloister* (Jenson) and *Garamond* of the American Typefounders' Company, the English foundries become of slight consequence. The World War effectively postponed the production of new English designs and the following years witnessed advertising types imported in the main from America. Germany also led in this department for several years, and German typefounders, profiting by the liveliness of the intelligence of their designers, concentrated upon the production of grotesque and decorative advertising and publicity faces.

In America the Mergenthaler Linotype company, the Monotype company, the Intertype corporation, the Ludlow company and the various foundries have issued a profusion of type faces for advertising purposes, many of true artistic merit. Fashion in types is almost as cyclical as that in women's dress. For several years, especially after 1930, the various sans-serif faces *(Kabel, Vogue, Futura, Tempo,* etc.) were much in demand for their simplicity and modernistic appearance. Later *Girder* and *Stymie,* faces with pronounced serifs, rigidly straight, and with no variation in shading, came into prominence for both display and text, as did the script types such as *Trafton.* The Gothic faces and *Ultra Bodoni,* a heavy type based somewhat on the original *Bodoni,* are perennial favourites with advertisers. Soon or late, however, most designers of advertising return to the historic founts or modifications of them, especially *Caslon, Garamond, Baskerville, Scotch Roman,* and *Bodoni.* Among faces of late design are *Caledonia* (Dwiggins) and *Fairfield* (Ruzicka). *See* also TYPOGRAPHY. (X.)

BIBLIOGRAPHY.—Specimens of types in current use will be found in the catalogues issued by the typefounders and type-setting machine makers; specimens of superseded founts are conveniently given in the works of Updike and De Vinne. The following works should also be consulted: T. L. De Vinne, *Plain Printing Types (N.Y.,* 1900); Ch. Enschedé, *Fonderies de Caractbres dans les Pays-Bas* (Haarlem, 1908); P. S. Fournier, *Manuel Typographique* (2 vols., Paris, 1764–66); Edward Rowe Mores, *Dissertation upon Eng. Typographical Founders and Founderies* (1778; new ed., D. B. Updike, 1924); Stanley Morison, *On Type Faces* (1923); Talbot Baines Reed, *Hist. of the Old Eng. Letter-Founders* (1887; new ed., A. E. Johnson and Stanley Morison, 2 vols., 1929); Albrecht Seeman, *Handbuch der Schrzftarten* (Leipzig, 1926); D. B. Updike, *Printing Types* (2 vols., Cambridge, U.S.A., 1922); E. Wetzig, *Ausgewahlte Druckschriften* (Leipzig, 1920); H. H. Sparling, *The Kelmscott Press and William Morris* (1924). (S. Mo.)

HAND-PRESSES USED IN GRAPHIC ARTS

History.—In the beginning the only machines used by the graphic arts were hand-presses. These machines were used before either steam or electricity were thought of as a means of providing power. Of course, in modern times, the large machines used could not be operated by human power so it was necessary to invent something that was more powerful than the hand of man. The presses driven by steam and electricity were not expected to improve the quality of the work produced—nor have they improved it—but they were made to increase the quantity; hence, the power press.

When Alois Senefelder (1771–1834) invented lithography about the end of the 18th century, he was compelled to build some kind of a machine that would enable him to reproduce on paper what he had engraved or written on the limestone which he had used as a base for his work of printing music. He proceeded to make a machine which was called the pole-and-beam press, which, as the name indicates, was made of poles and beams. This first press that Senefelder made is said to have been completed during the year 1796. The pressure was applied by the workman standing on a treadle, his weight supplying the needed pressure—and the larger the pressman the better the impression he produced.

The pole-and-beam press was not an unqualified success and was soon discarded by the lithographic inventor and an entirely different machine was built in 1797. The new machine was called the "star press" and was patented in 1801, and, while very crude, was used by Senefelder for a number of years. Some of the parts of this press are followed in some of the hand-presses in use to-day. It was an improvement on the pole-and-beam press because of the use of a much larger stone. For many years this press was the "standard model in the lithographing business.

There is no record of a lithographic hand-press being built between the years 1798 and 1820, but during the last-named year a machine was turned out in England called "the English hand-press." This press and other similar ones were used until the power machines came into use in 1865. After the introduction of this power-press, which was called the "steam press," the hand-press was practically discarded except for pulling proofs and working off extremely short runs. While the "steam press" has been adopted all over the world as the standard lithographic machine, it is still maintained by many lithographers that better and more perfect work can be turned out by the hand-press.

The pressure that prints the image from the stone to the paper by the hand-press is entirely different from the pressure of any other printing machine in use. It is a scraping motion. After the paper is placed on the stone a piece of hard wood is drawn across the form to be printed, with sufficient pressure to make the paper take the ink. All other lithographic presses and type presses print by pressing down on the paper by some direct means.

About 1825 a hand-press was made of iron and its operation was entirely different from any previous ones. It had a roller made of brass and operated by a handle which caused a travelling carriage, on which the stone was placed, to run under a frame to which was attached the scraper. The pressure was regulated from beneath the carriage, which was forced up by a screw to give the correct amount of impression when the scraper was applied. After the print was made the pressure was released and the carriage drawn back by hand, thus giving the operation a saving of time and greatly increasing the output.

In 1846 there was constructed in Ireland a hand-press known as the Macbrair press. It was a great improvement on the English machine mentioned before, and did good work at what was considered in those days great speed. One of these machines was brought to America and a good-sized family was supported with it for several years. The largest edition worked on this machine ran about 500 copies in one colour. This press is now said to be in a museum on exhibition as a curiosity.

In reproducing the image to be printed by any make of lithographic hand-press the principle involved is the same—that of the scraper being forced across the plate. This scraper, no matter what kind of wood it is made from, must be perfectly straight and the face, which is V-shaped, must be carefully rounded so that it will not sag or bulge when pressure is applied. The bed of the hand-press, upon which the stone that is to be printed from is placed, must be level and neither concaved nor convexed for, while the stone is not supposed to bend, a convexed bed will cause the stone to balance and move slightly with every impression, thus making it impossible to register impressions on it; while a concaved bed will wear down the corners of the stone and put it out of plumb. More work has been spoiled by presses with uneven beds than in almost any other way.

In 1905 a new kind of lithographic press was invented in the United States called the "offset press." This was a steam-driven press, but it called for a hand-press to make the transfers to be used, and make them quickly and accurately. Several inventors started to make an offset hand-press. The first one offered resembled a washing machine wringer. The proof was pulled from a stone, laid on another piece of transfer paper, and the two were run through this wringer-like machine. Some work was turned out this way, but as there were no guides to feed the sheets to, it was next to impossible to make a sheet register properly, so this proposition was abandoned and other designs taken up. Finally, an offset hand-press equipped with a large rubber-covered cylinder was offered. This same principle has lasted to the present day. This large rubber cylinder travels over the stone or plate containing the image from which it takes an impression, and then it goes on to a bed upon which is laid the paper. As the cylinder goes over the paper the image is transferred from the rubber blanket to the paper and the work of printing is done, so far as the sheet is concerned.

It occasionally' happens that one wishes to pull a transfer of a piece of copper plate engraved work to use on a lithographic hand-press. From a purely mechanical point of view the construction of the copper plate press is an exceedingly simple matter. Its purpose is to produce a heavy and uniform pressure on the plate during the operation. To make a lithographic transfer from a copper plate engraving one should lay the plate face upward on the bed of the press, lay the paper on it and pass it between the two iron cylinders.

The material used in making lithographic transfers from copper plate engravings consists of transfer ink, whiting, transfer paper and a good supply of clean rags. The copper plate is first heated, but not enough to burn the ink; then the transfer ink is forced into the engraved parts until every part is fully charged. In cleaning the plate it should be carefully rubbed with a rag charged with whiting until all the surplus ink is removed. The transfer paper to be used is dampened--or commercial transfer paper may be used which is made to retain dampness—and the plate and paper used before the plate gets cold. Transfers made in this way may be used in lithographing on a hand-press.

(W. C. Br.)

PRIOR, MATTHEW (1664–1721), English poet and diplomatist, was the son of a Nonconformist joiner at Wirnborne Minster, East Dorset, and was born on July 21, 1664. His father moved to London, and sent him to Westminster, where he was enabled by the earl of Dorset to continue his education after his father's death. At Westminster he made friends with Charles Montagu, afterwards earl of Halifax. It was to avoid being separated from Montagu and his brother James that Prior accepted, against his patron's wish, a scholarship recently founded at St. John's college. He took his B.A. degree in 1686, and two years later became a fellow. In collaboration with Montagu he wrote in 1687 the *City Mouse and Country Mouse,* in ridicule of Dryden's *Hind* a d *Panther*. The satire made the fortune of both authors. Montagu was promoted at once, and Prior three years later was gazetted secretary to the embassy at The Hague. After four years of this employment he was appointed one of the gentlemen of the king's bedchamber. In 1697 he was secretary to the plenipotentiaries who concluded the Peace of Ryswick, and in 1698 he was sent to Paris in attendance on the English ambassador. At this period Prior could say with good reason that "he had commonly business enough upon his hands, and was only a poet by accident." His occasional poems during this period include an elegy on Queen Mary in 1695; a satirical version of Boileau's *Ode sur le prise de Namur* (1695); some lines on William's escape from assassination in 1696; and *The Secretary.*

After his return from France Prior became under-secretary of state and succeeded Locke as a commissioner of trade. In 1701 he sat in parliament for East Grinstead. He had certainly been in William's confidence with regard to the Partition Treaty; but when Somers, Orford and Halifax were impeached for their share in it he voted on the Tory side, and immediately on Anne's accession he definitely allied himself with Harley and St. John. After the return of the Tories to power in 1710, Prior was again employed, and until Anne's death he shared in all negotiations with the French court, sometimes as secret agent, sometimes in an equivocal position as ambassador's companion, sometimes as fully accredited but very unpunctually paid ambassador. His share in negotiating the treaty of Utrecht, of which he is said to have disapproved personally, led to its popular nickname of "Matt's Peace." When the queen died and the Whigs regained power he was impeached by Sir Robert Walpole and kept in close custody for two years (1715–1717). In 1709 he had already published a collection of verse. During this imprisonment, maintaining his cheerful philosophy, he wrote his longest humorous poem, *Alma; or, The Progress of the Mind.* This, with his most ambitious work, *Solomon,* and other *Poems on several Occasions,* was published by subscription in 1718. Prior died at Wimpole, Cambridgeshire, a seat of the ear! of Oxford, on Sept. 18, 1721, and was buried in Westminster abbey, where his monument may be seen in Poet's Comer. *A History of his Own Time* was issued by J. Bancks in 1740. The book pretended to be derived from Prior's papers, but it is doubtful how far it is authentic.

Austin Dobson, 1889); *The Shorter Poems of Matthew Prior* (ed. F. L. Bickley, 1923); also F. L. Bickley, *The Life of Matthew Prior* (1914); and L. G. W. Legg, *Matthew Prior: a study of his public career and correspondence* (1921).

PRIOR, a title applied generally to certain monastic superiors, but also in the middle ages to other persons in authority. Under the Roman Empire the word *prior* is found signifying "ancestor." In the early middle ages it was commonly applied to secular officials and magistrates, and it remained all through the middle ages as the title of certain officials in the Italian city states.

In the Rule of St. Benedict and other early rules the titles *praepositus* and *praelatus (see* PRELATE) are generally used, but *prior* is also found signifying in a general way the superiors and elders in a monastery; afterwards the title prior (or *claustral* prior) was restricted to the abbot's vicegerent, who was generally charged with the details of the discipline of the monastery. With the foundation of the order of Cluny in the 10th century there appeared the conventual prior, who ruled as head of a monastery. The Regular Canons, and the Carthusians and Dominicans, later gave this title of prior to the heads of their houses.

See Du Cange, *Glossarium mediae et infimae latinitatis,* new edition by L. Favre (Niort, 1883, etc.); Sir William Smith and S. Cheetham, edd. *Dictionary of Christian Antiquities* (1875–80), and the article "Prior" in the *Catholic Encyclopedia.*

PRISAGE AND BUTLERAGE, the names of ancient English customs duties which survived until the beginning of the 19th century. The oldest was a wine duty. Later it became customary to levy upon wool, woolfells and leather. This "customs" duty was known as "prisage." The earliest known prisage was levied in kind; one tun of wine being taken from every cargo of from 10 to 20 tuns, and two tuns from every cargo exceeding 20 tuns; a tun being 252 gallons. The king's man took the liberty of sampling all the wine so that the king got his tun or tuns from the best on board. Later, importers were allowed to make a money composition instead of paying in kind. Prisage was payable both by British citizens and aliens.

In the reign of Edward I., by a charter known as *Carta Mercatoria,* aliens were given liberty of trading upon paying "to Us and to our Heirs, by the name of Custom, two shillings (for every hogshead of wine) over and above the antient customs due." This duty was made payable to the king's butler, and was consequently termed "butlerage." Later, kings of England granted the produce of the duties of prisage and butlerage to certain of their subjects. In 1785 it was recommended that these duties should be re-vested in the crown. Thus, the duties of prisage and butlerage in Ireland had been granted to the dukes of Ormond, but parliament purchased those rights for nearly £200,000. In 1809 the duties were abolished by the Customs Consolidation Act of that year.

PRISCIAN [PRISCIANUS CAESARIENSIS], the celebrated Latin grammarian, lived about A.D. 500. This is shown by the facts that he addressed to Anastasius, emperor of the East (491–518), a laudatory poem, and that the mss. of his *Institutiones grammaticae* contain a subscription to the effect that the work was copied (526, 527) by Flavius Theodorus, a clerk in the imperial secretariat. His title *Caesariensis* points, according to Niebuhr and others, to Caesarea in Mauretania. Priscian was quoted by several writers in Britain of the 8th century—Aldhelm, Bede, Alcuin—and was abridged or largely used in the next century by Hrabanus Maurus of Fulda and Servatus Lupus of Ferrières. There is hardly a library in Europe that did not and does not contain a copy of his great work, and there are about a thousand mss. of it. The greater part of these contain only books i.–xvi. (sometimes called, *Priscianus major)*; a few contain (with the three books *Ad Symmachum*) books xvii., xviii. *(Priscianus minor)*; and a few contain both parts. The earliest mss. are of the 9th century, though a few fragments are somewhat earlier. All are ultimately derived from the copy made by Theodorus. The first printed edition was in 1470 at Venice.

The *Institutiones grammaticae* is a systematic exposition of Latin grammar. It is divided into 18 books, of which the first 16 deal mainly with sounds, word-formation and inflexions; the last two, which form from a fourth to a third of the whole work, deal with syntax. He has preserved to us numerous fragments which would otherwise have been lost, *e.g.,* from Ennius, Pacuvius, Accius, Lucilius, Cato and Varro.

Priscian's three short treatises dedicated to Symmachus are on weights and measures, the metres of Terence, and some rhetorical elements (exercises translated from the Προγυμνάσματα of Hermogenes). He also wrote *De nomine, pronomine, et verbo* (an abridgment of part of his *Institutiones),* and an interesting specimen of the school teaching of grammar in the shape of complete parsing by question and answer of the first 12 lines of the *Aeneid (Partitiones xii. versuum Aeneidos principalium).* He also wrote two poems, not in any way remarkable, a panegyric on Anastasius and a translation of Dionysius's *Periegesis.*

The best edition of the grammatical works is by Hertz and Keil, in Keil's *Grammatici latini,* vols. ii., iii.; poems in E. Bahrens' *Poetae latini minores,* the "Periegesis" also, in C. W. Müller, *Geographi graeci minores,* vol. ii. *See* J. E. Sandys, *History of Classical Scholarship* (1908), vol. i.; and A. Luscher, *De Prisciani studiis Graecis* (Breslau, 1912).

PRISCILLIAN (d. 385), Spanish theologian and the founder of a party which, in spite of severe persecution for heresy, persisted in Spain and in Gaul until after the middle, of the sixth century. He was a student of the occult sciences and of philosophy. He was a mystic, and regarded the Christian life as continual intercourse with God. He argued that to make himself a fit "temple of God," a man must, besides holding the Catholic faith and doing works of love, renounce marriage and earthly honour, and practise asceticism. On the question of continence in, if not renunciation of, marriage, he came into conflict with the authorities. Priscillian and his sympathizers, who were organized into bands of *spiritales* and *abstinentes,* like the Cathari of later days, refused the compromise which by this time the Church had established. *(See* MARRIAGE: *Canon Law.)* This explains the charge of Manichaeism levelled against Priscillian and to this was added the accusation of magic and licentious orgies. Priscillian's friends included two bishops, Instantius and Salvianus, and Hyginus of Cordova; but, through the exertions of Idacius of Emerita, the leading Priscillianists, who had failed to appear before the synod of Spanish and Aquitanian bishops to which they had been summoned, were excommunicated at Saragossa in October 380.

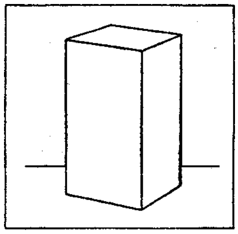
Meanwhile, however, Priscillian was made bishop of Avila, and the orthodox party appealed to the emperor (Gratian), who issued an edict (afterwards withdrawn) threatening the sectarian leaders with banishment. On the murder of Gratian and accession of Maximus (383) Idacius fled to Treves, and secured the summoning of a synod (384) at Bordeaux, where Instantius was deposed. Priscillian appealed to the emperor, with the unexpected result that with six of his companions he was burned alive at Treves in 385.

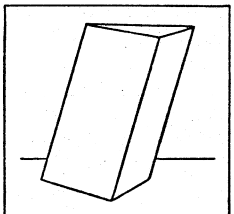
The heresy, notwithstanding severe repressive measures continued to spread in France as well as in Spain. As an openly professed creed it only disappeared after the second synod of Braga in 563.

At the Council of Toledo in 400, fifteen years after Priscillian's death, when his case was reviewed, the most serious charge that could be brought was the error of language involved in rendering ἀγένητος by innascibilis. It was long thought that all the writings of the "heretic" himself had perished, but in 1885, G. Schepss discovered at Würzburg eleven genuine tracts, since published in the Vienna Corpus. "They contain nothing that is not orthodox and commonplace, nothing that Jerome might not have written."

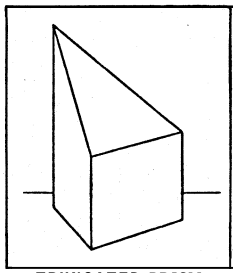
See E. Ch. Babut, Priscillian et le *Priscillianisme* (Paris, 1909).

PRISM, in geometry, a polyhedron having two of its faces, known as bases, congruent (identically equal) polygons in parallel planes, and the other faces parallelograms equal in number to the sides of the bases. The faces, excluding each base, are called the lateral faces, and the intersections of these faces are called the lateral edges, being all equal. The perpendicular distance between the planes of the bases is called the height or altitude of the prism. If the lateral edges are perpendicular to the planes of the bases, the prism is called a right *prism;* if they are oblique to these planes, it is called an oblique prism. Prisms are said to be triangular, quadrangular, pentagonal, and so on according as their bases are triangles, quadrilaterals, pentagons, and so on. A prism having parallelograms for its bases is called a *parallelepiped.* If the bases and lateral faces are all rectangles, it is called a rectangular *parallelepiped.* The part of a prism included between the base and a section made by a plane oblique to the base is called a truncated prism. A geometric solid which has for its bases two polygons in parallel planes, and for its lateral faces triangles or trapezia (Amer., trapezoids) with one side in one base and the opposite vertex or side in the other base is called a prismoid, a prism being a special case. In optics the word denotes a triangular prism. The volume of a prism of base B and altitude a is aB; of a prismoid with bases B and B', altitude a and area of a mid-cross-section M, is $\frac{1}{6}a(B+B'+4M)$. See CRYSTALLOGRAPHY, REFRACTION, LIGHT and SOLIDS (Geometric).

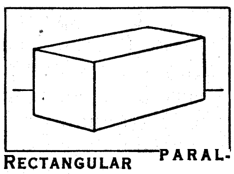




OBLIQUE TRIANGULAR PRISM



TRUNCATED PRISM



RECTANGULAR PARALLELEPIPED

PRISMOID, a solid bounded by any number of planes, two of which are parallel and contain all the vertices. The two parallel faces are called the bases. The volume V of such a solid was found by Thomas Simpson (1710–1761) as follows: Let M be a section made by a plane parallel to the bases B and B' and midway between them, and let h be the distance between the bases. Then $V=\frac{1}{6}h(B+B'+4M)$, a formula frequently used in finding volumes and applicable to most of the elementary geometric solids, and in general to any solid bounded by a ruled surface and two parallel planes.

PRISON. Only in comparatively recent times has the word "prison" come to denote the common penalty for acts hurtful to the community both grave and petty which the law forbids. In the old Roman law, *carcer* or prison was used only as the place for holding, not for punishing offenders.

The keep or dungeon of the lord's castle was usually the place of detention pending the payment of the fine or the execution of the sentence. Growth of population and the consequent increase in the number of offenders made it necessary to make special provision for their care; in 1166, the Assize of Clarendon directed the building of gaols in all counties and boroughs. While these gaols were for the most part under local authority, the king's courts at Westminster had, from time immemorial, maintained their own prisons of the king's bench, Marshalsea and the Fleet, almost entirely for debtors and others confined as a result of civil process or for contempt of court. By the middle of the 16th century the common gaol was supplemented by the workhouse or house of correction, established by virtue of an act of 1576 under the direct administration of the local justices of the peace. Modelled on the famous "Bridewell" (*q.v.*) organized in London in 1552, these institutions were commonly called by that name. Instituted for the humanitarian purpose of providing compulsory employment with pay for "sturdy beggars" and vagrants and for men and women thrown out of employment by depressed trade conditions, these houses of correction came to be employed more and more for the incarceration of petty offenders. This change was officially confirmed in 1720 by an act of Parliament.

Prison systems, in the sense they are understood to-day, cannot be said to have come into existence in any country till towards the end of the 18th century, though isolated experiments had been made in different parts of Europe, *e.g.,* in 1593 the protestants of Amsterdam built a prison for women, having for its object their moral reform by work and religious influences. There are records of similar establishments in Germany and Hanseatic towns. In 1703, Clement XI. built the famous prison St. Michel, at Rome, for young prisoners, and later on in the century the celebrated prison at Ghent was built.

In England it was not till 1729 that a report of a committee of the House of Commons brought to light the hideous cruelties practised in the Fleet and Marshalsea prisons. In the reign of Elizabeth (1561) these were the prisons of the Star Chamber and court of chancery respectively, and the office of warden was granted as a valuable bequest, or perquisite to be held through life. In course of time the reversion of this office was sold by auction to the highest bidder. Fees for safe custody were levied on the prisoners and were exacted by all forms of cruelty and oppression, until at last the scandal became so great that certain holders of this reversionary office were brought to trial for murder and cruel treatment.

As a result of the disclosures then made an act was passed (2 George II., 1729) but in spite of its enactment the system of payment by fees continued and no serious attempt was made to control the management, and it was not until fifty years later, that John Howard (*q.v.*), the sheriff of Bedfordshire, horrified by the conditions that he found to exist in his own county, entered upon his great crusade at home and abroad, to expose the terrible misery to which prisoners were made subject in England and foreign countries. The sudden stirring of the country's conscience by Howard's crusade was the dawn of prison reform, which at first with slow and halting steps developed into the great humanitarian movement of the present day.

In 1774 Howard received the thanks of the House of Commons and a Prison Act which was passed in 1778 is the beginning of the English prison system. The principle of separate confinement with labour and of moral and religious instruction was formally prescribed as a condition of imprisonment. It 1781 a further act was passed, making it compulsory for justices to provide separate accommodation for all persons convicted of felony.

It is difficult to say now, whether the formal adoption by Parliament of the "separate plan" at this date, anticipating by many years its world-wide adoption under American influences, would have taken place, but for the political necessity which arose for keeping British prisoners at home. The loss of the American colonies had closed the field for the deportation of the criminal classes—a policy of riddance easy of execution, which for a long time past had prevented serious consideration of the problem involved in the safe custody in English prisons of dangerous persons convicted of the more serious crimes; but the disclosures made as to the condition of treatment of all classes committed to local gaols, even those awaiting trial, and debtors, and young persons of both sexes, rendered it imperative that some formal prescription should be asserted by the Government.

But the principle, though laid down by statute, was not enforced, with a few notable exceptions. The justices, who then controlled the prisons of the country, paid small attention; but the justices of Sussex and Gloucester by building the local prisons of Horsham, Petworth and Gloucester on the "separate" plan furnish an interesting historical record of the formal adoption in this country of the new system, which was destined, though many years later, to become the sine quâ non of all civilized prison systems.

Although historically the British prison system may be said to date from the Prison Act of 1778, a long dismal history of ill-considered administration was destined to intervene before the principles of penal science, as now understood, obtained concrete expression. It is probable that the re-discovery of Australia by Captain Cook in 1770 was the circumstance which determined the prison history of Britain for nearly 50 years. The easy methods and means of transportation which this great colony afforded, relieved parliament of the necessity of devising any new and wise methods for the punishment of crime at home.

Early 19th Century Conditions.—The system instituted in 1788 for the transportation of offenders was regularly organized and extensively acted upon up to 1840. It could not, however, survive the condemnation of the parliamentary inquiry of 1837. It was denounced as being "unequal, without terror to the criminal class, corrupting to both convicts and colonists, and extravagant from the point of view of expense." This condemnation of the colonial system followed closely on another inquiry of the previous year into the hulks or "floating prisons" which had served to some extent as an alternative to transportation. These also were condemned.

In the meantime, in the early years of the 19th century, the declaration of parliament in favour of the "separate" or cellular system, had not been entirely lost sight of, and the best known plan is associated with the name of Jeremy Bentham. Previous to this, following on the Declaration of the Rights of Man in 1789, "imprisonment" had been formally installed, largely under the influence of Mirabeau, as the method for the expiation of an offence against the law in the French code of 1791.

Bentham's scheme known as the "panopticon" was based on cellular separation and hard labour, safe custody and diligence being guaranteed by close observation from a central standpoint. Although his professed desire to "grind rogues honest" has become proverbial, it was also a part of his plan to educate and classify and to make provision for discharge. He also laid great stress on the necessity of preventing crime by discovering and combating its causes. In this respect he was the founder of the modern school of "prevention." His writings exercised a considerable influence in France, where the jurists were busy preparing the penal code of the First Empire, and in Great Britain led indirectly to the purchase of lands by the Government for the erection of Millbank penitentiary, begun in 1813 and completed 1823. This was an important step forward, for though built for convicts only, it marked the acceptance by parliament of the principle that the reformation of prisoners could best be'secured by seclusion, employment and instruction.

To this end were labouring through these years a band of earnest and devoted workers, the "Prison Discipline Society," on whom the mantle of Howard had fallen, and who were determined that his work for the cleansing and purifying of gaols and houses of correction should not perish. These gaols were described by this society in 1812 "as relapsing into their former horrid state of privation, filthiness, cruelty and neglect." In London itself within easy reach of the new and much vaunted Millbank penitentiary, the chief prison of the City, Newgate, was in a disgraceful state. It was here that Elizabeth Fry entered upon her noble work. By her amazing courage and personality she transformed what was formerly described as a "hell above ground" to a scene, where in words of an eye witness "perfect stillness and propriety reigned." Her great success and example gave a stimulus to the movement of prison reform both at home and abroad. The Prison Discipline Society redoubled its efforts in the face of considerable criticism and opposition, for in those days, as sometimes now, the assertion of ordinary principles of humanity in dealing with captives and prisoners was sneered at as false sentiment.

At last, in the early years of George IV. (1823–24) a prison act was passed for all local gaols with the object over and above safe custody, of preserving health, improving morality and enforcing hard labour, and there was a curious provision that if each prisoner could not have a separate cell, he should at least have a separate bed. That such a provision should have been necessary only one hundred years ago, illustrates the advance in public sentiment and opinion since that date.

This particular act marked an advance, though its provisions were largely ineffective, owing to the reluctance of the local authorities to re-build or enlarge their gaols: and there was another reason. By the misconception of the teachings of Howard and of the Discipline society, it was a common belief that the secret of good prison discipline lay in "classification," which was deemed even more important than "separation." It was believed and very erroneously, that if priscners in the same categories, and therefore presumably of the same characters, were associated together in common rooms or dormitories, no evil results were likely to follow. Both Howard and Bentham were quoted as evidence in favour of classification as a means of facilitating labour. Many prisons were erected in conformity with the act—Maidstone, Derby, Westminster, Chelmsford and Leicester. The Governor's house was usually placed in the centre with blocks of cells radiating from it, the only inspection coming from a central office, according to Bentham's plan, and there was practically no interference with the unauthorised association of prisoners, according to the categories in which they were placed. It became more and more evident that there was no moral standard, by which "classification" could be regulated as a basis of prison discipline, and the reaction culminated in a system of almost solitary confinement.

Cellular Confinement.—It came about in this way. In 1831 a parliamentary committee went into the whole question, and advised that owing to the administrative difficulties of a good system of classification, all prisoners should be confined in separate cells and all prisons should be constructed accordingly.

America was at this time declaring that it had found the key to the solution of the great problem of all prison systems, which is that they shall be at once deterrent and reformatory, by the invention of the plan of strict cellular confinement by day and night in Philadelphia,—by night only in the rival system at Auburn in the State of New York, labour being in association by day, but under a strict rule of silence. The rival systems of Philadelphia and Auburn are the historic battle ground, concerning the comparative merits of the cellular and associated plans of imprisonment. The controversy excited great interest in England, France, Germany. Belgium. All these countries sent delegates to study the rival systems on the spot. They all travelled together through the United States: de Beaumont and de Tocqueville from France, Ducepetiaux from Belgium, Mittermeyer from Prussia, Crawford from England. The result was a strong endorsement of the principle of separate cellular confinement for all prisoners by day and night. In England the then home secretary (Lord John Russell) issued a circular to magistrates, calling attention to its advantages, and in 1839 an Act was passed, which, though permissive only, established the legality of the system; but the magistrates were at a loss how to proceed as the construction of existing prisons gave no facilities for the purpose.

Lord John Russell, then determined on the erection of a "model" prison, as an example of cellular construction and as a test of the merits of the separate or cellular plan. It was completed at Pentonville in 1842. The *corpus* on which this experiment was made, was first offenders between 18–3j sentenced to transportation. The period of isolation was for eighteen months and the separation was complete, even masks being worn to avoid recognition.

Five years later, the commissioners appointed to direct and observe the experiment gave, as their deliberate opinion, that "the separation of one prisoner frdm another was the only sound basis upon which a reformatory discipline could be established with any reasonable hope of success."

The effect on public opinion was immediate and striking—not only did the Pentonville plan become the basis of "penal servitude" then under the control of the Government, but it led directly to the establishment of the separate system throughout the country. For, though the secretary of State did not then directly control local prisons, recent legislation had provided that all rules should be subject to his approval, and the appointment of a surveyor-general of prisons in 1844 ensured that due attention was given by local authorities to the requirements of good prison construction.

Pentonville prison was built by Sir Joshua Jebb, the first surveyor-general. His report on its construction, "as a model to be appropriated for carrying into effect the separate system of discipline," was aptly designated as the model for the remainder of the 19th century, and the essential features of construction are still adhered to. Sir Joshua Jebb was succeeded by another eminent engineer, Sir Edmund Du Cane, R E. His largest undertaking was the construction of Wormwood Scrubbs prison for convicts by prison labour. The plan is what is known as the "separate block" system, and was adopted as an improvement on the "radial" or Pentonville plan, though many of the essential features of the latter were retained, *e.g.,* heating, ventilation, sanitation and size of cells. When the central authority took over control of all local prisons in 1878, the main building work consisted chiefly of alterations and additions, but these in many instances amounted to almost entire re-construction. Since then, the main building work has consisted of bringing old establishments up to date.

In addition great skill and ingenuity has been expended of recent years in the conversion of existing establishments into Borstal institutions, *e.g.,* the old convict prisons at Borstal and Portland, and the old reformatory school buildings at Feltham, Middlesex. All this work has been carried out under the direction of another able engineer, Colonel Rogers, R.E. who also designed the new prison at Camp hill, in the Isle of Wight, for the purpose of providing detention under the special conditions prescribed for habitual criminals under the Prevention of Crime Act, 1908.

But to revert to the history of the separate system, where we left it with the building of the model prison at Pentonville.

The English System.—It was at this period that the two principal features of the English system began to take shape, viz.: separate confinement and hard labour. The duration of the period of separate confinement and the regulation of the task of hard labour remained the problem of administration for many years and cannot yet be said to be finally settled. There will be found running through all this period an earnest attempt to reconcile the claims of the two admitted objects of imprisonment, viz.: deterrence and reform, and hard labour assumed a narrow and artificial meaning, great ingenuity being expended in devising forms of labour, which would not violate the sacred principle of separation, *e.g.,* cranks, treadwheel, shot-drill, stone-breaking, etc.

With these problems unsettled, with a strange and general ignorance of the true principles of punishments, with conflicting views and diverse authorities, the local prison system was in a very confused and chaotic state, until the parliamentary inquiries of 1850 and 1863 led formally to the establishment of a central authority in 1878, when the Government took complete control of all prisons, convict and local. In that year the prison commission was appointed.

It was the refusal of the colonies to become the dumping ground of transported convicts which led in 1857 to the introduction of the system of "penal servitude." Henceforth convicts were to be kept at home under a special form of discipline in what were known as "public work prisons," where opportunity existed for their employment on works of public utility, *e.g.,* the breakwater at Portland, docks at Chatham and Portsmouth, land reclamation at Dartmoor. The leading feature of the new convict discipline was the progressive stage system, borrowed from experience gained in the management of convicts in the Australian settlements. The rules prescribed a period of nine months' separate confinement, the remaining sentence being divided into three stages. Under the operation of the "mark" system, a considerable remission of sentence could be earned, not exceeding one fourth of the sentence imposed.

This system remains in its leading features the same to-day with many modifications, *e.g.,* the period of separate confinement and the increase of relaxations, and rewards in the differentstages. The opportunity for employment on public works no longer exists, and the comparatively few persons now sentenced to penal servitude would not provide a sufficient contingent of labour for the great operations carried on in former years. The fall in the convict population between 1854 and 1874 was from 15,000 to 9,000. Since then, the number of male convicts had fallen to 1,430 in 1926.

The introduction of the penal servitude system had a far-reaching influence and reaction on the local prison system and this was intensified when Sir E. Du Cane became chairman of the joint boards of directors of convicts, and commissioners of local prisons, in 1878. The State until now had had no experience in dealing with short sentences, and the problem was a new one, viz.: how to deal effectively with a man who was in prison for a few days or weeks or months, from whom during so short a period no useful productive labour could be exacted. Many of the features of the penal servitude system were introduced—the "mark" and progressive stage system, cellular confinement in the early stages, followed by associated industry so far as was practicable in the confined spaces of local prisons, built on the cellular plan. The new system was, however, justly credited with great administrative and financial success. But in spite of an admitted administrative success, the public conscience was uneasy. It was felt that too much had been sacrificed to the virtues of the separate system, to the passion for uniformity and that the "individuality" of the prisoner had been lost sight of and crushed under inflexible rule.

Modern Theories.—The re-action that became manifest towards the close of the last century against what is known as the "classical" conception of crime and punishments had an echo in England. This re-action came in the early 'eighties from a school of criminologists, known as the "Italian school," of which the chief was Lombroso. Theories of the "born criminal," *i.e.,* a human being foredoomed to crime by atavistic propensity, and distinguishable physical stigmata, created considerable sensation at the time and, though refuted by later enquiry, exercised a profound influence in Europe and gave a direct impulse to the scientific study of the causes predisposing to criminal acts. At this time, 1869, was founded on the continent of Europe "l'Union internationale de droit pénal"—chiefly under Belgian and German influences (Van Hamel, Liszt and Prins). It was an attempt to reconcile the extreme views of the Italian school with the modern doctrine which is known as "preventive treatment," *i.e.,* the scientific study of the causes of crime in each individual case, be they due to internal or external factors, either physiological, concerned with the mental or physical state of the offender, or external, *i.e.,* the result of social conditions.

This theory, which has been strongly endorsed by eminent French writers (*e.g.,* Saleilles), is known generally as that of *The individualisation of punishment.* Imprisonment, the one and only instrument for the punishment of crime, is flouted as an anachronism. In other words it is a protest in the general interests of humanity against the mechanical infliction of penalty with the resulting evil of a constant repetition of short sentences. Strangely enough, these controversies received but little attention in England, but their influence contributed to the criticisms made at the end of the century, against the English prison system.

A formal enquiry instituted by the Government in 1894 marks a new and distinct epoch in the prison history of Great Britain. It declared (a grave indictment) that "prisoners had been treated too much as a hopeless element of the community." These words may be said to mark the passage from the old to the new methods of punishment.

Among many and almost fundamental changes which were suggested, dealing with almost every branch of the administration, the principal was the grave importance attracted to the concentration of effort on the young or incipient criminal. At this time persons under 16 (even under 12) were being sent to prison in considerable numbers and the average number of youths 16–21 committed annually to prison was about 20,000.

At the same time, it was suggested that as a means of dealing effectively with crime in its later stages, technically known as "professional" crime, *i.e.,* with persons living systematically by crime and whom experience had shown not to be restrained by the fear of ordinary punishments, a new sentence should be placed at the disposal of judges, which supplementary to a sentence of penal servitude, might have a deterring or at least a protective effect.

At this time, 1890, on the retirement of Sir E. Du Cane, Sir E. Ruggles Brise succeeded as chairman of the prison commission. The following are the principal statutes which have altered the system since this date.

(1) **The Prison Act,** 1898.—The most notable changes introduced by this act are: (a) The triple division of prisoners according to degree and character of offence. (b) The power to earn remission of sentence. not exceeding one-sixth where the sentence is over a. month. (c) The power given to enable a prisoner whose sentence is in default of fine to obtain release by part-payment of the fine. (d) Provision against excessive or unnecessary exercise of the powers of corporal punishment. (e) Power given to secretary of State to effect any change in the system by parliamentary rule, without recourse to act of parliament. (f) The abolition of all forms of so-called hard labour, treadwheels, cranks, etc.

(2) **The Prevention of Crime Act,** 1908.—This act achieved two great and startling results. (a) The establishment of the Borstal system. (b) The system of preventive detention as a means of protecting society from the dangerous or habitual criminal.

These were the two objects on which special stress was laid by the inquiry of 1894, and since that date great and special attention has been given to effect the double purpose, viz.:—to check the criminal habit or tendency in the case of the young offender, and to increase the deterrence of punishments in the case of the older criminal, who could not be restrained by ordinary and repeated sentences.

(a) The *new* "Borstal" Act created an entirely new category of offenders between the age of 16–21, to be known colloquially as "juvenile-adult" or "adolescent" offenders. For these, where the court was satisfied that "criminal habit and tendency or association was proved," power was given to order detention for any period up to three years in a State reformatory, known as a "Borstal institution," taking its name from the village of Borstal on the Medway, where the first experiments, leading up to the system, were made. The successful efforts of the official staff have been aided by the Borstal association, a society created to safeguard and protect the case of every inmate, of either sex, on discharge from a Borstal institution.

(b) Preventive Detention.—Long experience had sufficiently demonstrated that successive sentences of imprisonment or penal servitude did not deter those who made a profession of the graver forms of crime from continuing their war on society with a cynical indifference to the methods devised for its protection.

Accordingly, the act provided that it is expedient for the protection of the public that where an offender is found by the courts, having regard to the numbers and characters of his previous convictions and sentences, to be an "habitual criminal," the court shall have power to pass a special sentence, ordering that on the determination of a sentence of penal servitude, passed for the particular offence, he may be detained for a period not exceeding ten, nor less than fire years under a system to be known as that of "preventive detention."

A new prison was constructed at Camp hill in the Isle of Wight, specially adapted to the custody and treatment of this new class of prisoner, for whom in conformity with the act, a novel system was devised, being less rigorous than penal servitude, and being based on the idea that by encouragement and hope and a progressive system of rewards, leading ultimately to conditional release, even a hardened criminal might be gradually induced to alter his mode of life and reinstate himself as an honest and industrious citizen.

At least, though the reforniatory results have been fitful and uncertain, there is reason to believe that a great deterrent value arises from the fear inspired in the mind of the dangerous and habitual criminal, that continued violation of law may entail the very unpleasant consequence of a long period of detention, supplementary to that inflicted for the particular offence.

(3) **The Criminal Justice Administration Act, 1914.**—This very important act, passed on the eve of the World War, has had a far reaching effect in providing a remedy for the admitted evil of mechanical commitment to prison in default of paying a fine. It is there laid down, that where any prisoner desires to be allowed time for payment, not less than seven clear days shall be allowed, in the absence of good reason to the contrary; and that in any case the imprisonment shall be without hard labour. It makes a breach for the first time in the old mechanical formula "with or without hard labour" which long custom had crystallized. without due regard to the circumstances of each case by giving a discretion to the court in all cases as to the imposition of hard labour.

As a provision against the admitted evil of short sentences of imprisonment, all commitment to prison for a less period than five days, is forbidden.

The act, moreover, gave a considerable extension to the Borstal system, removing the condition that a particular offence must be "indictable," raising the minimum period of detention and extending that of supervision after release.

The Children Act, 1908, **and the Probation Act,** 1907, have been called the "handmaids of the prison system" for it is by their operation that a way has been found not only to cut off crime at the source, but to provide the alternative to unnecessary commitment to prison, where the law can be adequately vindicated by other methods.

(1) The Children Act—This act, known as the "children's charter," revolutionized the penal law of Britain by prohibiting the imprisonment (except under very exceptional circumstances) of any person under the age of 16. It classified young offenders as "children" under 14, and "young persons" between 14 and 16; and various methods for dealing with them are prescribed. In lieu of prisons, the act created "places of detention," to be established by the police authority, for any period not exceeding a month. It consolidated. and amended the law relating to reformatory and industrial schools. Special courts called juvenile courts were created for dealing with charges against children and young persons.

(2) *The* Probation Act, 1907.—This act greatly extended powers already in existence for releasing on recognizance and gave power in any case either to dismiss the case or to bind the offender over for a period not exceeding 3 years, or to place him on probation—under the care of probation officers, appointed for the purpose.

This act was supplemented in 1925 by a very important measure, making it obligatory in all petty sessional courts (over 1,000 in number) to appoint one or more probation officers.

These acts, taken in conjunction with the Mental Deficiency Act of 1913, an invaluable measure far relieving prisons of the great burden and difficulty of providing for the custody under proper conditions of a very considerable number of persons of proved mental deficiency, practically complete the legislative changes of the last 30 years, and their salutary operation, aided of course by many other social causes making for the moral betterment of the community and the raising of the general standard of life, has had an almost phenomenal result, so far as the population of prisons is concerned

Fifty years ago the number of persons sent to prison in a year stood as high as over 600 per 100,000 of population A gradual, though not unbroken fall took place until the year before the war when it stood at 370. At the time of cessation of hostilities it reached its lowest point, 70, but with the return to ncrmal conditions it has not risen higher than 120 and the iast figure for

1926 was 115.

Before the war and the passing of the act of 1914, there had been nearly 100,000 sentences annually to two weeks or less. For the year ending Dec., 1926, there were under 7,000.

International Progress.—During the last 50 years, a remarkable movement has been in progress, having for its purpose, to internationalize certain principles or standards for the treatment and punishment of crime. The movement began in 1872 by the holding of an International prison congress in London. To America belongs the credit of having organized on British soil a movement which was the precedent and example of what has since grown into a well-established confederation of all civilized states for discussing and if possible, improving, a world-system of punishment. An international commission was created, which by means of quinquennial congresses, held in the different capitals of Europe, furnished the occasion for periodical discussion and exchange of views on all matters affecting both the régime of prisons and the reform of criminal law.

Great Britain and the United States did not adhere to this movement, until the Paris congress, 1895; at the congress of Washington, 1910, Sir E. Ruggles Brise was elected president and this led to an invitation of the British Government to hold the next congress in London, which took place accordingly in 1925, having been postponed from 1915 owing to the outbreak of the World War.

The leading note was struck by the resolution of the London congress 1872, viz., that "moral regeneration should be the primary aim of prison discipline and that hope should always be a more powerful agent than fear." Although before this date, there had been spasmodic movements in many countries of Europe for the reform of prisons and prisoners, prison "systems," so far as they can be said to have existed at all, were devised mainly with a view to repression or deterrence; and what has since become the leading principle in dealing with crime, viz.: *The individualization of punishment, i.e.,* the adaptation of punishment to the different degrees of moral guilt and the infinite variety of mental and physical attributes, affecting responsibility, found only a very limited expression in the penal law and prison management of different countries.

Twenty-four countries are now (1928) annually represented on the international prison commission, viz.: Great Britain, France, Germany, Italy, Spain, Belgium, Holland, Switzerland, Greece, Sweden, Norway, Denmark, Austria, Hungary, Poland, Bulgaria and Luxemburg, Yugoslavia, Czechoslovakia and, outside Europe, the United States of America, Union of South Africa, British India and New Zealand, and Japan. The frequent opportunity for intercourse and exchange of views, afforded by periodical meetings of the commission at their central bureau, Berne, Switzerland, has been now for many years slowly creating a *solidarité* between nations, resulting in a general agreement not only as to the fundamental conditions of imprisonment, but also as to those preventive measures which obviate the necessity for imprisonment at all.

The modern school of *l'hygiène préventive* to which succeeding prison congresses give increasing voice and impetus, holds the field today. It advocates prevention which will operate by the elimination of the social causes which create unhealthy environment and by the encouragement of scientific treatment of the weak in mind or in body, so that, if possible the germs of anti-social conduct may be diagnosed, before it is too late, and if possible destroyed by appropriate handling and treatment. These are counsels of perfection, which the future may see developed into actualities.

After 2,000 years we are coming back to the old Roman definition of prison, viz.: *ad continendos, non ad puniendos.* Prison will be primarily for safe custody and there will be no penal infliction beyond deprivation of liberty, which is, after all, the only and the greatest punishment. Subject to this, every possible effort will be made by industrial training, by education, moral and religious, by lectures and debates, by well-organized visitation, to create a sense of dignity and self-respect and of duty to the State and to all fellow creatures. (E. R -Br)

UNITED STATES

The establishment of prisons in America was associated with the Revolutionary War. The centre from which this innovation spread was Philadelphia, where the humanitarian influence of the Society of Friends was strongest. The movement towards the provision of prisons also owed something to the work of Beccaria and John Howard, with which the American reformers were well acquainted. The Pennsylvania constitution of 1776 ordered legislation introducing imprisonment and this was first actually provided by an act of 1786, which substituted for corporal punishment in case of certain crimes "continuous hard labour, publicly and disgracefully imposed."

The early history of American prisons centres chiefly in the struggle between the Pennsylvania and Auburn systems of prison discipline. The former, introduced in the Walnut street jail at Philadelphia in 1790 and applied in the Eastern penitentiary at Cherry Hill in Philadelphia from 1829 onward, soon followed in other States. It rested upon the principle of solitary confinement during the period of imprisonment, hoping that solitude would not only prevent vicious and degrading association with other criminals, but also promote earnest Christian reflection productive of efforts at self-reformation. The records show that it produced more insanity than reformation. The State penitentiary in Auburn, N.Y., established between 1816 and 1824, provided for separate confinement at night in small cells, but allowed congregate labour in the prison shops during the day and meals in common. Silence was enforced while the prisoners were congregated so that the Auburn system became known as the "silent" system, as contrasted with the Pennsylvania or "solitary" system. A prison on the Auburn plan was recommended as more economical to erect and administer. Due mainly to the efforts of Louis Dwight of the *Prison Discipline Society of Boston,* the Auburn system prevailed in the United States. The Pennsylvania system was experimented with briefly in Maryland, Massachusetts, Maine, New Jersey, Rhode Island, Virginia, as well as Pennsylvania; in Europe, however, it was much more highly esteemed than the Auburn plan.

The reformatory in Elmira, N.Y., in 1877 embodied most of the progress in penological thought and practice in Europe and America between 1825 and 1875, including, among other things, emphasis upon reformation, commutation of sentence for good behaviour, a system of grading, classification and promotion of inmates, a quasi-indeterminate sentence, and the provision of productive labour. The Elmira system was utilized for youthful first offenders guilty of the lesser felonies, and has not been extended to prisons for adults, except for the grading system. The inmates of the Elmira type of reformatories have usually been between the ages of 16 and 25.

The most notable innovation in prison discipline is found in the work of Thomas Mott Osborne, Auburn, N.Y. Undergoing voluntary servitude in the Auburn prison in 1913, he became convinced that no extensive reformation was possible in connection with the system of ruthless repression and corrupt politics which characterize the conventional prison administration. He saw that a convicted criminal could be taught habits of obedience and respect for order only while in prison, whereas the present prison system was designed to increase the anti-social tendencies of the convict. Accordingly, he introduced at the New York State prison at Sing Sing a system of convict self-government known as the "mutual welfare league." This aroused the bitter opposition of the exponents of harsh punishment and of the corrupt politicians and contractors, but it proved remarkably successful when applied by Mr. Osborne at Sing Sing and later at the U.S. naval prison at Portsmouth, N.H. The plan discards punishment and concentrates upon the objective of reformation.

A major phase of the progress of prison administration since 1800 has been the gradual differentiation of institutions according to the type of prisoner to be received. In 1790, in an institution like the Walnut street jail in Philadelphia, the same institution housed debtors, those accused of crime, those convicted of all types of crime, young and old, male and female, white, black and red, sane and insane. During the last century imprisonment for debt has been abandoned; those convicted of serious crimes are separated, though, pending trial, they are still housed with vagrants and others consigned to the county jail; separate institutions have been provided for the young, the youthful and adults; males and females are housed in separate institutions or in separate departments; in some States the races are segregated; and to an increasing extent the insane. Those convicted of misdemeanors and lesser felonies are sent to jails, houses of correction or reformatories, while those convicted of the more serious felonies are sent to State penitentiaries.

Prison labour has undergone many changes. It was first employed as a means of increasing the severity of punishment; from about 1830 to 1880 the chief emphasis was laid upon the economic aspects; in the last generation more concern has been shown with regard to teaching a useful trade and making prison industry an aid in reformation. At the outset the prison industries were conducted by the prison authorities; after about 1830 the labour of convicts was very generally sold to contractors subject to the disciplinary rules of the institution, About 1870 the labour leaders began a wide movement of protest against contract convict labour and restrictive legislation was passed in many States. Since 1880 there has been a gradual trend towards institutional control of all prison industries under either the public account or the State-use system. The start was made with crude work, like breaking stone and picking over wool and oakum. In the contract régime textile industries, tailoring, boot and shoe making, the manufacture of crude furniture and hardware, and making of cheap cigars were the common industries. Where the State-use system is employed the prison industries are devoted chiefly to manufacturing the clothing, furniture and hardware used in the State institutions and the registration plates used on automobiles. Many States have purchased large prison farms and carry on extensive agricultural enterprises; convict labour is also used on State and county highways. The attempt to provide types of labour which will train inmates for an improved economic status after discharge is still in its infancy

Prison architecture has made little progress. Leaving aside the archaic plumbing of that period, the Eastern penitentiary opened in Philadelphia in 1829 was the most spacious and habitable institution ever utilized for the detention of adult felons in the United States. The first prisons were composed of large rooms where congregate imprisonment was practised. After 1800 the trend was distinctly towards the cellular system. The Pennsylvania type of prison was constructed with a central corridor running down each wing, with cells opening off both sides of the corridor. The Auburn type of prison was constructed in the form of a cell-block of several storeys or tiers of steel and stone or brick cages. Practically all the modem American prisons are merely refinements of this original Auburn cage construction, the improvements being chiefly ingenious devices for opening and closing all the doors of an entire tier of cages with one motion. Illinois recently constructed a great new prison at Joliet on the circular plan, the cells opening on a large central space which makes the inspection of the cells relatively easy; it is but an adoption of the "panopticon" scheme proposed by Jeremy Bentham more than a century ago. Some of the institutions for juvenile delinquents have adopted the "cottage" system, first introduced from Mettray in France about 1855, but it has never been adopted for adult criminals. Almost without exception the American prisons are still surrounded by walls higher and thicker than those which protected ancient cities or mediaeval castles.

Imprisonment when introduced was both punitive and reformatory, designed to produce a mode of life markedly different from that led outside in the state of freedom; otherwise imprisonment would scarcely be punitive and painful. Mr. Osborne's plan was a humane effort to make the prison a school for social re-education. The more advanced criminologists would reconstruct prisons, making them hospitals for the socially sick or delinquent classes putting them under medical supervision comparable to the State hospitals for the insane. The prisons of the United States are to-day (1929) substantially what they were in 1830, as regards both architecture and disciplinary methods. There have been some improvements in construction and sanitation, but the old punitive system remains almost unimpaired, and any attempt to improve or mitigate it is attacked by the conservative judges and lawyers as a sentimental effort to coddle prisoners. Contemporary prison discipline is not supported by criminologists, and in time the system will change before the advance of knowledge. In October, 1933, Alcatraz Island in San Francisco Bay was assigned by the Federal authorities for use as a prison. There is accommodation for about 600 prisoners. (H. E. BAR.)

EUROPEAN COUNTRIES

A new chapter in the development of the prison régime has been opened in many countries in the years following 1918. There is on the European continent a certain movement away from the strict cellular system, where prisoners are separated entirely and all the time from one another, to a system of progressive stages, similar to the system in use in English prisons.

Austria.—Longer terms of punishment are undergone in different grades. The governor decides in his free discretion whether a prisoner is worthy to enter the next higher grade or not. There is no earning "marks." Only a small proportion of the prisoners is held in strict isolation; the bulk live and labour together. Prisoners of the highest grade are often occupied with work outside the prison, such as road building and farm work.

Belgium.—For decades the stronghold of the strictest cellular system, Belgium has recently acceded to some partial alterations. Prisoners, who are fit, still serve generally the first ten years of their sentence in strict isolation; but 10% of the prison population are working together. The "hood," meant to prevent the prisoners from seeing one another's face, is no longer compulsory. In one of the prisons part of the individual exercise yards has been pulled down. Remarkable efforts are made to individualize punishment. Nine anthropological laboratories have been created. There the offender is given a thorough physical and psychical analysis. The result is used to adapt the prison treatment as far as possible to the special need of the individual.

France.—Imprisonment up to 1 year is undergone in isolation as far as prison buildings permit. Longer sentences are served in common during day time, but separation during the night is aimed at. Recidivists and criminals sentenced to severe punishment are liable to transportation into the penal colonies.

Germany.—An agreement in 1923 between the different states of the German Republic has been animportant step towards entire unification of the prison system which is not reached yet. Germany has adopted the progressive system. Complete isolation is limited to 3 years. Prisoners convicted for mere political crimes, not arising from dishonorable motives, are to be kept in separate places of detention. There they enjoy practically every possible liberty and privilege.

Greece.—Greece has made considerable attempts in the period since the World War to develop a system of out-door labour for trustworthy prisoners, regardless of the length of the sentence to be served. Besides a few movable prison camps there were in 1928 four farm prisons. The moral influence of farming, road building and forest work on the prisoner is highly commended by the Government.

Holland.—Prisoners are kept in cellular separation for a period of not more than 5 years. There is a careful elimination of criminals who are for one reason or another unfit for the cellular régime. Corporal punishment for disciplinary purposes is provided but never used.

Italy.—Italy has a progressive system which starts with isolation of the prisoner for the first part of his sentence. He is compelled to earn a certain amount of "marks" in order to advance from one grade to the next one. In certain cases an intermediate prison with a sort of semi-liberty has to be passed through before final liberation. Irons are still in use as a disciplinary punishment.

Poland.—The prison regime was reformed basically in 1928. A progressive system, following the English example, is now in use. Strict cellular separation does not exist at all. A list of stimulating privileges, lectures and wireless performances of educational value are introduced to assist reformation.

Russia.—Attempts have been made in Russia to change the whole system of punishment into one of reformation and social protection. Even the name "punishment" has been eliminated. Prisons are gradually replaced by penal colonies where life in a free community is copied as far as possible. Prisoners in higher grades get a vacation of one or two weeks a year. Farmers who are imprisoned are able to get harvest leave up to 4 months. Political prisoners, on the other hand, are subject to a different, more severe, prison régime.

Sweden.—The penal system was reformed in 1921. A progressive system starts with cellular separation up to the first 3 years. A bigger cell for work besides the sleeping-cell is provided in many cases for prisoners in isolation. There are a few penal farms intended to be a link between prison and liberty for the promising prisoner. Three to four prisoners may sleep in one room in these farms. Corporal punishment is provided but strictly guarded against abuse.

Switzerland.—The different small cantons still rule the prison system, and there is as yet no unification. But there is a movement towards the development of farm-prisons following the example of the famous farm-prison at Witzwil in the canton of Berne. (E. M. F.)

PRISONERS OF WAR: see LAWS OF WAR.

PRIŠTINA, a town in South Serbia, Yugoslavia. Pop. (1931) 16,948, about three-fourths being Albanians, and the remainder Serbs and Vlachs with a few Jews. Priština was the seat of government of Stephen Nemanya, founder of the Serbian empire, and to the west lies the famous Field of Blackbirds (*Kosovopolje*) where it was destroyed by the Turks in 1389.

To the south-east is the monastery of Grachanitza founded by King Milutin of Serbia (1275–1321), with some remarkable frescoes.

Priština was occupied by German troops in 1941.

PRITCHARD, CHARLES (1808–1893), British astronomer, was born at Alberbury, Shropshire, on Feb. 29, 1808. He was educated at St. John's College, Cambridge, elected a fellow of his college in 1832, and became a schoolmaster. On his retirement in 1862 he settled at Freshwater, in the Isle of Wight, and took an active interest in the affairs of the Royal Astronomical Society, of which he became honorary secretary in 1862 and president in 1866. In 1870 he was elected Savilian professor of astronomy at Oxford. At his request the university determined to erect a fine equatorial telescope for the instruction of his class and for purposes of research, a scheme which, in consequence of Warren de la Rue's munificent gift of instruments from his private observatory at Cranford, expanded into the establishment of the new university observatory. By de la Rue's advice, Pritchard began his career there with a determination of the physical libration of the moon, or the nutation of its axis. In 1882 Pritchard commenced a systematic study of stellar photometry. For this purpose he employed the "wedge photometer" (see PHOTOMETRY: Celestial, and Mem. R.A.S. xlvii. 353), with which he measured the relative brightness of 2,784 stars between the North Pole and about −10° declination.

The results were published in 1885 in his *Uranometria* Nova *Oxoniensis,* and their importance was recognized by the bestowal in 1886 upon him, conjointly with Pickering, of the Royal Astronomical Society's gold medal. He applied photography to the determination of stellar parallax, publishing the results of his systematic measurement of the parallaxes of second-magnitude stars, in the third and fourth volumes of the Publications of the Oxford University Observatory. When the great scheme of an international survey of the heavens was projected, the zone between 25° and 31° north declination was allotted to him, and at the time of his death some progress had been made in recording its included stars. Pritchard became F.R.S. in 1840 and received many scientific honours. He died on May 28, 1893.

PRIVAS, town of France, capital of department of Ardèche, 95 mi. S.W. of Lyons. Pop. (1936) 5,999. It is first heard of in the 12th century, as a possession of the counts of Valentinois, and later as the seat of a separate barony. As a Protestant stronghold, it suffered during the Wars of Religion. It passed in 1619 to the vicomte de Lestrange, a Roman Catholic noble. A general rising followed, and in 1629 it was besieged and destroyed by Louis XIII, but in 1632 the inhabitants returned. Privas is the seat of a prefect. Confectionery is its chief industry.

PRIVATEER, an armed vessel belonging to a private owner, commissioned by a belligerent State to carry on operations of war. The commission is known as letters of *marque.* Acceptance of such a commission by a British subject is forbidden by the Foreign Enlistment Act 1870. Privateering is now a matter of much less importance owing to the Declaration of Paris, 1856 (*q.v.*), by which it was abolished. The declaration binds only the powers who were signatories or who afterwards assented, and those only when engaged in war with one another. Privateers stand in a position between that of a public ship of war and a merchant vessel, and the raising of merchant vessels to the status of war-ships has in recent wars given rise to so much difficulty in distinguishing between volunteer war ships and privateers that the subject was made one of those for settlement by the Second Hague Conference (1907). By Convention vii. a converted merchant ship cannot have the status of a war ship unless it is placed under the direct authority, immediate control and responsibility of the power the flag of which it flies (art. 1). Converted merchant ships must bear the external marks which distinguish the war ships of their nationality (art. 2). The commander must be in the service of the State and duly commissioned, and his name must figure on the list of the officers of the fighting fleet (art. 3). The crew must be subject to military discipline (art. 4). A converted merchant ship must observe the laws and customs of war (art. 5); and such conversion must be announced in the list of war ships of the belligerent country.

The effective use of privateers made by the United States in the Revolutionary War and the War of 1812 bred reluctance on its part prior to the Civil War to agree to foreign proposals to abandon the practice. The United States, however, was willing to accede to the Declaration of Paris upon the condition that the right to capture enemy property, other than contraband, on the high seas should be abolished, but such an amendment was unacceptable to the European powers. In 1863, during the Civil War, Congress authorized the president to commission privateers, but the power was not to be exercised unless the Confederate States were successful in commissioning privateers in Europe. No occasion appeared for the commissioning of privateers. During the Spanish-American War of 1898, despite the fact that neither Spain nor the United States had acceded to the Declaration of Paris, no use was made of privateers. The rise of the United States to the position of an important naval power, together with the realization that privateering belongs to the warfare of an earlier day, has disposed the U.S. to cease to incline favourably towards recognition of the practice as a method of modern warfare. Under the constitution issuance of letters of marque and reprisal is forbidden to the states and is vested solely in the national government.

PRIVET, any shrub of the genus *Ligustrum,* belonging to the family Oleaceae, and containing about 50 species, natives of temperate and tropical regions of the old world; only the common privet is a native of Europe and northern Africa. They have evergreen or nearly evergreen opposite entire leaves, and dense clusters of small, white, tubular four-parted flowers, enclosing two stamens and succeeded by small, globular, usually black fruits, each with pendulous seeds. The best-known species is the common European privet, *L. vulgare,* which makes good hedges; there are numerous varieties with variegated leaves. The so-called California privet *(L. ovalifolium),* native to Japan, is widely planted in the United States and thrives in Great Britain. L. *japonicum,* the wax privet, L. *lucidum* and *L. massalongianum* are fine evergreen species, hardy only in warm regions. Mock-privet, *Phillyrea,* a member of the same family, is an ornamental evergreen shrub, hardy only in warm places.

PRIVILEGE, in law, an immunity or exemption conferred by special grant in derogation of common right. The term is derived from *privilegium,* a law specially passed in favour of or against a particular person. In Roman law the latter sense was the more common; in modern law the word bears only the former sense. Privilege in English law is either *personal* or real—that is to say, it is granted to a person, as a peer, or to a place, as a university. The most important instances at present existing in England are the privilege oi parliament *(see* PARLIAMENT), which protects certain communications from being regarded as libellous *(see* LIBEL AND SLANDER), and the privilege of the client by which counsel and solicitor are protected from disclosing, in judicial proceedings, information which has come to them in that relation. This does not extend to clergymen or medical attendants *(see* Observations by Mr. Justice McCardie in *The Times,* July 19, 1927). Privileged copyholders were those held by the custom of the manor and not by the will of the lord. There are certain debts in most countries which are said to be privileged —that is, such debts as must first be defrayed by the executor out of the personal estate of the deceased, in payment, for example, of funeral expenses or servants' wages. There are certain deeds and summonses which are privileged in Scots law, the former because they require less solemnity than ordinary deeds, the latter because the ordinary *induciae* are shortened in their case (see Watson, *Law Dict., s.v.* "Privilege"). The priority formerly possessed by specialty debts was abolished in 1869. *(See* DEBT.)

In the United States the term privilege is of considerable political importance. By art, iv. s. a of the Constitution, "the citizens of each State shall be entitled to all privileges and immunities of citizens in the several States." By art. xiv. s. 1 of the amendments to the Constitution (enacted July 28, 1868), "no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States." It will be noticed that the former applies to citizens of the States, the latter to citizens of the United States. "The intention of this clause (art. iv.) was to confer on the citizens of each State, if one may so say, a general citizenship, and to communicate all the privileges and immunities which the citizens of the same State would have been entitled to under the like circumstances" (Story, *Constitution of the United States,* 1806). The clauses have several times been the subject of judicial decision in the Supreme Court. With regard to art. iv. it was held that a State licence tax discriminating against commodities the production of other States was void as abridging the privileges and immunities of the citizens of such other States *(Ward* v. *State* of *Maryland,* 12 Wallace's Reports, 418). With regard to art xiv. 1, it was held that its main purpose was to protect from the hostile legislation of the States the privileges and immunities of citizens of the United States, looking more especially to the then recent admission of negroes to political rights. Accordingly it was held that a grant of exclusive right or privilege of maintaining slaughter-houses for 21 years, imposing at the same time the duty of providing ample conveniences, was not unconstitutional, as it was only a police regulation for the health of the people *(The Slaughter-House Cases,* 16 Wallace, *36).* The same has been held of a refusal by a State to grant to a woman a licence to practise law *(Bradwell* v. *The State,* 16 Wallace, 130), of a State law confining the rights of suffrage to males *(Minor* v. *Happersett,* 21 Wallace, 162), and of a State law regulating the sale of intoxicating liquors (*Bartemeyer* v. *Iowa,* 18 Wallace, 129). Suits to redress the deprivations of privilege secured by the Constitution of the United States must be brought in a United States court. It is a crime to conspire to prevent the free exercise and enjoyment of any privilege, or to conspire to deprive any person of equal privileges and immunities, or under colour of law to subject any inhabitant of a State or territory to the deprivation of any privileges or immunities *(Revised Statutes of United States,* ss. 5507, 5510, 5519).

It is sometimes difficult to distinguish between "privileges" and "rights" in the United States, but privileges are more general and the act of suffrage is considered a "privilege" rather than a ('right."

PRIVY COUNCIL. The privy council, like all the British institutions of central government, excepting the House of Commons, is descended from the court of the Norman kings. This *curia regis,* composed of the king's tenants-in-chief, the household officials, and anyone else whom the king chose to summon, performed all the functions of central government without differentiating between them. According to feudal theory, tenants owed suit to their lord's court; but every great lord had also his household officials, his chancellor, his treasurer, his chamberlain and his steward to transact his daily business. Thus, too, the *curia regis* expanded or contracted according to the nature of the business under consideration. The ordinary routine would be carried out by the officials, assisted by such barons as happened to be at court; for more important business the king would secure the attendance of a greater number of his tenants-in-chief; and on really vital matters the household officials would tend to become a numerically insignificant technical element in a large feudal assembly.

As time went by the larger and smaller gatherings came to be distinguished adjectivally; later, these adjectives developed a technical significance, until at last, although still remaining for a time merely different manifestations of a one and indivisible body, the larger assembly developed into the great council and the parliament, the smaller into the king's council. In early days the presence of many barons at conciliar meetings was the mark of a strong king; later, as the barons came lo realize that attendance was not merely a tiresome incident of feudal tenure but a source of political power, that obligation became a privilege. Thus, in the later middle ages there developed a struggle between king and greater barons for the control of the king's council. Was it to be feudal or expert? In the end the barons failed to secure their greater demands—exclusive membership and the control of appointment and dismissal—because they were unable to discover a means of adequately reconciling the principle of the right of all to attend with the actuality of a small assembly, because, though collectively anxious to control and individually willing to be appointed, they could never be relied upon for constant attendance, and because, with the passing of the feudal organization of society, baronial counsel ceased to be expert advice on matters of government. But the struggle was not entirely without fruit. A conciliar oath was instituted, membership became more determinate, and methods were devised, however primitive and clumsy, for enforcing responsibility.

By the time of Henry VII. this council had become the instrument of the Crown. It was composed of an inner ring of counsellors proper, who took the conciliar oath and sat at the council board, and of an outer ring of technical experts and dignitaries (later, in the reign of Henry VIII., known as ordinary counsellors), who, though they might occasionally be called upon for advice, were not members of the board, did not take the conciliar oath, but merely that of their respective offices, and performed the technical and routine work of the central and provincial courts of the council. It was the policy of the Tudors to rule the country paternally by the prerogative exercised through the medium of the council.

Star Chamber and Privy Council.—This conception of government necessitated precision, sub-division and specialization, and thus, just as in earlier times, for analogous reasons, the undifferentiated curia *regis* had given birth and place to a number of descendent courts and councils, so in Tudor times the king's council and its functions were split up and divided between the privy council, the courts of Star Chamber, of requests and of high commission (qqv.), and such local offshoots as the courts and councils of the North, and of Wales and the Marches. A distinction between the council with the king and the council at Westminster had appeared from time to time during the middle ages. It now became "sharper and more permanent." The body "following the king was commonly known as the 'council at court,' while the other continued to be called 'the king's council in the Star Chamber.' The former body became the privy council."

This conciliar government was admirably suited to a period of transition. But the need of this somewhat arbitrary, if paternal, government had passed with the Tudors. Moreover, this small but all-powerful bureaucracy depended for its efficiency on a resolute and discriminating sovereign, capable of choosing the right men and of superintending their labours. The Stuarts did not possess these qualifications. The House of Commons, hitherto accustomed to follow the leadership of privy councillors, had now, with increased experience of partnership in government, developed a mind and policy of its own. Of the judicial aspect of the council's activities the common lawyers were coming to show an even more threatening jealousy, a jealousy justified by the misguided action of the Stuarts in checking the natural evolution of these courts towards independence of executive control and in using them to enforce, not justice, but policy. No wonder, then, that as religious and constitutional controversies developed between Crown and parliament the attention of malcontents became focussed on conciliar jurisdiction, nor that, when the parliamentary cause at last triumphed, in 1641, the whole system of conciliar government was swept away. Only the privy council was spared. It was never legally abolished. It perished in the interregnum (though the name was resuscitated in 1657) and revived with the return of Charles II. in 1660.

The personnel of the council was recruited from clergy, peerage and commons. The baronage, as we saw, had failed in the middle ages to secure exclusive membership. The Tudors preferred to employ men of low degree who would be wholly dependent on their master, and could be rewarded inexpensively by promotion in the Church, to the judicial bench or to other State offices, where their dignities would not become hereditary. Indeed, so professional did the council become that even the peers on it were members by virtue of office rather than of birth. The ecclesiastics also, who in the middle ages had predominated in the great offices of State, now declined in numbers and influence, partly because they had no longer a monopoly of education, and partly because, since the Reformation, they had ceased to be officials of an international hierarchy, semi-independent of secular control. Thus the majority of the council came to consist of lay commoners, and the proportion may fairly be illustrated from the council of Edward VI., which consisted of 17 commoners, two prelates and seven peers, only one of whom held a peerage of more than 12 years' creation.

Members.—Both in the middle ages and for several centuries later contemporary opinion favoured 20 as about the ideal total of conciliar membership. But seldom did practice conform with theory. When the privy councillor register begins, in 1540, we do, indeed, find 19 members, but by Henry VIII.'s death there were 29 In Edward's reign the record was 40, in Mary's 44, and, although Elizabeth reduced the numbers to between a dozen and a score, the Stuarts, as usual, were less successful. By 1623 the total had increased to 35, and Charles I.'s council averaged at about the same figure. The nucleus of principal officers, if a rough generalization be permitted, comprised the archbishop of Canterbury, the lord chancellor, the lord treasurer, the lord president (when there was one), the lord privy seal, the lord admiral, the lord steward, the lord chamberlain, the two secretaries of State, the chancellor of the Exchequer, the treasurer and the comptroller of the king's household, and the chancellor of the duchy of Lancaster. At the Restoration the problem of numbers became even more acute. Gen. Monk, we are told, presented Charles with a paper containing "the names of at least three score and ten persons, who were thought fittest to be made privy counsellors." Charles had also to remember the survival of his father's council and his own advisers, whom he had brought with him from beyond the seas. All things considered, it is not surprising that, though he managed to begin with only 28, the total had reached 47 by 1679. Temple's abortive attempt at conciliar reform temporarily reduced the figure to 33, but by 1688 it was back again at 48, by 1707 it had reached 60 and, by 1723, 67.

The Pre-eminence of the Cabinet.—In proportion as the numbers of the privy council rose, so did its powers decline. Even in Tudor times the increasing membership and the volume of work had led to the institution of committees, and already, under the early Stuarts, one of these committees, out of which was to develop the cabinet, was beginning to usurp the functions of the council. (For the development and extent of this usurpation see CABINET.) Unpopular as this tendency was, it could not be checked. The petition of Lords and Commons in 1642 "that matters of State proper for the privy council might be debated and concluded there" is only one instance of many unavailing protests. Charles II., after his restoration, carried caballing on official and unofficial committees beyond the limits of the nation's endurance, and was at last, in 1679, forced to submit to the first serious attempt to restore the powers of the council. Sir William Temple was the reputed father of the scheme, but it seems that the king played a, for him, not unusual part in the begetting of it. The reformed council was to consist of 15 "who shall be privy councellours by their places" and of 15 others representing the various sections of parliamentary opinion, plus princes of the blood, a lord president, and a secretary for Scotland when in England—33 in all. The scheme was, in fact, a failure from the start. Membership was still too numerous for efficiency, too diverse in opinion to be able to pursue, much less to dictate, a consistent policy; worse still, the experiment was received with cold suspicion by parliament. Charles, in spite of recent professions of loyalty to the new council, began flouting it at once. He prorogued the parliament without consulting it, dissolved the parliament contrary to the advice of a large majority, and finally, in spite of it, prevented for a year the meeting of the new parliament. Once more he had resort to caballing. Not unnaturally, the opposition members of the council ceased to attend meetings which were nothing but a farce, and with their disappearance the council may be said to have reverted to its former constitution.

The last serious attempt to restore the privy council to its former position and influence may be found in the clause of the Act of Settlement (1701), which enacted that, on the Hanoverian accession, "all matters and things relating to the well-governing of the kingdom, which are properly cognizable in the privy council by the laws and customs of this realm, shall be transacted there, and all resolutions taken thereupon shall be signed by such of the privy council as shall advise and consent to the same." But the proposal was by that date impracticable, and the clause was repealed in 1705 before it even came into force. The council board had been not merely short-circuited by the cabinet, it had even lost the power of debating such measures as came before it. In 1711 a debate on the subject in parliament elicited the remark that "the privy counsellors were such as were thought to know everything and knew nothing. Those of the cabinet council thought nobody knew anything but themselves." And the last occasion on which the council asserted its former rights was when, in 1714, as Queen Anne lay dying, certain Whig lords forced their way in at a meeting of the lords of the committee (see CABINET), claimed their right to be present as counsellors of the Crown, converted the meeting into a session of the privy council and, reinforced by their conciliar colleagues, ushered in the Hanoverian succession. From the accession of George I, the privy council may be described as a purely formal body meeting on purely foimal occasions to transact purely formal business. There are now (1928) nearly 300 "right honourable lords and others of His Majesty's Most Honourable Privy Council." They are mostly dignitaries who have held, or hold, high political, judicial or ecclesiastical office in Great Britain, the dominions, or the colonies; though the list, we are told, "occasionally" includes "eminent persons in science or letters." Office lasts for the life of the sovereign and six months after, but it is the modern custom for the new sovereign to renew the appointment.

FUNCTIONS

The curia *regis* performed all the functions of central government without differentiating between them. Later, with the multiplication and elaboration of business, as old methods became too stereotyped and cumbersome to meet new needs, the one court gave birth and place to many. But, since differentiation was along the lines of procedure rather than of function, every true offspring of the curia, however much it might come in time to specialize in one particular function, tended to retain at least some traces of the others as well. Thus, by the end of the mediaeval period the king's council was coming to be thought of mainly as an executive body, but it still retained extensive judicial, fiscal and legislative powers, and portions of all these (except the fiscal) have, in diminishing quantities, descended through the ages to, and been inherited by, the modem privy council, along with certain other duties which still defy expert analysis as exclusively executive or judicial or legislative.

Executive. — The consultative and advisory functions formerly exercised by the privy council were usurped, as shown above, by a committee of counsellors, who came to be known collectively as the cabinet (*q.v.*). The duties of the other committees of the council have been handed over, to a large extent, to State departments, such as the Board of Trade, the Local Government Board, the Board of Education and the Board of Agriculture, presided over by ministers responsible to parliament. The privy council itself now acts merely as the formal medium for giving expression, by Order of Council or by Proclamation, to the measures determined on by the Crown on the advice of its ministers, in the exercise of those executive functions which it possesses either by virtue of the prerogative or by statutory authority. Orders in Council are used when new rules and regulations are approved and passed by the King in council, or for proclamations to give publicity to such matters as the summons, dissolution, or prorogation of parliament, or the declaration of peace or war. These formal meetings are attended by a few councillors, generally ministers or officials, three of whom form a quorum, and the orders of the council are authenticated by the signature of the clerk to the council.

Nevertheless, there are still committees in existence exercising important functions of a mixed kind. For instance, it not infrequently happens that parliament, faced with the difficulty of enacting long and intricate legislation, confines its attention to general outline and principle, at the same time authorizing, under the act, the privy council to fill in the details. These powers are exercised usually by committees to which matters are referred by the Crown in council. Thus two applications in connection with the attention of the statutes of the universities and colleges of Oxford and Cambridge came before the universities' committee. And it is obvious that the work of such committees involves all the functions of government, administrative, judicial and legislative.

Fiscal. — The curia provided no machinery for national taxation, since the latter had no place in feudal society. It was the accepted doctrine that "the king should live of his own," that is, on the rents and services due to him: and these were adequately dealt with by the Exchequer. So exclusively was it an affair between lord and tenant that Magna Carta attempted to check, or regulate, the raising of exceptional revenue by providing that whenever the sovereign wanted more than his ancient feudal dues, he should consult a gathering of his tenants-in-chief. Only with the coming of the Commons to parliament and with the growth of the idea that money is granted in exchange for redress of grievances does national direct taxation find a place in the constitutional scheme, and that place, of course, is in parliament, and in parliament alone. But in the matter of indirect taxation the position was not so clear. The regulation of trade and the vicissitudes of foreign policy necessitated, in early times, the imposition and manipulation of customs duties by the Crown in council.

Later on, the growing jealousy of parliament led to the passage of statutes which did something to restrict, but very little to define, the royal powers in this direction. For two centuries or more, however, the issue was compromised. As long as the Crown was content to leave the question of the prerogative in abeyance, certain duties were annexed to the Crown in perpetuity and others voted to every new sovereign by his first parliament for life. It was James I. who violated this understanding by issuing a new Book of Rates, placing impositions upon articles produced and sold within the kingdom, and making other alterations, not, as the Tudors had done, in the interests of trade and foreign policy, but for purely fiscal purposes. Charles I., in consequence, was not voted tunnage and poundage, for life, on his accession, and the whole question of prerogative levies came up for discussion and decision. At the end of a struggle in which neither party had either the law or honesty completely on its side, parliament, by the Petition of Right (1628), and the Tunnage and Poundage and Ship Money Acts (1641), finally secured absolute control over all taxation, indirect and direct.

Legislative. — Many of the so-called statutes of the middle ages have no better authority than the Crown in council. By the end of the 15th century, however, statutes are quite distinct from ordinances or proclamations (as they were coming to be called). Conciliar legislation was vaguely considered to be subordinate to statute and common law, and less permanent also, its duration being apparently limited to the life of the enacting sovereign. Nevertheless, the legislative powers of the Crown in council were still wide and undefined. The Statute of Proclamations (1539) did something temporarily to regulate them on a firm basis and with a limited range, but was repealed at the accession of Edward VI., and as, later on, parliaments became less docile, there was a natural tendency on the part of the sovereign to claim greater authority and a wider scope for proclamations. "When the common state or wealth of the people require it," it was said in the Star Chamber, "the king's proclamation binds as a new law and need not stay a parliament." Finally, the ambitious pretensions of the first Stuart king brought the matter to a head. In 1610 the Commons complained that the number and range of recent proclamations made them fear "that proclamations will, by degrees, grow up and increase to the strength and nature of laws." And Coke, consulted as to the answer to be given, laid down in the Case of *Proclamations* an authoritative limitation. "The king cannot," he said, "change any part of the common law nor create any offence by his proclamation which was not an offence before, without parliament. . . . But a thing which is punishable by the law, by fine and imprisonment, if the king prohibit it by his proclamation . . . and so warn his subjects of the peril of it . . . this as a circumstance aggravates the offence." It was too much to expect either James I. or Charles I. to observe these principles, but the later Stuarts kept to the limits laid down, mainly, perhaps, because there was no longer a Star Chamber to enforce the ultra-legal acts of a sovereign.

But there is another aspect of the legislative functions of the council. It was completely, once, and is still, in part, a component of the legislature. Parliament was originally only the fullest assembly of the curia *regis*, a re-fusion, as it has been called, of all the elements into which the old, undifferentiated curia was coming to be resolved. As the king was the core of the council. so the council was the core of the parliament. Those members of the council who were lords, spiritual or lay, sat among their peers on the benches along the side walls, to right and left of the king respectively; the commoners sat on four woolsacks in the midst of the chamber. Their exact positions were regulated later by the Act for Placing the Lords (1539). But already, in the 14th century, as the parliament chamber began to develop into the House of Lords, peers and bishops began to regard the commoners present as inferior persons, with inferior, if any, rights.

As the commoners lost influence, so they lost interest, and in Wolsey's time began to seek election to the House of Commons; and this practice had become the rule for privy councillors, who were not bishops and peers, by the middle of the 16th century. The lord chancellor remained in the House of Lords because he was its presiding officer (only since Anne's reign has he been invariably made a peer), and thus retained his woolsack, but the other councillors — by non-attendance — have forfeited their seats, and even now a privy councillor, not being a peer or bishop, who wishes to attend the House of Lords, must content himself with standing on the steps of the throne. The so-called privilege of the Lords to require the attendance of the judges (who still sit on the woolsacks at the opening of parliament) is no more than a survival of the judges' regular attendance in the parliament chamber as members of the *curia* and counsellors of the Crown.

For the Judicial Committee of the Privy Council see below.

PRIVY COUNCIL, JUDICIAL COMMITTEE OF.

By the 19th century it had become apparent that the jurisdiction of the "King in council," wielded upon a wider and wider scale, must be regularized. In the year 1833 the judicial committee of the privy council, the present body, was constituted by the famous statutes 3 and 4 William IV. chap. 41.

While historically the existence of an approach by way of an appeal to his majesty had remained, a demand continually arose for systematizing the procedure of such appeal. This was accomplished and the whole institution was re-formed, methodized and regularized by the "Act for Administration of Justice in His Majesty's Privy Council," the authorship of which is attributed to Lord Brougham, and which was passed on Aug. 14, 1833. Much in that statute has been changed; in particular the admiralty jurisdiction has been wholly transferred to the court of admiralty, which, with the probate and matrimonial jurisdiction, has become one of the common law courts of the country under the Judicature Act of 1874. But the important work and sphere of the privy council in regard to the dominions of the crown finds its foundation in this statute.

Indian Business. — Before citing the Act, it may be well to pause and to consider not only how the jurisdiction of the council had extended (as we have seen) to various outlying portions of the king's dominions, but also how its authority over the East Indian possessions was originally established. The short history of this is as follows. By charter of George I. in 1726 courts were established in the three settlements — Madras, Bombay and Bengal, and an appeal to his majesty in council was given. Subsequent charters constituted supreme courts and these in time were replaced by various high courts created under the charter Acts 24 and 25 Victoria, chap. 104. These high courts were constituted by letters patent which contained rules providing for appeals to the privy council. Since then, further high courts have been established and these are also constituted by letters patent containing similar provisions as to appeals. The Civil Procedure Code also gives a right of appeal under prescribed conditions and there has followed an Order of Council of Feb. g, 1920, which replaces a much earlier one issued under the Judicial Committee Act of 1833. It is easily understood how upon a system thus developing in loyalty to the central jurisdiction and prerogative of the Crown, the Act of 1833 was completely in keeping with such development. So great has the growth of Indian judicial business before the committee become, that the committee has been divided into two working sections, one of which is entirely or almost entirely occupied with Indian appeals. By s. 30 of the Judicial Committee Act of 1833, two Indian retired judges are also eligible as members of the committee.

Before coming to the Statute itself, it may be well to apprize the reader of various items of privy council jurisdiction which stand quite apart from that exercised in appeals from India and the colonies and dominions.

Ecclesiastical Jurisdiction. — The ecclesiastical jurisdiction of the king in council is derived from the statute 25 Henry VIII. chap. 19, which followed the famous Act of the previous year, 24 Henry VIII. chap. 12, abolishing appeals to Rome. By the Act 25 Henry VIII. chap. 19 an appeal was given from the courts of the archbishop to the king in chancery and it was enacted that upon such appeal

> "A Commission shall be directed under the great seal to such persons as shall be named by the King's Highness his heirs or successors like as in case of appeal from the Admirall Court to hear and definitely determine such appeals and the causes concerning the same."

This commission in time became known as the High Court of Delegates, which was abolished by 2 and 3 William IV. chap. 92, and by 3 and 4 William IV. chap. 41, ecclesiastical appeals were transferred to the judicial committee. The result is that appeals from the two courts of archbishops (*i.e.,* arches court of Canterbury and provincial court of York) lie to the king in council.

With regard to appeals under the Clergy Discipline Act 1892 (dealing with morals), there is an alternate right of appeal from the consistory court of bishops either to the court of the archbishop or to the king in council direct. If the appellant elects the former there is no further appeal to the king in council. On the hearing of ecclesiastical appeals under the rules made under the Appellate Jurisdiction Act 1876, five bishops have to be summoned as ecclesiastical assessors, of whom three at least have to be present. Under the Endowed Schools Act, 36 and 37 Vic. chap. 87, appeals lie to his majesty in council from schemes prepared by the Board of Education affecting schools subject to the Endowed Schools Acts. Under the Union of Benefices Measure 1923 of the national assembly of the Church of England, an appeal lies to the king in council against a scheme of the ecclesiastical commissioners uniting two or more benefices.

The Statute of 1833. — The Act provides in its first section for the composition of the council headed by the president for the time being thereof, and the lord high chancellor and other learned dignitaries as there set forth. These "shall form a committee of his majesty's said privy council and shall be styled the judicial committee of the privy council." In later years the personnel of the committee has been changed and enlarged. It now consists of the lord chancellor, the lord president, the lord president of the council and the lords of appeal in ordinary, these being six in number, together with the two Indian members already mentioned. To them are added such other members of the privy council as shall from time to time hold or have held "high judicial office." These last render voluntary and valuable service, and without their assistance the increasing business of the committee would fall hopelessly into arrear.

It is provided by the third section:—

> "That all appeals or complaints in the nature of appeals whatever, which, either by virtue of this Act, or of any law, statute, or custom, may be brought before his majesty or his majesty in council from or in respect of the determination, sentence, rule, or order of any court, judge, or judicial officer, and all such appeals as are now

pending and unheard, shall from and after the passing of this Act be referred by his majesty to the said judicial committee of his privy council, and that such appeals, causes, and matters shall be heard by the said judicial committee, and a report or recommendation thereon shall be made to his majesty in council for his decision thereon as heretofore, in the same manner and form as has been heretofore the custom with respect to matters referred by his majesty to the whole of his privy council or a committee thereof (the nature of such report or recommendation being always stated in open court)!'

The British Dominions.—In 1867 the famous British North America Act was passed. It disclosed within its constitution questions of a high and delicate order. The principal of these questions was contained in the enumeration by s. 91 of the powers of the Dominion pariiament and by s 92 of the exclusive powers of provincial legislatures. It became at once evident that the task of clearing the boundary lines not only inter-provincially but between Dominion and province would be a task of severe strain. The authority of the judicial committee of the privy councii was clear from the Act of 1833, but the Canadian parliament thought fit to emphasize that situation by the 47th section of their Supreme and Exchequer Courts Act (38 Vic. chap, 11). That section is in the following terms:—

"The judgment of the Supreme Court shall in all cases be final and conclusive, and no appeal shall be brought from any judgment or order of the Supreme Court to any court of appeal established by the parliament of Great Britain and Ireland, by which appeals or petitions to her majesty may be ordered to be heard: saving any right which her majesty may be graciously pleased to exercise by virtue of her royal prerogative."

Under the powers vested in it, the judicial committee has pronounced a series of judgments the constitutional importance of which is recognized throughout the world. Every year appears to bring a fresh crop of questions to be solved, arising out of the construction of the British North America Act.

The settlement of the constitutional relations of the various States of Australia with each other, their federation into one commonwealth, and the adjustment of their reiations judicially with the imperial authority and royal prerogative were settled by the Commonwealth of Australia Constitution Act, 63 and 64 Vic. chap. 12. It has to be noted that in ordinary cases by force of the royal prerogative an appeal may be admitted to the judicial committee; but in constitutional cases such an appeal is only allowed on a certification of the High Court of Australia. Section 74 of the Act is in these terms:—

"No appeal shall be permitted to the queen in council from a decision of the High Court upon any question, howsoever arising, as to the limits *inter se* of the constitutional powers of the commonwealth and those of any State or States, or as to the limits *inter* se of the constitutional powers of any two or more States, unless the High Court shall certify that the question is one which ought to be determined by her majesty in council. The High Court may so certify if satisfied that for any special reason the certificate should be granted, and thereupon an appeal shall lie to her majesty in council on the question without further leave. Except as provided in this section, this constitution shall not impair any right which the queen may be pleased to exercise by virtue of her royal prerogative to grant special leave of appeal from the High Court to her majesty in council. The parliament may make laws limiting the matters in which such leave may be asked, but proposed laws containing any such limitation shall be reserved by the governor-general for her majesty's pleasure."

In 1909 there was passed on Sept. 20 an Act to constitute the Union of South Africa This Act was the result of severe parliamentary and constitutional struggles following the South African War. Judicial affairs were regulated substantially on the Canadian model. By s. 106 of the statute it was provided:—

"There shall be no appeal from the Supreme Court of South Africa or from any division thereof to the king in council, but nothing herein conrained shall be construed to impair any right which the king in council may be pleased to exercise to grant special leave to appeal from the appellate division to the king in council. Parliament may make laws limiting the matters in respect of which such special leave may be asked, but bills containing any such limitation shall be reserved by the governor-general for the signification of his majesty's pleasure: provided that nothing in this section shall affect any right of appeal to his majesty in council from any judgment given by the appellate division of the Supreme Court under or in virtue of the Colonial Courts of Admiralty Act 1899"

The effect of these provisions came prominently into view in the adjusting of the relations between the judicial committee and the Government of Ireland during the negotiations under which the constitution of the Irish Free State mas framed. By the Act of Dec. 5, 1922, the Irish Free State Constitution Act, the various articles of the constitution were set forth in schedule I. The 66th article is as follows:—

"The Supreme Court of the Irish Free State (Saorstát Eireann) shall, with such exceptions (not including cases which involve questions as to the validity of any law) and subject to such regulations as may be prescribed by law, have appellate jurisdiction from all decisions of the High Court. The decision of the Supreme Court shall in all cases be final and conclusive, and shall not be reviewed or capable of being reviewed by any other court, tribunal or authority whatsoever: provided that nothing in this constitution shall impair the right of any person to petition his majesty for special leave to appeal from the Supreme Court to his majesty in council or the right of his majesty to grant such leave."

It will be seen that the main lines of this judicial settlement followed almost precisely those applicable to the Dominion of Canada. And it will be further and particularly observed that there has not been granted to the legislature of Iieland the power granted to the parliaments of Australia and South Africa respectively, as just quoted, namely, to "make laws limiting the matters in which such special leave may be asked" with reservations by the governor-general

General Considerations.—No one considering this brief sketch of the widening of the scope of such a jurisdiction can fail to be impressed by several cardinal facts. In the first place, this jurisdiction has marked and kept pace with the development of the empire itself. Secondly, and in a singular degree, the judicial committee has formed a central and cohesive power attaching not Crown colonies alone, but the self-governing portions of the empire in homage to a jurisprudence which, developing from year to year and from precedent to precedent, has proved the adaptability of law under enlightened administration to circumstances and to peoples and even to stages of civilization, of infinite variety

The next consideration is of great import. It explains why the variety alluded to has been found compatible with the maintenance of law under conditions at once local and yet central and imperial. The reason is found in the genius of the British people, and the remarkable grasp within the sphere of iaw of the principle of self government. The difference between British jurisprudence and the jurisprudence of Rome or, say, in modern times, of Germany, is that to the world Rome gave Roman law, and io the modern world Germany desired to give German law; but the British empire gives to its component parts their own law. This imposes a task of great complexity. Systems of jurisprudence totally different in outward seeming, but respectively in entire accord with the historical and tribal traditions of the various populations and parts of empire, have to be administered in such a fashion as to accept and respect not only established local traditions, customs and laws but also the hereditary and prized rules of succession, rights of property and even of religion prevailing in various quarters of the globe To take India for an example, the appiication of Hindu law to the Mohammedans, or of Buddhist law to Hindus, instead of uniting the empire might break it to pieces.

In Canada the same variety in unity prevails. Each province feels safe. In 1774 the Quebec Act provided that in civil matters the old laws of Quebec should still apply. Among these were "First, the *coutumes de Paris* and the ordinances in force within the jurisdiction of Paris; second, the *arret du conseil du roi* and the ordinances published between 1663 and 1763." In short the legal situation in those respects in Quebec is that of Paris prior to the French Revolution, whereas in the other provinces the basis of law is the common law of England Each province of the Great Dominion developing its own provincial legislation, must have its statutes recognized by the Central Power and stands by its own system. The lines of function and jurisprudence of the provinces may thus differ from each other and each and ali from the Dominion itself. The resultant conflicts arouse in many cases the keenest feeling and these have been brought for settlement to the bar of the privy council administering and interpreting the law as laid down in the Act of 1867. These illustrations of variety in unity evolving into an imperial harmony need not be multiplied.

This principle of resolute and harmonious accord with local tradition, creed and custom extends as has been indicated even to the adoption and administration of whole systems of jurisprudence. As first noted, within Canada itself the range extends from modern English law to ancient French. Again, over no inconsiderable part of the empire it is a fact that Roman-Dutch law holds sway. This is shown in parts of the empire so wide apart as South Africa, Ceylon and British Guiana. Space forbids a further enumeration but sufficient has been said to indicate the stupendous difficulties which have to be overcome by this resolute respect for colonial and Indian jurisprudence. It is from quarters in which these difficulties have to be daily surmounted (Quebec and the empire of India being cited as examples) that the firmest support comes for the upholding of the dignity and jurisdiction of the Council as now existing.

This finally raises a problem as to future constitutional development. It is acknowledged that the rational foundations of the jurisdiction and administrative power of the judicial committee rest upon fundamental ethical principles which, finding varying expression under varying systems, are yet essentially the same. Simple illustrations occur such as these: that under the Roman-Dutch law one would naturally cite the old maxim, *sic utere tuo ut alienum non laedas;* when, in India, embarrassment is caused by the apparent failure to reach a common ground of principle, resort is had to "justice, equity and good conscience," and this principle finds its place in every Indian textbook; in Canada, the British North America Act expressly confers upon the Dominion confronted with provincial demands the province of preserving "peace, order and good government." Apart from these instances, no jurisprudence fortified by centuries of tradition can be finally found to rest on foundations less sure than the *recta ratio* of Cicero, the righteousness of ancient, and the justice tinctured with toleration of modern times.

Two points in conclusion may be noted. Section 4 of the Act of 1833 has been already cited, providing for a reference to the judicial committee of any such other matters as his majesty shall think fit. This nebulous and almost all-embracing provision has in spirit been followed in Canada by a reference to the courts of abstract questions for a guide to Government in its administrative policy. It must be said frankly that such provisions are received by courts, including the committee itself, with the greatest caution, for the simple reason that judicial tribunals should not be set to abstractions but to problems which have actually arisen and upon which *in foro contentioso* parties have argued out their differences. To forsake this principle would tend to turn a judicial tribunal into a mere philosophic academy. As a last resource however this branch of the prerogative may have to be resorted to. This was done in reference to the settlement of claims of compensation for civil servants who under statutory cessation of their British employment entered the service of the Irish Free State. A decision in a certain sense had been given by the privy council and had been challenged by the Free State, and thereupon s. 4 of the Act of 1833 was put into operation, substantially to reconsider a decided case. In these columns no discussion of such a point would be either possible or proper.

The rules of procedure and general methods of the conduct of business by the committee are found in books of practice.

In addition to the general constitutional authorities, *e.g.*, Hallam and others, on Privy Council, *see*, in particular, references to the work of the judicial committee in N. Bentwich, *Privy Council Practice* (2nd ed., 1926); Lord Shaw of Dunfermline, *The Law of the Kinsmen* (1928); J. H. Morgan, *The Law and Constitution of the Empire.*

(SH.)

PRIVY PURSE is the amount set apart in the civil list (*q.v.*) for the private and personal use of the sovereign in England. During the reign of Queen Victoria it was £60,000 a year, but on the accession of Edward VII. the amount was fixed at £110,000 a year, which was the amount paid to the last sovereign (William IV.) who had a queen consort. Under Queen Victoria the offices of keeper of the privy purse and private secretary were combined. These officials, with their subordinates, are of the king's *personal staff.*

PRIZE, in law, may be defined as the vessels or goods of the enemy or of a neutral, or of a subject of the captor's own State or of a subject of an ally, captured *jure belli* by a belligerent captor on the high seas, or in rivers, ports and harbours and even in some circumstances on land (*see* the *Roumanian,* 1914, I.B. & C.P.C. 75). For England the term "vessels" includes merchantmen, lighters, rafts, tugs, boats and all other naval craft together with their appointments, such as signalling instruments (*see* the *Anichab,* 1919, 3 B. & C.P.C. 611; 1922, A.C. 235). The term "goods" includes "cargoes" which covers "choses in action" (*q.v.*) (the *Fredrick VIII.,* 1917, *P.* 43); "bonds and securities" (the *Noordam* [No. 2], 1920, A.C. 904); and "moneys" (*Turkish moneys taken at Mudros,* 1916, 2 B. & C.P.C. 336). Not only goods shipped under a bill of lading (*Ten Bales of Silk at Port Said,* 1916, 2 B. & C.P.C. 13), but also goods despatched by parcels post are carried by the term (*see* the *Tubantia,* 1916, L.R.P.C. 282). The property in prize does not pass to the captor until it has been brought within the jurisdiction and adjudicated upon. But the property in captured war-ships passes, on capture, to the captor, and they are only brought into the prize court in order that the prize money may be determined.

United States.—The term prize is "used as a technical term to express a legal capture." (*Miller* v. *The Resolution,* 1781, 2 Dallas Reports, 1.) The courts "assume that 'capture' and 'prize' are not convertible terms, and that for the subject of capture to be made prize for the benefit of the captors the taking must meet the conditions imposed by the statutes." (*The Manila Prize Cases,* 1903, 188 U.S. Reports, 254.)

Captures made on inland waters of the United States are not "liable to condemnation as maritime prize." (*The Cotton Plant,* 1870, 10 Wallace Reports, 577.) The Act of Congress of July 17, 1862, "excludes property on land from the category of prize for the benefit of the captors." (*United States* v. *Alexander,* 1864, 2 Wallace Reports, 404.) The word "ship," however, "embraces her boats, tackle, apparel and appurtenances because part of the ship as a going concern, and, for the same reason, ship or vessel of war includes her armament, search-lights, stores, everything, in short, attached to or on board the ship in aid of her operations." (*The Manila Prize Cases,* 1903, 188 U.S. Reports, 254.) Non-seagoing boats such as barges propelled by sweeps and by poling, and boats having no means of propulsion are not regarded as maritime prize. (*Ibid.*) The United States long argued for the exemption from capture of private property at sea, but this doctrine was not accepted by other States or by the courts. The United States abolished prize money by an act of March 3, 1899. (30 U.S. Stat. 1007.)

Other Countries.—The French prize court will not adjudicate on the validity of captures of war-ships or on captures effected on lakes or other inland waters. Otherwise prize covers the same property as in England. In Italy prize extends to captures on the high seas and inland waters which include captures in ports, quays, docks and other places in which maritime traffic is carried on. According to the German Prize Code, 1909, prize includes enemy and neutral vessels and goods thereon, but not neutral public vessels. Enemy public vessels are confiscatable without other proceedings. German ships and cargoes and German goods on neutral or enemy vessels are excluded. During the World War the German prize courts declared themselves incompetent if the prize was destroyed without being first captured. Thus claimants were deprived of their legal remedy for the sinking at sight of their vessels, which was contrary to the accepted customs of war.

PRIZE COURTS AND PRIZE LAW. In England the admiralty court had jurisdiction in matters of prize from very early times, and although since the middle of the 17th century the *instance,* or ordinary civil jurisdiction of the court, has been kept distinct from the *prize* jurisdiction, they were originally both administered and regarded as being within the ordinary jurisdiction of the lord high admiral. The early records of the admiralty show that the origin of the prize jurisdiction is to be traced to the power given to the court of the admiral to try cases of piracy and "spoil," *i.e.,* captures of foreign ships by English ships.

Although the courts of common law hardly ever seem to have interfered with or disputed the admiralty prize jurisdiction, its exclusive nature was not finally admitted till 1782; but long previously royal ordinances (1512, 1602) and statutes (1661, giving an alternative of commissioners, 1670, 1706) had given the admiralty court the only express jurisdiction over prize. The statute of Anne and acts of 1739 and 1744 give prize jurisdiction to any court of admiralty, including the courts of admiralty for the colonies and plantations in North America.

Prior to the Naval Prize Act 1864, it was necessary for the Crown to confer prize jurisdiction upon the admiralty court by a special commission at the commencement of a war; this practice although no longer necessary has, however, been continued since on the outbreak of every war (see the Zamora, 1916, A.C. 77 96). By the Naval Prize Act 1864, the high court of admiralty and every admiralty or vice-admiralty court, or any other court exercising admiralty jurisdiction in British dominions, if for the time being authorized to exercise prize jurisdiction, were made prize courts. The high court of admiralty was given jurisdiction throughout British dominions as a prize court, and, as such, power to enforce any order of a vice-admiralty prize court and of the judicial committee of the privy council in prize appeals—this power *mutatis mutandis* being also given to vice-admiralty prize courts. An appeal was given from any prize court to the sovereign in council. Prize courts were given jurisdiction in cases of captures made on land by naval or joint naval and military forces or an expedition made conjointly with allied forces, and power to give prize salvage on recaptured ships and prize bounty; and a form of procedure was prescribed. The high court was also given exclusive jurisdiction as a prize court over questions of ransom and petitions of right in prize cases, and power to punish masters of ships under convoy disobeying orders or deserting convoy. By the Naval Discipline Act 1866, power to award damages to convoyed ships exposed to danger by the fault of the officer in charge of the convoy was also given to the high court. Under other statutes it had power to try questions of booty of war when referred to it by the Crown, in the same way as prize causes, and claims of king's ships for salvage on recaptures from pirates, which could be condemned as *droits* of admiralty, subject to the owner's right to receive them on paying one-eighth of the value, and also power to seize and restore prizes captured by belligerents in violation of British neutrality, or by a ship equipped in British ports contrary to British obligations of neutrality.

All jurisdiction of the high court of admiralty has since passed to the High Court of Justice, which is made a prize court with all the powers of the admiralty court in that respect; and all prize causes and matters within the jurisdiction of that court as a prize court are assigned to the probate, divorce and admiralty division; and an appeal from it as a prize court lies only to the king in council (Judicature Acts 1873 and 1891).

By the Prize Court Act 1894 further provision is made for the constitution of prize courts in British possessions. A commission, warrant or instruction from the Crown or the admiralty may be issued at any time, even in peace; and upon such issue, subject to instructions from the Crown, the vice-admiral of the possessions on being satisfied by information from a secretary of State that war has broken out between Great Britain and a foreign State, may make proclamation to that effect, and the commission or warrant comes into effect. The commission or warrant may authorize a vice-admiralty court or colonial court of admiralty to act as a prize court, or establish a vice-admiralty court for that purpose, and may be revoked or altered at any time.

By 4 and 5 Geo. V. c. 13 the provisions of the act of 1864 specified in the schedule to the act of 1914 relating to practice and procedure were repealed and rules in substitution in pursuance of 57 and 58 Vict. c. 39, s. 3, were made by Order in Council, with the proviso that nothing shall extend s. 16 of the act of 1864 to ships of war taken a prize, see *Rules* of Court in Prize Proceedings, Order in Council, Aug. *5, 1914,* which were subsequently amended by Order in Council issued as "Statutory Rules" on Nov. 28, 1914; Feb. 3, 1915; April 29, 1915; and Dec. 21, 1917.

British Prize Law.—The law to be administered by British prize courts is laid down in the commissions issued from time to time to the lord high admiral (now the lords of the Admiralty) "to empower the high court of admiralty (now the High Court of Justice and the judges thereof) to take cognizance of and judicially proceed upon all and all manner of captures, seizures, prizes and reprisals of all ships, vessels and goods that are or shall be taken, and to adjudge and condemn the same according to the course of the admiralty and law of nations; as also ships and goods liable to confiscation pursuant to the respective treaties with His Majesty and other princes and States" (Burchett's Naval History, 1719). The "course of the admiralty" was understood to mean the maritime law and customs of the sea, as recognized and applied by the maritime nations of Europe. "The law of nations" was wider. It included also treaties, the decisions of courts and the writings of jurists. Later it included international conventions, such as the Geneva Convention of 1906, Hague Conventions of 1899 and 1907, the Declarations of Paris 1856, and London 1909. Consequently British prize courts are bound to administer international law, but since they are municipal courts drawing their authority from the king in the parliament, they are bound by an act of parliament, even if it be contrary to the law of nations. They are not, however, bound by Orders in Council although they will act on them when they amount to a mitigation of the rights of the Crown in favour of the enemy or neutrai (see the Zamora, 1916, 2 A.C. 77; 2 B. & C.P.C. 1). Precedents are followed, but not blindly. As Sir Samuel Evans said in the Odessa (1914) 1 B. & C.P.C. at p. 175, they "should be treated as guides to lead and not as shackles to bind." By the Prize Court Rules 1914, captors may support their case by any evidence derived from extrinsic sources. In many cases of continuous voyage, for instance, it was only possible to detect and prove contraband trading by the interception of letters, cables and wireless messages.

See also Prize Cases Decided in the *United* States *Supreme* Court, *1789–1918* (1923). (X.)

The United States.—The Constitution of the United States vests the judicial power of the United States "in one Supreme Court and in such inferior courts as the Congress may from time to time ordain and establish." The judicial power shall extend "to all cases of admiralty and maritime jurisdiction" and the Supreme Court has appellate jurisdiction in prize cases. (Constitution, Art. III.) The Federal district courts have original jurisdiction "of all prize brought into the United States; and of all proceedings for the condemnation of property taken as prize." (42 U.S. Stat. 634.)

Art. I., section 8, of the Constitution provides that Congress shall have power "to declare war, grant letters of marque and reprisal and make rules concerning captures on land and water." Under this provision Congress has from time to time acted. On Jan. 15, 1780, even before the Constitution was adopted, it was resolved that a court of appeal be established which should hear appeals "in case of capture." The U.S. courts in the early days followed the recognized precedents as Mr. Justice Wilson said in 1796: "When the United States declared their independence, they were bound to receive the law of nations, in its modern state of purity and refinement." (Ware v. *Hylton,* 3 Dallas, 199.)

This applied to maritime capture as was said by Chief Justice Marshall in 1815: "The law of nations is the great source from which we derive those rules, respecting belligerent and neutral rights, which are recognized by all civilized and commercial states throughout Europe and America." (Thirty Hogsheads of *Sugar* v. Boyle, 181j, 9 Cranch, 191.) An early decision, in 1795, had said: "A prize court is, in effect, a court of all the nations in the world, because all persons, in every part of the world, are concluded by its sentences, in cases clearly coming within its jurisdiction." (*Penhallow* v. Doane, 1795, 3 Dallas, 54.) Mr. Justice Story in 1815 stated in the opinion of the Supreme Court: "The Court of Prize is emphatically a court of the law of rations, and it takes neither its character nor its rules from the mere municipal regulations of any country." (The Adeline, 9 Cranch, 244.) The aims of prize courts from the American point of view were stated from time to time by the Supreme Court in later decisions, as in 1882, when Justice Gray said: "Prize Courts are not instituted to determine civil and private rights, but for the purpose of trying judicially the lawfulness of captures at sea, according to the principles of public international law, with the double object of preventing and redressing wrongful captures, and of justifying the rightful acts of the captors, in the eyes of other nations." (*Cushing* v. *Laird,* 107 U.S. 69.)

The United States has also negotiated many treaties with the States of Central and South America which contain articles similar to the following of 1887 with Peru:—

Article XXV.

It is further agreed, that in all prize-cases, the courts especially established for such causes in the country to which the prizes may be conducted shall alone take cognizance of them. And whenever such courts of either party shall pronounce judgment against any vessel, merchandise, or property claimed by the citizens of the other party, the sentence or decree shall set forth the reasons or motives on which the same shall have been founded; and an authenticated copy of the sentence or decree, and of all the proceedings connected with the case, shall, if demanded, be delivered to the commander or agent of the said vessel, merchandise, or property, without any excuse or delay, upon payment of the established legal fees for the same. (25 U.S. Stat. 1444.)

In 1900 the Supreme Court, speaking through Justice Gray in regard to exemption of coast fisheries in time of war, said: "This rule of international law is one which prize courts, administering the law of nations, are bound to take judicial notice of, and to give effect to, in absence of any treaty or public act of their own government in relation to the matter." *(The Paquete Habana,* 175 U.S. 677.) In this same case it was said:—

"International law is part of our law, and must be ascertained and administered by the courts of justice of appropriate jurisdiction, as often as questions of right depending upon it are duly presented for their determination. For this purpose, where there is no treaty, and no controlling executive or legislative act or judicial decision, resort must be had to the customs and usages of civilized nations; and, as evidence of these, to the works of jurists and commentators, who by years of labour, research and experience, have made themselves peculiarly well acquainted with the subjects of which they treat. Such works are resorted to by judicial tribunals, not for the speculations of their authors concerning what the law ought to be, but for trustworthy evidence of what the law really is." (G. G. W.)

Other Countries.—The French court is an administrative not a judicial tribunal, with a *conseiller d'État* as president and six members chosen from the *maîtres des requêtes* and officials of the Ministries of Marine and Foreign Affairs. An appeal lies to the *conseil d'État.* The law is contained in treaties, national laws and decrees, custom and practice and in decisions of the prize courts. The latter are not regarded as binding and are not followed if they would entail inconvenient or inequitable results. The law has been codified in the "Instructions to Naval Officers" of Dec. 9, 1912 and Jan. 10, 1916 (see *Revue générale de Droit Inter. Public,* vol. 25, 1918; Fauchille, *Jurisprudence Française en Matière de Prises Maritimes,* 1919). Prize courts were established in Belgium during the World War. The court of first instance consists of two judges of the court of appeal and four members representing the navy and commerce. In cases exceeding 20,000 francs an appeal lies to the court of appeal, Brussels. The law administered is similar to that in France. The Italian prize court is also only partly judicial. It is composed of members appointed on the recommendation of the Ministries of Justice, Marine and Foreign Affairs. Appeal lies to the Supreme Court of Cassazione. The law administered is that contained in the law merchant and the naval instructions, the latest of which were issued on March 25, 1917. The court is bound by decrees duly promulgated *(see* Fauchille and Basdevant, *Jurisprudence Italienne en Matière de Prises Maritimes,* 1918). In Portugal the tribunal of commerce at Lisbon enjoys jurisdiction in prize automatically. Appeals lie to the Supreme Court of Justice.

During the World War prize courts were established for the German empire at Hamburg and Kiel composed of a judge as president and one legal member, a naval officer and two members representing shipping and commercial interests. Appeal lay to the superior court of prize sitting in Berlin, consisting of three judges, a naval officer and two lay members representing shipping and commercial interests. The law to be administered is contained in the prize code (*Prisenordnung*) of Sept. 30, 1909, and the prize court ordinance (*Prisengerichtsordnung*) of April 15, 1911, both of which were promulgated on Aug. 3, 1914, the latter being amended by an ordinance of March 26, 1916. By article 440 of the Treaty of Versailles, 1919, the Allied and Associated Powers reserved the right to examine all decisions and orders of the German prize courts whether affecting their own subjects or those of a neutral Power *(see* Fauchille and De Visscher, *Jurisprudence Allemande en Matière de Prises Maritimes,* 1922).

During the World War, prize courts were established by the Russian Government at Sebastopol, Kronstadt and Viadivostock. Each court was composed of an official of the Maritime Judicial Administration, two naval officers, two officials nominated by the minister of justice and one by the Foreign Office. An appeal lay to the admiralty council. The law to be administered was that contained in the prize code of 1895, amended in 1904 and revised in 1914. By an imperial ukase of Sept. 1, 1914, the Declaration of London, subject to some modifications, was declared obligatory and was, subject to some further modifications, applied by the courts. The Japanese prize court at Sasebo was composed of a judge as president and eight councillors selected from the navy and from the naval, legislative, foreign and diplomatic departments. Appeals lay to the higher prize court at Tokyo composed of a privy councillor and eight councillors. The law administered is contained in the Regulations issued in 1894, 1904 and 1914. The latter enacted that the principles of international law should be applied, subject to any national law, regulation or treaty, and in any event to reciprocal treatment (see *Rules of Naval War of Japan; Bulletin de l'Institut Intermédiaire International,* vol. XI. p. 9, 1924; Hurst and Bray, *Russian and Japanese Prize Cases,* 1912). By the Chinese Prize Courts Rules of Oct. 30, 1917, district prize courts were established with a personnel similar to that of the Japanese courts. An appeal lay to the high prize court composed of the president of the Supreme Court and eight members, representatives of the judicial, naval and administrative departments. The law to be administered is contained in the Chinese Prize Court Rules and Regulations, and when these are silent in the "law, treaties and international usage." The Hague Conventions II. and VI. were found by the courts to be binding (see *Chinese White Book,* 1918; *F. T.* Cheng, *Judgments of the High Prize Court of China,* 1919). Prize courts were established in Siam by the law of July 20, 1917. It was held by the Bangkok prize court that the law to be administered was the law of nations and not the municipal law (see *Reports of Prize Decisions* in the Fry library, London School of Economics).

An International **Prize** Court.—After much discussion, more particularly by the Institute of International Law and the International Law Association, a Convention for the institution of an international prize court was adopted by the Hague Peace Conference of 1907. By Convention XII. the court was to be a court of appeal from the prize court of a belligerent captor "upon the ground that the judgment was wrong either in fact or in law." In the absence of a treaty by the parties to the proceedings the court was to apply the rules of international law, and if no generally recognized rule existed, the court was to give judgment in accordance with the general principles of justice and equity. Owing, however, to the alleged uncertainty of the law the Convention was not ratified by any of the Powers, and a naval conference was held in London in 1908 for the purpose of codifying "the acknowledged principles of international law." The resulting Declaration of London purported to embody these principles in the rules which it formulated on blockade (*q.v.*), contraband (*q.v.*), unneutral service, destruction of neutral prizes, transfer to a neutral flag *(see* NEUTRALITY), enemy character, convoy (*q.v.*) resistance to search *(see* VISIT AND SEARCH), compensation.

PRIZREN, a town of S. Serbia, Yugoslavia. Pop. (1931), 18,952, chiefly Albanians, with some Serbs, Greeks and Vlachs, Prizren is beautifully situated 1,424 ft. above sea level among the Shar Planina mountains, and has an excellent water supply. The city is the seat of a Roman Catholic Archbishop, and a Greek bishop, and there is also a Serbian theological seminary. Its chief buildings are the citadel and many mosques, one of which is an ancient Byzantine basilica, originally a Serbian cathedral.

Prizren has sometimes, though on doubtful evidence, been identified with the ancient *Tharandus* or *Theranda.* In the 12th century it was the residence of the kings of Serbia. From the 13th century to the 16th Prizren had a flourishing export trade with Ragusa. The town was taken by the Serbians in 1912, and assigned to them by the Treaty of Bucharest (1913). Soon after the outbreak of World War I the government and the Serbian army retired there, followed by thousands of homeless refugees. Italy occupied Prizren during World War II.

PRJEVALSKY [PRZHEVALSKY] , **NIKOLAI MIKHAILOVICH** (1839–1888), Russian traveller, born at Kimbory, in the government of Smolensk, on March 31, 1839. He was educated at the Smolensk gymnasium, and in 1855 became a subaltern in an infantry regiment. In 1856 he became an officer, and four years later he entered the academy of the general staff. From 1864 to 1866 he taught geography at the military school at Warsaw, and in 1867 was admitted to the general staff and sent to Irkutsk, where he explored the highlands on the banks of the Usuri. This occupied him until 1869, when he published a book on the Usuri region, partly ethnographical in character. Between Nov. 1870 and Sept. 1873, accompanied by only three men, he crossed the Gobi desert, reached Peking, and explored the Ordos and the Ala-shan, as well as the upper part of the Yangtsze-kiang. He also penetrated into the then closed country of Tibet, reaching the banks of the Di Chu river.

On his second journey in 1877, while endeavouring to reach Lhasa through east Turkestan, he re-discovered the great lake Lop-nor (*q.v.*). On his third expedition in 1879–80 he penetrated, by Hami, the Tsai-dam and the great valley of the Tibetan river Kara-su, to Napchu, 170 m. from Lhasa, when he was turned back by order of the Dalai Lama. In 1883–85 he undertook a fourth journey in the mountain regions between Mongolia and Tibet. On these four expeditions he made valuable collections of plants and animals. He discovered the wild camel and the early type of horse, now known by his name (*Equw prjewalskii*). In Sept. 1888 he started on a fifth expedition to Lhasa, but on Nov. 1 he died at Karakol on Lake Issyk-kul. A monument was erected to his memory on the shores of the lake, and the town of Karakol (*q.v.*) was renamed Przhevalsk.

The English translation of the account of his first journey, *Mongolia, the Tangut Country, and the Solitudes of Northern Tibet (1876)* was edited by Sir Henry Yule; the account of his second journey, *From Kulja, across the Tian-Shun, to Lop-nor,* was translated into English in 1879.

PRQA (Malay, *prau*), the general term in the Malay language for all vessels, from the *sampan* or canoe to the square-rigged *kapal,* but in western usage confined to the swift-sailing craft that the pirates of the Indian Ocean made familiar to sailors in eastern waters. The chief points which characterize these vessels are that while the weather-side is rounded the lee-side is flat from stem to stern, that both stem and stern are exactly similar in shape, and that there is a small similarly shaped hull swung out from the side of the main hull on poles, which acts as an outrigger and prevents the vessel heeling over. The main hull carries the mast rigging and an enormous triangular-shaped sail.

PROBABILISM, a term used both in theology and in philosophy with the general implication that in the absence of certainty probability is the best criterion. Thus it is applied in connection with casuistry for the view that the layman in difficult matters of conscience may safely follow a doctrine inculcated by a recognized doctor of the church. This view was originated by the monk Molina (1528–1581), and has been widely employed by the Jesuits. In philosophy the term is applied to that practical doctrine which gives assistance in ordinary matters to one who is sceptical in respect of the possibility of real knowledge: it supposes that though knowledge is impossible a man may rely on strong beliefs in practical affairs. This view was held by the sceptics of the New Academy (*see* SCEPTICISM and CARNEADES). Opposed to "probabilism" is "probabiliorism" (Lat *probabilior,* more likely), which holds that when there is a preponderance of evidence on one side of a controversy that side is presumably right.

PROBABILITY (in Logic) is commonly contrasted with certainty. Some of our beliefs or judgments are entertained with certainty, others there are of which we are not so sure. The degrees of confidence with which the logic of probability is concerned are those which are correlated with different kinds of objective evidence, different degrees of objective cogency, not with the confidence which depends on mere feeling, or arises we know not how. In other words, we are concerned with degrees of *rational* belief or confidence. Again, the degrees of confidence attach to the beliefs or the judgments, or the propositions expressing the beliefs or judgments, so that strictly speaking the probability refers to the judgments or propositions, not to the things or events to which these refer. Things just are, and events just happen — there is no certainty or probability in *them.* Only our judgments about them can be more or less probable.

Cases of calculable probability are of two main types, namely, those which can be calculated a *priori,* or deductively, and those which can only be calculated *a posteriori,* or inductively. The *a priori* type is that in which the calculation can be made by reasoning deductively from the nature of the case, and without reference to actual observations of the kind of events under consideration. The *a posteriori* type consists of those cases in which the calculation can be made only with the aid of previous observations of similar events.

The A Priori Calculation of Probability. — In order to be able to calculate the probability of an event deductively from the nature of the case, the following conditions must be satisfied: (*a*) We must know the total number of mutually exclusive possibilities, one or other of which must be realized. (b) These possibilities must be equally likely. And (c) we must know how many of these possibilities are favourable to the event contemplated, that is, in how many of them it will be realized. The probability of the event in question is then expressed by means of a fraction in which the numerator gives the number of possibilities favourable to the event, and the denominator states the total number of equally likely possibilities. Clearly, the greater the total number of possibilities, the smaller is the probability (or chance) of any special one of them being realized; that is, if p represents the probability of an event and t the total number of equally likely events of which it is one, then p and t will vary inversely. For example, the chance of throwing head when tossing a coin is greater than that of throwing face six when throwing a die, because the former result is one of two possibilities, whereas the latter is only one of six. On the other hand, the greater the number of possibilities that are favourable, the greater is the probability. For instance, when throwing a die the probability of getting an even number is greater than that of throwing face six in particular, because there are three even numbers and only one six on a die. In this way, if the number of favourable possibilities be represented by f, we get the following general formula for probability: $p=f/t$.

A word may also be said about "odds" and "chances," terms which are more in popular favour than is the term "probability." The term "chances" is used sometimes for "probability" and sometimes for "odds." By "odds" is meant the ratio of favourable to unfavourable possibilities. By the odds *against* an event is meant the ratio of the unfavourable to the favourable possibilities.

In the case of simple events, like those of throwing a die or tossing a coin, there is no difficulty whatever in determining the values of favourable possibilities and of the total number of equally likely events and therefore of probability. With complex events (that is, those in which two or more separate events can be distinguished) care has to be exercised. The total number of possibilities in such cases is not the *sum* of the possibilities of the separate events, but their multiple, *e.g.,* if a die is thrown twice the total number of possibilities is not $6+6$, but 6×6 or 36, because for *each* possible result of the first throw there are six possibilities with the second throw. Now, the probability of a complex event may, according to circumstances, be either greater or less than the probability of the separate component events. The probability is less if the complex event contemplated is one in which certain component events must occur in a certain order, say *1* followed by *6* in two throws of a die, for either of the component events might happen without the other also happening, and then one of the component events would be there but not the compound event. In such cases the probability is obtained by multiplying the fractions expressing the separate probabilities of the several component events. On the calculations of probability *see* PROBABILITY AND ERROR.

Equally Likely Possibilities. — Why is it stipulated that the alternative possibilities must be equally likely? The point can be made clear by comparing two simple cases. Suppose one were to argue that a properly balanced coin when tossed must either throw head or not, so that there are two alternatives, of which head is one, and therefore its probability must be *1/2*. The answer would be true, but the reasoning would be wrong, as may be seen from the next case. Suppose one were to argue that a properly constructed die, when thrown, must either show face six or not, so that there are two possibilities of which face six is one, and therefore its probability is *1/2*. Here the answer is obviously wrong. But why? Because the possibility "not-six," that is, of face six not showing, really represents five different possibilities against the one "six," and must therefore be weighed accordingly as having a value five times that of "six." The probability of "not-six" is really *5/6*, while that of "six" is *1/6*. It was a mere accident that in the case of the coin "not-head" happened to represent only one alternative, namely, "tail." If no attention were paid to the equality of the alternative possibilities, then any statement, the truth of which we are not in a position to judge, would be judged to be as likely to be true as not—some logicians have actually assigned it a truth-probability of *1/2!* It would be just as accurate to say that there is a probability of *1/2* that an unknown marksman will hit the bull's eye—an absurd estimate when it is remembered that there are innumerable places, on and off the target, which are all included under "not bull's eye" as against the very limited area of "bull's eye." If the available data are insufficient, why estimate the probability at all? Why not suspend judgment? There is no particular virtue in emulating Bagehot's village maiden who must have an opinion about everything under the sun.

The next question is, how is one to make sure whether the alternative possibilities really are equally likely, or at least approximately so? Sometimes this is not very difficult to determine. In the case of a coin, or a die, *e.g.,* it is not impracticable to examine them sufficiently closely and ascertain whether or no they are properly balanced. And if properly balanced, the possibilities which they offer would be adjudged to be equally likely. But suppose one cannot be sure. Is there not some other way of testing the equality of the possibilities? Well, there is — namely, by actually tossing the coin, or throwing the die, a great many times, and noting the results. If, on an average, each side of the coin, or of the die, appears approximately an equal number of times, then the alternative possibilities would be regarded as equally likely. But the significance of this kind of test must be noted carefully, if only because of its bearing on the inductive, or a *posteriori* calculation of probability.

This kind of test is not direct but indirect, or inverse, in the sense in which induction is said to be inverse deduction. The logic of the test is this. We argue that if the possibilities represented, say, by the several faces of the die, are really equally likely, then when the die is cast a sufficiently large number of times, each face should, on an average, and in the long run, appear approximately once in six throws. This rate of appearance is called its *frequency.* So that this mode of procedure may be described as consisting in testing the equality of the possibilities by reference to the frequency which seems to be implied in the probability calculated on the assumption of their equality.

Now, in calculations of probability, "frequency" and "probability" are so frequently identified or confused that it is important to mark their difference. When the a *priori* probability, say, of face six appearing when a die is cast, is given as *1/6,* what this really means is that "the appearance of face six is one of six equally likely possibilities"; and so always f/t simply has reference to possibilities, which may never be tested at all. One never thinks of adding the expression "in the long run" to the fraction expressing a probability. On the other hand, when a frequency is stated, even or especially when it is expressed by the same fraction as the corresponding probability, the phrase "in the long run" is essential, otherwise the frequency given would be wrong, in view of the series of long runs of some one number, which are so common.

We may now turn to the a *posteriori* calculations of probability, a method the true character of which has already been suggested in the preceding remarks.

THE A POSTERIORI CALCULATION OF PROBABILITY

In many and most important cases, it is impossible to calculate the probability a *priori,* because the alternative possibilities cannot be regarded as equally likely. Take, for instance, the case of a sick man. What is the probability of his recovery from his illness? This cannot be calculated a *priori.* It is true, of course, that there are only two alternatives — either he will recover or he will not. But these two alternatives cannot be regarded as equally likely, without special evidence. If they could be so regarded, why then the chance of recovery from cerebral meningitis would be the same as that of recovering from a common cold—which is belied by actual results. And if the alternative possibilities are not equally likely, as indeed they are not, then the probability cannot be estimated a *priori.* How, then, shall it be calculated? Well, it can still be calculated a *posteriori* if the results of a sufficiently large number of cases have been observed, that is to say, if we know the *frequency* of the type of case under consideration. For then, just as it is possible, as we have seen it is possible, to derive the frequency of an event from its probability, where the probability can be calculated a *priori,* so it is possible by a *reverse process* to derive the probability of an event from its observed frequency, even in cases in which the probability cannot be obtained a *priori* at all. Suppose, for instance, that, in the above-mentioned case of the die, face six did not in the long run appear in approximately one out' of six throws, but, say in one out of nine throws. Then by treating this frequency as an index to its probability we should say that the probability of face six turning up is *1/9,* which means that it behaves *as if* it had an a *priori* probability of *1/9,* or as if it had been one of nine equally likely possibilities — which, of course, it is not. In this way, provided we have sufficient data to determine their frequency, the calculus of probability can be applied to all sorts of otherwise incalculable events, such as birth, marriage, death, and the thousand and one ills that flesh is heir to.

Writers on probability are frequently inclined to regard the a *posteriori* method of calculating probability as the fundamental method. They would either like to banish a *priori* calculations altogether or only tolerate them as more or less intelligent anticipations, or frequencies. But this theory (known as the frequency theory) of probability is hardly tenable. Frequencies show considerable variations with the number of cases observed, *e.g.,* when tossing a coin the proportion of heads to tails varies remarkably, accordingly as one stops at the 100th, 1,000th, 10,000th or 20,000th toss. One might obtain almost any proportion by stopping at the right moment. Hence the need of the saving clause "in the long run"—*in the long* run a die will throw six in one of the six throws, and so on. Even so the element of arbitrariness is not entirely disposed of. As here conceived, the fundamental form of the calculus of probability is the a *priori* form, of which, as already explained, the *a posteriori* method is simply an inverse process, which treats frequency as a measure of probability, although the two are really different things. There is nothing unusual in the use of the inverse process, or the resort to "as if" fictions. Our view of the calculable cases of probability makes it possible to keep together all types of probability without any artificiality or straining. In all cases alike the uncertainty arises from the presence of other possibilities than those contemplated.

In some cases these other possibilities can be allowed for by some direct or indirect calculation; in other cases they cannot be estimated at all, except in a very rough and unpractical manner. On the other hand, the frequency theory of probability does not really apply to non-measurable cases. Even in its modified form, in which frequency is taken to mean the truth-frequency of certain classes of propositions, it seems unsatisfactory. One is asked to determine the probability of a judgment by ascertaining the probability of the class of propositions to which it belongs. But suppose the proposition cannot be assigned to its proper class unless its probability is known?

The Use of the Calculus of Probabilities.—One may ask, in conclusion, what is the practical use of calculations of probability? Some people have exaggerated ideas on the subject. The exaggeration is due in great part to the common confusion of probability with frequency. Frequencies, when treated with the necessary precautions, may be of great practical value when we are dealing with large numbers of facts of the same kind. This is evident from their use in connection with all varieties of insurance schemes, etc., in which the certainty of large numbers can be relied upon to atone. in some ways, for the uncertainty in the lot of the individual. But whereas frequencies are always concerned with large groups, or with long series of events, or with what happens "in the long run," probability is also concerned with individual cases, or small groups of events. This makes all the difference, as may be seen, say, in roulette. The bank, doing business with a great many players, can rely on frequencies. The individual player, limited to a comparatively small number of hazards, relies on the ambiguous calculus of probability (when he is not guided by sheer superstition). The calculus is always right, even when the player loses. For the actual events are matters of frequency, not of mere probability. There are ingenious gambling systems based on frequencies; but even these systems have their day and cease to be. The best of them depend on "the long run," which easily outruns the resources of the average individual. For similar reasons, even in legitimate insurance business, the company has a great advantage over the individual client. But the practical exigencies of life induce responsible individuals to prefer high risks for comparatively small amounts rather than small risks for large amounts. No mere calculation can eliminate the uncertainty of the probable when individual cases are involved. Here, in the last resort, the only safe, or least unsafe, method of ascertaining its probability consists in a close examination of the actual conditions by a suitable expert. Even life insurance companies probably put more faith in the medical report on each case than in their statistical life-tables.

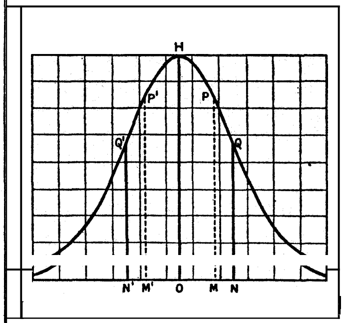
PROBABILITY AND ERROR. The theory of probability is that branch of mathematics which deals with the objective numerical measurement of probability. The theory of error, or the consideration of the frequency-distribution of errors, is the main link between the theory of probability and the theory of statistical frequency.

THEORY OF PROBABILITY

1. Rough estimates of relative probability are often easily made. I draw a ball from a box containing one red ball and four white ones: if I say that I am more likely to draw a white than the red, the statement is intelligible. But can I be more precise? Can I give a numerical measure to the probability of drawing the red ball?

A question of this kind might perhaps be parried by the question: Why should anyone want a numerical measure of the probability? The answer may be, in some cases, that it is a matter of scientific interest; or it may be, in other cases, that questions of this kind are important in games of chance. The study of the theory of probability was, in fact, in the first instance, the scientific study of gambling; though the primary question was not the numerical measure of a chance but its money value. Suppose, in the case of the five balls, that I am to receive £50 if I draw the red ball, but nothing if I draw a white; then (subject to certain conditions) my chance is worth £10. This suggests a numerical measure of probability. Suppose there is a prize W in a lottery, and my chance of winning it is worth V; then V is pW, where p is some fraction between 0 and 1. If the prize W were doubled, the conditions remaining the same, the value V of the chance would be doubled, and so on. Thus, the conditions of the lottery remaining the same, V bears a constant ratio to W; and this ratio, which is a fraction between 0 and 1, might be called the chance, or probability, of my winning the prize. The value of my chance is then found by multiplying the prize by this chance or probability. This definition, however, is not entirely satisfactory; for, the value V being based on, at best, a general agreement, its ratio to W cannot be regarded as a definite objective measure. We need some method of measurement that is based on facts, not on opinions. Two methods have been suggested (secs. 2 and 4).



STANDARD NORMAL FIGURE OF FREQUENCY
The relative frequencies of deviations are from the mean value, ON or N'O representing the "standard deviation." The ordinates M' P', OH, MP divide the area of the figure into four equal portions

2. Unitary Method.—The first method to be considered involves a definition which is stated in various ways, but can perhaps be best stated as follows. If an event will happen in one, and only one, of c ways, all of which are equally likely, and if a of these ways are called favourable, then the probability or chance of the event happening favourably is a/c. Thus, in the case of a ball being drawn from a box containing one red and four white balls, the event is the drawing of a ball, and the ways of the event happening are the drawing of a red ball and the drawing of one of the white balls; if all the balls are equally likely to be drawn, the probability of the red being drawn is $1/5$, and the probability of a white being drawn is $4/5$. Since the basis of the method is the supposition that the happening of the event can be subdivided under a number of ways, each of which is equally likely, and the chance of the event happening favourably is found by counting the number of the favourable ways, we can call it the *unitary* method.

3. Defects of the Method.—While the definition is a simple one as regards a good many problems, it has defects, of which the following may be mentioned.

(i.) It applies only to probabilities of subsequent events, not to those of concurrent or antecedent events (sec. 12).

(ii.) The phrase "equally likely" is not defined. If this means that the probabilities of the different ways are all equal, we are working in a circle. If it means that we do not see any reason why one way should occur rather than another, we are basing the definition on ignorance.

(iii.) There are a great many cases in which the possibility of an event happening cannot be split up into a number of ways all of which are equally likely, however this may be defined. If a box contains an equal number of red balls and white balls, and the red are of the same size as the white but are slightly heavier, the statement that a white is more likely to be drawn than a red is intelligible, but it is difficult to bring the case under the definition. A statement as to probability can here only have a statistical meaning, as explained in sec. 4.

4. Statistical Method.—The alternative to the unitary method is the *statistical* method. Suppose that an event (or fact or set of conditions, etc.) C might occur in a large number N of cases, and that whenever it might occur it would necessarily be associated with one of two or more mutually exclusive events E, E', E'' . . . ; "mutually exclusive" meaning that on each occasion only one of these events can occur. Of the total number N of cases, suppose that E would occur in pN cases, E' in $p'N$ cases,

E'' in $p''N$ cases .... Then p, p', p'' ... are said to be the probabilities of C being associated with E, E', E'' .... It is clear that $p+p'+p''+ \ldots = 1$.

In reference to cases of this kind we should use the word '(probability" rather than "chance," since the question is not necessarily as to the happening of some future event. The definition can be applied equally to the probability of a future or a present or a past event. The numerical probability is in each case the result of grouping the C-cases into classes according as they are associated with E or with E', etc., and taking the probabilities to be proportional to the numbers in the different classes. If, for instance, in the case considered in sec. 1, we say that the probability of the red ball being drawn is $1/5$, we mean that in the long run (sec. 8), or on the average, the red ball will be drawn about once in five times.

If an event E occurs in m cases out'of n, m is called the *frequency* of occurrence of E, and the ratio m/n is its relative *frequency*. Thus the probability of an event is the same thing as its relative frequency when the number of cases considered is very large.

5. Observations on the Definition.—The following are points in reference to the definition.

(i.) We say that the red ball will be drawn "about" once in five times, because we can never know the exact probability of any event; and it is, indeed, doubtful whether there is any exact probability of anything. We may throw a die 100,000 times, and note the number of cases in which a 6 occurs; but if we throw another 100,000 times we shall get a slightly different result. The study of variations of this kind forms part of the theory of error, which, again, is part of the general theory of frequency distributions.

(ii.) We proceed, however, as if any probability with which we are dealing has a definite value. For practical purposes, therefore, we should not use actual observations as the means for determining a probability unless we have made a fairly large number of observations; until we have done so, we may have to depend on a *priori* considerations.

(iii.) The determination of the probability of an event, on the statistical basis, involves a process of classification. A man comes to have his life insured for a year. We require, at least, to know his age. Knowing this, we put him into a certain class or category, namely, the category of men of that age; and we find that, of men of that age, 99 out of 100, on the average, survive for a year. We therefore say that his chance of surviving is 99/100. But this does not imply that there is such a thing as chance, in the ordinary sense; nor is it a statement as to the individual, as distinct from the rest of the class. We do not treat him as an individual, but as one of the class, taken at random. Further information may alter the chance. We find that he will be working in an unhealthy climate: this means a further limitation, defining more strictly the class in which he is to be placed; and so on. The ultimate probability assigned to him is the probability of survival for a year in the class in which he is ultimately placed.

6. Illustrative Example.—As a basis for illustration of the statistical definition, let us take a concrete case. A man being called short or tall according as his height is under or over 67) in., suppose that, in a community in which every man has one son who attains maturity, the statistical relation between height of father and height of son, in a representative (sec. 15) 1,000 pairs of father and son, is given in Table I. This table, if our supposition is correct, provides us with various statements as to probability, of which the following are examples.

TABLE I.
(Adapted from K. Pearson and A. Lee, *Biometrika* ii. [1903], 415)

	Father short	Father tall	Total fathers
Son short .	250	89	339
Son tall . .	215	446	661
Total sons .	465	535	1,000

(i.) The probability that a father is tall is 535/1,000. (This is a short way of saying: if a father is taken at random, the probability that he will be one of the tall fathers is 535/1,000. The phrase "at random" is considered in sec. 9.)

(ii.) The probability that a son is tall is 661/1,000.

(iii.) The probability that a tall father has a tall son is 446/535.

(iv.) The probability that a short son has a tall father is 89/339.

7. Relation Between the Two Methods.—To some extent the two methods—unitary and statistical—supplement one another. On the one hand, as was stated in sec. 5, a priori considerations may have to be brought into account in order to obtain a rough value of a probability. On the other hand, we may use the results of experience to check our a priori estimate of a probability. Consider, for example, the throwing of a die. The die is approximately a cube; it has six faces, so that, on the unitary system, we should say that the chance of a 6 being thrown is 1/6, or at any rate is about 1/6. But it should be observed that what is really of importance to us, if we are frequently risking. money on the throwing of a die, is not the probability, as estimated by the unitary method, of a particular face appearing, but the proportion of cases in which, in the long run, it actually does appear. If we record these, we may find that the 6 appears rather oftener than we had expected. We can then do either of two things. We can base our probability on the actual experience, or we can consider in what respect our original estimate was faulty. We must then take account of the fact that the pips of the die are hollowed out, so that the die is lighter on the 6-side and heavier on the opposite side. It would be very difficult to estimate the effect of the hollowing-out of the pips, and we should thus be driven to the statistical method, *i.e.*, to basing our probability on experience.

It will be assumed, throughout this article, that we are dealing with probability according to the statistical method. If, for example, we say that there are five balls in a box, and that they are all equally likely to be drawn, this is to be interpreted as meaning that in N drawings, where N is very large, each ball is drawn approximately $1/5 \cdot N$ times. Similarly, if it is said that the probability that a man will survive for a year is p, this is to be taken as meaning that, out of N men who would be put into the same class, the number who will survive for a year is about pN.

8. "The Long Run" and "Series."—The use of the phrase ('in the long run," and the description of a number of events as a "series" (*e.g.*, "a Poisson series"), are not to be taken as implying a definite arrangement, in time or otherwise. We might, of course, wish to observe the succession of observations, *e.g.*, the succession of colours at roulette; but in this case the succession is the event we are observing, and the order in which the individual events occur is not relevant. Phrases such as "in the long run" merely imply that the number of cases observed is very large.

9. Randomness.—In the statement of a problem in probability the expression "random" or "at random" is often used. Thus, in the case of balls in a box it may be stated that "a ball is drawn at random from the box." This may be regarded as merely an indication that we are dealing with a question in probability. On the other hand, the idea of randomness is implied in any statement as to the numerical measure of a probability. When we say "If a card is drawn from a pack, the probability that it will be a court card is 3/13," we really mean "If a card is drawn at random from a pack, the probability that it will be a court card is 3/13."

10. Addition and Multiplication of Probabilities.—The mathematical treatment of probabilities involves the addition and multiplication of their numerical measures. These are performed according to certain rules.

(i.) The rule for addition is as follows. Let E and E' be two mutually exclusive events which might be sssociated with C, and let the probabilities of their being so associated be p and p'

respectively: then the probability that either E or E' will be so associated is $p+p'$. This follows easily from the definition.

(ii.) The rule *for* multiplication is that, if C and D are two separate events, both of which occur, and if the probability of C being associated with E is p, and if, in the cases in which C is associated with E, the probability of D being associated with G is r, then the probability that C will be associated with E and D with G is pr. For, if N is the total number of cases in which C and D both occur, the number in which C is associated with E is pN, and the number of these in which D is associated with G is $r\times pN=prN$.

For an illustration of the multiplication rule, we can have recourse to Table I. If we take a father at random (which is the same thing as taking a pair, father and son, at random, since father and son go together), the probability that he will be short is 465/1,000; and, if a father is short, the probability that he has a tall son is 215/465. Hence, if we take a pair, father and son, at random, the probability that the pair consists of a short father and a tall son is 215/1,000; which agrees with the table.

If r has the same vaiue whether C is associated with E or not, or, to put it differently, if the probability of C being associated with E and D with G is the product of the separate probabilities of C being associated with E and D with G, the associations of C with E and of D with G are said to be independent.

11. Scope.—The earlier studies of probability led to the development of the theory of combinations and permutations; and the more simple problems of chance are largely concerned with applications of this theory. Many such problems are dealt with in text-books, as well as in previous editions of this work, and it is not necessary to give examples here. The part of the subject with which we are more particularly concerned may be taken as beginning with the theory of error, its stages being marked by the successive inclusion of frequency-distributions generally, and of correlation. Before dealing with these aspects, it is necessary to give brief consideration to the theory of probability of causes.

PROBABILITIES OF CAUSES

12. Direct and Inverse **Probability.**—Questions as to the respective probabilities of a specified event having been due to various possible causes have in the past produced a good deal of difficulty, and have been placed in a separate category as questions of inverse probability; questions as to probabilities of a specified cause leading to different events are then described as questions of direct probability. That difficulties should have arisen is not to be wondered at, as no clear definition of the probability of a cause seems to have been given: until we know what we mean by "probability," we cannot give a numerical value to it. A more serious cause of difficulty, in many cases, was the absence of sufficient information as to the antecedent probabilities of the causes themselves. The final death-blow to the classification of questions of probability under the heads of "direct" and "inverse" was given by the statistical treatment of correlation, which led to the study of probabilities of concurrent phenomena. What is the probability that a tall man has a tall wife? What is the probability that a boy who is good at arithmetic is good at composition? What is the probability that a girl with fair hair has blue eyes? Questions such as these found no place in the earlier classification. These difficulties have been met by the adoption of a statistical basis for the measurement of probability.

13. Typical Example.—The following may be taken as a typical question in inverse probability. A box contains 5 balls, and it is known that 1 of the balls is white and 3 are red, and that the remaining one is either white or red. A ball is drawn and is found to be white. What is the probability that the box contained 2 white and 3 red balls? It is impossible to answer this question without further information. The box has been filled in some way: the method of filling having led to the box containing 1 white and 3 red balls, we require to know the probability that it has led to the other ball being white or red, respectively. When we know this, the problem is a straightforward one.

Let us call the box a "W-box" or an "R-box" according as the other ball is white or red; and let us suppose that the probabilities, or relative frequencies (sec. 4), of W-boxes and of R-boxes are in the ratio of 3:2. Then the problem can be stated as follows. There are W-boxes containing 2 white and 3 red balls, and R-boxes containing 1 white and 4 red balls; their frequencies being in the ratio of 3:2. A box is taken at random; and a ball is drawn from it and is found to be white. What is the probability that the box is a W-box?

The ordinary method of answering the question is an application of the rule that, if an event E has happened which may be due to any one of the causes $C_1, C_2\ldots$, and if the *a priori* probability of occurrence of the cause C_f is P_f, and if whenever C_f occurs the probability that it will lead to E is p_f, then the probability that E is due to Cj is proportional to P_fp_f, *i.e.*, is $P_fp_f/(P_1p_1+P_2p_2+\ldots)$. In the present case we have $P_1=3/5$, $P_2=2/5$, and $p_1=2/5$, $p_2=1/5$; whence $P_1p_1:P_2p_2=6:2=3:1$, *i.e.*, the probability that the box is a W-box is $\frac{3}{4}$.

For statistical treatment, a tabular arrangement is useful, as in Table II. This table shows a representative frequency-distribution (sec. 15) for 1,000 drawings. The figures in brackets indicate the order of entry in the table. Of the total 1,000 boxes, 600 will (on the average) be W-boxes and 400 R-boxes. Of the 600 W-boxes, 240 (on the average) will give a white ball at a single drawing; of the 400 R-boxes, 80 will give a white ball. In the cases, therefore, in which a white ball is drawn, the probability of the box being a W-box is $240/(240+80)=\frac{3}{4}$.

TABLE II.

	From W-boxes	From R-boxes	From all boxes
White ball drawn . .	(3) 240	(3) 80	(4) 320
Red ball drawn	360	320	680
Total drawings	(2) 600	(2) 400	(1) 1,000

If the question had been "There are W-boxes containing 2 white and 3 red balls, and R-boxes containing 1 white and 4 red balls, their frequencies being in the ratio of 3:2; a box is taken at random and a ball is drawn from it; what is the probability that the ball will be white?" the question would have been a "direct" one; but the one table would have been applicable to the two questions. We have already seen this in reference to Table I. (sec. 6); the same table enables us to answer the two questions, "What is the probability that a tall father has a tall son?" and "What is the probability that a tall son has a tall father?" though one of these might be regarded as a question of direct and the other of inverse probability.

FREQUENCY-DISTRIBUTION OF ERRORS

14. Frequency-distribution and Frequency-polygon.—Suppose that, when an event happens, it may happen in either of two ways, which, in G. U. Yule's notation, we will call A and α; so that α is an abbreviation for "not-A." Let the event happen n times, and let the result be A in m cases and α in $n-m$ cases. Then this distribution of the n cases as m A's and n—m a's is called afrequency-distribution. More generally, suppose that the event may be classed under the $k+1$ heads $A_0, A_1, A_2 \ldots A_k$, and that, out of the total n, the numbers coming under these $k+1$ heads are respectively $m_0, m_1, m_2 \ldots m_k$; then the distribution of the n in this way is called a frequency-distribution. The number of heads is taken to be $k+1$ because the sum of the numbers $m_0, m_1, m_2 \ldots m_k$ is necessarily n, so that if we know k of the $k+1$ numbers we know the remaining one. The numbers $m_0, m_1, m_2\ldots$ are the frequencies of $A_0, A_1, A_2\ldots$; their ratios to n, *i.e.*, the ratios m_0/n, m_1/n, $m_2/n\ldots$, are the relative frequencies (sec. 4).

If on a line OX we take points M_{-1}, M_0, $M_1,\ldots M_k$, M_{k+1}, at successive intervals h, and at the points M_0, $M_1,\ldots M_k$ erect ordinates M_0P_0, $M_1P_1,\ldots M_kP_k$ whose ratios to a unit of measurement U are m_0/n, $m_1/n,\ldots m_k/n$, these ordinates constitute the graph of the relative frequencies. If we draw lines joining the points M_{-1}, P_0, $P_1 \ldots P_k$, M_{k+1}, we get a closed figure whose area (see MENSURATION) is

$$h(M_0P_0+M_1P_1+\cdots+M_kP_k)=hU$$

This figure may be called the frequency-polygon. It is not, of course, a graph of anything; the graph of the relative frequencies consists of the ordinates. It is usual to omit the units of measurement h and U, and say that the area of the figure is 1.

15. Representative Distribution.—Let the probability of occurrence of A_0, considered alone, *i.e.*, its probability when the division of cases is into A_0 and not-A_0, be p_0. Then, by the definition of probability, we should expect that in a very large number N of trials the number of cases of A_0 would be about Np_0. Provisionally—for reasons which will be seen later (sec. 18)—we might similarly expect that when the smaller number n of trials is made the number of cases of A_0 would be about np_0; and similarly for A_1, $A_2 \ldots$ with probabilities p_1, $p_2 \ldots$. The frequency-distribution which gives the numbers under the heads $A_0, A_1, A_2 \ldots$ as np_0, np_1, $np_2 \ldots$ is called a representative distribution. The definition applies whether these numbers are integers or not. The differences between these numbers and the actual numbers m_0, m_1, $m_2 \ldots$ which occur when n individuals are taken at random are the errors or errors of *random* sampling of m_0, m_1, $m_2 \ldots$.

We might have defined a representative distribution as a distribution in which the numbers under the different heads are proportional to the numbers which would "in the long run" come under these heads.

16. Law of Frequency of Error (Simplest Case).—Denoting, as before, "not-A" by a, suppose that the probability of A is p, and that that of a is $q \equiv 1-p$. Then as the result of n trials the number of A's might be any number from n to 0, the number of α's being the remainder out of the n. What are the respective probabilities of these different numbers?

Consider the probability of m A's and $n-m$ a's. For a simple example, take $n=6$, $m=4$. Then the probability of 4 A's and 2 α's occurring in the order $AAAA\alpha\alpha$ is $ppppqq=p^4q^2$; and the probability of their occurring in any other specified order is similarly p^4q^2. But there are ${}_6C_4$ orders in which they may occur; ${}_nC_m$ denoting the number of combinations of n things m together. Hence the total probability of 4 A's and 2 a's is ${}_6C_4p^4q^2$. Similarly the probability of m A's and $n-m$ a's is ${}_nC_mp^mq^{n-m}$. Taking the values of m from n to 0, we see that the probabilities of n, $n-1$, $n-2 \ldots 0$ A's (and 0, 1, 2 $\ldots n\alpha$'s) are the successive terms in the expansion

$$(p+q)^n={}_nC_np^n+{}_nC_{n-1}p^{n-1}q+{}_nC_{n-2}p^{n-2}q^2+\cdots+{}_nC_0q^n. \quad (16\cdot1)$$

If ${}_nK_m$ is the probability that in n trials there will be m A's and $n-m$ a's, then

$${}_nK_m={}_nC_mp^mq^{n-m}. \quad (16\cdot2)$$

In a representative distribution of N sets of n trials the numbers of cases in the $n+1$ categories (n A's, $n-1$ A's and 1 a, ...) would be found by multiplying the terms in (16·1) by N; *i.e.*, the number of cases of m A's and $n-m$ a's would be $N \times {}_nC_mp^mq^{n-m}$.

Suppose, for example, that $p=0\cdot6$, $q=0\cdot4$, $n=6$. Then it will be found that in a representative distribution of 1,000,000 cases the numbers of cases in which there are 6, 5, 4, 3, 2, 1, 0 A's would be 46656, 186624, 311040, 276480, 138240, 36864, 4096. The respective probabilities (relative frequencies in a representative distribution) are the ratios of these numbers to 1,000,000. A distribution of the above kind, showing the frequencies (theoretical or actual) with which an event happens n, $n-1$, $n-2 \ldots$ times out of n, is called a binomial distribution.

17. Mean, Standard Deviation, and Mode.—Suppose that the categories of a frequency-distribution correspond to values Y_0, Y_1, $Y_2 \ldots Y_k$ of a variable Y; thus, in the case we have just been considering, the Y's are the numbers n, $n-1, \ldots 0$ of A's or the numbers 0, 1, 2 $\ldots n$ of a's. Then the mean value of Y is found by multiplying Y_0, Y_1, $Y_2 \ldots Y_k$ by the numbers m_0, m_1, $m_2 \ldots m_k$ in the corresponding categories, adding the results, and dividing by the total number $m_0+m_1+m_2+\ldots+m_k$; *i.e.*, if $\overline{Y}$ is the mean Y, and $m_0+m_1+m_2+\ldots+m_k=n$, then

$$\overline{Y}=(m_0Y_0+m_1Y_1+\ldots+m_kY_k)/n. \quad (17\cdot1)$$

Similarly the *mean* square of Y is the mean value of Y^2, *i.e.*, is

$$(m_0Y_0^2+m_1Y_1^2+\ldots+m_kY_k^2)/n. \quad (17\cdot2)$$

The mean cube, mean fourth power, etc., are defined in the same way.

The deviation of Y from $\overline{Y}$ is $Y-\overline{Y}$. The mean square of the deviation from the mean is therefore

$$\begin{aligned}\{m_0(Y_0-\overline{Y})^2&+m_1(Y_1-\overline{Y})^2+\ldots+m_k(Y_k-\overline{Y})^2\}/n\\ &=(m_0Y_0^2+m_1Y_1^2+\ldots+m_kY_k^2)/n\\ &-2\overline{Y}(m_0Y_0+m_1Y_1+\ldots+m_kY_k)/n\\ &+(m_0\overline{Y}^2+m_1\overline{Y}^2+\ldots+m_k\overline{Y}^2)/n\\ &=(\text{mean square of } Y)-2\overline{Y}\overline{Y}+\overline{Y}^2\\ &=(\text{mean square of } Y)-(\text{mean of } Y)^2. \quad (17\cdot3)\end{aligned}$$

The square root of this quantity is called the standard deviation or dispersion: in the cases in which the Y is an error, it was formerly called the error of mean square. The above definitions apply, and (17·3) holds good, whether we are dealing with a representative distribution or with an actual distribution.

In some cases the numbers n_0, n_1, $n_2 \ldots$ in the categories of a representative distribution gradually increase up to a value n_f and then decrease. In such a case n_f is the *maximum* frequency; and the corresponding value of Y, namely Y_f, is called the modal value or mode. Thus in the example in sec. 16 the modal number of A's is 4. There might in some cases be two or more modes; in other cases there might be none—if, *e.g.*, the frequencies decreased throughout the whole range.

18. Mean, etc., for Binomial Distribution.—For a representative binomial distribution (sec. 16) in which ${}_nK_m$ is the probability that in n trials there will be m A's and $n-m$ a's, it is not difficult to show that, the probability of A at each trial being p:—

(a) the mean value of m is np, that of $n-m$ being $n-np=nq$;
(b) the mean square of m is n^2p^2+npq; and therefore
(c) the standard deviation (dispersion) of m is $\sqrt{npq}$.
(d) To find the modal value of m, we have

$${}_nK_m/{}_nK_{m-1}=\frac{n-m+1}{m}\,\frac{p}{q},\quad {}_nK_{m+1}/{}_nK_m=\frac{n-m}{m+1}\,\frac{p}{q}.$$

These ratios decrease as m increases; and the first ratio will be >1, and the second <1, if $(n+1)p$ lies between m and $m+1$, *i.e.*, if m is the integral part of $(n+1)p$. Taking m to have this value, ${}_nK_m$ is greater than ${}_nK_{m-1}$ and also greater than ${}_nK_{m+1}$, *i.e.*, it is the maximum frequency. Thus in the example in sec. 16 we have $p=3/5$, $n=6$, and therefore the modal value of m is 4. If $(n+1)p$ is an integer, and we take $m=(n+1)p$, then ${}_nK_{m-1}$ and ${}_nK_m$ are equal, each having the maximum value.

19. Errors of Frequencies of Error.—In Sec. 16 we really began with a representative distribution, namely, that in which the number of cases of "A" was np out of a total number n; and we considered the probabilities of the various possible deviations from this distribution, *i.e.*, we considered the entries in a representative frequency-distribution of the errors. We found that the frequencies, for N sets of n trials, would be given by the terms of a certain binomial expansion, each multiplied by N. Thus the frequency of the cases of 3 A's and 3 a's, p being 0·6, would be $N \times \cdot276480$. But it is to be observed that this is a representative distribution: we should not expect, in any particular group of N sets of n trials, to find exactly $N \times \cdot276480$ of these cases, just as in n of the original trials we should not expect to get exactly np A's and nq a's. If we took $\underline{N}$ groups of N sets of n trials, we should again get errors of random sampling. But these errors become relatively less as the numbers involved become greater.

20. Frequency for Continuous **Variation.**—(i.) We have hitherto been considering the frequency of occurrence of some

definite number of events, *e.g.*, of m events out of n. This is a case of discontinuous variation, and the graph of variation is composed of a limited number of ordinates. We shall presently have to consider the class of cases in which Y is a quantity which varies continuously, the number of its possible values being indefinitely great, and the probability of occurrence of any particular value indefinitely small. For these cases we require a different treatment of frequency. Let the probability that the value of the variable lies within limits $Y\pm\frac{1}{2}dY$, *i.e.*, lies between $Y-\frac{1}{2}dY$ and $Y+\frac{1}{2}dY$, be $U'dY$; and let U be the limit of U' when dY is made indefinitely small. Then the expression of U in terms of Y is the equation to the *frequency-distribution* of Y. The graph of U with respect to Y will then be a plane figure with a continuous boundary, which can be regarded as drawn on such a scale that its area is 1. The area of the portion of this figure which lies between ordinates corresponding to any values Y_1 and Y_2 of Y will be proportional to the probability that Y lies between Y_1 and Y_2. This figure is the *figure of frequency* of Y.

To represent an actual distribution graphically, suppose that we have observed the number of cases in which Y lies between Y_r and Y_{r+1}. Let M_r and M_{r+1} be points on the base-line Oy corresponding to Y_r and Y_{r+1}. Then the ratio of this number of cases to the total number can be represented by a rectangle whose base is M_rM_{r+1} and whose area is this ratio. The aggregate of these rectangles is a figure called a histogram: its area is 1, *i.e.*, is the same as that of the figure of frequency. This latter figure may be regarded as the limit of the histogram of a representative distribution when the intervals M_rM_{r+1} are made indefinitely small.

(ii.) But instead of expressing U in terms of Y, we might express Y in terms of certain total probabilities. The usual method of doing this is to regard the figure of frequency as divided into 100 equal parts by ordinates: the values of Y corresponding to these ordinates, with the two extreme values of Y, are called the percentile values. The important values, on this system, are the median and the quartile values. If M_1P_1, M_2P_2, M_3P_3 are ordinates dividing the figure of frequency into four equal parts, the value of Y which corresponds to M_2P_2 is the median value, and the values which correspond to M_1P_1 and M_3P_3 are the quartile values.

21. **The** Normal **Law** of Error.—(i.) The result obtained in sec. 16 gives the true law of frequency of error for the type of case considered, namely the law that ${}_nK_m$, the probability of occurrence of m A's and $n-m$ a's, is ${}_nC_mp^mq^{n-m}$. When n is small there is no difficulty in calculating any particular value of ${}_nK_m$ or even all the values; thus in sec. 16 we have seen that, if $p=0{\cdot}6$, the probabilities of occurrence of the values 6, 5, 4, 3, 2, 1, 0 of m are 0·047, 0·187, 0·311, 0·276, 0·138, 0·037, 0·004. But, when n is large, the single probabilities are very small, and we have to take them in groups. We therefore require a formula which will enable us to calculate the sum of the probabilities in any particular group, *i.e.*, the probability that the value of m will lie between any two stated values. An approximate formula—less or more correct according as n is smaller or larger—is given by the normal *law* of error. This law is also known as the *Gaussian* law of error, though it was discovered by Laplace: or as the law of large numbers. It would more correctly be called the normal *law of frequency of error* or the *law* of large frequencies.

(ii.) The method consists, essentially, in replacing a sum by an integral. To see how this happens, let us take p to have some definite value, and let us see how the form of the frequency-polygon (sec. 14) for a representative distribution alters as n increases. There are $n+1$ ordinates; as n increases, the number of ordinates increases, and their size decreases. If the interval between successive ordinates is always h, the frequency-polygon becomes wider and flatter. If, on the other hand, we take the interval to be h/n, so that (n being large) the breadth of the polygon is practically constant, it becomes higher and narrower in the middle. We can obtain regularity by adopting a middle course. We have seen in sec. 18 that the standard deviation, which is a convenient measure of the dispersion of the values about their mean, is $\sqrt{npq}$, *i.e.*, is proportional to dn. For purposes of comparison let us keep the maximum ordinate fixed in position, and take the interval between consecutive ordinates to be $h/\sqrt{npq}$ instead of h, the ordinates themselves being multiplied by $\sqrt{npq}$, so as to keep the area of the polygon unaltered. Then it will be found that the heights of the ordinates in any particular position, fairly near the maximum ordinate, alter comparatively slowly, and that the tops of the ordinates tend to lie on a certain curve, which is the limit of the upper boundary of the frequency-polygon. This curve is the normal curve of *error;* and the figure bounded by it, which is the limit of the frequency-polygon, is the normal *figure* of frequency.

The following short table (Table III.) illustrates this, so far as the maximum ordinate is concerned; p being taken to be 0·6.

TABLE III.

n	6	20	100	1,000
Max. prob.	·311	·180	·081	·026
$\sqrt{npq}\times$ max. prob.	·373	·394	·398	·399

The ordinate, in each case, is the unit U multiplied by the probability or relative frequency and by $\sqrt{npq}$. The actual limit of the numbers in the last line is (see sec. 22) $1/\sqrt{2\pi}=\cdot 399$.

(iii.) Algebraically, we proceed as follows: We want to find the sum of a number of consecutive values of ${}_nK_m$: let us say, the values for which m lies between $s-\frac{1}{2}$ and $t+\frac{1}{2}$. We therefore want to find a convenient expression for

$$S\equiv{}_nK_s+{}_nK_{s+1}+\ldots+{}_nK_{t-1}+{}_nK_t. \qquad (21{\cdot}1)$$

We can do this, subject to certain assumptions as to the magnitudes of n, p, q, and m; it being remembered that (see ii. above) the standard deviation of m from its mean value np is $\sqrt{npq}$. We assume that

(1) n is very large;

(2) neither p nor q is very small, so that np and nq and npq are very large;

(3) m is very large, but

(4) m−np (taken positively) is, at its greatest, not a large multiple of $\sqrt{npq}$.

On these assumptions, it may be shown that S is approximately equal to the area, from $m=s-\frac{1}{2}$ to $m=t+\frac{1}{2}$, of a figure whose ordinate corresponding to m is

$$u=\frac{1}{\sqrt{2\pi npq}}e^{-\frac{1}{2}V}, \qquad (21{\cdot}2)$$

where

$$V=\frac{(m-np)^2}{npq}; \qquad (21{\cdot}3)$$

i.e., approximately,

$$S=\int_{s-\frac{1}{2}}^{t+\frac{1}{2}}\frac{1}{\sqrt{2\pi npq}}\,e^{-\frac{1}{2}(m-np)^2/(npq)}dm. \qquad (21{\cdot}4)$$

The figure given by (21.2) and (21·3) is the normal figure of frequency.

(iv.) The figure is symmetrical about a central ordinate; and it admits of any value of m, positive or negative, so that its range is from $-\infty$ to $+\infty$. In these respects it differs from the (discontinuous) graph of ${}_nK_m$; and, as already stated, it is only for moderate values of m−np that a portion of its area represents the sum of a number of K's. It may, however, be noted that the figure agrees with the graph of ${}_nK_m$ in the following respects:

(a) the mean value of m, for the figure, is np;

(b) the standard deviation of m is $\sqrt{npq}$;

(c) the complete area of the figure is 1.

(v.) Since (sec. 15) m−np is the "error" of m, we denote it by the symbol ϵ; and (21·2) can then be written

$$u=\frac{1}{\sqrt{2\pi npq}}\,e^{-\frac{1}{2}\epsilon^2/(npq)} \qquad (21{\cdot}5)$$

We can also write it in another form. For a representative distribution of n cases between A and a, let n_0 and n_1 be the numbers of A's and of α's respectively; and let the actual numbers be $n_0+\epsilon_0$ and $n_1+\epsilon_1$, so that $\epsilon_0+\epsilon_1=0$. Then $n_0=np$, $n_1=nq$, $n_0+\epsilon_0=m$, $n_1+\epsilon_1=n-m$. With this notation, (21·2) and (21.3) give

$$u=\frac{1}{\sqrt{2\pi}}\left(\frac{n}{n_0 n_1}\right)^{\frac{1}{2}}e^{-\frac{1}{2}\chi^2}, \tag{21·6}$$

where

$$\chi^2=\frac{\epsilon_0{}^2}{n_0}+\frac{\epsilon_1{}^2}{n_1}. \tag{21·7}$$

(vi.) The equation to the figure can be written in the general form

$$u=\frac{N}{\sqrt{2\pi}\cdot c}\,e^{-\frac{1}{2}(Y-a)^2/c^2}, \tag{21·8}$$

where Y is the variable, a and c are its mean and standard, deviation, and N is the area of the figure. A variable Y, of which this represents the frequency, is said to be normally distributed.

22. Standard Normal Figure.—(i.) For practical application of the above result, we usually write—

$$Y=a+cx,$$

where x is numerical. If we make this substitution in (21.8), and treat x as the abscissa in the resulting figure, we are altering the unit of measurement of abscissa in the ratio of c:1, and must therefore alter the unit of measurement of u in the ratio of 1:c. Writing

$$u\equiv z/c,$$

we get

$$z=\frac{1}{\sqrt{2\pi}}\,e^{-\frac{1}{2}x^2} \tag{22·1}$$

which is the equation to the standard normal figure. The figure extends from $-\infty$ to $+\infty$; it is symmetrical about the axis of z; and its central (or maximum) ordinate is approximately ·39894.

(ii.) The portions on the two sides of the central ordinate are bisected by the ordinates for which $x=-·67449$ and $x=+·67449$ respectively; these are the quartile values of x. Similarly, for the more general form in (21·8), the quartile (including the median) values of Y are $Y=a-·67449c$, $Y=a$, $Y=a+·67449c$.

The form of the figure, with ordinates increased in the ratio 10:1, is shown on page 531. OH is the central ordinate; M'P' and MP are the quartile ordinates. $N'Q'$ and NQ are the ordinates at $x=-1$ and $x=+1$; Q' and Q are points of inflexion on the bounding curve.

23. Second Approximation.—In obtaining the above results we have assumed that n is so large that we can regard $1/\sqrt{n}$ as a small quantity, and have ignored terms in $1/n$. For a closer approximation we should take account of these latter terms. This gives as the equation to the figure of frequency

$$u=\frac{1}{\sqrt{2\pi}.D}\left\{1-\tfrac{1}{2}k\left(\frac{X}{D}-\tfrac{1}{3}\frac{X^3}{D^3}\right)\right\}e^{-\frac{1}{2}X^2/D^2},$$

where X is the deviation from the mean, D is the standard deviation, and k is (mean cube of deviation from mean)$\div D^3$. This is sometimes called the generalized law of error. It should be observed that the figure is skew, *i.e.*, unsymmetrical.

24. Frequencies of Improbable Events.—In secs. 21–23 we have been dealing with cases in which the probability of an event happening is neither very small nor very large, *i.e.*, is neither very nearly 0 nor very nearly 1. We have now to consider the class of cases in which the probability of an event happening is very small, and yet, in consequence of the number of trials being very large, we should not be surprised if it happened occasionally. As before, we take p to be the probability of A, so that $q\equiv 1-p$ is the probability of not-A or a; we assume that p is very small but n is so large that np is not negligible; and we want to see what is the probability of A occurring occasionally in n trials.

The probability of no A's is q^n, that of one A is npq^{n-1}, and so on; the probabilities being the terms in the expansion of $(q+p)^n$. Now

$$q^n=(1-p)^n=\{(1-p)^{1/p}\}^{np},$$
$$npq^{n-1}=np\{(1-p)^{1/p}\}^{(n-1)p},$$

and so on. But, since p is small, $(1-p)^{1/p}$ is approximately equal to $1/e$. Hence the terms in the expansion are approximately

$$e^{-np},\ npe^{-np},\ \frac{(np)^2}{1.2}e^{-np},\ \ldots$$

If therefore we write $\mu\equiv np$, so that (sec. 18) μ is the mean number of times that A occurs in n trials, then the probabilities of A occurring never, once, twice, three times ... are (approximately) the terms of the series

$$e^{-\mu}+\mu e^{-\mu}+\frac{\mu^2}{2!}e^{-\mu}+\frac{\mu^3}{3!}e^{-\mu}+\ldots$$

This theorem is due to Poisson; it is known as Poisson's exponential law or as the law *of* small numbers.

We can easily verify that the formula is consistent with the statement that μ is the mean number of times that A occurs; for this mean number is found by multiplying the terms of the series by 0, 1, 2, 3... and adding; and the result is

$$\mu e^{-\mu}+\frac{\mu^2}{1!}e^{-\mu}+\frac{\mu^3}{2!}e^{-\mu}+\ldots=\mu e^{-\mu}\left(1+\frac{\mu}{1!}+\frac{\mu^2}{2!}+\ldots\right)=\mu.$$

OTHER FREQUENCY-DISTRIBUTIONS

25. Genesis of Normal Distributions.—The normal figure of frequency has been obtained as the limit of the frequency-polygon for errors of random sampling from two categories. But it has other important relations.

(i.) If a quantity Y is distributed according to the normal law about a mean value a with mean square of deviation c^2, and n values of Y are taken at random, the mean of these values is distributed according to the normal law about the mean value a with mean square of deviation c^2/n.

(ii.) If a quantity Y is distributed according to (almost) any law whatever about a mean value a with mean square of deviation c^2, and ft values of Y are taken at random, the mean of these values is distributed about the mean value a with mean square of deviation c^2/n, and the distribution is approximately normal; the approximation being less or more close according as n is smaller or greater and according as the original distribution of Y is less or more similar to a normal distribution.

(iii.) In the frequency-distribution of a quantity Y, suppose that the deviation of any individual value of Y from the mean Y is the total effect of a very large number of very small deviations, due to causes which operate independently of one another. Then (in general) the distribution of Y is approximately normal.

26. Observation of Distributions.—The pioneer in the systematic study of actual frequency-distributions was L. A. J. Quetelet, the Belgian astronomer. In works published in and after 1835 he showed that variations in many kinds of phenomena—temperature, price of grain, astronomical observations, heights and chest-measurements of men—were distributed about a mean value in a manner similar to the binomial distribution (sec. 16). His standard distribution, with which distributions of the above kind were to be compared, was that due to drawing 999 balls from an urn containing white and black balls in equal proportions; it n-as therefore a symmetrical distribution, very close to the Gaussian distribution, but discontinuous. As an example of the frequency-distributions to which Quetelet called attention, we may take the following table (Table IV.) of chest-measurements of 5,732 soldiers in Scottish regiments.

TABLE IV.

Chest in inches .	33	34	35	36	37	38	39	40
Number of men .	3	19	81	189	409	753	1,062	1,082
Chest in inches	41	42	43	44	45	46	47	48
Number of men	93j	646	313	168	50	18	3	1

27. Laws of Distribution.—For comparisons similar to those made by Quetelet, the normal law was usually taken as a basis. But it had two obvious defects (*cf.* sec. 21 [iv.]). One was that it assumed the possibility of an infinite range of variation. The more serious defect was that it implied symmetry, whereas in many cases there was a definite asymmetry or skewness. The generalized law, mentioned in sec. 23, allows for skewness, but does not provide for restricted range of variation. Provision was therefore required for other types of frequency-distribution. This was necessary for two reasons. When we are studying a particular distribution, it is desirable to obtain a formula which fits it as closely as possible: for, when we have obtained a closely-fitting formula, the actual distribution can conveniently be represented by the constants of this formula. But there is a further question. We are studying, let us say, the distribution of men's heights in a fairly homogeneous population; the variations of height being produced by a number of small variations which are distributed by intermarriage and are being supplemented by new variations of the same kind. We find a formula, containing a few parameters or "arbitrary constants," which can be fitted very closely to the observations by obtaining suitable values for these parameters. But we are at any time studying only a limited number of persons, though this number may be a large one; and the result of this limitation of number is some irregularity as between the numbers in the various categories of classification—*e.g.*, the numbers of men of different heights, measured in inches. As the number of persons measured increases, these irregularities become relatively smaller. The question which thus arises may be stated as follows. We adopt the hypothesis that, as the number of observations is increased, not merely actually, but also potentially by supposing the causes of variation to be extended to a very large number of individuals, there is a tendency to a definite statistical law of variation. The question then is: Can the irregularities which appear in our data for n individuals be regarded as due to errors of random sampling of the n individuals from a hypothetical universe of this kind?

Thus the study of a frequency-distribution falls mainly under the following heads: (1) the choice of a suitable formula, (2) the determination of the constants of this formula from the data, (3) enquiry whether the data may reasonably be regarded as the result of random sampling from a universe in which the variations are distributed according to the formula chosen. There are also certain minor matters of consideration: in particular, the question (4) whether the data can really be regarded as homogeneous, or whether individual excessive variations—giants or dwarfs—ought to be excluded, either as not really belonging to the universe we are postulating, or as being sports, or, possibly, as being the result of incorrect observation.

28. Some Types of Formula.—The most familiar types of formula which have been fitted to observations are those given by Karl Pearson's extension of the Gaussian formula. This latter formula is essentially based on the differential equation

$$\frac{1}{u}\frac{du}{dx} = (\text{const.})x.$$

Pearson's extension takes

$$\frac{1}{u}\frac{du}{dx} = \frac{x+a}{b_0+b_1x+b_2x^2}$$

This gives a great variety of forms; and the increase in the number of arbitrary constants gives greater elasticity.

Pareto's formula

$$u=(\text{const.})x^{-c}$$

is included in Pearson's types.

Another form, of importance in vital statistics, is Makeham's formula, obtained from the differential equation

$$-\frac{1}{u}\frac{du}{dx} = a+bc^x.$$

29. Determination of Constants.—(i.) There are various ways of fitting a formula to a particular distribution by finding suitable constants. The most usual method is that of equating moments. The number of individuals being n, and the equation of the figure to be fitted being $nu=nf(X, a, b, c\ldots)$, so that $f(X, a, b, c\ldots)\,dX$ is the proportion of individuals for which X lies within the limits $X\pm\frac{1}{2}dX$, and a, b, c... are the constants to be determined, we equate the 1st, 2nd, 3rd... moments of nu to those of the actual distribution, and thus obtain equations for determining a, b, c.... In doing this, it must be remembered that the values of X are (usually) not given exactly for the observed individuals, since these latter are grouped in classes, *e.g.*, in the case of heights, they may be given to the nearest inch. The individuals in each class are therefore treated as having all the same X, and certain corrections are applied (see MENSURATION).

(ii.) If we want to find the most probable values of the constants, the problem becomes one of inverse probability, and we have to make some assumption as to the a priori probabilities of different values of the constants. When the number of individuals is large, this presents no difficulty. If, for instance, the distribution is of heights of men, and we require the most probable value of their mean, the range of practically possible values is small, and we can assume that within this range all values are equally likely. But caution is necessary when we are dealing with small numbers. In the case of a Gaussian distribution, the most probable values, on the above assumption, are obtained by taking first and second moments; subject to some qualification in view of the fact that measurements are grouped.

(iii.) When a value g has been found for a parameter, note should be made of the "probable error" of g. This is a quantity e such that it is an even chance that the true value of the parameter lies between $g-e$ and $g+\epsilon$.

30. Test of Closeness of Fit.—When we have chosen a formula, we have still to satisfy ourselves that it is a suitable one. The method of doing this belongs properly to correlation (sec 33), since it deals with the probability of joint occurrence of a number of variations. There are two classes of cases, In the one class the formula is completely settled a *priori*, and there are no constants to be determined. In the case of throwing a die, for instance, our hypothesis may be that all faces are equally likely to be uppermost; we test the hypothesis by comparing the actual numbers of throws of 1, 2...6 with the theoretical numbers, namely $1/6{\cdot}N$ for each face, and see whether the *discrepancies* between hypothesis and fact are such as might be due to random sampling. In the other class of cases there are unknown constants. Whatever values are taken for these constants, there will be discrepancies between the theoretical frequencies calculated from them and the actual frequencies; and there will be the same enquiry as to these discrepancies. Both cases are usually dealt with by a method due to K. Pearson, and known as the "χ^2" method.

31. Exclusion of Extreme Values.-Occasionally, in a set of observations of a group supposed to be homogeneous, extreme variations—giants or dwarfs—will occur. If the probability of their occurrence as the result of random sampling is extremely small, regard being had to the total number n, are they to be excluded? Their inclusion or exclusion may make a good deal of difference not only in the deduced values of the constants but also in the measure of closeness of fit. Several forms of criterion for exclusion have been proposed. But these relate to exclusion from a particular distribution. If we deal statistically with a number of distributions of the same kind, the extent to which these extreme variations occur may be an important element in our enquiries.

CORRELATION

32. Regression.—The importance of correlated variation in individuals was emphasized by Darwin, and the correlation of deviations from the average in parents and in offspring must have long been a matter of common observation, but it was

Francis Galton who, in papers leading up to his Natural Inheritance (1889), first stated a law governing the frequencies of such deviations. The special aspect to which he called attention was regression towards the mean. The sons of tall men are—on the average- all, but not so tall: the sons of short men are short, but not so short. But this does not mean that the parents of tall men are taller, or the parents of short men shorter. The regression works both ways.

Suppose, for simplicity, that heights, in both generations, are distributed about the same mean value a with the same standard deviation c, the distribution in each case being according to the normal law. Then, if we group together all the fathers whose heights are $a+\xi$, the average height of their sons (one son to each father) will not be $a+\xi$ but $a+r\xi$, where r is (in this case) somewhere about 0·5. And, if we group together all sons whose heights are $a+\eta$, the average height of their fathers will not be a+q but $a+r\eta$, where r has the same value as in the preceding sentence.

In the general case, suppose there are a large number of individuals having measurable attributes A and B, their measures being X and Y, and that the values of X are distributed about a mean value a with standard deviation c, and those of Y about a mean value b with standard deviation d; subject to an assumption mentioned below. (In the case considered above, the individual is the pair, father and son, and the attributes are the height of the father and the height of the son.) Then Galton's law of regression is that, if we group together all individuals for which X has the value $a+xc$, the mean value of Y for these individuals is $b+rxd$; and also, if we group together all individuals for which Y has the value $b+yd$, the average value of X for these individuals is $a+ryc$: where r is the same in the two cases and is between -1 and $+1$. The ratio $rxd/xc=rd/c$ (which is not necessarily a numerical ratio, since A and B may be different kinds of quantities) is the *coefficient* of regression of B on A, and the ratio $ryc/yd=rc/d$ is the coefficient of regression of A on B.

The whole of the above is based on the assumption that the values of X and of Y are normally distributed and normally correlated. The algebraical expression of normal correlation is considered below: its general character can be seen from Table V., which is a correlation-table showing the relation between brother and sister as regards span.

TABLE V.—*Correlation of brother and sister*
(Adapted from K. Pearson and *A.* Lee, *Biometrika* ii. [1903], **449.**)

33. Normal Correlation.—The form of the equation to a normal frequency-distribution was obtained (sec. 21 [iii.]) by considering the frequencies of deviations from a representative distribution in the case of alternatives A and a. The normal law of distribution of these latter frequencies having been obtained, we can easily deduce the corresponding formula for distribution in any number of categories, and thence obtain the general formula for a normal frequency-distribution of any number of variables. For the present we can limit ourselves to the case of two variables, which means three categories.

(i.) Suppose there are three categories P, S, T, the relative frequencies of which are p, s, t, so that a representative distribution of n individuals would give np, ns, nt in the three categories. Denote these by n_0, n_1, n_2, so that $n_0+n_1+n_2=n$. Then the probability of joint occurrence of numbers $n_0+\epsilon_0$, $n_1+\epsilon_1$, $n_2+\epsilon_2$ in the three categories (so that $\epsilon_0+\epsilon_1+\epsilon_2=0$) is approximately proportional to $e^{-\frac{1}{2}\chi^2}$, where

$$\chi^2=\frac{\epsilon_0^2}{n_0}+\frac{\epsilon_1^2}{n_1}+\frac{\epsilon_2^2}{n_2}.$$

By replacing ϵ_0 by $-\epsilon_1-\epsilon_2$, we get χ^2 as an expression involving ϵ_1^2, $\epsilon_1\epsilon_2$, ϵ_2^2.

(ii.) We therefore define the normal law of *correlation* of two attributes A and B as being such that the frequency of joint occurrence of deviations X and Y from the respective means a and b is proportional to $e^{-\frac{1}{2}U}$, where U is of the form

$$U=FX^2-2GXY+HY^2;$$

F and H being positive, and $FH>G^2$.

(iii.) By taking mean squares c^2 and d^2 of X and Y, and mean product of X and Y, it will be found that U can be expressed in the form

$$U=\frac{1}{1-r^2}\left(\frac{x^2}{c^2}-2r\frac{XY}{cd}+\frac{Y^2}{d^2}\right),$$

where $r=$ (mean product of X and Y) $\div cd$. Hence it follows (by fixing X in the one case and Y in the other) that the coefficient of regression of B on A is rd/c, and that of A on B is rc/d. Thus r is the same r that we considered in sec. 32. It is called the *coefficient* of correlation; its value is between -1 and 1. The correlation is said to be positive or negative according as r is positive or negative.

34. Determination of Constants.—When the joint distribution of two variables X and Y is supposed to follow a certain law, we proceed in exactly the same way as for the distribution of a single variable. We find values for the constants from the data; and we examine the discrepancies between the data and a corresponding distribution deduced from chosen values of the constants, in order to see whether these discrepancies can be reasonably regarded as due to errors of random sampling.

In the case of normal correlation, where the data are distributed in a sufficient number of categories formed by taking values of X at equal intervals, and values of Y also at equal intervals, the values of the means and standard deviations as found from the data are taken to be those of the distribution, and the mean product of the deviations from the means is taken to be the product of the standard deviations and the coefficient of correlation. Values of the constants having been determined, we must pay attention to the "probable errors" of these values. There are, however, numerous kinds of cases in which this method cannot be adopted. We can only consider them briefly.

3j. Other Kinds of Cases.—The assumptions we have hitherto made are that

(i.) the measures X and Y are normally distributed and normally-correlated, so that the regression is linear;

(ii.) the number of observations is very large;

(iii.) they are distributed into a fairly large number of categories, by tabulation at intervals in X and Y.

Actual cases, in which the attributes under consideration are clearly correlated, in the general sense of the term, and we should like to have some measure of the correlation, may present difficulties, especially in one or more of the following ways.

(1) The distributions may not be normal; or, even if they are normal, the correlation may not be normal;

(2) In addition, the regression may not be linear;

(3) The number of cases may be small;

(4) The number of categories may be very small;

(5) The attributes considered may not be continuously varying quantities.

36. Special Methods.—The following are some special methods for treatment of cases of the kind mentioned in sec. 3j.

(i) If we are dealing with quantities which have continuous variation, but the correlation is not normal, we can still define r as the ratio which the mean product of the deviations from the respective means bears to the product of the standard deviations. This applies whether the regression is linear or not.

(ii.) The definition may still hold, even if the number of categories is so small that we cannot determine the means, etc. Table I., for instance (sec. 6), gives sufficient data for us to find r on the assumption that the two sets of heights are normally distributed and normally correlated.

TABLE VI.—*Correlation of Hair-colour and Eye-colour in Men*

Eye-colour	Hair-colour				Totals
	Fair	Brown	Black	Red	
Blue	1,768	807	189	47	2,811
Grey or Green	946	1,387	746	53	3,132
Brown	115	438	288	16	857
Totals	2,829	2,632	1,223	116	6,800

(iii.) A common class of cases is of the kind shown in Table VI. (quoted from Yule, p. 61). Here there is clearly some correlation; the number of men with fair hair and blue eyes, for instance, would, if hair-colour and eye-colour mere independent. be about $2829 \times 2811 \div 6800 = 1169$; actually it is 1768, and the discrepancy is far too great to be due to error of random sampling. But there is nothing to suggest continuous variation of the measure of an attribute. For cases of this kind—usually called *contingency* cases—we must fix some definition of the ratio which is to be the measure of correlation. The usual ratio is K. Pearson's *mean square contingency coefficient,* which may be defined as follows. Divide the square of the number in each compartment of the main table by the product of the corresponding subtotals (*e.g.,* divide 1768×1768 by 2829×2811), and add the results. Let their sum be S. Then the coefficient is defined as being $\sqrt{\frac{S-1}{S}}$.

(iv.) A particular case of contingency is *association,* which is the relation exhibited by a *tetrachoric* classification, *i.e.,* one in which there is only a distribution of A and not-A under B and not-B. The contingency coefficient defined in (iii.) can be used for these cases; but various other methods have been suggested.

(v.) The last class of cases to be mentioned is that in which we are concerned with two attributes A and B which can be approximately represented by magnitudes X and Y, but the number of individuals is so small, and the laws of frequency of X and Y are so doubtful, that we cannot apply ordinary statistical methods. If, however, the individuals can be arranged in order according to their values of X, and also according to their values of Y, C. Spearman's "rank" method can be adopted. Suppose, as an example, that there are n boys, and that we want to calculate the correlation between their abilities in subjects A and B. Arrange them in order according to their ability in *A,* and give them the ranks 1, 2, 3...n. Do the same for B. Let d denote, for each boy, the difference between the ranks in the two subjects. Then the *rank coefficient of correlation* is

$$\rho = 1 - \frac{6\Sigma d^2}{n(n^2-1)},$$

where Σd^2 denotes the sum of the squares of the n d·s.

37. **Multiple Correlation.—The** methods which we have been using for dealing with correlation between two attributes can be extended to cases in which there are three or more correlated attributes. The normal formula expressing frequency of joint occurrence of deviations x, y, z...from the respective means involves an expression $e^{-\frac{1}{2}U}$ where U is a quadratic function of x, y, z....This leads to the consideration of partial correlation, *i.e.,* correlation between two of the variables when the remaining variables are taken to have fixed values.

PROBATE refers to the formal proof of a will, which in England has to take place at Somerset House, London, or at a district registry. The early jurisdiction of the English ecclesiastical courts over the probate of wills of personalty is discussed under WILL and ECCLESIASTICAL JURISDICTION. The Court of Probate Act 1857 transferred the jurisdiction both voluntary and contentious of all ecclesiastical, royal peculiar, peculiar and manorial courts to the court of probate thereby constituted, created a judge and registrars of that court, abolished the old exclusive rights in testamentary matters of the advocates of Doctors' Commons, and laid down rules of procedure. Contentious jurisdiction was given to county courts when the personal estate of the deceased was under f 200 in value. The Judicature Act 1873 merged the old court of probate in the probate divorce and admiralty division of the High Court of Justice. Probate may be taken out either in *common* or *solemn* form. In the former case, which is adopted when there is no dispute as to the validity of the will, the court simply recognizes the will propounded as the last will of the deceased. This formality is necessary to enable the executor to administer the estate of his testator. Probate in this form is granted simply as a ministerial act if the attestation clause declares that the formalities of the Wills Act have been complied with, or if other evidence to that effect is produced. Such grant is liable to revocation, but it is provided that any person dealing with an executor on the faith of a grant of probate in common form, shall not be prejudiced by its revocation. The executor may within 30 years be called upon to prove in solemn form. A person who doubts the validity of the will propounded may enter a caveat which while in force prevents any probate other than in solemn form. Separate representation may be granted in respect of real estate since the administration of Estates Act 1925, and of a trust estate only, but except or regards trust estates a separate representation may be granted of a known insolvent estate. Under the Law of Property Act, 1925, S. 11, probate and letters of administration convey the legal estate to the personal representative, and this makes the real estate directly available for payment of debt. Probate in solemn form is a judgment of the court in favour of the will propounded, and is only revocable by the discovery of a later will. In order, therefore, to obtain such grant proceedings have to be taken by action, and witnesses produced in support of the will, and the action proceeds in the usual way.

The principal rules now obtaining as to probate are these. Probate, which since the Land Transfer Act 1897 (*see* New Administration of Estates Act, 1925, ss 79, 80) must be taken out for wills of realty as well as wills of personalty, may be granted either in the principal or in a district registry, and should be obtained within six months after the testator's death. When no executor is named the will is not now invalid, as was once the case, but administration *cum testamento annexo* is granted. The same course is pursued where the executor renounces or dies intestate before administering the estate of the deceased. After probate, the probate itself (as the official copy of the will is called) becomes evidence, the original will being deposited in the principal registry at Somerset House, London. On grant of probate, estate duty is payable on the gross value of the personal estate and the English real estate (*see* ESTATE DUTIES). The act of 1881 enables any officer of inland revenue to grant probate where the personal estate does not exceed £300.

In 1867 an act on lines similar to the English act was passed for Ireland and under the Irish Judicature Act of 1877 the then existing court of probate was merged in the High Court of Justice.

In Scots law Confirmation includes both the probate and letters of administration of English procedure. It forms the executor's legal title to ingather the estate. Originally confirmation of testaments of movables fell, as in England, under the cognizance of the Church courts. It is now part of the jurisdiction of the sheriff courts and is regulated by statutes, the principal of which are, the Confirmation and Probate Act 1858, the Sheriff Courts Act 1876, and Executors Act 1900. When the will is attested and probation alluding to sects, forms for the execution of deeds, it proves itself, and the onus is on the person challenging it. In other cases the executor may be required to prove the validity of the will in the proceedings for confirmation.

UNITED STATES

Special Courts.—Probate is granted in some States by the ordinary chancery or common law courts, but more frequently by courts of special jurisdiction, such as the prerogative court in New Jersey, the surrogates' court in New York, the orphans' court in Pennsylvania.

"In a great majority of the States the original equitable jurisdiction over administrations is in all ordinary cases—without any special circumstances such as fraud, or without any other equitable feature such as trust--either expressly or practically abrogated. The courts of equity, in the absence of such special circumstances or distinctively equitable features, either do not possess or will not exercise the jurisdiction, but leave the whole matter of administrations to the special probate tribunals" . . . so that "unless the case involves some special feature or exceptional circumstances of themselves warranting the interference of equity, such as fraud, waste, and the like, or unless it is of such an essential nature that a probate court is incompetent to give adequate relief, or is one of which the probate court having taken cognizance has completely miscarried and failed to do justice by its decree, the courts of equity will refuse to interpose and to exercise whatever dormant powers they may possess, but will leave the subject matter and the parties to the statutory forum which the legislature plainly regarded as sufficient and intended to be practically exclusive" (Rice's Probate *Law,* pp. 4 and 5). For the old law on probate, see *G.* W. Marshall, Ancient Courts of Probate (1895).

Jurisdiction as to wills and their probate as such is neither included in nor excepted out of the grant of judicial power to the courts of the United States (*i.e.,* the Federal as distinguished from the State courts). So far as it is ex *parte* and merely administrative it is not conferred, and it cannot be exercised by them at all until in a case at law or in equity its exercise becomes necessary to settle a controversy by reason of the (diverse) citizenship of the parties. An action to set aside the probate of a will of real estate may be maintained in a Federal court when the parties on one side are citizens of a different State from the parties on the other side (Ellis v. Davis, 109 U.S. Reports, 485). Probate in solemn form, *i.e.,* after due notice to all parties in interest is the almost universal form in use in the United States. One reason for this no doubt is that all documents affecting title to real estate must be recorded and probate in solemn form concludes all parties to the proceeding and thus tends to establish the title to all real estate passing under the will.

In the United States wills of real property must be separately proven in the proper probate court in each State in which the real property is situated, unless statute dispenses with separate probate (each State being "foreign" to every other for this purpose). Copies of such will and probate should be filed also in the office of the register of deeds of each county in the State in which any real property belonging to the testator is situated.

In the State of New Jersey it has been held that an unprobated will is capable of conveying an interest in the property devised, and when a conveyance is made under a power in the will before probate, a subsequent probate validates the conveyance (1906, Mackey v. Mackey, 63 Atl. Rep. 984).

In Illinois a court of equity has no inherent power to entertain a bill to contest a will (1906, *O'Brien* v. *Bonfield,* 220 Ill. Rep. 219).

In Missouri a foreign (New York) will of real estate in Missouri, probate of which was duly recorded in Missouri, cannot be collaterally attacked, and cannot be set aside by direct proceeding after being filed for record more than five years in Missouri (1907; Cohen v. Herbert, 104 So. W. Rep. 84).

PROBATION. The principle on which the probation system is based originated in, and was a development of, the idea of the suspended sentence. Under this the accused person was adjudged to be guilty and his sentence determined upon, but it remained suspended, to be eventually cancelled, if the accused made a serious effort in the meantime to redeem his character. Some countries still retain this practice, but it is obvious that its efficacy must depend upon the reliability of the information furnished as to the conduct of the accused during the period of suspension. In order to provide this information it was essential to appoint some person who would be in a position to supply it accurately, and it soon became the function of this official, not only to keep observation, but to give advice, encouragement and assistance to those over whom he exercised supervision. These are precisely the duties which a probation officer now fulfils.

The credit for the earliest creation of these officers would appear to rest with the principal authorities of Boston, U.S.A., who appointed a number of them in the year 1878. The principle received legislative recognition in England in 1887, when the First Offenders Act became law. The value of the system was soon completely demonstrated. The Probation of Offenders Act of 1907 in Great Britain permitted the use of probation, not in the case of first offenders only, but also in that of persons who had been previously convicted, provided the circumstances justified such a course.

It is greatly to the credit of the Police Court Mission that its managers should have at once provided the required agents by offering their own missionaries for this purpose. The offer was accepted, and in very many provincial and in all the metropolitan police courts of Great Britain, the missionaries of the society are appointed to act as probation officers. In London, and a few other cities, special probation officers are appointed to devote themselves solely to the children's courts. In the metropolis these officers are appointed and paid directly by the Home Office, and are subject to no religious tests. A uniformity of system in this respect would seem to be ultimately necessary. There is a National Association of Probation Officers which exists to safeguard the interests of its members and to strengthen and standardize the system.

Under the act of 1907 the appointment of probation officers was not compulsory and, as many districts made inadequate provision, and some no provision at all, full advantage was not taken by the act. This defect has now been remedied by the Criminal Justice Act, 1925, which renders obligatory the appointment of a probation committee for every probation area. This area may be either that comprised in the jurisdiction of a single petty-sessional court, or a combined area of several such courts, approved by the secretary of State.

It is impossible at present to give statistics, of any real value, of the success of probation, but that it has been successful to an extraordinary degree is unquestionable. It would, however, be most helpful if a uniform test of "success" or "failure" could be adopted as applicable to each individual case. If the test used is only good behaviour during the probation period, the number of successes would, of course, be very much greater than if the period were extended to a term of years after the order had ceased. The terms "success" and "failure" likewise need definition. A single relapse does not necessarily imply failure.

Probation work amongst children (see JUVENILE OFFENDERS) differs materially from that amongst adults and is of even greater importance. It is essential that a child offender should, at first, be under very careful supervision; that his mental, physical and psychological characteristics should receive the closest study; that most friendly relations should be established between the parents and the probation officer; that the child should be brought in touch with outside agencies, such as boy scouts, clubs, etc., and that he should feel that in his own officer he has a real friend to whom he can always look for advice, sympathy and help. About half the number of children charged before the juvenile courts are now placed on probation. Where, however, this fails, there should be no hesitation on the part of the probation officer in bringing the child again before the court in order that he may be sent to a certified school. (W. C. HA.)

United States. — Every State in the union now has probation in more or less successful operation. The results obtained vary and are dependent largely upon whether trained probation officers are employed and upon whether these officers have assigned to them more cases than can be handled at one time with efficiency. Fifty cases are generally considered a maximum for a single officer. Rural communities are generally backward in providing probation officers. Generally speaking, however, the results of probation, as a principle, have been excellent. Apparently 75 to 85% of probationers do well while subject to probation, according to official reports. Adequate statistics are not available on the extent to which further relapses occur after the probationary period ends, but studies made seem to show that only a negligible portion of those who do well under probation subsequently succumb to criminal tendencies.

Probation has more than justified its value as an instrumentaiity of preventive penoiogy and has received increased pubiic approval. In this regard it is in marked contrast with parole with which it is closely related and with which it should not be confused. Probation, as stated, is an outgrowth of the suspended sentence and is a substitute for punishment, while parole is a part of penal discipline, akin to probation in its methods, to be employed after punishment is partly accomplished. Probation has obviously the larger chance of success.

In the first place, probation cases are generally those in which the prospect of social rehabilitation is more hopeful. Its cases, moreover, are more likely to co-operate with probation officers' services with a gratitude born of a consciousness of punishment avoided rather than, as in the case of those paroled, resentful in a present recollection of punishment endured. As a social agency in human reformation, probation still has great undeveloped possibilities and constitutes one of the great experimental fields for all the forces which deal with the understanding and prevention of crime.

PROBLEM, a question proposed for discussion and answer. (Greek *πρόβλημα,* from *προβάλλειν,* to throw before; a question placed before one for consideration.) In mathematics, a solution to be effected, such as that of the construction of an equilateral triangle having a given line segment as a side, or the finding of the mean proportional between two given numbers. In geometry it is usually a statement of a construction to be effected, whereas a theorem is a statement which is itself to be proved, as that the angles opposite the equal sides of an isosceles triangle are equal. The Greek geometers divided their propositions into theorems (*q.v.*), problems and porisms (*q.v.*). Pappus (*q.v.*) tells us that they recognized three classes of problems: (1) plane, (2) solid and (3) linear. The construction lines permitted were respectively (1) the straight line and the circle, (2) the conic sections ("solid loci") and (3) such higher curves as the conchoid, cissoid and quadratrix. (See CURVES, SPECIAL.) In solving a problem there is usually given (1) a statement of the construction to be effected with respect to a certain figure, (2) a statement of the steps in the construction and (3) a proof that the construction is correct.

PROBOSCIDEA, the scientific name of an order of Eutherian mammals represented at the present day by the African and Indian elephants. These animals (see ELEPHANT) differ very widely in their structure from all other living mammals but fossil remains of similar structure have long been known. Only during the past 20 years, however, have primitive Proboscidea been discovered capable of comparison with other mammalian forms. The leading characteristics of the living elephants are as follows.

The animal is of large size with pillar-like limbs. The neck is short and the large head is provided with a proboscis, a long flexible muscular organ capable of being turned freely in all directions, and provided with one or two finger-like processes at its tip which can be used to handle articles as small as a penny. The trunk can also be employed as a prehensile organ by being wrapped as a whole round a large object. It is capable of very considerable accuracy of movement and is used in feeding. The trunk represents the whole anterior part of the face, that is the nose and also the upper lips, the strip of skin along its ventral surface being essentially a part of the palate. The two nostrils lie at the extremity of the trunk and lead into great canals which perforate the whole of that organ opening into olfactory chambers at its base. The mouth is short, placed below the trunk and provided with thick fleshy lower lips meeting anteriorly so as to form a short spout. The eye is small, laterally directed and provided with a pair of eyelids often bearing stiff eyelashes. The pinna of the external ear is large, becoming enormous in certain races of the African elephants. It is usually carried close to the side of the neck but can be erected so as to stand out perhaps a yard from the side of the head. The female bears two teats placed on the pectoral surface just between and behind the forelegs. Most living adult elephants possess very few hairs; there are normally a certain number on the forehead and cheek and always a tuft of long extremely thick hairs at the end of the short tail.

The skeleton of an elephant is as peculiar and characteristic as his externai appearance. The skuli is very short from back to front, deep, and built up of spongy bone full of air-spaces. Within the great mass of bone there lies a relatively small, though actually large brain cavity, and the olfactory chambers form great perforations which with the naso-pharyngeal ducts penetrate obliquely through the skull uniting only quite posteriorly. The skull of the new-born elephant differs from that of the adult in that whilst the head increases greatly and disproportionately in size, the brain undergoes much less expansion. Thus during the period of growth of the animal the external surface of the skull, by the development of the great air-spaces in its middle layer, becomes more and more widely separated from the layer of hard bone which surrounds the brain. The bony lamellae which separate these air-spaces run radially so as to buttress the external surface. The great size of the adult skull is necessary in order to give adequate areas for the attachment of the immense neck-muscles which support and move the very heavy trunk and tusks, and take the great strains which are produced when these structures are used in digging up and tearing down trees.

The jaw-bones of the elephant and the whole structure of its palate are modified so as to receive and afford adequate support to the tusks and cheek teeth. The bony nostrils lie very high up and are overhung by very small nasal bones to which some of the muscles of the base of the trunk are attached. This attachment is brought as far back as possible in order to increase the range of action of the proboscis.

The dentition of an adult elephant consists of a single pair of exaggerated incisors, the tusks, and either one or two molars on each side of the upper and lower jaws. These molars are built up of a series of plates each composed of a core of dentine surrounded by a layer of enamel; the individual plates, continuous with one another at their base, are held together and supported by an infilling of cement. In the elephant the milk incisors, little teeth about two inches in length, are shed and replaced by the permanent tusks, but the milk molars instead of being pushed out by a permanent pre-molar which develops underneath them, replace one another from behind as follows. The new tooth is developed deep down in the posterior part of the jaw and travels obliquely forwards and towards the mouth, so that more and more of it cuts the gum as the preceding tooth is worn down to its root, until finally the latter is shed and its successor is well in wear. A living elephant in this way works through six teeth in each side of each jaw during its lifetime, wearing down a total thickness of nearly a yard of tooth over an area which increases from about half a square inch to nearly 30 sq. in. on each side of its mouth. This extraordinary dentition is unparalleled, but the process by which it came into existence is fortunately completely known from fossil material.

The elephant's backbone possesses a neck of seven very short vertebrae, the number of dorsals varies from 19 to 21, the anterior having exceedingly long neural spines for the attachment of the nuchal ligament which passes forwards to the back of the skull. There is a short lumbar region of three or four vertebrae and the sacrum is a compact bone built up by the fusion of four vertebrae: there are about 30 caudals. The ribs are of enormous length surrounding the very capacious thorax. The shoulder girdle consists of a very large triangular scapula placed vertically on the side of the thorax. The humerus is longer than the forearm so that the elbow of an elephant lies at a point relatively only a little higher than the wrist of a horse. The radius and ulna are peculiar in that their surfaces of articulation with the carpus are nearly equal, whilst the upper end of the radius is relatively small and lies in front of the ulna, the two bones crossing one another as they are traced downwards. The carpus of an elephant is unusual in that the bones of the two rows of which it is composed do not alternate but are superimposed on one another. In this feature the elephants resemble the Hyraxes. The elephant walks on the extreme tips of his fingers and toes, but the palm of the hand and the sole of the foot are swollen out into great pads of connective tissue which transmit the weight of the animal to the ground directly and so reduce the load carried by the phalanges. The elephant's pelvis is remarkable for its extraordinary width, the ilia being expanded into transversely placed sheets of bone from whose posterior surface muscles pass down to the hind-leg, whilst their margins give attachment to the muscles of the body-wall which support the weight of the viscera within the abdominal cavity. As in the fore-limb the upper segment of the leg is considerably longer than the lower one, and in the tarsus the astragalus is flattened, as a weight carrying adaptation, whilst the calcaneum is produced into a short heel directed backwards and downwards.

The anatomy of the soft parts of the elephant has been repeatedly described but presents few features of special interest except those which result from the modification of the nose and upper lips into the trunk. The animal is peculiar in that there is no pleural cavity. The fact that the testes are abdominal, the uterus bicornuate, and the placenta zonary and deciduate are of importance because similar conditions occur in the Sirenia which may have sprung from an early Proboscidean stock.

The most primitive and earliest known ancestors of the elephant belong to the genus *Moeritherium* and are found in Upper Eocene deposits in the Fayûm of Egypt. *Moeritherium* was an animal resembling in its external appearance and size the living tapir. The eye was placed far forward and the head was low and elongated, probably the end of the snout was slightly flexible and it may have been produced into a short proboscis. The legs were considerably more bent than those of the modern elephants but are still rather incompletely known. *Moeritherium* possesses three upper and two lower incisors of which the second pair are enlarged, those in the upper jaw projecting straight downwards, whilst the lower teeth are directed forwards so that their tips bite against those of the upper incisors. There is a small and very reduced canine tooth; three pre-molars are present in each jaw and there is evidence that each of these vertically replaced a milk predecessor. Three permanent molars occur in both upper and lower jaws, each consisting of two transverse ridges.

The next stage, represented by *Palaeomastodon* from the Lower Oligocene of Egypt, presents a great advance on *Moeritherium*. There are several species of which the largest is not very much smaller than a small elephant, whilst the smallest is little bigger than the largest *Moeritherium*. The back of the skull begins to show the separation of the outer surface from the brain-cavity by air-spaces, which is carried to an extreme in the living elephants. The bony nostril has shifted backwards to a point in the middle of the cheek-teeth, and in front of it the pre-maxillae form an open channel in which lay the base of the trunk. The second incisor is very much enlarged and directed forwards and downwards. The lower jaw is so much longer than the skull that the incisors, which lie horizontally, project forwards several inches in front of the upper jaw, and even extend beyond the tips of the upper incisors. The single "second" lower incisor is enlarged, and with its fellow forms a shovel-shaped termination to the lower jaw. The shape of this tooth is such as to show that its upper surface was worn by contact with some part of the animal and the only explanation of its structure is that the nose, upper lip and palate projected so far forward as to overhang the front of the lower jaw and form there a movable proboscis. The lower incisors are, however, worn all round in a way which suggests that the creature used them for grubbing about in the ground to secure food. There are three upper pre-molars each of which replace a milk tooth, whilst in the lower jaw the three milk molars are replaced only by two pre-molars. Both upper and lower molar teeth have three transverse ridges, thus differing from those of *Moeritherium*. The body of the animal was much like that of a small elephant but the neck was longer.

In the next stage, which is represented by *Tetrabelodon angustidens* from the Lower and Middle Miocene of Europe, North Africa and Baluchistan, we have an animal somewhat larger than the largest *Palaeomastodon*, with a completely elephant-like body, though with a somewhat longer and more flexible neck. The skull is much more elephant-like than that of *Palaeomastodon* because of the increased bulk of the air-cavities in its bones. It supports a pair of immense incisors, which, unlike the tusks of living elephants, are still down-turned and are provided with a belt of enamel lying on the outer surface of the ivory of which they are composed. The lower jaw is even longer than in *Palaeomastodon* nearly half its length projecting in front of the bony skull. The lower tusks are directed forwards and bear a wear facet on their upper surfaces made by friction against a pad on the flexible and unsupported anterior part of the face, soon to be, if it had not already become, a true trunk. *Tetrabelodon* still possesses milk molars which are replaced vertically by pre-molars, but these latter are comparatively small teeth soon displaced by the cutting of the second and third molars, which push their way forward from the cavity in the hinder part of the jaw in which they are formed. This process is carried so far that the adult has only two molars, the second and third, in position in each jaw. The individual teeth though larger than those of *Palaeomastodon* have still only three ridges, except in the case of the third, which has five. It seems evident that the enormously elongated jaws of *Tetrabelodon* developed as an adaptation to allow the animal to reach the ground, when as a whole it was increasing in height whilst its neck was becoming shorter.

In the next stage represented by such forms as *Tetrabelodon longirostris*, the elephants gave up the attempt to reach the ground and came to depend on their trunks both for eating and drinking. As the elongated lower jaw is thus no longer necessary, and must have interfered with the free use of the trunk, its anterior extension becomes very rapidly reduced in size so that it no longer extends in front of the bony upper jaw. In these animals only one milk molar is replaced by a pre-molar and the first two molar teeth have each four or five transverse ridges. The lower tusks are short and rounded whilst the upper tusks become still larger and outwardly directed. In these forms the shortening of the lower jaw allowed the trunk to fall down vertically, as it does in modern elephants and in external appearance they must have been entirely elephantine.

The later mastodons pass gradually into the elephants by a still further reduction of the lower jaw, the lower tusks becoming quite small and eventually disappearing altogether, finally the front of the lower jaw becomes reduced to a very small down-turned spout which is retained in the living elephants. In the later forms the milk teeth are no longer replaced vertically by pre-molars, whilst such teeth when they do occur must have been pushed out almost immediately by the forward movement of the molar teeth. At the beginning of the series, the second molar tooth in either jaw has four or five ridges, separated from one another by deep valleys in which there is no cement. In an intermediate stage, *Stegodon*, the number of ridges varies from 6 to 12 in different forms and the valleys between these ridges become filled up with cement. In the true elephants the ridges are not only more numerous but much higher and the cement forms a plate lying between them. Continuation of this process leads to the most highly specialized of all elephants, the mammoth, in which the number of ridges in the second molar may be as high as 16, and the whole tooth was extraordinarily deep.

The history of the evolution of the elephant set forth above is a mere outline. It is really greatly complicated by the existence of a large number of side branches, many of which migrated into North and some even into South America. Of these side branches much the most striking is that represented by *Dinotherium,* an animal with an elephant-like body, apparently with exceptionally long limbs and a trunk. This animal is remarkable because its molar teeth throughout the whole history of the genus have only two transverse ridges and are very low crowned. The upper tusks are completely absent whilst the large lower tusks are directed downwards at right angles to the lower jaw. This animal is probably of African origin and is found only in that continent and in Europe and India. (See ELEPHANT; MAMMOTH; MASTODON.)

(D. M. S. W.)

PROBOSCIS-MONKEY, a large, long-tailed, red Bornean species (*Nasalis larvatus*) characterized by the prolongation of the nose of the adult male, which hangs down in front of the upper lip. In the females and young the nose is less developed. This monkey is a leaf eater, nearly allied to the langurs. (See PRIMATES.)

PROBUS, MARCUS AURELIUS, Roman emperor A.D. 276–282, was a native of Sirmium in Pannonia. At an early age he entered the army. where he distinguished himself under the emperors Valerian, Claudius and Aurelian. He was appointed governor of the East by the emperor Tacitus, at whose death he was immediately proclaimed his successor by the soldiers. Florianus, who had claimed to succeed his brother, was put to death by his own troops, and the senate ratified the choice of the army. The reign of Probus was mainly spent in successful wars by which he re-established the security of all the frontiers, the most important of these operations being directed to clearing Gaul of the Germans. Probus had also put down three usurpers, Saturninus, Proculus and Bonosus. In time of peace he kept the soldiers at work such as planting vineyards, which made him unpopular, and while superintending draining operations at his native town he was killed by his own soldiers. Scarcely any emperor has left behind him so good a reputation; his death was mourned alike by senate and people, and even the soldiers repented and raised a monument in his honour.

Life by Vopiscus; Zosimus i. 64; Zonaras xii. 29; Aurelius Victor, *Caes.* and Epit. 37; H. Schiller, *Geschichte* der romischen Kaiserzeit (1883), vol. i.; E. Lépaulle, etude *historique sur M. A. Probus d'après* la *numismatique* (1885); Pauly-Wissowa, Realencyklopadie, ii. 2516 (Henze).

PROBUS, MARCUS VALERIUS, of Berytus, Roman grammarian and critic, flourished under Nero. His criticisms on Virgil may be preserved in the commentary on the *Bucolics* and Georgics which goes under his name. We possess by him part of a treatise De *notis,* probably an excerpt from a larger work. It contains a list of abbreviations used in official and historical writings (especially proper names), in laws, legal pleadings and edicts. Other works have been wrongly attributed to him.

See J. Steup, De Probis grammaticis (1871); Teuffel-Schwabe, *Hist.* of Roman Literature (Eng. trans.) 301.

PROCESS: *see* PRACTICE AND PROCEDURE.

PROCESS ENGRAVING: see PHOTO-ENGRAVING.

PROCESSION, in general, an organized body of people advancing in formal or ceremonial manner (M. Eng. *processioun,* Fr. procession, Lat. *processio,* from procedere, to go forth, advance, proceed). This definition covers a wide variety of such progresses: the mediaeval pageants, of which the Lord Mayor's show in London is the most conspicuous survival; the processions connected with court ceremonies; those organized to demonstrate political or other opinions; processions forming part of the ceremonies of public worship. In a narrower sense of "going forth, proceeding," the term is used in the technical language of theology in the phrase "Procession of the Holy Ghost," expressing the relation of the Third Person in the Triune Godhead to the Father and the Son.

Greek and Roman Processions.—Processions are included in the ritual of many religions, and in many countries, both in the East and West, they accompany such events as weddings and funerals. Religious and triumphal processions are abundantly illustrated by ancient monuments, *e.g.,* the religious processions of Egypt, those illustrated by the rock-carvings of Boghaz-Keui (see PTERIA), the many representations of processions in Greek art, culminating in the great Panathenaic procession of the Parthenon frieze, and Roman triumphal reliefs, such as those of the arch of Titus.

Processions played a prominent part in the great festivals of Greece, where they were always religious in character. The games were either opened or accompanied by more or less elaborate processions and sacrifices, while processions from the earliest times formed part of the worship of the old nature gods (*e.g.,* those connected with the cult of Dionysus, etc.), and later formed an essential part of the celebration of the great religious festivals (*e.g.,* the processions of the Thesmophoria, and that of the Great Dionysia), and of the mysteries (*e.g.,* the great procession from Athens to Eleusis, in connection with the Eleusinia).

Of the Roman processions, the most prominent was that of the triumph, which had its origin in the return of the victorious army headed by the general, who proceeded in great pomp from the Campus to the Capitol to offer sacrifice, accompanied by the army, captives, spoils, the magistrate and priests bearing the images of the gods, amidst strewing of flowers, burning of incense and the like (Ovid, Trist. iv. 2, 3 and 6). Connected with the triumph was the *pompa circensis,* or solemn procession which preceded the games in the circus; it first came into use at the *ludi romani,* when the games were preceded by a great procession from the capitol to the circus. The praetor or consul who appeared in the *pompa* circensis wore the robes of a triumphing general (see Mommsen, *Staatsrecht* I., 397, for the connection of the triumph with the *ludi*). Thus, when it became customary for the consul to celebrate games at the opening of the consular year, he came, under the empire, to appear in triumphal robes in the processus *consularis,* or procession of the consul to the Capitol to sacrifice to Jupiter. After the establishment of Christianity, the consular processions in Constantinople retained their religious character, now proceeding to St. Sophia, where prayers and offerings were made; but in Rome, where Christianity was not so widely spread among the upper classes, the tendency was to convert the procession into a purely civil function, omitting the pagan rites and prayers, without substituting Christian ones (Dahremberg and Saglio, *s.v.* "Consul"). Besides these public processions, there were others connected with the primitive worship of the country people, which remained unchanged, and were later to influence the worship of the Christian Church. Such were those of the Ambarvalia, Robigalia, etc., which were essentially rustic festivals, lustrations of the fields, consisting in a procession round the spot to be purified, leading the sacrificial victims with prayers, hymns and ceremonies, in order to protect the young crops from evil influences. (See Preller, Rom. Mythologie, pp. 370–372.)

Processions in the Christian Church.—As to the antiquity of processions as part of the ritual of the Christian Church, there is no absolute proof of their existence before the 4th century, but as we know that in the catacombs stations were held at the tombs of the martyrs on the anniversary of their death, for the celebration of the eucharist, it is quite probable that the faithful proceeded to the appointed spot in some kind of procession. There are, indeed, early instances of the use of the word processio by Christian writers, but it does not in any case appear to have the modern meaning "procession." Tertullian (2nd century) uses processio and procedere in the sense of "to go out, appear in public," and, as applied to a church function, processio was first used in the same way as *collecta,* as the equivalent of the Greek *συνάξις, i.e.,* for the assembly of the people in the church (Du' Cange, *s.v.* "Processio").

For the processions that formed part of the ritual of the eucharist, those of the introit, the gospel and the oblation, the earliest records date from the 6th century and even later (see Duchesne, *Origines,* 2nd ed. pp. 77, 154, 181; 78, 194), but they evidently were established at a much earlier date. As to public processions, these seem to have come into rapid vogue after the recognition of Christianity as the religion of the empire. Those at Jerusalem would seem to have been long established when described by the authoress of the *Peregrinatio Silviae* towards the end of the 4th century (see PALM SUNDAY, for the procession of palms).

Litanies or Rogations.—Very early were the processions accompanied by hymns and prayers, known as litaniae (Gr. λιτανεῖα from λιτή, prayer), *rogationes* or *supplicationes* (see LITANY). It is to such a procession that reference appears to be made in a letter of St. Basil (*c.* 375), which would thus be the first recorded mention of a public Christian procession. The first mention for the Western Church occurs in St. Ambrose (c. 388, Ep. 40 § 16, Ad Theodos.: "monachos . . . qui . . . psalmos canentes ex consuetudine usuque veteri pergebant ad celebritatem Machabaeorum martyrum"). In both these cases the litanies are stated to have been long in use. There is also mention of a procession accompanied by hymns, organized at Constantinople by St. John Chrysostom (c. 390–400) in opposition to a procession of Arians, in Sozomen, *Hist.* eccl. viii. 8. In times of calamity litanies were held, in which the people walked in robes of penitence, fasting, barefooted, and, in later times, frequently dressed in black (litaniae nigrae). The cross was carried at the head of the procession and often the gospel and the relics of the saint were carried. Gregory of Tours gives numerous instances of such litanies in time of calamity; thus he describes (Vita S. *Remig.* I.) a procession of the clergy and people round the city, in which relics of St. Remigius were carried and litanies chanted in order to avert the plague. So, too, Gregory the Great (*Ep.* xi. 57) writes to the Sicilian bishops to hold processions in order to prevent a threatened invasion of Sicily. A famous instance of these penitential litanies is the litania *septiformis* ordered by Gregory the Great in the year 590, when Rome had been inundated and pestilence had followed. In this litany seven processions, of clergy, laymen, monks, nuns, matrons, the poor and children respectively, started from seven different churches, proceeded to hear mass at Sta. Maria Maggiore (see Greg. of Tours, *Hist.* Fr. x. 1, and Johann. Diac. Vita Greg. Magn. i. 42). This litany has often been confused with the litania major, introduced at Rome in 598 (vide supra), but is quite distinct from it.

Funeral processions, accompanied with singing and the carrying of lighted tapers, were from very early times customary and in some ways similar to these; also very early, were the processions connected with the translation of the relics of martyrs from their original burying place to the church where they were to be enshrined (see, *e.g.,* St. Ambrose, *Ep.* 29 and St. Augustine, De civitate Dei, xxii. 8 and Conf. viii. 7, for the finding and translation of the relics of Saints Gervasius and Protasius). From the time of the emperor Constantine I. these processions were of great magnificence.

Origin of Christian **Processions.**—Some liturgists maintain that the early Church in its processions followed Old Testament precedents, quoting such cases as the procession of the ark round the walls of Jericho (Josh. vi.), the procession of David with the ark (2 Sam. vi.), the processions of thanksgiving on the return from captivity, etc. The liturgy of the early Church as Duchesne shows (*Origines,* ch. i.) was influenced by that of the Jewish synagogue, but the theory that the Church adopted the Old Testament ritual is of quite late growth. What is certain is that certain festivals involving processions were adopted by the Christian Church from the pagan calendar of Rome. Here we need only mention the *litaniae* rnajores et *minores,* which are stated by Usener ("Alte Bittgange," in Zeller, Philosophische *Aufsätze,* p. 278 *seq.*) to have been first instituted by Pope Liberius (352–366). It is generally acknowledged that they are the equivalent of the Christian Church of the Roman lustrations of the crops in spring, the Ambarvalia, etc. The *litania* major, or great procession on St. Mark's day (April 25) is shown to coincide both in date and ritual with the Roman *Robigalia,* which took place *a.d. vii.* Kal. Mai., and consisted in a procession leaving Rome by the Flaminian gate, and proceeding by way of the Milvian bridge to a sanctuary at the 5th milestone of the Via Claudia, where the *flamen quirinalis* sacrificed a dog and a sheep to avert blight (robigo) from the crops (Fasti *praenestini,* C.T.L.T., p. 317). The litania major followed the same route as far as the Milvian bridge, when it turned off and returned to St. Peter's, where mass was celebrated. This was already established as an annual festival by 598, as is shown by a document of Gregory the Great (*Regist.* ii.) which inculcates the duty of celebrating *litaniam,* quae major ab *omnibus appellatur.* The *litaniae minores* or rogations, held on the three days preceding Ascension Day, were first introduced into Gaul by Bishop Mamertus of Vienne (c. 470), and made binding for all Gaul by the 1st Council of Orleans (511). The litaniae *minores* were also adopted for these three days in Rome by Leo III. (c. 800). A description of the institution and character of the Ascensiontide rogations is given by Sidonius Apollinaris (*Ep.* v. 14). "The solemnity of these," he says, "was first established by Mamertus. Hitherto they had been erratic, lukewarm and poorly attended (vague, *tepentes,* infrequentesque); those which he instituted were characterized by fasting, prayers, psalms and tears." In the Ambrosian rite the rogations take place after Ascensiontide, and in the Spanish on the Thursday to Saturday after Whitsuntide, and in November (Synod of Girona, 517).

Processions in the Modern Roman Catholic **Church.—**It is impossible to describe in detail the vast development of processions during the middle ages. The most important and characteristic of these still have a place in the ritual of the Roman Catholic Church. The rules governing them are laid down in the *Rituale Romanum* (Tit. ix.), and they are classified in the following way:—

(1) Processiones *generales,* in which the whole body of the clergy takes part. (2) Processiones *ordinariae,* on yearly festivals, such as the feast of the Purification of the Virgin (Candlemas, *q.v.*), the procession on Palm Sunday (*q.v.*), the Litaniae *majores* and minores, the feast of Corpus Christi (*q.v.*), and on other days, according to the custom of the churches. (3) Processiones *extraordinariae,* or processions ordered on special occasions, *e.g.,* to pray for rain or fine weather, in time of storm, famine, plague, war, or, in quacunque *tribulatione,* processions of thanksgiving, translation of relics, the dedication of a church or cemetery. There are also processions of honour, for instance to meet a royal personage, or the bishop on his first entry into his diocese (*Pontif.* rom. iii.).

Reformed Churches.—The Reformation abolished in all Protestant countries those processions associated with the doctrine of transubstantiation (Corpus Christi); "the Sacrament of the Lord's Supper," according to the 28th Article of Religion of the Church of England, "was not by Christ's ordinance reserved, carried about, lifted up, or worshipped." It also abolished those associated with the cult of the Blessed Virgin and the saints. The stern simplicity of Calvinism, indeed, would not tolerate religious processions of any kind, and from the "Reformed" Churches they vanished altogether. The more conservative temper of the Anglican and Lutheran communions, however, suffered the retention of such processions as did not conflict with the reformed doctrines, though even in these churches they met with opposition and tended after a while to fall into disuse.

Lutheran Church.—The Lutheran practice has varied at different times and in different countries. Thus, according to the Wurttemberg *Kirchenordnung* of 1553, a funeral procession was prescribed, the bier being followed by the congregation singing hymns; the Brandenburg *Kirchenordnung* (1540) directed a cross-bearer to precede the procession and lighted candles to be carried, and this was prescribed also by the Waldeck *Kirchenordnung* of 1556. At present funeral processions survive in general only in the country districts; the processional cross or crucifix is still carried. In some provinces also the Lutheran Church has retained the ancient rogation processions in the week before Whitsuntide and, in some cases, in the month of May or on special occasions (*e.g.,* days of humiliation, *Busstage*), processions about the fields to ask a blessing on the crops. On these occasions the ancient litanies are still used.

Church **of** England.—In England "the perambulations of the circuits of the parishes . . . used heretofore in the days of rogations" were ordered to be observed by the Injunctions of Queen Elizabeth in 1559; and for these processions certain "psalms, prayers and homilies" were prescribed. The Puritans, who aimed at setting up the Genevan model, objected; and the visitation articles of the bishops in Charles I.'s time make frequent inquisition into the neglect of the clergy to obey the law in this matter. With "the profane, ungodly, presumptuous multitude" (to quote Baxter's *Saint's Rest*, 1650, pp. 344, 345), however, these "processions and perambulations" appear to have been very popular, though "only the traditions of their fathers." However this may be, the Commonwealth formally put an end to them, and they only survived in some remote country parishes; Sparrow, in his *Rationale upon the Book of Common Prayer* (London, 1668), speaks of "the service *formerly* appointed in the Rogation days of Procession."

Among the processions that survived the Reformation in the English Church was that of the sovereign and the Knights of the Garter on St. George's day. This was until Charles II.'s time a regular rogation, the choristers in surplices, the gentlemen of the royal chapel in copes, and the canons and other clergy in copes preceding the knights and singing the litany. In 1661, after the Restoration, by order of the sovereign and knights companions in chapter "that supplicational procession" was "converted into a hymn of thanksgiving." Akin to this procession also are the others connected with royal functions; coronations, funerals. These retained, and retain, many pre-Reformation features elsewhere fallen obsolete.

The only procession formally prescribed in the Book of Common Prayer is that in the order of the burial of the dead, where the rubric directs that "the priest and clerks meeting the corpse at the entrance of the churchyard, and going before it, either into the church, or towards the grave, shall say, or sing" certain verses of Scripture. Tapers seem to have been carried in processions, not only at royal funerals, until well into the 18th century. Processions, with the singing of the litany or of hymns, appear also to have been always usual on such occasions as the consecration of churches and churchyards and the solemn reception of a visiting bishop. Examples of processions in use in the English Church are the processional litanies, and the solemn entry and exit of clergy and choir. The use of the processional cross, banners and lights has been largely revived.

Serarius, *Sacri peripatetici de sacris ecclesiae catholicae processionibus* (2 vols., 1607); Jac. Gretser, *De ecclesiae romanae processionibus* (2 vols., Ingolstadt, 1606); Jac. Eveillon, *De processionibus ecclesiae* (1641); Edw. Martène, *De antiquis ecclesiae ritibus* (3 vols., Antwerp, 1763), etc. For the past usage of the Church of England, *Hierurgia anglicana*, ed. Vernon Staley, p. ii. pp. 3–22 (1903).

PROCESSIONARY CATERPILLAR or **ARMY WORM,** the name given to the larvae of the moth *Cnethocampa processionea*, which, when moving to a new feeding place, proceed in line, the head of each touching the tail of the caterpillar in front. The caterpillars feed upon pine-needles, and are common on the European continent, though not occurring in Britain.

See J. H. Fabre, *Souvenirs Entomologiques*.

PROCÈS-VERBAL, in French law, a detailed authenticated account drawn up by a magistrate, police officer, or other person having authority of acts or proceedings done in the exercise of his duty. In a criminal charge, a procès-verbal is a statement of the facts of the case The term is also applied to the written minutes of a meeting or assembly.

PROCIDA, an island off the coast of Campania, Italy (Gr. Προχύτη, Lat. *Prochyta*), 2 mi. S.W. of Capo Miseno, 2 mi. N.E. of Ischia on the west side of the Gulf of Naples, 12 mi S.W. of Naples. Pop. (1936) 9,452. It is about 2 mi. in length, and, reckoning in the adjacent island of Vivara, is made up of four extinct craters, parts of the margins of all of which have been destroyed by the sea. The highest point of it is only 250 ft. above sea-level. It is very fertile. Procida, the only town, lies on the east side; its castle is now a prison. It also contains a royal palace.

PROCLAMATION. In English law, a royal proclamation is a formal announcement, made under the great seal, of some matter which the king in council desires to make known to his subjects; *e.g.* the declaration of war, the statement of neutrality, the conclusion of peace, the annexation of territory, the summoning or dissolution of parliament, or the bringing into operation of the provisions of some statute the enforcement of which the legislature has left to the discretion of the king in council. Roya! proclamations of this character, made in furtherance of the *executive* power of the Crown, are binding on the subject "where they do not either contradict the old laws or tend to establish new ones" (Dicey, *Law of the Constitution,* 6th ed., 51). The Crown has often *legislated* by proclamation; and the Statute of Proclamations 1539 provided that proclamations made with the assent of the council should have the force of statute law, if they were not prejudicial to "any person's inheritance, offices, liberties, goods, chattels or life." But this enactment was repealed by an act of 1547; and it is well settled that the Crown cannot by proclamation make or remake any law unless the proclamation is issued under statutory authority. (*Ex parte Chavasse*, 1865, *1* De G. J. & S. 622; *Grieve* v. *Edinburgh, etc.*, 1918, *3*. C. [Scotland] 700; *see* also EMERGENCY LEGISLATION; MARTIAL LAW.) The Crown has power to legislate by proclamation for a newly conquered country (Jenkyns, *British Rule and Jurisdiction beyond the Seas*, pp. 95); and this power was freely exercised in the Transvaal Colony during the Boer War of 1899–1902. In the British colonies, ordinances are frequently brought into force by proclamation; certain imperial Acts do not take effect in a colony until there proclaimed (*e.g.* the Foreign Enlistment Act 1870); and proclamations are constantly issued in furtherance of executive acts. In many British protectorates the high commissioner or administrator is empowered to legislate by proclamation. Proclamations cannot be issued by private persons unless under customary or other valid authority, *e.g.* a proclamation by members of the Privy Council of the accession of a new sovereign.

(A. W. R.)

PROCLUS or **PROCULUS** (A.D. 410–485), the chief representative of the later Neoplatonists, was born at Constantinople, but brought up at Xanthus in Lycia. Having studied grammar under Orion and philosophy under Olympiodorus the Peripatetic, at Alexandria, he proceeded to Athens. There he attended the lectures of the Neoplatonists Plutarch and Syrianus, and about 450 succeeded the latter in the chair of philosophy (hence his surname Diadochus, which, however, is referred by others to his being the "successor" of Plato). As an ardent upholder of the old pagan religion Proclus incurred the hatred of the Christians, and was obliged to take refuge in Asia Minor. After a year's absence he returned to Athens, where he remained until his death. His epitaph, written by himself, is to be found in *Anthologin palatina*, vii. 451.

His great literary activity was chiefly devoted to the elucidation of the writings of Plato. There are still extant commentaries on the *First Alcibiades*, *Parmenides*, *Republic*, *Timaeus* and *Cratylus*. His views are more fully expounded in the Περὶ τῆς κατὰ Πλάτωνα θεολογίας (*In Platonis theologiam*). The Στοιχείωσις θεολογική (*Institutio theologica*) contains a compendious account of the principles of Neoplatonism and the modifications introduced in it by Proclus himself. the pseudo-Aristotelian *De causis* is an Arabic extract from this work, ascribed to Alfarabius (d. 950), circulated in the west by means of a Latin translation (ed. O. Bardenhewer, Freiburg, 1882). Other philosophical works by Proclus are Στοιχείωσις φυσικὴ ἢ Περὶ κινήσεως (*Institutio physica sive De motu*, a compendium of the last five books of Aristotle's Περὶ φυσικῆς ἀκροάσεως, *De physica auscultatione*), and *De providentia et fato*, *Decem dubitationes circa providentiam*, *De malorum subsistentia*, known only by the Latin translation of William of Moerbeke (archbishop of Corinth, 1277–1281), who also translated the Στοιχείωσις θεολογική into Latin. In addition to the epitaph already mentioned, Proclus was the author of hymns, seven of which have been preserved (to Helios, Aphrodite, the Muses, the Gods, the Lycian Aphrodite, Hecate and Janus, and Athena), and of an epigram in the Greek Anthology (*Anthol. pal.* iii. 3, *166* in

Didot edition). His astronomical and mathematical writings include Ὑποτύπωσις τῶν ἀστρονομικῶν ὑποθέσεων (*Hypotyposis astronomicarum positionum*, ed. C. Manitius, Leipzig, 1909); Περὶ σφαίρας (De *sphaera*); Παράφρασις εἰς τὴν Πτολεμαίου τετράβιβλον, a paraphrase of the difficult passages in Ptolemy's astrological work *Tetrabiblus;* Εἰς τὸ πρῶτον τῶν Εὐκλείδου στοιχείων, a commentary on the first book of Euclid's Elements; a short treatise on the effect of eclipses (De *effectibus eclipsium,* only in a Latin translation).

His grammatical works are: a commentary on the *Works* and Days of Hesiod (incomplete); some scholia on Homer; an elementary treatise on the epistolary style, Περὶ ἐπιστολιμαίου χαρακτῆρος (Characteres epistolici), attributed in some mss. to Libanius. The Χρηστομαθία γραμματική by a Proclus, who is identified by Suïdas with the Neoplatonist, is probably the work of a grammarian of the 2nd or 3rd century, though Wilamowitz-Mollendorff (Philolog. *Untersuch.* vii.; supported by O. Immisch in Festschrift *Th. Gomperz,* pp. 237–274) agrees with Suïdas. According to Suïdas, he was also the author of Ἐπιχειρήματα ιη κατὰ Χριστιανῶν (*Animadversiones duodeviginti* in christianos). This work, identified by W. Christ with the *Institutio* theologica, was answered by Joannes Philoponus (7th century) in his De aetern*itate mundi.* Some of his commentary on the Chaldaean oracles (Λόγια Χαλδαϊκά) has been discovered in modern times.

Bibliography.—There is no complete edition of the works of Proclus. The selection of V. Cousin (Paris, 1864) contains the treatises De providentia et *fato, Decem dubitationes* and De *malorum* subsistentia, the commentaries on the *Alcibiades* and Parmenides. The *Institutio* theologica has been edited by G. F. Creuzer in the Didot edition of Plotinus (Paris, 1855); the *In Platonis* theologiam has not been reprinted since 1618, when it was published by Acmilius Portus with Latin translation. Recent editions of individual works are: In the Teubner series, Leipzig, Commentary on Euclid (edit. G. Friedlein, 1878); Republic (edit. G. Kroll, 1899–1901); Timaeus (edit. E. Diehl, 3 vols., 1903–06); Cratylus (edit. G. Pasquali, 1908); *Hypotyposis* (edit. C. Manitius, with German trans., 1909); *Institutio Physica* (edit. A. Ritzenfeld, with German trans., 1912); also *Scholia* to Hesiod (edit. E. Vollbehr, 1844); Characteres epistolici (edit. A. Westermann, 1856); Hymns (edit. E. Abel, 1883); also A. Ludwich (1895); Λόγια Χαλδαϊκά (edit. A. Jahn, 1891); Commentaries on the Par*menides* (edit. A. E. Chaignet, French trans. and notes, also trans. of Marinus' Life, 1900–03). Thomas Taylor, the "Platonist," translated the Commentaries on Euclid, with the Life by Marinus and the Elements of Theology (2 vols., 1788–89); the Theology of *Plato* (1816); *Timaeus* (1820); Fragments of the Lost Works of Proclus (1825), and the three Latin treatises (1833).

On Proclus generally and his works see the article in *Suïdas* (edit. G. Bernhardy, 1853); Marinus, Vita *Procli* (edit. with Diogenes Laertius, *Lives* of the Philosophers, by C. G. Cobet, Paris, 1850); H. F. Muller, Dionysios, Proklos, *Plotinos* (1918) in *Beiträge zur Geschichte* der Philosophie des Mittelalters (edit. C. Baeumker, Münster; vol. xx., 1922) and Neoplatonism.

Extracts from the Χρηστομαθία are preserved in Photius (Cod. 239), almost the only source of information regarding the epic cycle; on the question of authorship, see Christ, sec. 637 and Sandys, p. 379; also D. B. Monro's appendix to his ed. of Homer's Odyssey, xii.–xxiv. (1901).

PROCOPIUS, Byzantine historian, was born at Caesarea in Palestine towards the end of the 5th century A.D. He became a lawyer, probably at Constantinople, and was in 527 appointed private secretary to Belisarius, whom he accompanied on his Persian, African and Italian campaigns. After the capture of Ravenna in 540 Procopius seems to have returned to Constantinople, since he minutely describes the great plague of 542 (*op. cit.* ii. 22). It does not appear whether he was with the Roman armies in the later stages of the Gothic War, when Belisarius and afterwards Narses fought against Totila in Italy; his narrative of these years is much less full and minute than that of the earlier warfare. Of his subsequent fortunes we know nothing, except that he was living in 559. Whether he was the Procopius who was prefect of Constantinople in 562 (Theophanes, Chronographia, 201, 202), and was removed from office in the year following, cannot be determined, though it is not improbable.

Procopius's writings fall into three divisions: the Histories (Persian, Vandal and Gothic Wars), in eight books; the treatise on the Buildings of *Justinian* (De aedificiis), in six books; and the Unpublished Memoirs (Ἀνέκδοτα, *Historia arcana*), so called because they were not published during the lifetime of the author.

The Histories are called by the author himself the Books about the Wars (οἱ ὑπὲρ τῶν πολέμων λόγοι). They consist of: (1) the Persian Wars, in two books, giving a narrative of the long struggle of the emperors Justin and Justinian against the Persian kings Kavadh and Chosroes Anushirvan down to 550; (2) the Vandal War, in two books, describing the conquest of the Vandal kingdom in Africa and the subsequent events there from 532 down to 546 (with a few words on later occurrences); (3) the Gothic War, in three books, narrating the war against the Ostrogoths in Sicily and Italy from 536 till 552. The eighth book contains a further summary of events down to 554. These eight books contain notices of some of the more important domestic events, such as the Nika insurrection at Constantinople in 532, and the plague in 542. They tell us, however, comparatively little about the civil administration of the empire, and nothing about legislation.

The De aedificiis contains an account of the chief public works executed during the reign of Justinian down to 560 which are of course ascribed to the personal action of the monarch. If not written at the command of Justinian (as some have supposed), it is evidently grounded on official information, and is full of gross flattery of the emperor and of the (then deceased) empress. In point of style it is greatly inferior to the Histories—florid, pompous and affected, and at the same time tedious Its chief value lies in the geographical notices which it contains.

The Anecdota (date probably 550) purports to be a supplement to the Histories, containing explanations and additions which the author could not insert in the latter work for fear of Justinian and Theodora. It is a furious invective against these sovereigns, with attacks on Belisarius and his wife Antonina, and on other noted officials. Owing to the ferocity and brutality of the attacks upon Justinian, the authenticity of the Anecdota has often been called in question, but the claims of Procopius to the authorship are now generally recognized. In point of style, the Anecdota is inferior to the Histories, and has the air of being unfinished, or at least unrevised. The history of Philip of Macedon by Theopompus probably furnished the author with a model.

The best complete edition of Procopius is by J. Haury (Teuhner Series, 1905–13). There are English translations of the History of the Wars, by H. Holcroft (1653), of the Anecdota (1674, anonymous), of the Buildings, by Aubrey Stewart (Palestine Pilgrims' Text Society, 1888) and by H. B. Dewing (Loeb Classical Library, 1914, etc.). Chief authorities: F. Dahn, *Procopius* von Casarea (1865); J. Haury, Procopiana (1891–93). On the genuineness of the Anecdota, see J. B. Bury (who agrees with Ranke in rejecting the authorship of Procopius), *A* History of the Later Roman Empire (1889), vol. i. and introd. to vol. ii. (p. 57) and appendix to vol. iv. of his edition of E. Gibbon, Decline and Fall (1925). See also C. Krumbacher, Geschichte der bysantinisclzen Literatur (2nd ed., 1897).

PROCOPIUS OF GAZA (c. A.D. 465–528), Christian sophist and rhetorician, was born at Gaza. What is known of him is to be found in his letters and the encomium by his pupil and successor Choricius. Of his rhetorical works only the panegyric on the emperor Anastasius alone is extant. His letters (162 in number) throw light upon the condition of the sophistical rhetoric of the period. The fragment of a polemical treatise against the Neoplatonist Proclus is now assigned to Nicolaus, archbishop of Methone in Peloponnesus (*fl.* 12th century). Procopius's theological writings consist of commentaries which are early examples of the catena (chain) form of commentary, consisting of a series of extracts from the fathers, arranged, with independent additions, to elucidate Scripture.

Complete editions of the works of Procopius in Migne, Patrologia graeca, lxxxvii.; the letters also in *Epistolographi* graeci, ed. R. Hercher (1873); see also K. Seitz, Die *Schule von* Gaza (1892); D. Russos, Τρεῖς Γαζαῖοι (Constantinople, 1893); L. Eisenhofer, Procopius von Gaza (1897); further bibliographical notices in C. Krumbacher, Geschichte der bysantinischen Literatur (1897), and article by G. Krüger in Herzog-Hauck's *Realencyklopädie* fur *protestantische* Theologie (1905).

PROCRUSTES, also called Polypemon or Damastes, in Greek legend, a robber dwelling in the neighbourhood of Eleusis, who was slain by Theseus (*q.v.*). The "bed of Procrustes" has become proverbial.

Bibliography.—*See* Diod. Sic. iv. 59; Hyginus, Fab. 38; Plutarch, *Theseus,* 11; Pausanias i. 38, 5.

PROCTER, ADELAIDE ANNE (1825–1864), English poetess, daughter of Bryan Waller Procter (*q.v.*), was born on Oct. 30, 1825. She began to contribute to *Household Words* in 1853. Her principal work is *Legends and Lyrics*, of which a first series, published in 1858, ran through nine editions in seven years, while a second series issued in 1860 met with a similar success (new ed.. 1914). She died on Feb. 2, 1864.

PROCTER, BRYAN WALLER (1787–1874), English poet, was born at Leeds on Nov. 21, 1787. By the death of his father in 1816 he became possessed of a small property, and soon after entered into partnership with a solicitor; but in 1820 the partnership was dissolved, and he began to write under the pseudonym of "Barry Cornwall." He was metropolitan commissioner of lunacy from 1832 to 1861. He died on Oct. 5, 1874.

His principal poetical works were: *Dramatic Scenes and other Poems* (1819), *A Sicilian Story* (1820), *Mirandola, a* tragedy performed at Covent Garden with Macready, Charles Kemble and Miss Foote in the leading parts (1821), *The Flood of Thessaly* (1823), and *English Songs* (1832).

PROCTOR, ALEXANDER PHIMISTER (1862–), American sculptor and painter, was born in Ontario, Canada, on Sept. 27, 1862. As a youth he lived at Denver (Colo.), spending much of his time in the Rocky Mountains, and his familiarity with the ways and habits of wild animals was supplemented later by study in the Jardin des Plantes, Paris. He was a pupil at the National Academy of Design and later in the Art Students' league, in New York, and first attracted attention by his statues of wild animals at the Columbian exposition, Chicago. In 1896 he won the Rinehart scholarship, which enabled him to spend five years in Paris, where he studied under Puech and J. A. Injalbert. Among his works of sculpture are: "Indian Warrior" (a small bronze); "Panthers," Prospect park, Brooklyn (N.Y.); "Quadriga," for the U.S. pavilion, Paris Exhibition (1900); the Princeton Tigers, for Princeton university; the equestian statue of Col. Roosevelt as rough rider, Portland (Ore.); and groups in the City park, Denver, and Zoological park, New York.

PROCTOR, RICHARD ANTHONY (1837–1888), British astronomer, was born at Chelsea, on March 23, 1837. He was educated privately, at King's college, London, and at St. John's college, Cambridge. He read for the bar, but turned to astronomy and authorship. His book, *Saturn and His System* (1865), though favourably received by astronomers, was a financial failure, and other financial losses obliged him to cultivate a popular style. He was for a time mathematical coach for Woolwich and Sandhurst.

In 1881 he founded *Knowledge,* a popular magazine, in which he wrote on a great many subjects. He became a fellow of the Royal Astronomical Society in 1866, and honorary secretary in 1872. He was an expert in map-drawing, and published two star-atlases. His most ambitious work, *Old and New Astronomy,* was completed after his death, by A. Cowper Ranyard, and published in 1892. Proctor settled in America in 1881, and died at New York on Sept. 12, 1888.

His many publications include *Half-hours with the Telescope* (1868); *Other Worlds than Ours* (1870); *The Borderland of Science* (1873); *The Poetry of Astronomy* (1880); *Mysteries of Time and Space* (1883); *Half-hours with the Stars* (1887). He contributed numerous papers to the *Monthly Notices* of the Royal Astronomical Society, and articles on astronomy to the 9th edition of the *Encyclopædia Britannica.*

PROCTOR, a variant of the word procurator (*q.v.*), very nearly equivalent in meaning to "agent" (*q.v.*). The title is used in England in three principal senses.

1. A practitioner in the ecclesiastical and admiralty courts. A proctor in this sense was formerly a qualified person licensed by the archbishop of Canterbury to undertake duties such as are performed in other courts by solicitors. The king's proctor is the proctor or solicitor representing the crown in the courts of probate and divorce. His power of intervening is limited, by the Matrimonial Causes act 1860, to cases of *collusion* only, but he may also, as one of the public, show cause against a decree *nisi* being made absolute (*see* DIVORCE). In the admiralty court a proctor or procurator was an officer who, in conjunction with the king's proctor, acted as the attorney or solicitor in all causes concerning the lord high admiral's affairs in the high court of admiralty and other courts. The king's proctor so acted in all causes concerning the king.

In the United States the term "proctor" is applied to practitioners in the admiralty and probate courts.

2. A representative of the clergy in convocation, A proctor in this sense represents either the chapter of a cathedral or the beneficed clergy of a diocese. In the province of Canterbury two proctors represent the clergy of each diocese; in that of York there are two for each archdeaconry. In both alike each chapter is represented by one.

3. The name of certain important university officials. At Oxford the proctors, with the vice-chancellor, supervise university business and appoint delegates for any particular affairs not otherwise provided for by statute. They are *ex-officio* members of nearly all the important delegacies. They also act as the assessors of the chancellor or his commissary. They supervise the voting at public meetings of the university and announce the results. They have jointly. power of veto in convocation and congregation: nc proposal can be passed into a statute or decree if twice vetoed by them. They are *ex officio* members of the hebdomadal council, the governing council of the university, and they are the assessors of the vice-chancellor when he confers degrees. They are empowered to punish undergraduates, or graduates under the degree of bachelor of civil law and master of arts, by fine or by confinement to their colleges or lodgings (familiarly known as "gating"). They have to see that all examinations are properly conducted. They are responsible for the good order of the streets at night, so far as members of the university are concerned, and perambulate the streets nightly, accompanied by the university marshal and two sworn constables, familiarly known as "bulldogs." The proctors are elected by the heads, fellows and resident members of convocation of each college in rotation.

At Cambridge the proctors are nominated annually by the colleges in rotation and elected (a formal proceeding) by the senate.

At present their functions are (1) taking part in all university ceremonials, (2) enforcing discipline in the case of members of the university who are *in statu pupillari* (*i.e.,* undergraduates and bachelors of arts and law). (1) The proctors are *ex officio* members of boards or syndicates such as those with which their duties are specially connected. But their presence is essential at all congregations of the senate, at which the senior proctor reads all the "graces" (already approved by the council of the senate). If any grace is opposed by any member of the senate saying *non placet* the proctors take the votes of those present and announce the result, and on very important occasions many hundreds of non-resident members of the senate come up to record their votes. (2) The proctors have authority to impose certain fines for minor offences. In the case of more serious offences the proctor generally reports the matter to the authorities of the offender's college to be dealt with by them, or brings the offender before the university court of discipline.

PROCURATION, the action of taking care of, hence management, stewardship, agency. The word is applied to the authority or power delegated to a procurator, or agent, as well as to the exercise of such authority, expressed frequently "by procuration" *(per procurationem)*, or shortly *per pro.*, or simply *p.p.* In ecclesiastical law, procuration is the providing necessaries for bishops and archdeacons during their visitations of parochial churches in their dioceses. Procuration is merely an ecclesiastical due, and as a consequence is suable only in a spiritual court. Procuration is also used specifically for the negotiation of a loan by an agent for his client, whether by mortgage or otherwise, and the sum of money or commission paid for negotiating it is frequently termed *procuration fee. See* also PROXY.

In French law, procuration means an authority given to an agent or representative, *e.g.,* a power of attorney.

The English criminal law makes the provision or attempted provision of any girl or woman under 21 years of age for the purpose of illicit intercourse an offence, known as procuration.

PROCURATOR, generally one who acts for another. With the Romans it was applied to a person who maintained or defended an action on behalf of another, thus performing the functions of a modern attorney. Roman families of importance employed an official corresponding to the modem steward and frequently called the *procurator.* Later, the name was applied especially to certain imperial officials in the provinces of the Roman empire. With the establishment of the imperial power under Augustus, the emperor took under his direct government those of which the condition or situation rendered a large military force necessary. Here certain officials, known as the *procuratores Caesaris,* took the place occupied by the *quaestor* in the senatorial provinces. They were either equites or freedmen of the Caesar and their office was concerned with the interests of the fiscus (the public property of the Caesar). They looked after the taxes and paid the troops. There were also officials bearing this title of *procuratores Caesaris* in the senatorial provinces. They collected certain dues of the *fiscus* which were independent of those paid to the *aerarium* (the property of the senate). This organization lasted with some modifications until the 3rd century. The *procurator* was an important official in the reorganized empire of Diocletian.

The title remained all through the middle ages to describe very different officials. Thus it was sometimes applied to a regent acting for a king, during his minority or absence; sometimes it appears as an alternative title to *seneschal* or *dapifer.* It preserved its legal significance in the title of *procurator animarum,* who acted as solicitor or proxy in the ecclesiastical courts, and was so called because these courts dealt with matters affecting the spiritual interests of the persons concerned. The economical significance remained in such titles as *procurator anniversariorum,* the exactor of dues for the celebration of anniversaries; this office was assigned to laymen. The *procurator draperii* was entrusted with the administration of matters pertaining to the art of cloth-making. The *procurator duplarum* was the collector of fines in certain churches from absent canons, etc. The officials entrusted with the administration of the goods of a church were called variously *procurator ecclesiae, procurator parcitatis, procurator universitatis.* Bishops and bishops-elect frequently described themselves by the title of procuratores ecclesiarum. The prior of a dependent religious house was sometimes styled *procurator obedientiae.* The official who represented the public interests in the courts of the inquisition was known as the *procurator fidei.* The administrator of the affairs of a large community was sometimes called the *procurator syndicus;* the administrator of goods left to the poor, *procurator pauperum.* In monasteries the *economus* was, and is, sometimes described as *procurator.* Thus the procurator has still the administration of material affairs in every Dominican priory. *Procurator di San Marco* was a title of honour in Venice.

The term procurator (Fr. *procureur)* is used in those countries whose codes are based on the Roman civil law for certain officials, having a representative character, in the courts of law. In Scotland the term procurator is now almost a law agent who practises in an inferior court. A procurator in the inferior courts has been, since the Law Agents Act 1873, exactly in the same legal position as other law agents. The procurator-fiscal is a local officer attached to the sheriff's court and charged with the duty of precognoscing witnesses regarding crimes, and with the prosecution of persons charged with a crime or offence in the sheriff's court. He also performs the duty of making enquiries into the circumstances of suspicious deaths. He was formerly appointed by the sheriff, but since 1907 has been appointed by the lord advocate. The procurator of the Church of Scotland is a member of the bar appointed by the general assembly as its legal adviser. A common English form of procurator is proctor (*q.v.*).

See Smith, *Dictionary of Greek and Roman Antiquities,* and *Du* Cange, *Glossarium mediae et infimae latinitatis.*

PROCYON, the brightest star in the constellation Canis Minor *(see* CANIS MAJOR), hence its Bayer equivalent, α Canis Minoris. It and Sirius (*q.v.*) in Canis Major were called the two dog-stars, though "the dog-star" refers to Sirius, which is the brighter of the two. Procyon is a double star consisting of one bright and one very faint component. *(See* STAR: *Double Stars.)*

PRODICUS OF CEOS (b. *c.* 465 or 450 B.C.), a Greek humanist of the first period of the Sophistical movement, was still living in 399 B.C. He came to Athens as ambassador from Ceos, and became known as a speaker and a teacher. Like Protagoras, he professed to train his pupils for domestic and civic affairs, and made ethics prominent in his curriculum. He advocated no hopeless resignation, but rather the remedy of work. The influence of his views may be recognized as late as the *Shepherd* of *Hermas.* As for the origin of the belief in the gods, he holds that first came those great powers which benefit mankind, and after these the deified men who have rendered services to humanity. Of his natural philosophy we know only the titles of his treatises *On Nature* and *On the Nature of Man.* Two of his discourses on words were specially famous; one, "On Propriety of Language," is repeatedly alluded to by Plato; the other, entitled Ὧραι, contained the celebrated apologue of the Choice of Heracles, summarized in Xenophon, *Mem.* ii. 1, 21 *seq.*

See Hummel, *De Prodico Sophista* (Leyden, 1846); Cougny, *De Prodico Ceio* (1858); and Überweg, *Grundriss der Gesch. der Philosophie,* Bd. I. (1926).

PRODIGY, an extraordinary or wonderful thing, person, event, etc.; something which excites amazement and astonishment. The term has been particularly applied to children who display a precocious genius, especially in music. The German expression *Wunderkind* has of late been often adopted by those who have found the name "infant prodigy" too reminiscent of the "infant phenomenon" familiar to readers of Dickens. Among the more notable of the almost countless number of musical prodigies who have excited wonder may be mentioned Mozart who composed minuets before he was four; Beethoven, who played in public at eight and composed works which were published at 10; Hummel, who gave concerts at nine; Schubert, who composed at 11; Chopin, who played a concerto in public before he was nine; Mendelssohn, who began to compose systematically at 12; Brahms, whose exceptional talents attracted attention from his earliest years; Dvořák to whom the like applied; Richard Strauss, who wrote a polka and a song at six; and last but not least the famous English composer and organist Samuel Wesley, who played the organ at three and composed an oratorio at eight.

In regard to prodigies of other kinds one of the most remarkable ever known was the boy William Henry West Betty (born at Shrewsbury in 1791, d. London 1874), who from his amazingly precocious talents as an actor was known as the Young Roscius (after the famous Roman actor Quintus Roscius). He appeared on the stage at 11 years of age in the heaviest Shakespearean parts, the vogue which he enjoyed being such that the House of Commons actually adjourned to witness his Hamlet.

PRODUCER GAS: *see* GAS MANUFACTURE.

PRODUCT INTEGRAPH. The product integraph belongs to that class of calculating machines which deals with curves and graphs rather than with numbers. It multiplies together any two given curves before the integration. Results are obtained by an automatically-drawn curve. It can be used, therefore, to determine the coefficients in the expansion of an arbitrary function into any chosen set of orthogonal functions. It can be extended to make the form of one or both of the curves to be integrated dependent upon the result of the integration by having the mechanism which operates the recording pencil also control the input curves as the operation of integration proceeds. The device is then capable of solving ordinary differential equations, and this is its most important use. The result of the first integration may be integrated again any number of times, thus raising the order of the equation solvable. In its most developed form, therefore, the product integraph is a machine for solving ordinary differential equations where the coefficients are given by means of curves. Hence the coefficients may be discontinuous or even multiple-valued without making the mechanical work any more involved, and the device allows the prompt solution of equations which are beyond formal treatment except by extremely labourious processes. The result given by the machine is in the form of a curve or family of curves, corresponding to numerically-chosen initial or boundary conditions.

The first product integraph constructed at the Massachusetts Institute of Technology is adapted for the solution of second-order differential equations of nearly, but not quite, general form. It will treat equations of the form: —

$$\frac{d^2z}{dx^2} = f_a(f_1+f_2)$$

where each of f_a, f_1 and f_2 may be functions of any one of the quantities z, x or $\frac{dz}{dx}$. By schemes of interpolation double-valued functions may be introduced, and any of the input functions may be functions of any two of the three quantities. Practically all of the second-order differential equations met in practice are therefore subject to treatment, with the reservation of course that graphical solutions, not formal solutions, are always obtained, The solution of equations having discontinuous coefficients has proved especially interesting.

To solve an equation such as the above, the procedure is as follows: The functions f_a, f_1 and f_2 are plotted and mounted on movable platens. Operators keep a movable pointer on each of the curves as the platens are moved by the machine. The ordinates given by the position of the pointers control the action of the device so that the necessary addition and multiplication are made, the two integrations performed, and the results plotted. The necessary operations are more clearly indicated when the equation is in the form: —

$$z = \int_a^x \int_b^x f_a(f_1+f_2)dx\,dx$$

the result curve thus being a plot of z as a function of x for chosen initial conditions a and b. The movement of the platens is controlled by the device itself. When all input platens are driven by the same mechanism which drives the result platen, the functions are evidently functions of x. A cross connection enables any input platen to be driven by the mechanism which operates the result pencil. Then an input function of z is being used. A drive can also be obtained from the result of the first integrations alone, giving an input function of $\frac{dz}{dx}$.

In this first instrument, multiplication and first integration are performed by a Thomson watt-hour meter, the second integration being mechanical. Servo mechanisms do the work of moving the parts without imposing load on the delicate integrating devices. Precision of 1–2% is attained, depending upon many conditions.

In the second instrument, now partially in operation, all integration, addition and multiplication is mechanical, servo mechanisms and torque amplifiers being utilized to enable precision apparatus to operate at practically no load. A unit system is adopted so that the range of the instrument may be extended at will. At present sufficient parts are made available to handle sixth-order equations, or a set of three second-order equations. The precision is much higher than in the first instrument.

The first instrument and some of its applications are described in detail in the following publications: V. Bush, F. D. Gage and H. R. Stewart, "A Continuous Integraph," *Jour.* of the Franklin Inst. (Jan. 1927); V. Bush and H. L. Hazen, "Integraph Solution of Differential Equations," *Jour.* of the Franklin Inst. (Nov. 1927). Early work on this type of instrument is presented in a series of articles by Sir William and Professor James Thompson, Royal Society Proceedings, Vol. **24**, 1875–76. *See* also MATHEMATICAL INSTRUMENTS (V. BU.)

PRODUCTION. For the meaning of this term see CAPITAL; ECONOMICS; VALUE; WEALTH.

PRODUCTION, CENSUS OF. In many countries no general survey of production is available. In countries mainly devoted to agriculture, the ascertainment of the distribution of the cultivated area, and of the quantities of the leading crops and the numbers of livestock maintained, gives information of the greatest importance Where the extraction of minerals is important, the quantities of such minerals produced are a necessary element in the survey of the country's industrial resources. In various countries in which manufacture has reached a considerable degree of importance, periodic returns of the output of various leading products of the manufacturing industries are added to the records of agricultural and mineral products obtained. These surveys are, however, not merely incomplete in that they fail to cover the productive activities of the country, but they also fail to furnish a satisfactory measure of the results of that activity. For that purpose a census not of products but of production is needed. For the extractive industries the record of products serves to measure production reasonably well, since the value of the products of other industries used up in the processes essential to the extraction of new products is, in general, comparatively small. Even in the instance of field crops, a sound estimate of the "production" of agriculture would need, indeed, a deduction from the gross total of crops harvested not only of the seed which has been required to produce those crops but also of the equivalent of manures used and of the requirements for the replacement of tools and equipment so as to maintain the stock of such tools, etc., undiminished. In dealing with animal products, allowances must, in like manner, be made for food consumed in the maintenance of the animals and for other supplies used up in the business of stock rearing, so far as these goods are obtained beyond the limits of the agricultural industries.

The distinction between a census of products and a census of production has special importance in reference to many manufacturing industries. Effective comparison of different industries, and of different divisions of the same industry, cannot be made on the basis of the aggregate value of the products of the industries compared. There are two important reasons for this. On the one hand, if industries were otherwise similar in character, but made use of different materials, they would yield aggregates of products, the value of which would be higher or lower according to the values of these different materials. Materials costing £50,000 might be worked up into products worth £100,000, and precisely similar operations on materials costing £75,000 might yield products worth £125,000. Measured by the value of products, the second industry appears to have a yield of 25% greater than the first, while the actual increments in value of materials used were the same in both cases.

On the other hand, the same materials may be advanced from stage to stage in manufacture in different establishments, and the products of the series of establishments will show values gradually increasing, the material of each being the product of the preceding. It would not be a sound conclusion from such a record that the productive importance of the successive establishments was in the order of the processes, and that the increasing values of the goods from stage to stage reflected the importance of the productive services of the series of establishments. In comparing establishments making use of different materials and conducting processes of manufacture dissimilar in character, as in the two types of cases dealt with above, no true comparison of the value of the productive contribution of each can be expected to result from a simple comparison of the values of their products.

A census of production must, accordingly, be something more than an enumeration of the products of the various establishments and industries surveyed and a record of their values. The products of other establishments or industries which have been used up in the productive processes surveyed must be ascertained if a true measure of the production carried on is to be secured. In strictness the effects of wear and tear, so far as not made good by the staff maintained within the establishment for that purpose, and also the effects of obsolescence on the plant and buildings, should be evaluated and included in the deduction from the value of the gross output needed in order to arrive at the value of the contribution made to production. In practice allowances for depreciation cannot be estimated with a precision approximating to that attainable with reference to cost of materials, and adjustments in respect of the consequent overestimate of the production have to be made by some means other than the simple aggregation of the depreciation suffered by each establishment. The result of deducting the value of materials used from the value of the products resulting from work on them is designated "net output" in the reports on the Census of Production in the United Kingdom and is dealt with under the title "value added in manufacture" in the reports on the Census of Manufactures in the United States.

In addition to an enumeration of the kinds and values of goods produced, there is needed, for a proper understanding of the significance of these data resulting from a census, a record of the numbers of persons employed in the production of those goods and of the mechanical aids to production at their disposal. Information as to the distribution of the value of the recorded production between wages, returns to capital, taxation, profits, etc., will also have much importance, in view of the reaction of distribution on productive efficiency; but inquiries regarding the distributive allocation of the values produced do not appear to be an essential part of the census of production itself.

Information on these matters, like information regarding the quantities and values of imports and exports of the various classes of goods with which the census is concerned, is of very great importance in the application of the results secured by means of the census. The comparison of the imports and exports of any class of products with the amounts and values of similar products made within any country affords information of fundamental importance. For the aggregate of all industries it furnishes measures of the dependence of the material welfare of the country on its foreign trade. Further, since the material income of a country consists in the goods produced and in those which are obtained from abroad in exchange, a census of production furnishes a basis for measuring the amount of, and the changes in, the total income of the community. In so far, too, as capital goods and consumption goods are capable of distinction, the total of products applied to capital purposes, replacement and increase together, can be ascertained. The formation of a reasonable estimate of what is required for maintenance of the existing stock of capital enables an estimate to be made, of a corresponding degree of reliability, of the increase of capital. Thus results of uncertain estimates formed on other principles can be submitted to useful tests.

CENSUSES OF PRODUCTION IN THE UNITED KINGDOM

In Dec. 1906 the legislative authority for the taking of a series of censuses of production in the United Kingdom was given in the Census of Production Act. (6 Edw. VII. c. 49) which provided for a census in respect of 1907 and for repetition of the enquiry as might be prescribed by the Board of Trade by an order to be laid before parliament. The order was duly made in 1911 and prescribed a series of enquiries at intervals of five years. The work of verifying and completing the particulars furnished in respect of 1912 was interrupted by the outbreak of war in 1914, and in 1917 an act was passed providing for the suspension of the series of enquiries, and for resumption on the making of a new order by the Board of Trade. On two occasions such orders were made and cancelled, but in 1923 the authority was given for a third census in respect of 1924. The preliminary results of this enquiry were published in 1927 and the early part of 1928.

The act of 1906, while providing for the collection of particulars of the output of each establishment of certain defined characters, of the total cost of the materials used, of the persons employed and of the mechanical power equipment in such establishments,. limited the range of the information obtainable by compulsion. While the details of the value of goods produced might be demanded in accordance with the forms prescribed by the Board of Trade, particulars of quantity can only be required in cases in which the goods to which they relate are such as, on importation or exportation, must be recorded, in the forms furnished to the Customs by the importers or exporters, in terms of quantity as well as of value; details of the kinds of materials used and their amount cannot be required to be furnished, but only the aggregate cost of all materials together; and while the numbers of persons employed may be demanded from the proprietors of the establishments liable to furnish returns, the wages paid are specifically excluded from the items of information to which powers of compulsion may be applied.

The enquiry of 1907 covered the United Kingdom of Great Britain and Ireland. Separate summaries of particulars relating to England and Wales, to Scotland and to Ireland were provided for, but the necessity for presenting results in a manner which should not reveal the particulars of any individual business (unless with the consent of the proprietors) rendered a complete separation of the information relating to Scotland and to Ireland impossible in the case of certain industries. The enquiry of 1924 was carried out for Great Britain separately, a parallel enquiry in Northern Ireland being made simultaneously on behalf of the Government of Northern Ireland by the Board of Trade. The necessity to preserve secrecy regarding the operations of individual businesses, and the lack of a separate summary of the results of the 1907 enquiry relating to Northern Ireland together form a serious obstacle in the way of satisfactory comparisons between 1907 and 1924 for Great Britain and Northern Ireland taken as a whole. For Great Britain taken by itself such a comparison can be made in respect of the more important results secured, but it will be obvious that it is far from satisfactory to compare production in Great Britain with the imports and exports of the United Kingdom (including Northern Ireland in 1924 and the whole of Ireland in 1907). For a few classes of products the non-comparability of the figures is of serious importance.

British Aggregates 1907 and 1924.—The following comparison of aggregate results for Great Britain in 1907 and 1924 excludes particulars for a few trades of very small importance in respect of which the enquiry made in 1907 was not repeated in 1924.

	1907	1924
	Thousands	Thousands

In use	1,704	4,969
In reserve or idle		1,538

*In order to render the particulars for different trades more comparable, these totals should be reduced by £14 million in 1907 and £93 million in 1924 in respect of duties included in value of output and not in cost of materials in certain cases. This has been carried out in the preparation of the table given later.

The numbers enumerated as at work, on the average of the prescribed days, in the establishments covered by the two enquiries showed, thus, an increase of 13·83 per cent. The aggregate population of Great Britain increased, between 1907 and 1924, by a little less than 10 per cent., and the numbers recorded as gainfully employed at the population census dates permit of an estimate for the dates of the census of production showing an increase of 13.87 per cent. The census of production thus covered practically the same proportion of the occupied population in 1924 as in 1907. Inasmuch as the totals recorded in the census of population as "gainfully occupied" include those not actually at work on the census date, and unemployment is known to have been much greater in 1924 than in 1907, and to have affected particularly those occupied in the industries covered by the census of production, these trades must, it would appear, have found employment for a definitely larger fraction of all persons earning a livelihood in 1924 than in 1907. If those actually at work in these trades and those connected with them but absent through unemployment, sickness, etc., on any or all of the specified days are taken together, their proportion to the total of the persons earning their living was, for the reason stated above, notably larger in 1924 than in 1907. If the figures for the two sexes be taken separately, the proportion of increase in the number of males at work as recorded in the census of production returns was somewhat smaller than that of all males having a gainful occupation, and that in the number of females definitely greater. It will be noted that the operative staffs have increased by only a little over 10 per cent. in numbers while the administrative, technical and clerical staffs have increased by 60 per cent. Among the former. taken as a whole, the proportion of females had not increased; it had, indeed, slightly diminished. Among the administrative and clerical staffs, the proportion of females had increased largely, and apart from this, the male members of these staffs have increased in proportion to the numbers of the operative staffs. The total of the controlling and clerical staffs amounted in 1907 to 7·1 per cent. of the total employed, and in 1924 to 9.9 per cent. The proportion of females to males in these staffs was 1 to 6 in 1907 and was 2 to 7 in 1924. An increase of clerical staff appears to be indicated as the principal element in this relative increase of females and a large element in the increased proportion to the operative staff of the other persons employed. Among probable reasons for these increases are the greater attention now given to cost accounting and other work of like nature, and some extension of the preparation for sale, and control of sales, carried out by the manufacturers' own staffs.

Increase of Mechanical Power.—Another feature of importance in the comparison of the two surveys is the increase of mechanical power provided. The information obtained regarding 1907 did not show what proportion of the engine power was not in use. In 1924 about 18 per cent. of the total was so classified. This percentage includes, in some cases if not generally, equipment that may never be taken into use again, as well as engines unused for the time being, whether maintained as necessary reserve power, or idle for lack of orders. Even without making any deduction from the 1907 total in respect of reserve plant, the figures show an increase from about 1.7 horse-power per operative in 1907 to practically 2 horse-power ordinarily in use per operative in 1924, taking all industries together, and including workshop employees as well as factory employees at both dates. The information obtained for 1924 shows, too, a large use of power in the form of electric energy, whether purchased or generated in the works. The details furnished for 1907 did not include data relating to electric motors used, but the information on this head furnished in respect of 1912 made it clear that the use of power in that form in 1907 was of comparatively small importance. The total capacity of electric motors installed reported for 1912 was, in round figures, 2,240,000 horse-power. In 1924 the capacity of the electric motors in use was nearly 7,000,000 horse-power, and motors of 1,100,000 horse-power were in reserve or idle. These figures show an important change in the type of equipment in industrial establishments and may be interpreted as meaning that, while the mechanical power available for direct application was not greatly diminished, there were important increases in the form of plant, the purpose of which was to provide electric energy for use in driving machinery, while installations of electric motors to be driven by purchased electricity represented a further increase of power available.

With this increase of mechanical power, it is important to compare the output per head. It is, however, difficult to make this comparison with any precision, the restrictions of the Census Act and the difficulty inherent in the nature of the problem combining to limit the comparison of the mass of products constituting the output in years so widely separated as 1924 was from 1907. The intervening period was one in which prices had undergone large changes far from uniform in different classes of products. The measurement of products in terms of quantity units presents obvious difficulties in such cases as machinery and clothing, as well as in such less important cases as furniture and fancy goods. The figures given above show a net output averaging £101 per head in 1907 and £211 in 1924. The proportion of increase shown by a comparison of these figures does not represent increase of quantity, since prices have advanced greatly. The advance in the case of finished manufactured products has been greater than in that of materials, and the ordinary indices of price change are based mainly on records relating to materials. It is, therefore, a matter of great difficulty to determine what is the measure of increase due to price change that should be applied in order to measure the quantitative change which is indicated by the increase of net output per head. The material at present available appears insufficient to solve completely the difficulties of this problem. Some increase in the volume of output per head, however, appears a probable interpretation of the figures.

Industrial Change.—The results of the enquiry relating to 1924 show a considerable change as compared with 1907 in the distribution of the productive energies engaged in industry in Great Britain. The following table summarizes some of the data relating to these changes, and relates to groups of manufacturing trades only, the numbers engaged in mines and quarries being omitted from the aggregates used in these comparisons.

Industrial Distribution of Persons Employed and of Net Output

(a) Operative and other staff

Groups of trades	Male operatives 1907	Male operatives 1924	Female operatives 1907	Female operatives 1924	Administrative, clerical, etc., staff 1907	Administrative, clerical, etc., staff 1924
Iron and steel, shipbuilding and engineering	28.6	30·2	4·7	8·0	20·8	26.3
Textiles	12·1	11·0	42·9	39.4	8.7	8·0
Clothing	5·0	4·5	29·2	24.2	15·8	10·9
Food, drink and tobacco	6·4	6·4	7·5	8·5	12·4	12·7
Paper, printing, etc.	4·7	4·7	6·3	6·8	7.9	7·6
Timber, etc.	4·7	4·0	1·3	1·6	4·7	4.5
Building and building materials	16·5	14·4	2·4	2·8	10·8	10·1
Public utilities	14·6	17·0	0·3	0·3	8.5	8.8
Other trades	7·4	7·8	5.4	7·1	10·4	11·1
Total manufacturing trades	100·0	100·0	100·0	100·0	100·3	100·0
Total numbers—thousands	3,727	3,897	1,551	1,693	455	727

(b) Total employed and net output

Groups of trades	All employed 1907	All employed 1924	Net output 1907	Net output 1924	Percentage proportion of net output per head in 1924 to that of 1907
Iron and steel, shipbuilding and engineering	21·5	23.8	23·4	21·8	189
Textiles	20·2	18·3	15·9	15·0	232
Clothing	12·4	10·5	8·1	7·5	244
Food, drink and tobacco	7.2	8·0	11·9	13·6	231
Paper, printing, etc.	5·4	5·5	5·8	6·8	259
Timber, etc.	3·7	3·4	3·2	3·0	227
Building and building materials	12·2	10·8	10·6	10·3	248
Public utilities	10·3	11·6	11·7	11·8	200
Other trades	8·1	9·1	9.4	10·2	213
Total, manufacturing trades	100·0	100·0	100·0	100·0	224
Totals	Thou. 5,733	Thou. 6,317	£ mn. 557	£ mn. 1,375	

The male operatives in manufacturing industry increased in number by 4½ per cent., the female operatives by 9 per cent., while the total numbers employed increased by just over 10 per cent., from 5,733,000 to 6,317,000. The great concentration of industrial employment for females in the textile and clothing trades is shown clearly in the table, 72.1 per cent. of all the female operatives being included in these groups in 1907 and 63.7 per cent. in 1924, the percentages in all other groups being increased. Only 17·1 per cent. of the male operatives were employed in these groups in 1907 and 15·5 per cent. in 1924. In these groups the female operatives exceeded the males in number in 1924 by 473,000 and in 1907 by 479,000. The largest numbers of males are shown in the iron and steel group of trades, which, as it includes engineering (the building of machines, ships, engines, motor vehicles, etc.), shows increased numbers in spite of the relative inactivity of certain sections in the trades concerned with building materials and building and in the public utility services (gas, water and electric supply, -constructional and repair work of government departments and public local authorities. These three groups included 59.9 per cent. of the male operatives engaged in manufacturing establishments in 1907 and 61·6 per cent. in 1924. The administrative, technical and clerical staffs were distributed, on the whole, in similar proportions in 1924 as in 1907 in the different groups distinguished in the table. The marked exceptions are a notable increase in the iron and steel group and a not less notable decrease in the clothing group. The transfer of much work in the garment-making trades from small workshops to factories may be a chief reason for this difference in the numbers included in the administrative class, in which proprietors of small enterprises are grouped.

When the distribution of net output is examined in comparison with that of persons employed, as in the second half of the table, the contrary movements of the relative numbers and the net output percentages stand out in the case of the iron and steel group. (A. W. F.)

CENSUS OF PRODUCTION IN THE UNITED STATES

The first census in the United States, taken in 1790, covered population alone and not until 1810 was any effort made to secure data on other subjects. As economic problems have grown in number and complexity, the data gathered through censuses of production have multiplied greatly and the figures are now put to a multiplicity of uses. Production figures gathered through regular censuses now cover manufacturing, mining, agriculture and forestry.

Manufacturing. — The first production statistics of any kind collected by a census in the United States were those relating to manufacturing for the year 1810. These data were collected in connection with the regular decennial census. Five items of manufacturing were included at this census, the kinds, quantities and values of manufactured goods, the number of establishments, and the number of machines. The data were inaccurate and incomplete, but for the first time a general indication of the extent and nature of the manufacturing industries of the country was available. In the census of 1820, the number of items on manufacturing was increased to 14. No manufacturing data were included at the census of 1830, but at the census of 1840, manufactures statistics were again introduced. The census of 1850, however, may be considered to be the first scientific enumeration of manufactures, the schedule calling for information as to the number of manufacturing plants, capital, value of materials, employees, wages, value of products, percentage of profit, home manufactures, as well as data relating to certain individual industries. Thereafter each decennial census saw a gradual expansion in the items for which information was collected.

Down through the census of 1900, which, like its predecessors, covered the quantities produced in the year previous, all the statistics on manufactures related to the output of industry, wherever made. These censuses thus covered goods made under the factory system and those made in the hand and neighbourhood industries. As the factory system expanded, the volume of goods produced outside of it declined in relative importance and the canvass of the non-factory industries added greatly to the cost of the census, on account of the great number of insignificant establishments to be covered. After 1900, the census was restricted to goods made in factories whose products during the year were valued at $500 or more. Furthermore, the census of manufactures was taken every five years instead of every ten years, so as to provide frequent information on the growth of industry. Thus censuses of manufactures were taken in 1905, 1910, 1915 and 1920, covering the output of the previous year in each case.

After the census of 1920 changes were made both in the interval between census periods and in the minimum size of reporting establishments. The World War of 1914–18 had shown the necessity for securing more frequent and prompt returns of manufacturing production, so the new census law provided for enumerations every two years. To facilitate the prompt issuance of these figures, the limit on establishments covered by the census was raised from a minimum of $500 value of product to $5,000. While this raising of the limit reduced the number of reports by 22% it reduced the number of wage earners and total value of products by less than 1%.

For the census of manufactures of 1939, the schedule called for the following information: the number of persons engaged, subdivided into five major groups, namely, (1) salaried officers; (2) employees whose duties were concerned wholly or chiefly with manufacturing; (3) employees who devoted all or the major portion of their time to selling, advertising, etc.; (4) those engaged in major construction and major repair work in the plant; and (5) all others. Those employees who were actually concerned with the manufacturing operations were further subdivided into three groups — (a) managers, superintendents, etc.; (b) clerks, stenographers and other clerical employees; and (c) wage earners. This detailed classification of the personnel was used for the first time in 1939. The separation of employees engaged in distribution and construction work, etc., from those actually engaged in the manufacturing processes is especially significant. The schedule also called for the number of wage earners employed each month; the salaries or wages of the various classes of employees; the cost of materials, fuel, etc.; the type of power equipment available; the types and amounts of fuel and electric energy used; expenditures for plant and equipment; a complete list of the major products made; quantity and value of such products; and finally, the value of all inventory goods. In addition, data were requested regarding the legal form of the organization — that is, individual proprietorship, corporation, etc., and the method of distributing the goods produced — that is, sales through manufacturers' own wholesale branch office or retail stores, sales to wholesalers and jobbers for resale, sales to consumers directly, and export sales.

The total value of products manufactured is often taken as a measure of manufacturing production, but this figure contains so many duplications that it is no longer considered the best for the purpose. The value of the product necessarily includes the value of the raw and partially manufactured materials which the manufacturer had to buy in order to fabricate his product. Of two products of the same value, one may be produced from expensive materials with little labour cost, while the other may require inexpensive materials but a large amount of fabrication. The value of the product does not show that the manufacturing process in the latter case is more important than in the former. Again, a manufactured product may in turn form the material for further manufacture in another industry, as, for instance, wood pulp, which goes into paper manufacture, while the paper or board produced from it may be used still further in the manufacture of boxes or in the printing industry. An industry in which the processes of manufacture are divided into different stages and result in separate products at each stage will show a relatively greater value of product than an industry where the processes are all within one organization, for in the latter case the product is counted only once, at the end of the line.

A better figure for measuring manufacturing output has been found to be the value added by manufacture. This is a figure computed by subtracting from the value of products the cost of materials used in making those products, and it thus represents the contribution of manufacturing to the value of the product. No matter how many industries an article must go through before reaching its final form, there is no duplication in value added by manufacture, for each industry's contribution is shown through these figures. As an example of the difference between the value of product and the value added by manufacture may be cited two industries with approximately equal value of products in 1939, namely, petroleum refining, and steel works and rolling mills. In the former, the value of products was $2,461,000,000, and the value added by manufacture (the difference between the value of products and the cost of materials) was $528,000,000, or 21·4% of the value of products. In the steel works and rolling mills industry, the value of products was $2,720,000,000 and the value added by manufacture, $1,148,000,000, or 54.6% of the value of products, the higher proportion resulting from the more complicated processes of manufacture in the latter industry.

Figures given for values, whether value of products or value added by manufacture, do not reflect true conditions when comparing years of different price levels, such as 1929 and 1933. When prices are high, as in 1929, totals given in values indicate a larger volume of activity or output than actually exists, while in a year of low prices industrial activity is minimized by using values. Figures on the number of employees give a measure of industrial activity that is not affected by price changes. The growth of mechanical power, however, has resulted in a continually increasing output of goods per employee, so that employment figures are liable to error on the conservative side. Power figures alone, on the other hand, show too rapid a growth to measure the increase in industrial activity, owing to the trend from hand to machine power. Thus it becomes necessary to resort to index numbers of the physical volume of production as a means for making such comparisons. These indexes are prepared by combining the production figures for each commodity for which quantity figures are available, weighing each commodity by its relative importance. (For an explanation of the method *see* census monograph *Growth of Manufactures* by E. E. Day and Woodlief Thomas.) Such indexes were included in the reports of the census of manufactures for the first time in the report for 1937. Similar indexes are computed by various agencies for dates more frequent than the biennial censuses.

The measure of physical volume of output for a commodity can be secured from the data on quantities of goods manufactured, which are given for most of the important industries. Such statistics have an added accuracy in that they represent, so far as possible, not only the goods made as primary products in one particular industry but also those goods made as secondary products in other industries. For instance, some steel castings are made directly in steel plants, while others are made in foundries, which are classified as a separate industry. The production of steel castings cannot be found without totalling the production in both industries. It will be seen from this example that the statistics for an industry do not always coincide with those for a commodity, since the element of secondary products has been given increasing importance in manufacturing in order to utilize the plant facilities to the fullest extent. Each plant is classified as a whole in some one industry according to its chief article of manufacture, and so it sometimes happens that an article belonging normally to one industry is made to a considerable extent as a secondary product in other industries.

As quantity figures have become increasingly important, not only as measures of growth of an industry but also as a means of securing basic information on the important commodities, more quantity production figures have been obtained at recent biennial censuses. In the census of 1939, 147 special schedules were used, covering 415 industries. The figures on quantity called for in these schedules have proved especially useful to trade associations and business firms interested in finding out what proportion of the industry their own operations covered.

The results of the census of manufactures are presented by states and for the larger cities and for important industrial areas in considerable detail, and in less detail for counties. The figures thus distributed indicate the growth and the relative importance of states and cities in manufacturing, the geographical movement of industries, and the relative importance of the several industries in each locality. These data serve as a guide in the location of new plants in those industries which produce materials for other industries. In many cases it is not possible to show details for all industries in a given state or city, as it is necessary to avoid revealing the operations of individual establishments, which is prohibited by the census law—the specific rule being that no separate figures are shown where fewer than three establishments would be covered by the tabulation.

Electrical Industries.—Closely allied to the data included in the census of manufactures are those in the census of electrical industries. This census was begun in 1902, although partial data covering various phases of the field had been secured in connection with some previous decennial censuses. Since 1902 this census has been taken at intervals of five years. It covers telephones and telegraphs, the electric light and power industry, and a group of transportation systems consisting of street railways and trolley bus and motorbus operations. It thus presents a picture of the electrical development of the United States. The statistics of telephone systems cover public systems only, excluding private lines--such as those within a mine, for example. Data are presented on the number of systems, miles of wire, number of telephones (classified as residence or business), number of calls, and financial operations. The telegraph statistics cover commercial land and ocean cable systems in the United States. Data similar to those given for telephone companies are presented for the telegraph companies. For the electric light and power industry there are presented data on generating facilities classified by type of prime mover, source of energy (whether generated, purchased or received from another source), fuel used in generation of electric energy, disposal of energy by class of service, employment, financial statistics and other relevant data. The census of street railways, etc., originally collected statistics only for street railways and interurban railways driven by other than steam power. When the motorbus came into use the street railway census included all such vehicles operated by street railway companies. The 1937 census included not only the motorbus and trolley bus lines operated by street railnays, but also other short-haul motorbus lines in cities having 100,000 inhabitants or more in 1930. The reports of this census classify the various aggregates by motor power and present statistics on their financial aspects, equipment, traffic and employment.

Mines and Quarries.—Incomplete and fragmentary data on the production of certain minerals were obtained at the census of 1810; but it was not until 1840 that any effort was made to collect data covering completely the production and employees of mines and quarries. These data were called for on the same schedule as those for manufactures, agriculture and fisheries. The mineral industries have been canvassed at each subsequent decennial census, with the exception of the 12th (1900), and a mines and quarries census was taken separately for 1902. Production figures are secured for all the minerals produced in the United States, including fuels (coal, petroleum and natural gas), metalliferous ores (iron, copper, gold, etc.), stone and miscellaneous minerals. Information from the 1939 census (which carries the designation "Mineral Industries," in place of the earlier "Mines and Quarries") includes the number of mineral enterprises; types of products; quantity and value of products; persons engaged, subdivided into salaried employees, wage earners, proprietors and firm members; the salaries and wages paid; wage earners classified by type of activity—that is, underground work, surface work, etc.; number of active and nonactive days; total man-hours worked during the year; quantity and cost of supplies, materials, fuels and electric energy consumed; amount paid to contracting corporations for work done during 1939; cost of buildings, machinery and equipment erected or installed during 1939; types of power equipment; and number of mechanical power loading machines. The collection of annual production data is carried on by the bureau of mines of the department of the interior.

In many establishments there are combined both mining and manufacturing operations, such as the mining and smelting of copper, or the mining of coal and the production of coke. These processes have been separated in the census returns as far as possible, the mining operations being covered by the census of mineral industries and the manufacturing operations by the census of manufactures. In certain cases where the "mining" is a very simple process, the entire activity of the establishment is included in manufacturing. This is done, for example, with respect to the process of securing clay, limestone, etc., as materials, when combined with the manufacture of clay products, lime, cement, etc.

Agriculture. — A beginning was made in the collection of statistics of agriculture in the census of 1840, when data were presented for the output of the principal farm products, and for the number of livestock and poultry on hand. At the census of 1850 the inquiries on agriculture were materially extended to include acreage of farms. value of farms and farm implements, and value of animals slaughtered, the schedule containing 46 items in all. The census of agriculture was taken decennially from 1850 to 1920, and has been taken every five years since 1920. The schedule has been expanded until, in 1940, it contained something over 300 questions concerning tenure, acreage and classification of farm land, value of farm property, mortgage debt, farm equipment, farm labour and various other miscellaneous items, crop acreage and production, the output of livestock products, and a detailed livestock inventory. By far the most important production items obtained through the farm census are the figures representing the quantities of crops harvested. The returns in the livestock industry are so classified by age and other characteristics, however, that they afford some basis for estimating the year's production of livestock. There are also questions with regard to the value of livestock sold and livestock slaughtered on the farm, though without specific classification or numbers of animals involved. The United States department of agriculture publishes each year estimates of the production of livestock, based in part on census figures and in part on information collected from a large number of representatives scattered throughout the country. This department publishes also annual estimates of crop production, farm income and other items having some relation to agricultural production.

From the census returns can be obtained figures representing the gross value of farm production. A rather detailed classification of farms by type, in combination with the gross value of farm production, is presented in the reports of the 1930 census of agriculture, and similar data will be presented for 1940. It is difficult, however, to get a figure representing the net value of farm production because of the fact that a considerable proportion of the production of several important crops, especially corn and hay, is fed to livestock on the farms, so that any figure obtained by adding the value of crops harvested to the value of livestock and livestock products would contain a very considerable element of duplication. The figures for gross sales contain far less duplication from this source than do the figures for gross value of production; but even these involve an appreciable amount of duplication from the point of view of the farming industry as a whole, growing out of the fact that farmers purchase large quantities of feedstuff for feeding to their livestock, this being particularly true of the dairy farmers in the northeast and of some stock feeders in the middle west.

The agriculture census figures are particularly useful to those selling articles used by farmers, in that the statistics on farm values, number of farms operated by tenants, kind of crops grown, etc., show the extent of the potential market by counties. Such figures enable manufacturers of corn-planters, for instance, to direct their sales efforts into the territory where corn is the major crop and to avoid sections farmed mainly by small tenants. Manufacturers of general articles also find these data of particular benefit in planning sales programs. Where the average value of farms is $30,000 to $40,000, for example, it will be possible to market a fairly expensive type of automobile, while in a section where the average value of farms is only $3,000 to $4,000, even the least expensive type of car may sell with difficulty. Bankers and mortgage companies use the census data to determine limits of territory or limits per acre for their loans. Location of the production of the various agricultural products, as shown by census returns, also plays a part in the location of manufacturing plants using these products, such as canners, manufacturers of condensed milk, etc.

Irrigation and Drainage. — A census of irrigation was taken in 1890 and decennially thereafter, also a special census in 1902. A census of drainage was made in 1920. While these are not strictly production censuses, they present data for crops grown in irrigated or drained areas. The irrigation census is confined to 19 states in the western part of the country, where irrigation is a recognized feature of agricultural practice. It covers the area of land under irrigation, capital invested in irrigation enterprises, character of irrigation, crops grown, prices of land and water rights, water used per acre and physical condition of irrigation works. The drainage census presents information concerning the amount of land reclaimed by drainage, crops produced thereon, land needing artificial drainage, character of drainage, capital invested in drainage enterprises, and the amount necessary to complete the work.

Fisheries. — Information regarding fisheries was collected at the decennial censuses from 1840 to 1890 and at a special census in 1908. Between that date and 1940, the bureau of fisheries of the department of commerce made statistical studies of certain districts from year to year to ascertain the fish catch. On June 30, 1940, the bureau of fisheries was consolidated with the bureau of biological survey, the two now forming the Fish and Wild Life service of the department of the interior. This service now conducts studies for the improvement of fishery methods, including the capture, preservation, utilization and merchandising of fishery products, and the compilation of statistics thereon, and provides current information on production, market movement and prices of fishery products.

Forest Products. — Statistical data pertaining to the production of lumber, lath and shingles are collected and published annually, as are also data for pulpwood consumption and wood-pulp production. The quantities of forest products used in various other manufacturing industries — such as wood distillation and the manufacture of dyestuffs and extracts, excelsior and veneers — and the amounts of cooperage stock and turpentine and rosin produced are shown in the reports of the biennial censuses of manufactures.

Methods of Collection. — The census figures described above are, except for the data on fisheries, collected at the intervals named by the bureau of the census of the department of commerce, in accordance with the census law, which specifies the years for which the various censuses are to be taken and their general nature and makes answers compulsory and confidential. The bureau of the census was established on a permanent basis in 1902, previous censuses having been taken by a temporary force recruited for the decennial censuses. Besides the production censuses mentioned here, the bureau also collects data on population, hospitals and benevolent and penal institutions, births and deaths; wealth, public debt and taxation; finances of cities and states; water transportation; distribution; and current business conditions. The census data on agriculture, irrigation and drainage are collected by means of a personal canvass by field agents and at the decennial censuses the same agents collect agriculture figures and population figures. The information is secured directly from the operator of each farm, from an official of each irrigation or drainage enterprise, or from each family and filled in on the forms provided. For the other censuses, most of the returns are secured by mail, so far as is practicable, since these are made out chiefly by organizations. Lists of organizations are kept up-to-date by means of directories, information from trade associations and chambers of commerce, trade papers and other sources, using the previous census list as a basis. Where returns have not been obtained within a reasonable time, field agents visit the delinquent firms.

Methods of Tabulation. — As the returns reach the bureau of the census, they are edited for omissions, errors, discrepancies, etc., and often correspondence must ensue with the individual firms to straighten out the matter. For the biennial census of manufactures alone, this correspondence amounts to over 100,000 letters. After the report has been edited, the information contained in it is taken off on to punch cards by operators trained in this kind of work. Each punch on the card by its particular place denotes certain information on the schedule. The punched cards are next run through an automatic machine which sorts them according to the various classifications to be used, and then they are run through an electric tabulating machine which mechanically counts the number of cards, adds the data recorded in each field of the cards and automatically prints the totals. In this manner a quick and accurate count is obtained.

Methods of Publication. — When a significant part of the tabulations is completed for a particular state or, in the case of manufactures, a particular industry, a preliminary statement is issued in processed form. Later, one or more printed bulletins are issued for each state or industry, and these separate bulletins are finallv collected into bound volumes which form the major part of the final report on the census, being in some cases supplemented by a general report or by additional reports on cities or other areas not completely covered by the state reports. The completed volumes for the censuses of manufactures and agriculture appear about two years after the end of the year to which the production figures relate, though the bulk of the figures are made available much earlier in the processed reports and the bulletins. The results of the 1935 census of agriculture were published in three volumes, the results of the 1937 census of manufactures in two volumes, and the results of the census of mines and quarries (mineral industries) in one volume. The reports of the decennial census of agriculture are more extensive, those for 1930 occupying four numbered volumes, two of which were bound in three parts.

Current Production Statistics. — Since the World War of 1914–18, there has developed an insistent demand for business statistics issued at more frequent intervals, in order to gauge the current trend of business. Production figures particularly have been demanded at monthly intervals, as indicators of the amount of commodities being supplied for consumption. The result of this demand has been the collection by government departments, by trade associations, and by other agencies of periodical data on production, stocks, shipments, orders, etc., for most of the important industries and many of lesser importance. Complete current data are collected by the bureau of the census monthly on cotton consumption and stocks, activity of cotton spinning, cotton-seed and cotton-seed products. Monthly reports of production are also collected on more than 50 other industries or commodities, including automobiles (manufacturers' sales); cellulose plastic products; hosiery; various phases of the clothing industry; wool stocks; wheat-milling products; and various phases of the steel and iron industry (including steel boilers, steel office furniture, malleable iron products, etc.). In addition, annual reports are issued on animal and vegetable fats and oils, clay products, farm equipment, etc. Among the most important of the periodic production reports of the census bureau are those relating to cotton ginned, which appear semimonthly during the ginning season, giving the amount of cotton ginned by counties and states. All of the current production reports are published in processed form shortly after the close of the period to which they relate. The current reports of the production of manufacturing industries do not in every case cover the entire industry to which they relate, but reports are received from a sufficient number of establishments to indicate satisfactorily the trends from month to month.

A large number of the monthly series of business statistics available from governmental and other sources is assembled in summary form in a monthly publication of the department of commerce called the Survey of Current *Business*, which is compiled in the bureau of foreign and domestic commerce. This publication presents, along with a wide variety of quantitative data representing current conditions in the fields of production, trade and finance, a number of monthly business indexes, including indexes of industrial production, factory employment and payrolls, freight car loadings, construction contracts, monthly income payments (with separate indexes for salaries and wages); cash farm income (with separate figures for income from crops and from livestock products); cost of living (with separate indexes for food, clothing, fuel and light, and housing), retail sales, foreign trade, wholesale prices (general and for specific commodities) and prices of industrial stocks. Weekly supplements are issued giving current data even more promptly and including weekly production figures for automobiles, bituminous coal, electric power, petroleum, steel ingots and market receipts of a number of farm products. There is also a special annual number in which is presented an economic review of the preceding year, comprising summaries of the various types of statistical data presented from month to month, these summaries often running back for a considerable period, together with analytical comment, discussion of interrelations and significant descriptive matter. Many of the indexes and series of production data are shown in graphic form both in the monthly numbers of the *Survey* and in the weekly supplements. (L. E. T.)

CENSUSES OF PRODUCTION IN VARIOUS COUNTRIES

While the taking of a census of industrial establishments, dealing with the numbers employed, the mechanical power used and the character of the industry in which they are engaged, is a fairly common practice, and is in some cases supplemented by particulars of the principal goods produced, only a small number of countries make a practice of carrying out a survey that will yield data relating to production, and not merely to products. In the United States that course has been long established, and has been carried out since the World War of 1914–18 at biennial intervals. The Dominion of Canada early adopted the practice of its powerful neighbour. Passing from a decennial to a quinquennial enquiry after 1900, the system of annual returns was established from 1917. The particulars obtained cover the total of wages and salaries paid as well as the particulars obtained in United States and information regarding materials used is obtained in some detail.

Annual enquiries of a similar character have been carried out in Australia since 1903, in New Zealand since 1918–19 (following quinquennial enquiries extending back to 1867) and in the Union of South Africa since 191j–16.

In Europe periodic enquiries of the character of the censuses of manufacturing industry in the leading Anglo-Saxon countries have not been carried out in the more important manufacturing countries. In Germany, before the war, certain industries were selected for special study, and annual particulars were obtained in respect of these from 1907 onwards. In Russia an enquiry on the Anglo-Saxon model was carried out for the year 1908. In Norway there was an incomplete enquiry for the year 1909 and in Sweden a very careful study of some of the country's principal manufacturing industries was carried out as part of a plan for dealing in a nine-year cycle with the whole of the industries. The results published were contained in three reports issued in the period 1914–1917. In Holland a census of production was found necessary in connection with war-time organization, and in 1918 an enquiry was made relating to 1916 and 1913. Later enquiries have been arranged on the principle of covering the principal industries by yearly instalments in periods of five years. In Norway the enquiry of 1909 was repeated in 1916 on a more complete basis, and a new inquiry was in progress in 1941.

More extended enquiries regarding production were begun or planned in a number of countries after 1918. In some cases the particulars to which the enquiry relates are sufficiently extensive to furnish not merely a census of products, but a census of production. This appears to be the case with the Bulgarian enquiry commenced in 1922, the summary results of which were published in 1924. The Irish Free State (Eire) commenced the publication of the results of a census of production in that state in 1926. The reports are distinguished from those of Great Britain in the detail furnished, which extends to particulars of leading materials used and wages paid, the larger and smaller establishments being generally grouped separately.

PROFESSOR, a term now confined to a teacher of a special grade at a university or college (Lat. *profiteri,* declare publicly, profess). The educational use is found in post-Augustan Latin. In the universities of the middle ages the conferring of a degree in any faculty or branch of learning meant the right or qualification to teach in that faculty, whence the terms magister, "master," and doctor for those on whom the degree had been granted. To these names must be added that of "professor." The "three titles of Master, Doctor, Professor, were in the middle ages absolutely synonymous." (H. Rashdall, The Universities of Europe in the Middle Ages, 1895, i. 21.) The first endowed professorship at Oxford was that of divinity, founded by the mother of Henry VII. in 1502 and named after her the "lady Margaret Professorship." The foundation of the Regius Professorship by Henry VIII. in 1546 no doubt tended to the general modern use of the word. In England subordinate public teachers in faculties, or in subjects to which a professorial "chair" is attached, are known as "readers" or "lecturers," and these titles are also used for the principal public teachers in subjects which have not reached professorial rank. In colleges and universities of the United States, professor indicates a teacher of the highest rank, those next below being "associate professor" and "assistant professor" respectively. The title is often erroneously, if not fraudulently, used by magicians, "quack doctors" and faith healers generally.

PROFIT, a term used by business men to describe the result of their operations when that result is favourable. When the result is unfavourable the term loss is commonly used. Strictly speaking, the word profit means "result," whether favourable or unfavourable; but it is obviously more convenient to speak of an unfavourable result as a "loss" than as a "minus profit." As used by business men, the word profit must not be confounded with profits assessable to income tax or super tax. The rules for determining the liability of individuals or companies to these imposts are determined by statute, and are extremely artificial; similarly, profits in the business sense must not be confused with the economist's idea of profit.

If it were practicable for the business man to wait until his business was discontinued and wound up before attempting to arrive at any idea of what his profits were, it would be possible for him to accept the economic definition of profits as "the surplus remaining over from the employment of capital after defraying all the necessary expenses and outlay incurred in its employment, and after the capital has been replaced or provision made for its replacement." But the business man has to determine his profits as he goes along (1) because in no other way can he determine the most advantageous way in which to carry on his business; (2) because, in general, it would be impossible to obtain capital for business purposes, save upon the terms of distributing profits not less frequently than once a year, so that those contributing capital to enterprise may receive in return income by way of dividends. Hence the necessity of determining divisible profits from year to year.

It is absolutely impossible to determine the profits of a going concern from year to year with precision, because nothing more reliable than estimates can then be formed of the value of its outstanding obligations and unrealized possessions. But it would be unwise to distribute the whole of the profits year by year even if they were ascertainable, as were this to be done there would be no margin left to cover contingencies, and experience shows that unexpected losses are bound to occur from time to time. The problem that besets the business man year by year is not therefore how to ascertain the precise annual profits, but how to determine a figure of profit which can be divided without unduly jeopardizing the future prospects of the undertaking. Further, because distributions out of profits are made regularly at definite intervals and are treated by those who receive them as income, it is important that no kind of gain should be treated as divisible profits which by its very nature cannot be expected to recur.

Capital **Profits** and **Revenue** Profits.—The business man accordingly distinguishes between capital profits and revenue (recurring) profits, and pays dividends only out of the latter. Capital profits are increases of wealth arising from causes not directly connected with the carrying on of the business of the undertaking, *e.g.,* increases in the value of its fixed assets (*i.e.,* those assets held permanently as part of its equipment), a rise in the market value of which adds nothing to the fund out of which alone dividends can be paid. Indeed, a permanent rise in the value of fixed assets is a source of embarrassment rather than of congratulation, in that it increases the ultimate cost of replacements as and when such assets are worn out, and thus then at least tends to deplete the fund available for the payment of dividends. Conversely, capital losses arising from a fall in the value of fixed assets do not affect divisible profits so long as these assets continue to be equally effective as profit-earning equipment, while a fall in the cost of renewals is advantageous from a revenue point of view.

Of course, if and when a business is discontinued and wound up, capital losses and profits will materialize. If on balance there have been profits on capital, the fixed assets will realize more than they otherwise would have realized, and a correspondingly larger sum will be available out of which to make a return of capital or, rather, there will be a balance of capital profits to divide after capital itself has been returned in full. Conversely, if on balance there have been capital losses, the fixed assets will not realize a sum sufficient to enable the whole of the capital to be returned, and there will therefore be a realized loss on liquidation. Where the business is owned by a limited company, this means that the shareholders (or the holders of some class or classes of shares) will not receive the whole of their capital back; but if the business be owned by a concern not subject to limited liability, *e.g.,* a partnership, the members will have to contribute among them the ascertained loss pro rata, according to the shares in which they were entitled to participate in profits, and there will then be a sufficient fund to enable the whole of the capital to be returned to those who provided it.

In the case of a partnership, it is usual to divide the whole of the profits as shown by the annual accounts; but in the case of a company, it is not usual to pay away as dividend the whole of the profits shown by the annual accounts. A part of these profits is normally held back as a reserve against unforeseen contingencies, and another part is normally "carried forward" partly with a view to equalizing dividends in good and bad years, partly to avoid the inconvenience of paying away profits which have perhaps not entirely been received in cash.

PROFITEERING. This word came into colloquial use early in the World War, and, having been included in the title of an Act of Parliament in 1919, may be considered to have received official recognition as part of the English language. It signifies the making of an unreasonably large profit on the sale of goods or services, particularly those in common use. The practice has always been liable to arouse intense indignation among the public, and the word profiteer is a term of abuse deriving its sting partly from implied contrast with the word volunteer.

In normal times before the war, opportunities for making unreasonably large profits were to a great extent restricted by the play of competition, and in fact competitive prices were widely regarded as being prima facie reasonable. When competition was excluded, the possibility of unreasonably large profits being made was obviously increased, and there was a widespread tendency on this ground to regard monopolies with suspicion. Some industries which could not ordinarily be run on competitive lines, or which tended to become monopolies, were consequently carried on as public undertakings, or were controlled by public authority as regards rates and conditions of trading.

Before the war there had been a tendency for competition to be excluded to a greater or less extent in an increasing number of industries through the formation of trusts or combines. Though the selling prices fixed by such organisations were not in all cases higher than those which would have prevailed under competitive conditions, they were certainly higher in many cases; while even when they were not, a feeling was apt to arise where large profits were being made that the trust or combine in question was taking for itself an unduly large share in the economies effected by the elimination of the wastes of competition. The belief that unreasonably large profits were being made was undoubtedly the most powerful motive in the campaign for the control of trusts and combines in various countries.

Various measures were taken during the war to restrict profiteering, especially in belligerent countries. These included the fixing of maximum prices, and in some cases of profit margins at each stage of production and distribution. Rationing of prime necessaries served to distribute supplies evenly and to prevent them from being sold to the highest bidder. The weapon of taxation was also employed in the form of highly graduated income taxes, excess profits taxes, etc., to secure for the public revenue a substantial part of the high war-time profits made by private interests.

As the result of inflation, profiteering was in some cases more rife after the war than during its continuance. Under conditions of extreme inflation, such as occurred in Germany in 1923, profiteering became widespread. The rise of prices was so rapid that profits of hundreds or thousands per cent. could be made by holding goods even for a few days. That, however, was a profit in paper marks, and it was obvious that paper marks, while circulating as currency, were entirely untrustworthy as a standard of value. The true position did not become clear until after a stable currency had been reintroduced. It was then seen that while a comparatively small number of persons had made and retained fortunes, a vast mass of people had been reduced to penury.

British Government Measures.—In Great Britain, inflation reached comparatively small dimensions. After the Armistice, the general level of prices was for a time downwards, and during this period many war-time controls were withdrawn. Subsequently, prices began to rise and continued to advance until the spring of 1920, when a rapid fall began. Public apprehension led in the summer of 1919 to the passing of an act to check profiteering, commonly cited as the Profiteering Act 1919. This act conferred upon the Board of Trade powers (a) to investigate prices, costs and profits at all stages; (b) to receive and investigate complaints regarding the making of excessive profits on the sale of any article to which the act was applied by the Board of Trade, and after giving the parties an opportunity of being heard either to discuss the complaint or to declare the reasonable price for such articles, and to order the seller to refund to the buyer any amount paid in excess of such reasonable price, the Board also having power, where it appeared to them that the circumstances so required, to take proceedings against the seller in a court of summary jurisdiction; and *(c)* to obtain from all sources information as to the nature, extent and development of trusts and similar combinations. The act was to remain in force for six months only, but it was subsequently continued for a further three months, and later, by an amending act, for six months more until May 19, 1921.

To deal with retail trade, local committees, numbering in all over 1,800, were set up, and the Board of Trade delegated to them the bulk of their powers under the act relating to retail sale. There were also 108 appeal tribunals to which the seller had the right of appeal against the decision of a local committee. The task of dealing with larger transactions of wholesalers or manufacturers affecting whole trades or industries was entrusted by the Board of Trade to a central committee, which worked through three standing committees: the investigation of prices committee, the complaints committee and the standing committee on trusts. These standing committees in turn appointed sub-committees as required to deal with particular questions. The investigation of prices committee made investigations into the cost of production of various articles in all stages of their manufacture. Reports were published as parliamentary papers on agricultural implements and machinery, aspirin, biscuits, boot and shoe repairs, brushes and brooms, clogs, costings in Government departments, furniture, gas apparatus, matches, metal bedsteads, motor fuel, pottery, standard boot and shoe schemes, tweed cloth, worsted yarns, wool and the wool top-making trade. The complaints committee undertook the investigation of specific complaints and also investigated specific transactions brought to their notice.

The committee on trusts was responsible for obtaining information as to the nature, extent and development of trusts and combines. Numerous investigations were made. Mention may be made further of a provision contained in the Profiteering (Amendment) Act, 1920, which authorized the Board of Trade to approve suitable schemes submitted by persons representing a substantial proportion of those engaged in the production or distribution of goods to which the original act was applied limiting the profit to be allowed on such manufacture or distribution. Only two such schemes were actually approved.

Since the lapsing of the Profiteering Act in 1921, there has been no special legislation in Great Britain against profiteering except for the continuance of restrictions on the rent which may be charged for certain classes of houses. Public feeling, however, continued to be very susceptible on the question, especially when a rise of prices occurred. Various public inquiries have been conducted into costs of production and distribution of foodstuffs and other articles of common consumption, the most important of these being (a) the inquiry of a committee appointed in 1922 under the chairmanship of Lord Linlithgow to enquire into methods and costs of selling and distributing agricultural, horticultural and dairy produce in Great Britain and the diminution of the disparity between the price received by the producer and that paid by the consumer; (b) the inquiry of the royal commission on food prices appointed in 1925 and *(c)* the proceedings of the food council appointed in 1925 following the report of the royal commission on food prices to watch over food prices and supplies. It may be noted also that since 1923 an interdepartmental committee appointed by the Minister of Health and the president of the Board of Trade has been in being for the purpose of surveying the prices of building materials and receiving and considering complaints in respect thereof. (C. K. H.)

United States.—Figures gathered by the Federal Trade Commission show the situation in the United States during the World War period. In 1917 there was apparently no limit to the price purchasers were willing to pay, the condition being one of panic. In the next year profits were somewhat abated by government regulation.

During the war period oil companies circulated reports that the supply of gasolene was dangerously short, for the purpose of maintaining prices of that commodity while making "enormous" profits on fuel oil. Concerns bottling or canning vegetables, which had made future contracts, sometimes withheld portions of their output from delivery on such contracts and sold in the higher "spot" markets. In frequent cases licences were revoked by the Food Administration. The practice of such concerns in maintaining re-sale prices for jobbers contributed toward maintaining the general high level of prices and increased profits in some instances. The steel companies in 1917, prior to Government price-fixing, made abnormal profits, and a number continued to make unusually heavy profits thereafter. The United States Steel Corp., which made 5% before the war, received 25% on investment in 1917; and ten smaller concerns made from 30% to 319% on their investments. Certain sulphur companies took advantage of the war demand for sulphur to raise their prices to such an extent as to reap net profits of approximately $15 a ton, which meant over 200% on investment in one case. The profits of tanners increased from two to five times, as they took advantage of the enormous demand for leather and exacted very high prices. The price of hides was rapidly advanced, notwithstanding that at the same time "great supplies were withheld from the public."

High prices do not necessarily indicate excessive profits, but there is reason to believe that profiteering was common in cement, petroleum, lumber, farm implements, wool, clothing, sulphur, naval stores, rice, sugar, sand and gravel, raisins and other products, in addition to those already mentioned.

The U.S. Government attempted to deal with profiteering in three ways: (1) taxation; (2) price-fixing; (3) direct action under the Food Control Act. The first and the last methods proved largely ineffective.

By special taxes levied on profits, many thought that the spoils of the profiteers could be regained by the public. In 1916 a tax of $12\frac{1}{2}\%$ was levied on the profits of munitions manufacturers; and a general "war profits tax" and an "excess profits tax" were imposed in 1917. In 1918 these taxes were combined. But, unfortunately, it proved so easy for most corporations to increase their investment accounts, and to pad their expenses, that the worst profiteers often showed small excess profits. Moreover, a considerable part of the tax was shifted to consumers in the shape of higher prices, as was possible during the inflation period.

Government price-fixing, while it did not prevent profiteering, did moderate the evil, notably through such substantial reductions as were made in the prices of wool, coal, sugar, flour and sulphuric acid. Unfortunately, this means was not used as vigorously and thoroughly as it would have been had there not been an ill-founded reliance upon profits taxes.

On Aug. 10, 1917 the Food Control Act became law. Section 4 of this act made it unlawful for any person to hoard or to make any unjust or unreasonable charge in transactions relating to "necessaries" (foods, feeds, fuel, fertilizers, farm implements and machinery), but imposed no penalty. Sections 6 and 7, however, provided for penalties and seizure, in case of hoarding. Section 5 authorized the licensing of dealers in necessaries and the fixing of fair storage charges, commissions, profits or practices. The fixing of prices for coal and coke was authorized in section 25. It was under this act that the Food Administration operated, and, as already indicated, its control over prices was partly effective. On June 30, 1919, however, the activities of the Food Administration were suspended; and as the agitation concerning the "high cost of living" grew in volume, the Department of Justice assumed the task of enforcing the law, which remained in force while a state of war was only technically in existence. But the attorney-general found his efforts limited by the absence of a penalty clause in section 4 and the restricted definition of "necessaries," and, at the president's request, Congress re-enacted the law in Oct. 1919, with amendments to cover these defects. In the year following the re-enactment of the law there were over 2,000 indictments, arrests and sentences, involving chiefly the commodities just mentioned, together with meats, potatoes and meals at restaurants. The great majority could not be sustained under the law. The act was declared unconstitutional by the U.S. Supreme Court in Feb. 1921. In the meantime prices had declined and the public lost interest in the subject of profiteering.

In a sense the U.S. Government was to blame for much wartime profiteering. In the first place it was lax in letting contracts and making purchases, either directly, or indirectly, by placing authority in the hands of interested persons. The "cost-plus system" invited profiteering as well as inefficiency. In the second place its combination of excess profits taxes and price regulation was unfortunate. Taxation proved at best to be an inadequate means of reaching profits, and early laxity in defining cost and investment made this means nugatory.

See the various *Reports* of the Federal Trade Commission; the *Report of the Massachusetts Commission on the Necessaries of Life* (1920); and *Senate Document No. 248* (65 Cong., 2 Session). (X.)

In European Countries.—Periods of inflation in different countries were marked by measures designed to check speculation and prevent further rises of price. Legislation to mitigate profiteering by combines was consequently passed in several countries, including notably Germany, Czechoslovakia and Norway.

The German experiment, represented by the "decree against the abuse of economic power," which came into force in Nov. 1923, is of particular interest. The decree provided amongst other things that the German minister of economic affairs may, when he considers a cartel agreement or the method of putting it into operation detrimental to the public interest, apply to the Cartel court set up in accordance with the decree to have the agreement declared void or the particular method of carrying it out forbidden. The public interest or the common good is to be considered as detrimentally affected, particularly when supply or demand is restricted in a manner not economically justifiable; when prices are raised or kept high; or when, in the event of prices being quoted in a stable currency, extras for risks are included; or when economic freedom is unreasonably restricted by boycott in buying or selling or by the fixing of discriminating prices or conditions. Until the summer of 1923, action by the government was confined to unofficial intervention, and it was claimed that this was successful in bringing about a large number of price reductions and in preventing price increases. In the latter part of that year the Government made a number of applications to the court with regard to business conditions or methods of price fixing adopted by particular cartels. These cases, however, were settled by arrangement, without the Cartel court giving a decision; and the Government made no further applications to the court. (C. K. H.)

PROFIT-SHARING, the term applied to an arrangement under which an employer, in accordance with an agreement freely entered into, hands over to his workpeople as supplementary remuneration a share, fixed in advance, of the profits of the concern in which they are engaged. This definition, it should be observed, excludes many forms of profit-distribution and bonus payment to workpeople. The condition "fixed in advance," for example, rules out of profit-sharing proper those cases in which an employer makes to his employees, at his absolute discretion, a present out of his profits, even though the payment is made regularly year after year; for such presents are gratuities lacking the elements of pre-agreement and rightful title. Again, the supplement distributed must be dependent on profits. Systems of payment by results, such as piecework, individual premium bonus, collective or fellowship bonus, and the like, are not profit-sharing. In such systems the payment, as a whole or in some supplementary part, is dependent upon the *output* of the individual or of the group, without reference to whether the production culminates in greater or less profit or loss to the undertaking.

The sponsors and guardians of profit-sharing as a system similarly rule out of their field such systems as that adopted in the remuneration of share fishermen or as the French *métayage* system (*q.v.*). These are methods of dividing, not the profits, but the gross proceeds of an undertaking.

Far more elusive is the distinction between profit-sharing and co-partnership, the essence of which is the issue on favourable terms of share capital to employees; indeed, it is hardly possible to make any clear-cut differentiation, the more so as the terms are constantly used as synonymous.

Early Examples.—The earliest known example of profit-sharing in any country seems to be a scheme introduced by the French National Fire Insurance company in 1820, the year of the company's foundation. The British Union Fire Insurance company followed in 1838, and the General Insurance company in 1850. These three schemes are still in active operation. One of the best known of all profit-sharing schemes is that of the Paris house decorator, Leclaire, which was introduced in 1842 and is still in operation. It was at first confined to the nucleus (*noyau*) of permanent employees belonging to the firm's Mutual Provident and Benefit society; but in 1870 it was extended to all employees. Some other French schemes are hardly less famous. Godin, of Guise, introduced profit-sharing in 1876; in 1880 the business was turned into a joint stock company, and became something in the nature of a co-operative society with domiciles, in a model village, for some classes of workers. The Bon Marché have a scheme dating from 1880, under which the whole of the shares in the company are to-day in the hands of actual or former employees. It will be evident that the historical origins of profit-sharing are mainly to be found in France.

Great Britain.—The success of profit-sharing in France attracted much attention in Great Britain, particularly among the "Christian Socialists" (F. D. Maurice, Tom Hughes, Charles Kingsley, Vansittart Neale and others). From about 1850 onwards this group had exercised a very strong influence upon the nascent co-operative movement; hence profit-sharing was at this time widely adopted by co-operative societies, and the subject was constantly discussed at the annual co-operative congresses. At the present time (with one important exception: the workers' co-operative productive societies organised from the point of view not of the consumer but of the producer) profit-sharing is little practised in the co-operative movement.

Outside the co-operative movement the first important scheme in England was that of Henry Briggs, Ltd., a firm of coal owners in Yorkshire, which was introduced in 1865, and was at first very successful but later failed.

A scheme introduced by Messrs. Hazell, Watson and Viney, Ltd., in 1886 was discontinued in its original form in 1895; but a supplementary scheme, introduced in 1890, is still in force, and is of especial interest as the earliest instance in Great Britain of the co-partnership type of scheme enabling employees to share in profits by the purchase of shares on specially favourable terms.

In 1889 a scheme of profit-sharing was introduced by the South Metropolitan Gas company, providing for the payment of a cash bonus varying inversely with the price of gas. As the dividends payable to the shareholders under the company's acts also varied inversely with the price of gas, the workers' bonus was linked with the shareholders' dividends, and thus with the company's profits. The scheme was revised in 1894, in such a way that only half of the bonus was thenceforward payable in cash, the other half being invested in the purchase of the company's ordinary stock. By successive revisions, strong inducements were given to the co-partners to leave the withdrawable half of their bonus on deposit, with a view to eventual investment; and from July 1910 onwards it was provided that the withdrawable part of the bonus must be left in the company's hands to accumulate at interest, or invested in the company's stock with the trustees; or it might be withdrawn by giving a week's notice, but only under special circumstances. This capitalisation of the bonus is a feature upon which the advocates of this type of scheme—following the models specially approved in France—strongly insist. The name of the scheme was changed in 1903 from "profit-sharing" to "co-partnership," as being more descriptive of the nature and purpose of the new relationship that had been established between the company and its employees. In 1920 the scheme became for the first time statutory, under the company's act of that year; and the basis of the scheme was slightly changed. The surplus profits, after the payment of prescribed basic rates of dividend on the company's stocks, are now divided in the proportion of three-fourths to the consumers (in the form of a reduction in the price of gas) and the remaining fourth in equal parts to the ordinary stockholders, by way of increased dividends, and to the employee co-partners, by way of a bonus at a uniform percentage on their salaries and wages. As before, half of the bonus is capitalised, and the other half may only be withdrawn in special circumstances.

At the end of the year 1926, the employees of the company owned capital in the company to the extent of about £500,000 besides deposits at interest to the extent of nearly another £250,000. In another large gas company—in fact the largest gas company in the world, the Gas Light and Coke company—the employees at the end of 1927 owned £750,000 of the company's ordinary stock. Nearly all the leading, and many of the smaller, gas companies have adopted co-partnership schemes framed on the same general lines.

Other schemes deserving of special mention are those introduced by Messrs. Clarke, Nicholls and Coombs, Ltd., in 1890; by Messrs. J. T. and J. Taylor, Ltd., in 1896; by Messrs. Lever Bros., Ltd., in 1909; by the Bradford Dyers' Association, Ltd., in 1912; and by Messrs. Rowntree and Co., Ltd., in 1923; also the scheme foreshadowed by Imperial Chemical Industries, Ltd., in 1927. These six schemes contain two examples of each of the three principal types of profit-sharing and co-partnership: the cash bonus type, the bonus-capitalisation type and the share-issue type.

The following table shows the total numbers of schemes started in the various periods mentioned, the numbers of such schemes no longer in existence at the end of 1927, and the numbers and range of those still in existence at that date, as given in the *Ministry of Labour Gazette* for June 1928:—

TABLE I.

Period in which started	Total schemes started	Schemes discontinued (or suspended) by end of 1927	Schemes still in operation at end of 1927		
			Number of schemes	Total number of employees	Approx. number of employees entitled to participate
Before 1881	35	31	4	1,700	800
1881–1890	80	69	11	17,100	13,900
1891–1900	78	65	13	8,900	7,500
1901–1910	82	44	38	87,500	54,700
1911–1918	95	37	58	56,300	24,700
1919	57	18	39	35,000	22,400
1920	56	12	44	58,800	16,600
1921	14	1	13	27,900	11,800
1922	12	1	11	3,300	2,700
1923	18	1	17	29,000	22,800
1924	13	..	13	31,200	12,800
1925	12	1	11	31,100	5,400
1926	11	..	11	15,700	10,000
1927	14	..	14	5,900	2,400
Total	577	280	297	409,400	208,500

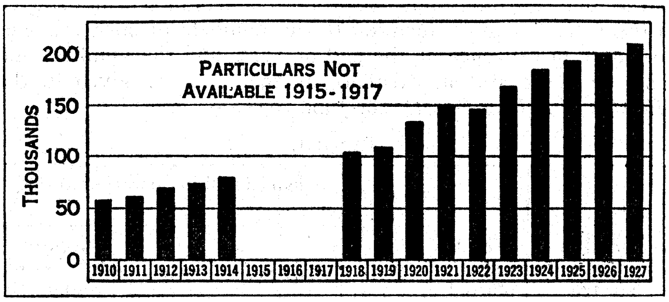
The following table, also taken from the *Ministry of Labour Gazette* for June 1928, shows how the schemes are distributed among the various industries:—

TABLE II.

Industry or business	Schemes in operation at end of 1927			
	Number of firms	Number of schemes	Total number of employees	Approx. number of employees entitled to participate
Agriculture	5	5	700	300
Glass, chemical, soap, oil, paint, etc.	15	1	52,000	29,700
Engineering, shipbuilding and other metal	42	44	67,700	23,900
Textile	29	29	46,800	19,900
Food and drink (manufacture)	31	33	43,400	28,500
Paper, printing, bookbinding, publishing, etc.	22	23	7,700	5,400
Gas, water, and electricity supply	53	53	49,500	41,900
Insurance, banking, and other financial businesses	9	9	37,200	33,000
Merchants, warehousemen and retail traders	44	45	40,400	11,200
Other businesses	40	41	64,000	14,700
Total	290	297	409,400	208,500

The growth of the movement, as will be seen, is irregular; indeed, the figures of new schemes started year by year show that the advance proceeds by spurts following periods of quiescence. The total of 208,500 employees entitled to participate in profit-sharing schemes is substantial, yet, considered relatively, it forms but a small proportion, less than 2%, of the total number of employees. Regarded industrially the proportion varies greatly and is insignificant, except in gas companies, in the banking, insurance and financial group, in the chemical trades and in food and drink manufacture; and in all these groups, with the one exception of gas companies, the profit-sharing statistics are dominated by the figures for two or three very large companies.

The growth in the number of employees known to be working under profit-sharing arrangements is illustrated in the following diagram:—



Discontinued Schemes.—It has already been pointed out that about half the schemes started have come to an end. Of the 192 schemes started before the beginning of the present century, only 28 were still in operation at the end of 1927. An analysis of the causes of discontinuance is attempted, on the basis of such material as is available, in the official *Report* already mentioned; and another more detailed analysis, supplemented by special enquiries, is made in S. Rowntree's *The Human Factor in Business.* Rowntree's final conclusion is that, taking all schemes, existing and discontinued, together, about 63% may be regarded as successes and 37% as failures; and in many of the cases written down as failures the causes of failure were obvious and might have been avoided. The statistics of discontinued schemes, taken as a whole, are thus somewhat inconclusive, but it is possible to draw some conclusions from the figures analysed *(a)* by industries, and *(b)* by types of schemes.

(a) The figures for industrial groups are given in the table (p. 559). Attention may be directed to the extremely unfavourable results in agriculture. Other industrial groups with a high proportion of schemes discontinued are paper, printing, bookbinding and publishing, while merchants, warehousemen and retail traders, show heavy casualties. On the other hand, all the schemes in banking, insurance and other financial businesses that had been started were still in operation at the end of 1927; and gas companies' schemes also had a remarkably high proportion still in operation.

(*b*) More value, perhaps, attaches to the analysis by types of scheme. The figures in the following table are taken from the 19th *Abstract of Labour Statistics,* and relate to the position at the end of 1927.

TABLE III.

	Total	Discontinued	In operation at end of 1927
Schemes consisting in the issue to employees of share capital on specially favourable terms	77	18	59
"Deposit" schemes, under which interest, varying with the profits, is allowed on deposits made by employees	32	6	26
Other schemes, analysed by method of paying bonus—			
(i) Bonus paid in cash, or credited to a savings or deposit account .	300	181	119
(ii) Bonus retained in a provident, superannuation, or other similar fund	23	10	13
(iii) Bonuses paid in shares, or invested in capital of undertaking .	50	16	34
(iv) Bonuses paid in other ways; combinations of above systems; and method of payment unknown .	92	46	46
Total	574	277	297

It will be seen that the best result is shown by the "deposit" schemes, followed by the two "co-partnership" types of schemes—the share-issue type, and the bonus-capitalisation type. Much the worst result is shown by the cash bonus type (which, however, remains much the largest single class)

Rate of Profit-sharing Bonus.—There is a remarkable uniformity in the average rate of bonus paid by profit-sharing firms to their employees, which works out at a little over 5% addition in ordinary earnings over a long period of years.

Although the average rate, for all industries is remarkably uniform from year to year, there is no corresponding uniformity in the rate of bonus for the several industries. The following table shows the percentage addition to wages made by the profit-sharing bonus in the various groups of industries in each of the three years, 1925, 1926 and 1927: the figures are taken from the 18th and 19th *Abstracts of Labour Statistics.*

TABLE IV.

Industry or business	Percentage addition of bonus to wages			
	1924	1925	1926	1927
Agriculture	1·4	2·1	0·9	0·2
Glass, chemical, soap, oil, paint, etc.	6·1	7·3	3·8	3·5
Metal, engineering, and shipbuilding	1·4	2·1	2.6	1·6
Textile . .	3·4	2·9	2·2	2·3
Food or drink (manufacture) .	7·1	6.3	5·6	3.9
Paper, printing, bookbinding, publishing, etc.	j.8	7·2	7·1	6.6
Gas, water and electricity* .	4.6	5·1	4·1	4·1
Insurance, banking, finance†	..			..
Merchants, warehousemen, or retail traders	9·7	13·3	11·0	10·4
Other businesses . . .	7·7	5·1	5·6	4·0
Total . . .	4·9	5·3	4·4	3·9

*Almost entirely gas companies.
†Cannot be stated.

Views of Employers and of Trade Unions.—It is impossible to make any general statement about the views of employers. It must be taken as significant, however, that, in spite of three-quarters of a century of active propaganda, only some 500 or 600 firms are known to have introduced any form of profit-sharing or co-partnership; and that a large proportion of this small minority have been dissatisfied with the results.

As regards the attitude of the trade unions to profit-sharing, there appears to be little doubt that this has been almost uniformly hostile, or at best indifferent. Naturally, the whole effort of the trade unions, in regard to remuneration, is directed to keeping the *general* level of wages *in an industry as a whole* as high as possible. They are not greatly concerned to secure special advantages for the workpeople in a works here or there, where the employers are exceptionally prosperous.

But further—and this is a point to which many critics of the movement attach great importance—it is conceived to be positively injurious to the trade union movement, as a mass organisation, to have the workpeople in a factory here and there isolated from their fellows by special privileges, since the workpeople so placed may be expected to be wanting in zeal for the defence of their less fortunate comrades, and averse from risking their employment if a dispute should come to the final arbitrament of a strike.

The practical importance of the fundamental distinction, referred to above, between profit-sharing and payment by results is that while payment by results offers a bonus based on factors which are wholly or largely under the control of the workers, profit-sharing offers a bonus based on factors which are in great part outside their competence, and which depend in great part on the judgment, skill and enterprise of the directors and the management. For this reason profit-sharing compares unfavourably with systems of payment by results, *if regarded simply as a method of industrial remuneration;* and it may be said at once that the shortcomings of profit-sharing as a method of remuneration are freely admitted by many modern advocates of the system. The emphasis is nowadays laid rather upon the means profit-sharing affords of giving the workers an assurance that they are receiving "a square deal."

The weakness of profit-sharing as a stimulus to effort lies partly in the remoteness of the connection between the individual effort and the reward accruing to the individual making that effort, partly in the length of time that usually elapses between the additional exertion and the receipt of the reward, and partly in the customary smallness of the reward.

France. — Reference has already been made to some of the historic French profit-sharing schemes.

The French Profit-sharing society published in 1924 a revised (third) edition of their monograph on profit-sharing, containing the names of 140 firms practising profit-sharing in France. This total shows a slight advance on the 114 given in the second edition of the monograph 12 years earlier; but it is to be noted that the definition of profit-sharing is much wider than that adopted in Great Britain; while schemes introduced by firms domiciled in Alsace-Lorraine are now included, which would, of course, not have been included in the earlier edition. Two points of special interest in the Report may be noticed. In the first place the historic schemes of Leclaire, Godin, the Bon Marché and others still appear in the list. Secondly, the preeminence of insurance companies' schemes is still very marked, a fifth of all the schemes in the list—28 out of 140—being in insurance companies.

The 1924 Report of the French ministry of labour on profit-sharing mentions two acts which make profit-sharing compulsory in two special cases, and a third which introduces a kind of permissive co-partnership. An act of Dec. 18, 1915, makes profit-sharing compulsory in workers' productive co-operative societies formed under the act. Particulars are given in the Report of 328 such societies, employing 12,000 workers, about half of whom are non-members. An act of Sept. g, 1919, makes profit-sharing compulsory under all mining concessions granted after that date, of which there were 51 at the date of the Report. An act of April 26, 1917, permits the formation of joint stock companies with labour co-partnership (*sociétés anonymes à* participation *ouvrière*) in the form of labour shares (actions de travail), which are the collective property of the employees organised in a co-operative society. Eleven companies had been formed under the act, at the date of the Report, of which six were actually working as joint stock companies with labour co-partnership; but it is stated to be too early to form any conclusion as to the success of the experiment.

So far as regards voluntary profit-sharing the inquiry covered 168 businesses; but 93 of these failed to satisfy even a very wide definition of profit-sharing. The remaining 75 undertakings employed 102,000 manual and non-manual workers, of whom 62,000 work for the Paris-Orleans Railway company. In more than one-third of the cases the adoption of profit-sharing was subsequent to the year 1919. The share in the profits varies from 5 to 70% and more; rates of 6 to 20% being commonest. Information regarding 62 establishments employing 99,550 workers indicates that, in 1921, nine of them, employing 63,050 workers, realised no profits, and there was consequently no distribution. Fifty-three establishments, employing 36,500 workers, distributed 25,743,000 francs among 20,415 workers, an average of 1,260 francs for each participant. The actual amounts varied between a minimum of 24 and a maximum of 4,169 francs. On the whole, profit-sharing appears to be on the decline.

Germany. — Profit-sharing had gained little ground in Germany prior to the War. The number of businesses known to be practising profit-sharing at that time was 21, with probably a little more than 15,000 workers. The most interesting of these schemes was that existing in the famous Zeiss works, at Jena.

The position after the War has been studied by the social attache to the Swedish legation at Berlin; and the following observations are largely based on the report of his investigation (*Sociala* Meddelanden, No. 11, 1923).

There was a revival of interest in profit-sharing in Germany after the revolution; and some of the leading industrialists, including Krupp and Stinnes, were among its advocates.

According to a report by Werner Feilchenfeld, secretary of the Berlin chamber of commerce, published in 1922, in which he carried his investigations as far back as 1824, a system of profit-sharing had existed in 95 undertakings; but of these only 29 were in operation in 1921.

The great majority of profit-sharing schemes in Germany provide for the payment of a bonus in cash, or for payments into savings bank accounts or into provident or benefit funds. As a rule, the distribution is based on the annual earnings.

Only two instances are apparently on record in Germany of the "co-partnership" type of scheme, both of which have been discontinued. The first was almost contemporaneous with the Briggs scheme in England, and was apparently modelled upon it. The latter was introduced in the great Krupp business in 1922, and discontinued in 1925, on the ground, it is stated, that it would not be possible in future years to pay the dividend (6% preferential) on the workers' shares. (J. H.)

United States. — Profit-sharing is a method of additional remuneration of employees under which the employees receive a share, fixed in advance in relation to profits. In other words the basis of distribution of the profits between the stockholders and the employees is predetermined. The actual amount distributed depends upon the profits earned and varies from year to year according to the company's ability to earn profits. The conception of profit-sharing in the Senate report of 1939, pp. 2–5 (which makes profit-sharing include "all payments to employees, regardless of the form in which they are allocated or distributed, which are in addition to the market rate") is incorrect.

Early Examples. — Experience with profit-sharing in the United States dates from at least 1867. The pioneer experiments were, however, short-lived. The first enduring plan appears to be that established by the Peace Dale Manufacturing Company of Peace Dale, R.I., in 1878. This company, which was engaged in the manufacture of shawls, worsted goods and woollen fabrics, employed about 450 workers. Its profit-sharing plan was typical of those most frequently adopted in subsequent years. It provided for the allotment of a percentage of the profits, after making certain deductions for depreciation, reserve and dividends, to be distributed among those employees who had been with the company for a specified time on the basis of their individual earnings. It was also provided that, if the profits were not sufficient to allow a distribution of at least 1% of the earnings, the profit-sharing bonus would not be paid. This situation arose in the first year of the plan's creation. Thereafter, for the succeeding 11 years, a share of the profits varying between 3 and 5% of earnings, was paid to all eligible employees.

Another conspicuous example of the early systems in the United States, and one similar to the Leclaire plan in France, was that adopted in 1886 by the N. O. Nelson Manufacturing Company of St. Louis, Missouri, which continued 49 years. Under the terms of this plan capital received the usual commercial return and the remaining profits, after setting aside 2½% for educational purposes and 5% for a provident fund, were proportionately divided between capital and labour on the basis of the relationship between the total pay roll and the total capital investment. Profit-sharing dividends from 8 to 10% were paid for a number of years. Until 1890 the employees were permitted a choice between payment in cash or in the stock in the company. After that time all payments were made in the form of stock. In 1894 it was decided to allow profit-sharing dividends only to those employees who invested 10% of their wages in the company's stock. During the dull years which followed, no dividends were paid, but in 1906 a total of $108,778 was distributed in the form of company stock to employees, customers and the provident fund.

Extent of Profit-Sharing. — Profit-sharing has never reached considerable proportions in the United States. Of 50 plans set up before 1896 only 12 remained in operation. in 1896. The United States Bureau of Labor Statistics found only 60 "true" profit-sharing plans in 1916; *i.e.* covering rank and file employees as contrasted with "limited" plans which apply only to "principal employees." There were probably not over 80 to go true profit-sharing plans in the United States in 1930 and some of those were discontinued during the depression years which followed. Seventy years' experience yielded a net growth of hardly more than one plan per year. The National Industrial Conference Board report on *Practical Experience with Profit-Sharing* (1920), which covered 41 true profit-sharing plans indicated two general conclusions: That profit-sharing is still in the experimental stage and may have more merit than its history indicates and that it has been successful thus far only in the hands of a minority of employers, men with social vision and unusual interest in policies of such a kind, and with workers of considerable intelligence and who have confidence in their employer.

The latest figures on the extent of profit-sharing in the United States are given in C. C. Balderston's *Profit-Sharing for Wage Earners, 1937,* which showed that 193 plans were known to have been initiated in the United States and Canada and 679 in Great Britain and Northern Ireland. Sixty-seven of these American and 266 of the British plans were in active operation in 1937. In a National Industrial Conference Board study published in 1928, which reported results of inquiries of 4,655 establishments in many industries, the percentages of profit-sharing establishments varied from 1·9% in the rubber industry to 12·7% in the case of mercantile establishments. Public utilities and the chemical industry ranked second and third, with 9·4% and 7·3%, respectively, of the companies investigated participating in plans of profit-sharing. Only six of the plans included in the survey began before 1916. The National Industrial Conference Board reached three conclusions in its report on profit-sharing:

(1) From experience with profit-sharing in the past and the plans now in operation, profit-sharing has been successful for limited periods.

(2) Judging from the long list of abandoned plans and the comparatively small number that have endured more than a few years, the effectiveness of profit-sharing in surviving the many vicissitudes of an industrial enterprise is decidedly uncertain.

(3) In the light of the high percentage of abandonment due to dissatisfaction among the workers, it is reasonable to conclude that wise and efficient management plays a very important part in the success of profit-sharing plans.

Analysis of Profit-Sharing Plans.—Profit-sharing plans introduced as an incentive for the employee to remain in the service of the company and to increase the loyalty and efficiency of the wage-earner almost always require a minimum period of employment as a pre-requisite for participation in the sharing of profits. In only 7 of the 41 cases included in the conference board's 1920 report were the workers permitted to share in the profits immediately after employment. The period of service specified ranged from three months to four years, with one year as the usual eligibility requirement.

Sharing of profits has been found to be most successful where a large proportion of workers are allowed to participate. In most cases after a certain period of employment no discrimination is made between employees on the basis of their efficiency or satisfactory service. The Barnett National Bank and the Oneida Community, Ltd., include all of their employees in the distribution of profits, although the share is increased in proportion to years of service.

The Hammermill Paper Company and the Charles Warner Company share their profits only with a limited number of their employees.

In a few instances employees share the losses of lean years, the most noteworthy example of this policy being the plan of the A. W. Burritt Company of Bridgeport, Conn., which was adopted in 1900 and abandoned in 1922. Under that plan 10% of the weekly wage of each employee electing to participate was held until the close of the current fiscal year. If no profits were earned, this fund was divided between the company and the participating employees on the basis of the ratio between capital stock and the annual pay roll of participants in the same way that the profits were distributed.

The payment of the profit-sharing bonus may be made in cash, stock or certificates which bear interest, or a combination of any two of these. Except where the payment is in cash the profit-sharing system is in effect a thrift or savings plan.

Some companies make a partial cash payment with a deferred share later in order to hold the employee after the period of distribution. Most plants make awards once a year, near the Christmas season.

Limited Profit-Sharing Plans.—In addition to profit-sharing plans of the general type, a number of establishments have plans limited to their principal employees and intended primarily to increase administrative efficiency. This policy has been adopted by the Dennison Manufacturing Company which also maintains a modified profit-sharing system for the wage-earners. The limited plan provides for the issue of industrial partnership stock solely to the principal employees in amounts based on total yearly profits after a guaranteed return to capital. This stock carries voting power provided that the dividends on first preferred stock have been paid, but the stock can be held only as long as its owner remains with the company.

When an employee leaves the company he is obliged to exchange his industrial partnership shares for second preferred non-voting stock.

Practical Difficulties.—Organized labour has been hostile to profit-sharing for a variety of reasons. Testifying before the Senate Committee, William Green said labour "is not opposed to principles involved in profit-sharing but . . . to the way in which it has developed and operated. . . . Labor cannot be asked to accept blindly management's decision on what constitutes profits." He insisted that all records ought to be equally available to both sides, that the company's sales policies, executive salary scale, financial policies, and wage structure should be mutually discussed as a basis for profit-sharing and that "collective bargaining should be extended to the field of profit-sharing." Under such conditions labour's attitude would be favourable. John Lewis maintained that labour could not accept as part of its just compensation a share in profits so long as the conditions which control the profits "are completely beyond its control or influence." Employers, too, have serious questions. They have established the plans for any one of several reasons: To promote social justice, reduce labour turnover, increase the interest and loyalty of their employees, encourage thrift, increase efficiency and decrease restriction of output. Often they cannot see that the end sought is achieved.

Many plans have failed to produce economies or increases in efficiency equal to their cost, others have been discontinued because of labour troubles.

A smaller percentage have been ended by the employees asking for higher wages in lieu of profit-sharing.

Uncertainty of profits is, perhaps, the most disturbing factor—uncertainty as to whether there will be any profits, how large they will be, and whether the distribution of them will be on a mutually satisfactory basis.

Present Status of Profit-Sharing.—Although profit-sharing has been successful in a number of instances, it is doubtful whether it is gaining ground at the present time. The underlying purpose of profit-sharing, which was to create a bond of mutual interest between management and workers and to promote greater co-operation and efficiency, has found expression in other forms, such as co-operative thrift and savings schemes, stock purchase plans, benefits for sickness and accident, group life insurance and pension or retirement plans. The profit-sharing systems of some companies have continued to exist through the years, although the details of the plans have been modified from time to time. The N. O. Nelson Manufacturing Company of St. Louis operated on a profit-sharing basis from 1886 to 1935. The Bourne Mills of Fall River, Mass., has continued to share profits with its employees each year, with the exception of 1904, since 1899. Although the plan of the Baker Manufacturing Company has been in existence since 1894, it was not until 1899 that profit-sharing actually became effective.

The most significant development in profit-sharing has been its application in unionized plants. At least seven companies now have profit-sharing in union plants. In all cases the control of profit-sharing is entirely in the hands of the companies but in three of them the unions have insisted upon discussion of the plan at bargaining time. A few unions have asked for profits-shares in addition to the wages provided by the agreement.

Other Countries.—The Dutch schemes, though mostly very small, present many interesting and original features; and Switzerland has the unique experiment of a scheme in the Federal postal service, which was, however, abandoned after four years, in 1873.

PRO FORMA INVOICE. When a consignment of goods is made for sale on commission, or when goods are forwarded on approval, it is usual to invoice them in a form identical with that of an ordinary invoice but bearing the endorsement "Pro forma." The consignee is thus fully advised of the contents, descriptions, qualities and prices of the goods consigned.

PROGNATHISM, the term applied with its opposite *Orthognathism*, to describe the degree of projection of the upper jaw, which is determined by the angle made by the face with the brain-cap. (*See* CRANIOMETRY.)

PROGNOSIS, a term used in modern medicine, as it was in Greek, for an opinion, forecast or decision as to the probable course, duration and termination of a case of disease. It is to be distinguished from "diagnosis," the determination or identification of a disease in a particular case from an investigation of its history and symptoms.

PROGRAMME MUSIC, a nickname which is the only current term for instrumental music without words but descriptive of non-musical ideas. Musical sounds lend themselves to descriptive purposes with fatal ease. A chromatic scale may suggest the whistling of the wind or the serenades of cats. Reiterated staccato notes may suggest raindrops or the cackling of hens. Again, music is powerfully suggestive of emotion; and the emotions it calls up may fit some particular story, or may resemble those inspired by a sunset or a storm. But chromatic scales, reiterated notes, emotional contrasts and climaxes, are also normal musical resources; and nothing infuriates a musician more than the non-musical explanation of such things where the composer's aim was purely musical. Sound as it occurs in nature is too inorganic to form the raw material for art, and so there is no natural tendency in music to include, as a "subject," any item not inherent in the art-form. Explicit programme music has thus never been a thing of cardinal importance, though it has often been prominent and always popular. Rut the conditions of artistic creation are not to be confounded with any correct theory of art. The doctrine of art for art's sake is correct: but it concerns results, not processes; and many of the purest works of art have been produced for ulterior purposes

Until recent times no composer has written for the voice without words; for speech is a privilege which the human voice will not willingly renounce No doctrine of absolute music will prevent a good composer from shaping his vocal music to the words which he sets. Good literature will inspire him to explore and express its inner meaning. Bad literature may suggest to him the truths it misrepresents; and the great composers are quicker to seize the truth than to criticize its verbal presentation or to suspect insincerity. The earliest mature musical art was, then, inevitably descriptive, since it was vocal. While programme music derives many of its characteristics from ancient times, it cannot properly be said to have existed until the rise of modern instrumental music, based upon external ideas and independent of the use of words.

A complete code of musical symbolism came to maturity in the 16th century. Part of it was profoundly true and characteristic of moods; part was harmlessly mechanical; and a few details were manifestly false, as when "atra nox" is represented by a curiously jaunty rhythm because that rhythm is indicated by black notes. When symbolism, true or false, has thus arisen in vocal music it may be expected to retain its intention in music without words. But we must not expect too much descriptive power in early instrumental music; and when a scholar tells us that a funeral piece for organ by Froberger depicts in its final rising melisma the ascent of the soul to heaven, he unwittingly accuses Froberger of sinister intentions in a precisely similar funeral piece which ends with a descent to the lowest bass.

The resources of the modern orchestra can attain a realism which at first seems iess ridiculous than that of earlier descriptive music. But the expensive realism of the dozen muted brass instruments that in Strauss's *Don Quixote* accomplish in ten rehearsals what a flock of sheep achieve extempore, is not less, but more childish than the thunderstorm in the Fitzwillian Virginal Book.

Beethoven's Theory of Expression.—On the other hand when superior persons object to the childishness of the birds and the thunderstorm in Beethoven's *Pastoral Symphony* it is they who are childish in supposing that realism is in question at all. The real cuckoo, nightingale and quail happen to be musical birds whose themes are exactly what Beethoven wants for a break in the rhythm at a point of repose in the coda of his slow movement. Similar final digressions can be seen in slow movements with no programme at all, *e.g.*, in the violin sonata of 24, the pianoforte sonata in D minor (op. 31 No. 2), and the string-quintet in C major, op. 29. Not a bar of the *Pastoral Symphony* would be otherwise if its "programme" had never been thought of. The "merry meeting of country folk" is a subject that lends itself admirably to Beethoven's form of *scherzo* (*q.v.*); and the thunderstorm, which interrupts the last repetition of this scherzo and forms a tremendous introduction to the peaceful finale, is as musical as other unique features in Beethoven's pure art-forms.

Beethoven is recorded to have said that he always composed according to a "picture" he had in his mind; and he sometimes gave his friends an explanation, jocular or evasive, of some particular composition. But the word *Bild* is much more indefinite than "picture"; and Beethoven's dull Boswell, Schindler, often exasperated him into defending himself by saying the first nonsense that would serve to stop foolish questions. Composers who have much to express cannot spare time for translating it into other terms than those of their own art. The *Eroica Symphony,* though inspired by Beethoven's short-lived belief in Napoleon as the liberator of mankind, is not programme music at all. The funeral march represents heroic death and a mourning world, but not the obsequies of a biographical subject; and when critics tell us that the finale is ('an inappropriate concession to sonata form" they merely show themselves unmusical without thereby becoming literary. The profound and subtle sonata *Les Adieux, l'Absence et le Retour* is true programme music. It represents Beethoven's feelings on parting from the Archduke Rudolph when the royal family left Vienna shortly before its bombardment. It deals only with the parting, the absence and rejoining of the two mrn. Nothing is heard of war, and the sentiment is as deep as it is manly. Beethoven's private sketch-books record that the work is "written from the heart": no courtly formula, even if this was shown to the Archduke. Ingenuity is misplaced in tracing external details. (The end of the first movement of *Les Adieux* has been compared to the departure of a coach.) The real emotional basis is universal and musical.

Beethoven summed up the whole theory of great programme music in his note to the Pastoral Symphony; "rather the expression of feelings than sound-painting." Overtures to plays or operas cannot so easily dispense with story-telling; but Beethoven refuses to be drawn into a chronological series of illustrations. His overtures to *Coriolan, Egmont* and *Leonora* deal with salient emotions roused by their subjects. Wagner was able to place the substance of the *Coriolan* overture in Shakespeare's scene between Coriolanus and his mother and wife before the gates of Rome; but Thayer found that the forgotten poet Collin's play, which was Beethoven's subject, sheds far more light on the music. The music, however, once it took shape, could do without Collin or Shakespeare. The *Leonora* overture was at first (in the form known as No. 2) a huge prelude to the opera, with a gigantic exposition and development, and the shortest wind-up compatible with adequacy, after the trumpet-call behind the scene has relieved the tension. In the later version (*Leonora No. 3.*) Beethoven ruthlessly compresses the exposition until the trumpet-call becomes the middle point of the design, which afterwards expands in a further development, full recapitulation and a climax which makes this overture the first and greatest of all "symphonic poems" (*q.v.*). Critics who cavil at the trumpet-call as a weakness from the point of view of absolute music only show that they cannot tell absolute music from absolute nonsense. Distance is surely too elementary a phase of sound to be excluded from absolute music, nor can the fanfares of a trumpet be separated either from the instrument or from its associations. As a piece of absolute music *Leonora No. 3.* is a huge movement in sonata form rising steadily to a point at which the tension is relieved by the new incident of a distant trumpet-call, after which the music expands from sheer joy. Beethoven's maxim *mehr Ausdruck der Empfindung als Malerei* therefore holds here, and bridges the gulf between absolute and illustrative music.

Portrayal of Characters and Moods.—This is equally true with archaic and modern programme music; it is always characters and moods that are successfully portrayed, while chronology is useless and the illustration of incidents is apt to be ridiculous unless it contrives to be witty. Thus, the *Bible Sonatas* of J. Kuhnau (published in 1700) and their clever imitation in Bach's early *Capriccio on the Departure of a Beloved Brother* rely mainly on moods, and are successful with incidents only when these would be accompanied by music in real life or drama. If Kuhnau's music were half as vivid or inventive as his prose introductions it would be immortal. But much may be learnt from noting how his unconsciously humorous prose describes other things than the music attempts to portray and omits the very things in which the music is at its best. While Kuhnau strains himself, like a bad nurse telling bogey-stories, in his prefatory description of the size and appearance of Goliath, in the music it is the boasts (*le bravate*) of Goliath that are portrayed. The best movement in the Goliath sonata is a figured chorale (*Aus tiefer Noth schrei' ich zu Dir*) representing the terror and prayers of the Israelites. On the other hand the cast of David's sling, with the fall of Goliath, is not nearly so sublime as the fall of a tea-tray. Kuhnau's other subjects (*Saul cured by David's music; The Marriage of Jacob; The Healing of Hezekiah; Gideon,* and *The Funeral of Jacob*) are all thoroughly musical; more so than he succeeds in making them. Bach's *Capriccio* describes the anxiety and sorrow of the friends of the departing brother; and his utmost realism takes the form of a lively fugue on the themes of the postilion's coachhorn and cracking whip. Buxiehud illustrated the "nature and characters of the planets." This is an astrological, not an astronomical subject: the planets signify temperaments and their motions are the music of the spheres. No wonder, then, that this musical subject has been adopted in one of the outstanding masterpieces of modern orchestral music, *The Planets,* by Rolst.

Adaptability of Lyrical Music.—Instrumental music on the lyric scale lends itself to illustrative purposes more readily than larger forms. Nearly all the harpsichord pieces of Couperin have fantastic titles, and a few of them are descriptive music. His greater contemporary and survivor, Rameau, wrote important operas and much extremely graphic harpsichord music. *La Poule,* with its theme inscribed "co-co-co-co-co-co-cocodai," is an excellent movement in spacious form, and is also one of the most minutely realistic compositions ever written. French composers have always contributed *con amore* to music that takes advantage of external stimulus; and already in 1801 descriptive music was considered so specially French that Haydn apologized for his imitation of frogs in *The Seasons,* saying that this "franzosische Quark" (rubbish), had been forced on him by a friend. But throughout the growth of the sonata style, not excepting Haydn's own early work, the tendency towards gratuitously descriptive music often appears; partly because there was no definite distinction between early symphonic music and overtures or incidental music to plays (*e.g.,* Haydn's *Il Distratto).* Dittersdorf's symphonies on the metamorphoses of Ovid are excellent music in which the descriptive elements do not disturb the symphonic form until the metamorphosis which is then illustrated in almost Wagnerian breadth. For instance, the first three movements of the *Change of the Lycian peasants into Frogs* show the rusticity of the peasants, the gracefulness of the goddess, and the rudeness of the peasants to the goddess; and then the finale indicates an altercation ended, after a pause, in a low mysterious quivering sound as of frogs in a marsh.

Dittersdorf is not a great composer; but many more learned and resourceful artists have shown less than his common-sense in distributing the descriptive and the formal elements of their music. It seems incredible that any composer could be so foolish as to commit himself to describing a chronological sequence in a sonata-form which compels him to go through a full restatement of events which only happened once; yet many composers refused to abandon either the sonata form or the chronological sequence. Lyric forms presented no such difficulties.

Schumann and **Spohr.**—Schumann sometimes invented his titles after his pianoforte lyrics were finished, and sometimes wrote on the inspiration of literature. In either case, as with Beethoven, the music throws far more light on the programme than the programme throws on the music. Musical people may profitably study E. T. A. Hoffman and Jean Paul Richter in the light of Schumann's *Novelletten* and *Kreisleriana;* but if they do not already understand Schumann's music, Jean Paul and Hoffman will help them only to talk about it. In revising his early works Schumann sometimes made them more musical and sometimes destroyed grotesque touches that are musically as well as psychologically true. For instance, in the *Davidsbündler-tanze* (op. 6.) the hot-headed Florestan, having finished an impassioned tirade, feels that he has been making a fool of himself. His last note pauses unharmonized and he sits down awkwardly. In a later edition, with unnecessary scruple Schumann suppressed this detail together with the prose titles and signatures. The fashion of fantastic titles affected even the most formal composers during the romantic period.

No one wrote more programme music than Spohr; and, while Spohr's programme constantly conflicted with the externals of his form and ruined the latter part of his symphony *Die Weihe der Tone,* it did not broaden his style. Mendelssohn's Scotch and Italian symphonies, and his Hebrides overture, are cases of generalized local colour. His Reformation symphony, which he himself regarded as a failure, and which was not published until after his death, is a descriptive work less attractive but more coherent than Spohr's *Weihe der Ton.* The overture to the *Midsummer Night's Dreatn* is a marvellous musical epitome of Shakespeare's play and the comparative slightness and conventionality of its second theme closely correspond with Shakespeare's two pairs of lovers, though it does not illustrate their quarrels under the fairy spells.

Influence **of Berlioz.**—Berlioz made programme-music a vital issue in the 19th century. With an inextinguishable gift for voluminous composition he is utterly incapable of focussing his attention on either his music or his programme. The most trivial external detail may distract him at the height of his rhetoric. The moonshine and sentiment of the *Scène d'amour,* in his *Romeo and Juliet* symphony is charming; and the agitated sighing episodes which interrupt its flow, can be understood in the light of

Shakespeare's balcony scene, if not by their musical sense. But when Berlioz thinks of the nurse knocking or calling at the door, he makes a realistic noise without either musical or dramatic purpose. It does not interrupt the duet, nor increase the emotional tension, nor illustrate Juliet's artifices for gaining time, nor her agitation at the interruptions of the nurse. Perhaps this was the passage on which a lady once congratulated Berlioz for his vivid representation of *Romeo arrivant dans son cabriolet.* This piece of purely orchestral music has an introduction in which real voices are heard from convivial persons returning home from the ball. Berlioz complains that the public has no imagination and that therefore certain sections which presuppose an intimate knowledge of Shakespeare's play *avec le dénouement de Garrick* should be omitted. But what the public lacks for these sections is neither imagination nor familiarity with Garrick-Shakespeare, but a capacity to take the butterfly vagaries of Berlioz's mind as their basis of reference.

With all his absurdities, Berlioz's genius for composition carried him further towards a new music than Liszt was able to advance in his symphonic poems. These, as has been said in other articles *(see* MUSIC, sections 8–10, and SYMPHONIC POEM) are the beginnings of an instrumental music that achieves the same continuity as Wagner achieved in music-drama. But Liszt hardly even began to achieve the right sort of movement; and his conscientious plan of deriving the whole piece from transformations of a single figure was quite irrelevant even when it was effective. As a musical illustrator he is clever; but he ties himself down to chronological sequence, which, though it does not conflict with his forms, is always open to Weingartner's objection that it cannot control the pace of the listener's thoughts. The composer's first view-halloo may make one listener fancy himself in at the death of the Blatant Beast, while the mind of another will plod to the end, to learn that that event never takes place.

Strauss.—The symphonic poems of Strauss are invulnerable by this objection, even though it is often true of their details. Most listeners will probably identify Don Quixote's tilting at windmills with the passage in which Strauss uses a stage windmachine; but this represents a later adventure in which Don Quixote and Sancho are seated blindfoid on wooden horses and are persuaded that they are flying on winged steeds through the air. Strauss's music, however, does not really depend on this sort of thing at all. His earliest symphonic poems are masterpieces of new form and movement: *Don Quixote* is sectional only because its subject lends itself to an episodic treatment which Strauss has as much right as Humpty Dumpty to call variations, and in it, no less than in *Also sprach Zerathustra, Ein Heldenleben,* the *Sinfonia Domestica* and their aftermath the *Alpensinfonie,* single designs are triumphantly accomplished in music of Wagnerian continuity. It is not necessary that the designs should be perfect. Uncles and aunts may interrupt it to say that the baby is the image of its dada or mamma; and the wickedness of critics may devastate pages of the music of the hero who gave them their opportunity when he paused on a dominant chord to look round for applause; but local defects do not annihilate fundamental qualities.

Caricature. — One thread remains to be gathered into this account. Caricature is a rare and dangerous element in music, but it is as old as Orlando di Lasso. Mozart, besides the subtleties of *Cosi fan tutte* and the comic parts of *Die Zauberflöte,* produced in his *Musikalischer Spass,* a burlesque of village players and bad composers. On paper the work is a delicious study in the psychology of "howlers," and in its finale Mozart idealises all the nightmare stagnation of the composer whose *tempo* gets faster and faster while his phrasing gets slower and slower. In performance the effect is even more surprising than analysis would lead the reader to expect. But the Leipzig editors of the parts have crowned Mozart's farce by correcting the mistakes!

Caricature enters prominently into Strauss's *Till Eulenspiegel, Don Quixofe* and *Ein Heldenleben;* and also into many passages in Mahler's symphonies. Its danger is that it often opens these composers to suspicion when they intend to be touchingly simple.

But nothing is more vexatious than the laying down of *a priori* limits to what is legitimate for artists. If sermons in the mind of the painter help him to paint, and pictures in the mind of the composer help him to compose, by all means let them get on with the work. (D. F. T.)

PROGRESSIVE EDUCATION MOVEMENT, THE (in Europe called New Education) is the 20th century expression of new ideas inherited from Comenius, Rousseau, Pestalozzi and Froebel. Progressive leaders sprang up in both America and Europe simultaneously but independently at the end of the 19th century. In Chicago, Ill., Col. Francis W. Parker and Prof. John Dewey, each for himself, began teaching and practising the philosophy of education which forms the intellectual basis of the movement. In Europe three men inaugurated the movement in their respective countries: Cecil Reddie in England, 1889, Herman Lietz in Germany, 1898, Edmond Demolins in France, 1898. In the United States the Progressive Education Association and in Europe the New Education Fellowship have for ten years led the movement and promulgated its underlying ideals. Progressivism with its new spiritual element, its discontent with traditional practices, and its vision of a finer procedure, has notably affected American education, both private and public, from nursery school to university. The leaders of the movement advocate, and put into practice, the following beliefs: (1) education at any age should be a natural growth involving experiences — physical, mental, moral, social and spiritual — adapted to the age, health, interests and abilities of each pupil; (2) genuine education develops, not through imposed formal learning from books and lectures, but only through self-directed, spontaneous activities, preferably pursued in group situations; (3) interest aroused in an atmosphere of freedom is the proper incentive to effort, not the external compulsions of authority, penalties and rewards; (4) the finest education is that which through inspiration and opportunity stimulates and releases native power, resulting in original thinking, action or creation; and (5) educational processes, like processes of growth, involve continuing change and are subject to improvement through experimentation.

Four influences have contributed vigour to the movement: (1) the needs created by recent social-economic developments; (2) the rise of the human sciences — biology, physiology, psychology and psychiatry; (3) the challenge of democracy and individualism to the authoritarian traditions of mass education; and (4) the extension of altruistic idealism to include childhood and youth. (M. S.)

PROGRESSIVE PARTY. The title Progressive party has been taken twice in the Cnited States by third-party movements, first in the presidential campaign of 1912 and again in 1924.

The Progressive party movement of 1912 was heralded by the "insurgent" outbreak among Republican members of Congress in 1910, which succeeded in reducing considerably the powers of the speaker of the House of Representatives. Opposition to the administration of Taft, then President, took concrete form early in 1911 when the National Progressive Republican League was organised under the leadership of Senator R. M. La Follette of Wisconsin. During the following year, however, Theodore Roosevelt placed himself at the head of the Progressive movement. Alleging unfair tactics on the part of the "Old Guard," his followers left the Republican national convention held in Chicago (June 1912), and Roosevelt was nominated for the presidency by a Progressive national convention also held in Chicago early in August of the same year. As a result the Republican party was hopelessly split, Roosevelt receiving a popular vote exceeding that of Taft by more than 600,000. Woodrow Wilson, Democratic candidate, was successful, obtaining the electoral vote of all except eight states.

In 1916 harmony was restored in the Republican party. Roosevelt declined a second Progressive nomination and supported the Republican ticket. During World War I partisanship was in abeyance, but upon its termination the old rift soon reappeared. The administration of Harding encountered increasing agrarian dissatisfaction, and this was true also of the first portion of the Coolidge administration. In 1924 the contingent from Wisconsin and neighbouring states, after sitting in the Republican convention at Cleveland, held a conference for progressive political action, made up chiefly of farmer, labour and socialist delegates. Senator R. M. La Follette was nominated for the presidency, and later Senator B. K. Wheeler of Montana for the vice-presidency. The platform promised a complete house cleaning in the executive departments, public control of national resources, public ownership of railways, tariff and tax reduction, agricultural relief, labour legislation, public referendums on peace and war, direct nomination and election of the president, extension of the initiative and referendum to the federal government, election of federal judges and a constitutional amendment providing that congress may by re-enacting a statute make it override a judicial veto. Republican strategy during the campaign of 1924 consisted largely in denouncing the alleged ultra-radicalism of the La Follette platform, particularly the planks concerning the judiciary, meanwhile for the most part ignoring Democratic attacks. This strategy was completely successful, Coolidge receiving an enormous majority both of the popular vote and in the electoral college. La Follette carried only his own state, but polled almost a sixth of the popular vote. No effort was made to continue the organization after the campaign. (See UNITED STATES: Hisfory.)

Robinson, *Evolution of American Political Parties* (1924); E. M. Sait, *American Politics and Elections* (1927); and H. R. Bruce, *American Parties and Politics* (1927). (R. C. B.)

PROHIBITION is a method for the legal regulation of the manufacture, sale and transportation of alcoholic beverages. It has such extensive and varied applications as to make its other uses in legal terminology of minor importance. National prohibition was adopted in the U.S.A. by the ratification of the 18th amendment to the constitution, Jan. 16, 1919, effective one year thereafter, and repealed by the ratification of the 21st amendment, Dec. 5, 1933. Both amendments were adopted by large majorities only after full and free discussion, with determined and well-directed opposition, and neither can truthfully be said to have been "put over" by a fanatical minority or selfish economic interest.

National prohibition was the logical result of nearly 100 years' experience with state and local prohibition. It was not adopted without due appreciation of the difficulties it would encounter, nor until other expedients were tried to avoid the necessity of this experiment. Some of these expedients and the legislative background of national prohibition and its repeal are more fully discussed in the article LIQUOR LAWS AND LIQUOR CONTROL (*q.v.*). Well-considered public opinion, pro and con, with respect to prohibition, cut deeper across the lines of political parties, rural and urban life, churches and families than any other question of the generation in which the 14 years 1920–33 fell. Its application on a national scale over an area so large as the U.S.A., and to a population living under such diverse racial and climatic conditions, made it by common consent the greatest social experiment of modern times.

Local Option and State Prohibition. — Local option started in Maine (P.A. 1829, c. 133), Indiana (L. 1832, c. 170) and Georgia (A. 1833, 125) in the first third of the 19th century, and state prohibition in Maine in 1851. Most local option statutes permitted the electorate in local political units, usually counties, but sometimes cities, villages, towns and even districts of a city, to vote "yes" or "no" on licences to sell "on" or "off" the premises for a limited period, usually one or two years. Some statutes embodied the local option principle by requiring a licence applicant to get the approval of a majority or two-thirds of the voters in the area to which the licence applies; or providing that no licence be issued, if a majority petitioned for its refusal. Other variations of local option were tried. Thus Arkansas (Digest Stat., 1884, par. 4515) had prohibition with a "licence" local option, and Iowa had prohibition for a time with selling permitted under the mulct law, Code (1897) par. 2448. (*Cf.* Clark Byse, "Alcoholic Beverage Control Before Repeal" [in "Alcoholic Beverage Control" (1940)], *Law and* Confemporary Problems, vol. vii, No. 4, Duke University Law School.)

Licensing systems date back to colonial times. Combined with local option they furnish for the U.S.A., in the light of its experience with both state and national prohibition, the best hope for the possible effective application of the principle of prohibition. A properly drafted high licence statute with local option for prohibition in well-defined areas, or a prohibition statute with local option for licence in carefully planned areas, would go far to remove the majority of the social evils of the liquor traffic without resort to absolute prohibition. State licence systems in the absence of similar legislation by congress have been upheld by the U.S. supreme court as a constitutional exercise of the state police power. (Cf. *The License Cases,* 46 U.S., 5 How., 504, 1847).

State prohibition stems from the development of the temperance movement of the second quarter of the 19th century. In the first quarter that movement was primarily individualistic. The thousands of temperance societies in the northern states, most of them in New England, resulted from a great religious revival and their efforts centred in personal regeneration and what the individual could do for himself. Its progress though encouraging was too slow to stem the rising tide of liquor consumption and its disastrous social consequences. The next logical step was to federate the temperance societies in strong state and national associations and exert political power to regulate or prohibit the production and sale of intoxicating beverages. The greater and more influential national organizations like the Woman's Christian Temperance Union (W.C.T.U.), the National Temperance society, the Total Abstinence brotherhood (T.A.B.), the National Prohibition party and others took up the cudgels after the Civil War; and the Anti-Saloon league with its powerful state and national organization, in the closing years of the century.

The continuous agitation of the temperance societies resulted in "limited" state-wide prohibition by an Indiana statute (1816) making sale of liquor on Sunday illegal, and the "15 gallon" law in Massachusetts (L. 1838 c. 157) prohibiting sale of "less than 15 gallons of spiritous liquor or mixed liquor part of which is spiritous (except for medicinal and mechanical uses) to be delivered and carried away at one time." This apparently accomplished little and was repealed in 1840. The first absolute state prohibition law, due to Neal Dow, organizer of the Maine Temperance Union, was an act "to restrict the sale of intoxicating drinks," approved Aug. 7, 1846. It was too weak in many of its provisions to be effective but was strengthened by the act "for the suppression of drinking houses and tippling shops" approved June 2, 1851. This act repealed all but 13 sections, those containing certain enforcement provisions, of the 1846 statute. The Maine law of 1851 remained substantially unchanged for 70 years and became the model in the next decade for no less than 13 state-wide prohibition laws. But by 1863 in all but five of these states the statutes were repealed or invalidated by state supreme court decisions.

(*Cf.* Ernest A. Grant, "The Liquor Traffic before the Eighteenth Amendment," in *Annals,* vol. 163, Sept. 1932.)

The second stage of organized effort for state prohibition was an outgrowth of reconstruction following the Civil War. It began with the organization of the National Prohibition party in 1869 at Chicago, and the Woman's Christian Temperance Union (1874); marked the return of sbme states that had tried prohibition in the first period and had given it up; and reached its zenith in the decade 1880–90. Eight states enlisted but only three remained by 1904.

The third and last stage of state prohibition before national prohibition was tried covers the first two decades of the 20th century, was largely due to southern and western rather than New

England forces, and was led by the Anti-Saloon League of America (1895) and the state anti-saloon leagues. Thus when national prohibition went into effect (Jan. 1920) state-wide prohibition under state laws was already in effect in 33 states (more than two-thirds of all the states), and in 18 of them by constitutional amendment adopted or ratified by referendum election. In addition Alaska, Puerto Rico, the District of Columbia and Hawaii were included in 1917–19 in the prohibition area. Ninety per cent of the townships and rural precincts, 85% of the counties and more than 75% of the villages of the United States were under prohibition by state legislation. Two-thirds of the members of the senate and house of representatives came from states or districts having state prohibition which together with local option had put 63.3% of the population and 95.4% of the land area under prohibition. These statistics and similar ones for local option alone may be misleading unless cautiously interpreted as to their real significance, as later experience with national prohibition amply demonstrated. They are not an exact measure of the dryness of a community because often they do not mean a desire to be rid of liquor altogether but only the ugly aspects of the saloon and the liquor traffic in a residential neighbourhood so long as ample supplies may be had from near-by wet areas. Many communities find the ubiquitous bootlegger the lesser evil, and "near-by" has been greatly extended by improved transportation facilities, roads and automobiles. (Cf. The *Local Option Fallacy,* Distilled Spirits Inst., Washington, D.C., rev. ed., Oct. 1942, p. 32; Raymond B. Fosdick and Scott, *Toward Liquor Control,* pp. 22–27.)

Federal Aid to State and Local Prohibition.—It has been said that "liquor consumption did not decrease during the period when the state-wide prohibition movement was strongest" (C. Byse, *op. cit.,* p. 561). The statistical support for such a statement is far from conclusive. Such evidence as does exist, like that regarding local option and state prohibition, must be examined with caution, and deductions and implications made with reserve. If per capita consumption of spirits, wine and beer be combined and some allowance be made for mounting illegal consumption in the years when state prohibition was strongest, possibly a fairly tenable case can be made for the assertion just quoted. but the implied charge that this is the measure of the so-called breakdown of state prohibition is far from true. The cost and difficulties of enforcement, and the protection of dry areas from the inroads alike of the liquor traffic and bootleggers from bases in near-by wet areas were objects of greater concern to the supporters of prohibition.

The states first sought in various ways to protect their dry areas by their own powers. For example, Texas in 1910 made the sale of liquors in no-licence territory a felony. All tried to check the flow of liquor having the constitutional protection of interstate commerce over which the federal government had exclusive jurisdiction. For 43 years the U.S. supreme court followed the rule laid down in the celebrated License Cases (46 U.S., 5 How., 504, 590, 1847) that state legislation could prohibit the sale of liquor without a licence even if imported in the original barrel brought in by interstate commerce. This reversed a ruling in 1827 that held a state law unconstitutional which imposed a licence tax on an importer of liquor. But the still more celebrated Original Package case in 1890 practically reversed the 1847 rule by holding that a state could not prohibit a liquor dealer from importing liquor in interstate commerce for resale in original packages (135 U.S. 100, *Leisy* v. *Hardin*). This nullified state prohibition and congress at once sought by the Wilson act (26 Stat. 313, 1890) "to divest intoxicating liquors of their interstate character" by providing that "liquors transported into a state . . . shall . . . upon arrival in such state . . . be subject to the operation and effect of the laws of such state enacted in the exercise of its police powers, to the same extent . . . as though such . . . liquors had been produced in such state." While this act presented grave constitutional difficulties, the supreme court upheld it in *In re Rahrer* in 1891 (140 U.S. 545), but in a later case (*Rhodes* v. *Iowa,* 170 U.S. 412, 1898) the court construed the word "arrival" to mean delivery to the consignee and not merely arrival in the state. So the mail-order business, skilful advertising and travelling salesmen still made the evasion of prohibition easy. The U.S. supreme court did try to help the states to find their own remedy, by upholding (1) a Missouri statute which imposed an inspection fee on all liquors shipped from other states into Missouri and offered for sale (190 U.S. 17, 1905), and (2) a South Dakota statute putting an annual licence charge on the business of soliciting orders to be filled from liquors at the time outside the state (*Delameter* v. *South Dakota,* 205 U.S. 93, 1907). In some other cases, however, the Wilson act was further emasculated, by refusing the state the right to prohibit C.O.D. shipments of liquor (*Adams Express Co.* v. *Kentucky,* 206 U.S. 129, 1907), and by not permitting a state to compel a resident-consignee to certify to a state official the quantity and kind of liquor to be imported, or a nonresident-consignor to attach a certificate to the package (*Vance* v. *Vandercock,* 170 U.S. 438, 1898).

The Webb-Kenyon Act.—Passed March 1913, over President William Howard Taft's veto, "An Act divesting intoxicating liquors of their interstate character in certain cases" (37 Stat. 699) was the most aggressive step that congress and the federal government had taken to aid state prohibition. Broader than the Wilson act which merely sought to remove the bar of the original package decision, it was intended to remove the federal protection which liquor enjoyed as an article of interstate commerce. It forbade the transportation of intoxicating liquors into a state by any persons interested therein "to be received, possessed, sold or in any manner used either in the original package or otherwise, in violation of any law of such state." Notwithstanding President Taft's own opinion, and that of his attorney-general, and able lawyers in the senate who advised him, to the effect that the act was unconstitutional, the supreme court sustained it in the Clark Distilling Co. cases, decided Jan. 8, 1917 (242 U.S. 311). This was further strengthened by the adoption of the Reed "bone-dry" amendment to the P.O. Appropriation act of March 3, 1917 (39 Stat. 1069, c. 162) which sought to eliminate completely the illegal mail-order liquor traffic.

The Webb-Kenyon law at first stimulated state prohibition. In 1914 state constitutional amendments were adopted by popular vote and substantial majorities in Arizona, Colorado and Oregon, but rejected by substantial majorities in California and Ohio. Statutory prohibition was adopted in Washington on an initiative measure by 18,632 majority, and in Virginia by a majority of 30,365 in 150,000 votes cast. Congress for the first time adopted in this year a resolution in one house by a majority vote (193–189), but it did not obtain the requisite two-thirds required for the submission of a prohibition amendment to the federal constitution. Considerable extension of dry territory under local option votes was secured in many other states. In 1915 Alabama re-enacted a prohibition law adopted in 1907 but repealed in 1911; and Idaho, Iowa. Arkansas and South Carolina adopted state prohibition statutes. Idaho also submitted to the people a constitutional amendment to the state constitution which was adopted the following year. The year 1916 also recorded the adoption of constitutional state prohibition in Michigan, Montana, Nebraska and South Dakota.

In 1917 the resolution for the submission of the prohibition amendment to the federal constitution received the necessary two-thirds vote in congress which also enacted prohibition for the District of Columbia and the territory of Alaska. A referendum on prohibition was voted on in Puerto Rico in July and adopted by 99,774 votes for prohibition to 61,295 against. Indiana, New Hampshire and Utah adopted state-wide prohibition statutes, and New Mexico, a state constitutional amendment. Minnesota voted also for a constitutional amendment by a majority of 15,932 of all the votes cast, but this was 756 short of the majority the state constitution required for its adoption. Missouri and California defeated constitutional amendments by substantial majorities. By the end of this year before the federal amendment was submitted for ratification, statutory or constitutional prohibition mas the law in 25 of the 48 states, and in the District of Columbia, Alaska and Puerto Rico. In nearly every state in one way or another dry territory had been greatly extended.

In 1918, while ratification was proceeding, Florida, Nevada, Ohio, Texas and Wyoming adopted state-wide prohibition statutes, and Utah a prohibition amendment to its state constitution. Congress enacted a prohibition statute for Hawaii, and passed the War Prohibition act as an amendment to the agricultural appropriation bill. Several states adopted constitutional prohibition amendments in 1919.

The 18th Amendment.—The text of the amendment ratified Jan. 16, 1919, by the 36th state making the necessary three-fourths of all the states required for its adoption is as follows:

> "Section 1. After one year from the ratification of this article the manufacture, sale, or transportation of intoxicating liquors within, the importation thereof into, or the exportation thereof from the United States and all territory subject to the jurisdiction thereof for beverage purposes is hereby prohibited.
>
> "Section 2. The Congress and the several States shall have concurrent power to enforce this article by appropriate legislation.
>
> "Section 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the Legislatures of the several States, as provided in the Constitution, within seven pears from the date of the submission hereof to the States by the Congress."

The amendment as ratified and proclaimed in effect on Jan. 16, 1920, was subsequently ratified by ten additional states, and in six of these (South Dakota, Idaho, Washington, Kansas, Utah and Wyoming) by unanimous vote in both houses of the legislature. Only two states (Connecticut and Rhode Island) did not ratify it. Dr. Ernest H. Cherrington in an article entitled "World Wide Progress Toward Prohibition Legislation" *(Annals,* vol. 109, p. 223, Sept. 1923) says: "No amendment to the Federal Constitution ever received as strong official sanction by the States as the 18th amendment. The original Constitution was adopted in the thirteen original States by a majority of about two to one. The aggregate vote in the State senates and State houses of representatives for the ratification of the 18th amendment shows a majority of more than four to one."

Forty-seven states enacted laws to help carry into effect the provisions of the 18th amendment, though one such law in Nevada was held unconstitutional because of a defect in title. New York, Montana and Wisconsin repealed their enforcement statutes by the end of 1929, but until then the great mass of state legislation tended to strengthen state efforts to enforce prohibition. In the next five years, however, by the end of 1934, all but nine states had voted to repeal their statutory or constitutional prohibition measures, or both, or they had enacted liquor control of the state monopoly or licence type, sometimes with local option for limited prohibition. After the repeal of the 18th amendment by the ratification of the 21st amendment, effective as of Dec. 5, 1933, and the repeal of the prohibition provisions of the Volstead act in Aug. 1935, there were only three states left (Kansas, Mississippi and Oklahoma) in 1942 with state-wide statutory prohibition.

THE ERA OF NATIONAL PROHIBITION

These 14 Years.—From Jan. 16, 1920, to Dec. 5, 1933, is 14 years lacking a few weeks, a short period in the life of a nation, but a momentous one in the social history of the American people. Not since the slavery issue of the middle years of the 19th century has any question been so widely debated, so bitterly contested or pursued with so much determination and idealism as national prohibition by the people of the United States. It came with surprising suddenness, yet the way had been prepared for over 100 years. The new techniques and devices of a greater variety of governmental agencies employed today in the work of liquor control, rather than prohibition, and a new reliance on scientific research for guidance on the complex problems of alcohol, as exemplified by the Research Council on Problems of Alcohol, of the American Association for the Advancement of Science, and as now carried on by temperance and educational organizations everywhere, and even by agencies of the liquor traffic itself, such as Distilled Spirits Institute, Inc.—these and other similar forces give some assurance that the "experiment noble in motive" of national prohibition may not have been in vain.

The Background Influences.—A sufficient indication of the long-time trends in prohibition legislation in state and nation has already been given lo account in part for the tidal wave of demand for action on a national scale. Social and economic factors played perhaps as great if not a more important role than the more noticeable moral, religious and political influences organized with increasing effectiveness. New scientific knowledge in the early years of the 20th century caused a mounting public interest in health and efficiency, and the new industrial economics of expanding large-scale produrtion brought increasing support, both moral and financial, to every effort to curb the liquor traffic and reduce the ravages of alcohol. New educational forces at work viewed with growing disfavour the saloon as the so-called poor man's club, and finally there was manifest everywhere increasing irritation with the saloon as a political menace.

World War I was not the cause of the demand for national prohibition though it probably did accelerate it. The absent soldier vote if cast at the time would not have made any substantial change in the decisions reached at the polls. As soon as the United States entered the war, two economic factors—the fear of the loss of manpower on account of intemperance, and the loss of food used in the manufacture of alcohol but needed to supply the army of the United States and that of its allies—served to crystallize an overwhelming sentiment in favour of permanent constitutional prohibition as well as war prohibition. The War Prohibition act of Nov. 1918, an amendment to the Agricultural Appropriation bill, enacted ten days after the Armistice was signed, did not go into effect until June 30, 1919, six months after the ratification of the 18th amendment, but it set a standard until the end of demobilization. It forbade the use of grain, cereals, fruit or other food products in the manufacture or production of beer, wine or other intoxicating malt or vinous liquor for beverage purposes, and made it unlawful to sell for any beverage purposes any such product or any distilled spirits from bond except for export. Such acts, together with earlier congressional enactments such as the Food Control act of Aug. 1917 and the act restricting or prohibiting the sale of liquor at military stations or to members of the military forces in uniform, or in or near military camps, all had a markecl effect in support of national prohibition.

The Volstead Act.—The National Prohibition act (41 Stat. 305), popularly known as the Volstead act, and sometimes referred to as the Prohibition Enforcement law, passed the house of representatives. July 22, 1919, by a vote of 287 to 100, three members voting "present." It passed the senate with slight amendments and without a roll call on Sept. 4, 1919. The conference report was adopted in the senate. Oct. 8, without roll call or record vote, and in the house by a vote of 321 to yo on Oct. 10. It then went to President Woodrow Wilson who vetoed it, and returned it Oct. 27. The house on the same day, by a vote of 176 to 55, passed it over the president's veto, and the senate did likewise the next day by a vote of 65 to 20. Therefore on Oct. 28, 1919, this measure became law applicable by its terms immediately for the enforcement of the War Prohibition act, and "when the 18th amendment to the Constitution goes into effect," intended to carry out the purposes of that amendment. The act is notable for its definitions, including the fixing of ½ of 1% of alcohol by volume as the test of intoxicating liquor, and the delegation of power to the commissioner of internal revenue to make regulations, with the approval of the secretary of the treasury, having the force of law, for carrying out the provisions of the act. The ½ of 1% definition was not new. It was in use in many state prohibition laws and had been the standard since 1902 for internal revenue taxation.

The constitutional validity of the adoption of the 18th amendment, and the constitutionality of the Volstead act with its definition of intoxicating liquor were tested in the U.S. supreme court and promptly sustained in the leading cases of *Hawke* v. *Smith,* decided June 1, 1920 (zj3 U.S. 221), and Rhode *Island* v. *Palmer,* decided June 7, 1920 (253 U.S. 350), in which the court disposed of several cases pending. Prohibition as embodied in the 18th amendment was held within the amending power, a part of the constitution, and "must be respected and given effect the same as other provisions of that instrument," and was "operative throughout the entire territorial limits of the United States . . . [and] of its own force invalidates every legislative act, whether by Congress, by a state legislature, or by a territorial assembly, which authorizes or sanctions what the [first] section forbids." The court had previously sustained the War Prohibition act and the ½ of 1% limit which it specified. The liquor interests hoped for greater latitude by construction of the first section of the 18th amendment which did not specify the content or define intoxicating liquor. The court, however, without stating or discussing this contention, cited the war prohibition cases in support of the conclusion that while "recognizing that there are limits beyond which Congress cannot go in treating beverages as within its power of enforcement, we think those limits are not transcended by the provisions of the Volstead Act."

THE WORKING OF THE NATIONAL PROHIBITION ACTS

Enforcement.—The Volstead act provided for drastic enforcement, and was intended to give the government ample powers, through the commissioner of internal revenue of the treasury department, to detect and suppress all manner of violations. Congress was at liberty to amend these administrative features and set up any agency of enforcement it chose. It did in fact put the prohibition unit of the treasury under a new assistant secretary, and by the act of March 3, 1927, created a bureau of prohibition in the treasury department with a commissioner of prohibition responsible directly to the secretary of the treasury.

The Supplemental Prohibition Enforcement act of Nov. 23, 1921, (42 Stat. 222) made the already drastic regulations for physicians' prescriptions, and for sacramental wine, more so. It provided that only spirituous or vinous liquor, the latter containing not more than 24% of alcohol by volume, could be prescribed, and that not more than ¼ gal. of vinous liquor nor any quantity of liquor containing more than ½ pt. of alcohol could be prescribed for the use of any one person within 10 days, and that no physician might have more than 100 permits within 90 days unless to meet emergency needs, to be demonstrated to the satisfaction of the commissioner who issues such permits. These restrictions on physicians' prescriptions were upheld as constitutional by the supreme court in *Lambert* v. *Yellowley* (272 U.S. 581). Other provisions of the Supplemental act gave the enforcing authorities control over importations for non-beverage purposes; provided that both the Supplemental and the National Prohibition acts applied not only to the United States but to all territory subject to its jurisdiction; that liquor laws in force when the National Prohibition act mas adopted, and not in conflict therewith, should continue in force; and also made it unlawful for any U.S. officer to search any private dwelling without a search warrant. The court, however, in 192; in *Carroll* v. *U.S.* (267 U.S. 132) upheld the search of an automobile or vehicle of transportation without a warrant where the search was not malicious or without probable cause. A Georgia statute which prohibited the possession of liquor which had been legally acquired before national prohibition went into effect was upheld as within the police power of the state, in another supreme court decision, *Samuels* v. *McCurdy* (69 L. ed. 371). The department of justice approved the wider use of the padlock and abatement of nuisance provisions of sec. 22 and other sections of the National Prohibition act. The methods employed in the enforcement of prohibition, as in the case of tariff and revenue laws generally, and in other laws where there is a strong motive to defeat their purpose, raise many nice questions of constitutional guarantees of liberty and the protection of innocent persons, but the supreme court decisions throughout the prohibition era went far to sustain the government and congress in the exercise of the fullest constitutional powers to enforce prohibition.

The Concurrent Power.—The second section of the 18th amendment clearly indicates by the grant of concurrent power "to congress and the several states" the joint duty and responsibility of the national and state governments to enforce prohibition through co-operation and each government performing that part of the task for which it was peculiarly fitted. In *Rhode Island* v. *Palmer* (253 U.S. 350) the court defined and interpreted "concurrent power" as the power to enforce prohibition by appropriate legislation, but not to enable congress or the several states to defeat or thwart it; that it is not joint power requiring that the legislation thereunder by congress to be effective should be approved or sanctioned by the several states or any of them; neither does it mean that the power to enforce is divided between congress and the several states along the lines which separate or distinguish foreign and interstate commerce from intrastate affairs. The court also added that concurrent power, "while not exclusive, is territorially co-extensive with the prohibition of the first section of the amendment, embraces manufacture and other intrastate transactions as well as importation, exportation and interstate traffic, and is in no wise dependent on or affected by action or inaction on the part of the several states or any of them."

As thus construed the concurrent power section of the amendment reserved to the states their police power over intoxicating liquors, with the single limitation that they could not exercise it to permit what the amendment prohibits. The former policy of strengthening the police power of the state by removing constitutional barriers was now changed to one of co-operation in which the states and the federal government had equal responsibility and power. It was not a grant of any new police power to the states, but an enlargement of the police power they possessed, by extending concurrent power to interstate commerce and to importation and exportation of intoxicating liquors. Neither did concurrent power impose any new obligation on the states, but merely emphasized an old one, as Governor Alfred E. Smith noted as follows: "After repeal there will still rest upon the peace officers of this State the sacred responsibility of sustaining the Volstead Act with as much force and as much vigor as they would enforce any State law or local ordinance" (memo accompanying his approval in 1923 of the repeal of the N.Y. Prohibition law).

If the plain intent and ideal of sec. 2, as interpreted by the U.S. supreme court, had been realized more fully, enforcement would not have broken down so soon nor would have come the demand for repeal with overwhelming force in 1933. The states, however, with few exceptions, refused to co-operate whole-heartedly; and partly on account of old conflicts under the federal-state system, but chiefly because of practical politics and partisan advantage, by so doing sealed the doom of the 18th amendment.

Administrative Difficulties.—The chief obstacles to efficient enforcement did not come from the courts, but rather from administrative difficulties arising from untrained and incompetent personnel, and the lack of enforcement machinery, or its location in several departments of the government. The failure at the outset to put all enforcement officers under civil service caused increasing trouble. Some conflict and overlapping in the efforts of the treasury and the department of justice led the judicial conference of the senior circuit judges, with the concurrence of Chief Justice William Howard Taft, to recommend in Nov. 1924 that the prohibition unit of the treasury be transferred bodily to the department of justice, and that all appropriations for enforcement be expended under the attorney-general. It was thought that a closer co-ordination of the experience and technique of the treasury department with prosecutions by the department of justice would avoid the prosecution of trivial, futile and unimportant cases which crowded the dockets, and would enable district attorneys better to prepare those cases which would really deter the principal offenders. Partly because of the nature of the proceedings in federal courts requiring jury trial, and partly due to the absence of federal police courts to dispose of petty cases, "the resources of the federal government in administration and judicial machinery were sufficient to cope successfully only with what might be called the 'wholesale' aspects of the enforcement problem—smuggling, including report of arrests, seizures, etc., made by federal prohibition officers, the withdrawals of bonded liquors, the diversion and conversion of industrial alcohol to beverage uses, interstate transportation of liquors and the major conspiracies to violate the law, some of which are of giant proportions" (*see* BOOTLEGGING AND SMUGGLING). For the rest, state and local machinery would have to be relied upon to enforce the law.

In response to these and many other suggestions, and to bring the problems of prohibition enforcement more directly under the eye of the secretary of the treasury and the president, congress reorganized the prohibition unit, and created by act of March 3, 1927, a bureau of customs and a bureau of prohibition in the department of the treasury. This was recommended by the secretary of the treasury and centralized responsibility for enforcement of prohibition in a commissioner directly responsible to the secretary of the treasury. It provided for the appointment of a staff under the commissioner, subject to the provisions of the civil service law. In the opinion of the commissioner the civil service requirement did bring about a marked improvement in personnel, and enabled the new bureau to continue more effectively the policy previously followed, namely, decentralization of the prohibition service, and concentration upon the things that federal enforcement could do best, whether the state and local authorities did their part or not.

Treaties to check liquor smuggling were negotiated with Great Britain in Jan. 1924 (ratified and proclaimed, May 22, 1924) and the principal countries of Europe, and Canada, Cuba, Panama and Mexico. These treaties embodied the so-called 12-mile limit, or one-hour run, for boarding and examination of private vessels under foreign flags. They were liberally construed by the U.S. supreme court. (*See* SMUGGLING.)

The major effort in the reorganization of prohibition enforcement was the Prohibition Reorganization act of May 27, 1930 (Pub. No. 273, 71st Cong.). This act, effective from July 1, 1930, established the bureau of prohibition in the department of justice, and the bureau of industrial alcohol in the treasury department. They were previously a single bureau in the treasury department. It was a functional change which greatly accelerated improved enforcement of the prohibition laws, but it came too late to repair the public's shattered confidence in the enforcement agencies, either federal, state or local. Albert E. Sawyer, technical expert of the National Commission on Law Observance and Enforcement, thought that there were losses as well as gains in the reorganization, and that "the undeniable improvement in the effectiveness of prohibition work since the transfer may be the direct result of the aggressiveness which has characterized the attorney-general and his assistants." (For chart and excellent discussion, *see* "The Enforcement of National Prohibition," *Annals*, vol. 163, Sept. 1932, pp. 10–29.)

National Commission on Law Observance and Enforcement.—President Herbert Hoover appointed May 20, 1929, a commission of 11 eminent citizens including one woman, the president of Radcliffe college, to make "a thorough inquiry into the problem of the enforcement of prohibition under the provisions of the 18th amendment of the constitution and laws enacted in pursuance thereof, together with the enforcement of other laws." Eight days later the commission with George W. Wickersham as chairman met at the White House and President Hoover emphasized that he wanted a broad inquiry dealing not only with one law or the laws of the federal and state governments separately, but with the enforcement of, obedience to, and attitude toward all law.

The commission performed its task ably, thoroughly and with commendable speed. Through public hearings in various parts of the country, by special studies of experts engaged by the commission, it assembled from both official and unofficial sources much valuable data not previously available in consolidated form. A preliminary report was submitted in Nov. 1929, and a supplementary report in Jan. 1930. Both dealt chiefly with legal and constitutional questions of procedure in law enforcement. The president sent both reports to congress on Jan. 13, 1930, with a message, accompanied by memoranda from the attorney-general and the secretary of the treasury, endorsing recommendations for more centralization of administrative responsibility for enforcement, more courts and better judicial and prosecuting procedure (H.R.Doc. No. 252, 71st Cong., 2nd Sess.). Congress and the public alike, however, awaited the appearance of the major report on the larger issues involved. This appeared a year later with the title: "A Report on the Enforcement of the Prohibition Laws of the United States," and was sent to congress with a message from the president on Jan. 7, 1931 (H.R.Doc. No. 722, 71st Cong., 3rd Sess.). After a time several volumes of documents and evidence followed.

Thus the commission under pressure for too great speed in making a full report had not quite achieved the larger purposes for which it was organized. It was courageous in its exposé of the weakness of the first seven years of what it called "imperfect enforcement," and sparing in its praise of the improvement of the three years of reorganization. The lack of a master plan, of skilful leadership, of proper co-operation and a united front between such important key agencies as the customs, coast guard, and prohibition bureau, and even the activities of the pressure groups and political forces, pro and con enforcement, are dealt with frankly and fearlessly, and if the report could have been issued five years earlier might have built up normal support of public opinion for normal observance of the prohibition laws. But in 1930 it was too late to expect that, and the commission seemed to think that some modification of the prohibition policy was necessary to restore public confidence in the enforcement agencies of government, either federal, state or local. Yet five of the nine major recommendations and conclusions of the report were squarely opposed to repeal of the 18th amendment; the restoration in any manner of the legalized saloon; the modification of the N.P. act to permit light wines and beers; authorizing federal or state governments to go into the liquor business; inadequate co-operation of the states. Condensed and authoritative statements and interpretation of the commission's report by its chairman, and chief technician, will be found: (1) *Amer. Bar Ass'n Jour.*, vol. 16, Oct. 1930, pp. 654, 660–61 (Wickersham, "Program of the Commission on Law Observance and Enforcement"); (2) two articles by A. E. Sawyer, *Michigan Law Review*, vol. xxx, Nov. 1931, and *Annals*, American Academy of Political and Social Science. vol. 163, pp. 10–29, Sept. 1932.

The Economic and Social Results of Prohibition.—Here is the nub of the controversy that raged so violently in the decade preceding repeal of the 18th amendment. That much more heat than light emanated from the millions of spoken and written words on this theme was to be expected. Scientific standards of measurement and scientific data on which to base sound judgment were, for the most part, lacking, even for such items as uniform records of arrests for drunkenness, of law violations, prosecutions, sentences, alcoholic morbidity and mortality, etc., on which the government should have been able to disseminate accurate information. Looking back it is clear that the prohibition "authority" of the federal government, wherever located, did a poor educational job, because in the last analysis it was the social and economic aspects of national prohibition, rather than the moral or legal, that decided the fate of the 18th amendment. In every state of the union there was a middle-of-the-road contingent, which cast perhaps 75% of the vote. It could have been lined up for or against national prohibition on clear-cut statements of fact concerning social and economic consequences of one policy or another.

The report of the Federal Council of Churches *(Research Bulletin No. 5,* p. 83, 1925) is one of the best of the unofficial inquiries and furnishes some significant conclusions based on good scientific handling and sampling of questionnaire testimony of social workers. This shows a preponderant opinion at that time that prohibition had helped secure better furnished homes for working people; better mental health of the home as shown by better family co-operation, respect of children for parents, and of parents for children, and by better educational ideals; also larger proportion of the husband's income going to wife and family, and improved marital relations. Favourable community effects were recorded in this special poll: less children's delinquency; less malnutrition; liquor for minors less accessible. But in contrast the inquiry also showed more drinking by young people, and a worse attitude toward law enforcement and respect for laws in general. The Federal Council report, however, does not support the theory that prohibition had caused a moral breakdown among young people. The report's most conclusive finding is that social legislation is no substitute for social education, and that "the illicit liquor traffic will be finally overcome only when and where education in temperate living strongly reinforces the arm of the law."

Similar reports, not all of them so well documented, appeared from many social agencies, business men's organizations, and civic groups, and some dealt more definitely with the wage-earner's stake in prohibition. Still other reports emanated from organizations and groups opposing prohibition: the Association Against the Prohibition Amendment, Repeal Associates, Women's Organization for National Prohibition Reform, the Moderation League, the Crusaders, etc., presented studies of the new evils, and their social and economic consequences, attendant on the failure to enforce, or as some contended, the unenforceability of national prohibition. Matters emphasized in these reports are: the speakeasy as a substitute for the saloon; the public disregard for all laws; public corruption for protection of illegal traffic; the effect on the administration of justice of overflowing prisons and courts cluttered with prohibition cases; the threat, to social and economic security, of huge revenues from the illegal liquor traffic in the hands of well-organized criminals.

Among the many individual studies of the social and economic consequences of prohibition, typical and well-balanced, are: (1) Prof. Irving Fisher's *Prohibition at Its Worst* (1926) and *Prohibition Still at Its Worst* (1928), and his report to the American Economic Association (1927, *A. E. Review,* xvii, No. 1, suppl. March) which claimed that the country was at least $6,000,000,000 better off as a result of prohibition. (2) Prof. Herman Feldman's *Prohibition: Its Industrial and Economic Aspects* (1927) based on a nine months' personal study of industrial plants, documentary material, and questionnaires sent to 1,200 concerns with over 1,250,000 employees. Feldman finds that "the economic benefits of legal prohibition are based upon substantial prohibition in fact; on the actual abolition of the saloons, or their reduction to a negligible quantity, not on the mere change in name; on a greatly lessened consumption of alcoholic beverages; on a general influence in promoting temperance and discouraging over-indulgence." (3) Dr. Clark Warburton's *Economic Results of Prohibition* (1932), and in briefer form, *Prohibition and Economic Welfare (Annals,* American Academy of Political and Social Science, vol. 163, pp. 89–97, Sept. 1932). This is an able study, but largely negative in its conclusions and results because of the lack of positive statistical evidence and unwillingness to weigh or consider any other kind of evidence. In general, Dr. Warburton concludes that "prohibition had little to do with the prosperity of the Nation from 1923 to 1929 and the increased purchases during those years of many types of luxury and semi-luxury goods."

To this brief statement of very general conclusions from many sources, and in rather sharp contrast to that of Dr. Warburton, just cited, should be added the statement of Secretary of Commerce Herbert Hoover in an address before the U.S. chamber of commerce, as quoted in the *Christian Science Monitor,* March 11, 1925, as follows:

"There can be no doubt of the economic benefits of prohibition. Viewing the temperance question only from this angle, prohibition has proved its case. I think increased temperance over the land is responsible for a good share of the enormously increased efficiency in production, which statistics gathered by the Department of Commerce show to have followed the passage of the dry law. Exhaustive study from many angles of production . . . indicates that while our productivity should have increased about 15% due to increase in population, the actual increase has been from 25% to 30%, indicating an increase of efficiency of somewhere from 10% to 15%. . . . There is no question in my opinion that prohibition is making America more productive."

REPEAL OF THE 18TH AMENDMENT AND THE POST-REPEAL ERA

The revolt against the 18th amendment, and the agitation for its repeal, did not assume serious proportions until the presidential campaign of 1932 when it became a national issue. Conscientious objectors, like Dr. Nicholas Murray Butler, had voiced their protest even before the amendment was ratified. In the Borah-Butler debate in Boston, April 8, 1927, Dr. Butler said:

"The 18th amendment must come out of the Constitution because it does not belong there. It affronts and disfigures it. It contradicts every principle upon which the Constitution rests, and the difficulties, the embarrassments, the shocking scenes reported daily from every part of the land are the natural and necessary result of the inner contradiction that has been set up between the Constitution as it was and the 18th amendment added to it in 1919. . . .

"We talk of law enforcement. You cannot enforce conflicting laws—something must give way; and, when it is the 18th amendment and the legislation based upon it on the one hand and the whole body of the Constitution, the Bill of Rights, the whole of political English and American History on the other, which do you suppose will have to give way? It must be this new and invading element in our public law."

Such was the moral objection which was intelligently and forcibly presented by a sincere small minority. It might have won more sustainers if it had shown greater recognition of the economic facts that underlie public morals, and of the effectiveness of the constitution and the government it set up, to deal with the social problems of modern democracy.

The Modificationists.—They were a second and more numerous group of less conscientious objectors. They wanted more alcohol, "light wines and beer" (or by any other name the people might prefer), than the 18th amendment allowed under the implementing Volstead act, or than the supreme court would sanction if that act were amended to increase the ½ of 1% standard of intoxicating liquor. Hence they advocated repeal of the Volstead act, leaving to the states the enactment of such prohibitory laws as their citizens might desire to implement the 18th amendment within their boundaries and provide varying degrees of dryness or wetness to suit local tastes. Prof. Howard Lee McBain *(Prohibition: Legal and Illegal* [1928]) considered this suggestion and others like it to circumvent the 18th amendment, but his conclusions gave scant encouragement to those who did not want to conform to the dictates and spirit of national prohibition while the 18th amendment remained a part of the constitution.

The political demand for repeal lagged behind the changes taking place in public opinion. In 1928 the national party platforms of both major parties pledged vigorous (Republican) and honest (Democratic) enforcement, but by 1930 the state party platforms in 21 states (14 Democratic and 7 Republican) demanded repeal of the 18th amendment, and in 1932, both national party platforms favoured repeal with safeguards to protect state prohibition territory, or the submission of a proposal to revise in a way to furnish such safeguards.

Supporters of the Experiment.— Opposed to repeal or modification were two groups: (1) the extreme and uncompromising upholders of constitutional prohibition as the only practical method of dealing with the organized liquor traffic and bringing it under social control. In the main the officials of the Anti-Saloon leagues and most of the temperance societies, and such political leaders as Senator Morris Sheppard and Congressman Volstead were spokesmen for this group; (2) a larger group of no less sincere but more moderate prohibitionists who were more keenly alive to the economic foundations and implications of national prohibition. This included such national leaders as Senator William E. Borah, Herbert Hoover and many captains of industry, like Henry Ford, Thomas A. Edison and others. This group favoured a longer trial and a greater effort to secure co-operation of both state and national governments, and enlist the active support of the great mass of law-abiding citizens, before saying that the 18th amendment and its supporting legislation could not be enforced. Many excellent suggestions offered in the W. C. Durant prize contest, Aug. 27–Nov. 30, 1928, "for the best and most practical plan to make the 18th amendment effective," showed conclusively that it was not lack of brains or technical skill on the part of the leaders who would and could have enforced the 18th amendment if they had had the strong support of a favourable public opinion such as caused its adoption. Countersuggestions showing the trend towards and the character of the demand for repeal, will be found in the W. R. Hearst temperance prize contest, Jan.–Apr. 1929, "for the best plan to repeal the 18th amendment and substitute in place of prohibition a more liberal and more American measure," later changed to "the best plan to achieve temperance." For a full account of these contests and the winning plans *see* W. C. Durant, ed., *Law Observance,* p. 573 (1929); and Francis J. Tietsort, ed., *Temperance or Prohibition,* p. 397 (1929).

The presidential campaign of 1932 settled the issue overwhelmingly for repeal. The plank in the Democratic platform was unequivocally for repeal, and the Republican plank, as recommended by the majority of the resolutions committee, apparently favoured the submission of a proposal to revise the 18th amendment with some safeguards attached. Dr. Butler, Senator Borah and other leaders claimed, however, that the minority recommendation of the resolutions committee favouring outright repeal more nearly represented the majority sentiment of the convention, but had been defeated by controlled votes. The *N.Y. Times* of June 7 and 9, before the Republican convention had acted, quoted two of the most influential supporters of the 18th amendment, John D. Rockefeller, Jr., and John R. Mott, as respectively in favour of repeal and resubmission.

Submission and Ratification of the 21st Amendment, Repealing the 18th.—The second session of the 72nd congress meeting within a month of the November elections lost no time in preparing a joint resolution which was adopted by two-thirds majority in both houses; in the senate, where the joint resolution originated, by a vote of 63 for, to 23 against, on Feb. 16, 1933, and in the house on Feb. 20 by a vote of 289 for, to 121 against. It was deposited in the department of state, Feb. 20, and the following day was sent by the secretary of state to the respective governors of the 48 states.

The proposed amendment, as subsequently ratified, becoming the 21st amendment to the constitution, reads as follows:

"Section 1. The eighteenth article of amendment to the Constitution of the United States is hereby repealed.

"Section 2. The transportation or importation into any State, Territory, or possession of the United States for delivery or use therein of intoxicating liquors, in violation of the laws thereof, is hereby prohibited.

"Section 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by conventions in the several States, as provided in the Constitution, within seven years from the date of the submission hereof to the States by the Congress."

This was the first use to be made of the method of ratification by conventions instead of by legislatures, but in less than 10 months conventions did meet in 36 states which ratified and two (North Carolina and South Carolina) which rejected the amendment. On Dec. 5, 1933, the secretary of state certified the ratification. The president followed this certification on the same day with a proclamation, pursuant to sec. 217a of the National Industrial Recovery act, in which he declared the 18th amendment repealed. While the president did call on all citizens to co-operate with the government in getting rid of the illicit liquor traffic, and to note the new prohibition against wet states invading the territory of those who wished to remain dry, not even the president seemed to realize the full significance of the second section of the 21st amendment. That was left for Justice Louis D. Brandeis and the supreme court to reveal in two little-noticed but remarkable decisions: (1) *State Board of Equalization of California* v. *Young's Market Co., et al.* (299 U.S. 59) decided in 1936; and (2) *Finch & Co.* v. *McKittrick* (305 U.S. 395) decided Jan. 3, 1939. The gist of these two decisions of Justice Brandeis may be seen in two sentences. One taken from the first, speaking of the 21st amendment, says that the words of the amendment "are apt to confer upon the States the power to forbid all importations which do not comply with the conditions which it prescribes"; and the other, from the second decision, to the effect that: "Since that amendment (the 21st), the right of a State to prohibit or regulate the importation of intoxicating liquor is not limited by the commerce clause." Prof. Noel T. Dowling of the Columbia university law school noted within a month after the first decision was handed down, its revolutionary character in constitutional law and history. He raises the question whether it was the intent of the 21st amendment to go so far, and whether the court would go the whole way to permit the states to put themselves in a position of economic isolationism with respect to intoxicating liquors. The second decision gives an affirmative answer to both questions. (*See* Noel T. Dowling, "Liquor and the Constitution," *Independent Journal*, Dec. 18, 1936, Col. Univ.) The second section of the 21st amendment not only put the Webb-Kenyon law substantially in the constitution, and thereby placed it beyond the power of congress to change, but by the interpretation given to it in the Brandeis decisions "the states," as Prof. Dowling says, "seem to have been lifted to a new, surprising, extraordinary position of power in the American federal system."

After Repeal.—At the end of nearly a decade after repeal (1943) it was still impossible to predict how far the states would succeed with the new powers in doing what they failed to do before national prohibition, and what the federal government without their full co-operation failed to do during the era of national prohibition. The president's proclamation of repeal also promised federal aid, and among other things said: "The objective we seek through a national policy is the education of every citizen toward a greater temperance throughout the Nation."

Steady progress toward legal tax control has been made by the Federal Alcohol administration, and in the states through the "licensing" and "monopoly" control in all except the three "prohibition states" (Kansas, Mississippi and Oklahoma). (*See* LIQUOR LAWS AND LIQUOR CONTROL.) During 1942, local option elections in nearly 1,500 geographical areas showed more pronounced dry gains than in any one of the previous nine years, all of which showed some dry gain. It was reported that in that period in over 12,000 local option elections the drys won nearly two-thirds of them. Both the liquor interests and the temperance forces were suspicious of each other fearing that advantage would be taken of the war situation to renew old controversies. Polls indicated a rising tide of dry sentiment even to a reported 36% in one poll favourable to national prohibition. Although there was something in the pattern of World War II events to suggest the antecedents of prohibition in the years 1917–19, the background of legislative demands and action was radically different. The temperate statement of the executive committee of the Federal Council of Churches on Nov. 27, 1942 (*Information Service*, Dec. 5, 1942), presented positive measures to control and reduce the evil effects of beverage alcohol, with particular reference to the wartime situation. These probably fairly represented the attitude of the Protestant Churches, and indicated the trend of thought in most of the temperance societies, Protestant and Catholic.

Too great or sole reliance on legal compulsion defeated national prohibition. The better course that combines education and restraint, both legal and voluntary, in the suppression of the evils of the liquor traffic, was well illustrated in a broadcast of Prime Minister Mackenzie King of Canada, on Dec. 16, 1942, from Ottawa, on "Temperance and a Total War Effort." He asked the provinces to further restrict the hours of sale to eight per day; he lamented the increased consumption of alcoholic beverages as unseemly in wartime when so many are sacrificing so much; and he announced the decision of his government under its war powers to prohibit after Feb. 1, 1943, all liquor advertisements throughout Canada for the duration.

Whatever may be said of prohibition, law, enforcement or repeal, these facts remain: During the prohibition era, a vast, illicit and vicious business of bootlegging was active. It could not have existed without enormous purchases, *in toto*, of bootleg stuff by otherwise reputable citizens who not only resisted the law but defied it and disobeyed it, thus lowering the standards of civic honour.

When repeal came in, it proved to be no immediate remedy for the appalling disintegration of social, intellectual and moral ideals, caused in large part by the illegal practices connected with bootleg liquor. In 1942, war brought additional questionings and difficulties. Many were inclined to believe that certain strict governmental protective and prohibitory measures might still be necessary for social welfare, but that the real progressive solution of the liquor problem might lie in the acceptance of individual responsibility; in voluntary commitment to the temperance cause; in scientific study; in home training and parental example; in the teaching and nurture of the church; and in better social customs.

In a word, the solution might lie more in the educational and spiritual realm, than in the legislative and political.

A new pragmatic emphasis on social and economic results and less controversy about ideologies may characterize the post-repeal era.

PROHIBITION IN LAW, a term meaning the action of forbidding or preventing by an order, a decree, etc. As defined by Blackstone, prohibition is "a writ directed to the judge and parties of a suit in any inferior court, commanding them to cease from the prosecution thereof, upon a surmise either that the cause originally or some collateral matter arising therein does not belong to that jurisdiction, but to the cognizance of some other court." A writ of prohibition is a prerogative writ—that is to say, it does not issue as of course, but is granted only on proper grounds being shown. Before the Judicature Acts prohibition was granted by one of the superior courts at Westminster; it also issued in certain cases from the court of chancery. It is now granted by the High Court of Justice. By the Judicature Act, 1873, s. 24, it is provided that no proceeding in the High Court of Justice or the court of appeal is to be restrained by prohibition, a stay of proceedings taking its place where necessary. In the case of courts of quarter sessions, the same result is generally obtained by *certiorari (see* WRIT).

In Scots law prohibition is not used in the English sense. The same result is obtained by suspension or reduction. In the United States the Supreme Court has power to issue a prohibition to the district courts when proceeding as courts of admiralty and maritime jurisdiction.

Most of the States have also their own law upon the subject, generally giving power to the supreme judicial authority in the State to prohibit courts of inferior jurisdiction. *(See* LIQUOR LAWS AND LIQUOR CONTROL; TEMPERANCE.)

Prohibition is a writ which lies to restrain the unlawful exercise of judicial functions on the part of a lower court, issuing from a court of higher jurisdiction. Again, it may be used to restrain an official from doing an administrative, ministerial or legislative act not falling within his province.

PROHIBITION PARTY, THE NATIONAL, a minor political party of the United States which has had for its primary objective the legislative prohibition of the manufacture and sale of intoxicating liquors. From time to time it has also proclaimed its interest in other reforms. The party was organized in 1869 and in 1872 placed its first candidate for President in the field. It has offered candidates for President and Vice-President in every succeeding Presidential election. Though one of the most persistent of the third parties it has polled fewer votes in most elections than some others of more radical character. Its highest figure, 255,000 votes out of a total of 12,000,000 cast, was in 1892. In 1920 it polled 192,000 votes, in 1928 20,101 votes, and in 1932 81,869 votes. While the amendment was in effect the party agitated the necessity for its enforcement, but growing hostility to prohibition and the amendment's final repeal forced the party to resume the political struggle within individual states.

PROJECTION, IN MATHEMATICS. Let A, B, C, D, etc., represent points of a straight line 1 and A', B', C', D', etc., points of another straight line 1' in the same plane with 1. If the straight lines, AA', BB', CC', DD', etc., are all perpendicular to the line l', the set of points A', B', C, D', etc., is said to be an orthogonal projection of the set, A, B, C, D, etc., (fig. 1). The correspondence between the two sets of points, by which A corresponds to A', B to B', etc., is called an orthogonal projection. In case the straight lines AA', BB', etc., are all parallel, without being necessarily perpendicular to l', we use the term parallel projection instead of orthogonal projection (fig. 2). In case the lines AA', BB', CC', etc., all meet in a point O we speak similarly of central projection. In all three cases we say that the two sets of points A, B, C, D, etc., and A', B', C', D', etc., are in perspective and that the points of one set are projected into the points of the other set. The point O is called the centre of perspectivity or the centre of projection of the two sets of points as indicated in the accompanying diagram (fig. 3).

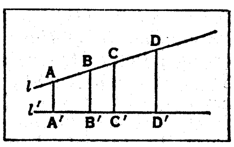

FIG. 1

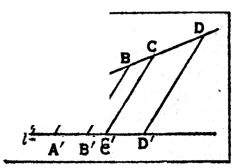

FIG. 2

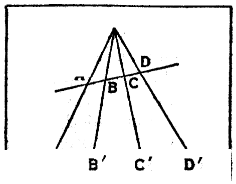

FIG. 3

These conceptions have been generalized in various ways. For example, let A, B, C, D, etc., be the points of any figure F in space and A', B', C', D', etc., be corresponding points of a figure in a plane π. If the straight lines AA', BB', CC', etc., are all parallel or all meet in a point O the figure in the plane π is called a projection of the other figure. If the lines AA', BB', etc., are all perpendicular to the plane π, the figure in π is called an orthogonal projection of the other figure. (*See* also PROJECTIVE GEOMETRY.)
(O. V.)

PROJECTIVE GEOMETRY. Projective geometry is a branch of mathematics which originated in the study of projections as applied to problems of perspective in the drawing of pictures and in optical instruments. These practical applications are now studied under the captions of descriptive geometry *(see* DESCRIPTIVE GEOMETRY) and geometrical optics (*q.v.*), while projective geometry itself is cultivated for its intrinsic interest. It is a well co-ordinated and symmetrical theory of considerable aesthetic merit, which on the one hand enables us to view elementary geometry as a completed whole, and on the other hand serves as the starting point of the higher algebraic geometry. For a more detailed study the reader is referred to one or more of the text books listed at the end of this article. The article itself attempts merely to state some of the general ideas, definitions and theorems in an introductory way and without proof.

One-dimensional **Projectivities.**—The notion of projection is defined in the article on that subject *(see* PROJECTION). Suppose that the points of a line a are projected into the points of a line b, and the points of b into the points of a line c, the points of c into the points of a line d, and so on, ending up with the points of the line k. Every point A of the line a then corresponds to a definite point K of the line k. This correspondence is called a *projective transformation* or *projectivity,* and is sometimes indicated symbolically by

$$\{A\} \barwedge \{K\}$$

The set of all points of a line l is called a ***range*** (or a ***pencil*** or ***row)*** of *points,* so that in the books on projective geometry there is often talk of projective ranges. In case we wish to discuss the correspondence, not of all the points of a, but only of certain ones, say A_1, A_2, A_3, A_4, we may write

$$A_1A_2A_3A_4 \barwedge K_1K_2K_3K_4.$$

The first theorem about projectivities is that any three points of a straight line can be projected into any three points of a straight line. In other words the statement

$$A_1A_2A_3 \barwedge K_1K_2K_3,$$

is true whenever it is true, (1) that A_1,A_2,A_3 are distinct and collinear, and (2) that K_1,K_2,K_3 are distinct and collinear. It is also true that if the points A_1,A_2,A_3 and K_1,K_2,K_3 are on different lines the projectivity can be brought about by the intervention of not more than two intermediate projections. That is, if the points A_1,A_2,A_3 and K_1,K_2,K_3 are given on different lines it is possible to find a line b such that A_1,A_2,A_3 can be projected respectively into the points B_1,B_2,B_3 of b, and these points into K_1,K_2,K_3, respectively. If A_1,A_2,A_3 and K_1,K_2,K_3 are on the same line, three intermediate projections may be needed.

A second theorem is that any projective transformation of a line is fully determined by the fate of three of the points of the line. In other words, if it is specified that A_1 goes to K_1, A_2 to K_2, A_3 to K_3, then for any point A_4 of the line A_1A_2 there is a uniquely determined point K_4 of the line K_1K_2 to which A_4 goes. This theorem is often referred to as the ***fundamental theorem of projective geometry.***

Points at Infinity.—From the point of view of elementary geometry, there are certain exceptions to these theorems, due to the existence of parallel lines. For example in fig. 1, the point A_0 is not projected into any point of the line b because the line from

A_0 to the centre of projection is parallel to b. This circumstance complicates the statement of the theorems about projections if we adhere to the point of view of elementary geometry. In projective geometry it is avoided by introducing the conception of *points* at *infinity*, or *ideal points*. To every straight line a there is attributed one point at infinity and every line parallel to a is said to meet a in the point at infinity of a. In fig. 1 the point A_0 is therefore said to be projected into the point at infinity of the line b. The points at infinity of the straight lines of a plane are said to constitute a straight line, the *line at infinity* of this plane. All the points at infinity of a three-dimensional space are said to constitute a plane which is called the *plane* at *infinity*.

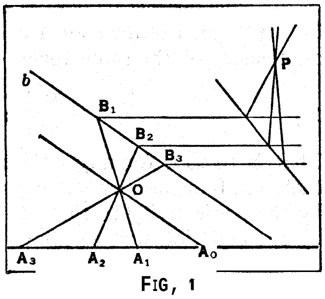

FIG. 1

We shall not attempt here to justify the conception of points at infinity. The question is discussed at length in the books on projective geometry. It may be remarked however that the ordinary points are just as much idealized as are the points at infinity. No one has ever seen an actual point or realized it by an experiment of any sort. Like the point at infinity it is an ideal creation which is useful for some of the purposes of science. With the aid of these conceptions we obtain great simplicity and symmetry in the statements of geometry. For example we have: (a) any two points have one and only one straight line in common; (b) any two straight lines in a plane have one and only one point in common; (c) any two planes have one and only one line in common; (d) a straight line and a plane have one and only one point in common, unless the line lies in the plane; (e) a straight line and a point are on one and only one plane, unless the point is on the line. Each of these statements would have to be split up into at least two propositions in order to state its full content in the language of elementary geometry; and each of the propositions would be more complicated to state than the more general projective proposition in which it is contained.

Principle of Duality.—If we restrict attention to the points and lines of a single plane there is a duality between the two propositions (a) and (b) in the list above. They can be written:

(a) Two points are on one and only one line.

(b) Two lines are on one and only one point.

Either proposition remains true if the words point and line are interchanged. The same thing is true of every theorem of the projective geometry of the plane. If it is properly formulated it remains valid when the words point and line are interchanged. This statement is called the principle of duality in the plane. (See DUALITY.) Its exact meaning depends, of course, on what we mean by a theorem of projective geometry. This is explained below with the aid of the notion of the projective group.

After the principle of duality in the plane has been comprehended it is necessary only to state one of each pair of dual theorems. The other one goes without saying. Indeed, after we have arrived at a number of propositions from which we are going to deduce all the rest by logical processes without appeal to other knowledge, and after we have verified the duals of these fundamental propositions, we know in advance that the principle of duality will hold for all the theorems which we are going to derive. This way of dealing with the principle of duality requires that the material of projective geometry shall be organized as a distinct body of knowledge (*see* the remarks on axioms, etc., below).

The principle can also be established by showing the existence of "duality transformations" which carry every plane figure into a dual figure in which the points and lines of the first are replaced by the lines and points of the second.

There is also a principle of duality in space, according to which the propositions of three-dimensional projective geometry when properly stated remain valid when the words point and plane are interchanged. In the list above, the propositions (a) and (c) are dual, (d) and (e) are dual, and (h) is dual to the proposition that any two straight lines with a point in common are in a common plane. In like manner there are principles of duality in spaces of any number of dimensions.

Pencils of Lines.—We must now understand that the statements which we have made about one-dimensional projectivities hold without exception, and therefore include all the special cases which arise when one or more of the points in question is a point at infinity. Glancing again at fig. 1, it is evident that there is a one-to-one correspondence between the points of the line a and the lines through the point O which are in the same plane with a, namely, each point corresponds to the line joining it to O. Such a system of lines is called a *pencil of lines* and the point O in which all lines of the pencil meet is called the *centre of the pencil*.

The notions of projectivity and perspectivity are now extended so as to apply to pencils of lines as follows: The correspondence between a range of points and a pencil of lines in which each point lies on its corresponding line is called a *perspectivity;* and any correspondence between two pencils of lines, or between a pencil of lines and a range of points, or between two ranges of points which is the resultant of any number of perspectivities is called a *projectivity*. This definition includes the definition previously given of a projectivity between two ranges of points as a special case. Under this definition, in fig. 1, the range of points on a is projective with the pencils of lines at O and P as well as with the pencil of parallel lines; and each of these pencils of lines is projective with the others; each of the projectivities being a one-to-one correspondence determined by the figure. Just as in the analogous case of ranges of points, if a_1,a_2,a_3 are lines of one pencil and b_1,b_2,b_3 are lines of another pencil, there is one and only one projectivity in which a_1,a_2,a_3 correspond to b_1,b_2,b_3 respectively.

Conic Sections.—The corresponding lines of two distinct projective pencils of lines in the same plane intersect in the points of a conic section (*q.v.*), provided the line joining the centres of the two pencils does not correspond to itself. For example, in fig. 2, the two pencils of lines at A and B are projective in such a way that corresponding lines are perpendicular, and they intersect in points of a circle. If the corresponding lines had not been perpendicular the corresponding lines would have intersected in an ellipse, or in a parabola, or in a hyperbola.

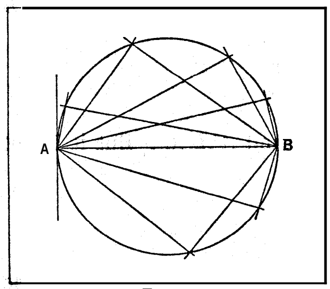

FIG. 2

This theorem of the generation of a conic by means of projective pencils makes it possible to deduce all the properties of conic sections from the theory of one-dimensional projectivities. For example, the fact that there is one and only one conic through five coplanar points, no three of which are collinear, is an immediate consequence of the fact that a projectivity between two pencils of lines is fully determined by the correspondence of three lines of the one pencil with three lines of the other. The theorem is a good example of the unifying power of projective geometry, for it includes as special cases a host of theorems about the construction of conic sections when the given five points are in special position from the point of view of elementary geometry. An equal number of additional theorems is obtained by applying the principle of duality in the plane; and a corresponding group of theorems about cones is obtained by space duality.

The Ruled Quadric.—Let A_1,A_2,A_3,A_4 be four points of a line a and B_1,B_2,B_3,B_4 four points of a line b which is not in the same plane with a. In case

$$A_1A_2A_3A_4 \;\overline{\wedge}\; B_1B_2B_3B_4,$$

then any straight line c which meets the three lines A_1B_1, A_2B_2, A_3B_3, will also meet A_4B_4. Hence there is a whole family of straight lines which meet the lines A_1B_1, A_2B_2, A_3B_3, A_4B_4. The lines of this family fill up a surface which is called a *quadric surface* because its equation is of the second degree. It is called a *ruled quadric* because of the straight lines which lie upon it. Indeed, the surface may be described as follows: let a, b and c be the three lines already described under these names. There is a family of lines each of which meets a, b and c and there is just one line of this family through each point of a, b or c. This family may be called the *first ruling* or *regulus* of the quadric. Any line which meets three lines of the first ruling meets all lines of this ruling, and the family of all such lines is a regulus just like the first ruling. The quadric consists of the points on the two rulings. There is one line of each ruling through each point of the quadric, and the plane containing these two lines is tangent to the quadric. But for further discussion of this question the reader must be referred to the article on surfaces (*see* SURFACE) and to the appropriate chapters in books on projective and analytic geometry. The ruled quadric from the point of view of Euclid is either a hyperbolic paraboloid or a hyperboloid of one sheet, according as the plane at infinity is or is not tangent to it.

One-dimensional Forms.—This by no means exhausts the list of seemingly complicated geometric figures whose theory can be deduced from the simple propositions about one-dimensional projectivities. The essential element in any such deduction is to find a family of geometric figures which are in such a correspondence with the points of a line that the theory of projectivities can be applied. Any such family of geometric figures is called a *one-dimensional form*. Examples are: a range of points, a pencil of lines, the set of all planes having a line in common, the points of a conic section, the lines of a regulus, the generating lines of a cone, the points of a rational cubic curve in space, the tangents to a conic section, the set of all conic sections having four points in common, and so on. When the general ideas about projectivities of one-dimensional forms are combined with simple theorems about the particular figures to which they are being applied, they often give us flashes of insight into unexpected branches of mathematics, such as, for example, quaternions (*q.v.*) and biquaternions.

Cross Ratio.—If two points, A,B, go by projection to two points, A',B', there is no general relation between the distance AB and the distance $A'B'$. The same remains true of the ratios

$$\frac{AB}{AC} \text{ and } \frac{A'B'}{A'C'}$$

of two sets of collinear points A,B,C, and A',B',C'. But it is not true of the ratio of two ratios

$$\frac{AC}{AD} \div \frac{BC}{BD}$$

(each ratio computed with proper regard to algebraic sign). The fact is that

$$ARCD \barwedge A'B'C'D'$$

if and only if

$$\frac{AC}{AD} : \frac{BC}{BD} \quad \frac{A'C'}{A'D'} : \frac{B'C'}{B'D'}$$

provided the points in each set of four are collinear. Such a ratio of two ratios is called a *cross ratio* or a *double ratio* or an *anharmonic ratio.*

A cross ratio of four collinear points is the same as the corresponding cross ratio of any iour points into which they are projected. This fact enables us to define the cross ratio of any four elements of any one-dimensional form, and in each case the cross ratio has a significant geometrical meaning. For example, we can define the cross ratio of four points of a conic as that of any four points of a straight line which are projective with the given four points of the conic. It then can be proved very simply that whenever the cross ratio $ABCD$ is -1 the tangents to the conic at A and B intersect on the line CD; and conversely, if the tangents at A and B intersect on the line CD then the cross ratio $ABCD$ is -1. Whenever the cross ratio $ABCD$ of any four elements of a one-dimensional form is -1 we say that the four elements form a *harmonic set* and that the elements AC *harmonically separate* the elements BD.

Co-ordinates in One-dimensional Forms.—If A,B,D are three elements of a one-dimensional form (*e.g.,* three points of a line) any fourth element C is uniquely determined by its cross ratio $ABCD$. That is, if C is given, the cross ratio is a unique number x, and if a number x is given, there is one and only one element C such that x is the cross ratio $ABCD$ (if $C=A$, $x=0$; if $C=B$, $x=\infty$; if $C=D$, $x=1$). The number x is what we call the *co-ordinate* of the element C of the one-dimensional form. A co-ordinate is a number which serves as a name for the element; and these names have been assigned in such a way that any two distinct elements have distinct names. It can be proved that any projectivity by which each element of a one-dimensional form corresponds to an element of the same form, can be represented by an equation

$$\bar{x} = \frac{ax+b}{cx+d}, \quad ad-bc \neq 0.$$

That is to say, for any projectivity of a one-dimensional form, there are four numbers a,b,c,d such that every element x is carried by the projectivity to that element whose name $\bar{x}$ is related to x by the equation written above.

Invariants of Binary Forms.—This theorem opens the way for a study of projective geometry by means of algebra. In practice it is found advantageous to use homogeneous co-ordinates (*see* CO-ORDINATES). An element whose non-homogeneous co-ordinate is x is represented by any pair of numbers x_1,x_2 such that

$$\frac{x_1}{x_2} = x.$$

In case $x_2=0$, the pair of numbers $(x_1,0)$ represents the element ∞ (represented by B in the discussion above). Homogeneous co-ordinates give a multiplicity of names for the same element, for whenever

$$\frac{x_1}{x_2} = \frac{y_1}{y_2}$$

(x_1,x_2) and (y_1,y_2) represent the same element. Any homogeneous algebraic equation represents a finite number of elements. For example

$$px_1^3+qx_1^2x_2+rx_1x_2^2+sx_2^3=0$$

represents three elements, because there are three values of the ratio x_1/x_2 which satisfy this equation. The left-hand member of a homogeneous equation of this sort, of any degree, is called a *binary form* (binary because there are two variables: *see* FORMS, ALGEBRAIC).

A projective transformation is represented in homogeneous co-ordinates by linear homogeneous equations of transformation

$$\begin{aligned} \bar{x}_1 &= ax_1+bx_2 \\ \bar{x}_2 &= cx_1+dx_2 \end{aligned} \qquad ad-bc \neq 0$$

and the projective geometry of one-dimensional forms reduces. algebraically, to the study of the effect of transformations of this sort upon binary forms This study centres about the theory of *invariants* (*see* ALGEBRAIC FORMS) of binary forms, an invariant being a function which is unaltered except for a factor by the transformations In geometric applications it is found, in general, that the vanishing of an invariant represents a geometric property which is unaltered by projectivities.

Two-dimensional Projective Geometry.— It is natural to call such collections of elements as the set of all points in a plane, or the set of all lines in a plane, or the set of all planes through a point, etc., *two-dimensional forms*. The concept of a projective transformation can be extended to two dimensions without difficulty. It turns out that any projective transformation of a two-dimensional form is fully determined by the 'fate of any four elements no three of which are in the same one-dimensional form.

Non-homogeneous co-ordinates are introduced in such a way that an element is named by an ordered pair of numbers $(x,y,$ the first and second names of the element). If the elements are points, then these co-ordinates are ordinary cartesian co-ordinates (*see* ANALYTIC GEOMETRY). Homogeneous co-ordinates are sets of three numbers (x_1,x_2,x_3) such that

$$x = \frac{x_1}{x_3}, \qquad y = \frac{x_2}{x_3},$$

and projective transformations of the points of a plane into points of the same plane are given by equations of transformation of the type,

$$\bar{x}_1 = a_1^1x_1 + a_1^2x_2 + a_1^3x_3$$
$$\bar{x}_2 = a_2^1x_1 + a_2^2x_2 + a_2^3x_3$$
$$\bar{x}_3 = a_3^1x_1 + a_3^2x_2 + a_3^3x_3,$$

in which the determinant of the coefficients is not zero. These transformations are also called collineations because they transform collinear points into collinear points.

Geometry of the Complex Domain. — Since it is possible to perform all the operations of algebra with complex numbers (see COMPLEX NUMBERS)—that is to say with the numbers of the form $u+v\sqrt{-1}$ where u and v are real—it is possible to work out the algebraic theory of projective transformations on the assumption that the co-ordinates, x_1,x_2,x_3, and the coefficients of the equations of transformations, are complex numbers. The objects which are transformed are sets of triads of numbers (x_1,x_2,x_3) where a given set contains all triads $(\rho x_1,\rho x_2,\rho x_3)$ obtained by letting ρ be any real or complex number except zero. We call these objects complex *points*. The collection of complex points which satisfy a homogeneous first degree equation

$$ax_1+bx_2+cx_3=0$$

is called a complex line, and the collection of complex points which satisfy a homogeneous second degree equation a complex *conic*, and so on The totality of complex points is called a complex projective plane Thus there is built up, by simple algebraic processes, a complex projective geometry.

The propositions of this geometry are, to a large extent, the same as those of the projective geometry of reals. Two points determine one and only one line; two lines meet in a point; five points, no three collinear, determine a conic; and so on But a great many propositions assume a simpler and more symmetric form than they do in the real geometry. For example, in the real geometry a line which is not tangent to a conic may meet it either in two points or not at all; in the complex geometry a line which is not tangent always meets the conic in two points. This is because the problem of finding the points of intersection of a straight line and a conic reduces to the solution of a quadratic equation. In general any geometric problem depending on the solution of an algebraic equation of higher than the first degree will assume a simpler form in the complex than in the real domain.

Among the complex points there is a sub-class consisting of those for which the ratios x_1/x_3 and x_2/x_3 (or x_1/x_2, if $x_3=0$) are real. The co-ordinates of these points can aiways be taken to be real, so that these points can be identified with the ordinary real points. Hence the real projective plane is habitually thought of by mathematicians as immersed in a complex projective plane. Every real straight line or real conic is thought of as containing not only all its real points but also a collection of complex points. Moreover, free use is made of Imaginary straight lines, conics, and so on. For example, if we were to limit attention to real figures we should have to say that from certain points of the plane it is impossible to draw lines tangent to a given conic. From the point of view of complex geometry we say that there are two tangents through any point not on the conic; if the point is exterior to the conic the two tangents are real lines, but if the point is interior they are conjugate imaginary lines. No attempt is made to visualize the "imaginary" complex elements We simply make such inferences about them as follow by the rules of logic from the definitions adopted. The results so obtained are bound to be as self-consistent as any theorems about numbers.

Geometry of N Dimensions. — Three-dimensional projective geometry can be approached from the point of view of elementary geometry much as we have approached one and two-dimensional projective geometry in the discussion above; or it may be derived by a purely logical process on the basis of its own axioms; or it may be taken up analytically in the manner explained above for the two-dimensional complex geometry. Points are then defined in terms of sets of homogeneous co-ordinates (x_1,x_2,x_3,x_4). If ihese co-ordinates are restricted to real numbers we obtain the real projective geometry of three dimensions. If they are allowed to be any complex numbers we obtain the complex projective geometry of three dimensions.

From the algebraic point of view, there is no reason why the number of homogeneous co-ordinates should be restricted to four, and no such restriction is made by mathematicians. A point in a projective space of n dimensions is defined by $n+1$ homogeneous co-ordinates $(x_1,x_2, \ldots, x_{n+1})$ and projective transformations are defined by equations of the form

$$\bar{x}_1 = a_1^1x_1 + a_1^2x_2 + \cdots + a_1^{n+1}x_{n+1}$$
$$\bar{x}_2 = a_2^1x_1 + a_2^2x_2 + \cdots + a_2^{n+1}x_{n+1}$$
$$\cdot$$
$$\bar{x}_{n+1} = a^1_{n+1}x_1 + a^2_{n+1}x_2 + \cdots + a_{n+1}^{n+1}x_{n+1}.$$

If the co-ordinates and coefficients are real we arrive at the real projective geometry of n dimensions, if complex, at the complex projective geometry of n dimensions

As the number n increases the geometry becomes more complicated because the number of primary figures to consider becomes greater, but it does not become more difficult in principle. It is no longer possible to visualize our results as we do in the one-, two- and three-dimensional cases, but the logical processes by which they are proved remain the same. In order to explain the situation rapidly we have based the conception of an n-dimensional space on the notion of co-ordinates, but this is not necessary. It can alsa be developed without the use of co-ordinates from a purely descriptive set of axioms.

Projective, Affine and Metric Geometry. — The set of all projective collineations of a plane form a group (see the article GROUP). The properties of any figure which remain unaltered when this figure undergoes the transformations of this group are called *projective* properties For example, the property of a curve of having a second degree equation, *i e*, of being a conic section, is unaltered. Likewise the property of a point, line and conic section, that the point is the pole of the line with regard to the conic is a projective property. The theory of all projective properties of plane figures is the subject matter of the projective geometry of the plane.

The set of all projective collineations of a plane which leave a particular straight line invariant is a group which is called an *affine* group, and the theory of those properties of plane figures which are unaltered when the figures undergo the transformations of this group is called affine geometry (see AFFINE GEOMETRY). The invariant line is called the line at infinity of the affine geometry. An affine group has several subgroups, the most interesting being the ones determined by requiring that two points of the line at infinity shall be invariant. If the two points are real, the subgroup is one studied in the special theory of relativity (*q* v) and includes the Lorentz transformations. If they are conjugate imaginaries, the group is the group of similarity transformations of Euclidean geometry.

The Euclidean geometry can be characterized as the group of theorems which state those properties of figures which are left unaltered by tiie group of similarity transformations. Thus it makes no essential distinction between a large triangle and a small one which is similar to it, though it does deal with the ratio of the two triangles But the latter is an attribute of the figure composed of the pair of triangles, not of either triangle separateiy. The theorems of affine and projective geometry are all included in Euclidean geometry, because any property which is left invariant by the projective group is of course left invariant by all its subgroups. Thus affine geometry is a subclass of very general the. orems of Euclidean geometry which it seems desirable to isolate from the rest and study together. Projective geometry is a strll smaller class of still more general theorems. We seem by leaving out some of the details which distract our attention in the more elementary way of looking at geometry to get a deeper insight and a better grasp of the subject as a whole. Afterwards we are able to return to these details and grasp them rapidiy by studying the particular subgroup which determines the Euclidean metric. A study of the latter group with special reference to the two invariant points gives a rapid and comprehensive survey of Euclidean geometry. For example, the circles are the conic sections which pass through these two points—and the points are therefore called the *circular points at infinity.* Perpendicular lines are pairs of lines which meet the line at infinity in pairs of points which harmonically separate the circular points. The four tangents to a real conic from the circular points meet, in general, in four other points. Two of these are real and are the foci of the conic, and so on.

Non-Euclidean Geometry.— Another sub-group of the projective group which is of great interest is the group leaving a conic invariant. In the real geometry there are two cases to consider according as the conic is real or is composed entirely of imaginary points. The theorems stating properties invariant under the first group constitute what is called the hyperbolic non-Euclidean geometry *(see* NON-EUCLIDEAN GEOMETRY), those stating properties invariant under the second group constitute what is called the elliptic non-Euclidean geometry. The metric geometry or system of measurement of geometric figures, which is developed in these geometries is quite different from, though analogous to, the system followed by Euclid. Historically they were developed in antithesis to the Euclidean system, but they have the same projective geometry.

Axioms.— In attempting to give an introductory sketch of projective geometry we have started from the point of view of elementary Euclidean geometry and freely made use of conceptions which do not belong in projective geometry as the subject is finally defined with the aid of the group idea. This is probably the course which will be generally regarded as advisable in first approaching the subject. But since projective geometry is a collection of very general and significant propositions from which it is possible to specialize in a variety of directions, it is an attractive idea to make projective geometry the starting point of the logical formulation of geometry as a whole and arrive at the various more special branches by a process of specialization. The still more general branches will of course continue to be reached by the process of generalization. The problem of stating the axioms in purely projective terms and deriving the theorems from this foundation by purely logical processes has engaged the attention of several mathematicians in recent years and is quite fully developed in the last two books cited in the bibliography below.

History.— The conception of points at infinity goes back to G. Desargues *(cf.* his *Brouillon-projet,* 1639, in *Oeuvres de Desargues,* 1864), and many of the individual conceptions of projective geometry can be traced back to remote antiquity; but it may be said to appear first as a definite branch of science in 1822 in the *Traité des propriétés projectives des figures* of J. V. Poncelet. The development of the science was participated in by nearly all the geometers of the nineteenth century, notably by Carnot, Brianchon, Gergonne, Chasles, Mobius, Monge, Steiner, Plucker, Clifford, Cremona, H. J. S. Smith and H. Wiener. The clear separation of projective from metric properties dates from the publication of the *Geometrie der Lage* of K. G. Ch. von Staudt (Nurnberg, 1847) and his *Beiträge zur Geometrie der Lage* (Nurnberg, 1857). The formulation of the group-theoretic classification of geometries is due to F. Klein. The study of the axioms and the logical organization of the science as a separate entity has been participated in by many mathematicians during the last forty years, notably by M. Pieri.

PROKOPIEV, SERGEI (1891–), Russian composer, was born at St. Petersburg (Leningrad) in 1891. In 1910 the Rubinstein prize was awarded him for his first piano concerto. From the first his compositions attracted attention by their originality and audacity. In writing for the stage he chooses subjects which have elements of grotesqueness or harsh satire, such as *Chout* (*The Buffoon*), played by Diaghilev's ballet corps in Paris (1921) and *The Love for Three Oranges,* a fable, produced in Chicago in the same year. His *Scythian Suite* for orchestra has also an obvious programme. Other orchestral works are the *Symphonie classique* op. 25 *a Sinfonietta,* and the *Overture* on *Yiddish Themes.*

PROKOP, the name of two of the most prominent Hussite generals.

1. PROKOP, surnamed "Veliky" (the great) or "Holy" (the bald), was a married utraquist priest who belonged to an eminent family of Prague. Though a priest, he became the most prominent leader of the advanced Hussite or Taborite forces during the latter part of the Hussite wars, commanding them at their great victories at Usti nad Labam (Aussig) in 1426 and Domailice (Tauss) in 1431, during their frequent incursions into Hungary and Germany, particularly the Bohemian invasion of Saxony in 1429, after which Prokop concluded the treaty of Kulmbach (Feb. 6, 1430) with Frederick of Brandenburg, burgrave of Nuremberg. He was the most prominent member of the Bohemian embassy to the Council of Basel (1433). On the return of the embassy from this fruitless journey, when renewed fighting broke out, he besieged the Romans at Plzeň, but was forced by indiscipline in his own camp to raise the siege and return to Prague. The Bohemian nobility, both Romanist and utraquist, having leagued itself against the Taborites, a struggle began at Prague. Aided by the nobles, the citizens of the old town took the more democratic new town, which Prokop unsuccessfully attempted to defend. He now called to his aid Prokop "the Lesser." *(See* below.) They jointly retreated eastward from Prague, but their forces, known as the army of the towns, were defeated by the nobles at Lipan, between Kourim and Kolin, Prokop the Great perishing in this battle (May 30, 1434).

2. PROKOP "the Lesser," or PROKUPEK (the Bohemian diminutive of the word Prokop), was one of the greatest Hussite generals. Little is known of his early life. He took part in all the later campaigns of Prokop the Great in Germany, and succeeded him as commander of the Taborite army that besieged Plzeň. After the formation of the confederacy of the nobles he was recalled by Prokop the Great, with whom he shared the command of the army of the towns at the battle of Lipan, in which he also perished.

See Count Lutzow, *Bohemia: A Historical Sketch;* Palacky, *History of Bohemia;* Toman, *Husitske Valečnictvi* (Hussite Warfare).

PROKOPOVICH, THEOFAN (1681–1736), Russian archbishop and statesman, one of the ablest coadjutors of Peter the Great, was educated at the Orthodox academy of Kiev in Poland, and at Rome in the College of the Propaganda. On his return to Russia he became professor, and subsequently rector of, the academy of Kiev. He reformed the teaching, substituting the historical method of the German theologians for the antiquated Orthodox scholastic system. In 1709 Peter the Great, while passing through Kiev, was struck by the eloquence of Prokopovich in a sermon on "the most glorious victory," *i.e.,* Poltava, and in 1716 summoned him to St. Petersburg. Theofan was rapidly promoted, becoming, in 1718, bishop of Pskov, and finally, in 1724, archbishop of Novgorod. As the author of "the spiritual regulation" for the reform of the Russian Church, Theofan must, indeed, be regarded as the creator of "the spiritual department" superseding the patriarchate, and better known by its later name of "the holy synod," of which he was made the vice-president.

See I. Chistovitch, *Theofan Prokopovich and his Times* (Rus.; St. Petersburg, 1868); P. Morozov, *Theophan Prokopovich* as *a Writer* (Rus.; St. Petersburg, 1880).

PROLEGOMENON, a preface or introduction to a book, especially a preliminary introductory essay to a learned work, or a treatise which serves as a general survey or introduction to the study of some subject or as a special survey of the subject. The word is more often used in the plural.

PROLETARIAT or **PROLETARIATE,** a term borrowed from the French and used collectively of those classes of a political community who depend for their livelihood on their daily labour, the wage-earning, operative class as opposed to the capital-owning class. The Latin *proletarius*, from which the word was formed, was the name given to the body of citizens possessed of no property and who therefore served the state with their children (*proles,* offspring). This division of the members of the state was traditionally ascribed to Servius Tullius.

PROLOGUE, a prefatory piece of writing, usually composed to introduce a drama. The Greek πρόλογος, included the modern meaning, but was of wider significance, embracing any kind of preface. In Attic drama, a character, often a deity, stood forward or appeared from a machine before the action of the play began, and made from the empty stage such statements as it was necessary that the audience should hear. It was the custom to explain everything that had led up to the play, the latter being itself, as a rule, merely the catastrophe following on the facts related in the prologue. The importance, therefore, of the prologue in Greek drama was very great. With Euripides, as has been said, it takes the place of "an explanatory first act." On the Latin stage the prologue was often more elaborately written than in Athens, and in the careful composition of the poems which Plautus prefixes to his plays we see what importance he gave to it; sometimes, as in the preface to the Rudens, Plautus rises to the height of his genius. Molière revived the Plautine prologue in the introduction to his Amphitryon: Racine introduced Piety as the speaker of a prologue to Esther. The tradition of the ancients vividly affected our own early dramatists. Not only were the mystery plays and miracles of the middle ages begun by a homily, but when the modern drama was inaugurated, the prologue came with it, directly adapted from the ancient practice. Sackville prepared a sort of prologue in dumb show for his *Gorboduc* of 1562; and he also wrote a famous *Induction* (practically a prologue) to a miscellany of short romantic epics by diverse hands. In the Elizabethan drama the prologue was very far from being universally employed. In the plays of Shakespeare it is rare. After the Restoration, prologues became de rigueur. They were always written in rhymed verse, and were generally spoken by a principal actor or actress. See also EPILOGUE. (E. G.; E. E. K.)

PROLONGATION OF VIGOUR: see REJUVENATION.

PROME, a district in the Pegu division of Lower Burma, with an area of 2,938 sq.m. and a pop. (1931) of 410,651. It occupies the breadth of the valley of the Irrawaddy, between Thayetmyo district on the north and Henzada and Tharrawaddy districts on the south, and originally extended to the frontier of Independent Burma, but in 1870 Thayetmyo was formed into an independent jurisdiction. There are two mountain ranges forming respectively the eastern and western boundaries. The Arakan Yoma extends along the western side. The portion of the district on the right bank of the Irrawaddy is broken up by thickly wooded spurs running south-eastwards. Cultivation is confined to the parts adjacent to the river. On the eastern side lies the Pegu Yoma, and north and north-east of the district its forest-covered spurs form numerous valleys and ravines, the torrents from which unite in one large stream, the Na-weng. The principal river is the Irrawaddy, which intersects the district from north to south; next in importance are the Tha-ni and its tributaries and the Na-weng system of rivers. The district lies on the southern borders of the dry belt and the rainfall ranges from about 35 to 60 inches. The staple crop is rice, but cotton and tobacco are grown, while the custard apples are famous. The forests yield teak and cutch.

The early history of the once flourishing kingdom of Prome is veiled in obscurity. After the conquest of Pegu in 1758 by Alompra, the founder of the last dynasty of Ava kings, Prome remained a portion of the Burman kingdom till the close of the second Burmese war in 1853, when the province of Pegu was annexed to British territory.

Prome, the chief town, is on the Irrawaddy, 161 m. N. of Rangoon, pop. (1931) 28,295. It has a somewhat evil reputation for infectious diseases.

South and south-east the town is closed in by pagoda-topped hills, on one of which stands the conspicuous gilded Shwe Tsandaw. The town was taken by the British in 1825 and in 1852. In 1862 it was almost entirely destroyed by fire. It became a municipality in 1874. Other towns are Shwedaung (pop. 8,408) and Paungdé (pop. 13 479).

PROMETHEUS, son of the Titan Iapetus by the sea-nymph Clymene or by Themis (occasionally other parents are named). He was the friend and benefactor of mankind. He defended men against Zeus, who, according to a widely diffused mythical theory, desired either to destroy the human race and supplant it by a new and better species, or to avenge himself because men had got the better of him. The pedigree and early exploits of Prometheus are given by Hesiod (Theog., 510–616). At a meeting of gods and men at Mecone, it was the business of the assembly to decide what portions of slain animals the gods should receive in sacrifice.

On one side Prometheus arranged the best parts of the ox covered with offal, on the other the bones covered with fat, as the meat was covered in Homeric sacrifices. Zeus, invited to make his choice, chose the fat and found only bones beneath. A similar fable of an original choice, in which the chooser is beguiled by appearance, recurs in Africa and North America. See also Ada Thomsen in Archiv f. *Religionswissenschaft,* XII. 460 et seq. Zeus, enraged at this trick, according to Hesiod, or, according to other versions, desirous of exterminating the few people who had escaped the deluge of Deucalion, either never bestowed the gift of fire, or later withdrew it. Prometheus stole fire, concealed in a hollow fennel stalk (Hesiod, *Works* and *Days*); and a fennel stalk is still used in the Greek islands as a means of carrying a light (cf. Pliny, Nat. *Hist.*, XIII. 126). According to some legends, he gained the fire by holding a rod close to the sun. Probably the hollow fennel stalk in which fire was carried got its place in myth from the fact of its common use. We thus find Prometheus in the position of the fire-bringer, or fire-stealer, and so connected with a very wide cycle of similar mythical benefactors, divine, human, or bestial, among all sorts of peoples from the Murri of Gippsland[1] to Europeans and Vedic Indians[2].

In considering the whole question of fire mythology, one must beware of the hasty analogical method of reasoning too common among mythologists. For example, when a bird is spoken of as the fire-bringer, we need not necessarily conclude that, in each case, the bird means lightning. Again, because a hero is said to have stolen or brought fire, we need not regard that hero as the personification of fire, and explain all his myth as a fire-myth. The legend of Prometheus has too often been treated in this fashion, though he is really a culture hero, of whose exploits, such as making men of clay, fire-stealing is no more than a single example. This tendency to evoive the whole myth of Prometheus from a belief that he is personified fire, or the fire-god, has been intensified by Kuhn's ingenious and plausible etymology of the name Προμηθεύς, which he would connect with Skr. *prāmantha,* a fire-stick.

But there is no real reason to reject the classical interpretation, "fore-thinker" (cf. his brother Epimetheus, "after-thinker," "wise after the event"), for, as already shown, the myth of the stealing of fire and of the fire-stealer is current among races which are not Aryan, and never heard the word *prāmantha.*

Prometheus and Hephaestus (q.v.) are frequently brought into contact, generally as opponents; in some forms of the legend, Prometheus steals fire from Hephaestus's workshop, not from heaven. It is quite possible that Prometheus was an old and genuinely Greek deity, whose province included fire and its earlier industrial applications, but that he was later superseded by the popular oriental deity. If such were the case, it must have been very early, before either Homer or Hesiod wrote,

PROMOTER: *see* COMPANY.

PRONAOS, in architecture, the porch, portico or colonnade in front of the *naos, cella* or enclosed portion of a classic temple.

PRONGHORN or **PRONGBUCK,** the sole existing representative of a family (*Antilocapridae*), intermediate between deer and cattle; the forked horns resemble those of the latter group, but are annually shed and renewed. Standing about 3ft. high at the shoulder, the male prongbuck has the black horns rising vertically above the eyes. The colour is bright sandy fawn, with much white on the face, three white bars on the throat and white under parts and buttocks. The long white hair on the buttocks can be erected and expanded into bunches, these being guides to the herd when in flight. The tail is short. Female prongbuck produce one or two young at a birth, and are either hornless or furnished with more or less rudimentary horns.

Prongbuck, of which two races, the typical *Antilocapra americana* and A. *mexicana,* are recognized, inhabit the open plains of the temperate districts of western North America, where they were formerly abundant.

PRONUNCIATION. By means of his organs of speech man has at his disposal, for the purpose of speech, certain devices. He can make a great variety of sounds, and, subject to the limitations imposed upon him by the physical structure of his speech apparatus, he is able to modify these sounds in certain ways:—

(1) He can modify the length of time during which a sound persists.

(2) He can modify the degree of physical energy devoted to the production of a sound.

(3) He can, in the case of sounds that involve a periodic vibration of the vocal cords, regulate the periodicity of this vibration so as to produce varieties of pitch.

These modifications of Length, Stress and Pitch may serve different purposes, or may be used in various combinations.

1. Nature.—The spoken variety of a language consists of a certain number of sounds, influenced by the three modifications outlined above. These features, in the case of any given spoken language, constitute what we may term the acoustic matter of the language and the reproduction of these acoustic features by a speaker is what is known as a pronunciation of the language. The term "pronunciation" is used to denote the general acoustic features of a language; thus we speak of English Pronunciation, or the Pronunciation of Marathi. It is also used to denote the particular variety of acoustic phenomena used by an individual speaker, or by a particular section of a community; thus we may speak of disliking a man's pronunciation, or of liking the pronunciation of a certain district or social class.

2. Analysis of Pronunciation.—Detailed analysis of the pronunciation of individual speakers is the foundation of our knowledge of the pronunciation of languages and dialects, and those whose business it is to carry out such analysis should so train themselves that they can give reliable and accurate information upon all the aspects outlined above. Sounds must be described in detail, and the modifications, their function and distribution must be noted. Such detailed description of pronunciation is necessary for:—

(1) The study and teaching of the mother tongue, and of foreign languages.

(2) The devising of scientific systems of orthography for hitherto unrecorded languages.

(3) Comparative philological work.

(4) Pronouncing dictionaries.

3. Pronunciation and Language.—A spoken language persists as a "language" so long and only so long, as those who speak it pronounce it in such a way as to be readily intelligible amongst themselves throughout the area in which the language is spoken. Local variants, or fashions of pronouncing, arise in proportion to the extent of the territory over which the language is spread, but so long as those who use these local variants are conscious that they are in the main using the same language, and provided that they continue to use the written language common to the rest of their compatriots, their speech will be regarded as a variant, a dialect, of the main language.

If, for political or other reasons, any one group of dialect speakers desires a linguistic tradition of their own, and propose to make a new written form of their pronunciation, embodying a new and local vocabulary, then the seed of a new language is sown. In the past, whenever a language has, through the political expansion of a nation, spread over an area larger than that which gave it birth, disintegration has set in, beginning with divergence of pronunciation, ending with the establishment of new languages. Thus Sanskrit has given birth to the Aryan languages of India—Hindi, Bengali, Marathi, Gujarati, etc.; Latin has given us Italian, Spanish, French, Portuguese and Rumanian.

4. Pronunciation and Nationality.—Speech habits, amongst which we must include habits of pronunciation, differ from language to language; there is however a certain measure of similarity between the pronunciation of the various languages of a language family; and the language families of the world differ among themselves as considerably in the matter of pronunciation as in any other respect. The clicks of the Hottentot Bushman languages are found only in certain of the Bantu languages. The cerebral consonants of the Aryan and Dravidian languages of India are seldom found in other language families. When a language takes over words from another language, embodies what we call foreign words, the pronunciation of such words will be made to fit in with the general scheme of pronunciation of the borrowing language. French words taken into English will receive English sounds, English rhythm, English stress and English intonation. The very considerable Arabic element in Persian is pronounced in the Persian way, for the pronunciation system of Persian has nothing in common with that of Arabic. So European words are squeezed into Japanese moulds.

It very seldom happens that a language will adopt exotic sounds, or embody in its system sounds other than those which are its linguistic heritage. Instances of this, however, do happen; the cerebral consonants of the Indo-Aryan languages, which are uncommon in the rest of the world, are presumed to have been taken over from the Dravidians. The Arabic ق is preserved in educated Urdu, but in Southern Urdu colloquial is replaced by χ (the sound of "ch" in "loch"), and in Persian, except in the case of speakers who are influenced by a knowledge of Arabic, it is generally replaced by ǥ (the sound of Arabic غ).

5. Representation of Pronunciation.—Among a civilised community, language consists of two forms—a series of sounds, and a series of visual symbols, or letters, representing sounds. This method of making a visual language is known as a phonetic method of writing, and the system of symbols used is known as an alphabet.

On the other hand the visual language may be made without any apparent reference to the pronunciation of the oral language. Such a system is known as an ideographic system.

Most of the languages of the world have a phonetic visual form, the important exception being Chinese. The most widely used alphabets are the Roman, the Arabic, and the Indian, each with certain additions and modifications. The Arabic alphabet, for instance, is made to represent such widely diverse phonetic systems, as those of Arabic, Malay, Hausa, Persian, Urdu, and, until recently, Turkish.

So it has come about that alphabets, designed to represent the pronunciation of specific languages spoken many centuries ago, have spread over the modern world, and are used to express the pronunciation of many languages that have nothing in common with the pronunciation systems for which they were designed.

Since, as has been said, sight and sound are irreconcilable, it follows that any attempt to represent by means of visual symbols things that have no visual existence will be at best but partially successful, and will rest upon a variety of conventions. Each symbol will originally do duty for one "sound"; various devices may be employed to indicate the relative length of sounds, if it is felt desirable to denote this feature of the pronunciation; the position of what is known as the stress or accent may, or may not, be marked; it may be evident from other data. The intonation is not as a rule indicated, but there are certain devices, such as punctuation marks, interrogation and exclamation marks, the use of a form of type differing from the rest, which are conventionally associated with certain features of the intonation. The phonetic medium, although evidently the most expedient, is a clumsy one for the general purpose of representing language, but it is the only one for representing pronunciation. The world's great alphabets are, as we have seen, in reality obsolete, because each was designed to represent the pronunciation of one language many centuries ago. When extended to other languages they have proved either inadequate or redundant. The Roman alphabet, suitable for a language like Latin with its simple system of five vowel sounds, is completely inadequate for English with its twelve vowel sounds. The Arabic alphabet, designed for the peculiar word formation of Arabic, with its scanty vowels and abundant consonants, is inadequate for the Persian vowel system, and redundant for the Persian consonant system. Similarly the Devanagari alphabet proves inadequate to represent the pronunciation of the modern Indian vernaculars.

When, for various reasons, the visual language is a poor representation of the existing state of the pronunciation of a language, the language is commonly said to be unphonetic. This means that there is an absence of regularity in the conventional relationship between sound and symbol, which may be due to the unsuitability of the alphabet, or to the fact that the visual language, having become established in popular use at some distant period, has refused to register the phonetic changes that have taken place since. Attempts to readjust the relationship between spelling and pronunciation are usually vigorously resisted in all languages, there being a universal desire, apparently, to see in the historical form of the visual language something either sacred, as in the case of Arabic, or etymologically valuable, as in the case of English. In some parts of the English speaking world tentative attempts at this readjustment, which is known as Spelling Reform, are being made.

Where, as in the case of many African languages, no traditional visual languages exist, systems of writing, usually with the Roman alphabet, less frequently with the Arabic alphabet, have been designed, but here again the inadequacy of the alphabets has proved a serious obstacle. The sound systems of the great African language families have nothing in common with the sound systems of Europe, and little in common with one another. It is interesting to note that there is now being designed a special alphabet, based largely on the Roman, suitable for the representation of the pronunciation of the principal African languages, and that literature using the new script is beginning to appear.

To remedy the deficiency of traditional alphabets, many more detailed and adequate visual systems have been designed for the representation of pronunciation. These are of four classes:—

(1) Based on no existing visual forms, *e.g.*, The Bell-Sweet system.
(2) Based on a code, *e.g.*, Jespersen's Analphabetic system.
(3) Based on existing Roman letters with abundant diacritical marks, *e.g.*, The Lepsius Alphabet.
(4) Based on existing Roman signs, but using new letters instead of diacritical marks, *e.g.*, The International Phonetic Association Alphabet.

One or other of these systems must be used when it is desired to describe a pronunciation in detail, as in pronouncing dictionaries, descriptions of languages, and in comparative philological works.

Phonetically there is little to choose between these systems, but recent investigation into their comparative merits would appear, upon psychological, pedagogical and typographical evidence, to favour alphabets of the fourth class.

6. Influence of Spelling upon Pronunciation.— There is observed, in the case of highly civilized and educated communities, where the majority of the speakers are familiar with the visual language, a very marked influence exerted by the visual language upon the pronunciation. The visual language, which was originally designed to represent the pronunciation, and to be subservient to it, tends to become the criterion of accuracy, and to dominate the pronunciation.

As familiarity with the visual language increases so a new standard of accuracy in pronunciation arises, namely, the printed word. This is very evident from a consideration of the pronunciation of English place names. Historical pronunciations are being abandoned in favour of pronunciations more in keeping with the visual forms, which become familiar only with the advent of postal and railway communication. Daventry is now pronounced as written, though a local pronunciation, Daintry, has existed for centuries. It is interesting to record these old pronunciations, but it is doubtful whether they can now be restored to general use. If Daintry is to be admitted at the expense of Daventry, then "ain't" must be given preference to "haven't," for the principle that governs the disappearance of the medial "v" is the same in both cases. The influence of the visual upon the spoken language is likely to be a prominent feature in determining the future pronunciation of language.

7. Standards of Pronunciation.— The impression that one form of pronunciation is "better" than all others appears to be common in the languages of most civilized communities; it is found even in the case of those African languages that have never been written. The prestige of this form of pronunciation varies from language to language, and the degree of adverse criticism levelled at those who do not use it varies from country to country. It is by no means certain that there is now, or that there has ever been at any time, in any language, with the possible exception of Classical Arabic, what is popularly called a standard pronunciation; but it is quite evident that the desire for such a criterion is widespread.

The greater the territorial extent of the nation, the greater will be the number of metropolitan centres; the more organized and complex the social life, the greater will be the number of social classes, each with its own conventions of pronunciation. Where, as in the case of English, separate nationalities, at different ends of the earth, speak the same language, there will tend to grow up in each centre of national life, a different ideal as to what is considered the most desirable pronunciation. There is no more evident manifestation of national entity than a national language, and a new national language will begin when any one of the national groups of the English-speaking world desires to establish a national standard of pronunciation at variance with that in vogue in the geographical area where the language was born. History tends to teach that disintegration was inevitable in the conditions that prevailed in the past; it may be checked by increased oral communication, increased intermingling of population, but most of all by the definite teaching throughout the area, of one form of pronunciation. This teaching has preserved the entity of Classical Arabic; it has not prevented the disintegration of the Arabic into the various colloquial pronunciations that prevail in the different parts of the Arabic-speaking world.

In England there are local variants and class variants of pronunciation. The higher we ascend the social scale in all districts, the greater the uniformity in the pronunciation. The uniformity of the educational system—public school and university—of certain social classes leads to a uniformity in the pronunciation of those classes. This type, provided it is free from pedantry and affectation, is generally regarded as the nearest approach to a standard pronunciation of southern English. It is the style of pronunciation heard most often in public speech, in parliament, in the church, in the law courts, in the universities and the public schools, and in such of the State schools as recruit their teaching staff from the ranks of those who use this style of pronunciation. In detail it may differ slightly from county to county. from school to school, from speaker to speaker, but in the main it is recognizable as one pronunciation. Those who use it have approximately the same vowels; its rhythm is the same wherever we hear it; its intonation follows the same general principle; it uses the same means to achieve the effects of emphasis: and it is characterized among other things, by a peculiar treatment of the "r" sound. In most of these respects southern pronunciation differs from what is known as northern pronunciation, and in all of them it differs from American and Canadian pronunciation which have their own vowels, their own rhythm, their own intonations, their own distinctive treatment of the "r" sound, which reacts in no uncertain manner upon their vowel systems. America and Canada have their own pronunciation problems, for their enormous geographical extent is giving rise to local varieties, and localized standards. There is no standard pronunciation of English in these countries, any more than there is in Great Britain. The increased use of inter-continental oral communication, by means of telephone and wireless broadcasting, the interchange of teachers and actors, the use of the speaking film, may tend towards a certain degree of uniformity in the pronunciation of the English-speaking world, but these must be supported by definite action on the part of those responsible in all countries for the teaching of the mother tongue. It is agreed that a uniform pronunciation of English is desirable, but it is by no means certain how it is to be brought about. A group of English and American linguists met in London in 1927 to discuss the matter.

In 1926 the British Broadcasting Corporation set up an Advisory Committee to deal with doubtful questions of English pronunciation, and to settle, in the case of (1) unfamiliar words, (2) words having alternative pronunciation of equal currency and authority, (3) foreign words, upon one pronunciation to be used by the official speakers of the Corporation. The first list of this committee's recommendations was published in 1928.

8. Change of Pronunciation. — The study of language reveals an inability, on the part of pronunciation, to persist unchanged in any given place, or community, over a long period of time. The universal law is change; during their lifetime languages change slowly, imperceptibly, but nevertheless surely. It is not possible to assign any adequate reason for this universal and eternal change. It is possible that the change has its origin in man's physical and mental limitations. The link that holds the speech of one generation to that of the next is but a feeble one; speech persists as a series of recollected auditory images, associated with certain kinesthetic movements, which are however of secondary importance as far as the speaker is concerned. He is more concerned with the expression of his thought than with the physical adjustments by means of which his thought receives audible expression. This combined mental and physical process appears to produce upon the mind of the listener impressions of a fugitive character, which are less durable than the impressions created by the combined visual and physical processes involved in the visual language. Speech, as such, perishes instantaneously, having no permanent existence, being handed on by oral tradition, and suffering, during the centuries, like all else that lives only by word of mouth. So pronunciation changes from age to age, partly because it hangs on so fragile a thread as man's aural memory, and partly because the unconscious physical processes that give rise to the sounds, in themselves suffer modification owing to the lack of consciousness with which they are controlled. "Pottage" and "porridge" are now different "words" They are in reality but two pronunciations of the same word, and the curious story of their separate existence can still be learnt by listening to the bus conductor who announces Swiss Cottage as Swiss "Corridge." It is probable that wider study will tend to establish the fact that a given speech sound, under given conditions, will always change in a certain way. But it must not be forgotten that it has hitherto proved impossible to define what is meant by the term "speech sound," and we should do well to remember that the governing conditions are likely to prove more complicated than they appear upon examination of cases that have happened in the past. The principles governing the change in vowel sounds, the formation of which involves no tactile sensation in the mouth, appear to have nothing in common with the principles governing the change of consonant sounds, in the formation of which there is definite contact between two parts of the mouth, or enough constriction to give an impression of contact.

g. Teaching of Pronunciation. — The study of the mother tongue, and of foreign languages, must, if it is to be sound, rest upon a knowledge of pronunciation, which lies at the root of things so widely apart as sentence structure, syntax, rhythm and systems of versification.

The teaching of pronunciation requires, on the part of the teacher, training of a highly specialized order, and it should not be considered that a teacher is competent to teach the pronunciation of a language merely because that language happens to be his mother tongue. We are all, without special training, unaware of the various features that constitute the pronunciation of our language; we become conscious that there is a highly complicated system underlying our pronunciation only when we hear the system disturbed by foreigners who speak our language badly, *i.e.,* with the pronunciation system of their own.

The pronunciation of most European languages has been studied on modern phonetic lines, and there is an abundance of reliable literature on the subject. Research into the phonetic structure of American, Asiatic and African languages is proceeding, and reference libraries of gramophone records of languages and dialects are being established in many universities.

Pronunciation of the mother tongue is taught in the principal centres of education in the countries of Europe and America. It has already been stated that the traditional pronunciation of Arabic, reputed to have been that used by Mohammed, is still regularly taught throughout the Mohammedan world.

In Europe we find, in the case of French, a traditional stage pronunciation taught at the Conservatoire in Paris, and used in the State Theatres and Opera House. In Germany an attempt has been made to standardize a form of German pronunciation suitable for the theatre throughout German-speaking countries.

No such attempt at standardization has been made in England or America. As far as England is concerned, the pronunciation current upon the stage is that used by the educated people in the south-eastern part of the country.

This pronunciation, with, however, a certain degree of latitude, is taught in England for use on the stage, in public speaking, and in singing In the universities and public schools of England the pronunciation is left to look after itself, but there is, however, a strong tradition as to what is and what is not permissible.

In the State schools there appears to be an awakening to the importance of equipping children with a form of pronunciation that will not prove a handicap in social life; and endeavours are being made to provide instruction.

10. Conclusion. — It is difficult to forecast the future, for we are faced with a new set of conditions. Increased speed of transport has made the world smaller; the complication of modern life leads to an international vocabulary; increased travel and increased oral communication familiarize us with hitherto unfamiliar pronunciations; the increase of education familiarizes millions with visual language, while wireless broadcasting tends to make the inhabitants of a widely spread linguistic area acquainted with a selected form of pronunciation. It is possible that these combined forces may tend to prevent linguistic disintegration of the principal languages of the modem world.

(A. Ll. J.)

PROOF, that which establishes the truth of a fact or the belief in the truth (*see* Logic). In law "proof" is the establishment of the facts in issue in a particular case, by proper legal means, to the satisfaction of the court (*see* Evidence) ; specifically, documents so attested as to form legal evidence, written copies of what a witness is prepared to support on oath, and the evidence of any case in the court records are all termed "proofs." In Scots law the term is used of a trial before a judge alone as opposed to trial by jury. A trial impression, in printing, on which corrections and additions can be made (*see* Proof-reading) and, in engraving and etching, one of a limited number of impressions made before the ordinary issue is printed, are known as "proofs." In the earlier history of engraving a "proof" was an impression during the process of printing made for the artist's inspection. In the modern use of the term, where the impression has been taken before the inscription has been added to the plate, it is called a "proof before letter."

PROOF-READING, the process of correcting for the press the printed "proofs" of articles or books or other matter before publication. The signs most commonly used in proof-reading follow:

Sign	Meaning	Sign	Meaning
	Delete	em |	Em dash
	Delete and close up	en |	En dash
	Reverse	; |	Insert semicolon
	Close up	(:)	Insert colon and en quad
#	Insert space	(.)	Insert period and en quad
¶	Paragraph	? |	Insert interrogation point
□	Indent one em	(?)	Query to author
[	Move to left	⌒	Use ligature
]	Move to right	(sp)	Spell out
	Lower	tr	Transpose
	Elevate	wf	Wrong font
∧	Insert marginal addition	bf	Set in **bold face** type
V∧	Even space	rom	Set in roman type

	Insert comma		Lower-case letter
	Insert apostrophe	stet	Let it stand
	Insert quotes	no ¶	Run in same paragraph
=|	Hyphen	ld >	Insert lead between lines

PROOF SPIRIT. The term applied to standard mixtures of alcohol and water which form the basis of charge of Customs and Excise duties in Britain and elsewhere.

The Spirits Act of 1816 (Great Britain) in legalising Sikes' hydrometer for revenue purposes gave for the first time a legal definition of proof spirit as follows:—"that which at the temperature of 51° F weighs exactly % of an equal measure of distilled water." The act did not state the temperature of the water and considerable discussion has taken place on this point. Documentary evidence has been discovered recently which places beyond all doubt that the temperature of the water was intended to be 51° F. The most recent investigation has established the fact that, at 60° F, proof spirit has a specific gravity of 0·91976, compared with water at the same temperature, and that it contains 49.28 per cent by weight or 57·10 per cent by volume of alcohol.

The British Proof system is based upon volume percentage at 50° F. Owing to the difference in the rate of expansion of alcohol and water the volume composition of any mixture of these two substances varies with the temperature. The British system ignores this change and allocates to a mixture the volume percentage and therefore the proof strength appropriate to it at 50° F. Although not strictly correct at other temperatures, the system has the merit of being highly convenient to both the revenue authorities and the spirit trade. Spirits, at strengths other than "proof," may be described as containing a percentage of proof spirit or as being "over proof" or "under proof." The percentage of proof spirit is that number of volumes of Proof Spirit which can be obtained from one hundred volumes of the mixture Thus at 50° F 100 volumes of absolute alcohol if diluted with water to proof strength give 175·35 volumes. It is therefore said to contain 175·35% proof spirit or to have a strength of 75.35 over-proof. In order to ascertain the number of gallons of proof spirit equivalent to the alcohol contained in a mixture of known strength and volume the number of gallons of the mixture is multiplied by the percentage of proof spirit and divided by 100.

American proof spirit contains 50% by volume of Tralles' alcohol at 15·6° C (60° F). This alcohol is not quite anhydrous having a specific gravity, at 15·6° C, of 0·7946, as compared with 0·79359 for absolute alcohol. In the Dutch system Proof Spirit contains 50% of anhydrous alcohol at 15° C (59° F.)

(F. G. H. T.)

PROPAGANDA. The purpose of propaganda is to influence opinion and conduct. Between the purpose itself and the methods employed to attain it a distinction should be made, and also between the original meaning of "propaganda" and the meaning which the word has gradually acquired. Since the World War, when all belligerent countries undertook it as an adjunct to their diplomatic and military operations, propaganda has come to be looked upon as mere advocacy of special interests or as an attempt to gain credence for statements partially or wholly untrue. Though this meaning was, and still is, justified, it is not exhaustive, nor are coloured or partial presentations of a particular point of view necessarily the most effective form of propaganda.

In one form or another, propaganda is probably as old as mankind. Rulers of States and political leaders, the founders of religions, of schools of philosophy and of new social systems have usually sought to persuade others of the goodness of their ideas and deeds. The most notable instance is the injunction of the Founder of Christianity to the disciples—"Go ye into all the world and preach the gospel to every creature" (Mark XVI. 15.). Obeyed by the early Christians, this injunction was presently reflected in the official style of the committee of cardinals of the Roman Church in charge of foreign missions—*Congregatio* de propaganda *fide.* It is likewise held to warrant the activities of non-Catholic Christian missionary societies.

Other religions, especially Islam, have frequently sought to propagate their faith by persuasion or force. The sword was for long the most effective agency of Islamic propaganda—widened later by moral persuasion also—though Islam was by no means the first or the only religious creed to spread its doctrines by physical violence. The Hebrew scriptures contain many references to "the sword of the Lord." The spread of Christianity itself was hastened by military means—witness the campaigns in which Charlemagne imposed it upon pagan tribes, and the forcible conversion of Mexico and other countries of central and southern America by the Spanish Conquistadores and their successors. The papacy itself sanctioned wars and persecutions as means of propaganda; and the annals of protestantism are not wholly free from violent deeds. To propagate or to defend beliefs supposedly salutary was the purpose. The use of force was the means.

Propaganda Before the War.—Official propaganda, organised by Governments, is mainly a post-war undertaking. Before 1914 Germany alone among the great countries of the world carried it on systematically. While other countries and other Governments engaged, from time to time, in special propagandist campaigns for definite objects, German propaganda was continuous and widespread. It was carried on chiefly by the Press Bureau of the German Foreign Office among the representatives of foreign newspapers resident in Berlin; by foreign press bureaux and telegraph agencies affiliated to the German press bureau and to the German official telegraph agency; by the staffs of German embassies and legations abroad, and by the head offices of foreign branches of German banks and shipping companies. Its object was to spread impressions favourable to Germany, to secure the publication of German views in the press and, as far as possible, to prevent or to neutralise unfavourable comment upon or criticism of German policy and German affairs. One drawback of this kind of propaganda is that those who engage in it are apt to be its victims. They end by mistaking the impressions which they have sought to convey for the convictions of those who receive them, and therefore to misjudge the effects produced.

War Propaganda.—For some months after the war broke out

German propaganda had the field to itself. The Allied Governments were unprepared to meet it. Directly, by wireless, and indirectly from centres established in neutral countries, German versions of the causes of the war and of the aims of the belligerents were circulated throughout the world. Undeniable military successes gave point to many of the German claims. Some Allied Governments were so fearful lest these versions and claims undermine the confidence of their peoples that they forbade even the publication of the German military bulletins. In Great Britain a wiser course was followed. The German bulletins were issued to the Press by the British press bureau and were regularly published, in whole or in part, by British newspapers since they, like the Government, were confident that the public would assess the German statements at their true value. This system was, in itself, a form of counter-propaganda since it used the exaggerations or the inaccuracies of enemy bulletins to neutralise their effect and to enhance the belief of the British public that it was being told substantially the truth about the progress of the war.

In France, on the other hand, the press was not allowed to publish the German bulletins. The French Government thought the French people might suspect it of hiding the truth if another than its own version of events were issued. Consequently a demand arose in France for the French-Swiss newspapers which contained the German bulletins. In this way their effect as propaganda was actually increased, and served to strengthen the direct influence of the subtle "defeatist" propaganda which the clandestine agents of Germany carried on among the French people.

Allied Propaganda. — When the Allied Governments, in their turn, decided to organise propaganda, they found themselves at a disadvantage. Their organisations had to be improvised, whereas the German organisation had been set up in peace time and perfected in the early months of the war. Moreover, German propagandists understood that, in propaganda as in actual warfare, the initiative is precious and that the offensive is better than the defensive. At first, Allied propaganda was everywhere on the defensive. Its purpose was conceived as the correction of the misstatements sent out by the enemy. However truthful the denial of a misstatement may be, "a lie has long legs." The inferiority of Allied propaganda in this respect became evident to the public in neutral countries; and the position was not improved when the Allied and British organisations began to issue large quantities of dull literature to explain the purity of Allied intentions and the formidable character of British military preparations. To be effective, propagandist literature needs to be interesting. Compilations of figures and declarations of lofty purpose can make little headway against news so attractively embellished as to kindle the imaginations of those who read it. In its early phases British war propaganda was not merely ineffective but inept. It failed to realise that appeals to enemy and neutral opinion must take account of enemy and neutral standpoints. It assumed that arguments convincing to British minds would equally convince foreign minds.

Before 1914, war had been commonly looked upon as a legitimate method of promoting national interests. Yet, in 1914, the chief belligerent countries felt, almost instinctively, the importance of proving that they were guiltless of having caused the struggle. Nobody claimed credit for having planned it or forced it on. The German imperial chancellor admitted from the outset in the Reichstag, on Aug. 4, 1914, that Germany was doing "wrong" by invading neutral Belgium. He claimed that "necessity knows no law" and promised to make good the wrong "as soon as our military goal has been reached." Other German spokesmen and agents attempted to throw the blame first on England and then on Russia; while the Allied countries unanimously blamed Germany and Austria-Hungary. By degrees, the conquest of neutral opinion was seen to be almost as important as victory in the field.

With the recognition of this aspect of the struggle came the search for means of waging it. Here, again, Germany outdistanced her enemies. Neutral war correspondents were invited to accompany the German armies and to supplement the German military bulletins by ostensibly independent accounts of their own. The Allied military authorities long hesitated to follow this example. Strong pressure was needed to make them realise that the war was a war of peoples, and therefore of opinion, not solely a war between armies; that even their own peoples' enthusiasm for a "war in the dark" might wane; and that it was expedient to counteract the effect upon neutral opinion of reports from the German front by equally graphic reports from the Allied fronts, attested by the names of writers whom neutral countries would trust. Thus, very tardily, regular war correspondents were attached to the Allied armies for the enlightenment of the Allied peoples, while neutral correspondents of recognised standing were invited to see things for themselves. In this way the influence of German journalistic propaganda was gradually offset, and the significance of the war as a war of opinion was recognised.

Propaganda and Policy. — Yet it was not until the beginning of 1918, in the middle of the fourth year of the war, that the need for a propagandist offensive, not only in neutral countries but among the enemy peoples themselves, began to be felt by Allied Governments. Confronted with a position of stalemate in the field, and perplexed by the protraction of the struggle, they realized at last that propaganda, in itself, no matter how skilful its methods, would be futile unless it were the expression of a definite policy. Until then, the only policy of the Allied Governments had been to secure military victory. They had not seriously attempted to express their eventual victory in terms of a lasting peace, so as to give enemy peoples something to hope for as well as something to fear. True, the President of the United States, Woodrow Wilson, had taken a step in this direction when, in Dec. 1916, he had invited all the belligerents to define their war aims. The necessity of answering this invitation had compelled Germany and Austria-Hungary, on the one hand, and the Western European Allies, on the other, to state broadly what they were fighting for, lest failure to respond to the American invitation should influence adversely the opinion of the — still neutral — American people. But it was not until more than a year later that the British prime minister, D. Lloyd George, spontaneously issued a statement of British war aims on January 5, 1918, in the form of an outline of peace conditions. This statement, which was clearly propagandist, was followed, three days later, by an important American pronouncement. On Jan. 8, President Wilson delivered to a Joint Session of the American Congress an address containing his famous "Fourteen Points," or principles, on which the United States would insist in the negotiation of peace. Whether or not he conceived this address primarily as propaganda, its propagandist effect was immediate. Nowhere was it greater than in Austria-Hungary and Germany.

Propaganda Against the Enemy. — Shortly afterwards, the British Government decided to establish a special department for propaganda against the enemy. The late Lord Northcliffe was persuaded to take charge of it; and, acting under expert advice, he made it a condition that the statements to be disseminated by his department should correspond strictly to the policy which the Government was determined to follow. The condition having been accepted, his department drew up an outline of policy which was submitted for official sanction. Then the first inter-Allied propaganda conference was summoned to coordinate means of action on the basis of this policy. Its main postulate was that the Allied Governments should promise freedom and independence to the subject races in the Austro-Hungarian Monarchy and to the Poles of Prussia and Russia. To this postulate the British Government at first demurred. Not until after the great German offensive of March 21, 1918, did it assent. Then, under stress of circumstances, the postulate was admitted; and, in proclamations sanctioned by the congress of the oppressed Austro-Hungarian peoples held in Rome at the beginning of April 1918, the non-German and non-Magyar troops of Austria-Hungary on the Italian front, and their peoples in the interior, were assured of the Allies' determination to liberate them.

The effect exceeded expectations. The Austro-Hungarian front quickly showed signs of disintegration, and the Habsburg Monarchy itself began to totter. Austro-Hungarian soldiers belonging to the subject races came over into the Allied lines in Italy bring

ing valuable information. The efficacy of propaganda as an instrument of sound policy was proved; for the policy itself corresponded to the underlying facts of a situation which the Allied Governments had been reluctant to recognise. The result was not achieved merely by the propagandist method of passing resolutions at the Rome Congress of the oppressed Habsburg peoples or by that of disseminating paper manifestos among the Austro-Hungarian troops on the Italian front. The adoption of the policy which those resolutions and manifestos proclaimed was itself a sequel to steady propagandist work which had been carried on in Western Europe and in the United States by representatives of the subject Habsburg peoples, notably by Czechoslovaks like Professor Masaryk and Dr. Beneš; by refugees from the Southern Slav provinces of Austria-Hungary like M. Supilo and Dr. Trumbitch; and by prominent Poles like MM. de Paderewski and Dmowski. They had gradually educated public opinion in Allied countries to an understanding of the conditions indispensable to a lasting peace in Central Europe. From the outset their propaganda had been conceived in terms of policy, and their policy framed in accordance with historical and contemporary fact. In order to make fact more convincing, Professor Masaryk had gone to Russia in May 1917 where he had succeeded in raising a force, or legion, of nearly 50,000 men from the Czech and Slovak soldiers of the Austro-Hungarian army who had surrendered to the Russians; and, after the Bolshevist Revolution in Russia, he had decided that his legion should march from the Black Sea through Siberia to Vladivostok on its way to join the Allied forces in Western Europe. In the United States and in Europe the propagandist effect of this march was overwhelming. It was "propaganda by deed" on the largest scale.

Allied policy in regard to one enemy country, Austria-Hungary, having been settled—if only as a basis for propaganda, in the first instance—it remained to work out and to apply a policy for propaganda against Germany and the German army. Obviously this policy was bound to reflect the military and political situations; and not until these situations began to turn in favour of the Allies could it be effectively framed or pursued. Once again, inaccurate or merely "propagandist" statements were eschewed. It was recognised that, in the long run, truth alone is persuasive, and that declarations of intention must swiftly be substantiated by events. Therefore the leaflets, which were distributed by millions over the German lines in France and Flanders in the summer of 1918, bore, on one side, an accurate map of the front, indicating gains and losses of ground in recent fighting; and, on the other side, comments upon the situation in Germany taken from German newspapers which were not allowed to reach the troops at the front. In a short time the German rank and file, which knew how much ground they had gained or lost, were convinced that these leaflets were truthful; while the extracts from the German press gave them, for the first time, an inkling of the state of affairs on their "home front." In conjunction with the successes of the Allied armies, these leaflets demoralised the German forces to such an extent as seriously to perturb the German commanders.

Propaganda at the Peace Conference.—The demonstration that successful propaganda must express a definite policy and that policy must be framed in accordance with actual or prospective fact, remains as the chief lesson of Allied propagandist activities during the war. Yet the lesson was soon forgotten. While preparations for the Paris Peace Conference were being made, some Allied Governments resumed propaganda of the older and less truthful type in the hope of promoting their interests during the negotiation of peace. This propaganda vitiated the whole atmosphere of the peace conference. In the presence of propagandist maps, drawn to substantiate the conflicting territorial claims of a dozen peoples, President Wilson exclaimed, indignantly: "Bring me maps that do not overlap." Drawn, written or spoken inaccuracies were accompanied by intrigue and pressure until the responsible statesmen of Europe found themselves so enmeshed that their expert advisers could not wholly disentangle them. Had not the framework of a peace settlement been created by the necessities of policy, as a basis for propaganda, during the war, the peace conference might have failed to reach even an approximately equitable settlement. As it was, the force of facts was too strong to be entirely overcome by interested misrepresentation.

Post-war Propaganda.—For some years after the peace conference, propaganda of the less laudable kind continued. It surrounded every meeting of the Supreme Allied Council for the adjustment of post-war difficulties. Alongside of it ran persistent German propaganda of which the object was to disprove the charge that the Government of pre-war Germany had been especially responsible for the war. Among the German people this propaganda was highly successful, and it made some impression in Allied countries. A monumental collection of German diplomatic documents, covering the period between 1870 and 1914 was issued in more than 50 volumes. The British Government, in its turn, presently authorised a similar publication of its documents, and at length, the French Government decided to follow the German and the British examples. Gradually the distinction between good propaganda and bad was again recognised, and a preference was shown for impressive presentations of truth. Realising that the public is entitled to information, and that declarations susceptible of being controverted on the morrow have little lasting value, many Governments established central offices to supply information, and attached special officials to their embassies, legations and consulates abroad in order to furnish it. Even if the line of demarcation between information and propaganda has not been everywhere scrupulously observed by these agencies, the general tendency has undoubtedly been towards greater truthfulness—except in the case of propaganda emanating from Governments which have suppressed freedom of opinion in their own countries.

Russian Communist propaganda, in particular, has been wholly unscrupulous in its efforts to promote a world revolution; and Western Governments have been obliged repeatedly to insist, as a condition of normal relations with Russia, that it should cease. But, as often as this condition has been accepted, it has been violated, for revolutionary propaganda abroad is looked upon as essential to the maintenance of a "dictatorship of the proletariat" in Russia. In point of fact, the world has become, since the war, the scene of a contest between incompatible views of social and political organisations just as it was during the war an arena for contending opinions upon the aims of the belligerents.

Propaganda for Peace.—In substance, the principle at issue is whether or not force shall be recognised as the final arbiter in human affairs. Against the advocates of force, propaganda is being vigorously pursued for the promotion of international peace and for the elimination of violence from international relations. In many countries influential peace societies have been formed to urge peoples and Governments to abandon the very idea of resorting to force in their dealings with other Governments and peoples. This propaganda derived strength from the establishment of the League of Nations by the Peace Treaties; and the United States of America, though not a member of the League of Nations, promoted in 1928 the conclusion of a world-wide treaty to renounce war as an instrument of national policy.

The Outlawry of War.—Peace propagandists are agreed upon their main object—the prevention of war and the enthronement of law as the supreme arbiter between nations—but they differ upon the means of attaining it. Some hold it incompatible with the pacifist ideal to apply "sanctions," that is to say, coercive measures, against the warlike. Others believe that "sanctions" are as necessary in upholding international law as pains and penalties are recognised to be in vindicating the laws of individual communities. The founders of the League of Nations were convinced that some provision should be made to coerce Governments guilty of making war without submitting their claims in advance to mediation, arbitration or conciliation. For this reason "sanctions," economic and military, were contemplated in the League of Nations Covenant. On the other hand, the partisans of the "outlawry of war" urge that it would suffice to forbid war by international agreement. Only thus, they claim, can peoples and governments be brought to conceive international relations in terms of peace instead of in terms of war as the *ultima ratio*.

Between these two schools of thought, controversy has been lively and protracted. Propaganda for the definition of an eventual 'aggressor," on the one hand, and for the simple "outlawry of war" on the other, has been vigorously carried on; but the practical efficacy of the arguments advanced on both sides may depend upon political and economic circumstances. The increasing rapidity of communication between nations, and the inter-twining of their financial and commercial interests appear to operate in favour of peace. However strongly individual peoples may cling to their several rights and sovereignties, the leading nations feel that a violent clash between their aims and the aims of others might expose them to disaster if not to destruction. Circumstances are thus propitious to propaganda for peace, inasmuch as they tend to make it representative of sound policy; and, in the light of experience, this condition should suffice to ensure its success.

(H. W. S.)

PROPELLER. For a description of the propeller as applied to aircraft see the article AIRSCREW. For marine propellers, see SHIPBUILDING.

PROPERTIUS, SEXTUS (*fl.* 30–15 B.C.), the greatest of the elegiac poets of Rome, was born of a well-to-do Umbrian family at or near Asisium (Assisi), the birthplace also of the famous St. Francis. We learn from Ovid, that Propertius was his senior, but also his friend and companion; and that he was third in the sequence of elegiac poets, following Callus, who was born in 69 B.C., and Tibullus, and immediately preceding Ovid himself, who was born in 43 B.C. We shall not then be far wrong in supposing that he was born about 50 B.C. His early life was full of misfortune. He lost his father prematurely; and after the battle of Philippi and the return of Octavian to Rome, Propertius, like Virgil and Horace, was deprived of his estate to provide land for the veterans, but, unlike them, he had no patrons at court, and he was reduced from opulence to comparative indigence. The widespread discontent which the confiscations caused provoked the insurrection generally known as the *bellum perusinum* from its only important incident, the fierce and fatal resistance of Perusia, which deprived the poet of another of his relations, who was killed by brigands while making his escape from the lines of Octavian. The loss of his patrimony, however, thanks no doubt to his mother's providence, did not prevent Propertius from receiving a superior education. After, or it may be, during its completion he and she left Umbria for Rome; and there, about the year 34 B.C., he assumed the garb of manly freedom. He was urged to take up a pleader's profession; but, like Ovid, he found in letters and gallantry a more congenial pursuit. Soon afterwards he made the acquaintance of Lycinna, about whom we know little beyond the fact that she subsequently excited the jealousy of Cynthia, and was subjected to all her powers of persecution (vexandi). This passing fancy was succeeded by a serious attachment, the object of which was the famous "Cynthia." Her real name was Hostia, and she was a native of Tibur (iv. 7, 85; iii. 20, 8). She was a courtesan of the superior class, somewhat older than Propertius (ii. 18, 20) but, as it seems, a woman of singular beauty and varied accomplishments. Her own predilections led her to literature; and in her society Propertius found the intellectual sympathy and encouragement which were essential for the development of his powers. Her character, as depicted in the poems, is not an attractive one; but she seems to have entertained a genuine affection for her lover. The intimacy began in 28 and lasted till 23 B C. These six years must not, however, be supposed to have been a period of unbroken felicity. Apart from minor disagreements an infidelity on Propertius's part excited the deepest resentment in Cynthia; and he was banished for a year. The quarrel was made up about the beginning of 25 B.C.; and soon after Propertius published his first book of poems and inscribed it with the name of his mistress. Its publication placed him in the first rank of contemporary poets, and amongst other things procured him admission to the literary circle of Maecenas. The intimacy was renewed; but the old enchantment was lost. Neither Cynthia nor Propertius was faithful to the other. The mutual ardour gradually cooled; motives of prudence and decorum urged the discontinuance of the connection; and disillusion changed insensibly to disgust. Although this separation might have been expected to be final, it is not certain that it was so. It is true that Cynthia, whose health appears to have been weak, does not seem to have survived the separation long. But a careful study of the seventh poem of the last book, in which Propertius gives an account of a dream of her which he had after her death, leads us to the belief that they were once more reconciled, and that in her last illness Cynthia left to her former lover the duty of carrying out her wishes with regard to the disposal of her effects and the arrangements of her funeral. Almost nothing is known of the subsequent history of the poet. He was alive in 16 B.C., as some allusions in the last book testify. And two passages in the letters of the younger Pliny mention a descendant of the poet, one Passennus Paullus. Now, in 18 B.C. Augustus carried the *leges Iuliae,* which offered inducements to marriage and imposed disabilities upon the celibate. Propertius then may have been one of the first to comply with the new enactments. He would thus have married and had at least one child, from whom the contemporary of Pliny was descended.

Propertius had a large number of friends and acquaintances, chiefly literary, belonging to the circle of Maecenas. Amongst these may be mentioned Virgil, the epic poet Ponticus, Bassus (probably the iambic poet of the name), and at a later period Ovid. We hear nothing of Tibullus, nor of Horace, who also never mentions Propertius. This reciprocal silence is probably significant. In person Propertius was pale and thin, as was to be expected in one of a delicate and even sickly constitution. He was very careful about his personal appearance, and paid an almost foppish attention to dress and gait. He was of a somewhat voluptuous and self-indulgent temperament, which shrank from danger and active exertion. He was anxiously sensitive about the opinion of others, eager for their sympathy and regard, and, in general, impressionable to their influence. His over-emotional nature passed rapidly from one phase of feeling to another; but the more melancholy moods predominated. A vein of sadness runs through his poems, sometimes breaking out into querulous exclamation, but more frequently venting itself in gloomy reflections and prognostications. He had fits of superstition, which in healthier moments he despised.

The poems of Propertius, as they have come down to us, consist of four books containing 4,046 lines of elegiac verse. The first book, or Cynthia, was published separately and early in the poet's literary life. It may be assigned to 25 B.C. The dates of the publication of the rest are uncertain, but none of them was published before 24 B.C., and the last not before 16 B.C. The unusual length of the second one (1,402 lines) has led Lachmann and other critics to suppose that it originally consisted of two books, and they have placed the beginning of the third book at ii. 10, a poem addressed to Augustus, thus making five books, and this arrangement has been accepted by several editors.

The subjects of the poems are threefold: (1) amatory and personal, mostly regarding Cynthia—72 (60 Cynthia elegies), of which the last book contains three; (2) political and social, on events of the day—13, including three in the last book; (3) historical and antiquarian—six, of which five are in the last book.

The writings of Propertius are noted for their difficulty and their disorder. The workmanship is unequal, curtness alternating with redundance, and carelessness with elaboration. A desultory sequence of ideas, an excessive vagueness and indirectness of expression, a peculiar and abnormal latinity, a constant tendency to exaggeration, and an immoderate indulgence in learned and literary allusions—all these are obstacles lying in the way of a study of Propertius. But those who have the will and the patience to surmount them will find their trouble well repaid. For power and range of imagination. for freshness and vividness of conception, for truth and originality of presentation, few Roman poets can compare with him when he is at his best. And this is when he is carried out of himself, when the discordant qualities of his genius are, so to say, fused together by the electric spark of an immediate inspiration. His vanity and egotism are undeniable, but they are redeemed by his fancy and his humour.

Two of his merits seem to have impressed the ancients themselves. The first is most obvious in the scenes of quiet description and emotion in whose presentation he particularly excels. Softness of outline, warmth of colouring, a fine and almost voluptuous feeling for beauty of every kind, and a pleading and melancholy tenderness—such were the elements of the spell which he threw round the sympathies of his reader, and which his compatriots expressed by the vague but expressive word *blanditia.* His poetic *facundia,* or command of striking and appropriate language, is more noticeable still. Not only is his vocabulary very extensive, but his employment of it extraordinarily bold and unconventional. New settings of use, idiom and construction continually surprise us, and, in spite of occasional harshness, secure for his style an unusual freshness and freedom. His handling of the elegiac couplet, and especially of its second line, deserves especial recognition. It is vigorous, varied and even picturesque. In the matter of the rhythms, caesuras and elisions which it allows, the metrical treatment is much more severe than that of Catullus, whose elegiacs are comparatively rude and barbarous; but it is not bound hand and foot, like the Ovidian distich, in a formal and conventional system. An elaborate symmetry is observable in the construction of many of his elegies, and this has tempted critics to divide a number of them into strophes.

Propertius's poems bear evident marks of the study of his predecessors, both Greek and Latin, and of the influence of his contemporaries. He tells us himself that Callimachus and Philetas were his masters (iii. 1, seq.), and that it was his ambition to be the Roman Callimachus (iv. 1, 64). But, as Teuffel has said, his debt to these writers is chiefly a formal one. Even into his mythological learning he breathes a life to which these dry scholars are strangers. We can trace obligations to Meleager, Theocritus, Apollonius, Rhodius and other Alexandrines, and amongst earlier writers to Homer, Pindar, Aeschylus and others. Propertius's influence upon his successors was considerable. There is hardly a page of Ovid which does not show obligations to his poems, while other writers made a more sparing use of him.

BIBLIOGRAPHY.—There is no existing ms. of Propertius older than the 12th century. Up till the publication of Bahrens's edition (1880), the oldest one, Neapolitanus (N., now at Wolfenbiittel), was universally regarded as the best, and even now critics are found to maintain its paramount claims. But the more judicious admit the value of the four mss. collated by Bahrens. Vossianus, *c.* 1300 (A); Laurentianus, end of the 14th century (F); Ottoboniano-Vaticanus, 15th century (V); Daventriensis, 15th century (D), to which has to be added the Holkhamicus, 1421 (L), collated by Postgate, *Cambridge Philological Transactions* (1894) vol. iv.

The *editio princeps* of Propertius is that of 1472 (Venice). Among later editions we may mention the following, those with explanatory or critical notes being marked with an asterisk: *Scaliger (1577, etc.), *Broukhusius (2nd ed., 1577), *Passeratius (1608, with *index verborum*), *Vulpius (1755, with *index verborum*), *P. Burmann (and Santen) (1780), *Lachmann (1816), *Hertzberg (1843–1845), L. Müller (1870), Haupt-Vahlen (last ed., 1904), *Bährens (1880), *A. Palmer (1880), *Postgate (1881), selections with introduction (text with critical notes in the *Corpus poetarum latinorum,* 1905, also issued separately), *Rothstein (1898), *H. E. Butler (1905) and with translation in Loeb library (1912) *index verborum* (to his own text), J. S. Phillimore (1911), Hosius (1911 and 1922). A. E. Housman (without publishing an edition) has done much to improve and explain the poems. For further information we may refer to F. Plessis, *Études critiques sur Properce et ses élégies* (1886), and to Teuffel's and Schanz's *Histories of Roman Literature.*

The following translations into English verse are known G. F. Nott (1782), bk. i.; C. A. Alton, selections in his *Specimens of the Classic Poets* (1814), ii. 21; *scq.;* C. R. Moore (1870); J. Cranstoun (1875); F. A. Paley (1866), verse translations from bk. v. with notes; also a few translations by the poet Gray, vol. i. (Gosse 1884); S. G. Tremenheere (1899), bk. 1. Prose translations: P. J. F. Gantillon (with Nott's and Elton's versions, Bohn, 1848); J. S. Phillimore (1906). (J. P. P.)

PROPERTY, LAW OF: see LAWS RELATING TO REAL PROPERTY AND CONVEYANCING.

PROPERTY, PRIMITIVE. Property is bound up with every aspect of social life. It gives a stimulus to economic effort, enters into questions of marriage, family life, and inheritance, forms the subject of legal judgments, provides compensation for offences, and acts as a frequent incentive to war. It is held in goods such as food, clothing and weapons; and immaterial items (songs, personal names, mythological tales, magical spells, social offices) are in many communities a matter for precise ownership. The tie between man and property is often not one of mere economic interest; the basis of attachment is of the nature of a sentiment, a complex set of emotional considerations centring in the object. Thus to the Maori his tribal land is his greatest treasure, a fact which is illustrated by many proverbial sayings, *e.g.,* "The blood of man is the land" or "Man perishes but the land remains." This love of his ancestral soil is a factor which greatly complicates the economic aspect of alienation. The association of ownership with a tie of sentiment is common to other primitive communities, as with the Lango and their cattle.

The precise meaning of ownership is different in every culture, varying according to custom, tradition and the relative social status of those who enjoy its privileges. Failure to recognize the essential nature of the primitive conception of ownership has led to the formulation of many unreal hypotheses in anthropology—and, in the practical sphere, to misunderstanding and conflict between native and white man.

Primitive Communism.—From a partial study of the evidence, certain social theorists, as Friedrich Engels, were lured by their political ideals—for which this notion formed a useful precedent—to advance the thesis that the most primitive form of ownership was communism. This idea was championed on more scientific grounds by W. H. R. Rivers, who thought he had discovered in Melanesia evidence for the existence of a communistic type of economy marked by a lack of differentiation of personal interests. The institutions of every primitive people show a much closer relation between the individual and his group than that which animates European culture, and a greater readiness (inspired by custom) to yield to the corporate claims of the society. Thus among the Gilyak the catch after fishing is freely divided among the members of the community, even families which have taken no part in the work receiving a share. Yet at the same time private ownership is distinctly recognized in such articles as swords, shields, etc. Among the Mekeo people, again, a pig, an item of family property, is seldom killed except by command of a chief. At the same time the close grip retained by communal interests upon even a man's personal property does not indicate any sweeping suppression of his individuality. Communism, if this term be employed, signifies not a lack of recognition of individual interests, but a conscious subordination of them in major affairs—under the pressure of custom and public opinion—to the control of the group as a whole. That the process is one of integration of interests, not mere blind absence of any sense of individuality, is shown by the existence of complicated individual claims and privileges within the sphere of communal ownership. Thus in the case of the Melanesian canoe, the management of which was adduced by Rivers as a proof of communism, the deeper researches of Dr. Malinowski reveal a complex system of control with one man as master of the vessel and paramount owner, the others having lesser shares, each well defined, and all having specified duties and responsibilities to their fellow members. No irrational, undifferentiated absorption of the individual in the group can be discovered. This position is supported by the results of intensive research in material from Old Peru, Australia and New Zealand, while study of the problem of ownership in more general context suggests that this blend of "communism" with individualism is characteristic of all primitive society.

Land Tenure.—These conclusions apply also to the specific case of ownership in land, the precise system of which varies according to the economic conditions and social structure of the community concerned. Among hunting peoples the measure of tribal control of the territory over which they range appears to be fairly communal, though even here, as in the case of the north-eastern Algonkin tribes or the Vedda of Ceylon, the portion of land on which each family catches game may be very sharply demarcated and protected by heavy penalties from intrusion on the part of neighbours. With changes in the form of economy the partition of interests varies, until among people such as the Melanesians the delimitation of rights allows of ownership of the land by one man and of the fruit trees upon it by another. Again, a person's admitted status as an owner is often qualified by rights of other people, such as relatives, the chief or the village magician, to certain portions of the produce. The key to the understanding of a system of native land tenure lies in realizing the inadequacy of such simple labels as "communistic" or "individualistic" and in grasping the complex scheme of titles, claims, privileges and obligations on the part of individuals and the community with which the native himself invests the control of the soil.

Attempts have been made by Kohler, de Laveleye, Lafargue, Biicher, Lewinski and others to group the various types of ownership in a chronological sequence, to trace their origins, and on this basis to lay down theories of the evolutionary development of the idea of property. Such efforts, however, lack reality, and the undoubted contributions of these writers have come incidentally from their descriptive and analytical studies.

PROPHET (προφήτης), a Greek word used in the Greek Old Testament to translate the Hebrew *Nābī* נביא and consequently adopted into other European languages. In classical Greek it denoted one who, uttering or interpreting an oracle, was believed to speak not his own thoughts but a revelation "from without"; cf. the description of Cassandra (Agam.) and the Prophet of Apollo (*Eumen.*), by Aeschylus; of the blind seer, Teiresias, by Sophocles (Oed. *Tyr.*), and by Euripides (*Bacchae*); of the Cumaean Sibyl, by Virgil (Aen vi.); and note Plato, *Timaeus* 71 b., where he argues that persons who seek to give rational meaning to oracles "are not to be called prophets at all," but only those who speak in ecstasy. At the Delphic Oracle, however, not the frantic priestess, the Pythia, was designated "prophet," but the Guardians of the Shrine who ostensibly shaped her frenzied ejaculations into comprehensible replies. Etymologically προφήτης denoted "forth-telling," not "fore-telling"; but since προ could mean "before" in time, and since prophecies constantly dealt with future events and foreknowledge is not deemed to occur in conditions of normal consciousness, the notion that prediction and ecstasy are the essential elements in prophecy was an easy growth. Thus in the Hellenic period Philo of Alexandria looked on divination and oracular interpretation as imposture, but had high regard for the ecstatic who "speaks nothing of his own." Προφήτης was the best word available in Greek, for rendering the Hebrew Ndbi (it was preferable to μάντις), but the Hellenistic view of prophecy as ecstatic prediction obscured for centuries the wealth of religious interest in the Hebrew prophets. Why προφήτης was used to translate *hm-ntr,* the title of certain Egyptian priests, is unascertained.

HEBREW PROPHECY

The Hebrew noun Ndbi ("Prophet," *pl. Nebi'im*) is obscure in origin. Derivations implying intense excitement (נבע "to bubble up"; נבע Assyr., "to fall in transports") are etymologically improbable. The verbal form (an intensive) used in Hebrew often denotes frenzy or even lunscy, but this may reflect merely one aspect of prophetic development, and the fact that it is an intensive stem may imply simply that it is a loan-word in Hebrew. Conceivably it is not Semitic at all—there are Hittite possibilities. The likeliest Semitic connections are Arab. naba'a "to announce" (conjug. ii.); Bab.-Assyr. *nabû* "to name" (cf. the god, Nebo, Is. xlvi. 1). Ndbi, like προφήτης, may thus in origin be a colourless term: "One who utters a god-given message."

The **Fanatical** Prophets.—From a trustworthy narrative in I Sam. x. we learn that bands of prophets (Nebi'im), devotees of the national deity, Jehovah (Yahweh), existed c. 1000 B.C. at Hebrew localities (Gibeah, Ramah). Stimulated by rhythmic music, dancing and chanting, they wrought themselves into ecstasies when their frenzied behaviour and abnormal physical power exercised hypnotic effect over onlookers (I. Sam. x. 5–13), and, as it seemed to testify the might of the god whose spirit possessed them, encouraged popular trust in Jehovah and resistance to the Philistines. Since there is no earlier reference to collective prophesying in Hebrew history (Nu. xi. 25 *sqq.* cannot be regarded as of the Mosaic age), probably it was a feature of Palestinian-Syrian religion, first evoked in Israel in Samuel's time. There is no direct evidence for Wellhausen's assertion that "among the Canaanites such Nebi'im had long been familiar" but the indirect evidence is impressive. An Egyptian record (*c.* 1100 B.C.) relates how an envoy, Wenamon, secured a hearing when a youth in attendance on a Phoenician prince prophesied ecstatically in Wenamon's favour. Very instructive is the famous passage in I. Kings xviii. 19 sqq. concerning the 850 prophets of the (Phoenician?) Baal and of the Asherah, maintained by Queen Jezebel. At a much later period the orgiastic rites celebrated by devotees in honour of certain ostensibly Greek deities (Apollo, Dionysos) prove to have connections with the Baal worship of Syria and Phoenicia (so T. H. Robinson). When parallel phenomena are still exhibited by the dervish fraternities in Islam, it seems probable that this form of religious excitement was peculiarly congenial to the peoples of Western Asia Minor, and may well have been of immemorial antiquity in Palestine.

Certain it is that fanatical prophets became a feature of Israelitish society. They are mentioned in connection with many towns of special sanctity and importance, *e.g.,* Bethel, Jericho, Samaria. Possibly they had some organization (the phrase "schools of the prophets" has no warrant), and were supported by popular piety or by kings anxious to obtain inspired counsel in perilous moments. Along with the priests and the wise men, they were esteemed one of the three indispensable sources for the guidance of the State (Jer. xviii. 18). Even in the post-exilic period they lingered on, distinctive by their rough mantle and leathern girdle, mouthing out oracles for the superstitious (cf. the χρησμολόγος in Aristophanes, *Birds,* 959 *sqq.*)—so great a public nuisance that father and mother are exhorted to slay the son turned "prophet" (Zech. xiii. 3). The causes of degeneracy can be discerned. Thanks to Eastern respect for the psychologically abnormal, the calling afforded a livelihood and might attract impostors, for it was easy to share in, or simulate, ecstasy, and declare "Thus saith Jehovah." The violent emotions were dangerous to the moral stability of even the honest Nebi'im, and if simpler means of inducing ecstasy failed, the temptation to use noxious drugs was great.

The fanatical prophets, it may be concluded, manifested a real patriotism that helped to establish the State during the Philistine and the Syrian conflicts, but contributed nothing to the discernment of those dynamic religious beliefs which, as the power of Assyria and Babylon rose and engulfed the petty monarchies of Israel and Judah, alone made possible the astounding survival of the Jewish nation.

The Seer.—But the word Ndbi acquired a wider connotation. Later than the age of Samuel it came to be applied to persons who in earlier times would have been called Seers (*Rō'eh,* "Visionary"; or *Hōzeh,* "Gazer": I Sam. ix. 9). The Seer, ubiquitous in antiquity and ranging in dignity from the itinerant soothsayer to the guardian of some famous sanctuary, was credited with power, through interpretation of omens or (more impressively) through trance-visions, to gain knowledge from a spiritual being inaccessible to ordinary men: he was, as others were not, a "man of God." Balaam (Nu. xxii.–xxiv.) is typical: "essentially an Arab *Kāhin* or seer of that early type which combined the priest's offices of ritual and sacrifice, the diviner's reliance on omens and lots, and the prophet's experience of ecstasy and dreams" (G. A. Smith). The possibilities in the calling for good and evil are obvious. Affinities with the baser forms of divination—wizardry, necromancy, etc.—were close, and degenerate seers became only too numerous in Israel (Is. ii. 6, Mic. iii. 7), notwithstanding a strong tradition that such arts were peculiarly abhorrent to the God of Israel (I Sam. xxviii. 3, sqq. Ex. xxii. 18, Is. viii. 19). But the famous seers created the expectation of individuals in mysterious contact with God, "standing in his counsel," "knowing his secret," whose words should therefore have absolute authority in hours of crisis. Much more than the Nebi'im with their collective "inspiration," the seer is of the lineage of the great prophets. Yet a distinction may be drawn. The ordinary seer made his powers his profession and livelihood (Am. vii. 12), and his functioning was habitually passive: he waited to be consulted. The great prophets were men of diverse callings, driven by an irresistible constraint actively to declare to Israel the word of its God. Thus to his contemporaries Samuel was not one of the Nebi'im but the Priest-Seer of Ramah, whom a Saul could consult about strayed animals. Later generations rightly accounted him a prophet of the great type because of his initiative in rousing the people against the Philistines, in creating a monarchy, and later in rejecting Saul for David.

The Higher Prophecy.— But all the seers and prophets of antiquity would have but infinitesimal interest, were it not for the appearance in Israel of certain individuals of amazing spiritual insight, whom we, like their contemporaries, for lack of a better word must call "prophets." Their work and words endow Prophecy with almost inexhaustible importance for religion and for social organization. The diversity of the occupations and circles to which these higher prophets belonged is significant. A few, especially in the earlier period, pertained to the professional prophetic class: Samuel was a famous seer, Gad and Nathan official prophets of David's court, Micaiah one of the recognized Nebi'im (I Kings xxii.—a passage which should be studied). But Elisha was a prosperous farmer, Amos a shepherd of Judaea, Isaiah a citizen of Jerusalem, Micah a Judaean villager, Jeremiah a youth of ancient priestly family, Ezekiel a priest of the Temple. The unifying characteristic is that to each came an overmastering conviction that, temporarily or permanently, he must forsake his way of life and declare what God would say to His people. Their prophesying was the constraint of a vocation, not the pursuit of a profession. When their teaching is coordinated certain principles they held in common can be analysed (see articles on the several prophetical Books, HEBREW RELIGION, etc.) with results sufficiently impressive. But such surveys are meagre and mechanical: what counts is the stress of circumstance from which the great ideas were won, and the heroic application of beliefs to events. Knowledge of Hebrew prophecy is knowledge of the lives of glorious personalities; only when name after name of the prophets calls up the memory of lonely insight into truth, of unbreakable loyalty to duty, maintained through scorn and hatred and despite despair, can its splendour be realized.

Historical Development. — Complex as are the Pentateuchal narratives concerning Moses, it seems certain that an influential section of the mixed population under the Hebrew monarchies held a tradition that a great leader of prophetic character (yet not an ordinary seer, Nu. xii. 6–8; but such as Samuel had been, a man whom a Hosea or Jeremiah could call a Prophet, Ho. xii. 13, Jer. xv. 1) had led their ancestors out of Egypt to the independence of the desert, and had fired them with such confidence in the God Jehovah as had given them the unity necessary for a successful assault on Canaan. However dimly recalled, and by however few, the tradition of Moses, it may be held, preserved potent ideas: that Jehovah required a standard of morality that differentiated Him from other gods, and that in Moses himself — remembered as a life of splendid patience and mercy, of unswerving integrity and awe-inspiring intimacy with the invisible God — there had been seen a true servant of Jehovah. Subsequently in Canaan the leadership of Samuel not only established the national existence, but created in the popular consciousness the sense that their kingdom was truly, and not nominally, a theocracy, where kings must heed the word spoken by God's prophets to an extent startling in the ancient East (I. Kings xxi. $). The vigilance of prophetic censorship over the dynasty was notably displayed against David (by Gad and Nathan), against Solomon (by Ahijah), against Rehoboam (by Shemaiah); and momentously in Flijah's adamantine opposition to Ahab and Jezebel, whereby the alliance with Phoenicia was broken and Israel left to face unsupported the impending attack by Damascus.

The deep motives in the higher prophecy now became apparent. Not by political wisdom was Elijah actuated, but solely by an imperious religious instinct which swept aside all other considerations in the assertion that Jehovah demands an absolutely exclusive worship, and that He champions the rights of the humblest against even the king. This principle holds good throughout. Attempts (cf. Winckler) to explain the actions and attitude (*e.g.*) of Isaiah or Jeremiah primarily by political foresight or predilections can be shown in detail to be misconceived. Prophecy had created the nation, and wished to sustain it; not, however, in the interests of the nation, but in the interests of its God. The important account of Elijah's flight to Horeb, I. Kings xix. (taken in conjunction with the sequel: Elijah's sense of a commission to anoint Jehu king over Israel, and Hazael over Syria, followed by the achievement of those ends by Elisha, his disciple, and by high-minded prophets) shows that the parable read by Elijah in the quiet of the enduring mountain, following the storm, was not that the ways of God are gentleness alone, but on the contrary that the prophet's resolve to overthrow the house of Ahab must be pursued to its bitter end through revolution in Israel and war with Syria. The nation must pass through the tumult: thereafter the unalterable good purpose of its God would be apparent. In face of the grim realities of evil true religion must send first not peace but a sword.

The Golden Age.—A century later (c. 750 B.C.) the Golden Age of Hebrew prophecy, wherein the universal aspects of religious truth were perceived as the real significance of Israel's national faith in Jehovah, began with the oracles of Amos and Hosea in Northern Israel, to be continued in Judah, especially by Isaiah, Micah and Jeremiah. For Amos there is but one God of the whole earth, controller of other nations as well as Israel, whose favour everywhere is determined solely by such concern for moral conduct that not even the wrongs of a slave go unheeded by Him. Amos is styled the "Prophet of the Justice of God," but the phrase is wholly inadequate. Positive goodness, forbearance, mercy, kindness are the inexorable divine demand. Between Jehovah and Israel a special relation exists; but the implication is not (as the people imagine) favouritism, but responsibility: "to whom much is given, of them shall much be required" (Am. iii. 2). Faced by the iniquities of their times, earlier prophets had assailed the dynasty at whatever risk to the national fortunes; but Amos, appalled by corruptions that rotted society from top to bottom, uttered logically a judgment almost incomprehensible to the ancient mind — God will bring overwhelming ruin upon the nation itself (Am. vi.–ix. passim). Lastly, Amos marks a new era for religion by his special declaration that the immemorial forms of worship — sacrifices, fasts and feasts — are sheer futility: God is to be sought not through material offerings, but spiritually in upright and generous conduct (Am. v. 5, 14, 21–24). Here is the enunciation practically, if not also theoretically, of ethical monotheism. The profundity of these beliefs, which thenceforth became the gospel of the higher prophets, needs no emphasising. Not unjustly Amos has been called the forerunner of Kant.

To Hosea love seemed fundamental in the attitude of God to Israel. Deeper than the necessity for moral retribution lay the divine love. It has been observed that Amos and Hosea significantly complement one another; they "form a pair — law and love" (S. A. Cook).

Taught, it would seem, by some poignant personal experience, Hosea agonized with the dilemma: God must shatter the sinful nation, yet to do so would seem to end his gracious purpose in defeat (Ho. xi. 8, 9). What if the disaster, which is sure, be after all a means to an end—πάθει μάθος? Out of the ashes of Retribution, Hope must rise (Ho. ii. 15). Far more deeply than Amos, Hosea probed the problem of sin. The cultus was not merely futile; it was a prime source of iniquity, and must be abolished. He pities the masses; they sin indeed, but it is for lack of knowledge (Ho. ii. 8) Thus was prophecy released from pessimism. However near and overwhelming the "day of the Lord" in judgment, the prophet must exhort men to penitence and belief in an ultimate divine salvation.

The view (Gressmann, Gunkel) that Amos and his successors inherited a cut-and-dry eschatological expectation of woe followed by bliss—whether derived from native Israelite sources (Sellin) or influenced by Egyptian (Ed. Meyer) or Babylonian literature—rests on inadequate or misinterpreted evidence. The message of doom announced by Amos was startling to his hearers, and it would seem that the higher prophets' anticipation of some impending judgment catastrophic yet congruous with an undefeated divine purpose was radically the unaided product of their own reflection on the righteousness, power and goodness of God. In Hosea and Isaiah the element of hope beyond catastrophe is prominent. Whether it was conceived very vaguely, or more definitely (Messianic) depends on the dubious authenticity of certain passages (see APOCALYPSE, MESSIAH). For the achievement of an order of perfect righteousness apocalyptic cataclysm is, in reality, irrelevant; since love cannot be compelled. In their passionate pleading for reform the prophets were feeling their way to a deeper comprehension, which at last was attained when Jeremiah based his hope of a divine consummation simply on faith in God's effecting the moral regeneration of the human heart (Jer. xxxi. 31–34).

Isaiah *and Jeremiah.*—The task which lay before the great prophets of Judah (c. 740–586 B.C.)—who, in contrast to the facile optimism of the ordinary prophets "healing lightly the hurt of the daughter of Zion," continued convinced that the ruin of the State was at hand—was to discover how faith in Jehovah could survive the political destruction. In effecting this infinitely difficult task it was their sublime achievement "to liberate the eternal truths of religion from their temporary national embodiment, and disclose their true foundation in the immutable character of God and the essential nature of Man" (Skinner).

To Isaiah is due the conception of an Israel within Israel, a believing nucleus; a "Church of God." Convinced that he knew the mind and power of the living God ("Mine eyes have seen the King, the Lord of Hosts," Is. vi. 5), he reasserted on a higher level the earlier prophetic claim to control the national policy. Thorough social reform must accompany quiet trust in God, and in Him alone, for the fate of the nation (cf. Is. xxx. 15). Assyria is resistless, not in virtue of its vaunted might but because it is the weapon in Yahweh's hand against his sinful people (Is. x.). Whatever sufferings it inflicts in invading Judah will be the discipline of divine wisdom, and will leave behind a purified remnant of the faithful in Zion, through whom God's purpose shall be fulfilled (cf. Is. x. 2—23, xxviii. 16). Rejected by king and people, apparently he gave substance to his hopes by seeking disciples who accepted his principles (Is. viii. 16). At the crisis of the Assyrian invasion (701 B.c.?), he foretold the inviolability of Zion and this momentary form of his teaching was preserved in popular memory superstitiously apart from its spirit and the moral conditions on which his doctrine of Faith (Trust) rested (cf. Jer. vii. 1–15).

"Prophecy had already taught its truths, its last effort was to reveal itself in a life"—the life of Jeremiah. Living through the dreadful years which saw the two successful sieges of Jerusalem by the Babylonian armies, ending in the destruction of the city and temple and the deportation of its chief inhabitants, Jeremiah found himself forced either to utter unrelieved predictions of ruin to a people distracted alternately with panic and delusive relief, or, being silent, to deny the conviction of inspired knowledge that burned like a fire in his bones. The task entailed for him desperate loneliness, hatred and persecution—sufficient torment to a man of shrinking and sensitive temperament. But further he was tortured at times by doubt of his inspiration. Was he but self-deceived or even deceived of God? Were the confident prophets of peace right? And if the nation perished, how could the worship of Jehovah survive? "Hitherto there had been nations with their religions, but there never had been in the world a religion without a nation to act as its embodiment" (A. C. Welch). Out of the agony of his perplexity, preserved in some infinitely moving passages (Jer. xv. 10–18, xviii. 9, 10, 14–18, xx. 7–18) came the solution: recognition of how wonderful was the fact of the relation between his conscious self and the Divine Being he longed to serve. In his ultimate peace in God and victory over "fears without and fightings within," we mark the beginning of the modern view of religious faith. Whatever the function of the nations in God's sight, no conception of a moral God is credible unless the unit of divine interest be the human personality. Jeremiah had discovered that, wheresoever men live, they may find God, if in humility they do justice and love mercy. So he wrote (xxix. 4–14) to the exiles in Babylonia to live there that life of goodness which the prophets had seen to be the worship God desires: a momentous letter, for in the acceptance of his belief lay the continuance of the Jewish race, and the future of religion. "The spirit of Jeremiah, which breathed out on his people after his death, bore fruit in an experience of fellowship with God which satisfied the deepest aspirations of the human soul" (Skinner).

It was now conceivable that religion might survive the State. The last act of the higher prophecy was to give effect to the possibility. Through the constructive idealism of Ezekiel, and the magnificent, monotheistic, oracles preserved in Is. xl.–lv., and no less through the courage and insight of Haggai and Zechariah, whose exhortations effected the rebuilding of the temple in Jerusalem (520 B.c.) and thus set religion in the forefront of the renascent community's life, the Jews—sole link between the ancient Semitic empires and the new era of Persian and Greek domination—began both to preserve their identity in exilic settlements, and in Palestine to revive as a people increasingly conscious that it existed through, and for, its distinctive faith.

The Achievement of Prophecy.—The prophets were thus the saviours of their people. But their achievement should be realized in a wider setting. In their declaration of monotheistic belief and social idealism the world received an interpretation of human life applicable to every people and every age.

Ethical *Monotheism.* For intelligent men they shattered for ever the mental and moral dangers of polydaemonism and polytheism, proclaiming instead the reality of one only God, to be conceived as the infinitude of moral perfection. If modern terminology is permissible, they held both the transcendence and the immanence of God, and whatever the philosophical obscurities, this doctrine of God, as not less than "personal" in His relation to us, has been the succour of the human spirit, and the source of high and generous virtue for Western civilization. The precise stage at which monolatry (God as the only Being his people must worship, but one among other gods) rose into the pure monotheism patent in II. Isaiah—whether it goes back to Amos, to Elijah, to Moses—cannot be determined; for who shall measure genius? Perhaps the question is wrongly put. In antiquity no one ceased to believe in the existence of many spiritual beings (cf. Eph, vi. 12), and practical monotheism was achieved whenever it was felt that there is but one creative Spirit, alone meriting worship, other "gods" being wrong conceptions of God as He truly is, or lesser Spirits who beguile men's worship, and their images assuredly "non-entities," the works of men's hands.

The Worth of *the Individual.* The prophets discovered the immeasureable worth of human personality. It may be that not until Jeremiah did the significance of the individual's aspiration towards God become vividly apparent; but his experience was creative, and thereafter, aided by Ezekiel's teaching concerning individual responsibility, the instincts of personal piety were liberated to reach out, even through the problem of death, into deeper confidence in Man's worth to God. But this religion of the individual, the product of Prophecy's fundamental thinking and genius for ultimate values, was in no wise individualistic. The heart of prophetic doctrine had been insistence that the will of God is to create a world-order of perfect justice, and that, so long as the moral obligations of each and all go unhonoured, and the lowliest is denied mercy and kindness. there shall be no peace for Man. To the prophets therefore we owe that inestimable incentive for good, the idea of the "Kingdom of God" as the goal of social order.

Worship. "In primitive life," wrote Robertson Smith, "all spiritual and ethical ideas are still wrapped in the husk of a material embodiment. To free the spiritual truth from the husk was the great task that lay before the ancient religions . . . but none of the ritual systems of antiquity was able by natural development to shake itself free from the congenital defect inherent in every attempt to embody spiritual truth in material forms. A ritual system must always remain materialistic, even if its materialism is disguised under the cloak of mysticism." (Religion of the Semites, ed. S. A. Cook, whose note, p. 676, should be studied.) The prophets' criticism of worship was revolutionary, but fundamental and constructive, because they saw with absolute lucidity that true worship is a relation of personality, therefore spiritually, and not materially, determined. The human spirit can so use, or regard, material objects that (with vigilance) they may be symbolically or aesthetically helpful to the communion of God and man; but the material must never under any circumstances be treated as in itself an indispensable aid, or barrier, to the reception of divine influence by man. To suppose so is fatally to misapprehend the essential nature of a personal relationship. The prophets were clear: "God's favour is to be found by man's becoming, like Himself, just and merciful . . . Not gifts but fellowship, and the way to fellowship lay not through the sacrificial system re-interpreted, but through conduct; not gifts but justice, not sacrifice but mercy" (G. Buchanan Gray, Sacrifice, p. 44).

Privilege. The prophets did not abandon the old idea of Israel as a nation privileged of God; but they transfigured it by the contention that privilege is responsibility, election a call to service. And prophecy itself culminated in the vocation of Jeremiah to a life of sorrow and suffering, heroically accepted for a nation that hated him; and secondly, in the Servant-Songs of II. Isaiah (see ISAIAH) where the function of Israel is conceived as a self-sacrificial consecration, through unparalleled trials, for the redemption of mankind.

Knowledge of God. There were very many prophets in Israel. How came it that the few advanced towards a rational faith, and the many—equally convinced that their "Word" was from the Lord—failed? To whom, and why, is revelation given? Here again Jeremiah is illuminating. No outward criteria, he felt, avail to discern the true from the false prophets. Ultimately he saw that they were not sensitive, as he was, to the moral obliquity around them, or alive to the evil in their own heart; and he rested at last on the faith that if he surrendered himself absolutely to God's service, accepting whatever loneliness, pains or even death it might entail, God would speak truly through him (Jer. xv. 19). But this attitude had been the basic fact regarding all the great prophets; diverse in many ways, they were men of absolute sincerity and self-surrender. The example of their character is the last and greatest gift of the prophets to mankind, for it is the clue to sound religious experience everywhere: "the pure in heart shall see God."

The Prophetic Consciousness.—Until as late as the 17th century A.D., interest in the prophetic writings was almost exclusively concentrated on the predictive element.

As to this aspect, it should be noted that there are indeed instances of fulfilled presentiments (*e.g.*, Ez. xxxiii. 21, 22), and close correspondences of events with prophetic anticipations; but the prophets are wronged when, as is still sometimes maintained, the validity of their inspiration is felt to depend crucially on fulfilment of predictions, instead of broadly on the rightness of their interpretation of Life as ethical duty, dependent on the reality of the living God. The Suffering Servant anticipates Jesus Christ because the prophet was inspired by the vision of a life of absolute self-sacrifice, and Jesus accepted the conditions of that life and endured its issues. After the Reformation recognition of the poetical form of the prophetic literature led to the necessary analysis of the Books bearing the prophets' names. Criticism in the 19th century was marked by enthusiasm for the prophets as preachers of social righteousness; but present research, psychological and historical, reveals them primarily as men of religious genius, who must be studied in intimate connection with their Eastern environment. Recently it is urged (especially Hölscher) that the inner experiences, and outward behaviour, of the great prophets were closely akin to the ecstasies of the early Nebi'im. Certainly the subconscious is a highly important consideration in studying Hebrew prophecy, but the theory has been pushed to extremes and is sometimes maintained by grotesque forcing of the evidence. There ought to be more careful discrimination of terms, and "ecstasy" reserved for conditions in which the subject has lost all control of mind and body. Stress, inducing at times trance, with audition and vision, is exemplified in the great prophets (especially the "Call" experiences, cf. Is. vi.); but to argue that these men virtually never felt conviction break on them at any less intense level of the infinite gradations of emotion, never saw an illuminating parable in nature, never employed a symbolic action, unless in a state of uncontrolled ecstasy, is to go too far. There are indications that they distrusted increasingly the fervours of their opponents (so A. B. Davidson). Whatever resemblances they had to the ordinary prophets, it is the profound differences that will repay study. The extreme forms of the theory are ruled out by the grand consistency of the great prophets: the coherence of their teaching is the supreme psychological fact; and either the oracles we possess are the record of passionate but conscious reflection, or in these men conditions existed which caused the subconscious to produce the rational and the relevant to an unpsralleled extent. In any event, an Amos or an Isaiah is infinitely better understood by the analogy of Paul, with his vision on the Damascus road and his enthusiastic yet controlled temperament, than of the ecstatic seer or frenzied Nebi'im. It is true that the Hebrew prophet says, never "I saw," "I know," but "The Lord shewed me," "Thus saith Jehovah." Explanation is found in the psychological ideas which he shared with his contemporaries. H. Wheeler Robinson rightly emphasizes that Man was regarded as intimately dependent on God in his psychical as well as his physical properties; his "breath-soul" open to the invasion of spirits divine and demonic. Hence not only in the trance-experience, but under any intense emotional stress the Hebrew felt that he had "become another man," the "spirit of the Lord had laid hold upon him"; so that it is easy to realize sympathetically why the prophet was convinced that he spake never of himself but as "the messenger of Him that sent me."

The Prophetic Succession.—Hebrew prophecy possesses the unity of a single movement, having origin, development and climax. It ended not in exhaustion, but in the liberation of energy, manifested in personal piety, in efforts to systematize the great ideas (Judaism), and in inextinguishable Hope of a divine purpose in the world (Apocalypse). Hebrew Prophecy recurs not, but "true" prophets—called by many names, Saint, Preacher, Reformer, Scholar—have not ceased to be; for it was part of the work of prophecy to reveal that "all the Lord's people should be prophets," and that the prophet is he for whom God is the living God. Whenever discernment of truth in new aspects is imperative, the interpreting prophetic personality is prominent, and is ever the vitalizing element in religion Amidst the turmoil at the close of the last century B.C. and the first A.D., it is easy to see why individuals appeared who were manifestly prophetic in type—John the Baptist, Jesus Christ (though the term be inadequate for Him), Paul, Johanan ben Zakkai.

PROPHETS IN THE CHRISTIAN CHURCH

In the nascent organization of the Christian communities (Acts xi. 27, Eph. iv. 11, 1. Cor. xii. 28) prophets are mentioned, ranking next to the Apostles. Sometimes itinerant, sometimes settled in one locality, they were the evangelists of the early Church, credited with a direct spiritual inspiration (χάρισμα) for enlightenment and edification. Men can be appointed to an office; they cannot be appointed to prophecy. The conviction that in Christ all things were made new evoked minds sensitive to spiritual issues.

Therein the Christian prophets were in the true succession; but in all else how different from the lonely Hebrew seers. The Christian prophets were expected to provide intelligible utterances (1. Cor. xiv. 32), and were thus differentiated from the ecstatic "speaker in tongues," whilst they were also distinct from the permanent local officials—catechists, deacons, presbyters, bishops. From the valuable information in the *Didache* it appears that the high regard felt for them lasted fully a century; yet their position was always precarious. Sane enthusiasm might lapse into futile ecstasy (1. Cor. xiv. 29–33). Hypocrites might simulate the gift—the *Didache* insists that the prophet is worthy of maintenance and respect only if his piety is indubitable, and his conduct "worthy of the Lord." The prestige of the permanent officials increased in comparison with the occasional prophet, whose sole virtue seemed to be his edifying speech. But that gift might also be found among the regular ministers: and if so, how preferable! Lastly the zeal of the prophets might claim an authority, or make ascetic demands, on the Church which roused antagonism. At the end of the 2nd century the wild prophesying in the Montanist party (significantly of Phrygian origin) hastened the end. Armed with the now-accepted Canon of Holy Scripture ("the law and the prophets until John"), the authorities ruled that "Ecstasy was of the devil not of God" and that "Prophets must not accept gifts," and ere long they ceased as a distinctive class in the Church's organization.

BIBLIOGRAPHY.—The literature on this subject is so extensive that only a selection of important, or recent, works can here be cited. (W. A. L. E.)

PROPIOLIC ACID, colourless crystals melting at 6° C and boiling at 144° C, soluble in water, with an odour like that of acetic acid. It has the constitution of acetylenemonocarboxylicacid, $HC{:}C{\cdot}CO_2H$, and is of interest as being the prototype of *ortho*-nitrophenylpropiolic acid, a substance prepared by the action of alcoholic potash on *ortho*-nitrocinnamic acid dibromide (A. v. Baeyer, 1880). This *ortho*-nitrophenylpropiolic acid, which crystallises in needles decomposing at 153–156° C, is readily converted into indigo (*q.v.*). Propiolic acid itself is obtained by the following reactions: Succinic acid is brominated, and dibromosuccinic acid by the action of alcoholic potash yields acetylenedicarboxylic acid, $CO_2H{\cdot}C{:}C{\cdot}CO_2H$. This acid or its monopotassium salt on boiling with water loses carbon dioxide, and propiolic acid is produced. On exposure to light it polymerises into trimesic acid (benzene-I:3:5-tricarboxylic acid).

PROPORTIONAL REPRESENTATION, an electoral arrangement designed to secure that the representative assembly shall be an exact reflection, a "snapshot," of the voting strength of parties among the electorate. The case for the system is fundamentally the case for representative government. Every trace of opinion, be it ever so small, ought to be represented in the legislature as near as possible to its proportional mathematical claim. That, and nothing else, is true democracy. The system first obtained principal support through the advocacy of John Stuart Mill who, about the middle of the 19th century, recommended the Hare system, on the ground that democracy must be especially careful that minorities get their appropriate representation. The appeal of this argument has been widespread and there are few democratic countries to-day which are without some such system.

The *Second* Ballet *system,* as practised in France, provides that, if there is not an absolute majority for any one candidate in the first poll, the bottom candidates shall be struck out and the two top candidates shall proceed to a second contest. This system raises political difficulties since the period between the first and second ballot is employed in unsavoury intrigues. To obviate these difficulties the Australian States use the system known as the Alternative Vote, which requires an absolute majority and where there is only one ballot, in which the voter instead of marking his choice with an X, marks the candidates in the order of his preference (whence Preferential Vote system), 1, 2, 3, etc.; and then the returning officer eliminates the bottom candidates in turn, distributing among the top candidates the preferences marked on the eliminated ballots.

These two systems attempt to correct the main defects of a single-member constituency: proportional representation proper seeks a more radical and creative end. It desires the creation of large constituencies with a number of seats. In the English Proportional Representation society's suggested programme, called the "Single Transferable Vote," a constituency of at least 300,000 inhabitants is suggested and at least five seats. In the German system prevailing since 1919, the constituencies average nearly one million electors, and 15 or 16 representatives. The severalty of representatives makes it possible for any well-knit minority with a quota of votes, *i.e.,* the lowest number required, in the circumstances, to get representation. Votes cast for a member shall not be lost to the party if he personally should fail, for they are transferred or accredited to other members of the party who hold them to make up the quota. This can be done in a number of ways. The system advocated in England is that the voter shall be free to indicate his preference by numbers against the long list of candidates, the returning officer then distributing the surplus preferences of successful candidates and those with no chance among those who are designated by the preferences, until all the seats are filled by those with quotas. This system leaves the voter free of party dictation. The Belgian system has a party list which the voter may either adopt as it stands or vary the order of the candidates—but he cannot vote outside the party which he has chosen. The parties (and the members) get the mathematical share of the seats to which their aggregate vote entitles them, measured by the d'Hondt system. In Germany the variation of the party list as determined by the party machine is not allowed, and each party gets one representative for each 60,000 votes it secures, while fractions of 60,000 are added together for each party (within certain limits) and again for each such 60,000 the party is permitted to nominate an extra member.

The merits, regarded from the standpoint of equity, are obvious. The demerits of the systems as they operate in Europe are these: (1) The personal contact between member and constituency is reduced; in its place the party machine rules by deciding the order of candidates on the list, and by requiring teamwork among candidates which results in the "star" man helping in the mediocrities. (2) A premium is placed upon the use of mechanical devices to make electors go to the poll—this is a direct result of a large constituency. (3) Small parties are kept in existence, which seriously disturbs the process of parliamentary government where a compact and single party majority in office faced by an opposition similarly constituted is thought to give the best results.

PROPOSITION, in logic, means usually the verbal expression of a judgment (*q.v.*). Propositions like judgments, are classified in various ways. See CATEGORY, JUDGMENT, LOGIC.

PROPYLAEA, the name given to a porch or gate-house, at the entrance of a sacred or other enclosure in Greece; these usually consisted, in their simplest form, of a porch supported by columns both without and within the actual gate. The name is especially given to the great entrance hall of the Acropolis at Athens, which was begun in 437 B.C. by Pericles, to take the place of an earlier gateway. Owing probably to political difficulties and to the outbreak of the Peloponnesian War, the building was never completed according to the original plans; but the portion that was built was among the chief glories of Athens, and afforded a model to many subsequent imitators. The architect was Mnesicles; the material Pentelic marble, with Eleusinian blackstone for dados and other details.

The plan of the Propylaea consists of a large square hall, from which five steps lead up to a wall pierced by five gateways of

(LEO VON KLENZE, ARCH.) THE PROPYLAEA AT MUNICH, GERMANY, 1862

graduated sizes, the central one giving passage to a road suitable for beasts or vehicles. On the inner side towards the Acropolis, this wall is faced with a portico of six Doric columns. At the other end of the great hall is a similar portico facing outwards; and between this and the doors the hall is divided into three aisles by rows of Ionic columns. The western or outer front is flanked on each side by a projecting wing, with a row of three smaller Doric columns between Antae at right angles to the main portico. The north wing is completed by a square chamber which served as a picture gallery; but the south wing contains no corresponding chamber, and its plan has evidently been curtailed; its front projected beyond its covered area, and it is finished in what was evidently a provisional way on the side of the bastion before the little temple of Victory (Nike).

From this and other indications Prof. Dorpfeld has inferred that the original plan of Mnesicles was to complete the south wing on a plan symmetrical with that of the north wing, but opening by a portico on to the bastion to the west; and to add on the inner side of the Propylaea two great halls, faced by porticoes almost in a line with the main portico, but with smaller columns. This is questionable as it would have interfered with sacred objects such as the precinct of Artemis Brauronia and the altar of Nike. Nevertheless, the unfinished surface of the walls and the rough bosses left on many of the blocks show that the building was never completed. The Propylaea were approached in Greek times by a zig-zag path, terraced along the rock; this was superseded in Roman times by a broad flight of steps. In mediaeval times the Propylaea served as the palace of the dukes of Athens; they were much damaged by the explosion of a powder magazine in 1656. The tower, of Frankish or Turkish date, that stood on the south wing, was pulled down in 1874.

The term is also applied to various monumental gateways of modern times, especially in Germany. Outstanding examples are: the propylaea at Munich, by von Klenze (finished 1862), with sculpture by Schefzky; and that in Berlin, also known as the Brandenburger Tor, by Langhaus (1784), which was directly inspired by the propylaea at Athens.

(E. GR.)

PROPYL ALCOHOLS, two compounds of this name, with the same formula C_3H_7OH exist, and both come into prominence in connection with modern developments of industrial organic chemistry.

Normal *propyl* alcohol, $CH_3{\cdot}CH_2{\cdot}CH_2{\cdot}OH$, is now obtainable as a by-product in the synthesis of methyl alcohol (*q.v.*) by condensing carbon monoxide and hydrogen in presence of a zinc-chromite or zinc-cobalt-chromite catalyst at 400° C under 200 atmospheres pressure. (See PRESSURE CHEMISTRY.) It is a colourless fragrant liquid boiling at 97·4° C and miscible with water in all proportions. It cannot be separated from water by distillation since the two compounds form an azeotropic mixture. (See DISTILLATION.) n-Propyl alcohol occurs in fusel oil and may be prepared by any of the synthetic methods applicable to primary alcohols. (See ALCOHOL.)

Iso-propyl alcohol, $(CH_3)_2CH{\cdot}OH$, is now manufactured on an extensive scale from propylene, $CH_3{:}CH{:}CH_2$, obtained by the cracking of petroleum. (See OLEFINES.) This olefine is absorbed in sulphuric acid, the liquid diluted with water and distilled, when isopropyl alcohol is obtained. It is a colourless, fragrant liquid boiling at 82·7° C. It is used industrially in the extraction of alkaloids and other compounds of therapeutic interest.

PROPYLON, in architecture, a small pylon, or monumental gateway, in front of a larger gateway or pylon (*q.v.*), especially in Egyptian architecture, in which the propylon is frequently a single truncated pyramidal form with the gateway in its centre.

PROROGATION, a postponement, specifically, in Great Britain, the termination without dissolution of a session of parliament by discontinuing the meetings until the next session. A prorogation of parliament affects both houses, and thus differs from an "adjournment," which does not terminate the session and is effected by each house separately by resolution.

PROSCENIUM, originally, in the Greek theatre, the entire area of the stage between the back wall or *σκηνή* (Latin scena), and the orchestra. In the modern theatre the word proscenium is used particularly in connection with the arch (proscenium arch) framing the stage.

PROSE, the plain speech of mankind, when written or composed without reference to the rules of verse. It has been usual to distinguish prose very definitely from poetry (*q.v.*). Ronsard said that to him prose and poetry were "mortal enemies." But "poetry" is a more or less metaphysical term, which cannot be used without danger. For instance, an ill-inspired work in rhyme cannot be said to be poetry, and yet most certainly is not prose. On the other hand, a work of highly wrought non-metrical writing is often called a prose-poem. This shows that the antithesis between prose and poetry is not complete. Prose, therefore, is best defined as comprising all forms of careful literary expression which are not metrically versified, and hence the definition from *prorsus* (direct or straight), the notion being that it is straight and plain, and is used for stating precisely that which is true in reason or fact.

Prose, however, is not everything that is loosely said. True, it is the result of conversation, but that conversation is not necessarily, nor often, prose. Prose is not the negation of all laws of speech; it rejects merely those which depend upon metre. What its laws are is not easy to say. But this is plain; as prose depends on the linking of successive sentences, the first requirement is that these sentences should be lucidly arranged. In prose, that the meaning should be given is the primal necessity. But as it is found that a dull, clumsy, monotonous arrangement of sentences is fatal to the attention of the listener or reader, it is needful that to plainness should be added various attractions and ornaments. The sentences must be built up in a manner which displays variety and flexibility. There should be a harmony, and even a rhythm, in the progress of style, care being taken that this rhythm and this harmony are not recognizably metrical. Again, the colour and form of adjectives, and their sufficient yet not excessive recurrence, is an important factor in the construction of prose. The omission of certain faults, too, is essential. In every language grammatical correctness is obligatory. Here we see a distinction between mere conversation, which is loose, fragmentary and often even ungrammatical; and prose, which is bound to weed away whatever is slovenly, and to watch closely lest merely colloquial expressions should slip in. What is required is a moderate and reasonable elevation without bombast or bathos. Not everything that is loosely said is prose, and the celebrated phrase of M. Jourdain is not exactly true, for all the loose phrases which M. Jourdain had used in his life, though they were certainly not verse, were not prose either. We must be content to say that prose is literary expression not subjected to any species of metrical law.

Greek.—The beginnings of Greek prose are very obscure. It is probable that they took the form of inscriptions, and gradually developed into historical and topographical records. We come down to something definite when we reach Hecataeus and Herodorus; and, although their writings have disappeared, we know enough to see that by the 5th century B.C. the use of prose in its modern sense had been established. We even know the character of the style of Hecataeus, and we hear of its clearness, its grammatical purity, its individuality—qualities which have been valued ever since. These writers were succeeded by Hellanicus, who wrote many historical books now lost, and by Herodotus, whose noble storehouse of chronicle and legend is our earliest monument of European prose. When once non-metrical language could be used as by Herodotus, it was plain that all departments of human knowledge were open to it. But it is in Ionia and the Asiatic islands that we find it cultivated by philosophers and critics. The earliest of these masters of prose survive only in much later records of their opinions; in philosophy the actual writings of Thales, Anaximander, Pythagoras and Empedocles are lost, and it is likely that their cosmological rhapsodies were at least partly metrical. We come into clearer air when we cross to Attica: Thucydides' priceless work has most fortunately come down to us; and Xenophon continued it in the spirit of Thucydides, and carried Greek prose to a great height of easy distinction. But it is in philosophy that prose in Greece gains flexibility and-variety, proving itself an unsurpassed vehicle for the finest human thought. The philosopher Plato is the greatest prose writer of Greece, and, in the view of many well qualified to judge, of the world. In his dialogues we see what splendour, what elasticity, what exactitude, this means of expression had in so short a time developed; how little there was for later prose-writers to add. The rhetoricians were even more highly admired by antiquity than the philosophers, and ancient, unlike modern, opinion would perhaps have set Demosthenes higher than Plato. In Aristotle we see the conscious art of prose-writing subordinated to the preservation and explanation of facts, and after Aristotle's day there is little to record in a hasty outline.

Latin.—The Romans obeyed the universal law by cultivating verse long before they essayed the writing of prose. The earliest historians of whom we have definite knowledge, Fabius Pictor and Cincius Alimentus, wrote in Greek. The earliest annalist who wrote in Latin was Hemina; the works of all these historians are lost. A great deal of primitive Roman prose was occupied with jurisprudence and political oratory. By universal consent the first master of Latin prose was Cato, the loss of whose chief works is to be deplored; we possess from his pen only a treatise on agriculture. In the next generation we are told that oratory was carried to the highest point by Marcus Antonius and Licinius Crassus—"by a happy chance their styles were exactly complementary to one another." Unfortunately none but inconsiderable fragments survive to display their qualities. Happily, however, those qualities were combined in a man of genius, whose writings have come down to us; this is Cicero, whose prose exhibits the Latin language to no less advantage than Plato's does the Greek. From 70 to 60 B.C. Cicero's literary work lay mainly in the field of rhetoric; after his exile he was chiefly occupied with theoretical treatises. The beautiful essays of his old age comprise two little masterpieces, *De amicitia* and *De senectute* (45 B.C.). It is to the collection of the private letters of Cicero, published after his death by Atticus and Tiro, that we owe our intimate knowledge of the age in which he lived, and these have ever since been held models of epistolary prose. Of Cicero's greatest contemporary, Julius Caesar, much less has been preserved, and this is unfortunate because Roman critical opinion placed him among the very chief of prose-writers; but we retain his *Commentaries.* The prose of Sallust, who followed Caesar, is hard, brief and sententious. The writers who succeeded him neglected these qualities, and Latin prose became more diffuse and rhetorical. But it was wielded by one writer of the highest genius, Titus Livius, who enriched the tissue of Latin prose with ornament which hitherto had been confined to poetry; this enables him "to advance without flagging through the long and intricate narrative where a simpler diction must necessarily have grown monotonous" (Mackail). The periodic structure of Latin prose, which had been developed by Cicero, was carried even further by Livy. The style of Pollio, who wrote a *History of the Civil Laws,* was much admired, and the loss of this work must be deplored. A different species of prose, the *plebeius sermo,* or colloquial speech of the poor, is partly preserved in the fragments of a Neronian writer, Petronius Arbiter. Of the Latin prose-writers of the silver age, Seneca, Quintilian and Tacitus, nothing need here be said.

English.—The independence of English prose is a fact which rests on a firm basis. "The Code of Laws of King Ine" dates from the 8th century, and there are various other legal documents which may be hardly literature in themselves, but which are worded in a way that seems to denote the existence of a literary tradition. After the Danish invasion, Latin almost ceased to be known, and translations began to be required. In 887, Alfred wrote in English, with the help of scholars, his *Hand-Book;* this, probably the earliest specimen of finished English prose, is unhappily lost. His English version of the *Cura pastoralis* was probably completed in 890. Later still Alfred produced translations from Bede, Orosius, Boethius and other Latin authors, and, in 900, closing a translation from St. Augustine, we read "Here end the sayings of King Alfred." The prose of Alfred is simple and clear without pretension. After him the first name of eminence which we encounter is that of Aelfric, who, about 997, began to translate, or rather to paraphrase, certain portions of the Bible into a very finished English. A little later vigorous prose was put forth by Wulfstan, archbishop of York (d. 1023). At the Conquest, the progress of English prose was violently checked, and, as has been said, it "was just kept alive, but only like a man in catalepsy." The *Annals* of Winchester, Worcester and Peterborough were carried on in English until 1154. Except in a few remote monasteries, English ceased to be used, even for religious purposes, and the literature became exclusively Latin or French. We may perhaps say that modern English prose begins with the *Testament of Love* of Thomas Usk (*c.* 1388). To the same period belong *The Tale of Melibee* and *The Parson's Sermon* by Chaucer; the treatises of John of Trevisa, whose style in the *Polychronicon* has a good deal of vigour; and the three versions of the *Travels* of Jean à Barbe, formerly attributed to "Sir John Mandeville." The composite text of these last-mentioned versions really forms the earliest specimen of purely secular prose which can be said to possess genuine literary value, but again the fact, which has only lately been ascertained, that "Sir John Mandeville" was not an original English writer robs it of much of its interest.

The anonymous compiler-translator can no longer be styled "the father of English prose." That name appears to belong to John Wyclif, who, in the course of his career as a controversialist, more and more completely abandoned Latin for English. The translation of the English Bible was begun by Nicholas Hereford. The completion of this work is usually attributed, but on insufficient grounds, to Wyclif himself. A new version was almost immediately started by John Purvey, another Wyclifite, who completed it in 1388. We are still among translators, but towards the middle of the 15th century Englishmen began, somewhat timidly, to write original prose. Capgrave, an Augustinian friar, wrote a chronicle of English history down to 1417; Sir John

Fortescue produced about 1475 a book on *The Governance of England;* and Reginald Pecock attacked the Lollards in his *Repressor of Over Much Blaming of the Clergy* (*c.* 1450). The prose of Pecock is sometimes strangely modern, and to know the ordinary English prose of the 15th century it is more useful to turn to *The Paston Letters.* The introduction of printing into England is coeval with a sudden development of English prose, a marvellous example of which is to be seen in Caxton's edition of Malory's *Morte d'Arthur,* in which the capacities of the English language for melody and sweetness were for the first time displayed. Caxton himself, Lord Berners and Lord Rivers, added an element of literary merit to their useful translations.

With the Renaissance, *Richard III.,* whether by Sir Thomas More or by Cardinal Morton, was a work of considerable importance; *Utopia* (1516) was unfortunately composed in Latin, which still held its own as a dangerous rival to the vernacular. In his *Governor* (1531) Sir Thomas Elyot added moral philosophy to the range of subjects thought proper for English prose. In the same year Tyndale began his version of the Bible, the story of which forms one of the most romantic episodes in the chronicles of literature; at Tyndale's death in 1536 the work was taken up by Coverdale. The *Sermons* of Latimer (1549) introduced new elements of humour and vigour. The earliest true biography was the *Life of Cardinal Wolsey,* by George Cavendish, written about 1557, but not printed until 1641. In the closing scenes of this memorable book, which describe what Cavendish had personally experienced, the perfection of easy English style is reached for the first time. The prose of the middle of the 16th century—as exemplified in Sir Thomas Wilson, Roger Ascham, and Sir John Cheke—is clear, unadorned and firm, these Englishmen holding themselves bound to resist the influences coming to them from Italy and Spain. Equal simplicity marked such writers as Foxe, Stow and Holinshed, who desired a straightforward prose in which to present their information. But Hoby and North introduced not a few exotic graces, and prepared the way for the innovations of Lyly in *Euphues* (1579). The extravagances of Lyly outdid those of his continental prototypes, and euphuism became a disturbing influence which, it may be, English prose has not, even yet, entirely thrown off. In spite of its popularity, it was opposed in its own day, not merely by the stately sobriety of Hooker, but by the sweetness of Sir Philip Sidney. Raleigh wrote an English prose perhaps more majestic than any which preceded it, but he revelled in length of sentence and ponderosity of phrase, so that the prestige of *The History of the World* on the whole delayed the emancipation of English prose. The direct influence of euphuism was seen for some time in the work of poets like Lodge and Greene, and divines like Andrewes; its indirect influence in the floweriness and violence of most prose down to the Restoration.

Donne had a sonorous majesty of style; and Burton could use English with humour and vivacity when he gave himself the chance. In spite of the skill with which, during the civil wars and the Commonwealth, authors like Jeremy Taylor, Fuller and Milton manipulated prose, and in spite of the magnificence of Sir Thomas Browne, it was not until shortly before the Revolution that English prose reached its perfection. According to Dr. Johnson, Sir William Temple (1628–99) was the first writer who gave cadence to English prose. The new tendency was all in favour of brevity and crispness of shorter sentences and easier constructions. Not a little of the majesty of the earlier age was lost; but for practical purposes prose became a far more businesslike implement than it had hitherto been. The treatises of Halifax, or the sermons of South, mark the change. The power of English speech was first comprehended perhaps by Dryden, who combined dignity and even pomp of movement with an ease and laxity on occasion which gave variety to prose, and approximated it to ordinary speech. This then may be called the foundation of modern English prose, which has extended into no departments not recognized, at least in essence, by Bunyan, Dryden and Temple. The ensuing varieties have been mainly matters of style. In the 18th century, for instance, there was a constant alternation between a quiet, rather cold elegance and precision, which was called the Addisonian manner, and a swelling, latinized style, of which Johnson is the most famous exemplar. But as far as arrangement and syntax are concerned, it cannot be said that English prose has altered essentially since about 1680. It is, however, to be noted that in the course of the 19th century attempts were made to restore the beauty and variety of early 17th-century diction.

Icelandic.—The independent invention of prose by the Icelanders is one of the most singular phenomena in history. It resulted from the fact that story-telling was a recognized form of amusement in the isolated life of an Icelandic household. Something of the same kind had existed in Norway before the exodus, but it was in Iceland that it was reduced to an art. It is remarkable how suddenly the saga, as a composition, became a finished work. The deliberate composition of sagas began about the year 1030, and it is recorded that Ari Fródi (1067–1148) was the first man in Iceland who wrote down stories. Many of Ari's books are lost, but enough survive to show what Icelandic prose was in his hands, and the impress of his rich and simple style is felt in all the succeeding masterpieces. Snorri, and the anonymous authors of *Njala, Laxdaela,* and the rest, exhibit simple prose style at its highest. The great historian, Sturla (1214–84), is the latest of these classic writers of Iceland, and after his death there was a rapid decline. The splendid prose of these two centuries stands unrelated, an unparalleled portent in European literature.

Spanish.—In Castilian, as elsewhere, verse is far advanced before we meet with any distinct traces of prose. A religious treatise is attributed to a monk of Navarre, writing in the 13th century. Between 1220 and 1250 a chronicle of Toledo was indited. But the earliest prose-writer of whom Spain can really boast is King Alphonso the Learned (1226–84), in whose encyclopaedic treatises "Castilian makes its first great stride in the direction of exactitude and clearness" (Fitzmaurice-Kelly). Almost all the creditable prose of the end of the 13th century is attributed to Alphonso, who was helped by a sort of committee of authors. The king's nephew, Juan Manuel (1282–1347), author of *Conde Lucanor,* carried prose to a further point in delicacy and precision. The poet Ayala (1332–1407) was another gifted artificer of Spanish prose, which suffered a setback in the hands of his successors, Santillana and Mena. It rose once more in *The Sea of Histories* of Pérez de Guzmán (1378–1460), in whom the lucid purity of Castilian prose is for the first time seen. In the 15th century the shapeless novel of chivalry was predominant, while in the age of Ferdinand prose decayed. The next great writer whom we meet with is Guevara (d. 1545), whose *Dial of Princes* exercised an influence which even extended to English prose (in North's well-known version). The historians of this period were of less value. The earliest picaroon novel, *Lazarillo de Tormes* (1554), introduced a new form and exhibited Castilian prose style in a much lighter aspect. Still greater elegance is met with in the writings of Juan de Valdés and of Luis de León. Of the latter Fitzmaurice-Kelly says that "his concise eloquence and his classical purity of expression rank him among the best masters." The instrument, accordingly, was ready to the hand of the supreme magician Cervantes, whose *Don Quixote* was begun a few years (about 1591) after *Los Nombres de Cristo* of Luis de León. The prose of Lope de Vega is stately and clear, but admittedly has little importance in comparison with his verse. Quevedo's style had the faults of antithesis and obscure ingenuity; but his *Visions* (1627) are of course famous. The latest struggles of a decadent critical conscience, battling against affectation, are seen in Gracián (1601–58) and Molinos (c. 1640–97). When Spanish prose revived in the 19th century, in the person of Larra (1809–37), the influence of French models was found to have deprived it of distinctly national character, while giving it a fresh fluidity and grace.

French.—There had long been a flourishing versified literature in the vernacular of France, before anyone thought of writing French prose. It was the desire to be exact in giving information which led to a partial divergence from metre. The translator of the *Chronicle of Turpin* mentions that he writes in prose "because rhyme entails the addition of words not in the Latin." Thus about 1200 verse began to be abandoned by chroniclers who had some definite statements to impart. They ceased to sing;

they wrote as those around them spoke. The earliest French prose was translated from the Latin, but Baldwin VI. (d. 1205) is said to have commissioned several scribes to compile in the vulgar tongue a history of the world. If this was ever written it is lost, but we possess a *Book of Stories* written about 1225 by a clerk at Lille, which may fairly be said to be the beginning of French prose history. When once, however, a taste for prose was admitted, the superiority of that medium over verse as material for exact history could not but be perceived. The earliest French prose-writer of genius was Villehardouin, who put down memoirs of his life between 1198 and 1207; he left his book, *The Conquest of Constantinople,* incomplete. In the history of prose, Villehardouin takes an eminent place. In his style are seen many of the most precious elements of French prose, its lucidity, its force, its sobriety and its charm. He had been trained as an orator, and was content to write as he had learned to speak. He was followed by other admirable writers of memoirs, Robert of Clari, Henri of Valenciennes, the anonymous chronicler of Béthune, to whom we owe the famous description of Bouvines, and the Minstrel of Reims. The last-named finished his *Récits* in 1260. These works in the new easy manner of writing were found to be as elegant and as vivacious as any in verse. They led the way directly to the earliest historian of modern Europe, Joinville, who finished his *Histoire de St. Louis* in 1309. A century later Froissart left his famous *Chroniques* unfinished in 1404, and again 100 years passed before Philippe de Commines dropped the thread of his *Mémoires* in 1511. These three are simply the most eminent figures in a great cloud of prose-writers, who helped to facilitate the use of the national language. In the 15th century, moreover, Antoine de la Salle deserves mention as practically the earliest of French novelists. But with the Renaissance came the infusion into France of the spirit of antiquity, and in Rabelais there was revealed an author of the very highest genius. The year 1532, in which the first brief sketch of *Gargantua* appeared, was critical in French literature. In 1549 appeared the *Défense et illustration de la langue française* of Joachim du Bellay, in which the foundations of French literary criticism were firmly laid. The liberation of the language proceeded simultaneously in all directions. In 1539 it was officially decreed that all judicial acts were thenceforward to be written "en langage maternal français." Calvin led the theologians, and his precise and transparent prose gave the model to a long line of sober rhetoricians. It is in Calvin that we meet for the first time with a simple French prose style, which is easily intelligible to-day. There is some pedantry in St. François de Sales, some return to the spirit of mediaeval French in Montaigne; so that the prose of these great writers seems to us more antiquated than that of Calvin. Yet the *Institution* belongs at latest to 1560, and the immortal *Essais* at earliest to 1580. We are approaching the moment when there should be nothing left for French prose to learn. But we pause at Brantôme, in whom the broad practice of French as Froissart and the mediaeval chroniclers had used it was combined with the modern passion for minute and picturesque detail. With the beginning of the 17th century there sprang up almost an infatuation for making prose uniformly dignified, for avoiding all turns of speech which could remind the reader of the "barbarous" origins of the language; the earliest examples of this subjection of eloquence to purely aristocratic forms have been traced back to the *Servitude volontaire* of La Boétie (1530–63). In the pursuit of this dignity the prose writers of the 16th century ventured to borrow not words merely but peculiarities of syntax from Greece and Rome. The necessity of remaining intelligible, however, checked excess, and after a few wild experiments the general result was discovered to be the widening of the capacities of the language. In the 17th century a great stimulus was given to easy prose by the writers of romances, led by d'Urfé, and by the writers of letters, led by Balzac, with whom French prose lost its heaviness and its solemnity; it became an instrument fit to record the sentiments of social life; here was discovered what Voltaire calls the *nombre et harmonie de la prose.* French style became capable of still more when it was used by Descartes and by Pascal to interpret their majestic thoughts. At this moment, in 1637, the French Academy was founded, for the distinct purpose of purifying and enlarging the French language; and in time, out of the midst of the academy, arose the important *Remarques* (1647) of Vaugelas, a work of grave authority, which was the earliest elaborate treatise on the science of prose in any language. Antiquated as Vaugelas now seems, and little regarded by modern writers his work is still the basis of authority on the subject. In common with his colleagues he laid down laws by which harmony of structure, a graceful sobriety and exactitude of expression, could be secured to every practised French writer. He was not accepted as infallible, even in his own age; he was immediately exposed to the criticism of La Mothe le Vayer, who, however, was radically at one with him regarding the basis of his definition. The great demerit of the early academicians was that they knew little about mediaeval French. They thrust everything aside which they regarded as barbarous, and the work of the 19th century was to recover from a past behind Rabelais elements of great value which the 17th had arbitrarily rejected. In the succeeding centuries there has been a vast extension of the practice of French prose, but in spite of all neologisms, and of the waves of preciosity which have periodically swept over the French language, the treatise of Vaugelas remains the final code in which the laws that govern French prose are preserved.

Italian. — The case of prose in Italian has this unique feature that, instead of gathering form obscurely and slowly, it came into sudden existence at the will of one of the greatest of writers. Latin had almost universally been used in Italy until the close of the 13th century, when Dante created a vernacular prose in the non-metrical part of his *Vita Nuova* (*c.* 1293). For a long time the prose of Dante stood practically alone, and Petrarch affected to despise the works which his great predecessor had written in the vulgar tongue. But about 1348 Boccaccio started his *Decameron,* which gave classic form to the prose romance of Italy. It should have been greatly to the advantage of Italy that in the hands of Dante and Boccaccio prose was born full-grown, and had not to pass through the periods of uncertain development which awaited it elsewhere. After this brilliant beginning, however, there was a decline, the writers of the next age lacking the courage to be independent of antiquity. There was a return to Latin phraseology which made many works almost macaronic in character; the famous *Hypnerotomachia* of Colonna is an instance. Something of the purity of Boccaccio was recovered by Sannazaro in his *Arcadia* (1489); even Sannazaro, however, did not see how needful it was to cast off Latin constructions. At length Machiavelli and Guicciardini succeeded in releasing prose from the yoke of Rome, and in writing undiluted Tuscan. In the 16th century the prose writers of Italy became extremely prolific, with Pietro Bembo at their head. The novelists were now prominent, but, although they take a foremost place in the history of Italian literature, there was little art in their employment of language. Many of them were born out of Tuscany, and, like Bandello, never learned the rules of pure Italian prose. Since the 16th century Italian would seem to have undergone no radical changes, and its prose has been stationary in form. At the close of the 19th century a new school of writers, with Gabriele d'Annunzio at its head, created a demand for a new prose, but the remedy suggested by these innovators was neither more nor less than a return to Boccaccio and Machiavelli.

German. — The earliest attempts in German prose belong to the age of Charlemagne, and the first example usually quoted is the *Strassburger Eidschwüre* of 842. For all literary purposes, however, metrical language was used exclusively during the *mittelhochdeutsch* period, which lasted until the end of the 13th century. What little prose there was, was limited to jurisprudence and theology. David of Augsburg (d. 1272) is named as the earliest vernacular preacher, but only one of his sermons has reached us. More important was Berthold "the Sweet" (1220–72), whose sermons were published in 1824. Historical prose began with the Saxon Chronicle of 1248. There was little to record in the next two centuries, until prose was revived by Geiler von Kaisersburg (1445–1510) in his sermons. About the same time translations were made of the *Decameron* and other Italian novelle. The development of prose in Germany is, however, negligible until we reach Luther's Bible (N.T., 1522), on which all classic German prose is based. Johann Fischart composed important secular books in the vernacular, in particular the *Bienenkorb* (1579) and an imitation of *Gargantua* (1575), the earliest German novel. Nearly a century passes before we reach the curious picaresque romance of *Simplicissimus* (1669) of Grimmelshausen. But the neglect of prose by the German nation was still general. Even men of the stamp of Leibnitz wrote in Latin or French. What Luther had done was, however, completed and confirmed in the middle of the 18th century by Lessing, the creator of modern German prose. The critical period in this revival was 1764 to 1768, which saw the production of *Laocoon* and the *Hamburgische Dramaturgie*. We pass presently to Jean Paul Richter, and so to Goethe, in whose hands German prose became the organ of thought and eloquence which it has been ever since.

PROSECUTION, the procedure by which the law is put in motion to bring to trial a person accused of crime (*see* CRIMINAL LAW; INDICTMENT). In theory in Great Britain the king is in all criminal offences the prosecutor, because such offences are said to be against his peace, his crown and dignity, but in practice such prosecutions are ordinarily undertaken by the individuals who have suffered from the crime. This is a different procedure from that prevailing in Scotland and European continental countries, in all of which a public department or officer undertakes the prosecution of offences.

In the United States, crimes against the Federal Government are prosecuted by the different United States attorneys and their assistants under the general supervision of the United States attorney-general. In the States, prosecution is by district, State's or county attorneys, or their assistants, somewhat under the supervision of the State attorney-general. Sometimes a special prosecutor is named. So it has come about that those who comprise the prosecuting force are termed collectively the prosecution.

PROSERPINE, generally accounted the Latin form (*Proserpina*) of Persephone, a Greek goddess, daughter of Zeus and the earth-goddess Demeter (*q.v.*). Some, however, regard *Proserpina* as a native Latin form, not borrowed from the Greek, and connected with *proserpere,* meaning the goddess who aided the germination of the seed. (*See* PERSEPHONE.)

PROSODY, properly the study of accent, breathing and quantity. In modern use, the theory of versification. (*See* VERSE.)

PROSPECTING, whether it be the search for minerals by a lone prospector, or by two or more prospectors, or by an organized party of trained men in a more or less unknown region, or by an operating company in its producing property at depth, is how our mineral deposits are discovered and developed. Geophysical prospecting has helped, particularly with petroleum. In prospecting, time, patience, optimism, and money are essentials. (*See* GEOPHYSICS; PETROLEUM.)

The mineral industry of any advanced country is second in importance to its welfare, agriculture being first; therefore, prospecting for and the mining, metallurgy, and manufacturing of metals are basic to civilization.

Generally, when prospecting is mentioned, gold comes to the mind of the layman, but there are many other minerals of considerable marketable value and industrial use—antimony, asbestos, bauxite, beryllium, chromite, graphite, manganese, mercury, mica, molybdenum, nickel, platinum group, tantalum, tin, titanium, tungsten, uranium, vanadium, zinc, and zirconium, for example.

Seepages of oil and structures favourable thereto, and oil-bearing shale should be examined.

Even deposits of building stones, cement-making rock, and sand and gravel should not be overlooked.

In recent years, to list a few important deposits found throughout the world. the following minerals may be mentioned: Aluminium ores (bauxite) in Europe; chrome ore in Turkey and the Philippines; copper ores in Rhodesia and Nevada (Rio Tinto); gold in California (Golden Queen), Nevada (Jumbo), Fiji, New Guinea, and the Philippines; manganese in South Africa; nickel in British Columbia and Brazil; potash in New Mexico; and radium and silver in north-west Canada. These particular discoveries were made in regions ranging in climate and topography from the Arctic Circle to the tropics and from plains to mountains and jungle. No conditions are too severe for the determined and experienced prospector; but it can be said that the natives or mountain people of some countries, as in South America and Asia, do some searching and occasionally bring worthwhile deposits to the attention of engineers or scouts for exploration companies.

Minerals of similar appearance frequently mislead prospectors and others: Mica, iron pyrite, pyrrhotite, and chalcopyrite are mistaken for gold; graphite, for molybdenite; dolomite, for colemanite; stibnite, for bismuthinite; marcasite, for tellurides; zincite, and erythite, for cinnabar; stannite, for tetrahedrite; barite, for scheelite; garnierite, for malachite; and obsidian, for pitchblende.

Surface rocks stained by copper, iron, manganese, and mercury are misleading because frequently there is no persistence of ore at depth.

The black sands of certain beaches and river bars, and such sands caught in the sluices of hydraulicking and dredging operations, have misled many a man into believing that they are high in gold and platinum. In a few places these sands, which are mostly iron minerals, have paid to work. They have also on some dredging operations in which they are a highly concentrated product.

Gold does not exist in colloidal condition in ores and waters or in any other form such that assays cannot detect it; assays get all the gold and silver, and custom plants pay on assays only.

Because not more than one property in two hundred submitted for examination to exploration companies becomes a mine, a prospector should make sure by development and by assays of representative samples that a claim is really worth attention. An outcrop or a small pit does not mean an "enormous tonnage," nor will companies that are looking for deposits consider such a showing.

Prospecting is permitted on public lands in certain countries under regulations which require that a certain amount of work be done each year. If work is not continued each year, claims become forfeitable to anyone who re-stakes or re-pegs them. No prospecting is permitted on private property unless an arrangement is made with the owner. There are regulations for placers and for lodes.

At one time, and now in some regions, prospectors set out afoot or with a burro, mule, horse, camel, or canoe for some area they had in mind; nowadays, for those who can afford it, transport is made easier by motor-cycle, motor-car, motor-truck, and aeroplane. The aeroplane leaves men and departs, but a motor-car or truck is locally useful in getting supplies and for haulage, and often is a source of power for any small equipment.

Many veins reveal themselves by their outcrops; and by stripping away the country rock and trenching across them, any ore-shoots may be discovered and developed. If the outcrop of a vein has been eroded and only pieces of "float" ore are to be seen on a hillside, these should be traced to what appears to be their source. Then some trenching may uncover the vein.

A prospector should have a pick, shovel, hammer, short drills, dynamite, pan, and something for crushing samples, say a mortar and pestle. The pan is used for washing gravel or crushed ore for gold, cinnabar, tin, and heavy sulphide minerals. A good hand lens is a more useful device for magnifying minerals than is generally recognized. A man should have ample food and clothes suitable to the district he is prospecting.

When a prospect shows enough ore for a small mill or for shipment to a custom mill or smelter, the owner should try to arrange for this. An ore may be suitable for sorting out the waste rock and then shipping the remainder to a custom plant, or it may be sorted and treated locally.

Several firms in the United States, Canada, Australia, New Zealand, and Africa make milling and treatment plants for prospects.

The question arises: Where to search for minerals? Semi-desert, rivers, foothills, and mountains have produced much wealth. Mountain chains are or may be, as they have been, great future sources of minerals — the Rocky mountains; the Cascades; the Sierra Nevada and Coast Range; the chains of Idaho, Nevada, and Arizona; the Sierra Madre of Mexico and the Andes of South America, have been productive. Some mountains have not revealed much. Volcanic areas or those made up of flow rocks are generally favourable. Faulting, folding, and intrusions of igneous rocks are part of the formation. Every outcrop, especially of quartz, should be closely examined, sampled, and panned. If a formation is "likely" in appearance, prospect it thoroughly before moving camp. Placers may occur at high elevation: the drift gravels of the Sierras and gravels of the Rockies, or along and at the mouths of rivers. They may contain gold, precious stones, tin, tungsten, and zircon.

Prospectors and miners with ambition and money enough can attend the special, free summer courses given by certain schools of mines, some of which send lecturers into the field. In such manner, prospectors can enlarge their knowledge of minerals and the occurrence and identification of them. Booklets and sets of minerals are available at a low price.

Makers and dealers in mine machinery and equipment are always glad to send information to those who would like to install some type of plant. Several books on general prospecting or on gold alone are procurable at reasonable charge from firms in New York city; Gardendale, Quebec; London; and Sydney, Australia. By such means the prospector becomes better informed regarding rock formations and the minerals likely to be in them, as well as in methods of testing what the minerals are.

To some extent, governments encourage and aid prospectors and engineers through their State or Provincial and Federal Bureau of Mines, Departments of Mines, and Geological Surveys. Various investigations are made and the results are published and are available free or at a low charge. This statement refers particularly to the United States, Canada, and the British Empire. Some governments appropriate money for certain field investigations and some allot cash loans to prospectors, miners, and small companies. Sometimes free assays and tests on ores are run, and free identification of minerals is made. In some countries the government operates mills for small producers. (M. W. v. B.)

PROSPECTUS: *see* COMPANY.

PROSPER OF AQUITAINE or PROSPER TIRO (*c.* 390–*c.* 465), Christian writer and disciple of St. Augustine, was a native of Aquitaine, and seems to have been educated at Marseilles. In 431 he appeared in Rome to interview Pope Celestine regarding the teachings of St. Augustine and then all traces of him are lost until 440, the first year of the pontificate of Leo I., who had been in Gaul and thus probably had met Prosper. In any case Prosper was soon in Rome, attached to the pope in some secretarial or notarial capacity. Gennadius (*De script. eccl.* 85) mentions a rumour that Prosper dictated the famous letters of Leo I. against Eutyches. The date of his death is not known, but his chronicle goes as far as 455, and the fact that Ammianus Marcellinus mentions him under the year 463 seems to indicate that his death was shortly after that date. Prosper attacked the Pelagians in a polemical poem of about 1,000 lines, *Adversus ingratos,* written about 430. After Augustine's death he wrote three series of Augustinian defences, especially against Vincent of Lerins (*Pro Augustino responsiones*). His chief work was against Cassian's *Collatio,* his *De gratia dei ut libero arbitrio* (432). He also induced Pope Celestine to publish an *Epistola* ad *episcopos Gallorum* against Cassian. He corresponded with Augustine and made an abridgment of his commentary on the Psalms, a collection of sentences from his works. He also put into elegiac metre, in 106 epigrams, some of Augustine's theological dicta.

Prosper's *Epitoma chronicon* is a careless compilation from St. Jerome in the earlier part, and from other writers in the later, but the lack of other sources makes it very valuable for the period from 425 to 455 of which he had personal knowledge. There were five different editions, the last of them dating from 455, after the death of Valentinian. For a long time the *Chronicon imperiale* was also attributed to Prosper Tiro, but without the slightest justification, for it exhibits Pelagian tendencies.

The *Chronicon* has been edited by T. Mommsen in the *Chronica minora* of the *Monumenta Germaniae historica* (1892). The complete works are in Migne's *Patrologia latina.* Tome 51. *See* L. Valentine, *St. Prosper d'Aquitaine* (Paris, 1900) and A. Potthast *Bibliotheca historica* (1896).

PROSTEJOV or PROSSNITZ, an old town in Moravia, lies in the fertile valley of the Hanna, a tributary of the Morava. Pop. (1930) 33,487. Germany occupied the town in March 1939, at the time of Czechoslovakia's dismemberment.

PROSTITUTION, a word which may best be defined as promiscuous unchastity for gain. In German law it is described as *Gewerbsmassige Unzucht.* It has always been distinguished in law and custom from concubinage, which is an inferior state of marriage, and from adultery and other irregular sexual relations, in which the motive is passion. Prostitution has existed in all civilized countries from the earliest times, and has always been subject to regulation by law or by custom. The more important of the external reasons which induce women to turn to prostitution for a livelihood in modern times are: (1) difficulty of finding employment; (2) excessively laborious and ill-paid work; (3) harsh treatment of girls at home; (4) promiscuous and indecent mode of living among the over-crowded poor; (5) the aggregation of people together in large communities and factories, whereby the young are brought into constant contact with demoralized companions; (6) the example of luxury, self-indulgence and loose manners set by the wealthier classes; (7) demoralizing literature and amusements; (8) the arts of profligate men and their agents. Alcohol is often an aid to prostitution, but it can hardly be called a cause, for the practice flourishes even more in the most abstemious than in the most drunken countries. These observations apply to the West. In Oriental countries girls are commonly born into or brought up to the trade, and in that case have no choice.

In Eastern Religions. — Among the ancient nations of the East, with the exception of the Jews, prostitution appears to have been connected with religious worship, and to have been not merely tolerated but encouraged. The code of sexual morality laid down in the Book of Leviticus is prefaced by the injunction not to do after the doings of the land of Egypt, nor after the doings of the land of Canaan, where all the abominations forbidden to the Jews were practised; and whenever the Israelites lapsed from their faith and "went a-whoring after strange gods," the transgression was always associated with licentious conduct. In Egypt, Phoenicia, Assyria, Chaldea, Canaan and Persia, the worship of Isis, Moloch, Baal, Astarte, Mylitta and other deities consisted of the most extravagant sensual orgies, and the temples were merely centres of vice. In Babylon some degree of prostitution appears to have been even compulsory and imposed upon all women in honour of the goddess Mylitta. In India the ancient connection between religion and prostitution still survives; but that is not the case in China, a most licentious country, and, considering the antiquity of its civilization, and its conservatism, we may perhaps conclude that it formed an exception in this respect among the ancient nations.

Among the Jews, who stood apart from the surrounding peoples, the object of the Mosaic law was clearly to preserve the purity of the race and the religion. Prostitution in itself was not forbidden, but it was to be confined to foreign women. Jewish fathers were forbidden to turn their daughters into prostitutes (Lev. xix. 29), and the daughters of Israel were forbidden to become prostitutes (Deut. xxiii. 17), but no penalty was attached to disobedience, except in the case of a priest's daughter, who was to be burnt (Lev. xxi. 9). This distinction is significant of the attitude of Moses, because the heathen "priestesses" wrre nothing but prostitutes Similarly, he forbade groves, a common adjunct of heathen temples and a convenient cover for debauchery Again, his purpose is shown by the severe penalties imposed on adultery (death) and on unchastity in a betrothed damsel (death by stoning), as contrasted with the mild prohibition of prostitution. So long as it did not touch the race or the religion, he tolerated it; and even this degree of disapproval was not maintained, for Jephthah was the son of a harlot (Judges xi. 1).

There is abundant evidence in the Old Testament that prostitution prevailed extensively in Palestine, even in the earlier and more puritan days. The women were forbidden Jerusalem and places of worship; they infested the waysides, and there is some evidence of a distinctive dress or bearing, which was a marked feature of the trade among the Greeks and Romans. In the later period of aggrandizement that increase of licentious indulgence which Moses had foreseen took place, associated with infidelity. The remarkable series of ordinances laid down by Moses in the interest of public health contains unmistakable recognition of venereal disease and its contagious character (Lev. xv.).

In Ancient Greece.—Passing on to the ancient Greeks, we find prostitution treated at Athens on a new principle. The regulations of Solon were designed to preserve public order and decency. He established houses of prostitution (dicteria), which were a state monopoly and confined to certain quarters. The dicteriades were forbidden the superior parts of the town, and were placed under various disabilities. They were compelled to wear a distinctive dress, and so far from being connected with religion, they were not allowed to take part in religious services. These laws do not seem to have been carried out at all effectually, and were presently relaxed. After the Persian wars more stringent regulations were again introduced. The *dicteriades* were placed under police control, and were liable to prosecution for various offences, such as ruining youths, committing sacrilege and treason against the state. It is clear, however, that as time went on the Athenian authorities experienced the difficulties encountered by modern administrations in carrying out state regulation. There were grades of prostitution, socially though not legally recognized, and women of a superior order were too powerful for the law, which failed to maintain the ban against them. The Greek *hetaerae,* who were prostitutes, not "mistresses," and the most gifted and brilliant members of their class known to history, wielded great and open influence. The test case of Phryne, in which the stern attitude previously maintained by the Areopagus broke down, established their triumph over the law, deprived virtuous women of their sole advantage, and opened the door to general laxity. In later times any one could set up a dicterion on payment of the tax. In other Greek cities extreme license prevailed. At Corinth, which was famous for sensual practices, a temple, with a huge staff of common prostitutes for attendants, was established in honour of Aphrodite and for the accommodation of the sailors frequenting the port. The worship of this goddess became generally debased into an excuse for sexual excesses.

Ancient Rome.—The Romans united the Jewish pride of race with the Greek regard for public decency, and in addition upheld a standard of austerity all their own. In early days female virtue was highly honoured and strenuously maintained among them, of which the institution of the vestal virgins was a visible sign. Their attitude towards prostitution differed, accordingly, from that of other ancient nations. Among them, alone, it was considered disgraceful to a man to frequent the company of prostitutes; and this traditional standard of social conduct, which markedly distinguished them from the Greeks, retained sufficient force down to the later days of the Republic to furnish Cicero with a weapon of rhetorical attack against his political opponents, whom he denounced as scortatores. Prostitution was more severely regulated by them than by any other ancient race. They introduced the system of police registration, which is the leading feature of administration in most European countries to-day. From the earliest days of the Republic prostitutes were required to register at the aediles' office, where licenses were issued to them on payment of a tax. They were placed under stringent control, had to wear a distinctive dress, dye their hair or wear yellow wigs, and were subject to various civil disabilities; but the severest feature of the system was that, once registered, their names were never erased, and consequently remained for ever under an indelible stain. As in our times, registration became ineffective, and neither law nor tradition could check the demoralizing influence of ease and luxury when once external conquest left the Romans free to devote their energies to the pursuit of pleasure. An attempt was made, by the enactment of severer laws against prostitution, to stem the rising tide of immorality, which threatened to taint the best blood in Rome with the basest elements in the later days of the Republic. Citizens were prohibited from marrying the descendants or relatives of prostitutes, daughters of equestrians were forbidden to become prostitutes, and married women who did so were liable to penalties. More stringent regulations were also imposed on prostitutes themselves, in addition to the old disabilities and police system, which remained in force. If these laws had any effect at all, it was to promote the general prevalence of immorality; they certainly did not diminish prostitution. The profligacy of imperial Rome has never been surpassed for gross and obscene sensuality.

Under Christianity.—The greatest change introduced by Christianity with regard to prostitution was the adoption of a more charitable attitude towards these social and legal outcasts. The Roman state tax, which had descended to the emperors and had been further regulated under Caligula, was partly given up in the 4th century by Theodosius, on the representations of Florentius, a wealthy patrician, who offered to make good the ioss of revenue out of his own pocket. It was fully and finally abolished by Anastasius I. in the next century, and the old registers were destroyed. Then some of the civil disabilities of prostitutes were removed by Justinian in the 6th century. Gibbon, who never gave credit for a good motive when a base one could be found, attributes Justinian's action solely to his desire to marry Theodora, whose life had been notorious; and no doubt she influenced him in the matter, but it is permissible to assume a good motive. Even Gibbon is constrained to admit her virtue after marriage, and to give her credit for "the most benevolent institution" of Justinian's reign, the rescue home for fallen women in Constantinople, which was at any rate disinterested. Though it did not succeed, it marks a turning-point in the treatment of a class which had never met with public sympathy before. At the same time procuration and connivance were severely punished, which is in keeping with the Christian attitude. The early Christian Church laid great stress on chastity, which probably suggested to its Roman persecutors the horrible punishment of forcibly prostituting Christian maidens. Such malignity enhanced the glory of martyrdom without shaking the constancy of its victims; and the triumph of purity in an age of unbounded licence was conspicuously recognized by Alaric, the Gothic conqueror, who gave strict orders in the sack of Rome that the virtue of Christian women was to be respected. The Church, however, was not severe upon prostitutes, to whom the altar was open upon repentance, and some of the fathers explicitly recognized their trade as a necessary evil. Among them was St. Augustine, a man of the world, who saw that its suppression would stimulate more destructive forms of immorality. Gradually charity degenerated into patronage. Rome, conquered spiritually by Christianity and materially by the northern barbarians, sapped the virtue of both.

Charlemagne made an effort to suppress the prevailing disorder, but his private life was licentious, and his capitularies, which ordained the scourging of prostitutes and panders, were not inspired by any regard for morality. A period of reform followed. The rise of chivalry, with its lofty idealization of women, and the wave of Christian fervour connected with the crusades, inspired a vigorous and high-minded campaign against an all-prevalent evil. The Church became exceedingly active in prevention and rescue work, and was assisted by a devout and zealous laity. Rescue missions were organized, convents were founded everywhere for the reception of penitents, and dowries were subscribed to procure them husbands. Fulke de Neuilly was a conspicuous figure in this work. He held missions, preached, and collected large sums for marriage 'dowries. Pope Innocent III. (1198–1216) pronounced it a praiseworthy act to marry a prostitute; and Gregory IX., a few years later, wrote to Germany that brothel-keepers were not to prevent prostitutes from attending missions, and that clergy and laity who drew profit from prostitution were banned. "Urge bachelors," he wrote. "to marry repentant girls, or induce the latter to enter the cloister."

Regulated by Law.—In spite of such eiforts, and of occasional spasms of severity by individual rulers, prostitution flourished everywhere throughout the middle ages. It was not merely tolerated, but licensed and regulated by law. In London there was a row of "bordells" (brothels) or "stews" in the Borough near London Bridge. They were originally licensed by the bishops of Winchester, according to John Noorthouck, and subsequently sanctioned by parliament. Stowe quotes the regulations enacted in the year 1161, during the reign of Henry II. These were rather protective than repressive, as they settled the rent which women had to pay for the rooms, and forbade their compulsory detention. The act was afterwards confirmed in the reigns of Edward III. and Richard II. In 1383 the bordells belonged to William Walworth, lord mayor of London, who farmed them out, probably on behalf of the Corporation, according to analogy in other parts of Europe. They were closed in 1506, but reopened until 1546, when they were abolished by Henry VIII. In London we get the earliest known regulations directed against the spread of venereal disease. The act of 1161 forbade the bordell-keepers to have women suffering from the "perilous infirmity of burning"; and by an order of 1430 they were forbidden to admit men suffering from an *infirmitas nefanda.* Probably it was by virtue of this order that in 1439 two keepers were condemned to eleven days' imprisonment and banishment from the city. In 1473, again, it is recorded that bawds and strumpets were severely handled by Lord Mayor Hampton.

Elsewhere in Europe much the same state of things prevailed during the same period. Prostitution was both protected and regulated, and in many places it constituted a source of public revenue. In France prostitutes were distinguished by a badge, and forbidden to wear jewels and fine stuffs and to frequent certain parts of the town. Public brothels on a large scale were established at Toulouse, Avignon and Montpellier. At Toulouse the profits were shared between the city and the university; at Montpellier and Avignon the trade was a municipal monopoly, and farmed out to individuals; at Avignon, where the establishment was kept up during the whole period of the popes' residence, the inmates were subjected to a weekly examination. In 1254 Louis IX. issued an edict exiling prostitutes and brothel-keepers; but it was repealed two years later, though in this and the succeeding century procuration was punished with extreme severity. In some parts of France prostitutes paid a tax to the seigneur. In Germany, according to Fiducin, the public protection of Lust-Dirnen was a regular thing in all the large towns during the middle ages. "Frauenhäuser," similar to those in London and in France, existed in many places. They are mentioned in Hamburg in 1292; and from later records it appears that they were built by the corporation, which farmed them. So also in Ulm, where special regulations were issued in 1430. We find them existing at Regensburg in 1306, at Zürich in 1314, at Basel in 1356 and Vienna in 1384. According to Henne-am-Rhyn, admission to these houses was forbidden to married men, clergy and Jews, and on Sundays and saints' days they were closed.

The laws of the emperor Frederick II. in the 13th century contain some curious provisions. Any one convicted of a criminal assault on a prostitute against her will was liable to be beheaded; if she made a false accusation she was subject to the same penalty. Any one not going to the assistance of a woman calling for help was liable to a heavy fine. In these ordinances the influence of chivalry may be detected. At the same time prostitutes were forbidden to live among respectable women or go to the baths with them. Hospitality to important guests included placing the public Frauenhauser at their disposal. So King (afterwards Emperor) Sigismund was treated at Bern in 1414 and at Ulm in 1434, so much to his satisfaction that he publicly complimented his hosts on it. Besides the municipal Frauenhauser, there were "Winkelhäuser," which were regarded as irregular competitors. In 1492 the licensed women of Nuremberg complained to the mayor of this unfair competition, and in 1508 they received his permission to storm the obnoxious Winkelhaus, which they actually did. In Italy and Spain the system appears to have been very much the same. At Bologna prostitutes had to wear a distinctive dress, in Venice they were forbidden to frequent the wine-shop, and in Ravenna they were compelled to leave a neighbourhood on the complaint of other residents. At Naples a court of prostitutes was established, having jurisdiction over everything connected with prostitution. It led to great abuses, was reformed in 1589, and abolished about a century later.

The Reformation.—In the 15th and 16th centuries a great change took place. It was due to two very different causes: (1) fear of disease; (2) the Reformation. With regard to the first, there can be little doubt that both the slighter and graver forms of venereal disease existed in very remote times, but until the 15th century they attracted comparatively little attention. The constitutional character of syphilis was certainly not understood—which is by no means surprising, since its patholdgy has only recently been elucidated (see VENEREAL DISEASES)—but one would still have expected to find more notice taken of it by historical, moral and medical writers in classical and mediaeval times. Nor is it possible to explain their reticence by prudery, in view of the unbounded literary licence permitted in those ages. One can orily conclude that the evil was less widely spread or less virulent than it afterwards became. At the end of the 15th century it attracted so much notice that it was supposed to have originated then *de* novo, or to have been brought from the West Indies by Columbus—both untenable hypotheses; and, as usual, each country accused some other of bringing the contagion within its borders. To speculate on the cause of this increased prevalence would be idle; it is enough to note the fact and its consequences. It was immediately followed by the Reformation, and the two together led to a general campaign against the system of licensed prostitution. The last Frauenhaus was closed in Ulm in 1531, in Basel in 1534 and in Nuremberg in 1562. In London, as already noted, the bordells were abolished in 1546. In Paris an ordinance was issued in 1560 prohibiting these establishments, and later all prostitutes were required to leave the city within twenty-four hours.

It is observed by Henne-am-Rhyn—no friend of toleration—that their suppression was followed by the appearance of the crime of infanticide, by the establishment of hospitals for foundlings and for syphilis. This suggests an indictment against humanity which is hardly justified by the facts. Infanticide was no new thing, and foundling hospitals date from the beginning of the 13th century. Their marked increase and the establishment of syphilitic hospitals came a century later than the Reformation campaign against the Frauenhauser. The suppression of the latter did not affect the prevalence of prostitution. In the 17th century another spasm of severity occurred. In 1635 an edict was issued in Paris condemning men concerned in the traffic to the galleys for life; women and girls to be whipped, shaved and banished for life, without formal trial. These ordinances were modified by Louis XIV. in 1684. The Puritan enactments in England were equally savage. Fornication was punishable by three months' imprisonment, followed by bail for good behaviour. Bawds were condemned to be whipped, pilloried, branded and imprisoned for three years; the punishment for a second offence was death. In Hamburg all brothels were pulled down and the women expelled from the town. If these measures had any effect, it was speedily lost in a greater reaction; but they have some historical interest, as the present system was gradually evolved from them.

The Protection of Health.—It would be tedious and unprofitable to follow all the steps, the shifts and turns of policy, adopted in different countries during the 18th century for the suppression or control of an incurable evil. They involve no new principle, and merely represent phases in the evolution of the more settled and more systematic procedure in force at the present time. Its chief feature, as compared with the past, is the establishment of an organized police force, to which the control of prostitution is entrusted, coupled with a general determination to put the subject out of sight and ignore it as far as possible. The procedure on the continent of Europe is virtually a return to the old Roman system of registration and supervision, except that there is no State tax, and names can be removed from the register. The objects are the same, namely, public order and decency, with one important addition, which has given rise to much controversy. This is the protection of health.

From what has gone before, the reader will have gathered that it is not, as frequently supposed, a new thing. Already in the middle ages the question occupied the attention of parliament in England, and a weekly examination of public women by the barber (the surgeon of that time) was instituted at Avignon. The practice was adopted in Spain from about 1500, and later in many other places. But the abolition of licensed brothels, and the consequent growth of private prostitution, rendered it a dead letter. To meet the difficulty, registration was devised. It was first suggested in France in 1765, but was not adopted until 1778. The present regulations in France are based on the ordinances of that year and of 1780 which in their turn were borrowed from those of the 16th and 17th centuries, previously mentioned. The *theory* of the modern attitude towards prostitution is clearly laid down by successive ordinances issued in Berlin. Those of 1700 stated that "this traffic is not permitted, but merely tolerated"; the more precise ones of 1792 pronounced the toleration of prostitution a necessary evil, "to avoid greater disorders which are not to be restrained by any law or authority, and which take their rise from an inextinguishable natural appetite"; and the regulations of 1850 and 1876 are headed: "Polizeiliche Vorschriften zur Sicherung der Gesundheit, der offentlichen Ordnung und des offentlichen Anstandes." This embraces the whole theory of present administration, and if Gesundheit be omitted, is not less applicable to the United Kingdom than to the continent. The last attempt to suppress prostitution in Germany is worth noting, as it occurred so late as 1845. Registration was stopped and the tolerated houses were closed in Berlin, Halle and Cologne. The attempt was a complete failure, and it was abandoned in 1851 in favour of the previous system.

White Slave Traffic.—In recent years the question of prostitution has become international through the movement to suppress the "white slave traffic." A congress was held in London in 1899, and in 1902 the French Government summoned an official conference, which resulted in the Convention of 1904, signed by the 12 principal European nations, with the exception of Austria. By this Convention the States bound themselves to coordinate information relative to the procuring of women from abroad, to keep a watch at places of entry and to repatriate women who wished it. In 1910 the United States passed the White Slave Traffic Act, which imposed severe penalties on the transport of women for immoral purposes. In the same year an international Convention for the suppression of the White Slave Traffic was signed in Paris by 13 nations, including Austria. This convention went much farther than the previous one. It bound the parties to punish anyone who had "procured, enticed or led away, even with her consent, a girl under age for immoral purposes" and also anyone who had "by fraud or by means of violence, threats, abuse of authority or any other method of compulsion, procured a girl or woman over age for immoral purposes, notwithstanding that the various acts constituting the offence may have been committed in different countries." This involved altering the internal law relating to prostitution in certain countries. Voluntary committees were formed in the principal countries to collect information and push the matter.

After the World War of 1914–18, the League of Nations took up the problem in accordance with Article 23, which entrusted the League with "the general supervision over the execution of agreements with regard to the traffic." In 1921 the League summoned an international conference at Geneva, attended by delegates from 34 nations. It proposed that the words "white slave traffic" should be altered to "traffic in women and children," that a new convention should be drafted, that an advisory committee be set up and that Governments should be invited to make annual reports on the traffic and on the measures taken for checking it. All these proposals were carried out. In 1923 the advisory committee recommended that "pending the abolition of the system of State regulation, no foreign woman should be employed in or carry on her profession as a prostitute in any licensed house"; that a questionnaire be issued to the Governments; and that a study of conditions on the spot should be undertaken by experts. In 1927 the committee of experts appointed in pursuance of the foregoing recommendation published a report in two parts containing information obtained by visits to 28 countries and the replies of Governments to the questionnaire sent out. This report has been used in the following observations on the principal countries.

Great Britain.—In Great Britain there is no system of licensed houses or registration of prostitutes. The law is mainly governed by the Criminal Law Amendment Act of 1885, as amended in 1912 and 1922, which makes procuration or attempted procuration a misdemeanour. The law further makes it a felony to have carnal knowledge of a girl under 13, and a misdemeanour in the case of a girl between 13 and 16. The same applies to the occupiers of premises who knowingly permit these offences, to persons taking a girl under 18 out of the possession of her parents or guardians for the purpose, and to the detention of any woman or girl in a brothel. The maintenance of brothels is prohibited, and by the Vagrancy Act of 1898 males are prohibited from living on the earnings of prostitutes. The traffic in women and children is dealt with by the Children (Employment Abroad) Act of 1913, which prescribes the conditions for a magistrate's license to take girls under 16 out of the country for "singing, playing, performing or being exhibited for profit"; and by the Aliens Order of 1920. The Licensing Act of 1872 contains a provision, adopted from 1847, which makes it an offence for publicans to allow "common prostitutes to assemble and continue" in licensed premises. Otherwise they are not interfered with by the police except for disorder or annoying persons by solicitation: in regard to the latter, which also applies to males, the police exercise their own discretion and exhibit much variation of practice.

There is some evidence that street-walking by prostitutes, which used to be the great feature of London as compared with other capitals, has diminished; but the diminution may be partly explained by the practice, which has greatly increased, of motorcars waiting about and picking up girls. There is no reason to believe that prostitution has diminished; but on the other hand it is clear that the foreign traffic in girls is of very small account. Englishwomen are too independent to make good subjects, and the Criminal Law Amendment Acts have been successful in preventing such exploitation as there was. Great Britain is a party to all the international conventions.

The Question of Compulsory Examination.—NOaccount of Great Britain mould be complete without a reference to the partial adoption in certain garrison centres of the system employed elsewhere. In 1864 a Contagious Diseases Prevention Act was passed providing for the coinpulsory medical examination of prostitutes and the detention in hospital of those found affected. It applied to 11 garrison towns, was amended in 1866 and in 1869 was applied to 18 towns. This gave rise to a campaign in the opposite direction, with which Mrs. Josephine Butler's name was prominently associated. A royal commission investigated the question in 1871 and a select committee did the same in 1879. The majority reported in favour of the acts, being impressed by the evidence, which was strongly for them, and much of which was quite unbiased. Nevertheless in 1883 the House of Commons passed a resolution condemning the medical examination of women, and as this would have entailed refusal to vote the money required to carry on the system it was immediately dropped. In 1886 the acts were formally repealed.

In India the system was introduced for military cantonments in 1865, partially suspended in 1884 and stopped in 1888 on account of the action of the House of Commons. A new Cantonment Act was passed in 1889 and an amending act in 1893, which prohibited the compulsory and periodical examination of women. In consequence of the enormous increase of syphilis—from 75.5 to 174·1 per 1,000 for primary and from 29·4 to 84.9 for secondary cases—which followed, a new order was made in 1897, which gave power (1) to call on persons suffering from a contagious disorder to attend a dispensary, (2) to remove brothels,

(3) to prevent the residence or loitering of prostitutes near cantonments. Troops in India or in other stations abroad are in a different position from those at home and show a much larger proportion of men affected. If the army statistics of the different countries are examined over a number of years, two things appear:— (1) wide variations between the several countries, (2) a sort of epidemic rise and fall. The variations may be explained by the degree of care exercised in the regulated countries, Prussia having consistently the best record; the English figure is higher than for any regulated country. Flexner, arguing against regulation, suggests that the important factor is the size of the town, but that takes effect through the difficulty of carrying out the measures, which increases with the size.

United States.—The system is the same as in England; that is to say, there are no licensed houses or registration and periodical examination of prostitutes. The Federal Government has adhered to the convention of 1904, but not to those of 1910 and 1921, owing to the fact that the several States have their own laws in relation to prostitution. The Attorney-General of the United States is charged under the law of 1910 with the prosecution of cases of international and inter-State traffic in women and girls. The severe immigration law of 1917, which prohibits the importation of aliens for prostitution makes it difficult to pass; but there is no interference with emigrants on this account.

France.—French law has been considerably affected by the conventions of 1904, 1910 and 1921, France having signed and ratified the first two and adhered to the last. The criminal law takes no cognizance of prostitution, but the police have power to regulate it, in Paris under the prefect of police, elsewhere under that of the mayor. Brothels are licensed in two categories—(I) *maisons* de *tolérance* (residential), (2) *maisons* de passe or de rendez-vous (houses of call); the keeper of the former must be a woman who is the owner of the premises or has a registered lease. Only women of 21 and of French nationality are allowed to reside; the inmates are medically inspected every week, while other registered prostitutes are examined fortnightly. Registration is either voluntary or compulsory after repeated arrests. There are in Paris about 235 licensed houses, of which 30 are *maisons de tolérance;* the number of inmates is about 2,100 and it remains pretty constant. Girls under 18 are not registered, but are dealt with under Articles 270 and 271 of the penal code, as amended by the law of 1921, under which they are brought before the juvenile court and subjected to reforming measures. The registered prostitutes form only a small proportion of the total number. Procuration is an offence recognized by the penal code, which has been strengthened by a law passed in 1922. France appears to be the headquarters of the outgoing traffic in women and girls, especially to Cuba, Mexico, Panama and the South American republics. The incoming traffic is comparatively small. In 1924 the official returns of the registered prostitutes showed a total of 583, of whom 223 were Italians and 146 Belgians.

Germany.—Prostitution is not forbidden, but under article 361 of the penal code women are liable to arrest for practising prostitution without being under police control or for contravening regulations after being placed under control. The regulations include weekly or fortnightly medical examination, together with strict rules in regard to public demeanour and conditions of life. There are in Berlin about 6,000 registered prostitutes, and 2,200 in Hamburg; and these are reckoned at one-third of the total number. Procuration is prohibited, under the name of Kuppelei, by article 180 of the penal code, which was strengthened in 1927 by a provision of the law for combating venereal disease, which explicitly names the conducting of a brothel or of a business akin to that of a brothel as included in procuration. Nevertheless most large towns, except Berlin, still have them. There is (1) ordinary *Kuppelei,* which is simply assisting procuration for gain and (2) aggravated *Kuppelei,* which includes false pretences and procuration by parents, guardians, teachers, etc., and entails a much more severe penalty. With regard to the international traffic the German Government states that Germany is not at present a country of destination, but only one of transit. Foreign women, when arrested for prostitution, are expelled; eight such women were deported from Berlin in 1924 and 21 procurers. The outgoing traffic is much the same as before the war, but attempts are being made to prevent it in accordance with the international conventions, to all of which Germany is a party. A law passed in 1923 requires that all agencies providing employment abroad must be licensed and supervised. and another, passed in 1924, provides further protection for girls under 18 by requiring the consent of the juvenile court.

Italy.—After a fluctuating policy Italy has adopted the French system. Under the law of 1926 prostitution is regulated, and all inscribed women must submit to medical examination. In 10 cities there were 324 licensed houses in 1924. Strict conditions are laid down in the law of 1926. Procuration is an offence under the penal code, which was strengthened in 1923. With regard to the traffic, the law governing the outgoing traffic was made more stringent in 1919, but there appears to be considerable evasion of the passport regulations. The incoming traffic shows an increase. Out of 11,924 prostitutes interrogated in 15 months of 1923–24, 782 were found to be of foreign nationality. During 1925 that number had risen to 865, most of whom were Austrians and French.

Other European Countries.—A similar system prevails in Belgium, Portugal, Spain, Rumania, Greece, Hungary and Austria, excepting Vienna, where licensed houses have been abolished. The German or the English plan is followed, more or less, in Holland, Poland, Czechoslovakia, Switzerland and the Scandinavian countries. Colonies, dominions and dependencies usually follow the example of the mother-country.

Cuba.—The licensed areas were abolished in 1913, but conditions still remained very bad, particularly in Havana, until 1925, when a vigorous movement was initiated by the Government, under the inspiration of the League of Nations Committee, which visited Cuba in 1924. The police became very active, and the houses where prostitution was carried on were reduced from 477 to 224. The incoming traffic, which had greatly increased since the war, was largely stopped in 1925 by a decree making it an offence to assist immigration for the purpose of prostitution and providing for the deportation of foreign women and keepers of prostitutes. The number of women so engaged in Havana was stated to be 700, chiefly French, Spanish and Italian. Except for the deportations the outgoing traffic was small. Cuba is a party to all the conventions.

The Argentine Republic.—South America has become the main objective of the traffic from Europe. The Argentine is a party to none of the conventions. Prostitution is there regulated by the municipalities. Houses are licensed and prostitutes are registered and medically examined. In Buenos Aires there were 585 licensed houses in 1923, showing a considerable increase. The women are chiefly French, Poles, Italians and Spaniards, but "there is a constant flow of foreign prostitutes from every corner of Europe to the Argentine around all barriers devised to check it. . . . It is clear that the traffickers manage to evade every restriction, and the evidence discloses an elaborate system for running the business of prostitution and securing girls therefor to the great profit of third parties." (Report of committee.)

Brazil.—Brazil is a party to the conventions of 1904 and 1910 and has signed the convention of 1921. There are no laws regulating prostitution and no licensed houses. The penal code, as modified in 1915, makes procuration and brothel-keeping an offence; but brothels, and ostentatious ones, abound in Rio de Janeiro. With regard to the traffic Brazil is a country of demand and prostitutes come there from everywhere. A memorandum prepared by the medical officer of health of Rio de Janeiro gave the nationality of 1,683 prostitutes; of these 987 were Brazilians, 158 Russian, 148 French, 144 Poles and 69 Portuguese.

It is hoped that the foregoing notes will sufficiently indicate the general position in the Western world There are two main differences between the treatment of prostitution in the several countries. The first difference is the licensed house, which generally exists on the Continent but not in Great Britain and her dominions or in the United States. There is, however, a tendency to follow the example of Germany or, at least, of Berlin and abolish them. This has been done in Switzerland, Holland, Czechoslovakia and the Scandinavian States. It is largely a geographical and racial question, but the tendency is in that direction. The second difference lies in the registration and examination of prostitutes. There is none in Great Britain, Holland, Switzerland and the United States; the institution of venereal clinics does something to protect the public health in its place, and does it better. The great object of the police in regard to prostitution is the maintenance of public order, which is undoubtedly assisted by licensing. But to-day prostitution is essentially an urban problem, and the vast size of modern cities makes clandestine prostitution so easy that the licensed houses hold only a small proportion of the total number. What proportion it is impossible to say; the estimates freely made are mere guesses.

Another modern problem is the international traffic, maintained by *souteneurs* and capitalist principals. The fact that this question has been taken up by the League of Nations is highly significant. No nation can wish to retain the traffic, with its abominable accessories, and the new immigration laws and, to a lesser extent, the greater protection afforded to girls going abroad, show that the action of the League is having a marked effect. But more than that, it has stirred the Governments to look into an unsavoury subject and has affected the whole anti-prostitution movement, which began in Great Britain with the campaign against the Contagious Diseases Acts.

PROSTYLE, in architecture, a portico projecting in front of a building, or a building with such a portico.

PROTAGORAS (*c.* 481–411 *B.C.*), Greek philosopher, was born at Abdera. He is known as the first of the Sophists (*q.v.*), *i.e.,* he was the first to teach for payment. It is said that he received nearly £400 from a single pupil. He learned philosophy in the Ionian school, and was perhaps a pupil of Democritus, though this is doubtful on chronological grounds. He was an older contemporary of Socrates. Pericles entrusted him with the task of framing laws for the new colony of Thurii (Plut. *Pericles,* 36). At the age of 70, having been accused by Pythodorus, and convicted of atheism, Protagoras fled from Athens, and on his way to Sicily was lost at sea. Besides *Truth,* and the book Of *the* Gods which caused his condemnation at Athens, Diogenes Laertius attributes to him treatises on political, ethical, educational and rhetorical subjects. Protagoras was the first to systematize grammar, distinguishing the parts of speech, the tenses and the moods.

Menzel, *Protagoras als Gesetzgeber von Thurii* (1910). *On* Protagoras' philosophy *see* Th. Gomperz, *Greek Thinkers* (Eng. trans. L. Maynus and S. S. Berry, 4 vols., 1901–12); and works quoted under SOPHISTS.

PROTEACEAE, a family of dicotyledonous plants comprising about 50 genera and some 960 species, of which about 600 are Australian, including the silky oak (*Grevillea* robusta) introduced into Ceylon for shade and timber, the Queensland nut (*Macadamia ternifolia*), cultivated in Hawaii, California, and Florida, and the Australian honeysuckles (Banksia); there are about 260 species in southwestern Cape of Good Hope, including the silver tree (Leucadendron *argenteum*); the remaining species have a wide but irregular distribution in Asia, Africa, America and Australasia. Most of the species are trees or shrubs, and the majority are xerophytic (*i.e.,* inhabit arid country).

PROTECTION. By protection in the restricted sense is meant the use by the Government of special forms of regulation or restraint, particularly import duties and analogous fiscal expedients, in order to encourage or to maintain essential industries which are endangered by foreign competition. What industries are essential must be determined by the requirements of public policy. Protection is one phase of national policy, and its ultimate object is national security. The free trade theory assumed that every man knew his own interest better than anyone else did; that everyone would follow his own interest rather than the interest of anybody else, and thirdly that the interest of the individual coincided with the interest of the community. On these assumptions rested the whole doctrine of *laisser faire* (*q.v.*), that economic movements should be left to follow what was called their natural course under free competition. Society was an aggregate of individuals assumed to be equal to one another in the competitive struggle, and all individuals consciously or unconsciously pursued their own interests. Protection on the other hand involved a different conception. There was the interest of the individual, the interest of trade, and the interest of the commonwealth. The last was the most important. On the free trade theory the government should not interfere by tariff or other regulations in order to foster trades which did not make their own way in the competitive struggle, or to direct existing trades into channels in which they did not flow under purely individualist conditions. In so far as such attempts were successful they involved loss to the whole body.

The country practising free trade was realising "natural" conditions; tariffs or other regulations which interfered with such conditions, were artificial, imposing obstacles in the way of free movement associated with the "natural" state. Protection was therefore prejudicial to the realization of the greatest prosperity. A reversion to protection as a policy involves not merely the sporadic use of tariffs in order to safeguard particular industries, but a conception of the State, its constitution, its functions and its ultimate aims, different from the underlying conceptions of the free traders. To the free trader wealth is the end in view; to the protectionist wealth is the means. The real end governing the policy of protection may not be economic at all in the narrow sense, but may be national or imperial solidarity and power, though undoubtedly a protectionist holds that while the free trade policy may lead to the greater wealth of individuals, the protectionist policy properly administered, will bring about a balance of economic activities, involving a higher maximum of efficiency to the community as a whole and a more equitable distribution between the economic groups.

If agricultural enterprise under free competition and free trade cannot be made to pay, the free trader would abandon it and concentrate on those industrial lines of activity which under such conditions are at the time more profitable. The protectionist on the other hand would argue that this is a shortsighted view. In the first place agriculture is necessary to the State for its security, the maintenance of a healthy population and many other purposes not directly and immediately economic. But more than that, the protectionist would say that it is absurd from the economic point of view for a country to sacrifice its agriculture, for agriculture is the guarantee of a large home market for the country's manufactures, and the large and expanding home market is the best security for the successful exportation of manufactures. Given the home market, continuous running of the manufactories and the proportionate reduction of the burden of standing charges, cheapens cost of production and makes possible easier entry into markets abroad and a higher remuneration for the workers at home. The free trader would say that if an industry does not pay its way under a policy of free importation, it is better that the capital employed in that industry should be invested in some other branch of economic activity which is remunerative; that the artificial maintenance of such an industry by the imposition of protective tariffs is an economic loss to the community. The protectionist would point out that the capital of such a depressed industry cannot be transferred to another industry, that capital is in the concrete form of factories and workshops and machines and many other forms which cannot be realised if the industry has fallen. It may indeed be desirable in certain circumstances to abandon it, but such a question cannot be decided without weighing carefully the number of persons employed, the possibility of their finding employment in other industries, the place of the industry in the national life, its relation to other industries in the scale of production, the possibility of obtaining its products in a suitable manner from other sources, its bearing on national security, and many other considerations of the highest importance. The free trader would not use tariffs or other artificial means for establishing in a country a new industry not hitherto practised. If such an industry were not likely to develop as the result of the unaided efforts of individuals, the free trader would not use government aid to promote it. The protectionist would consider the resources available in the form of raw materials, the possibility of acquiring the necessary skilled labour, the available organising ability, the demand for the products of such an industry at home and the accessibility of markets, and if the prospects were favourable would not hesitate to impose a definitely protective tariff with the intention to encourage the industry in view, even though for a few years it might involve higher prices to consumers at home, and he would do that all the more readily if there was plenty of capital for investment in the country for which he was responsible. Doctrinaire views on the question of protection have greatly declined in recent years, especially as a result of the Wòrld War. There are very few people who have influence in public affairs at the present time who would not be prepared to admit important exceptions to the free trade view and be willing to adopt a protectionist policy in particular cases, especially in regard to industries which are essential for the national security.

The justification of protection is to be found not in its conformity or its departure from an abstract theory, but in the conditions which govern the development of actual states and the laws of their development. It does not really belong to the domain of abstract economics, but to statecrait and practical organisation. The range of philosophical and other assumptions underlying the pure theory of economics is neither wide nor accurate enough to cover the varied motives and activities of an organic community, and men may at the same time accept and make use of the theory of economics so far as it goes, and yet be strong protectionists in action. In the article on ECONOMICS it has been shown how to use economic theory in investigation in opening up the relations between different series of economic facts and in suggesting approximations for the solution of practical problems. But the world we live in is a world of realities and of varying policies. We are dealing with nations, communities, human beings and concrete things, and it can never be assumed that the world does or ought to conform to the requirements of a purely theoretical system. The objections to protection in a hypothetical world where there is complete mobility of labour and capital, and time is an abstraction, are not relevant when we have to consider the great industries and the lines of commerce of the actual world, the tangled relations of the groups of human beings, their different histories and environment, and the divergent interests with which statesmen have to deal. If we keep in view the wide gulf between the world of pure theory and the conditions of actual life, we shall not hastily come to the conclusion that the states which have practised a protective policy have achieved success in spite of the measures they have adopted to secure it.

The Fall of the Old Policy.—In the middle ages the source of England's wealth was the exportation of raw materials, with which she purchased the manufactures and the luxuries of other countries. In those ages many of the regulations adopted were not, as they have been regarded by free trade writers, restraints upon liberty, but the conditions of its exercise. Freedom is only possible where there is security. Before the close of the middle ages manufactures were greatly extended as a result of encouragement, by the native aptitude of the people, and by the immigration of skilled artisans. Movements analogous to those of modern times took place on a small scale, and there were signs of a growing nationalism long before the close of the middle ages. Action taken by the trading companies, especially the great Merchant Adventurers Company, encouraged foreign trade, and we can trace in numerous statutes the foundations of what was subsequently called the mercantilist system. Then took place a development not dissimilar to that in continental countries in modern times. Internal barriers were removed. England and Scotland were united. Great Britain and Ireland became one economic area. By that time the United Kingdom, under the policy which was so widely condemned later on by economists, achieved economic supremacy. With apparently illimitable supplies of coal and other requisites of production, her industries growing by leaps and bounds from the use of new inventions, the whole organisation and structure of great industries rapidly changing, the old laws and methods of regulation became obsolete, and the tariffs worked out to suit the more primitive stages of industrial development were simply embarrassing or irrelevant in the new conditions. Attempts to adapt them failed and the old duties were swept away, not so much in obedience to a theory but because the necessary adaptations could not be made. It might have been more statesmanlike and prudent to keep at least the framework of the old system, but with wealth as the supreme end in life and with the opportunities which the new industrialism gave, this was the accepted course of contemporary statesmen. By 1860 free importation was the established policy of the country and the methods by which English statesmen had built up the economic power of the country were remembered simply as the economic fallacies of a former generation.

The Mercantile System in England.—In order to bring out the character of protection in its modern form we must make some further historical contrasts in British policy. The older policy was not protection in the narrow sense in which the word has been used in modern controversy. The idea of building up a great industrial commercial state by that policy ran through most of the economic measures which were adopted, affecting agriculture, trade and commerce, commercial treaties, finance, labour legislation, the poor laws, and colonial policy for several generations, and discriminating duties were imposed not from logical necessity or through loyalty to some theoretical system, but as practical expedients like any other form of regulation to deal with problems as they were at the time understood. Whole trades and branches of trades were left free. The mercantilism of England was always different in important respects from the Colbertism of France, and the tariff systems, generally, of continental states. Adam Smith comments on the "liberality" of English policy as contrasted with that of other states. It was a "free trade" system in (1) its extension of the powers of the central government over the trade and industry of the country at the expense of local and sectional bodies, close corporations, etc.: (2) the consequent equalising of opportunities and development of free enterprise, (3) the "nationalising" of great trades such as the East India trade, the trade of the Levant, etc., (4) the removal of internal restrictions, such, for example, as those on the corn trade. (5) the introduction of free trade first between England and Scotland and then between Great Britain and Ireland.

The term "free trade" was used in many different senses in contemporary literature and practice, but scarcely at all in its modern sense. It was applied to the freedom of intercourse between states as secured by treaty, to privileges granted to alien traders by which they were put on equal terms with the denizens of the country. It sometimes suggested illegality, piracy and unfair avoidance of established regulations; it was applied to the "interlopers" who carried on free trade with no regard to the regulations of the chartered companies, and to the smugglers who escaped the payment of duties levied by the state. In modern times free trade does not necessarily involve the meaning applied to it in England, but the policy of free exchange, and the levelling up of conditions by means of a tariff or other regulations to secure equality of competition between the countries concerned. Free importation in the modern English sense is peculiar to England, just as in England the term protection has come to be restricted in its application to the imposition of duties. It is also to be noted that the rôle played by the colonies under the mercantile system was roughly that which Cobden and his followers expected both colonies and foreign countries to play when the United Kingdom adopted free importation, and if the mercantilists sometimes imposed special regulations to direct colonial trade into channels considered favourable for the development of the mother country, the adherents of the Manchester school not infrequently used the power and influence of England to keep the economic activities of neutral and eastern countries in a stage considered favourable to the interests of British industry and to prevent the due expansion of those countries on lines more in accordance with the wishes of the people and the national resources of those countries.

There is a further distinction between the older system and Cobdenism. Both were forms of "national" as distinct from "imperial" policy, but under the former the colonies had a great part to play. They were in a position entirely different from that of foreign countries, in relation to the United Kingdom; and the system of preferences which then existed would have lent itself to the building up of the empire. Under the Cobdenite system the colonies had no part to play at all different from that of foreign countries, and the "interests of the consumer" took the place of the "interests of the commonwealth" as the basis of public policy. The older system looked forward, as it were, to the establishment of a great empire. Cobdenism was not really internationalism viewed from the point of view of British policy, but nationalism in a narrow, insular sense and the policy of England under its influence was based upon the economic monopoly secured by the rapid progress of invention. The influence of the new industrialism broke the cautious continuity of British policy. Walpole and Pitt revised the fiscal system by removing duties on raw material and reducing other duties with the view of increasing revenue. Huskisson revised the fiscal system in much the same spirit. The measures throughout this period were more in accordance with the cautious and statesmanlike line of Adam Smith's *Wealth of Nations* rather than with the later economists. If this movement had not been interrupted England would probably have retained the means of conducting international negotiations for consolidating the empire and providing a wide basis for revenue without any violent changes, but under later influences the policy of free importation was carried to extremes. People pursued the logical consequences of free trade rather than the practical interests of the country. The free traders on the one hand and the protectionists on the other were in violent and direct opposition on grounds of abstract theory rather than practical policy. But there is no important economist of the free trade school who does not admit important exceptions to the doctrine of free importation. The idea that all economists of that school were Cobdenites is without foundation. Reference has been made above to Adam Smith and his cautious attitude, but the great classical economists fairly generally admitted cases in which duties on imported manufactures might be desirable. Allowing therefore for the very different philosophical conceptions which were the basis of economics at that time as compared with our own, and the very different economic conditions which prevailed, there is not so much to distinguish the attitude of the writers of the early part of the nineteenth century from those of our own day in regard to practical policy as may be thought from manifestations of feeling during the fiscal controversy. The views of economists must be distinguished from the use made of them by political and social controversialists. The Ricardian theory of rent, the high prices and the practical difficulties of the times gave such people magnificent opportunity for working up a crusade against landlords, and the free trade movement which at first had been a most reasonable and proper effort to get rid of tiresome obsolete restrictions, became in the hands of extremists an instrument of social and political revolution. It is in England especially that the free trade movement was directed mainly against the landlord class and later on the capitalists, and it has grown by natural stages into the socialistic movement of modern times, while protectionism in all its branches has been more identified with methods of creating an industrial and commercial state of the modern type.

The qualifications of the free trade doctrine admitted by John Stuart Mill went far to undermine the whole basis of the doctrine. His famous admission in regard to infant industries of a new country could be made to cover a very large proportion of the protectionist expedients adopted in modern countries. The economic conditions and the rapid growth of the United States in the 19th century naturally made an immense impression. It was necessary to work out an explanation for such progress under an economic policy so different from that of England. But historically speaking, analogies to the development of the United States policy could be found all the world over. The word "new" in regard to industry cannot be confined in its application to the historic position of a country or an industry. It must apply to the stage of organisation of particular industries and if it is once admitted that a high tariff is justified from that point of view, the tariff policy of Europe during the nineteenth century finds much justification from the writings of the economists. But the admission could easily be extended to cover many other important steps of policy. The case may be taken of the country whose industries have been actually devastated by war or destroyed in the sense that the existing organisation for production had broken up, markets lost by the diversion of great works into activities for which they were not built and where vast works of reconstruction are required to bring them back to the peace efficiency which they once had. On Mills' admission it is difficult to deny the claim for protection while reorganisation is being carried out. The question becomes a matter of practical expediency, when we have to consider whether in given circumstances duties should or should not be imposed as an instrument of organisation. Obviously the policy to be pursued cannot be decided on purely abstract grounds.

The German Zollverein.—The most remarkable instance in modern times of the constructive use of a protective tariff in the building up of a great empire is to be found in the history of Germany. At the beginning of the 19th century Germany consisted of a number of small states each enjoying fiscal autonomy, separated from one another by customs frontiers, and after the era of the Napoleonic wars, German statesmen and economists saw that if national industries were to be established on a modern scale, these numerous areas would have to be unified. Standing alone and more or less isolated economically from their neighbours, they could not get the full advantages they could obtain in production by the development of their materials from their numerous population and from their mutual commercial relations. Germany had to choose between a large-state and a small-state policy, and Prussia began the work of organisation by the adoption of the tariff of 1818. Internal tariffs in the provinces of Prussia were swept away. Prussia as a whole was given protection against all external competitors, and other German States were invited to enter into union with her. The result of this movement was the formation of the Prusso-Hessian Zollverein. This was followed by the Zollverein between Wurtemberg and Bavaria and other combinations. These combinations were then brought into union and the first treaty of the Zollverein was adopted in 1834. The larger part of Germany thus became more or less a homogeneous economic area, except for a survival of a number of internal duties which it took many years to get rid of. The treaties were in the first instance for 12 years. By the end of the first period other states had acceded and so the process went on until the German Zollverein was completed. The Zollverein was not co-terminous with the German Empire, but it was the condition and the means by which the German Empire was created.

This movement was not understood in England, where it was regarded as protectionist in the narrow sense in which the word was used in English controversy. There were gloomy prophecies as to what would happen to Germany and what would happen to the trade of England with Germany. In fact the German movement was not dissimilar from that extending over a long period of time during which the economic union of England, Scotland and Ireland was effected, and many internal barriers were swept away.

The formation of the Zollverein brought about freedom of trade over a vast area, and its trade was protected against foreign competition by a carefully devised tariff round its external frontier. It is obvious that the internal union could not have been secured without the external protection. The German tariff and the internal organisation were necessary parts of the same movement, and the tariff organisation was supplemented by great schemes of reconstruction affecting every aspect of German life. The progress which followed the movement is without parallel; and the German empire became the most powerful competitor in the world with other countries. This feat of statesmanship was all the more remarkable as it was carried out in the teeth of British competition. When Great Britain entered upon her era of rapid commercial progress, she was first in the field with the inventions which revolutionised industrial processes, and she had the manufacturing monopoly of the world. Germany at the beginning was technically behind Great Britain, but she had one great help to her progress. Just when she was applying on a vast scale the principles of policy which had made Great Britain mistress of the world, that country turned her back on her o n traditions and made a free present of her market to any country which could exploit it. The rapid industrial progress of Germany was undoubtedly partly due to the fact that German exporters had free entry into the English market for their goods. Before the World War, it was quite common for great German factories to be planned, erected and organised on the basis that they could always dispose of their surplus productions in the English markets to an advantage at any price they could fetch.

This illustration from Germany is given in order to show how misleading was and is the practice of abstract English free traders of grouping the commercial policies of the world under two categories, of free trade and protection. Actual policies as they have been carried out can never be described in that simple manner. It is not enough to say that the actual policies are a combination of both theories. They are not. The actual policies of countries are the expression of the living activities of great societies as they have been determined by their long history and the powers and functions which they have developed, and they never follow the lines of an abstract theory divorced from the facts of that development. All countries have followed or are following much the same general course of development as Great Britain up to the modern era, but no country in any part of the world has ever deliberately adopted the practice of free importation in modern times. Many German students for years before the mar studied very carefully the course of events in England in order to avoid the mistakes which had been made.

We can see how the growth of the Zollverein brings into clear relief the mutual relations of the measures adopted in carrying out a great policy of economic nationalism, and the conditions under which such a policy can be achieved. Internal fiscaldifferences have to be swept away as far as possible, and that requires the provision of some alternative means for furnishing the revenue which in the first instance has to be sacrificed. So we get the organisation of a tariff against external countries and the development of means of direct taxation. The process further involved a policy for application to the means of communication, especially the railway system and transport by sea. In all these processes there was necessary some political reorganisation. The small States had to sacrifice their autonomous fiscal powers when they entered into the new union. The Zollverein on the German model could not be achieved without such sacrifice, a condition which could not be realised in the British empire where the dominions would certainly not give up their fiscal autonomy.

The German measures could not be carried through without social reorganisation and mainly under the influence of the German Centre Party and their arrangement with Bismarck a whole code of new social laws was evolved. To enlarge still further the economic borders and to bring fresh markets on the continent within their ambit, the Germany treaty system was developed. Later on in order to meet the economic pressure which followed from their rapid development, Germany pushed into a colonial policy and the exigencies of diplomacy, quite apart from the necessities of defence, forced Germany into a naval policy, and the German navy was established. Thus the German empire was gradually forced to adopt in a modern form all the leading characteristics of the old English national system, and the instrument by which these changes were brought about was the German tariff. This immense constructive movement, the greatest example we have of modern economic nationalism, obviously cannot be described as simple protection. It was a great scheme of organisation in which for one purpose or another the German tariff had to be used as an instrument.

Modern Attitude to Protection.—A certain practical attitude to the question of protection characterises the policy of all countries in modern times. It is recognised that every case has to be examined on its merits. No two tariff systems are the same, nor can it be decided which is more protectionist than another without the most careful examination not only for the actual rates of duty, but of all surrounding circumstances. (See TARIFFS.) French and German policies have been in their main features singularly permanent during the nineteenth century. The broad lines of policy have remained and are likely to remain as long as these countries subsist. There are no signs of any considerable modification. French policy, it may be said, is certain, since the acquisition of Alsace and Lorraine, to become more nationalist in character and the features which have marked successive tariffsfor many years are more likely to be emphasised than abandoned. Italy is showing all the signs of a nationalist régime, and she will proceed along much the same path as Germany and France. The new states which have been formed since the World War all show the marks of strong nationalism and this has found expression in the high tariffs they have one and all imposed. Under the pressure of modern economic conditions which are unfavourable to the existence of small States, many of them, while they may retain their political independence, will be forced by circumstances into economic combination, and the course of development followed by the German empire will be repeated in the economic sphere.

In the Far East the same movement is making rapid progress. It is many years since Japan embarked upon her own national policy. The development there is not in the least likely to be checked, still less will there be any return to the stage from which it was the departure. The old economic régime in China is at an end. Whether politically that huge country settles down to internal peace or not, it is certain that there will be an effective tariff in China organised for the purpose of Chinese industrial development and not as it has been, a revenue tariff while the Chinese market provided the means of disposing of the produce of European states. India is pursuing the same course, a fact of the utmost significance to Great Britain, because the Indian market as the Lancashire exporter has known it, is diminishing in importance; and the effect of this development upon the cotton trade and all the other 40 industries bound up in the cotton trade is of the greatest political and economic importance to Great Britain and the whole of the British empire. Egypt is following the same course. Within three years the conventions come to an end. Egypt will then have ready a new tariif. Every one of the British dominions is following the same course of development on national lines, and there is no sign that any other course, preference within the empire excepted, will be seriously considered. Great Britain, no longer the economic mistress of the world, one amongst many great nations at least as well equipped as she is, all pursuing with conviction the policy which they believe made the British empire, has abandoned her free trade attitude. There are now thousands of import duties in the British tariff. There is nothing between the present piecemeal application of protection and the working out of a tariff on a sczle suited to domestic and imperial needs except transitory influences and questions of immediate expediency.

It seems therefore that both protection and free trade in the academic sense of loyalty to a particular theory in which these words were used, have ceased to cover in any way the developments of policy in the world as we know it. There is a reversion all the world over to a conception of policy similar to that which inspired the earlier national policy of England under which protective tariffs are used or not used on the grounds of pure expediency to assist the aims of modern nationalism or imperialism, and this modern nationalism or imperialism is not a policy based upon the exploitation of any country or race, but the due adjustment of the economic relations of countries in such a manner as to secure their autonomous development and the efficiency of production. (W. A. S. H.)

UNITED STATES

The Civil War divides the protection policy of the United States into two distinct periods of approximately equal length. During the first 70 years there was a quarter-century (1789–1816) during which tariff making was governed primarily by revenue considerations; this was followed by a period of vigorous protection to rising young manufactures (1816–32), a period which was succeeded in turn by a quarter-century of declining protective duties (1833–60). With the Civil War, new forces came into operation, and since 1862 the United States has followed a rigid and consistent protective policy, interrupted thus far only by the relatively moderate Wilson and Underwood tariffs of 1894 and 1913.

When Congress met under the Constitution, the first bill introduced in the House of Representatives was a measure to provide revenue by means of a customs tariff. Various States had protective duties before the Constitution was adopted, and the debates on the revenue bill show clearly a general willingness to use the tariff to encourage domestic industries. Yet the rates enacted were low (in general but 5%), with specific duties on certain articles selected for special encouragement. During the 20 years following, the European wars created a great foreign market for American raw products, and made ship-building and shipping highly profitable, notably in New England; so there was little growth of American manufactures, and no appreciable increase of protectionist sentiment, despite the strong argument for protection put forth in Hamilton's *Report on Manufactures* (1792). As more revenue came to be needed, tariff rates were raised from time to time, but no special attention was given to their protective aspects, and down to 1816 the actual operation of the customs duties was only remotely protective.

From 1808, however, the industrial situation changed abruptly. The Embargo act (Dec. 1807), followed by the Non-Intercourse act (1809) and the war with England, cut off a large part of the export and import trade. Small manufactures sprang up in various parts of the country to meet pressing needs. Financially weak, and often ill-equipped, they were in no position to meet the sharp competition of the more advanced British manufactures with which they were faced on the return of peace. Their cries of distress, together with the need for more revenue, in 1816 brought new tariff legislation. Though designed to aid the manufacturers, this measure embodied only moderate duties, running as high as 25% on textiles for three years only, with a provision for minimum valuation. Though bad crops in Europe for a time kept the price of farm products high, the farmers too found themselves in difficulty after the crisis of 1818–19, and their thoughts turned toward the possibility of a home as opposed to a foreign market. As a result of these conditions there sprang up after 1819 an agitation for internal improvements and a vigorous protective movement, which aimed to insure national self-sufficiency by encouraging young manufactures and affording the farmer a home market. This so-called "American system," popularly identified with the name of Henry Clay, its foremost spokesman, had its early strength in the middle and Western States, New England at first holding aloof because of its predominant shipping and commercial interests. As industrialization proceeded, however, New England swung over, and from the latter part of the '20s that section became a foremost advocate of the protective system, which Pennsylvania had favoured from the first.

In response to the demand for protection, Congress passed the Tariff act of 1824, raising the duties on textiles, and also on iron, wool, hemp and other articles of particular interest to the middle and Western States and to the farmers Agitation was renewed after the crisis of 1825–26, culminating in the celebrated Harrisburg convention of 1827. In the following year, as a result of extraordinary political manoeuvres, a new law was enacted, the so-called "tariff of abominations," which brought further sharp increases of rates, particularly on wool and other goods whose protection was specially distasteful to the New England protectionists. Four years later this measure was superseded by another act, which put the tariff into a form satisfactory to its friends. Goods not produced in the United States paid low rates while textiles, iron and other articles which it was desired to protect, paid high ones. Woollens, for example, were taxed 50%, while the specific duty on rolled bar-iron at 1832 prices was equal to 95%.

The Southern States were unable, because of slavery, to develop manufactures, and they were interested chiefly in a good market for their raw cotton. Rightly judging that protection was bound to work directly to their disadvantage, they had from the beginning sharply opposed protection. The opposition became so fierce that South Carolina undertook to nullify the Act of 1832, but the firmness of President Jackson maintained the Federal authority. As a consequence of Southern opposition, however, the compromise tariff of 1833 was enacted, providing for a slow reduction of duties over a period of 10 years, until in 1842 no rate should exceed 20%. Manufactures had in fact by 1832 become settled on a firm basis, and interest in the tariff waned, while other questions, like internal improvements and slavery, came to occupy public attention. The final low rates of the act of 1833, it so happened, were in effect but two months, as the Whig Party in 1842, for political rather than economic reasons, passed a new high-tariff measure, which remained on the statute books for four years. The protective movement had largely lost force, however, so this measure was without much difficulty replaced in 1846 by the so-called Walker tariff, a moderate measure under which the most important protected articles paid 30% except cottons, which paid 25%. There was little interest in the tariff, and in 1857 a redundancy of revenue led to further reductions, the 30% rate going down to 24%. Often called a free-trade tariff, the act of 1857 in fact marked the lowest level of protective rates since the beginning of active protection. Under the circumstances then existing, the reduction of duties commanded general approval, even among the manufacturers. The protective movement of the '20s, the period in which manufactures were becoming firmly established, had gradually lost fervour after 1832, leaving the way clear for the fixed opposition of the Southern States to make itself effectively felt. The interest of farmers and manufacturers alike turned to other methods than tariff legislation as a means of insuring prosperity, and no real or supposed national interest was successfully invoked to stay the growing movement toward greater freedom of international trade. A revenue shortage following the crisis of 1857 occasioned the enactment of the Morrill tariff of 1861, framed to attract protectionist votes to the Republican Party in the campaign of 1860. Undertaking only to restore the rates of 1846, its authors yet sought to give added protection to Pennsylvania and the Western States by changing *ad valorem* to higher specific duties and by raising rates on iron and wool. Even so, the measure belongs essentially to the period of tariff liberalization beginning in 1833.

The Civil War brought profound industrial changes, and gave a new direction to tariff policy. Hitherto, customs duties had been practically the sole source of government revenue, and tariff legislation had therefore been dictated to no small extent by the condition of the Treasury. The war, with its insatiable demands for revenue, called into existence an elaborate system of internal-revenue taxes, of which the imposts on liquor and tobacco remained as a permanent and highly important part of the revenue system, thus affording legislators somewhat more leeway to deal with customs duties without primary consideration of their effects on the revenue. The internal-revenue acts of 1862 and 1864 laid heavy taxes on the production of commodities of all sorts, taxes which were naturally accompanied by corresponding increases of duties on imports. As those who framed the laws were protectionists, they were eager to see that no domestic producer was injured; accordingly, almost any duty asked for was granted. A tariff structure, "in many ways crude and ill-considered," establishing "protective duties more extreme than had been ventured on in any previous tariff act," to quote the leading authority, was thus suddenly built up. Like the other hasty financial legislation of the period, it was originally designed to meet the war emergency. At the end of the war, however, the structure thus erected, instead of being rebuilt, was preserved practically intact, and with relatively minor modifications continued to serve as one of the two pillars of Federal finance down to 1913.

After the war, the internal-revenue taxes, except those on liquor and tobacco, were promptly swept away, but the protected interests successfully resisted the reduction of protective duties, thus retaining what had been granted during the war both as compensation for internal taxes and as protection. The demand for tax reduction and tariff reform was met in 1870 by a lowering of rates on revenue articles like tea, coffee, sugar and spices, but an actual raising of certain protective duties, including those on steel rails and nickel. Two years later it became necessary to do something more to reduce revenue. Fearing worse things, the protectionists consented to a horizontal 10% reduction of all duties, on condition of the entire repeal of the non-protective duties on tea and coffee. When more revenue was needed in 1875, the 10% was easily and quietly restored. On the other hand, the high war rates on wool and woollens had been in 1867 raised yet higher, at the instance of certain woollen manufacturers and sheep breeders represented in the Syracuse convention; and the elaborate scheme of classified duties on wool, together with compound specific and *ad valorem* compensating and protective duties on woollens, introduced in the Morrill act, had been further developed. Similarly, the Lake Superior copper producers succeeded in 1869 in getting Congress to raise the duties on copper ore and ingot copper. By this means a combination of copper producers for a decade obtained extra prices equal to a good part of the duty. In 1870 the 45% duty on steel rails was changed to a slightly higher specific duty of $28 a ton. Rail costs fell rapidly, and by 1877 this amounted to almost 100%. The small number of American companies owning the Bessemer patent made enormous profits and expanded their business rapidly. At the request of interested producers, though with less striking results, there was a similar raising of duties on marble and nickel.

No general revision of duties occurred until 1883, when a redundant revenue compelled a reconsideration of the entire situation. A tariff commission was appointed, made up of protectionists. Its recommendations looked, on the whole, towards reduction, but little attention was paid to them. The protectionist forces in control of Congress managed, by skilful parliamentary management, to get rates raised on goods which continued to be imported despite the existing protective duties—articles such as fine woollen cloths and dress goods, cotton hosiery, laces and embroideries, iron ore and various special manufactures of steel—while duties were lowered chiefly in cases where the new rates were no less prohibitory than the old, such as cheap cottons, steel rails and copper. The act made no fundamental change in the protective system. Tariff discussion continued, and President Cleveland's annual message to Congress in Dec. 1887, urging general tariff reduction, particularly on raw materials, made protection the outstanding issue of the presidential campaign of 1888. The Republicans were successful, and they proceeded accordingly to revise the tariff in order to make it more highly protective. By the McKinley act (1890) the duties on wool and woollens were raised, as were also those on such cottons as continued to be imported, particularly knit goods. Linens went up sharply, and velvets and plushes of all sorts, of which imports were heavy, were charged high rates in the effort to establish a new industry. With the same purpose, tin-plate, with which the United States had been supplied almost entirely by importation, was charged $2\frac{2}{10}$ cents a pound, but with the proviso that it should be admitted duty free after 1896 unless domestic production should equal $\frac{1}{3}$ of imports in some one year between 1890 and 1896. The existing duty of two cents a pound on sugar, which was practically a revenue duty, since only a tenth of the supply was produced at home, was repealed. and the domestic producer was given a two-cent bounty instead, the two measures together taking something like 60 millions a year out of the Treasury. The whole act was a bold attempt to extend the protective system distinctly farther.

In the two succeeding political campaigns the Republicans were overwhelmingly defeated, and the Democrats returned to power pledged to tariff reduction. Party quarrels over the silver question, however, together with the narrowness of the party majority in the Senate and the determination of certain Democratic senators to maintain protection for particular interests, resulted in the emasculation of the tariff measure passed by the House, and the Wilson act of 1894 was allowed to become law without the president's signature. Even so, it constituted a break in the series of increasingly protective measures enacted since the Civil War. First, and most important, wool was made free, and the complicated duties on woollens were replaced by simple *ad valorem* duties, which, however, afforded the manufacturers a protection equal to the full amount that they had nominally enjoyed under the McKinley act. Rates on the finer cottons were lowered somewhat. Iron and steel duties were lowered, though not in any significant manner, and the rate on tin-plate was cut in two. Coal and iron ore, as raw materials, were made free by the House, but the Senate restored both to the dutiable list, though at reduced rates. The great battle was waged over sugar; the outcome was a duty of 40% *ad valorem* on raw sugar, and of 40% plus one-eighth of a cent a pound, plus an extra tenth of a cent a pound on sugar coming from any country that gave an export bounty, on refined sugar. This result was commonly regarded as a victory for the "sugar trust" and a violation of party pledges. The measure as a whole was a great disappointment to the tariff reformers. It went into effect, moreover, in the early stages of a period of business depression.

The money question carried the Republicans back into power in 1897, but political conditions made monetary legislation impossible, and President McKinley called Congress in extra session for the sole purpose of tariff revision. A new bill was promptly reported, and the Dingley act was passed without delay, restoring essentially the system of 1890. The wool and woollens duties of that year were re-established, with some changes, mostly upward. Specific duties, even higher than the previous high *ad valorem* ones, were laid on silks, and linens were treated likewise. The farmer got a duty on flax, and the ranchman, for the first time in 25 years, a tax on hides. As the iron and steel industry was largely beyond reach of foreign competition, rates were left in good part where they had been put in 1894, but certain specialties, like razors and cutlery, which continued to be imported, were raised by changes in classification, while tin-plate, the manufacture of which in the United States had been greatly aided by the relative cheapening of American steel sheets in the years immediately preceding, was given rates little in advance of those of 1894. Rates on raw sugar mere pushed above those of the Wilson act, thus at once increasing revenue and giving added protection to the beet-growing industry, and the refiners kept the $\frac{1}{8}$ cent differential of 1894. The Dingley act, it will thus be seen, gave up no part of the protective structure of 1890, and at a number of points extended it beyond its previous limits.

The rapid growth after 1898 of industrial combinations, popularly supposed to be special beneficiaries of the tariff, and the rise in the cost of living, led in time to increasing criticism of the protective system, and aided, along with the restiveness of the Middle-West farmers and the growth of manufactured exports, in putting the protectionists more or less on the defensive. The Republican Party, accordingly, in the campaign of 1908 enunciated the so called "true principle" of protection, that duties should equal the difference between cost of production at home and abroad, plus a reasonable profit to American industries. Theoretically and practically impossible as the principle is, it yet indicated the line of defense to be adopted in the tariff revision promised by Taft as a presidential candidate. The Payne-Aldrich act of 1909 was in fact written along the same lines as its predecessors, with little more than lip-service to the "true principle." The House committee proposed to admit coal, lumber, iron ore and hides free. Hides were freed in fact, bringing some reductions in leather and shoes; the other materials continued to pay duties, though at reduced rates. As usual, practically important upward changes were made in the textile schedules, as in the rates on mercerized cotton, cheap hosiery and silks. The iron and steel duties, most of which had long since ceased to have practical significance, were generally reduced; but razors were given another upward turn, as were also pliers, cheap cotton gloves, asbestos fabrics, and other particular articles whose claims were effectively presented by their producers to the legislators. Figs, prunes and lemons were protected. The act brought no substantial modification of the protective system, but the whole tone of its supporters indicated inability or unwillingness to push much farther the aggressive protectionist policy of the '90s.

The back-handed reciprocity provisions of the acts of 1890 and 1897, authorizing the president by proclamation to impose duties on certain goods otherwise free, if coming from countries that discriminated against products of the United States, were omitted from the Act of 1909. Instead, the rates of 1909 were declared the minimum tariff and those rates plus 25% (of the value of the goods) the maximum. After March 31, 1910, the maximum rates were to go into effect automatically, except in the case of those countries where the president had satisfied himself that "no undue discrimination" was exercised against the United States. By strenuous exertions the administration managed to avoid the imposition of the maximum rates in any case, though tariff wars with France, Germany, and especially Canada, were narrowly averted. The president also construed a provision of the maximum and minimum clause as authorizing him to appoint a tariff board, which proceeded to make studies on the basis of the "true principle," the moderate protectionists believing that its findings might serve as a second line of defense against the reduction of genuinely protective duties. The same moderate group, under the leadership of President Taft, were eager to do something for the export manufacturers, whose eagerness for foreign markets had been recognized in the Act of 1909 only in the ill-judged maximum and minimum provisions. A measure was accordingly driven through Congress, against the bitter opposition of the extreme protectionists, approving a treaty for a moderate measure of reciprocity with Canada, and freeing wood-pulp irrespective of Canadian action. To the disappointment of the moderates, Canada rejected the treaty.

The year 1913 found the Democrats in control of the presidency and of both branches of Congress. President Wilson promptly called Congress in special session, and a new tariff measure was enacted which was widely hailed as marking the beginning of a new era in American tariff policy. Announcing the principle of a "competitive tariff," and declaring their intention to injure no "legitimate industry," the party in power yet proceeded to a downward revision looking to definitely moderate protection. Wool was admitted free; and woollens after Jan. 1, 1914, were to pay a straight ad valorenz rate of 35%. Sugar, the duty on which, with the growth of the beet industry, had become a protective one, was to be free after May 1, 1916, by which time it was thought that the newly enacted income tax would be in running order and would be yielding income effectively. Cottons were sharply reduced; though most of the reductions were nominal the ne rates meant the probability of increased imports of the finer goods. Silks were cut somewhat, though the general rate was still 45%. Coal and lumber were freed, and leather and boots and shoes followed hides to the free list. Iron ore and crude iron and steel products likewise were made free, and rates were cut to a maximum of 20% on the advanced products. To meet the farmers' wishes, agricultural implements, by a harmless gesture, were carried to the free list; but at the same time wheat, flour, cattle and meats were freed in response to the demand for a lowered cost of living, thus introducing the possibility of a less restricted border trade. The "jokers," special rates imposed at the behest of particular favoured producers, which had become so conspicuous and unpleasant a feature of protective acts, for the greater part disappeared. The act repealed the maximum and minimum provisions of 1909, and in 1916 a tariff commission was established. While many of the reductions of the Underwood act were politically rather than economically important, it represented a genuine though cautious attempt at a wider freedom of trade.

After the outbreak of the World War, for half a decade American industries, despite reduced duties, had no European competition whatever. Various of the so-called "war babies," notably the chemical industry, grew enormously to meet immediate needs. With the return of peace, some of them faced sharp foreign competition. The spectacular fall of prices in 1920 plunged agriculture into distress, and the farmers turned to protection as a supposed remedy. When the Republicans returned to power in 1921, they promptly laid high duties (quite incapable of raising prices under the circumstances) on various farm products that had been freed in 1913, notably wheat, corn and meat, as also wool and sugar. This "emergency" measure was followed by the Fordney-McCumber tariff of 1922, following the lines of the Act of 1909, but surpassing it in the application of protection. Agricultural rates were higher than in 1909. Generally without economic significance, they did in fact mean the probability of higher prices for such products as California fruits, wheat on occasion, and notably sugar. Wool was given increased protection, and the elaborate system of compensating and protective duties on woollen manufacture was restored. Textiles generally fared about as in 1897 and 1909. Iron alloys and specialties subject to foreign competition, like cutlery and firearms, were raised above the rates of 1909, as were china ware, jewellery, toys and laces, the last-named paying 90% ad *valorem.* Coal-tar products, dye-stuffs and chemicals, which had sought absolute prohibition, were granted extremely high rates.

The Act authorized the President, after investigation by the tariff commission, to raise or lower rates (within the limit of 50% of the prescribed duties) as might be necessary to equalize costs in the principal competing country. Under this provision the president raised rates in a number of cases, but lowered them in no important instance.

The farmers failed to share the prosperity of the twenties, and early in his administration President Hoover called Congress in extraordinary session to revise the tariff for their benefit. Congressional action promptly took the form of a general upward revision of duties, giving rise to a fierce legislative struggle. Export manufacturers urged moderation, financial experts pointed out the necessity of increasing imports in view of the creditor position of the United States, protests against threatened injuries came from forty foreign countries, and more than a thousand economists signed a memorial advocating the defeat or veto of the measure. Nevertheless it was enacted in 1930, after a notorious process of log-rolling. According to the calculations of the tariff commission, the Act raised the average rates in every schedule, the increase being greatest on agricultural products. Sugar, cattle, dairy products, grains, lemons and other California products, wool, woollen and silk goods, manganese and tungsten bearing ores, and pig iron all went up. Lumber, brick, cement, hides, sole leather, and boots and shoes, all of which had been free, were subjected to duties.

There were increases on many small manufactured products, like watch and clock movements, cheap toys and matches, unimportant to the United States, but highly important to certain foreign exporting countries.

The flexible tariff provision was retained. The raising of American duties at a time when international trade was already declining caused sharp resentment abroad, and was promptly followed by higher tariffs in many countries. From 1929 to 1933 the foreign trade of the world, according to League of Nations figures, fell by 25 per cent in quantity and 65 per cent in value.

In 1934 a reciprocity act was passed authorizing the President for three years to make trade agreements with other countries; this act was later extended to 1940. Under it 19 nations made reciprocal trade agreements with the United States up to Jan. 1, 1939.

PROTECTIVE COLOURATION: *see* COLOURS OF ANIMALS, MIMICRY.

PROTECTORATE, in international law, now a common term to describe the relation between two States, one of which exercises control, great or small, direct or indirect, over the other. It is significant of the rare use of the term until recent times that the word does not occur in Sir G. C. Lewis's book on *The Government of Dependencies.* Yet the relation is very ancient. There have always been States which dominated their neighbours, but which did not think fit to annex them. Engelhardt *(Les Protectorats anciens et modernes)* and other writers on the subject have collected a large number of instances in antiquity in which a true protectorate existed, even though the name was not used. Thus the hegemony of Athens, as it existed about *467* B.C., was a form of protectorate; though the subject States were termed allies, the so-called "allies" in all important legal matters had to resort to Athens (Meyer, *Geschichte des Alterthums,* vol. iii. s. 274).

In dealing with dependent nations Rome used terms which veiled subjection (Gairal, *Les Protectorats internationaux,* p. 26). Thus the relationship of subject or dependent cities to the dominant power was described as that of *clientes* to the *patronus* (Marquardt, *Romische Staatsverwaltung,* 2nd ed., vol. i. p. 80). Such cities might also be described as *civitates foederatae* or *civitates liberae.* Another expression of the same fact was that certain communities had come under the power of the Roman people; *in deditionem* or *in fidem populi romani venire* (Marquardt, *Romische Staatsverwaltung,* i. *73,* 81). The kingdoms of Numidia, Macedonia, Syria and Pergamum were examples of protected States, their rulers being termed *inservientes.* The Romans drew a distinction between *foedera aequa* and *foedera iniqua.* The latter created a form of protectorate. But the protected State remained free.

In mediaeval times this relation existed, and the term "protection" was in use. But the relation of subordination of one State to another was generally expressed in terms of feudal law. One State was deemed the vassal of another; the ruler of one did homage to the ruler of another. In his book *De la République* Bodin treats of *ceux qui sont en protection* (I. *c. 7),* or, as the Latin text has it, *de patrocinio et clientela.* In Bodin's view such States retain their sovereignty (I. c. 8). Discussing the question whether a prince who becomes a *cliens* of another loses his *majestas,* he concludes that, unlike the true vassal, the *cliens* is not deprived of sovereignty. Elsewhere he remarks, "le mot de protection est special et n'emporte aucune subjection de celuy qui est en protection." He distinguishes the relation of *seigneur* and *vassal* from that of *protecteur* and *adherent* (p. 549, ed. 1580). At times letters of protection were granted by a prince to a weak State, as *e.g.,* by Louis XIII. in 1641 to the prince of Monaco (Gairal, p. 81).

Reverting to the distinction in Roman law, Grotius and Pufendorf, with many others, treat protection as an instance of unequal treaties; that is, "when either the promises are unequal, or when either of the parties is obliged to harder conditions" *(De jure belli et pacis, I.* c. 13. 21; *De jure naturae, 8.* c. 9).

Definitions.—"The one common element in protectorates is the prohibition of all foreign relations except those permitted by the protecting State. What the idea of a protectorate excludes, and the idea of annexation, on the other hand, would include, is that absolute ownership which was signified by the word *dominium* in Roman law, and which, though not quite satisfactorily, is sometimes described as 'territorial sovereignty.' The protected country remains, in regard to the protecting State, a foreign country; and this being so, the inhabitants of the protectorate, whether native-born or immigrant settlers, do not by virtue of the relationship between the protecting and the protected State become subjects of the protecting State" (Lord Justice Kennedy, *Rex* v. *Crewe,* 1910, 2 K.B. *576).*

The term is used very loosely. Often it designates a relation which is deemed politic to leave indefinite: a State desires to obtain the reality of conquest without the responsibilities attaching thereto. Protectorate may mean no more than what it says: "One State agrees to protect or guarantee the safety of another." The term is also employed to describe any relation of a political superior to an inferior State, It is also used as the equivalent of suzerainty. As appears from the article SUZERAINTY, the terms are distinguishable. But both imply a desire to carry out changes without friction and not to break up ancient forms; both proceed on the plan of securing to the stronger State the substance of power while allowing the weaker State a semblance of its old constitution.

Certain protectorates originate in treaties; others have been imposed by force. Some are accompanied by occupation, in which case it is difficult to distinguish them from annexation. Thus the treaty of May 1881, art. 2, between France and Tunis, provides for the occupation of strategical points by the protecting State (A. Devaulx, *Les Protectorats de la France,* p. 21).

Strictly speaking, a protectorate cannot exist over a domain uninhabited or ruled by no organized State; in such cases the elements of the true protectorates are wanting. But the distinction is not adhered to.

Indian Protectorates.—It has been the policy of the British Government in India to establish on the frontiers, as elsewhere, protectorates. The political advantages of the system are pointed out in Sir A. Lyall's *Rise and Expansion of the British Dominion in India.* It is a system "whereby the great conquering or commercial peoples masked, so to speak, their irresistible advance"; it was much practised by the Romans in Africa and Asia; it has been chiefly applied in modern times in India (p. 326). The Indian States are sometimes described as "Feudatory States," sometimes "Independent and Protected States" (Twiss), sometimes "Mediatized States" (Chesney), sometimes "Half-Sovereign," sometimes as in a position of "subordinate alliance" (Lord Salisbury, *Parliamentary Papers,* 1897 [c. 8700]. s. 27). The Interpretation Act 1889 refers to the Indian native princes as under the "suzerainty" of the British Crown These States are really *sui generis,* and their precise position can be understood only by a private examination of the treaties affecting them. *(See* Ilbert, *Government of India,* and the article INDIAN LAW.)

There are two principal classes of protectorates; the first being those exercised generally by treaty over civilized countries. Of the first, Andorra, protected by Spain and France as successors of the counts of Foix, is an example *(see* ANDORRA). The second class of protectorates consists of those exercised by one civilized State over an uncivilized people, sometimes called a "Colonial Protectorate" or "pseudo-protectorate," and usually the preparatory step to annexation. These have become common, especially in Africa, since 1878. The second class may be subdivided into two groups: *(a)* protectorates exercised over countries with organized Governments and under recognized sovereigns, such as the Malay States; and *(b)* those exercised over countries possessing no stable or definite Governments and rulers. The territories of chartered companies, when not within the dominion of the protecting State, may also for some purposes be regarded as protectorates. For details, the specific treaties must be consulted.

Protectorates and International Law.—The legal position of protectorates is still somewhat undetermined; there is an old view and also a new view of their nature. The relation may be one of international law, two States having entered into obligations by treaty. Or the relation may be one of public law; one of two States has become subordinate to, and incorporated with, the other. The general rule is that the protected State does not cease to be a sovereign State, if such was its previous status Its head is still entitled to the immunities and dignity of a sovereign ruler (see *Development Co* v *Kelantan [Government] and A. G.,* 1924, *A* C. *797)* Further, the establishment of a protectorate does not necessarily rescind treaties made between the protected State and other States, at all events when it is not in reality conquest or cession, or when any modification would be to the injury of third parties (*Parl. Papers,* "Madagascar," 1897 [c. 8700]; Trione, 187). Nor does the new relation make any change as to the nationality of the subjects of the two States, though in some countries facilities are afforded to the subjects of the *Unterstaat* to transfer their allegiance; and they owe a certain ill-defined degree of obedience to the protecting State. Nor, speaking generally, does the territory of the protected State become part of the territory of the *Oberstaat;* in this respect is it unlike a colony, which may be regarded as an extension or outlying province of the country. At the same time, the question whether a particular protectorate forms part of the "dominion" or "territory" of the Crown for any purposes or within the meaning of any statute cannot be regarded as wholly free from doubt; its terms and intention must be examined. *(See* Hall, *International Law,* 8th ed., 150; Heilborn, *Das völkerrechtliche Protectorat* [1891], 535; Tupper, *Indian Protectorates,* 336; Laband, *Das Staatsrecht des deutschen Reiches* [1876–82], 2, s. 70; *Sub Luza II.* v. *Miller and Swaziland Corporation,* 1926, D.C. 518).

The older view of the position of a protectorate according to international law is contained in the decision of Dr. Lushington in the case of the "Leucade" (8 S.T., N.S., 432), to the effect that, the declaration of war by Great Britain against Russia notwithstanding, the Ionian islands, which were then under the protectorate of Great Britain, remained neutral. The king of Great Britain had the right of declaring peace and war. "Such a right is inseparable from protection." But the Ionian States did not become necessarily enemies of the State with which Great Britain was at war. According to one view, the protected State is implicated in the wars to which the protecting State is a party only when the latter has acquired a right of military occupation over the territory of the former. "Cette solution a été reconnue par la France en 1870, à propos de la guerre contre l'Allemagne pour les iles Taiti alors soumises à notre protectorat; elle s'imposerait pour la Tunisie, l'Annam et Tonkin, et pour le Cambodge, oh les traités nous conférent le droit d'occupation militaire" (M. Despagnet). In the event of hostilities between the protecting and protected States, such hostilities would be regarded not as of the nature of an insurrection, but as a regular war (Trione, 149).

By the General Act of the Berlin Conference it was agreed that the acquisition of a protectorate should be notified to the signatories to the agreement (art. 34), and it has been the practice to give such notice.

Many writers adhere to the doctrine that there is no impairment of sovereignty of the weaker State by the establishment of a protectorate. They also allege that it is *res inter alios acta,* an arrangement which concerns only parties to it. But the trend of recent policy and purport of much recent legislation are against this view. The probability is that in such cases Governments and courts applying international law would probably be guided not by technical facts—such, to take the 'case of British possessions, as the fact that an order in council permitted appeals to the Judicial Committee—but would look to the facts of the case. "Any State which undertakes to protect another assumes towards the rest of the world responsibility for its good behaviour—the more complete protection the more extensive the responsibility—and this responsibility involves a duty to interfere if need be" (Coolidge, *United States as a World Power,* p. 167; and to the same effect Liszt, *Volkerrecht,* p. 31; and Zorn, *Volkerrecht,* p. 45). The tendency is for protecting States to assert jurisdiction over foreigners within the territories of the protected States (Westlake, 187; Jenkyns, p. 176; Ilbert, 3rd ed., ch. 6). Hall remarks (*International Law,* 8th ed., p. 150 n.) that "all the States represented at the Berlin Conference of 1884–85, with the exception of Great Britain, maintained that the normal jurisdiction of a protectorate includes the right of administering justice over the subjects of other civilized States." The General Act contemplated measures which are scarcely compatible with the exemption of European traders and adventurers from the local civilized jurisdiction. He points out that Great Britain—which until lately took the view that a protected State possesses only delegated powers, and that an Eastern State cannot grant jurisdiction over persons who are neither its own subjects nor subjects of the country to which the powers are delegated—had by the Pacific order in council of 1893 and the South African orders in council of 1891–94 asserted jurisdiction over natives and foreign subjects. "The Orders show a gradual increase of the assumption of internal sovereignty" (Jenkyns, 193). The fact is that in the case of protectorates over uncivilized or semi-civilized countries a development is inevitable: control quickly hardens into conquest, and international law more and more takes note of this fact. *(See* also MANDATE, SOVEREIGNTY, SPHERES OF INFLUENCE, STATE.)

PROTEINS are highly complex substances found in all living cells, in blood and in materials elab'orated for the development of the young animal or plant, such as milk, eggs and seeds. The word is derived from the Greek πρῶτος, meaning first, because proteins are apparently of first importance in respect of the phenomena which we call life, which can only exist in association with a material called protoplasm, which consists very largely of proteins. The composition of proteins varies somewhat. They all contain carbon, hydrogen, oxygen and nitrogen; most of them contain sulphur, and some contain phosphorus. The average composition is, C 51%, O 25%, N 16%, H 7%, S 0·4%, P 0·4%. They are formed by the union of a certain number of substances called amino-acids, of which about 20 have been discovered.

Amino-acids.—The living cells of the plant are able to form the amino-acids from relatively simple compounds, such as nitrates or ammonium salts, obtained from the soil. These amino-acids are then built up into the characteristic proteins of the particular plant. Animal cells are unable to form amino-acids from simple inorganic substances; the amino-acids must consequently be supplied in the food, in the form of plant proteins in the case of herbivorous animals, and animal proteins in the case of the carnivora. By the processes of digestion these food proteins are broken down into their constituent amino-acids, which are absorbed into the blood and are then available for building up the proteins of the tissues. It is probable that certain of the amino-acids can be formed in the body from other amino-acids, but on the other hand some essential amino-acids cannot be formed thus, *i.e.,* they must pre-exist in the protein of the food. The essential amino-acids are tryptophane, lysine, histidine, cystine, and possibly tyrosine and arginine. It follows that the nature of the amino-acids of which a protein is composed determines, to a certain extent, its value as a foodstuff for animals. Protein is disintegrated into its constituent amino-acids by boiling with dilute mineral acid, which converts tryptophane into a black substance called humin. Some proteins can be broken down by the action of certain digestive ferments, notably trypsin.

The amino-acids isolated by breaking protein down into its constituents are substances which contain both an acid (carboxylic) group and a basic (amino-) group. They can be divided into classes depending on the number of these groups, as follows:—(a) neutral amino-acids, containing one acid and one amino-group, *e.g.,* glycine, alanine, leucine, tyrosine and cystine, (b) acid amino-acids, containing two acid and one amino-group, *e.g.,* aspartic and glutaminic acids; (c) basic amino-acids, containing one acid and two amino-groups, *e.g.,* arginine and lysine; (d) heterocyclic compounds, in which a ring compound of carbon and nitrogen is united to an amino-acid group, the two most important members being histidine and tryptophane. The amino-acids are united to one another by a condensation (or subtraction of the elements of water) between the carboxylic group of one compound and the amino-group of its neighbour:

$$\underset{\text{Alanine}}{H_2N{\cdot}CH(CH_3)\,COOH} + \underset{\text{Glycine}}{HHN\,CH_2{\cdot}COOH} \longrightarrow \underset{\text{Alanyl-glycine.}}{H_2N{\cdot}CH(CH_3){\cdot}CO{\cdot}NH{\cdot}CH_2\,COOH}$$

The compound formed by such an union (peptide linkage) is called a di-peptide.

Very long chains of amino-acids have been formed synthetically, and the resulting compounds, called polypeptides, closely resemble the proteins in many ways. These *peptides* are split up into their constituent amino-acids by prolonged boiling with dilute mineral acids, the elements of water being added. This splitting or hydrolysis is also effected by two of the digestive enzymes found in the body, viz., trypsin of the pancreatic juice and erepsin of the intestinal juice. It is almost certain that there is at least one other type of union between the amino-acids, for pepsin, the enzyme of the gastric juice which digests proteins, is unable to split the peptide linkage, yet can break the highly complex food proteins into relatively simple compounds.

Classification of Proteins.—The system of classification adopted by the American Society of Biochemists is in general use and is closely followed in Great Britain; where the British Physiological Society uses a different name this is indicated by (B). The three main groups are those of the simple, conjugated and derived proteins, as follows:—

I. Simple Proteins: naturally occurring proteins formed from amino-acids only.

Albumins. Coagulable by heat, soluble in water and dilute salt solutions; *e.g.,* serum albumin, egg albumin and lactalbumin.

Globulins. Coagulable by heat, soluble in dilute salt solutions and dilute solutions of acids and alkalis. Generally insoluble in water, but a few ("pseudo-globulins") are soluble in water; *e.g.,* serum globulin of the blood and myosin, the chief protein of meat.

Glutelins. Found in cereals. Heat coagulable, insoluble in neutral solvents, but soluble in dilute acids and alkalis.

Prolamines (Gliadins [B]). Also found in cereals, but distinguished from the glutelins by their solubility in 75% alcohol; *e.g.,* zein from Indian corn (*Zea mais*), and gliadin from wheat.

Albuminoids (Scleroproteins [B]). Found in the skeletal and connective tissues of animals. They are characterized by their insolubility in most reagents; *e.g.,* keratin of hoofs and hair, elastin of yellow elastic tissue, collagen (the anhydride of gelatin) from tendons and white connective tissue.

Protamines. Basic proteins which are formed from a few amino-acids only and these mainly the basic amino-acids. They are found in the heads of ripe spermatozoa and in ova.

Histones. Similar to the protamines, but less rich in the basic amino-acids. They are not so basic as the protamines. They are present in unripe spermatozoa, in the red blood corpuscles and in the lymphoid tissues of the body.

II. Conjugated Proteins: proteins joined to a non-protein or prosthetic group.

Chromo-proteins. The prosthetic group is coloured, *e.g.,* haemoglobins of vertebrate blood, and haemocyanin of invertebrate blood, both of which are connected with respiration.

Glycoproteins (Glucoproteins [B]). The prosthetic group contains a carbohydrate radical; *e.g.,* mucin and mucoids.

Nucleoproteins. The prosthetic group is nucleic acid, which contains phosphorus, purine bases, pyrimidine bases and a sugar group. They are widely distributed in animal and vegetable cells, especially in nuclei.

Phosphoproteins. The prosthetic group is phosphoric acid. They are distinguished from the nucleoproteins in that they do not contain purine or pyrimidine bases; *e.g.,* casein of milk and vitellin of egg-yolk.

III. Derived Proteins: these are the decomposition products of any of the above, produced by boiling in water or by hydrolysis with dilute acids, alkalis or by the action of enzymes; the artificially synthesized polypeptides are also included.

Metaproteins. Insoluble in water or dilute salt solutions. Soluble in dilute acids or alkalis. Coagulated by heat if they are in suspension.

Proteoses. Soluble in water, not coagulated by heat. Precipitated by saturation with ammonium sulphate.

Peptones. Similar to the proteoses, but not precipitated by saturation with ammonium sulphate. They are relatively simple proteins and are much more diffusible.

Peptides. Simple peptones, generally of known constitution.

Reactions and Properties.—In the foregoing scheme of classification physical properties are mainly used for the characterization of the proteins. Certain colour reactions can be obtained arising from the chemical structure of the protein molecule and due either to the presence of certain amino-groupings in the protein molecule or to the special linkages formed by their union with one another. The more important of these colour reactions are, (1) the xanthoproteic, indicating such aromatic groups as tyrosine and tryptophane; (2) the glyoxylic, due to the presence of tryptophane; (3) Millon's, due to tyrosine; (4) the sulphur test, due to cystine; and (5) Molisch's test for a carbohydrate complex. It follows that a protein like gelatin, which does not contain either tryptophane, tyrosine or cystine, fails to give the glyoxylic, Millon's or sulphur tests. Zein does not contain tryptophane, but does contain tyrosine; hence it gives Millon's test but not the glyoxylic reaction. The biuret colour reaction, however, is of a different character, in that it is not given by any amino-acid but is given by all proteins, owing to the particular way in which the amino-acids are linked together.

The proteins are precipitated by certain complex acids called the alkaloidal reagents because they were first used for the precipitation of alkaloids (*q.v.*). The more important of these acids are tannic, picric, phosphotungstic, phosphomolybdic, metaphosphoric, sulphosalicylic, tri-iodo-hydriodic and ferrocyanic. These reagents only precipitate in acid solutions, the precipitates being soluble in alkalis. The peptones and peptides are less readily precipitated than the more complex proteins. The proteins are also precipitated in neutral or slightly alkaline solution by the salts of certain metals, especially those of copper, lead, mercury, iron and gold.

Of considerable importance in connection with the general physical properties of the proteins is the fact that the solutions are usually in the colloidal state (see COLLOIDS). The feature of this condition is that the material is suspended in the solvent (water, salt solution, etc.) in particles of a certain size. If they are larger than 0·0001 mm. (0·1μ) they can be retained by filter paper or porcelain and are visible with an ordinary high-power microscope, and constitute a "coarse suspension" or precipitate; if they are smaller than 1×10^{-6} mm. (1$\mu\mu$) they form a "molecular solution," and the substance will diffuse through parchment or collodion membranes. Between these limits we have the colloids, in which the particles are too large to pass through parchment membranes and too small to be removed by filter paper, or be seen with an ordinary microscope, but are large enough to interfere with the passage of light rays, being thus rendered "visible" by the ultramicroscope. The proteins, and particularly the complex natural proteins, exist in the colloidal state owing to the great size of the molecules. The length of the molecule of egg-albumin has been found to be 4·17$\mu\mu$, that of the molecule of serum albumin 4·41$\mu\mu$, whilst the molecules of serum globulin or of gelatin may be as large as 50–100$\mu\mu$.

The particles in suspension may in some cases exist in the form of single molecules, but a slight change in the conditions may cause these to coalesce to form larger clumps, even to the extent of providing visible aggregates, or a precipitate. This can sometimes be effected by altering the acidity or alkalinity of the fluid, sometimes by the addition of a small amount of a particular neutral salt. When the aggregates formed cannot be dispersed by reverting to the original conditions, the phenomenon is known as coagulation. The best known example is that of the coagulation of the albumins and globulins of the egg by boiling, an alteration ("denaturation") taking place in the native proteins. The altered protein is precipitated at a certain reaction, which is generally on the acid side of strict neutrality. At the coagulating temperature the particles of protein in the precipitate adhere together to form an irreversible coagulum. To produce this coagulation, a given temperature and reaction and the presence of certain inorganic substances are necessary. The first two conditions vary somewhat with different proteins and have been used for the characterization of some of the albumins and globulins.

The use of strong solutions of neutral salts as a method for the precipitation of certain proteins is of considerable importance. The chief salts employed are magnesium sulphate, sodium sulphate and particularly ammonium sulphate. When a solution is fully saturated with the last substance all proteins with the exception of the peptones and peptides are completely precipitated. The addition of one part of a saturated aqueous solution of ammonium sulphate to one part of a fluid is called "half-saturation" and is used for the separation of globulins from albumins. The methods for the complete removal of proteins from a solution depend on the nature of the proteins present. In the case of the albumins and globulins, heat coagulation at the correct reaction may sufhce. The most important precipitants are tungstic acid, metaphosphoric acid and colloidal iron, though tannic and mercuric and lead salts are sometimes employed.

Uses of Proteins. — The most important use of protein is that of a food-stuff for man and the domestic animals, since protein is the only form in which they can obtain a supply of the amino-acids that are essential for the building-up and maintenance of the protoplasmic tissues of the body. Some of the amino-acids are used for the formation in the tissues of certain derivatives (generally known as "internal secretions") without which it is impossible for the body as a whole to function properly. It will be seen therefore that the nature and balance of the various amino-acids in a particular protein will have a marked effect on what is known as the "biological value" of the protein as a food. Thus the chief protein of Indian corn is zein, which does not contain any tryptophane — one of the essential amino-acids — and consequently persons whose sole protein is that of Indian corn are apt to suffer from the disease known as Pellagra, which may be due to the deficiency of tryptophane.

Another function of protein in the diet is that of supplying energy by combustion in the body. The proteins also are concerned in promoting the oxidation of the carbohydrates and particularly of the fats in the body. Thus the inhabitants of very cold climates can withstand the low temperatures on a diet very rich in protein and fat, the high protein content enabling the fats to be oxidized more readily in the body. This action is known as the "specific dynamic action" of the proteins. The inhabitants of the tropics, on the other hand, subsist on a diet that contains a relatively small amount of protein, the energy requirements for the maintenance of body temperature being very low. It was at one time thought that the muscular energy of the body was obtained from the proteins alone, but it has been found that this is erroneous. Carbohydrates normally function in this way, but the requisite carbohydrates can he supplied from certain of the amino-acids in animals fed on a pure protein diet. Any excess of protein in the diet over the immediate needs of the body is usually oxidized in a few hours, the body being unable to store protein as it can fats or carbohydrates. But within certain limits it seems that if abundant protein is taken with regular muscular exercise, as in the training diet of some athletes, a small percentage of this protein can be stored for increase in the size of the protoplasmic masses of the individual muscle fibre. The utilization of proteins as food-stuffs is primarily dependent on their digestibility. Proteins like the keratins of hair and horn are not broken down into amino-acids by the enzymes of the alimentary canal and cannot serve as foods. The average amount of protein in the adequate diets of adult inhabitants of the temperate climes is about 100 grams per diem.

The industrial uses of proteins are dealt with in other articles (*see* GELATIN, GLUE, CASEIN, HAIR, WOOL, SILK, LEATHER, etc.). Other uses are in the manufacture of water-resisting adhesives, distempers, small articles, such as buttons, and in the special transparent preparation known as "galalyte" which is used for artificial amber.

(S. W. C.)

PROTESILAUS, a Thessalian hero, son of Iphiclus, and husband of Laodameia. He was the first to spring ashore on Trojan soil, although he knew it meant instant death. His wife prayed that he might be permitted to return to earth for three hours. Her prayer was granted, and on the expiration of the time allotted she returned with him to the nether world. Hyginus gives (*Fab.*, 104) what seems to be a rationalistic version of this. It is curious that no surviving Greek author tells the story. In another account (Conon, *Narrationes,* 13) Protesilaus survived the fall of Troy and built the city of Scione. His tomb and temple were near Eleus in the Thracian Chersonese.

Iliad, ii. 698; Ovid, *Heroides,* xiii.; Lucian, *Dial mort.* xxiii., 1; Philostratus, *Heroica,* iii.

PROTESTANT, the generic name for an adherent of those Churches which base their teaching on the principles of the Reformation. The name is derived from the formal *Protestatio* handed in by the evangelical states of the empire, including some of the more important princes and imperial cities, against the *recess* of the diet of Spires (1529), which decreed that the religious *status quo* was to be preserved, that no innovations were to be introduced in those states which had not hitherto made them, and that the mass was everywhere to be tolerated. The name Protestant seems to have been first applied to the protesting princes by their opponents, and it soon came to be used indiscriminately of all the adherents of the reformed religion. Its use appears to have spread more rapidly outside Germany than in Germany itself, one cause of its popularity being that it was negative and colourless, and could thus be applied by adherents of the "old religion" to those of the "new religion," without giving offence, on occasions when it was expedient to avoid abusive language.

As the designation of a Church, "Protestant" was unknown during the Reformation period and for a long while after. In Germany the Reformers called themselves usually *evangelici,* and avoided special designations for their communities, which they conceived only as part of the true Catholic Church. It was not until the period of the Thirty Years' War that the two main schools of the reformed or evangelical Churches marked their definitive separation: the Calvinists describing themselves as the "Reformed Church," the Lutherans as the "Lutheran Church." In France, in England, in Holland the evangelicals continued to describe their churches as *ecclesiae reformatae,* without the *arrière pensée* which in Germany had confined the designation "Reformed" to the followers of a particular church order and doctrine. As to the word "Protestant," it was never applied to the Church of England or to any other, save unofficially and in the wide sense above indicated, until the style "Protestant Episcopal Church" was assumed by the Anglican communion in the United States.

PROTESTANTENVEREIN is the name of a society in Germany the general object of which was to promote the union (*Verein*) and progress of the various established Protestant Churches of the country in harmony with the advance of culture and on the basis of Christianity. It was founded at Frankfort-on-the-Main in 1863 by a number of distinguished clergymen and laymen of liberal tendencies, representing the freer parties of the Lutheran and Reformed Churches of the various German states, amongst whom were the statesmen Bluntschli and Von Bennigsen and the professors R. Rothe, H. Ewald, D. Schenkel, A. Hilgenfeld and F. Hitzig. The more special objects of the association were, beside the promotion of mutual toleration and respect among adherents of different creeds and of all Christian works necessary for the moral strength and prosperity of the nation, the assertion of the right of the clergy, laity and both lay and clerical professors to search for and proclaim freely the truth in independence of the creeds and the letter of Scripture.

PROTESTANT EPISCOPAL CHURCH, in the United States of America is spiritually the direct descendant of the Church of England, and is a part of the Anglican Communion. From the Church of England the Protestant Episcopal Church inherits its faith, its liturgy and its spiritual traditions, though it is entirely independent in its own life and government. The preface of the American Prayer Book, officially set forth in 1789, affirms the substantial identity and continuity of the two Churches in the following words "This Church is far from intending to depart from the Church of England in any essential point of doctrine, discipline or worship; or further than local circumstances require.': The Protestant Episcopal Church is therefore in full fellowship with the Anglican Communion, while at the same time it is wholly free and independent in the ordering of its life and the fulfilment of its mission in the United States. It is significant that in the year 1642 members of the English Church meeting in the Colony of Maryland, and frequently other groups in that early period, described themselves as Protestant Catholics, and this designation, if rightly interpreted in the light of history, describes well the doctrinal position of the Protestant Episcopal Church, catholic and also free, apostolic and evangelical, orthodox and also modern in its spirit.

The first permanent establishment of the Church was at Jamestown, Va., in 1607, although services were held earlier in various parts of the country by the clergy who as chaplains accompanied groups and parties engaged in exploration. On the Pacific coast services were held by Francis Fletcher, chaplain of Drake's ship the "Pelican." Before the end of the 17th century the English Church had become the established church of Virginia and Maryland. In New York, Trinity parish received its charter from the British Crown in 1697, with the bishop of London, Henry Compton, as its first rector. A few years earlier, in 1686, the Church obtained a precarious foothold in Massachusetts; it was planted in Connecticut in 1706. The growth of the English Church in the colonial period was due in large part to the help of the Society for the Propagation of the Gospel in Foreign Parts, founded through the efforts of the Rev. Thomas Bray, a missionary in Maryland. From the foundation of the Venerable Society in 1701, until the Revolution, its missionaries were primarily responsible for the vitality of the English Church in America. Through all this period however, the Church had no bishop in the American colonies. It was under the jurisdiction of the bishop of London, who naturally could do little for this far distant field. Without bishops, the Episcopal Church was in an anomalous position. Those desiring to be ordained to the ministry were compelled to make the long and perilous voyage to England. The people could not be brought to confirmation. Efforts to secure the consecration of bishops by the mother church in England were strongly opposed by the Nonconformist churches in the colonies, especially in New England.

Revolutionary Period.—The Revolution was a time of severe trial for the Church of England in the colonies. Many of the clergy felt called upon to give up their parishes and return to England, though others, especially in the South, remained at their posts and gave their support to the American cause. Of the laity a large majority were on the side of the Revolution, and many of them were among its most active leaders. Two thirds of those whose names are signed to the Declaration of Independence were members of the Episcopal Church. William White, afterwards the first bishop of Pennsylvania, was chaplain of the Continental Congress. George Washington, himself a member of the Church, went, accompanied by both Houses of Congress, to St. Paul's chapel, still standing on Broadway and Vesey street, New York, for the religious service which completed the ceremonies of his inauguration as first president of the United States, and this service was conducted by Samuel Provoost, the first bishop of New York and rector of Trinity church.

At the close of the war the Church was so disrupted that to many its survival seemed doubtful. Steps were taken for its reorganization, but the process proved to be a protracted one, and continued far into the next century. It was recognized that the episcopate must now be secured without delay. The clergy of Connecticut met and elected Samuel Seabury to the office of bishop and requested him to proceed to England and seek episcopal consecration. Meeting with discouragement in England, Seabury turned to the Scottish Episcopal Church and was consecrated by the Scotch non-juror bishops, in Aberdeen, on Nov. 14, 1784, thus becoming the first bishop of the Church in America. The consecration of Bishop Seabury established a close bond between the Episcopal Churches in America and Scotland. This was further strengthened by a Concordat in accordance with Art. V. of which the Eucharistic Canon of the American Prayer Book is framed on the Scottish rather than the English model. More than two years later on Feb. 4, 1787, William White, of Pennsylvania, and Samuel Provoost, of New York, were consecrated bishops in Lambeth chapel, by the archbishops of Canterbury and York and two other English bishops. On Sept. 19, 1790, the Rev. James Madison, of Virginia, was also consecrated bishop in England.

At a Convention held in 1789, after much previous discussion, the Book of Common Prayer was set forth and the constitution and canons were adopted. The Church was organized for her work, but the conditions which she faced were full of difficulties. As a result of the revolutionary war there was much popular prejudice against any institution claiming connection with England, in the communities influenced by Puritanism there was strong opposition to the principles and teachings of the Episcopal Church, and there were divisions within her own household. At the Convention of 1811 only one of the six bishops attended, and there were few more clergy and laymen present than in 1789.

Period of New Vigour.—But at this time a new spirit was stirred in the Church largely by the devotion, zeal and spiritual power of three men, John Henry Hobart, Alexander Viets Griswold and Richard Channing Moore, consecrated bishops respectively of New York, the eastern diocese and Virginia. In Virginia, Bishop Moore's powerful preaching and strong personality roused the Church to new life. Bishop Griswold's diocese included an immense region comprising the collapsed diocese of Massachusetts (which had already had two bishops, Bass in 1797 and Parker in 1804), Maine, Rhode Island, New Hampshire and Vermont. His achievements were truly amazing; with only 16 clergy in all at the outset of his episcopate he had the satisfaction of ending it with a fivefold increase in the number both of parishes and communicants, and with the redivision of his cumbersome territory into five separate dioceses. Bishop Hobart's episcopate was even more far-reaching in its effects. His labours were prodigious and his power as a teacher was felt by all. He anticipated the main positions of the Oxford Movement in the Church of England and left his spiritual impress not only on the diocese of New York but on the whole Church, taking his place as one of the greatest bishops the Church in America has had. The interest of Hobart and Moore in theological education, and in the training of candidates for the ministry, resulted in the foundation of the General Theological seminary in New York in 1819 and of the Theological seminary in Virginia, in 1824.

The Church was now aroused to meet the new conditions and opportunities of its reconstituted life. The Domestic and Foreign Missionary Society, founded in 1821, gave fresh impetus to the work of Church extension. Philander Chase, the pioneer bishop of the West did his great work in Ohio and founded Kenyon college, obtaining from churchmen in England funds for this undertaking; Jackson Kemper went further into the North-west where his arduous labours prepared the way for future dioceses; James Harvey Otey did noble missionary work in Tennessee and the South-west. James Lloyd Breck, priest and missionary, started schools in Minnesota, at Faribault, and pushed on across the country, establishing new foundations as he went, until he reached the Pacific coast. During this period the Episcopal Church grew steadily from a proportion of one communicant to 400 of the population in 1830 to one communicant to 107 at the end of the century. With the growth and development of the country new dioceses and missionary districts were established. In 1853 Bishop Kip began his labours as first bishop of California; in 1854 bishops were consecrated for Oregon and Iowa; in 1859 Bishop Whipple was sent to Minnesota to take up his work among white people and Indians. Another outpost of this period was the Theological seminary at Nashotah, Wis., established by alumni of the General seminary in 1842, and to this day styled The Mission.

The spirit of the Church at this time was strikingly illustrated in the "Muhlenberg Memorial" of 1853. Its impassioned and moving appeal to the Church to weigh more earnestly its unique opportunity, to slough off sectarianism and realize the implications of a Catholic but non-papal Episcopacy, to view without disquiet the possibility of modifications in method and technique which might lead to a more adequate effectiveness, displays in rare degree both practical wisdom and prophetic vision. While this appeal led to some changes in current practice the essential challenge which it offered has not yet been fully faced. It was a challenge which might have brought forth new and great things, had not the struggle which was to issue in the Civil War precluded this.

Separate Administrations. — The breaking out of this great conflict compelled the separation in administration of the Northern and Southern dioceses, but it produced no permanent division in the Church. The dioceses in the South met together as "The Protestant Episcopal Church in the Confederate States," but when the general convention met in New York, in 1862, the Southern dioceses, although absent, were included as usual in the calling of the roll, and immediately upon the conclusion of the war, the two groups of dioceses came together without friction.

Since the period of the Civil War, the Church has made progress, its growth more than keeping pace with the increase in population. Its organization covers every part of the United States and its dependencies, and it carries on missionary work in other lands. It has bishops and organized missionary work in Alaska, Porto Rico, the Panama Canal Zone, the Hawaiian Islands, the Philippine Islands, Cuba, Mexico, Brazil, China, Japan, Liberia, Haiti and the Dominican Republic.

Among the educational institutions of the Church are Trinity college at Hartford, Conn.; the University of the South at Sewanee, Tenn.; Hobart college at Geneva, N.Y.; Kenyon college at Gambier, O.; St. Stephen's college at Annandale, N.Y.; and the American Church institute for negroes. The Theological schools, in addition to the General Theological seminary in New York, which is the official institution of the whole Church, and the Virginia seminary previously mentioned, are the Berkeley Divinity school at New Haven, Conn.; the Divinity school in Philadelphia; the Episcopal Theological school in Cambridge, Mass.; Nashotah house at Nashotah, Wis.; Seabury Divinity school at Faribault, Minn.; the Theological school at Sewanee, Tenn.; the Seabury–Western Theological seminary at Evanston, Ill.; the Church Divinity school of the Pacific, San Francisco, Calif.; the College of St. John the Evangelist, Greeley, Colo.; the Bishop Payne Divinity school at Petersburg, Va.; Bexley hall, Gambier, O.; the Du Bose Memorial Church Training school, Monteagle, Tenn.; and the De Lancey Divinity school at Buffalo, N.Y. The Church has also, especially in the East, many important schools for boys and girls.

Church Development. — The life of the Church finds expression in a great number of societies and organizations, such as the Women's Auxiliary to the National Council; the Brotherhood of St. Andrew; the Girls' Friendly Society; the Seamen's Church Institute of America; the Social Service Commissions; the Church clubs of the various dioceses; the Church Mission of Help, and the Church Congress in the United States. Among the religious orders are the Society of Mission Priests of St. John the Evangelist; the Order of the Holy Cross; St. Barnabas Brotherhood; the Community of St. Mary; the Sisterhood of St. John the Baptist; the Sisterhood of St Margaret; the All Saints Sisters of the Poor; the Sisterhood of the Holy Nativity; and others. The institutions for the training of deaconesses include the New York Training School for Deaconesses; the Church Training and Deaconess House of the Diocese of Pennsylvania; the Chicago Church Training school; and the School for Christian Service and Deaconess Training School of the Pacific at Berkeley, Calif.

The governing body of the Protestant Episcopal Church is the General Convention which meets every three years, and which consists of the House of Bishops and the House of Deputies, the two Houses sitting and deliberating separately. The House of Bishops has as its members all the bishops of the Church. The House of Deputies is composed of not more than four presbyters and four laymen elected by each diocese and not more than one presbyter and one layman elected by each missionary district. Either house may originate and propose legislation, and all acts of the Convention must be adopted and authenticated by both houses. In the House of Deputies the vote on any question may be taken by orders, the clerical and lay deputies voting separately and a concurrent vote of the two orders being required for the adoption of the resolution. The laity thus have their full share and responsibility in the legislative action of the Church. No alteration in the Book of Common Prayer may be made unless this is proposed at one meeting of the General Convention and adopted at the next succeeding triennial meeting. Each diocese holds its own annual Convention, presided over by the bishop, in which both clergy and laity have their part. The diocese adopts its own constitution and canons for the regulation of its internal affairs, with the provision that these must not conflict with the constitution and canons of the General Convention. A bishop is elected by the diocese, but the election must be confirmed by a majority of the bishops exercising jurisdiction within the United States, and by a majority of the standing committees of all the dioceses. Missionary bishops are elected by the House of Bishops, the choice being subject to confirmation by the House of Deputies if the General Convention is in session, and at other times by a majority of the standing committees of the several dioceses. As regards the ministry, the Episcopal Church, in common with the Anglican Communion, holds to the historic threefold order of bishops, priests and deacons. The official pronouncements on this subject are contained in the Preface to the Ordinal. The constitution of the Church (Art. viii.) provides that no person shall be consecrated bishop, or ordained priest or deacon, until he shall have made in writing, in presence of the ordaining bishop or bishops, the following declaration: "I do believe the Holy Scriptures of the Old and New Testaments to be the Word of God and to contain all things necessary to salvation; and I do solemnly engage to conform to the Doctrine, Discipline, and Worship of the Protestant Episcopal Church in the United States of America." And every person before being baptised and received into membership in the church is required to answer affirmatively the question "Dost thou believe all the articles of the Christian Faith as contained in the Apostles' Creed?" Neither the clergy nor the laity are required to subscribe to the Thirty Nine Articles.

Church Activities. — An important change in the organization of the Church was made in 1919 by the establishment of a national council, with the presiding bishop at its head, to act as the executive body of the General Convention between its sessions, and to have charge of the general missionary, social and educational work of the Church; with the provision that, for the future, the presiding bishop should be elected instead of succeeding to this office by seniority of consecration. The national council has given new impetus and effectiveness to the work of the Church and strengthened her corporate life. The revision and enrichment of the Book of Common Prayer, undertaken in 1913, has been given much consideration at each meeting of the General Convention since that time. The statistics reported at the last meeting of the Convention in 1925 included the following: dioceses and missionary districts, 104; communicants 1,193,321; clergy, 6,140; candidates for Holy Orders, 454; lay readers, 3,740; enrolled in Sunday Schools 498,814; total contributions for the year 1925, $41,746,055. It is the earnest and increasing desire both of clergy and people that the Protestant Episcopal Church in the United States should make the utmost of her opportunity to serve the cause of Christian reunion; and at the General Convention in 1910 a movement was initiated to bring about a world conference on faith and order. After 17 years of preparation and effort, the conference was held in 1927 at Lausanne, and was attended by representatives of all the major Churches of Christendom with the exception of the Roman Catholic Church.

PROTEUS or **OLM,** a blind, water-breathing, tailed amphibian, inhabiting the limestone caves to the east of the Adriatic. It is a small eel-like animal, with minute limbs, the anterior pair having three toes on each, the posterior two, a narrow head, with flat truncate snout, minute rudimentary eyes hidden under the skin which is pale flesh-coloured, with the short, plume-like external gills blood-red *(Proteus anguinus)*. *Proteus* forms with *Necturus* the family Proteidae. The second genus, which is widely distributed in eastern North America, is more generalized in structure, having better developed limbs, with four digits, and is adapted to live in the light. Its thyroid gland is very much reduced, but, unlike the axolotl (*q.v.*), it cannot be transformed into a terrestrial form by feeding with thyroid. Exposure to white light causes the skin to become black, even over the eyes; however, in red light, no blackening occurs, and the eyes grow large and functional.

In 1896 a Proteus-like Amphibian *(Typhlomolge rathbzini)* was unexpectedly discovered in Texas during the boring of an artesian well 188 ft. deep, when it was shot out with a number of remarkable and unknown crustaceans. This form agrees with *Proteus* in the absence of functional eyes, the presence of external gills, and the unpigmented skin. It differs in the short body and the long slender limbs with four to five digits. It is remarkable in having no thyroid gland at all. While *Proteus* has lungs in addition to gills, *Typhlomolge* lacks the lungs, and with them the trachea and larynx. Both the *Proteus* and *Typhlomolge* are permanent larval forms.

Another blind Urodele, *Typhlotriton spelaeus,* is known from caves in the Mississippi valley. It has neither gills nor lungs in the adult, and is found under rocks in or out of the water. It is not allied to *Proteus* but to *Amblystoma (see* AXOLOTL). The eyes are normal in the larva, but in the adult have undergone degeneration. It is not a persistent larva.

See H. Gadow, *Amphibia* (*Cambridge Natural History*).

PROTEUS, a Greek sea-daimon, shepherd of the flocks of the sea (seals, etc.) and a great prophet. According to Homer, his dwelling place was the island of Pharos, near the mouth of the Nile; in Virgil his home is the island of Carpathus, between Crete and Rhodes. He knew all things, past, present and future, but disliked telling what he knew. Those who wished to consult him had first to surprise and bind him during his noonday slumber in a cave by the sea, where he spent his time during the heat of the day surrounded by his seals. Even when caught he would try to escape by assuming all sorts of shapes, that of a lion, a serpent, a leopard, a boar, a tree, fire, water. But if his captor held him fast the god at last returned to his proper shape, gave the wished-for answer and plunged into the sea. He was subject to Poseidon.

In post-Homeric times the story (invented by Stesichorus?) ran that Proteus was the son of Poseidon and a king of Egypt, to whose court Helen was taken by Hermes after she had been carried off, Paris being accompanied to Troy by a phantom substituted for her. This is the story followed by Herodotus, who got it from Egyptian priests, and by Euripides in the *Helena*. From his power of assuming whatever shape he pleased, Proteus came to be regarded, especially by the Orphic mystics, as a symbol of the original matter from which the world was created.

See Homer, *Od.* iv; Virgil, *Georg.* iv; Stesichorus, p. 26 (44) ed. Bergk, with his notes; Euripides, *Helena;* Herodotus, ii, 112, 118.

PROTHERO, SIR GEORGE WALTER (1848–1922), British historian, was born in Wiltshire Oct. 14, 1848, being the eldest son of the Rev. G. Prothero. Canon of Westminster Abbey. Educated at Eton, he went from there to King's college, Cambridge, where he became a fellow. For a time a master at Eton, he soon returned to Cambridge as lecturer and tutor at King's college, where he was senior tutor from 1881. In 1884 he was appointed university lecturer in history; in 1894 he went to Edinburgh as professor of history; and in 1899 he succeeded his brother Rowland, afterwards Lord Ernle (*q.v.*) as editor of *The Qziarterly Review*. During World War I he was director of the historical section of the Foreign Office and in that capacity he attended the Peace conference in Paris. He was created K.B.E. in 1920 and died in London July 10, 1922.

Prothero's chief historical works are *The Life and Times of Simon de Montfort* and the collection of authorities entitled *Select Statutes and other Constitutional Documents Bearing on the Reigns of Elizabeth and James I.* He also wrote a *Memoir of Henry Bradshaw*, a *School History of Great Britain and Ireland* (to 1910) and *German Policy Before the War*. He edited Voltaire's *Louis Quatorze* and J. R. Seeley's *Growth of British Policy* as nell as the Cambridge "historical series," and he was one of the editors of *The Cambridge Modern History*.

PROTHESIS, in the liturgy of the Orthodox Eastern Church, the name given to the act of "setting forth" the oblation, *i.e.* the arranging of the bread on the paten, the signing of the cross (σφραγίζειν) on the bread with the sacred spear, the mixing of the chalice, and the veiling of the paten and chalice *(see* F. E. Brightman, *Liturgies Eastern and Western, 1896)*. (Gr. **πρόθεσις** a setting forth). The term is also used, architecturally, for the place in which this ceremony is enacted, a chamber on the north side of the central apse in a Greek church, with a small table. During the reign of Justin II (565–574) this chamber was located in an apse and another apse was added on the south side for the diaconicon (*q.v.*), so that from his time the Greek church was triapsal. In the churches in central Syria both prothesis and diaconia are generally rectangular, and the former, according to de Vogué, constitutes a chamber for the deposit of offerings by the faithful. Consequently it was sometimes placed on the south side, if when so placed it was more accessible to the pilgrims. There is always a much wider doorway to the prothesis than to the diaconicon, and there are cases where a side doorway from the central apse leads direct to the diaconicon, but never to the prothesis.

PROTIĆ, STOJAN (1857–1923), Yugoslav statesman, was born at Krusšvak Jan. 29, 1857, and at first entered the government service. He soon came into conflict with the repressive régime of King Milan and in 1882 became editor of *Samouprava* and a leader of the new Radical party. He was imprisoned for a press offence in 1883 and again in 1885. He held subordinate posts in the Radical cabinet of 1887. In 1899 an attempt on King Milan's life was used by the government to rid itself of its Radical rivals. Protić was sentenced to 20 years' hard labour, although, in fact, he had no connection with the crime. Pardoned nine months later, he became director of the National library. After the revolution of 1903 he represented the Radicals in the first provisional cabinet under King Peter and remained minister of the interior in most of the succeeding cabinets down to 1907. He was finance minister during the Bosnian crisis and again became minister of the interior during the period of the Balkan Wars and the European crisis of 1914. In 1914, when leaders of the secret "Black Hand" organization were implicated in the murder of Serajevo, this organization was actually at daggers drawn with the Serbian government owing to a quarrel with Protić.

Protić remained out of office during the period of coalition government from Dec. 1914 to June 1917, but continued to exercise great influence in the background. He was returned to office in 1917 and played an active part in the negotiations leading to the Corfu agreement between the Serbian government and the Yugoslav committee.

He showed more comprehension for the Croat and Slovene standpoint than his colleague Pašić, and when the conflict between Pašić and Trumbić in 1918 delayed the recognition of Yugoslavia by the Allies and created an awkward situation with Italy, Protić was appointed the first premier of the new Yugoslav state. He was keenly interested in the constitutional problem, and after his resignation in Aug. 1919 published his own draft project. Disagreeing with the exaggerated centralism of Pašić, he declined office in 1921 and drifted steadily away from his old colleague. Protić died in Belgrade in Nov. 1923.

His publications include *The Aspirations of Bulgaria* (1916) and *Le problème Albanais,* etc. (1913), issued under the pseudonym of "Balkanicus."

PROTISTA: *see* PROTOZOA.

PROTOACTINIUM, a radioactive element of atomic number 91 and estimated atomic weight 232. It is the "parent" of actinium, which it forms by loss of an a-particle. *(See* RADIOACTIVITY.)

PROTOCOL, in diplomacy, the name given to a variety of written instruments. The French word *protocole* is derived from the late Latin *protocollum,* from the Greek *πρῶτος* first, and *κολλᾶν* to glue, *i.e.,* originally the first sheet of a papyrus roll. The *protocollum* under the late Roman empire was a volume of leaves, bound together with glue, in which public acts were recorded, so as to guard against fraud or error on the part of those responsible for preparing them; and in later usage it came to be applied tu the original drafts of such acts. Thus, too. the work *prothocollare* was devised for the process of drawing up public acts in authentic form.

In diplomacy the name of "protocol" is given to the minutes (*procès-verbaux*) of the several sittings of a conference or congress; these, though signed by the plenipotentiaries present, have only the force of verbal engagements *(see* CONGRESS). It is also given to certain diplomatic instruments in which, without the form of a treaty or convention being adopted, are recorded the principles or the matters of detail on which an agreement has been reached, *e.g.,* making special arrangements for carrying out the objects of previous treaties, defining these objects more clearly, interpreting the exact sense of a doubtful clause in a treaty (*protocoles interpretatifs*) and the like. Occasionally also an agreement between two or more powers takes the form of a protocol, rather than a treaty, when the intention is to proclaim a community of views or aims without binding them to eventual common action in support of those views or aims.

Finally, "the protocol" *(pvotocole diplomatique, protocole de chancellerie*) is the body of ceremonial rules to be observed in all written or personal official intercourse between the heads of different states or their ministers. It lays down the styles and titles of states, their heads and public ministers, and indicates the forms and customary courtesies to be observed in all international acts. "It is," says M. Pradier-Fodéré, "the code of international politeness."

See P. Pradier-Fodéré, *Cours de droit diplomatique* (1899), ii, *499;* E. Satow, *Diplomatic Practice.*

PROTOGENES, a Greek painter, born in Caunus, on the coast of Caria, but resident in Rhodes during the latter half of the 4th century B.C. He was celebrated for the minute and laborious finish which he bestowed on his pictures, both in drawing and in colour. Apelles, his great rival, standing amazed in the presence of one of these works, could only console himself by saying that it was wanting in charm. On one picture, the "Ialysus," he spent seven years; on another, the "Satyr," he worked continuously during the siege of Rhodes by Demetrius Poliorcetes (305–304 B.C.) notwithstanding that the garden in which he painted was in the middle of the enemy's camp. Demetrius, unsolicited, took measures for his safety; more than that, when told that the "Ialysus" just mentioned was in a part of the town exposed to assault. Demetrius changed his plan of operations. Ialysus was a local hero, the founder of the town of the same name in the island of Rhodes, and probably he was represented as a huntsman. This picture was still in Rhodes in the time of Cicero, but was afterwards removed to Rome, where it perished in the burning of the Temple of Peace.

The picture painted during the siege of Rhodes consisted of a satyr leaning idly against a pillar on which was a figure of a partridge, so life-like that ordinary spectators saw nothing but it. Enraged on this account, the painter wiped out the partridge. The "Satyr" must have been one of his last works. We would then be about 70 years of age, and had enjoyed for about 20 years a reputation next only to that of Apelles, his friend and benefactor. Both were finished colourists so far as the fresco painting of their day permitted, and both were laborious in the practice of drawing, doubtless with the view to obtaining bold effects of perspective as well as fineness of outline. It was an illustration of this practice when Apellrs, finding in the house of Protogenes a large panel ready prepared for a picture, drew upon it with a brush a very fine line which he said would tell sufficiently who had called. Protogenes on his return home took a brush with a different colour and drew a still finer line along that of Apelles, dividing it in two. Apelles called again, and thus challenged, drew with a third colour another line within that of Protogenes, who then admitted himself surpassed. This panel was seen by Pliny (*N.H.* xxxv, 83) in Rome, where it was much admired, and where it was destroyed by fire.

In the Propylaea at Athens was a painting by Protogenes representing personifications of the coast of Attica, Paralus and Hammonias. For the council chamber at Athens he painted figures of the Thesmothetae, but in what form or character is not known. Probably these works were executed in Athens, and it may have been then that he met Aristotle, who recommended him to take for subjects the deeds of Alexander the Great. In his "Alexander and Pan" he may have followed that advice in the idealizing spirit to which he was accustomed. To this spirit must be traced also his "Cydippe" and "Tlepolemus," legendary personages of Rhodes. Among his portraits are mentioned those of the mother of Aristotle, Philiscus, the tragic poet, and King Antigonus. But Protogenes was also a sculptor to some extent, and made several bronze statues of athletes, armed figures, huntsmen and persons in the act of offering sacrifices.

PROTOGUEROFF, ALEXANDER NICHOLOFF (1867–1928), Macedonian revolutionary leader, was born at Ochrida, Macedonia, in 1867. He went to the military school of Sofia, and, after some military service in Bulgaria, joined the Macedonian movement in 1895 and commanded a band of insurgents. He was a moderate member of the Superior Macedonian committee in Sofia, a rival of the Secret committee which was responsible for the rising of 1903. From 1908 to 1911 Protogueroff served in the army, and after a period in retirement, was elected in 1912 president of the Executive committee of the Macedonian societies.

When World War I broke out he organized the 11th Macedonian division, and commanded the 3rd brigade, later becoming assistant to the Bulgarian governor of Macedonia. In Sept. 1918 he was made commandant of Sofia, and maintained order when the Bulgarians were driven back. Later he left the army and entered politics, being arrested on Nov. 4, 1919, with Radoslavoff's cabinet. He escaped, and after two years in hiding, reached Macedonia in Oct. 1921, where he joined Todor Alexandrov, the Macedonian leader, and his chief lieutenant Peter Chaiileff.

On Aug. 31, 1924, Alexandrov was assassinated by Chaiileff's friends, as a result, it is supposed, of an agreement between Chaiileff and the Communists. Protogueroff in his turn arranged for the assassination of four of the persons responsible for Alexandrov's death. Chaiileff himself was assassinated on Dec 23, 1924, and two more of his followers in the following year. During the later years of his life Gen. Protogueroff retired from active participation in the revolutionary movement, and became interested in spiritualism.

PROTOPHYTA. The designation Protophyta ("first plants") is applied to all simple one- and several-celled organisms that obtain their nourishment after the manner of a plant. Such forms probably afford a fairly accurate picture of what the early stages in the evolution of the vegetable kingdom were like. The simpler Algae (*q.v.*) are of course embraced in the Protophyta. Together with Protozoa (*q.v.*) the latter constitute the Protista, which comprise all the most elementary forms of life. There are many classes of Protista. some definitely holophytic (*i.e.,* feeding like a plant), others definitely holozoic (*i.e.,* taking in solid food like an animal), while still others exhibit a mingling of plant and animal characteristics, so that it depends to some extent on personal bias whether they be referred to Protozoa or Protophyta. A rigid definition is impossible and undesirable. The Protophyta may, however, justifiably be taken to include all simple organisms carrying on photosynthesis. In this process organic compounds are built up from carbon dioxide and water with the help of solar energy absorbed by pigments which are held within the cells in special protoplasmic bodies, the chromatophores. The latter always contain green chlorophyll which predominates in the green Algae (Chlorophyta), but in many classes is associated with other pigments (yellow, brown, red, etc.) which give a distinctive colouration to their respective members. Moreover, the carbon-compounds, that accumulate in the cells after active photosynthesis, vary in the different classes (starch, fat, leucosin, etc.), an indication that distinct metabolic processes are associated with the diverse types of pigmentation. The various classes can thus be distinguished on a physiological basis by their special mechanisms for nutrition.

TYPES OF PROTOPHYTA

1. Chromulina, motile cell (Chrysophyceae). **2.** Ochromonas, motile cell. **3.** Cryptomonas, motile cell. **4.** Glenodinium, motile cell (Dinophyceae) **5.** Hypnodinium, motionless cell (same). **6a.** Chrysosphaera, motionless cell (Chrysophyceae). **6b.** Chrysosphaera, Zoospore (same). **7a.** Thallochrysis, branched filament (same). **7b.** Thallochrysis, Zoospore (same)

Motile and Stationary Forms.—Many of the simplest unicellular Protophyta are actively motile with the help of delicate protoplasmic threads, the cilia or flagella, whose number and arrangement is usually distinctive for each class (figs. 1–4). Every class, however, also includes motionless organisms of varied type, partly unicellular (figs. 5, 6a) and partly multicellular (fig. 7a). Many of these reproduce themselves by means of naked swarmers (zoospores), which are essentially similar to the motile unicellular individuals of their class and which, after a period of movement, lose their cilia and give rise to the stationary organism. This fact has led to the assumption—now generally accepted—that such sedentary forms have evolved from motile unicells in much the same way as they arise from their zoospores during their individual life-history. It is, however, probable that in some series of Protophyta (*e.g.*, Myxophyceae) no motile organisms were ever evolved, even the unicellular individuals being motionless from the first.

In certain classes of Protophyta (Chlorophyceae, Xanthophyceae, Myxophyceae) the majority of the known genera are stationary, *i.e.*, they exhibit the essentially plant-like characteristic of immobility. These are usually grouped under the name of Algae (*q.v.*) which also comprise some series that have evolved beyond the level of the Protophyta and in which no simple forms are known. In other classes of Protophyta, however, the majority of the species are motile and, for this reason, and also because the simpler individuals are ordinarily not clothed by a cell-wall, they have been regarded as something apart from the Algae more nearly related to Protozoa and grouped as Flagellata. But in several of these classes (Dinophyceae, Chrysophyceae) motionless unicellular and filamentous types corresponding to those found in Chlorophyceae, Xanthophyceae, etc. (see ALGAE) have been discovered in recent times, and there is thus no valid reason for separating them from those Protophyta that are grouped as Algae.

A number of colourless Protista resemble plants, since they feed mainly by absorbing (organic) solutions and not by ingesting solid particles, *i.e.,* they are saprophytes or parasites. Such forms are probably in part descended from holophytic types which have lost their chromatophores, while others may have been devoid of them from the first. From such primitively colourless Protophyta various series of fungi may have originated, although some fungi may have been derived from pigmented types by loss of chromatophores.

(For classification see ALGAE.)

Range of Form.—Most classes exhibit a more or less extensive range from simple unicells to branched multicellular filaments. One can distinguish motile and motionless unicells, colonies of motile and motionless individuals, palmelloid forms with numerous cells embedded in mucilage, simple and branched filaments, etc. Analogous forms, often almost identical in shape though with the differences in pigmentation, etc., characteristic of the relevant groups are met with in most classes of holophytic Flagellata. Thus, Chrysosphaera (fig. 6) is a spherical unicell, similar to Chlorococcum (Chlorophyceae) or Halosphaera (Xanthophyceae), but it possesses the orange chromatophores and leucosin of Chrysophyceae and reproduces by zoospores closely resembling a Chromulina, one of the motile unicells of that class; similarly *Hypnodinium* (fig. 5) is such a motionless member of Dinophyceae, whose protoplasmic body before dividing during reproduction acquires temporarily the typical transverse and longitudinal furrows. Palmelloid forms, analogous to *Tetraspora* (Chlorophyceae), are seen in *Phaeosphaera* (Chrysophyceae) and *Phaeococcus* (Cryptophyceae), while filamentous types are represented by Phaeothamnion or *Thallochrysis* (fig. 7) (Chrysophyceae) and *Dinothrix* (Dinophyceae), all reproducing by zoospores resembling closely the motile unicells of their particular classes. Further details cannot be given in the confines of a short article, but it will be clear that there is a far-going parallelism in the evolution of the different classes of Protophyta.

Reproduction.—The reproductive processes are of the simplest kind, most commonly consisting in a mere division of the individual into two parts, which in the motile forms may even take place during movement. Reproduction by zoospores, as already mentioned, is frequent in the more advanced stationary forms (figs. 6, 7). Sexuality, altogether lacking in the Myxophyceae, is rare and restricted to the higher forms in most classes. Oogamy (see ALGAE) is encountered alone in the Chlorophyceae, where altogether the reproductive methods show a greater elaboration than among other Protophyta.

Relation to Other Groups.—The definite range from simple to complex implies an upgrade evolution which is recognizable also in the reproductive processes. As far as present knowledge goes, however, the multicellular filamentous types are of the simplest kind in most Protophyta. Even when branching occurs, there is no differentiation among the cells and the formation of reproductive units takes place in the simplest possible way. In other words these classes have ended blindly without developing far in the direction of the multicellular plant and it is only in Chlorophyceae (as well as in Phaeophyta and Rhodophyta which, as explained above, must have had a Protophyte ancestry) that a considerably greater specialization is found; and this is accompanied by more complex reproductive methods and the development of an oogamous sexual process. While in the two classes of seaweeds massive and complex bodies have been evolved, this is not the case in the green Algae, although in other respects their advanced forms are almost as highly specialized as those of seaweeds. The absence of more elaborate types in Chlorophyceae is probably due to their further evolution into land-plants in the far past, just as the simpler (extinct) Phaeophyta and Rhodophyta evolved into the seaweeds of the present day. In the same way other classes of Protophyta must have given rise to the various groups of fungi. There is little evidence of relationship between the known classes of Protophyta; most, if not all.

seem to represent separate attempts at the evolution of a holophytic organism. The occasional resemblances to classes of Protozoa are no doubt due to the fact that plant and animal tendencies were not clearly segregated in all the different evolutionary series.

BIBLIOGRAPHY.—For a general account of Protophyta, *see* F. E. Fritsch, *Presidential Address* to *Section K, British Associztion* (1927).

PROTOPLASM, defined by Huxley as "the physical basis of life," is the essential material of which living creatures are composed. A typical multicellular organism can be analysed into component organs, which are built up of diverse tissues, in turn consisting of cells. In pursuing the analysis the biologist reaches, within the cell, the essential living matter or protoplasm. But a cell often includes material which cannot be thought of as alive, or as playing an essential rôle in the characteristic chemical routine or metabolism. Such non-living material is conveniently called metaplasm, and may be illustrated by waste pigments or by crystals. If the whole of this metaplasm could be subtracted from the entire cell-substance or cytoplasm, and from the whole nuclear substance or nucleoplasm, the remainder would be protoplasm.

Soon after the vague recognition of the cellular structure of plants and animals in the later 17th century by Hooke, Malpighi and Grew, there began to be some appreciation of the fact that the cells had contents. Yet it required another century before Corti and Treviranus saw the streaming movements inside the cells of some plants. Even then the open secret was missed, for the objective envisaging of life as involving an intricate series of physical and chemical changes within the cells was still far distant.

The term "protoplasm" was first used by Purkinje in 1840 in reference to the formative material of animal embryos. It was taken over by von Mohl (1846) and applied to the "slimy, granular, semifluid" constituents of plant-cells, as distinguished from cell-wall, cell-sap and nucleus. Some time before that, however, Dujardin had discerned the living material in Foraminifera. He called this "sarcode" (1835), and defined it as a "living jelly, glutinous and transparent, insoluble in water, and capable of contracting into globular masses and of adhering to dissecting needles so that it can be drawn out like mucus." Soon there came an identification of Dujardin's animal "sarcode" and von Mohl's plant "protoplasm," and yet the acceptance of this unifying idea was slow. This was partly because the statement of the cell-theory by Schwann and Schleiden (1838) gave undue prominence to the importance of the cell-wall. Indeed it was not till 1861 that Max Schultze won conviction for the fundamental idea that throughout the whole world of life there is one general kind of living material, protean, yet nevertheless always essentially similar. (J. A. TH.)

The various methods of studying living matter may be grouped under three general headings: (1) microscopic observations of the structure and behaviour of the great variety of cells which constitute living organisms, both plant and animal; (2) a chemical analysis of the materials composing protoplasm and (3) the application of experimental methods on living cells to ascertain the extent to which protoplasmic phenomena can be explained in physico-chemical terms and to study chemical reactions within the living cell. All of these methods have been used since protoplasm was first recognized as the physical basis of life. However, the results obtained were largely empirical or purely speculative until the newer developments in the fields of physics and chemistry could give some significance to the physical configuration and chemical constitution of protoplasm.

The technical difficulties of making observational studies on cellular structures in the living state have resulted in the elaboration of methods for the fixation of tissues and cells with killing agents. As for chemical analyses of cellular tissues the usual procedure entails complete destruction of the cell. The results obtained by such methods can be accepted only with the qualification that the passage from life to death undoubtedly occasions structural and chemical changes in the form of recombinations and decompositions so that the structures and compounds found in dead matter can offer at best a very incomplete idea of the composition of living protoplasm.

Protoplasm exists only in discrete units almost always of microscopic dimensions. The living cell contains the protoplasmic unit which exhibits all the properties characteristic of living beings. In many kinds of cells the protoplasm becomes highly specialized by the predominance of one or a few of the life functions, as explained in the article HISTOLOGY. In multicellular organisms there are well-established cases which indicate a continuity between the protoplasm of neighbouring cells. The extent to which this phenomenon occurs and its significance are still in question. There is no doubt, however, that the cells composing an organism exert mutual interactions which are of the greatest functional importance in the general economy of the whole.

The protoplasmic unit within each cell always is bounded by a sharply outlined surface and contains at least one differentiated structure, the nucleus, the removal of which ultimately leads to the death of the protoplasm. From what is known regarding the chemical constituents, especially the proteins and fatty substances, and from the optical behaviour of protoplasm, it has been concluded that the components of protoplasm exist largely in the colloidal state. Beyond the visible structure of protoplasm as revealed by the microscope we must therefore look for the existence of an ultra-microscopic, colloidal structure. Whatever this structure may be there is no doubt that the extraordinary properties of surfaces especially characteristic of colloids play a large part in protoplasmic phenomena. (See COLLOIDS.)

One of the many difficult problems in a consideration of the constitution of protoplasm is the significance of the many and varied visible structures within the protoplasm. (See CYTOLOGY.) In addition there is reason to believe that the nucleus of the cell contains a large number of discrete, self-propagative particles of colloidal dimensions—the genes. (See HEREDITY.) So far as the rest of the protoplasm is concerned investigations have pointed in a different direction. Nevertheless, experimental studies in embryology have indicated that the cytoplasm of the unsegmented egg, for example, contains specifically different, but not necessarily visibly formed, materials which play an important part in development. We must conclude that the concept of regional differentiation within the cell must be taken into serious account in any attempt to interpret protoplasm in terms of physics and chemistry.

Chemical Analysis. (a) Inorganic Components.—Water is the most abundant single component of protoplasm. It is important in promoting chemical activity by dissociation of electrolytes. It also takes an intimate part in the building up and breaking down of such chemical compounds as proteins and carbohydrates, a procedure which must be occurring constantly in the metabolism of a living cell.

The common salts in protoplasm are the chlorides, carbonates, and phosphates of sodium, potassium, ammonium, calcium, magnesium and iron. These substances are present in certain relative concentrations so that the specific properties of one balance those of others in the normal chemical equilibrium of the cell. Gases are also present in solution, viz., oxygen and carbon dioxide which play an important rôle in the oxidation processes.

(b) Organic Components.—The organic compounds obtained from protoplasm are the carbohydrates, lipins and proteins. The most stable of the carbohydrates probably serve as structural materials, others supply energy by undergoing oxidation. The lipins, or fatty substances, serve similar purposes. They have a much higher energy content. Their insolubility in water together with their ability to combine with electrolytes to form soaps with varying water-soluble properties are of considerable significance in the constitution of protoplasm.

The proteins are the most complex of the organic compounds. In common with the fats and carbohydrates they are composed chiefly of carbon and hydrogen, but they also possess certain radicals (NH_2 and COOH) which give them the peculiar property of behaving both as acids and as bases. The proteins readily combine with inorganic ions to form salts; this is one of the factors which enables protoplasm to retain a high concentration of certain inorganic elements relatively independent of that of the environing medium. Because of their varying acid and basic groups the proteins can likewise maintain the protoplasm at its own peculiar degree of acidity and basicity. Proteins are mostly all colloidal, their solutions are often viscous and exhibit reversible states of solidity and fluidity. These remarkable properties of the proteins probably serve as a basis for the complex system of structure and chemical interactions in protoplasm.

Many of the chemical changes which involve either the breakdown or the synthesis of the compounds discussed in the preceding paragraphs can be made to occur in vitro extremely slowly or under conditions (*e.g.*, high temperature) which cannot possibly obtain in living protoplasm. It is known, however, that certain substances, called enzymes, have been extracted from animal and plant tissues, which enable reactions to occur at a relatively high velocity and under conditions probably existing in living protoplasm. Many inorganic substances, called catalysts, are known whose effects are analogous to those of enzymes.

The Physico-Chemical Structure of Protoplasm. (a) The Protoplasmic Surface.—Protoplasm is always surrounded by an aqueous environment. This, obviously true for all organisms which live in water, is equally true for land-living forms whose outer coating of dead and dying cells is so constituted as to form a waterproof layer to maintain the proper conditions of moisture for the living cells within.

In order to account for the fact that the protoplasm maintains its integrity we must assume either that the entire mass of protoplasm is practically insoluble in its surrounding medium or that its immiscibility is due to an enveloping layer or membrane. There is considerable proof that the second assumption is the correct one. For example, when the protoplasmic surface of a variety of living cells is torn with microneedles (see MICROMANIPULATION) the interior protoplasm tends to flow out and dissipate in the surrounding aqueous medium. The material, as it flows out, especially when the surrounding medium has the proper salt content, frequently forms a new surface membrane which encloses it and keeps it intact. Another experiment which indicates the existence of a differentiated membrane is the microinjection of coloured solutions which normally do not penetrate the protoplasm from without. The colour quickly spreads through the protoplasm but remains within its boundary.

Differences in the penetrating powers of various chemical substances have given us some idea as to ,the nature of this membrane. Water passes in freely especially when it contains certain salts in solution, viz., NaCl and KCl, to pure solutions of which the plasma membrane, in many instances, appears to be relatively permeable. Other salts, *e.g.*, $CaCl_2$ and possible $MgCl_2$ in pure solutions have no appreciable powers of penetration. The rate of penetration of acids and bases appears to be a function of their degrees of ionization, viz., those which are the most highly ionized appear to be least able to penetrate. The most universally penetrating substances seem to be those which are lipoid or organosoluble. These facts have convinced many investigators that the surface membrane of protoplasm is at least largely lipoid or fatty in nature, an assumption which is supported by the immiscibility of protoplasm with water.

In all probability we must consider the physiologically active part of the membrane as a shifting, dynamic structure resulting from interactions of protoplasmic components with the environment and undergoing reversible reactions with the various chemical substances dissolved in the surrounding medium. Non-living membranes which exhibit rapidly reversible reactions of this type are well known.

Some substances to which the protoplasmic membrane appears to be freely permeable are known to be unequally distributed between the interior of the protoplasm and its environment. This is accounted for in part by the chemical combinations of the freely penetrating substance with nonpenetrating substances present on one or the other side of the membrane.

Mention must also be made of a different type of penetration, viz., that by which particulate matter may enter protoplasm. Insoluble particles may adhere to, or be wetted by, and consequently sink into the protoplasmic surface layer after which they may gain access into the interior by the reactive changes occurring between the interior and the surface membrane. Space permits only the recital of a list of the possible factors which play a part in the passage of substances through membranes, viz., simple diffusion, osmosis, electro-endosmose, surface tension and solubility in the material of the membrane.

(b) The *Internal* Protoplasm.—The necessity of the nucleus for the life of the protoplasm of a cell has been so well recognized that the term "protoplasm" is generally applied to an organized system consisting of a differentiated nucleus contained within a mass of so-called cytoplasm.

The nucleus is a differentiated part of the protoplasm of the cell. Usually it readily coagulates when the cell is injured or killed and then appears as a network of granular fibrils enclosed within a membrane. The importance of the nucleus is most evident during the reproductive activity of the cell which is heralded by the transformation of the nuclear materials into peculiarly constant bodies, the chromosomes. (See CYTOLOGY.)

Interchanges between the nucleus and cytoplasm undoubtedly occur, possibly during the entire life cycle of the cell. However, not enough is known at present regarding the nature of this relation to permit any certain interpretation. What is known is that a relation does exist which is essential for the continued life of the cell.

Under the microscope the substance of the cytoplasm appears to be a translucent, optically structureless fluid, the hyaloplasm in which lie various sized granules, globules and fibrillae in varying amounts. In many instances these visible bodies are grouped in definite patterns, some of which constitute specialized structures. (See CYTOLOGY.) The significance of these structures must be left to the future.

The presence of visible granules, fibrils and vacuoles in the hyaline matrix is such a universal feature that many of the older conceptions of protoplasm were based on the assumption that these inclusions form an essential part of protoplasmic structure. However, in view of the fact that these structures vary in the protoplasm of different cells, not only in form but also in number, and may be entirely absent in some cells or appear only at some stages in the life of a cell, we must regard them rather as specialized differentiations in each case.

A feature which strikes the eye of the observer is the constant movement of the visible granules in the hyaline matrix of the protoplasmic substance. This continual, translational movement, as distinguished from the vibratory Brownian movement, is very noticeable and rapid in some cells and barely perceptible in others. True Brownian movement is also seen in protoplasm, sometimes in restricted areas and at other times throughout the entire protoplasm of a cell. The protoplasm of some cells is very fluid, in others it is quite viscous. The viscosity may change at different periods in the life history of a cell.

A factor which has been found to be important in the maintenance of protoplasm is the antagonistic action of certain salts in the protoplasm and in the fluids which bathe it. As an example we may discuss the action of two of the most common salts: sodium chloride and calcium chloride. The fluids contained in all living organisms, plant or animal, contain these (or very similar) salts in definite, relative concentrations which approximate those of the same salts in the ocean. Protoplasm will not survive beyond very narrow limits of those relative concentrations, the proportions being about fifty parts of sodium to one of calcium. The actual concentrations of these elements do not appear to be as important as are the proportions in which the two exist. The significance of these salts probably lies in the fact that the salts of sodium have a dispersive action while those of calcium have an aggregative action on two of the most important constituents of protoplasm, viz., proteins and fats.

The chemical state of the proteins and fats probably also accounts for the fact that protoplasm can survive only within narrow limits of an acid-base equilibrium. This is maintained by the buffer action of the acid and basic combinations of certain salts, *e.g.*, the carbonates. In this way any excess acid or base liberated during metabolic activity is neutralized before the protoplasm is affected injuriously. Temperature and oxygen tension in the environment also play important rôles in controlling chemical interactions in protoplasm.

Conclusion. — Protoplasm is the material basis of life and maintains its peculiar properties only as it exists in the form of organized, structural units of microscopic dimensions and under limited environmental conditions. Each unit possesses all the life properties of motility, responsiveness, nutrition, growth and reproduction. Its complicated chemical and physical state is essentially unstable and can be maintained only by chemical interactions involving a continuous expenditure of energy. Moreover, the chemical reactions are controlled by definite structural conditions. It continually and intermittently receives energy (*e.g.,* potectial chemical energy of foodstuffs) and releases energy in kinetic form (mechanical energy, heat, light, electricity). The instability of protoplasm is shown by the ease with which a slight change in the constitution of its chemical environment or even mere mechanical disturbances destroy it and convert it into a nonreversible and unorganized mixture of substances.

PROTOPOPOV, ALEXANDER DMITRIEVICH (1864–1918), Russian statesman, was born in 1864 and educated in a military school. He served for some time in the army before going into business. As a big landowner of the Simbirsk province, he took an active part in the Zemstvo life, and was elected member of the Executive board of the Simbirsk Zemstvo and marshal of the nobility of the Simbirsk province. He was elected member of the third (1907) and of the fourth State Duma, where he joined the left wing of the Octobrist (Moderate Liberal) party. Later he became vice-president of the State Duma. In March 1916 he visited the capitals of western Europe as one of the leaders of the Russian parliamentary delegation. At the beginning of Oct. 1916 he was appointed minister of the interior in the Stiirmer cabinet, proving to be now the strongest upholder of reaction. He enforced the censorship, and interfered dangerously with the food-supply work of the Zemstvos and Towns Union. At a stormy meeting held at the Duma he was asked to resign his post, and when he refused his name was struck off the list of members of the party. Hated by the Liberal circles and by the Duma, Protopopov not only supported the reactionary policy of Stiirmer and Prince Galitzin, but he is said also to have been one of the secret organizers of the disturbances of Feb. 1917, which he proposed to suppress by military force, and which, unexpectedly for him, resulted in the overthrow of the empire and of himself. He was arrested by the Provisional Government and committed for trial. He remained for many months in the Peter and Paul fortress and was executed by order of the Extraordinary Commission in Sept. 1918.

PROTOZOA. The forms of life included under the name Protozoa are enormously varied. The separation of the group from the Metazoa (higher animals), plants and bacteria, is based to some extent on convenience in classification, but it does rest on certain definite characters which distinguish the Protozoa from the three main groups.

Single protozoans are as a rule extremely small, so small that they can only be seen with the heip of the microscope, and the unaided and inexperienced eye will only pick them out where by chance a great mass of one kind or another have collected together: heaped together in this way they will scarcely look like living creatures. When we see the surface of a small stagnant pond covered with a sheet of green, we really have in front of us a great host of the flagellate organism *Euglena* (fig. 16). When, on board ship, we see phosphorescence at night so strong that every drop of water seems to sparkle we are really watching the antics of countless millions of the luminous protozoan *Noctiluca miliaris* (fig. 18). Chalk is in reality the mud of an ancient sea purified by various chemical processes but consisting ultimately of the calcareous shells of Foraminifera and little else.

But much oftener people come into contact with Protozoa without knowing it; in water of every kind there are Protozoa without number; nearly every human being harbours protozoans of various innocuous species, living as parasites; not rarely other parasitic species will make their presence felt most disagreeably, although they do not play as important a part in this connection as Bacteria do. The exciting agent concerned in blackwater fever, malaria, sleeping sickness, amoebic disentery, Nagana cattle plague in East Africa, coastal fever of cattle in South Africa, to mention a few examples, is in each case a protozoan. Apart from these practical considerations, interest centres on the Protozoa on account of the picture they show us of the infinite diversity of living organisms.

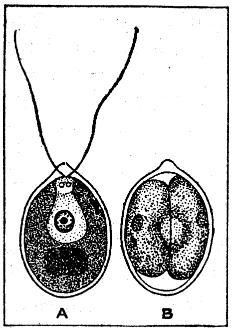
In common usage the Protozoa are said to be "unicellular animals" in contrast to the higher animals and plants which are built up of many cells. The protozoan corresponds to a single such element; it is an isolated cell (*q.v.*). What do we mean by this? A comparison between a protozoan and a multicellular animal of comparable size may make this clear. When we look at a small nematode (an organism related to the thread worm) under the microscope we find that its body is made up of separate organs—gut, nervous system, sexual organs and so forth; these organs appear to consist of more or less clearly defined and separated parts which we call cells. These cells are not all alike; the cells of the gut look quite different from those of the nervous system or of other organs; these small, fundamental elements of the animal body only resemble one another in the ground plan of their structure: In each of them we can distinguish a cell-body and a cell-nucleus. Now let us consider the protozoan chosen as a type (fig 1); it has organs: its body has an opening through which it takes in its food; a skeletal structure provides the body with a distinctive form and ensures its rigidity; fine hair-like processes serve for locomotion, but the body of the animal as a whole, instead of being made up of individual elements, consists of one single cohering mass of protoplasm. And if we look for cell nuclei, we find only one. The protozoan thus agrees with the individual cell of a higher animal or plant in this essential character of the organization of the cell—its division into cell-body (cytoplasm) and cell-nucleus; but only in this, for if we look carefully at the individual cells of the worm we have just taken as an example we find none that equal in complexity the single cell of the protozoan.

It is not hard to see why this should be so. The protozoan is a cell by itself; it swims about freely, finding its own food; it leads a life of its own. The muscle-cells of the worm on the other hand are incapable of independent existence; they rely for nourishment on the cells of the intestine, while these cells in their turn, absorbing nutriment, have no power of contraction. In other words, the protozoan is constitutionally versatile, the cells of the worm specialize; they stand in relation to one another on the principle of division of labour; they are viable only when brought together into a many-celled individual.

Furthermore, if we compare the protozoan as *an individual,* as a creature capable of living an independent life, with a many-celled worm or insect then without question the protozoan is much more easily regarded as the simpler, the less complex. But there is another way of approaching the question. We can as well compare the protozoan with the particular cells of the multicellular organism, and then we find that the protozoan leaves the cells of the higher animals far behind: the most complex known cells are found in the Protozoa.

For these and for various other reasons C. Dobell has pronounced this comparison of the protozoan with a single cell of a many-celled organism to be essentially inadmissible, for by it we compare *whole* independent individuals (Protozoa) with dependent parts (cells) of an individual. According to Dobell, the Protozoa are not unzcellular but *non*-cellular organisms This idea is not difficult to understand: if we compare the protozoan with the nany-celled animal as a whole, we may say that the latter is divided into cells, the former not; therefore the protozoan is not organized in a cellular manner. Nothing can be said against this conception in so far as it is limited to the physiological aspect, that is, to the functions of the individual; and yet it can easily be shown that the Protozoa are unicellular.

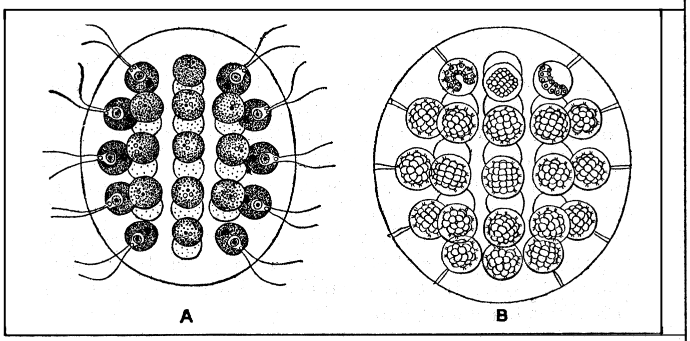
It has been mentioned above that in many protozoans we only find a single nucleus Moreover this nucleus not only looks like the nucleus of any animal or plant cell, but also behaves in precisely the same way when the protozoan reproduces itself This process generally takes the form of division; one individual splits into two (or more) new individuals. The nucleus of the mother-cell also divides at the same time; this division of the nucleus proceeds like the nuclear division of a cell in animal tissue. It is therefore clear that, while from the physiological point of view we may compare the protozoan individual as a complete organism with a worm or a butterfly, from the structural and physiological point of view (i e., with reference to its organization) we must compare it with a single cell of the worm, etc ; for the protozoan does not multiply like a worm, but like a single cell of a worm.



FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN" (BORNTRAEGER)

FIG. 1—CHLAMYDOMONAS ANGULOSA, (A) ADULT INDIVIDUAL, (B) CELL SPLITTING INTO TWO INDIVIDUALS

The unicellular condition of many, but not all, protozoans may be demqnstrated in yet another way. There are groups of Protozoa, such as the Volvocineae, which include unicellular and multicellular species. The obvious close relationship between these single-celled and many-celled forms makes it quite clear that these latter are nothing but cell-colonies functioning as individuals. Let us compare Chlantydomonns (fig 1) with *Eudorina* (fig. 2): the *Chlamydomonas* individual has a nucleus, a chromatophore and two flagella; when it reproduces it splits into two new independent individuals. The individual of Eudorina is made up of 32 cells, which have a perfectly regular arrangement inside an egg-shaped mucilage-sheath. When Eudorina reproduces, each of the 32 separate cells has to divide first into two; each of these two divides again; their products divide, and so on until after a series of five divisions each original cell of Eudorina has given rise to 32 cells which are



FROM HARTMANN, "ALLGEMEINE BIOLOGIE" (GUSTAV FISCHER)

FIG. 2.— EUDORINA ELEGANS (GREEN MULTICELLULAR PROTOZOAN. ALLIED TO CHLAMYDOMONAS): (A) ADULT INDIVIDUAL. (B) LAST STAGE OF VEGETATIVE DIVISION (MAGNIFIED 100 TIMES)

held together iri a common wall of mucilage (fig. 2b). At this point the gelatinous wall of the "mother colony" dissolves and each of the 32 new cell-groups slips out of the "skin" of its mother-cell, and begins an independent existence as a new *Eudorina* individual. Now if we look more closely at a single cell of a Eudorina individual we find that it is exactly like an individual of *Chlamydomonas* (fig. 1a). But the *Eudorina* colony has already reached a true multicellular condition; its single cells, although like one another, are not capable of independent life. Yet we need not hesitate to compare them with the independent individuals of *Chlamydomonas.*

This example enables us to enlarge our original definitian of Protozoa. We have said above that Protozoa are unicellular organisms, but to be more accurate we had better say "most Protozoa," because there are also these multicellular protozoans like Eudorina which are connected by transitional forms with single-celled species. There are also Protozoa that we cannot call unicellular (although they do not form cell colonies) because they contain numerous nuclei (fig. 24). But nearly all these polyenergid forms, as these multicellular and multinuclear protozoans are called, in contrast to the truly uninuclear and unicellular, monoenergid forms, differ essentially from multicellular animals: there is no difference amongst the single cells, or nuclei, as the case may be, of such a polyenergid protozoan; they are all approximately equal in regard to structure, as well as function. This difference between protozoans and higher multicellular organisms has been expressed by the terms homoplastic and heteroplastic. The multicellular or multinucleate protozoans, composed of similar cells, are designated as homoplastic; multicellular higher animals and plants, on the contrary, composed of unlike cells, are heteroplastic.

What we have just said still does not apply to all Protozoa; it is, indeed, almost characteristic of living organisms that they do not admit of neat classification. There are a few Protozoa that are heteroplastic (Volvox, the Myxosporidia, etc.). The colonies of Volvox (fig. 19), a protozoan closely allied to *Eudorina,* are made up of 12,000 to 22,000 cells, but only a small number of these are capable of developing into new colonies; most of the cells are incapable of this and degenerate and die when the old colony gives rise to new ones; these cells are only capable of vegetative functions of movement and nutrition, whereas the reproductive cells are non-motile. Thus in Volvox we have already arrived at a division of labour between vegetative body- and reproductive germ-cell.

If in spite of this we number these forms amongst the Protozoa it is either because, like Volvox, they are linked by a series of transitional forms to typical unicellular species, or because, like the Myxosporidia, they are separated by their lack of proper organs from the lowest multicellular animals, the sponges. On the other hand the division between the Protozoa and the lower plants (Algae and Fungi) can only be arbitrary and therefore difficult to determine.[1] We may give as an illustration of this the fact that there is a long-standing dispute between botanists and zoologists as to whether certain forms, such as the Volvocineae, should belong to the Protozoa or to the Algae; for this group has undoubted affinities with true multicellular plants (the green algae). But we will not concern ourselves with these difficulties here. We need only emphasize the fact that we know of no single protozoan type that could be looked upon as the ancestral form of any known multicellular organism.

We can divide the Protozoa into numerous groups (orders or classes) which we may call natural, *i.e.,* protozoans belonging to one of these groups appear to be related as the dog is to the bear and the cat. But it is only rarely that we can trace between the various groups of Protozoa a relationship like that which exists between the mammals and the birds. Many protozoans are as little related to one another as the mammals are to the insects. On this account it is naturally difficult to make generalizations about anatomical and other similar characters which will hold for all Protozoa. A cursory glance at the text figures will show that the form can be extremely diverse. Some are completely shapeless, others rigidly constructed; some are asvmmetric, and others completely symmetrical. A comparison of the magnifications given in the figures shows further that the absolute size can be immensely variable. There are protozoans that only measure about $\frac{1}{10,000}$ in. and others some thousand times this diameter; indeed there are some giants, like *Nummulites* (a foraminiferan) which are as big as a shilling piece, and the plasmodia of many niyxomycetes are many times larger

[1]All protozoans are marked off from the Bacteria by the possession of a typical cell-nucleus.

BODY STRUCTURE

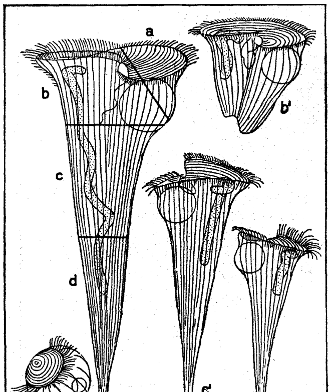
In considering the anatomical form of the Protozoa we have already mentioned that the protozoan always consists of a cell-body (cytoplasm) and cell-nucleus (or "nucleus" for short). Cell-body and nucleus are composed of that mysterious substance we call protoplasm (*q.v.*), which is the very material of life.

We can often study the structure of protozoans thoroughly enough in the living animal. As a rule, however, for the purpose of making more complete observations we make use of two technical processes that are indispensable in work on the microscopic anatomy of the higher animals and plants. First we clot, or coagulate, the protoplasm with various chemical reagents, just as we coagulate the albumen of an egg by boiling it; we then soak it with various dyes; the individual constituents of the cell-body have now, in their coagulated condition, the property of absorbing these dyes and they have moreover particular preferences for certain colouring materials (see CYTOLOGY); making use of this we can stain different parts of the cell different colours, and so make them more clearly visible.

Cytoplasm.—There seems to be no essential difference between the protoplasm of the Protozoa and that of other forms of life. We therefore content ourselves with saying here that it is more or less colourless, translucent or even transparent, and slimy or more toughly gelatinous; it chiefly consists of substances allied to white of egg, the so-called proteins. It is not infrequently differentiated into distinct zones and is capable of producing all kinds of structures—bubbles of liquid (vacuoles), delicate threads (fibrillae), granules, membranes, crystals and—to a certain extent—of changing into various substances—starch, oil and so forth.

Nucleus.—The nucleus of Protozoa is a clearly defined protoplasmic body, usually of rounded shape although there are other forms; as a rule only the so-called nucleolus, a small spherical body of albuminous substance whose structure and function are not as yet exactly understood, stains differently from the rest of the nucleus and can be distinguished from the main body of the nucleus proper, the karyoplasm. Nucleoli which are very big in comparison with the rest of the nucleus and are only present singly are called karyosomes. The surrounding karyoplasm may show various kinds of structure, granular, spongy, thread-like, or it may appear homogeneous.

It is with regard to the function of the nucleus that the Protozoa have provided some interesting facts; it is easy enough to cut in two a large uninucleate protozoan such as Amoeba, and if we watch the later behaviour of the two pieces, one of which is of course without a nucleus, we find that only the part with the nucleus can develop again into a complete individual; the part without a nucleus, on the other hand, although it can remain alive for a little while and even move about, is quite unable to take in and digest food; above all it is incapable of developing into a complete individual and sooner or later it consequently degenerates and dies (fig. 3). A nucleus can only come from a nucleus; it cannot arise *de novo* from the cytoplasm. The nucleus is therefore an organ essential for the life of the cell; we cannot yet define its functions in the Protozoa more exactly. Investigations of inheritance in the higher plants and animals have shown that it is the seat of the hereditary material and this is no doubt also the case with the Protozoa (see HEREDITY).



FROM HARTMANN, "ALLGEMEINE BIOLOGIE" (GUSTAV FISCHER)

FIG. 3.—STENTOR ROESELI REGENERATION: ANIMAL ON LEFT CUT, AS INDICATED BY LINES, INTO FOUR PIECES: (B, C, D) WITH NUCLEUS, (A) WITHOUT; (A', B', C', D') THE SAME PIECES A DAY LATER (ALL BUT A' HAVE DEVELOPED INTO SMALL STENTORS)

We have already shown that many protozoans are multinucleate, and in these forms the nuclei are usually all alike. Yet there are Protozoa with dissimilar nuclei. These are the Ciliata, possessing in the simplest case two nuclei (fig. 4), the so-called macronucleus and the much smaller micronucleus. We shall discuss the importance of this "nuclear dimorphism" later.

Organoids.—Cytoplasm and nucleus are the only body-parts that all Protozoa have in common[1]; of all other organs we can only be sure that they occur in certain species. We shall therefore deal with these structures quite briefly. A distinction can be made between organoids and non-protoplasmic inclusions. The organoid,

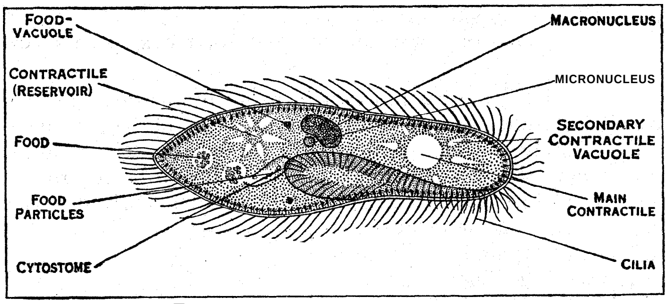


FIG. 4.—PARAMAECIUM CAUDATUM

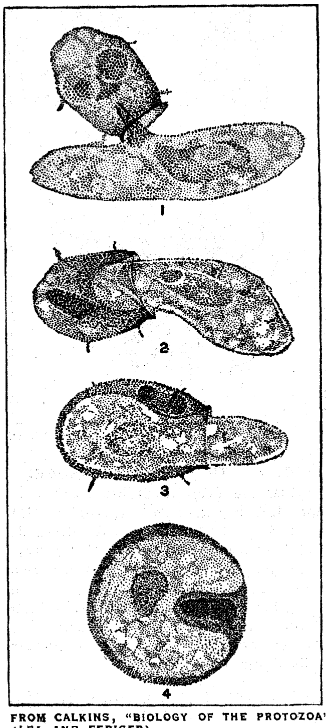
e.g., a chromatophore, cilium or myoneme contractile element, is composed of living protoplasm which is more or less clearly delimited from the cytoplasm and performs a particular function, and comparable in one way therefore with an ordinary organ of a multicellular animal such as stomach, eye or muscle. Non-protoplasmic inclusions, on the other hand, such as a membrane or a siliceous skeleton, are non-living, like a snail's shell.



FROM CALKINS, "BIOLOGY OF THE PROTOZOA" (LEA AND FEBIGER)

FIG. 5.—DIDINIUM NASUTUM (CILIATE) DEVOURING A PARAMAECIUM: (1) DIDINIUM HAS SEIZED THE PARAMAECIUM WITH A KIND OF SUCKER: (2 & 3) SWALLOWING PREY; (4) PARAMAECIUM COMPLETELY SWALLOWED

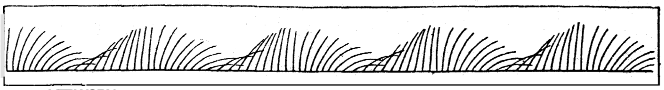
One of the most important organoids—indeed we may say in a certain sense the most important organoid—is the chloroplast or *chromatophore,* which we only meet with in those protozoans which feed like green plants. The chromatophore is sharply marked off from the cytoplasm and consists of protoplasm saturated with chlorophyll, the green colouring matter of leaves (fig. 1); like the nucleus it can only arise from division of another chromatophore.

There are several kinds of such cell-constituents capable of division. Amongst these are to be included the centrosomes which play such an important part in nuclear division; these are spherical and for the most part they are rather small structures. Closely related organically to the centrosome is the basal granule, a nodular thickening at the base of a flagellum or cilium (figs. 1, 16, 17; for further discussion, *see* below).

Most of the organellae developed in the protozoan cell are however incapable of division; that is, they arise usually out of the undifferentiated cytoplasm and can disappear again into it. To this group belong the static fibrillae, more or less stiff threads or little bristles which serve as an internal skeleton for many protozoa. They thus ensure the maintenance of the typical body-form of the organism much as the metal framework keeps an

[1]Whether also the so-called mitochondria and Golgi-bodies (see CYTOLOGY: *Cell inclusions*) are present in all protozoans is not yet known; they have only so far been found in a few species.

umbrella in shape (fig. 1). In all probability such static fibrillae take part in the formation of flagella and cilia. We speak of flagella when these are long, as compared with the body itself, and few in number (figs. 7, 16). Cilia are relatively short and numerous (figs. 4, 8). Cirri are nail-shaped structures which consist of several cilia stuck together. These hair- or string-like appendages of the



FROM VERWORN, "ALLGEMEINE PHYSIOLOGIE" (GUSTAV FISCHER)

FIG. 6.— DIAGRAM OF A WAVE OF MOVEMENT THAT RUNS OVER A ROW OF CILIA

body have a locomotive function in many protozoans and in all probability always consist of a rigid axis (static fibril) surrounded by a relatively less viscous mantle of protoplasm. The rigid axis arises from a basal granule which is probably to be regarded as its centre of formation; many protozoans can be deprived of their cilia—shaved, as it were—and then the basal granule can be seen to grow a fresh cilium (fig. 8).

A third kind of fibrillar organoid is the myoneme, a contractile fibre or band which is the muscle of the protozoan; very little is known of the structure of this element except that, in most cases at least, it corresponds to the non-striated rather than to the striated muscle of the higher animals (see MUSCULAR SYSTEM).

We do not know definitely whether there are in some Protozoa, as many investigators have claimed, apart from the fibrillar organoids just mentioned, fibres which serve, like the nerves of the higher animal, for the conveyance of sensory impulses.

No more can we be certain of true sense-organs in the Protozoa, although the red granule, or stigma, found at the fore-end of all green protozoans is very frequently considered as analogous to an eye. Its sensitiveness to light has not yet, however, been critically demonstrated, although it is quite possible that it represents a sense-organ (for a more detailed discussion *see* below).

Another organoid, found in protozoans living in fresh water, but not as a rule amongst those living in the sea or as parasites. is the contractile *vacuole.* This 'may be called the kidnev of the protozoan. In the simplest cases it is merely a bubble or-bladder which pours out its contents at intervals through a very minute opening. The lining of this bubble is marked out by special properties which we need not go into more deeply here. The contractile vacuoles of many protozoans are much more complicated and consist usually of a chief vacuole, emptying itself directly into the exterior, and a system of subordinate or accessory vacuoles emptying themselves into the central vacuole. The accessory vncuoles therefore work in alternation with the central vacuole: when the accessories empty the central one swells and when it empties the accessories fill up again (fig. 4).

Up to now we have only been dealing with relatively simple organoids; we meet a more complicated type in the cytostome, the mouth of some protozoans. Many protozoans have no mouth at all and yet are able to take in food *(see* below, Nutrition) but others have a proper mouth. In the simplest cases it is nothing but a trough or slit-like deepening of the body surface (fig. 1). In more complex forms the cytostome is a cavity held open by supporting fibrillae (fig. 8); it is moreover carpeted with cilia which drive the food in a current into the blind end of the cytostome (fig. 4). Uniike the mouth of a higher animal, the cytostome is not continued in a stomach but comes to a blind end. The food is driven against the blind end of the cytostome, which then swells out until a so-called food-vacuole is cut off from it; this is pushed into the inside of the cell-body and the food there digested (fig. 4).

Many protozoans have also a cell anus or cytoproct which usually consists of a mere hole held open by supporting fibrillae.

Non-protoplasmic Bodies.—Amongst the by-products of the protoplasm, which we shall call alloplastic bodies, are the skin and the various kinds of protective covering or armour. Some Protozoa are completely naked, *i.e.,* their surface consists of ordinary protoplasm. With other forms, the surface, though still living protoplasm, is hardened into a more rigid skin (pellicula). With still others the protoplasm differentiates on its surface a non-

living, more or less rigid coat, and this coat is often separated by a space from the body of the cell. Nothing exact is known of the chemical composition of these skins; possibly they are often of a material related to the chitin of an insect's skin; in many green protozoans the skin consists of cellulose, as in plants, but frequently it is not rigid at all but merely a slime-coat (fig. 2). Finally by the deposition of mineral matter such as chalk or silica some protozoans change their skins into a protective shell or armour, in the same way that a lobster's shell is constructed by deposition of chalk in a ground mass of chitin. Some protozoans, for example the *Euglypha,* also secrete mineral substances inside their bodies for later use in building up a hard skeleton.

We need not discuss here all the other non-living substances that we meet with in the bodies of Protozoa (starch, fat, etc.); as far as we understand their rôle they seem to act as reserve materials or exist as superfluous products of the organism's economy. We must just mention the fact that some protozoans have pigments (blue, red, etc.) that are distributed in the form of granules in various parts of the body; colourless forms are however in the majority.

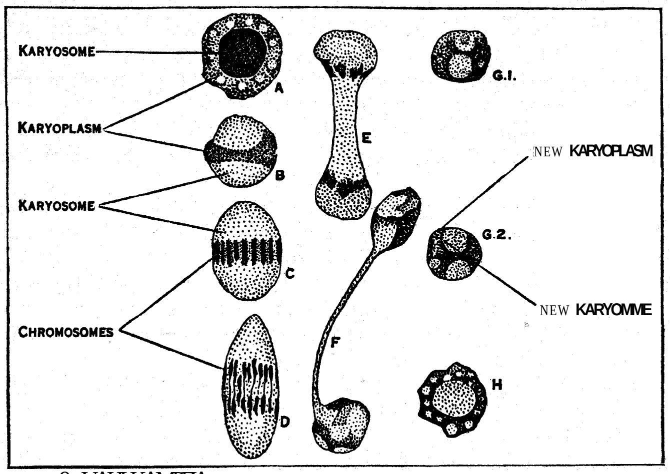

FIG. 9.—VAHLKAMPFIA BISTADALIS. (A–H) SUCCESSIVE STAGES IN CELL DIVISION

Colony Formation.—All protozoans, as we have already shown, are not unicellular and uninucleate; actually there are all intergrades between the unicellular and uninucleate forms and the multicellular and multinucleate. A protozoan that almost always has four nuclei we can still call unicellular; a plasmodium of a myxomycete (slime mould), whose thousands of nuclei are embedded in a single mass of protoplasm, scarcely has a title to this name; yet we can hardly call it multicellular, so the name "polyenergid" has been invented for this kind of creature. The gap between one-celled and many-celled Protozoa is filled by Protozoa that form colonies; when the progeny to which a protozoan has given rise by division stay together, the aggregate is called a colony. Polyenergid Protozoa arise from uninucleate germ-cells in a similar way, but only the nucleus divides while the cytoplasm remains undivided. When the individual cells of a colony are arranged in a particular order and especially when they are no longer capable of independent existence we have arrived at the stage at which we can call the colony a multicellular individual.

PHYSIOLOGY

Nutrition.—We can divide the Protozoa according to their method of nutrition into four groups. The first consists of organisms provided with chromatophores (figures 1, 2, 16, 17, 19). These organisms create their own food just like plants, by producing starch out of carbonic acid gas (CO_2), their chlorophyll enabling them to use the energy of sunlight for this purpose; then, absorbing various salts from the water, they build up with the starch those albuminous substances of which their bodies are composed. These organisms are therefore self-supporting in the fullest sense of the word, for they can exist without the help of any other living creatures: they are "autotrophic." There are, we ought to say, some amongst them that are also capable of feeding on other organisms. All other Protozoa are "heterotrophic," *i.e.,* they use for their nutrition either other organisms directly or, more rarely, substances produced by other organisms. Protozoans forming this second group of nutrition types (the saprophytes) live on the products of putrefaction; that is, on substances formed when bacteria decompose organic materials.

A third group, including most heterotrophic Protozoa, live like so many animals by eating more or less solid food. They will attack almost anything; living organisms from the most minute bacteria to small multicellular animals—water-fleas, small worms and so forth. As parasites they prey upon the tissue-cells of the animals in which they live. Still others live on dead bodies, or parts of bodies of other protozoans or multicellular animals, or particles of nutritive material yielded by other organisms—starch, wood, and so on.

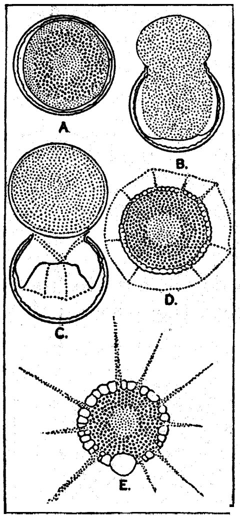

FIG. 11.—ACTINOPHRYS SOL

(A) Mature cyst; (B) bursting of cellwall; (C) young individual free: (D) young begins to form pseudopodia; (E) young individual nearly complete (X 350)

The last group of nutrition types comprises the majority of the parasitic Protozoa. They live on the dissolved food they imbibe through their body-surface from the blood, stomach-content and lymph of their host.

A word is necessary with regard to the ingestion of the food. The autotrophous species, those living on putrefying material, and also most of those living as parasites, feed osmotically; the food they need is dissolved in water; it permeates and is absorbed through the protoplasm surface. The solid food of the other heterotrophic protozoans must be swallowed whole before it can be absorbed. This can be done in various ways; those protozoans that have no cytostome are often capable of taking in food at any point of their surface and eat merely by flowing round and engulfing their prey, a process which is called "amoeboid ingestion." A variation of this habit is the engulfing of the food material not by the body of the protozoan itself but only by special outgrowths of the body called "pseudopodia" and its absorption into the body proper only later or not at all. The delicate, hair-like or netted pseudopodia of some protozoans, *e.g.,* heliozoans, are sticky and are used as traps; the victim comes up against the pseudopodium, sticks to it and is engulfed.

Protozoa having a cytostome naturally absorb their food through it; whether they are of the kind that wafts its food with cilia into the cytostome, or whether the prey is seized by the cytostome, the process of absorption is completed by the protozoan pushing itself over the prey in such a way that the latter is gradually covered up by the body (fig. 5). In the first case a sort of fore-mouth is often developed; this is called a peristome, and is lined with cilia which drive the prey towards the cytostome, as in fig. 4.

The so-called Suctoria actually do not devour their prey at all but suck it with the aid of stiff suckers or tentacles (fig. 12). Although most Protozoa swallow their prey alive, there are certain kinds that first kill their victims with poisons.

The food particles are absorbed into the inside of the cell-body in both eating and sucking protozoans; the space in which they lie engulfed is spoken of as the "food vacuole." Its walls are of living protoplasm, but we can regard it as a primitive gut. Substances are secreted into it to kill and dissolve the engulfed substances; the food-materials extracted from these latter are absorbed by the protoplasm. We do not yet know very much of the details of digestion, although certain digestive ferments have been identified in some protozoans. In many species the food vacuole follows a definite course round the body, while digestion is in progress. When an indigestible remnant is left at the end, the vacuole is brought to the surface and its contents expelled, often through the so-called cytopyge or cell anus.

Like all other forms of life the Protozoa do not need to use at once, for building up their bodies, all the food they absorb; they

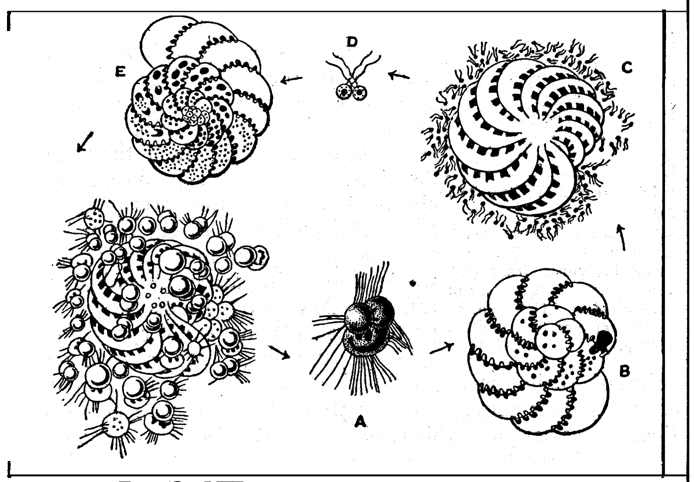

FIG. 13.—LIFE CYCLE OF POLYSTOMELIA CRISPA

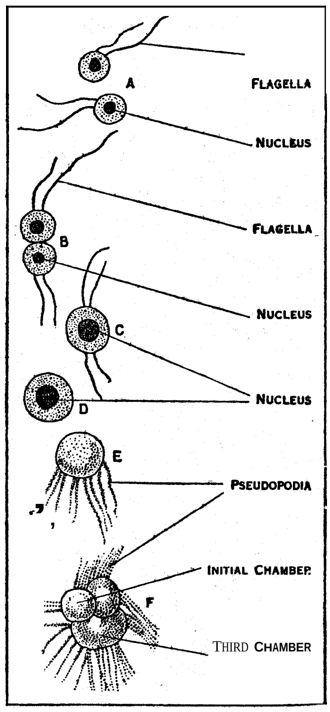
put a proportion of it by as reserve material to be used in case of necessity. Various kinds of materials—such as starch and the so-called paramylon, a starch-like body—are stored in this way both by the autotrophic species and by those living on decomposing organic matter; the other heterotrophous Protozoa store fat, glycogen and volutin.

Respiration.—All protozoans need oxygen for production of energy; most free-living (or non-parasitic) protozoans, and the blood parasites, absorb oxygen directly from the medium they live in. They require no special arrangements such as the lungs or gills of other animals; oxygen can diffuse to where it is wanted. Intestinal parasites and some living free in very putrid water not only do not require free oxygen but are incapable of living in a medium containing any appreciable amount of it; they are "anaerobic"

Excretion.—We know very little of the expulsion of the products of the decomposition of the body substance and reserve materials. In the bodies of many protozoans are to be found crystals partly consisting of salts of uric acid; these are probably to be considered as excretions. In all probability most excreta escape through the surface of the body or are expelled from the contractile vacuole.

Movement.—In many Protozoa the constituents of the protoplasm can be displaced inside the body, actually by means of currents in the cytoplasm (*see* CELL; PROTOPLASM) and some Protozoa can contract their whole bodies, some even particular parts of the body, by means of their myonemes

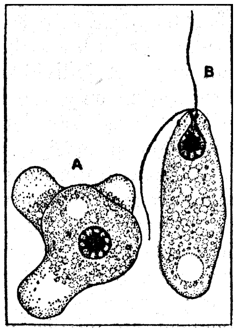
Active locomotion on the other hand is achieved in some form by nearly all Protozoa; there are certainly a few almost incapable of movement, either because they have settled and grown on a fixed body (fig. 12) or because they do not possess true motile organs. The movement of protozoans can be effected either by proper organs for the purpose or in various other ways. The simplest organs of motion are the so-called pseudopodia, which are outgrowths from the body, of the most varied form; these can be extended or withdrawn at will. They serve for a kind of creeping movement; the pseudopodium is formed and sticks to the material underfoot; then a new pseudopodium is stretched out on the side of the old one in the direction in which movement is to take place, and protoplasm now flows on to this In this simple way the whole protoplasmic mass is rearranged bit by bit and the protozoan moves forward. Protozoans whose pseudopodia are relatively small in proportion to the whole body form their pseudopodia just like Amoeba, but use them much more like real feet, putting them out in the direction of movement and then drawing them in again These pseudopodia may be quite thin and delicate, branched or netted, and are then called rhizopodia The mechanism of amoeboid movement is not yet fully explained.



FROM DOFLEIN, "LEHRBUCH DER PROTOZOENKUNDE" (FISCHER)
FIG. 14 —POLYSTOMELLA CRISPA
Copulation of the gametes (A–C) flagella being thrown off; (D) young microsphaerical individual which has arisen from zygote; (E–F) formation of the chambers. Magnified 2,000 times

Quite another kind of movement is that by means of cilia and flagella. The whip-like flagella (fig 16) either rotate, as in a circle described by an index-finger with the hand at rest, or strike like the lash of a whip; the rotation has a sucking effect like that of an aeroplane propeller and this drives the protozoan forward. The whipping action of the flagellum is not so well understood.

The cilia are usually arranged in thick complex bands (fig. 6) and beat, *i.e.,* they move like an index-finger that bends to strike a keyboard and then straightens again. Usually the cilia work together, every cilium in the row beating a little later than the next before it, so that a wave appears to pass completely over the row. This phenomenon has often been compared to the effect of a gust of wind passing over a cornfield. The blows of the cilia have a rowing action very like that of a duck's foot. The cilia of sessile protozoans produce currents in the water which carry the particles of food into the neighbourhood of the cytostome. The lightning quickness with which the forward movement may be modified is due to an alteration in direction of the beats of the particular cilia or through co-ordinated work of individual rows of cilia. "Cirri" strike just like cilia but being so much stiffer function more like legs.



FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN" (BORNTRAEGER)

FIG. 15.—VAHLKAMPFIA BISTADIALIS

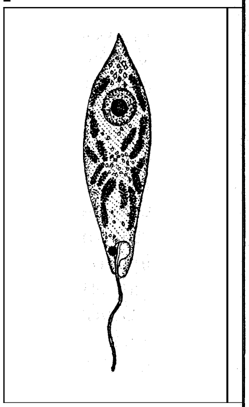
(A) Ameboid stage in semi-damp surroundings; (B) flagellate stage in water. (Magnified 800 times)

The myonemes of protozoans serve in the main only for alteration of the form of the individual's body. Some protozoans can pull themselves together like a hedgehog or as a snail draws itself into safety within its shell. They do not do this slowly, however, but suck together with lightning rapidity; the best known example is the pulling together of the stalk-muscle of the vorticellids. Some protozoans can creep along with the help of their myonemes in a way probably not very different from snails.

The rapidity of all these kinds of movement is very variable. The most efficient are ciliar and flagellar movement, although even these are in no way comparable in their effect with the rapid movements of the higher animals. The movements of flagella and myonemes are often amazingly quick yet the greatest speed they could induce in the protozoan would be usually not more than $\frac{1}{10}$ or even $\frac{1}{20}$ in. a second. Creeping by muscles or pseudopodia is naturally much slower, at the most $\frac{1}{1000}$ in. a second.

Physiology of Sensation.—Protozoa are sensitive to the following stimuli: (1) light; (2) mechanical disturbance, such as a blow; (3) change of temperature; (4) chemical stimuli; (5) electrical stimuli. Not all protozoans react to all of these stimuli; there are, for example, many protozoans that seem to have no sense of light.

Proper sense organs are as yet scarcely known amongst the Protozoa. Only a peridinean (Erythropsis) has a stigma constructed in a complex fashion which may be thought to function like an eye, although this has not been proved. Probably, however, all stigmata serve for light perception and some cilia may sometimes function as feelers.



FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN (BORNTRAEGER)

FIG 16.— EUGLENA VIRIDIS VEGETATIVE INDIVIDUAL (MAGNIFIED 850 TIMES)

The mode of transmission of sensations, like the presence of sense-organs, is as yet unknown. When the fore-end of certain protozoa is disturbed, and as a result the whole animal contracts, we can only conclude that the point touched has given an impulse to the myoneme.

Practically the only reactions we can recognize at sight in protozoans are those consisting in movement. Light-sensitive protozoans swim towards the light. Touch-sensitive protozoans contract when they are touched, alter their direction of movement or try to swallow the offending object. Some chemical stimuli, e g , weak acids, have the effect of frightening protozoans away from the region, whereas others such as oxygen or a food-particle have the opposite effect.

REPRODUCTION

Most higher animals reproduce sexually, *i e.,* they produce eggs and sperm and bring them together so that the egg is fertilized by a sperm and then develops into a new individual. Only a few Protozoa can be shown to multiply in this way, and most can reproduce without this process; indeed in many protozoans reproduction does not depend on fertilization and there is no connection between them (see below).

The method of reproduction which is found most frequently is simple division into two. An individual splits into two pieces of which each soon appears just like the animal before splitting (fig. 7, 8). This seemingly simple division is in reality a very complex process. First the nucleus divides and if several are present they all divide about the same time; then the cell body usually splits by stretching out and being constricted; a ring-shaped furrow gradually cleaves the cell in two as if a loop of string had been put round the middle and were being pulled tight. This division furrow has usually a defined position on the axis of the protozoan; some divide longitudinally (fig. 7), others transversely (fig. 8).

In many cases the "new-born" daughter-animals, as mentioned above, are soon indistinguishable from their parents; this means that they have reconstituted the set of cell-organoids, which is done for some of the latter, such as the chromatophores, by division as in the nucleus; other organoids are merely distributed and each daughter-cell makes good those it lacks; in this way the flagella and cilia are divided. When the basal granule splits one piece of it takes the flagellum with it and the other forms a new flagellum (fig. 7). Finally there are organoids in no way taken over from the old individual, having been pushed out during the division or even dissolved in the protoplasm. Such organoids are formed anew in each daughter animal (fig. 8). Protozoa that are enclosed in a hard shell often divide in such a way that although the protoplasm has divided quite equally only one of the two parts takes over the shell while the other slips out and builds a new shell.

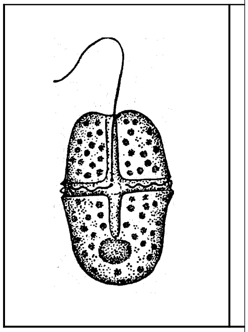
Nuclear Division.—Before considering the other kinds of division, something must be said of the division of the nucleus in the Protozoa. In multicellular plants and animals division is a highly developed process whose most important feature is the appearance of thread-like or rod-shaped bodies called chromosomes. At the same time—often under the influence of the centrosomes, ball-shaped organoids present in the cell at first singly but at division splitting into two separate halves—a fibrous, often spindle-shaped body is constituted; this is the spindle, and to it the chromosomes attach themselves in such a way that they come to lie in a plate across the spindle, at either end of which the centrosomes are found.

At this stage the nuclear membrane dissolves. And now each chromosome splits along its whole length into two exactly equal halves, which pass to opposite poles of the spindle. As all the halves do this at the same time, two groups of daughter chromosomes are constituted, each with a number of chromosomes exactly equal to that which the mother-nucleus had at the beginning of the division. Finally each group of chromosome halves gradually takes the form of a nucleus and the spindle disappears.

Nowadays we know fairly well what this complicated process called *mitosis* (see CYTOLOGY) really means. The chromosomes are protoplasmic bodies having an individual character, that is, they can only arise by division of other chromosomes exactly like themselves. Moreover in the so-called resting nucleus, *i.e.,* the non-dividing nucleus, they carry on their individual existence. We know further, that they are the bearers of the hereditary properties of the animal. It is for this reason that they are so carefully divided and distributed to the daughter-nuclei at division. The spindle is the apparatus that organizes the exact separation.

Besides mitosis there is another kind of division called direct nuclear division or amitosis. It consists of a simple cleavage of the nucleus into two pieces and only appears in cells that are more or less abnormal or at any rate are incapable of giving rise to offspring with any chance of prolonged survival.

Earlier it was thought that amitosis was very widespread as the normal method of division in the Protozoa; it was even thought that in contrast to mitosis it was the primitive, the original, **type** of nuclear division and that in some of the Protozoa the transitional forms between mitosis and amitosis were preserved. Such is not the case; in all groups of Protozoa we recognize to-day the occurrence of true mitosis, as complicated in every way and indeed often much more complicated than in multicellular animals. As a matter of fact those processes which were thought to be transitional are nothing but mitoses whose true nature has been concealed by a variety of peculiar circumstances (fig. g). In no case can we say that the method of nuclear division in the Protozoa is simpler or more primitive than in the higher animals and plants; the chromosomes of the Protozoa are no fewer than, and show in most cases the same peculiarities as, those of multicellular organisms, so that we may be permitted to regard them also as the bearers of the hereditary characters.



FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN" (BORNTRAEGER)

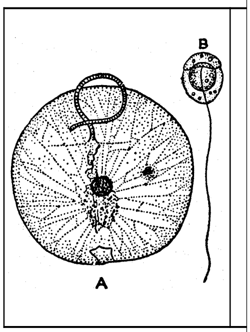
FIG. 17.—GYMNODINIUM AERUGINOSUM, A NAKED DINOFLAGELLATE (MAGNIFIED

Most cases of true amitosis in the Protozoa are more or less pathological; only the so-called macronuclei of the Infusoria divide regularly by amitosis (fig. 8), and we shall see later with what exceptional condition this is associated.

Apart from these types of division there is one more, multiple nuclear division, where the nucleus breaks up at the same time into numerous nuclei; this phenomenon is still very inadequately known. The so-called free nuclear formation has already been referred to.

Other Kinds of Division.—Some Protozoa do not divide into two daughter cells of equal size but into one large and one small. In these cases we call the division budding or gemmation and the smaller animal we call a gemma or bud (fig. 12). Yet another method of multiplication is a "multiple division" in which the noth her-animal divides at once into more than two—often several hundred—daughter-individuals (figs. 7, 13); sometimes the "mother" disappears entirely but sometimes a portion is left over, the so-called residual body, which finally degenerates. This process is preceded by a series of nuclear divisions (fig. 7).

The daughter-individuals arising by this process are rarely like the mother-individual. They are called, when provided with flagella, swarm-spores (fig. 12, 18b), and when surrounded by a stiff membrane and non-motile, spores; as a type these two forms are known as agametes. This unlikeness is also generally the case with gemmation and may occasionally arise from ordinary simple division. In all these cases, of course, the newly arisen smaller individual has to pass through some process of development.



FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN" TRAEGER)

FIG. 18.—NOCTILUCA MILARIS

(A) Adult animal, (B) One of the swarm spores

Requirements of Reproduction.—A protozoan reproduces itself only once, for the mother protozoan divides itself into its daughter products. Further the protozoan, like the higher animals and plants, only reproduces when it is grown up and mature, having its special organization fully developed, and having reached its full specific size. When it arrives at this stage, division occurs automatically. The rate of multiplication, *i.e.*, the time that must elapse before a protozoan just arisen from division can divide again, is very different in different species and depends, apart from many other things, on the food-supply and normal size of the species. Relatively small protozoans that are well nourished are often mature in a few hours.

FERTILIZATION

We understand by fertilization (*q.v.*) the fusion of two cells and nuclei which are unequal, being differentiated sexually into male and female. The two cells that fuse together are called gametes, the product of their fusion the zygote. In the higher animals the gametes are called eggs and sperm and the zygote the fertilized egg. The latter rapidly divides to form a many-celled embryo, which later becomes a new individual of the species to which it belongs (see EMBRYOLOGY).

Amongst the Protozoa, most can multiply by simple division and many are only to be driven to the act of fertilization by exceptional external influences, such as lack of food, overcrowding, accumulation of the products of metabolism and so on. And even then fertilization is sometimes not associated with multiplication but rather with a reduction of numbers, for the gametes are here not parts of individuals but often whole individuals so that at fertilization only one individual is produced by two. The zygote produced develops into an ordinary individual which only then can begin to multiply.

With such protozoans fertilization seems merely an intermezzo, virtually superfluous, which, as we shall see later, can be left out entirely under favourable conditions of life; it may be mentioned here that there are many protozoans in which we know no sexual process and in which there very possibly is none, *e.g.,* euglenoids and trypanosomes. There are protozoans on the other hand as dependent on fertilization for their reproduction as most of the higher animals. A gregarine for example cannot multiply by plain division; once mature it shuts itself up, together with another individual, in a capsule and each breaks up by multiple division into a large number of small gametes, leaving over the so-called residuary body. After this the gametes of the one fuse with those of the other; each of the numerous zygotes formed in this way surrounds itself with a thick membrane: it is now called a spore; inside this membrane the zygote divides into eight elongated cells, the sporozoites. These sporozoites are embryonic gregarines which, as soon as the spores get into the gut of the animal in which the particular gregarine grows—its "host"—slip out and grow into mature animals. Here then sexual reproduction is apparently indispensable to the continuance of the species.

It has been supposed, almost down to the present day, that fertilization is necessary to all protozoans, if not actually as a means of reproduction then for some other reason; it was thought to have been proved that Protozoa that had for some time multiplied only asexually, gradually aged; that they became weaker, showed all kinds of symptoms of degeneration and finally petered out altogether as a strain if they failed to find an opportunity of fertilization. After fertilization, on the other hand, the organism's vitality appeared to be restored. Hence it was concluded that for the maintenance of the race mere asexual division was not enough; that after a certain period of this kind of multiplication a process of senescence necessarily supervened and that this danger could only be escaped by sexual reproduction or some other kind of reorganization such as parthenogenesis (*q.v.*). Hence fertilization was called a process of rejuvenation. The observations on which this assumption was based are undoubtedly correct, yet the conclusions that have been drawn from them are only applicable to a limited group of Protozoa—the infusorians—and not even applicable to all species of these.

Other protozoans of various kinds (*Eudorina, Actinophrys*) have been kept for years under the most careful observation and it has been determined that so long as they are kept under favourable conditions of life they will reproduce asexually year in and year out, probably indefinitely, without degeneration.

This fact is referred to as the "potential immortality" of the protozoan; a multicellular animal must die because it can only reproduce by discharging from its system cells which develop into new individuals while its body cells are incapable of indefinite reproduction or existence. A protozoan, on the other hand, which divides into two and passes into its offspring entire, does not need to die. Such death as it undergoes is not the result of senility but of an accident. It is indeed potentially immortal.

Let us now turn to the different kinds of fertilization that occur amongst the Protozoa; we find here a much greater diversity than amongst the higher animals and plants. The gametes of the Protozoa are not always so different from one another as the sperm and egg-cells of the higher animals. It is true that some types exist in which the female gametes look just like animal egg-cells;

i.e., they are relatively large, stationary cells, rich in reserve materials. The male gametes in these species are constructed on the same plan as animal spermatozoa; they are relatively small, deficient in protoplasm and are exceedingly mobile. We call the protozoans whose gametes differ in this way "oogamic," the female gametes "macrogametes," the male "microgametes." But there are protozoans in which the pairs of gametes are absolutely indistinguishable; in these cases we speak of "isogamy" (fig. 10). All imaginable transitional stages are to be found between isogamy and oogamy.

The point must be made clear that in the so-called vegetative phase individuals of most protozoans do not show whether they are male or female. Sex-determination itself, that "something" that makes the difference between a male and a female, is not really understood in most cases. In some species it has been shown that the distinction is the result of the "reduction-division" that follows fertilization. This reduction-division consists in the separation of the two chromosomes, determining respectively maleness and femaleness, and their distribution to opposite cells which take the sex determined by these chromosomes. In those sexually differentiated Protozoa in which the reduction-division takes place immediately before fertilization, sex-determination is probably of the same kind as in the higher animals (see SEX).

Two remarkable variations of merogamy are specially worth noticing. One is called autogamy. While as a rule only gametes from different individuals are capable of fusing, in some Protozoa it happens that gametes that are the progeny of one individual will fuse. When this occurs, as in Actinophrys, a heliozoan, where the vegetative individual first splits up into two gametes, one male, the other female, which then fuse, we call the process "paedogamy." When however the cell-division that follows the so-called pregametic nuclear division is suppressed, and the whole sexual process really consists in a nucleus dividing and the two halves fusing straight away we speak of "autogamy."

Of quite another kind from those just considered is the process called conjugation, found only in the infusorians and suctorians. Two individuals meet, unite at one point and exchange gamete nuclei. It must be remembered that the infusorians have nuclei of two kinds, large macronuclei and small micronuclei (fig. 4). In the simplest case an infusorian has one nucleus of each kind. The two conjugating individuals (conjugants) unite first at their cytostomes (fig. 10). Then, as the next step, the micronucleus of each conjugant divides; the products of its division divide again and now three of the four new nuclei degenerate. The remaining nucleus divides itself again so that each conjugant has now two nuclei, offspring of its micronucleus. The macronucleus of each conjugant has meanwhile broken up and later disappears altogether. And now out of each individual one nucleus, the "migrating nucleus," wanders into the other cell and fuses with the stationary nucleus there left behind. The two infusorians, now called "ex-conjugants" separate at this point and from the fusion-product of the stationary and the migrating nuclei arise new micro- and macro-nuclei; in the simplest form of the process the fusion nucleus simply divides and the two halves develop into micro- and macronucleus respectively.

In conjugation therefore it is not two cells that fuse to make one, but two hermaphrodite cells each of which forms a male, migrating, and a female, stationary, gamete-nucleus; the cells then exchange their male nuclei just as pairing snails or earthworms exchange their sperm. It is not hard to see why conjugation should rejuvenate these Protozoa, because the macro-nucleus degenerates and is re-formed from the fused gamete-nucleus; in doing this the organism dispenses with an old cell-constituent, the new one being supplied from the "potentially immortal" micronucleus.

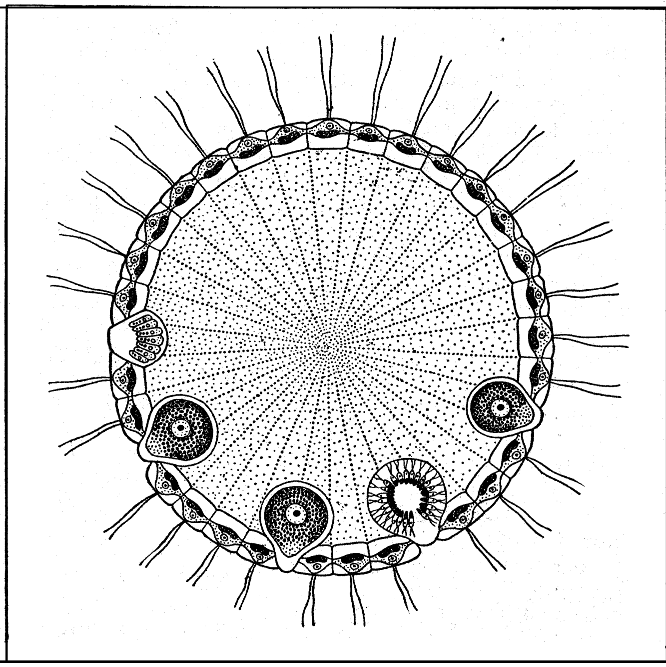
We have so far only concerned ourselves with the gametes of the Pratozoa; nothing more need be said about the process of their fusion, but what happens afterwards? The question is not at all easy to answer. The fate of the zygote amongst different species of Protozoa is very various. Only very seldom does the zygote turn directly into an ordinary vegetative individual, as is the case with the infusorians. Foraminifera (fig. 14) and myxomycetes. Usually at least a short resting-stage is intercalated; the cell surrounds itself with a stiff membrane and only later escapes from it to become again a vegetative individual; such is the case with the heliozoan, *Actinophrys,* and the Volvocineae. Very often however the zygote begins soon after fertilization to multiply in some special way. It breaks up by multiple division into a number of uninuclear cells which may surround themselves with membranes and inside these divide further. Only from the germs formed in this way can new vegetative individuals arise.

Amongst Protozoa, as in the higher animals and plants, reduction divisions of chromosomes have also been shown to occur; in some the division takes place just before gamete-formation; in others (Volvocineae, Coccidia), shortly after fertilization. In view of what we already know of nuclear division in the Protozoa it is not at all surprising that the course of reduction division turns out to be in some cases (*e.g.,* in *Actinophrys*) quite as complex as in the higher animals. (See CYTOLOGY.)

Parthenogenesis.—The egg cells of some animals and plants are known to be capable of developing without fertilization into new individuals; this kind of development we call parthenogenesis (*q.v.*), and it is not unknown among the Protozoa. In Actinophrys for example both gametes instead of fusing can encyst separately, shutting themselves up in a capsule, and later reappear as vegetative individuals.

ENCYSTMENT

We have already had occasion to show that zygotes may become enclosed in a rigid membrane. But the vegetative individuals of many Protozoa are also capable of doing so. This process, called encystment, is only met with as a rule when a shortage of food sets in or when the water in which the creatures live begins to dry up. This kind of cyst we call, in contradistinction to the "fertilization cyst" referred to earlier, a "protective cyst." Apart from these we



FROM KUHN, "GRUNDRISS DER ALLGEMEINEN ZOOLOGIE FUR STUDIERENDE" (THIEME)

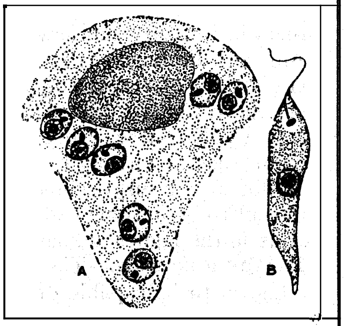
FIG. 19.—VOLVOX GLOBATOR: DIAGRAMMATIC SECTION THROUGH A GAMETE-FORMING COLONY

ought to mention the "reproductive cyst"; some protozoans do not divide in the free motile state, but first encyst, the products slipping out again after division.

When about to encyst the protozoan rounds itself off, secretes a membrane—which can afterwards be strengthened—and throws off or absorbs most of its organoids, such as flagella, static fibrillae, etc. (those of course remain which can only be reproduced by division, such as the centrosome and chromatophores). Finally it exudes a portion of the sap present in the protoplasm. Encystment consists then not only in the formation of a capsule but of a process of dedifferentiation of the individual, a reversion to a quasi-embryonic condition. The membranes are to ensure that the cyst shall be able to withstand complete drying out and the action of chemical compounds such as weak acids that would kill the vegetative individual. The thickening (dehydration) of the protoplasm ensures the resistance of some protozoans to temperatures as high as 60° C (180° *F*) which certainly could not be borne by the same species in the vegetative condition.

The encysted protozoan is in a condition of dormancy; it has no metabolic activity that can be proved, and it can in consequence survive in this "latent" condition for a very long time.

Germination (encystment) calls for little comment. The cysts sf many protozoans have weak places left in the coat at which they open as at a hinge or suture or even pores filled with plugs of silica; but in most cases the cyst-envelope bursts open like the shell of a lizard's egg (fig. 11). This explosion is often due to the absorption of water by the protoplasm and its consequent swelling in the early stages of growth, but sometimes it is due to the swelling of the inner layers of the cyst membrane.



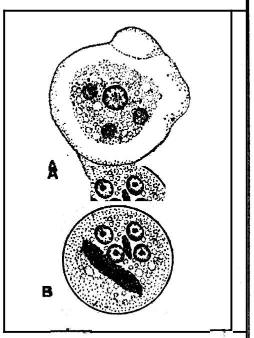
FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN (BORNTRAEGER)

FIG. 20 — LEISHMANIA **DONOVANI** (A) White blood-corpuscles, in which the non-flagellate individuals lie (magnified 3,000 times): (B) individual provided with a flagellum (magnified 1,800 times)

The protozoan shortly before it emerges usually reconstitutes many of its typical organoids; on swimming out it completes this process and resumes its vegetative life.

DEVELOPMENT AND REGENERATION

A process equivalent to the development we find in the higher animals and plants from embryo to adult is found to some extent in nearly all Protozoa with the exception of those in which the dividing mother-animal splits every one of its organoids and distributes them to its daughter-cells. But this process of development, being limited in many Protozoa to the regeneration of the organoids after encystment or division (fig 8) takes very little time and does not give any impression of complexity. Complications that strike us as being like the early steps of embryonic development in multicellular organisms are found in the Volvocineae, at whose reproduction one cell gives rise to a colony (fig. 2, 19). The development of other protozoans such as the foraminiferans is a lengthy process (fig. *13*, 14), and in some we even find that peculiar roundabout way of developing, by repetition of ancestral forms, that is so often found in the higher animals. These processes are comparable to the formation of the gill-arches in early life by mammals (*see* EMBRYOLOGY and VERTEBRATE EMBRYOLOGY).



FROM KUHN, "MORPHOLOGIE DER TIERE IN BILDERN" (BORNTRAEGER)

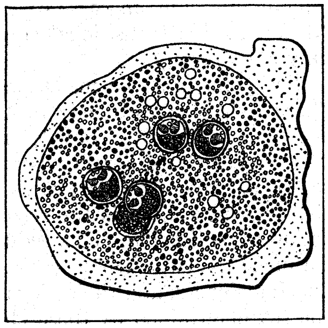
FIG. 2.—ENTOMOEBA HISTOLYTICA (A) Vegetative individual, (B) four-nucleated cyst type of this organism

A process physiologically related to development is regeneration (*q.v.*), the replacement of lost body parts. Some protozoans are not capable of this; the capacity of the others varies in degree Some can only reconstitute their flagella, which they may have been caused by certain stimuli to cast off. Others may be cut into small pieces, and every one of these will grow up into a new individual—provided of course that it has at least part of a nucleus (fig. 3).

LIFE-CYCLES: ALTERNATION OF GENERATIONS

The successive stages of development of a higher animal such as a bird can be looked upon as a cycle; if we begin with the fertilized egg the embryo follows, then the young animal, then the mature animal that again produces eggs; the cycle is complete. In some animals, such as the green-flies or aphids (*q.v.*), several generations have to be gone through before this cycle is closed. In each of these instances, in birds and in aphids, we can speak of a life-cycle; in the aphids we can also recognize an "alternation of generations."

Naturally every organism has a life-cycle, even a protozoan that multiplies by division, for here also young animals are produced by division that only later come to resemble the creature that produced them. But it has become usual to speak of a life-cycle only when some other special process is introduced into the life history. An infusorian can for example multiply by division, but it can also encyst or it can conjugate. Now we speak of an obligatory or of a facultative life-cycle according to whether the succession of events in the life-history is strictly determined, on the one hand, or capable of a certain amount of adjustment, on the other. The obligatory life-cycle is governed solely by the intrinsic properties of the individual, running its course, provided only that the ordinary requirements of life are met; the other, the facultative life-cycle, is profoundly influenced by such external conditions as temperature, nutrition and the condition of the medium in which the organism lives.



FROM THEOLAN, "LES MYOSPORIDIES" (LES PRESSES UNIVERSITAIRES)

FIG. 22.—SPHAEROSPORA DIVERGENS A small adult individual containing 5 spores (magnified 540 times)

There are Protozoa on the other hand that have a clearly facultative career, as they can reproduce by simple fission for an indefinite number of generations; whilst under certain conditions they are forced to copulate or encyst (*e.g., Antinophrys*).

There is also an obligatory life-cycle in those protozoans that show an alternation of generations. By this alternation we understand a succession of generations that are distinct from one another both in their form and in their method of reproduction. The classical example of protozoans with an alternation of generations is the Foraminifera (fig. *13*, 14). In most of these two distinct types can be recognized, the so-called micro- and macro-spherical individuals. The microspherical individuals are the asexual generation; as soon as they are mature the protoplasm breaks up into numerous germs, "agametes," which creep out of the shell of the mother-individual and gradually develop into new individuals—but individuals of the other, the macro-spherical, type. Then the protoplasm of these breaks up, this time into gametes, and after fusion we have the microspherical generation again (fig. 14).

FIG. 23.—MYXOBOLUS ELLIPSOIDES (A) Frontal view with capsules not yet exploded, (B) side view of same, (C) frontal view with capsules exploded

VARIABILITY, POLYMORPHISM, HEREDITY

Like all other organisms the Protozoa can be profoundly modified by various external conditions such as temperature, nutrition and state of the environment. Scarcity of food supply often leads to dwarfing, a rich supply to relatively giant growth. Some protozoans are so dependent on eternal factors, so malleable, that they may be altered beyond recognition. For example some *Amoebae* that live in half-moist surroundings by transference to water come to develop flagella and turn into flagellates (fig. 1j). In view of this mutability it was earlier hoped—when the protozoans were regarded just as primitive organisms—that changes from one species to another might be observed directly. This hope has not been fulfilled.

In other words, the inheritance of acquired characters is as little proved in the Protozoa as in the higher animals and plants. Certainly characters "acquired" by a protozoan under the influence of special external conditions reappear in the offspring. But this reappearance does not last very long.

Modifications of this kind are called "enduring modifications," in contrast to genuine hereditary variations (so-called mutations) which have been observed in some forms and remain constant through any number of divisions and fertilizations.

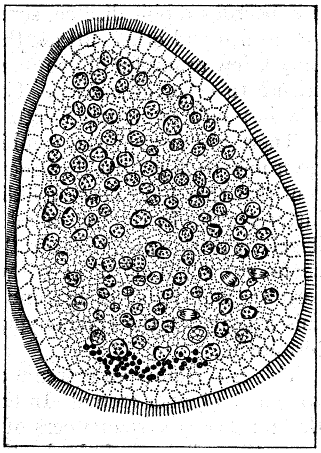
PHYLOGENY

We have already pointed out in the introduction that the different classes and orders of the Protozoa are not related to one another as those of the vertebrates are; that on the contrary a vast number of groups have been united under the "phylum" Protozoa for the sake of convenience. On this account it is useless to speak of the "phylogeny" of the Protozoa as a whole. In a few groups only is it possible to distinguish more primitive from more highly developed forms and make a kind of genealogical tree. An example of such a developmental series has already been touched upon. In the Volvocineae it can be clearly seen how cell-colonies have arisen from single-celled types and how a division of labour has followed.

HABITS OF LIFE

The protoplasm of all living creatures contains water and it can only survive dry conditions so long as it is in some way protected from drought. The vegetative stages of nearly all Protozoa being unprotected they can only live in a moist medium; their cysts on the other hand can remain dried up for a long time. We find Protozoa therefore in all kinds of fresh waters, as well as in the sea. They are also found free in moist earth and moss, and as parasites they occur in the body-fluids (blood, intestines, etc.) and tissues of animals, occasionally even of plants. Their cysts can be found wherever they are carried by wind and by other organisms,

Not only is the distribution of the Protozoa strictly limited by water-content but it is further limited by temperature and salt-content. Most free-living, *i.e.*, non-parasitic, Protozoa will scarcely stand temperatures of more than 30° C (86° F) and temperatures of above 45° C (113° F) or below zero C (32° F) are fatal to most species in the vegetative condition. In hot springs, however, infusorians have been found at temperatures of 64° C (148° F) and freezing has been resisted by some species. In the same way too strong solutions of salts such as those in the Algerian salt lakes render protozoan life impossible.



FROM METCALF, "OPALINID CILIATE INFUSORIANS"

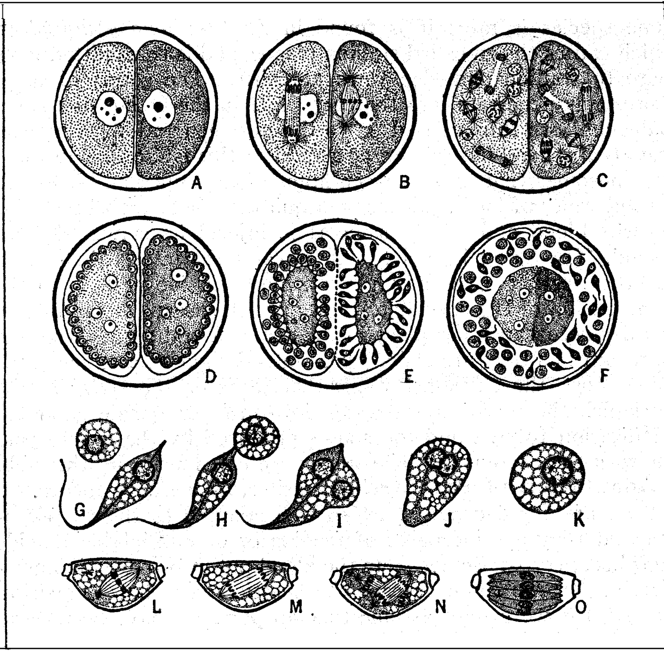
FIG. 24.—OPALINA RANARUM: (VEGETATIVE INDIVIDUAL) WHOLE ENDOPLASM FILLED WITH DARK-COLOURED BODIES, AS INDICATED IN THE LOWER HALF OF THE FIGURE. [MAGNIFIED 230 TIMES)

Naturally one of the essentials of life is the possibility of getting food; this requirement is met in each of the habitats that we have mentioned for one species or another. It is the most important factor, apart from temperature, that exercises a decisive influence in determining the life-cycles of protozoans which go into a period of winter rest in the encysted condition.

Every protozoan is more or less strictly adapted to its natural environmental conditions. Thus it may find life altogether impossible in conditions varying a little from the normal, although these may be the natural ones for another species. For example, a freshwater protozoan cannot exist in the sea, nor a blood-parasite in fresh water. Yet there are Protozoa that are very adaptable in these respects; some species normally living in fresh water can live for a considerable time in the intestines of animals or in the dissolving fluids secreted by carnivorous plants; intestinal protozoans of some animals can live on in the intestines of others that have eaten their first host.

Free-living Protozoans.—We can divide the Protozoa into ecological groups according to their modes of existence, remembering however that these groups are joined by every intergrade. The one all-important distinction is of course that between free-living and parasitic Protozoa.

The free-living Protozoa are composed of plankton forms, swimming forms, bottom-dwelling forms and soil forms. Plankton forms, though also present in fresh water, are characteristically found in the sea. They are Protozoa that, for the most part, although unprovided with any special motile organs, are able to float in the water and are carried by the currents.



FROM LEGER, 'REPRODUCTION SEXUEE CHEZ LES STYLORHYNCHUS" (GUSTAV FISCHER)

FIG. 25.—DIAGRAM OF THE LIFE-CYCLE OF A GREGARINE

(A) Two gregarines encysted together; (B) beginning of nuclear division; (C) later stage of nuclear division; (D) cutting off of the gametes; (E) gametes fully developed: (left) female, (right) male; (F) wall between the gametes dissolved, and gametes come together; (G–H) male and female gametes; (I–K) union of the gametes and of their nuclei; (L–N) nuclear division in the xygote (spore); (O) division of the contents of the spore into numerous sporozoites

Swimming forms (Nectonta) are protozoans that swim about with cilia and flagella, and in so far as they are heterotrophic do not as a rule waft in their prey but actually chase it. We find them in all kinds of water, from the sea down to mere puddles.

Bottom dwellers (creeping forms) live only on the bottoms and sides of ponds, lakes and so on, and creep only upon firm ground; some can swim a little, others are rooted firmly in their place. Their food is varied; at very great depths the autotrophic forms cannot of course exist because they need light, but they occur nevertheless in every possible kind of watery place. Most foraminiferans and amoebae are typical bottom dwellers.

Parasitic Forms.—Amongst Protozoa endoparasites are in the majority. Most parasitic Protozoa flourish in or on animals including other Protozoa, and there is scarcely any animal group that is free from them. A few forms parasitize plants; some, *e.g.*, flagellates, are found in the latex (or "milk") of the spurges (*Euphorbia*). Ectoparasites are naturally commonest on water animals and on moist or mucilaginous parts of the skin of land animals; these can either creep about or swim or remain rooted to one place. Most ectoparasites however are not true parasites, and merely use their foothold on their host to extract food for their environment, moving away as occasion requires.

Endoparasites inhabit body-cavities like the gut, veins, gall-bladders and so forth, as well as every conceivable tissue, where they lie between the cells, as tissue parasites, or bore their way inside the cells, as cell-parasites. Some move about fairly freely, others are almost immobile.

The great majority of the endoparasites feed by osmotic absorption; that is they live on dissolved nutriment that they either find ready for them, as in the blood or the digestive tract, or that they have to prepare by secreting substances to dissolve the cells of the host.

Most parasitic protozoa are transferred from one host to another by forming cysts, which escape into the open and are then picked up by the new host quite by chance—usually by being eaten. Direct transmission from one animal to another of the same species-is rare; it is found in *Trypanosoma equiperdum,* which causes the so-called stallion plague, and is transmitted from mare to stallion and vice versa at coitus. The germs of other protozoans penetrate into the eggs while in the bodies of the females and are thus carried on to the next generation. Very frequently a second host serves as a carrier; this is the case in those trypanosomes that pass between human or mammalian blood and the intestines of insects such as mosquitoes; the insect when biting absorbs blood and at the same time injects its saliva into the wound. The insect is called in these cases the intermediate host. In other instances the host plays a more passive part, as in the transmission of the coccidian Aggregata: the asexual reproduction of this protozoan takes place in the gut of a crab; the germs (or merozoites as they are called) pass into the gut of a second—the chief—host, the cuttle-fish Sepia that feeds on the crab. In the cuttle-fish the merozoites develop into male or female gametes; fertilization follows and the spores produced by the zygote pass cut with the excrement. The spores are eaten again by the crab.

Adaptation of Parasites.—Parasites, as we have mentioned before, are for the most part so well adapted to their habit of life that they are incapable of feeding or of multiplying outside their host; trypanosomes from the blood put into water die immediately. Yet we cannot escape the question as to how parasitism started, for we cannot assume that all parasites have been parasites since the beginning of time; on the contrary, they must have arisen from free-living forms. We have now a few facts that make the transition from a free-living to a parasitic form if not entirely clear at least to some extent intelligible.

For one thing the resistance of many free-living Protozoa to the digesting fluids released by insectivorous plants, *e.g.,* pitcher plant, shows a remarkable degree of adaptability. Another thing is the extraordinary adaptability of some parasitic protozoans; the gut-parasites of the frog tadpole live for instance in the gut of the horse-leech, which eats the tadpole, and there grow and multiply; and some gut-parasites can live equally well in the blood of their host, if by chance they should get into it.

Most striking are the reproductive adaptations of the parasites, for the reproductive mechanism is often governed absolutely by its requirements in relation to its host or hosts as the case may be. First the remarkable fertility of parasites must be mentioned as an adaptation to their form of life, for in spite of their easy existence the possibility of their dying in or with their hosts is a serious menace to the maintenance of parasitic species, for only a minute proportion of the germs can have a chance of finding another host. We have already referred to an adaptation of an entirely different order, namely the division of the life-cycle into two periods spent in different hosts; the combination of an alternation of hosts with an alternation of generations. The classical example of this is that of the malaria parasite. The bite of the mosquito injects the sporozoites into the blood; there they bore their way into the red blood corpuscles and develop into the agamonts; these break up by multiple division into the merozoites and in doing this burst the corpuscles whose substance is already depleted by the parasite. The merozoites bore into fresh corpuscles and repeat the story, or they can transform themselves into macrogametocytes and microgametocytes, which wait for some time until chance takes them into the stomach of a sucking mosquito. If they have to wait too long they die, but if they succeed in getting into the mosquito's stomach without undue delay they are able to complete their life-cycle; the microgametocyte breaks up into microgametes, these fertilize the macrogametes and the motile zygote bores into the stomach-wall of the mosquito. Here it grows, its nucleus divides many times and finally the sporont, as we now call the adult zygote, breaks up into a number of sporozoites. These migrate to and collect in the salivary glands of the mosquito and, if this should bite a human being, make their way with the injected saliva into the bloodstream of the victim. The cycle is now complete.

Relations of Parasite and Host.—The most important of the conditions governing the relationship of host and parasite have already been discussed. The host offers the parasite, unwilling to be sure, board and lodging; hence the name. In many cases however, the host seeks to protect himself from his guest or even if possible to destroy it; he sends out his phagocytes against the intruder, and these are frequently able to eat it; he isolates the parasite as far as possible, by shutting it off from the neighbouring tissue in a capsule; and finally makes and releases into his body-juices all kinds of poisons, anti-bodies, agglutinins and lysins (see IMMUNITY) which cripple or even destroy the parasite. A host that can build up enough of such protective materials can not only annihilate the enemy but can actually protect himself for some time against any repetition of the attack; he is said to be immune.

When we speak of parasitism it is difficult to avoid thinking that the host is necessarily injured by the parasite. Most parasitic Protozoa however are actually harmless; they live on surplus food and body-substance and do their host no harm at all. Every man, every frog, cockroach and earthworm, shelters innumerable parasitic protozoans without being injured by them in the slightest degree. Other protozoans on the contrary injure their host in a greater or less degree, not by taking away food, but by demolishing the body-cells of their host. Some types secrete poisons (toxins). As we have already mentioned, the malaria parasite destroys the red blood corpuscles of man. (See MALARIA.)

The malaria parasite is not the only pathogenic (*i.e.,* disease-causing) protozoan. Trypanosomes (fig. 7) have been shown to be the cadse of African sleeping-sickness and of a human disease not rare in South America, schizotrypanosis. *Leishmania donovani* (fig. 20) causes the kala-azar disease in India; Entamoeba histolytica (fig. 21) the tropical amoebic dysentery of man; many trypanosomes cause serious cattle plagues. A coccidian is responsible for a dangerous rabbit disease, some microsporidians are a great danger to fish and others attack the silk-worm caterpillar. These are only a few examples of the menace that parasitic protozoans constitute to other organisms. The pathogenic forms, however, are few in number compared with the harmless ones.

There are further the symbiotic Protozoa, which not only do no injury to, but actually benefit, their host; some to such an extent that they have become indispensable. We will begin with this latter group. In the gut of all wood-eating termites live peculiar flagellate protozoans, the so-called Trychonymphidae. These protozoans eat small particles of wood, the masticated food of the termite, and digest them; and it has now been determined that this activity of the trychonymphid is essential to the life of the termite.

This is certainly an extreme case of symbiosis between a protozoan and a higher animal. In the stomachs of the ruminants (cattle and sheep) vast numbers of infusorians are found, which consume the cellulose of the host's food and are probably as useful as the flagellates are to the termites; but they are not indispensable. Most of this work is done by bacteria, which also inhabit the stomach. Similarly, some radiolarians can easily do without the autotrophous peridineans that live with them.

ECOLOGY AND DISTRIBUTION

Many autotrophic planktonic Protozoa serve as food for other plankton organisms, such as the larvae of worms, sea-urchins and fishes—not exclusively, indeed, for the diatoms which far surpass them in number are more important as a source of food. In so far as, with diatoms, they supply food for fishes and smaller animals eaten by fishes, these protozoans are not without importance to man, fish being one of his staple sources of food supply.

Other marine Protozoa (Radiolaria and Foraminifera) that form shells of mineral matter, play quite a different part. In certain circumstances they can go to form solid rock. The shells of dead individuals collect, often in enormous numbers. on the sea-floor and form, generally with other mineral particles but sometimes without any other constituent, the fine silt or ooze that covers the bottom of the deep sea. In the Pacific (Rose atoll) a cubic metre of *Globigerina* ooze is laid down yearly over a surface of 150 sq m.; in other words a layer 0·66cm. thick every year or over two feet in a hundred years. 29.2% of the whole floor of the ocean, *i.e.*, over 40 million square miles, is covered with *Globigerina* ooze; the area covered with radiolarian ooze is estimated at nearly 12%. Chalk and sandstone are nothing but the ooze and silt of antediluvian seas; and certain rocks consist, entirely or almost entirely, of the shells of fossil Protozoa, Foraminifera, Radiolaria and Coccolithophorida.

As compared with the marine forms the fresh water Protozoa play a modest part; they certainly provide food for some animals, but they do not figure very largely in the diet as a whole. In waters with much decomposing animal and vegetable débris the protozoans take some part in what is called biological water-cleansing. In a ditch or pond containing much decaying matter the water is polluted with all kinds of bodies, but gradually cleans itself. First the decaying matter is broken down by bacteria and partly consumed. In this materials are found—mostly evil-smelling—that are needed by certain Protozoa for food and the water is therefore freed of them. The bacteria themselves are eaten by other protozoans. A similar part is played apparently by the soil Protozoa. In one gramme of earth from 100–50,000 amoebae, 1,000–100,000 flagellates and as many as 1,000 infusorians have been found. On the one hand they keep down the nitrifying bacteria (*see* BACTERIOLOGY) so necessary for higher plants; on the other hand they may effect nitrogen fixation themselves and so have the same effect as manure.

The species of fresh water and soil Protozoa are cosmopolitan; the protozoan fauna of pools and rivers is the same in Africa as in North America. This is due to the fact that the conditions of life in pools are much the same all over the world, and that the fresh-water protozoans can be carried very easily, especially in the encysted form, by wind and animals. In the sea the case is rather different; the water of the Pacific is distinctly different in salt content, temperature and other respects from that of the Mediterranean and corresponding to these differences we find different species limited to different seas. As an example of a cosmopolitan species on the other hand we have *Noctiluca miliaris,* the luminous flagellate (fig. 18). The geographical distribution of parasites naturally follows that of their hosts.

HISTORY OF PROTOZOOLOGY

Protozoa were first discovered in the latter half of the 17th century by A. van Leeuwenhoek (1632–1723) a Dutch amateur naturalist and chamberlain to the sheriff of Delft. Leeuwenhoek carried on his investigations with magnifying glasses and microscopes he had designed and made himself.

A systematic investigation and description of all known Protozoa was undertaken for the first time by the Dane, O. F. Miiller (1730–84). In the 19th century C. G. Ehrenberg, professor of zoology in Berlin (1795–1876), tried to show that Protozoa had an organization similar to that of the higher organisms. This attempt failed because Ehrenberg's scientific opponent, the Frenchman Dujardin, was able to demonstrate the unicellularity (in essence at least) of the Protozoa. The fact that Protozoa were unicellular was enunciated by the German zoologists M. Schultze (1861) and von Siebold. In the era of Darwinism the Protozoa were principally looked at from the point of view of the evolutionary theory; in them were seen the rbot-forms of the higher animals. Later on protozoans were recognized as causers of disease; the first pathogenic protozoan, *Nosema bombycis,* was discovered by Pasteur. The greatest advance in the study of pathogenic Protozoa began with the investigation of the Nagana cattle plague by David Bruce; by showing that this disease was caused by *Trypanosoma brucei* he opened a new era of activity in protozoological research which has carried us on to the present day. In this period the study of the body-structure, life-cycles and physiology have equally received attention. Amongst these the classical researches of the Englishman Ronald Ross and of the Italian B. Grassi deserve special mention, on account of their achievement with malaria, also the work of the German F. Schaudinn (1877–1906) on the life-cycle of the Coccidia and of many other Protozoans especially in regard to cytology.

CLASSIFICATION

We have already mentioned the fact that the different forms of life included under the name Protozoa do not show the same relationships as the different classes that we recognize amongst the vertebrates; indeed that many of them cannot be shown to have any relationship whatever with one another. This is true for some, but not for all, classes and orders of the Protozoa; some of these, such as the Flagellata, Protomonadina, Rhizopoda, Heliozoa, are not to be regarded as natural groups at all. They are convenient assemblages of organisms not demonstrably related.

We divide the Protozoa into five great classes:—

1. Mastigophora (Flagellata)
2. Rhizopoda
3. Telosporidia
4. Neosporidia
5. Ciliophora (Infusoria)

It should be clearly understood that (1) and (2) are both unnatural groups.

1. Class Mastigophora. (Flagellata).—Amongst the Mastigophora we count all Protozoans in which the vegetative individual is provided with flagella. The class itself is artificial; the first six of its nine orders are, however, natural. The Protozoa belonging to these orders are mainly autotrophic, but nearly all of these orders include colourless forms that are believed to have arisen by loss of their chromatophores; this process has been directly observed in some cases. Amongst these flagellates we ought therefore to regard the green forms as more primitive than the heterotrophous. Protozoa actually without a flagellum but showing a close relationship structurally to flagellate forms are naturally included in the Mastigophora.

1. Order *Chrysomonadina.* Very small autotrophic flagellates; one or two flagella; always free-living, in fresh and salt water; the chromatophores usually contain a brown pigment. The cyst, furnished with plugged hole, is characteristic of many Chrysomonadina; its membrane contains silicic acid. Unicellular and uninucleate; reproduction by simple fission; fertilization processes are only known in a few forms. A very large order in the number of its species; the most important family is the Coccolithophoridae consisting of marine chrysomonadines, which have shells composed of chalk disks and are important as food for many plankton organisms. Important types: *Chromulina, Oclzromonas, Dinobryon, Syracosphaera.*

2. Order *Cryptomonadina.* Biflagellate, autotrophic, entirely free-living flagellates of fresh water and sea. Chromatophores chiefly brown, characteristic flattened form of cell, unicellular, uninucleate. Reproduction by simple fission. Fertilization processes unknown. Important types: *Cryptomonas, Cltilomonas* (colourless).

3. Order *Chlorontonadina.* One or two flagella autotrophic; chromatophores with bright green colouring matter, the nature of which is not yet exactly known. One-celled, uninucleate.

4. Order *Euglenoidina.* Most have one, a few two, flagellae; usually autotrophic with a peculiar cystostome; (fig. 16); some of the autotrophic forms as well as the heterotrophic kinds can also eat solid food. Chromatophore green. In stagnant ponds and cesspools. The structure and division of the nucleus is characteristic. Unicellular and uninucleate. Reproduction by simple fission; fertilization only known in certain heterotrophic forms such as *Scytomonas.* Important types: *Euglena, Phacus, Trachelomonas, Peranenta* (heterotrophic).

5. Order *Dinoflagellata.* Usually with two flagella, lying in a special and characteristic way in two body furrows, one disposed longitudinally and the other spirally around the body (fig. 17). Both the structure and method of division of the nucleus are also characteristic. Most dinoflagellates are autotrophic; but

there are also some that eat living organisms, heterotrophic, and many parasitic forms which flourish in marine animals; these do not possess a flagellum. The autotrophic dinoflagellates are most generally provided with a plated cellulose armour. They live for the most part as plankton organisms in the sea. Usually unicellular—a few of the parasitic forms are multicellular—and uninucleate. Reproduction by simple fission or multiple division (swarm-spore formation) fertilization processes unknown. Important types: *Ceratium, Gymnodinium* (naked) *Blastodinium* (parasitic) *Oödinium* (parasitic).

The organism responsible for phosphorescence is *Noctiluca miliaris* (fig. 18) a rather large swollen bladdery uniflagellate protozoan, faintly red-coloured, heterotrophic, eating living organisms, which produces an intense light at night but only under the stimulus of a physical or chemical shock. The relationship of this form with other dinoflagellates is shown by the organization of its swarm cells.

6. Order *Phytomonadina* (Volvocineae). A group containing entirely free-living autotrophous biflagellate species with cup-shaped green chromatophores; a very few species are destitute of chromatophores and feed themselves in the way described above. The lower phytomonadines are unicellular, the higher, multicellular. Uninucleate. Reproduction by simple fission, or, in the multicellular forms, by rapidly succeeding divisions (fig. 2). Fertilization: in the lower forms (*Chlamydomonas*) hologamous and morphologically isogamous; in the higher forms (*Volvox*), oögamous. The zygote has a resting period and following this, in the unicellular forms four individuals slip out, and in the multicellular forms, a colony. The reduction division takes place shortly before the germination of the zygote. Important types:—*Chlamydomonas* (fig. 1), Polytoma (heterotrophous) *Gonium, Eudorina* (fig. 2), *Pleodorina,* Volvox (fig. 19). See also ALGAE.

7. Order Protomonadina (an artificial group). Heterotrophous organisms with one or two flagella. To this group belong the most important of the parasitic flagellates, the trypanosomes which are put with other forms in the family Rerpetomonadinae. The possession of a so-called blepharoplast is characteristic of the trypanosomes and various closely related forms. This organoid is a little ball of protoplasm lying directly under the basal granule of the flagellum; it resembles the nucleus in several characteristic properties and divides by simple fission (fig. 7). Earlier it was often regarded as a second nucleus, and was even given the name "kinetonucleus," but this view cannot be supported. The trypanosomes have only one flagellum; this is developed in the blood parasites as a characteristic undulating membrane (fig. 7). The equally parasitic Trypanoplasmae have also a second free flagellum; the free-living Bodonidae have two free flagella. The trypanosomes are blood parasites of the mammals, birds, amphibians and fishes; they swim in the blood plasma and are for the most part carried from one host to another by blood-sucking insects, or (in the case of fishes and frogs) by leeches. The related Leishmaniae are cell-parasites which only pass through the body fluids and are normally not equipped with flagella (fig. 20). Other relatives of the trypanosomes, the Leptomonadae, live in the intestines of insects that do not suck blood and are supposed to be the ancestral forms of the trypanosomes. Some trypanosomes are harmless, great numbers on the other hand are pathogenic; *e.g., Trypanosoma* gambiense, the cause of African sleeping sickness of man; Trypanosoma rhodesiense, cause of another kind of sleeping sickness; *Schizotrypanum cruzi* cause of schizotrypanosis of man in Brazil; Leishmania *donovani* (fig. 20) cause of the kala-azar disease of man; Leishmania *tropica,* cause of Oriental sore; *Trypanosoma brucei* (fig. 7) cause of the Nagana pest of hoofed animals in Africa; Trypanosoma evansi, cause of the surra pest of hoofed animals in India; *Trypanosoma equiperdum,* cause of the stallion plague (dourine) of horses.

The Trypanoplasmae flourish in the blood and intestines of many fishes as well as in the intestines of many invertebrates; it is not yet certain whether any of them are pathogenic. All parasitic Herpetomonadina feed osmotically. The group is unicellular and uninucleate, and reproduction is by simple or occasionally by multiple division. Sexual processes are unknown.

Another important family of the Protomonadina that must be mentioned is the Craspedomonadidae; it consists of free-living, unicellular, heterotrophic flagellates; they have a delicate collar around the flagella. They are unicellular and uninucleate. Reproduction by simple division, fertilization unknown. Important types: Codosiga, *Salpingoeca.*

8. Order *Polymastigina.* Flagellates, parasitic and "eating," with a very characteristic division of the nucleus. The lower forms (trichomonads) have 2–5 flagella, the higher (hypermastigina) have often several hundred. All are innocuous intestinal parasites of vertebrates, including man, and of insects. The Trichonymphidae are symbiotic with the wood eating termites (see above). The Polymastigina are unicellular and usually uninucleate; only a few of the higher forms such as *Calonympha* are multinucleate. Reproduction is by simple fission, no sexual process being known. Important types: *Trichomonas* (T. *intestinalis* is a harmless intestinal parasite of man, T. *buccalis* Iives in the tooth-insertion of man), *Trichonympha.*

9. Order *Distomatina.* Heterotrophic, free-living and eating living organisms or parasitic; they have the appearance of two flagellates stuck together. They have two nuclei and two flagellar apparatuses. Reproduction is by simple fission; fertilization processes are unknown. Important type: Giardia, an intestinal parasite (probably innocuous) of man and many other mammals,

2. **Class Rhizopoda.**—These are heterotrophic protozoans in which the vegetative individual moves and feeds with the aid of pseudopodia. It is an altogether unnatural group; this faculty of producing pseudopodia cannot be regarded as a specific character, for it' is found in such widely distinct structures as leucocytes (white blood corpuscles) and some spermatozoa of animals and even in the gametes of some algae.

1. Order *Amoebina.* Rhizopoda that have amoeboid movement, *i.e.,* they travel by means of broad pseudopodia produced over the whole body surface. This group is as unnatural as the class Rhieopoda (see above). The amoebae were for a short time regarded as the most primitive, because structurally the simplest, of living organisms. Nowadays this view is not held. We know, for instance, that certain Chrysomonadae are definitely without flagella and show amoeboid movement; they are amoebae. Yet in every other character they are typical Chrysomonadae. It is therefore entirely reasonable to imagine that many amoebae are extreme secondarily altered forms of the other groups of Protozoa. All amoebae are heterotrophic and feed on living organisms; many are free-living, in fresh water, sea water and soil; some are parasitic, as a rule in the gut. They are entirely unicellular and for the most part uninucleate. Reproduction is by simple fission or multiple division in cysts (Entamoeba fig. 21). Fertilization processes are known only in very few species. The amoebae are divided according to their method of nuclear division. Important types:—*Wahlkampfia* (fig. 15) and *Hartmanella* (free-living, feeding on bacteria), Amoeba *proteus* (living in water), Entamoeba histolytica (fig. 21), the cause of amoebic dysentery of man, Entamoeba *coli,* an innocuous gut-parasite of man, Entamoeba gingivalis, a parasite, possibly harmless, of the slime covering the tooth-bases of man. (See also AMOEBA.)

2. Order Thecamoebina. Free-living Rhizopoda whose bodies are surrounded by a cup- or flask-shaped shell. Pseudopodia are extruded from the opening in the shell. Characteristic also is the presence of layers or zones of protoplasm which stain deeply with the so-called nuclear stains, and are therefore described as chromidia (see above). The shell may be composed either of a stiff protoplasmic skin or of "pseudochitin" or of plates of silica, produced by the animal itself (*Euglypha*), or of foreign bodies picked up by it as it goes along and saved for the purpose (*Difflugia*). The group is entirely unicellular and as a rule uninucleate. Reproduction is by simple fission, or, in the hard-shelled forms, characteristically by gemmation. The mother individual extrudes a portion of its protoplasm from its aperture and this grows a new shell. In the "wall-building" forms the "building materials" accumulated by the mother-animal pass to the surface of the gemma; only then does a daughter-nucleus from the newly divided mother-nucleus wander into the gemma,

which then becomes free. Fertilization is unknown in this order.

3. Order Foraminifera. Relatively large Rhizopoda; the body is enveloped in a many-chambered porous calcareous shell. The pseudopodia, usually branched, make their way through the pores. They are free-living, heterotrophic, and feed on living organisms; entirely marine. Inland they appear only in salt-lakes—residues of earlier seas—as in Transylvania. The shells of many Foraminifera are very complex in structure but the principle is always the same. The germ-cell (agamete or zygote) surrounds itself with a shell and usually resembles a *Thecamoeba;* after some time, protoplasm makes its way out of the opening in the shell, spreads over a part of the shell-surface and forms a new shell; this makes the second chamber. This process goes on until the number of chambers in an adult animal may exceed a hundred. Only rarely are all the chambers arranged in a row, usually they are rolled up to form a spiral like a snail-shell, (fig. 13). Very frequently each chamber is completely built around by the one following. The shell-material is either the chalk that the animal excretes or extraneous material (grains of sand, etc.). There are also Foraminifera with unchambered shells and others whose shells are imperforate.

Most foraminiferans live on the bottom of the sea, only a few are plankton forms. All are unicellular and most uninucleate. Reproduction is by multiple division and gamete formation. Fertilization is effected by flagellate gametes. An alternation of generations is established. The Foraminifera, especially some fossil forms, are the largest unicellular organisms. They are of practical importance as stone-formers. Important types: Rotalia, Polystomella (figs. 13, 14), *Globigerina* (plankton, see GLOBIGERINA), *Miliolina, Nummulites* (fossil).

4. Order Heliozoa. Relatively small Rhizopoda characterized by the possession of so-called axopodia. Entirely free-living, heterotrophic, feeding on living organisms. Pound as a rule in fresh water. A small group; the only natural sub-order is the Centrohelidia, ball-shaped protozoans with a so-called central granule; this is a cytoplasmic structure capable of division, which lies in the middle of the cell and serves as the *point d'appui* of the axopodium. It was earlier thought to be a true centrosome, but it really is nothing of the kind. Some primitive forms (Dimorpha) have a true centrosome which functions both as a basal granule and as the insertion-point of the axopodium. Many species have a peculiar shell made of loosely packed silica needles. They are unicellular and chiefly uninucleate. Reproduction is by simple fission or gemmation; the gemmae grow into flagellate "swarming" individuals. Fertilization processes unknown. Important types:—Acanthocystis, *Dimorpha* (always provided with two flagella), Wagnerella (sessile, with a stalk; marine).

The remaining Heliozoa are probably related neither with one another nor with the Centrohelidia. Actinophrys (fig. 11) is unicellular, uninucleate, in fresh water, fertilization paedogamous. *Actinosphaerium* is multinuclear, the fertilization process as in *Actinophrys;* every individual breaks up into numerous gamonts, each one of which behaves like an Actinophrys preparing for fertilization. *Clathrulina* elegans has a ferruginous lattice-work shell: fertilization process unknown. *Nuclearia* is like *Clathrulina* without a shell; reproduction by simple fission.

5. Order Radiolaria. Relatively large Protozoa. The body of the protoplasm is divided into two parts by an internal membrane, the central capsule; the so-called intra-capsular cytoplasm contains the nucleus or nuclei and in the extra-capsular cytoplasm the food is digested. They are usually provided with a silica skeleton and also with a gelatinous sheath. The pseudopodia are intermediate in form between the Rhizopodia and Axopodia. Always free-living, heterotrophic, eating living organisms, marine plankton organisms. Some are capable of devouring multicellular animals as big as a water-flea. Many Radiolarians contain symbiotic Dinoflagellates, so-called Zooxanthellae. For the most part these forms are unicellular and uninucleate. Reproduction by simple fission and multiple agamete formation; the agametes are flagellate and may sometimes show a strong resemblance to dinoflagellates; some contain peculiar crystals. The life-cycle of Radiolarians is still very imperfectly understood, part of it being carried through in the deep sea. The Radiolaria are classified according to their skeleton and the form of the central capsule into four sub-orders:—

(a) Sub-order Spurnellaria. Central capsule pierced in all directions by fine pores. Skeleton may be wanting or may be composed simply of fine, loose needles. Some species form colonies. Important types: *Collozoum,* Thalassicolla.

(b) Sub-order Acantharia. Central capsule pierced in all directions; skeleton consists generally of 20 needles sticking together in the central capsule. Myonemes are attached to the needles and their contraction stretches the gelatinous integument and makes the animal lighter. Important types: Acanthometra, *Xiphacantha.*

(c) Sub-order Nasselaria. Central capsule provided with only one complicated aperture. Skeleton very complex.

(d) Sub-order Tripylea. Central capsule with three complex apertures. Skeleton very highly developed. Important types:—*Aulacantha,* Coelacantka.

6. Order Mycetozoa, also known as slime moulds but are not true fungi. (a) True Mycetozoa (Myxogasteres). These are Rhizopoda whose vegetative stage, the so-called plasmodium, is a gigantic Amoeba with thousands of nuclei. A contracted plasmodium of Fuligo *varians,* "flowers of tan," can be as large as a man's fist. These Amoebae are not compact, but form a peculiar net in whose meshes the endoplasm flows back and forth. The creeping forward movement of the plasmodium is caused by the fact that the plasma streams longer in one direction than in the other. The plasmodia live in moist earth, dung and rotten wood and they live partly on particles of decaying vegetable matter and partly on bacteria. The plasmodia cannot as a rule multiply vegetatively, they can only increase in size and in number of nuclei. When the plasmodium dries it changes to a number of thickly crowded multicellular cysts and is then known as a sclerotium. When food runs short the plasmodium forms fruiting bodies, the protoplasm collecting itself into little clumps at various parts of the net; from every clump a stalked ball-shaped body grows up; this fruiting structure is surrounded by a firm membrane and contains a great number of unicellular cysts or spores. At the formation of the fruit-bodies only a portion of the protoplasm is used up in the formation of spores; the rest goes to the making of the stalk, fruit-body membrane and fibres of a particular kind called elaters, which lie between the spores. The spores can stand drought, but as soon as they come in contact with water uniflagellate swarm-spores escape from them which either mate immediately or change first into Amoebae, losing their flagellae. The amoeboid zygote then grows straight on into a new plasmodium. Important types: *Didymium nigripes,* on dung and garden soil; Fuligo *varians,* on tanner's bark.

(b) The Acrasiaeae are also counted with the Mycetozoa although in no way related to them. The vegetative stage is a uninucleate amoeba multiplying by fission; on the formation of fruit-bodies many thousands of these organisms come together, and gradually build ball-shaped fruit-bodies which are often stalked; some of the amoebae are transformed into stalk cells, others into the membrane, the greater number form uninucleate spores. Important type: Dictyostelium mucoroides.

(c) Perhaps other plasmodia1 Rhizopoda such as *Labyrinthula, Leptomyxa* and such forms should belong to the Mycetozoa but we know as yet little of their life cycles. (See FUNGI.)

3. Class Telosporidia.—A small group of exclusively parasitic Protozoa whose zygotes break up inside a membrane into numerous sporozoites. Nutrition purely osmotic. Chromosome reduction at the first division of the zygote nucleus.

1. Order Coccidiomorpha. Telosporidia in which the vegetative individual dispenses with every cell organoid; they flourish inside cells and reproduce by multiple division.

(a) Sub-order Coccidia. From the sporozoites or merozoites arise the vegetative individuals or macrogametocytes and microgametocytes, which give rise to a large number of gametes. The zygote breaks up inside its membrane into several sporoblasts which themselves grow an enveloping membrane to become spores and whose protoplasm breaks up into sporozoites. Coccidians are found in many different groups of animals, including man, and in the most diverse tissues, very often in gut cells; some cause dangerous diseases, as *Eimeria stiedae*, a serious intestinal complaint of the rabbit; others are practically innocuous. Important types: *Eimeria stiedae* (rabbit), *Eimeria schubergi* (intestine of *Lithobius forficatus,* a centipede), *Aggregata eberthi* (intestine of *Sepia* and crabs).

One family of the Coccidia, the Haemogregarinae, provides the transition to the Haemosporideae. The Haemogregarinae are distinguished from other coccidians, with which the resemblance is otherwise very close, in that the zygote, called the ookinete because it is at first motile, is enveloped in a membrane; the sporozoites have no spore membrane. The haemogregarines are parasites of the red blood corpuscles of reptiles, frogs and mammals; some of them have a similar alternation of host to that of the Haemosporideae; some are pathogenic, such as *Hepatozoön perniciosum,* of the wild rat. Important types: *Karyolysus* (chief host, lizards, intermediate host, mites), *Hepatozoon* (rats).

(b) Sub-order Haemosporidia. Coccidiomorpha whose zygotes are without a membrane; they show alternation both of generations and of hosts. They are parasites of the red blood corpuscles of mammals and birds. Many pathogenic. Important types: *Plasmodium vivax*, *P. falciparum* (the cause of ague or tertian fever in man), *Plasmodium malariae* (quaternary malaria), *Laverania malariae* (tropical fever of man), *Haemoproteus* (various birds).

The Babesiae lie very close to the true haemosporidians but their fertilization and development are insufficiently known. They are parasites of the red blood corpuscles (intermediate hosts, ticks) and often pathogenic. Important types: *Theileria parva* (coastal fever of cattle in Africa), *Babesia bigemma* (Texas fever of cattle in America), *Babesia canis* (malignant jaundice of dogs).

2. Order *Gregarinidae.* Telosporidia whose bodies have usually a definite individual shape. The zygote changes into a spore which contains many sporozoites.

(a) Sub-order Eugregarinaria (Gregarines). The body of the typical gregarine is made of at least two elements—the protomerite and the deuteromerite, the latter containing the nucleus *(see* fig. 25); a third element when present is called the epimerite, and is usually developed as an attachment organ. The possession of longitudinal and circumferential myonemes is highly characteristic; the peculiar creeping movement described earlier is also characteristic. The gregarines are parasites of the gut and body-cavities of invertebrate animals and are for the most part harmless. They occur chiefly in insects and annelid worms, living not inside the cells but (at least in their young stages) clinging to them by the epimerite. The mature animals are usually quite freely motile. Alternation of hosts does not occur. True gregarines cannot reproduce agametically but only sexually, as shown above. It should also be mentioned that the cysts in which the gametes are enclosed can produce processes of various forms which assist in the distribution of the spores. Important types: *Monocystis* (in the seminal vesicles of various earthworms), *Gregarina blattarum* (in the gut of the cockroach), *Gregarina cuneata* (in the gut of the larvae of the meal-bug).

(b) Sub-order Schizogregarinaria. These gregarines are transitional forms between the true gregarines and the coccidians; the vegetative individuals are not far removed in body structure from the gregarines but can reproduce asexually like the coccidians by multiple division. Fertilization however is like that in the gregarines; but only small numbers of gametes and spores are formed. The Schizogregarinaria flourish in various invertebrate animals, such as insects and crabs, but are for the most part innocuous. Some, such as *Porospora,* have an alternation of hosts. Important types: *Ophryocystis* (Malpighian tubules of the meal-bug), *Porospora* (gut of the lobster and other crustaceans, with fertilization in mussels).

4. Class Neosporidia.—Multinucleate plasmodial Protozoa almost destitute of cell organoids; the spores are equipped with a complex polar capsule. Entirely parasitic, nutrition osmotic. No flagellate stage. Some forms show an amoeboid movement.

1. Order *Myxosporidia.* The vegetative individuals are more or less formless clumps, often showing amoeboid movement; they contain in the fully developed condition many thousands of nuclei. They are able to reproduce themselves asexually both by simple fission and by gemmation; they can also form spores, though whether fertilization precedes this process, or follows it, we cannot say. The Myxosporidia flourish in the tissues and body cavities (such as gut and gall-bladders) of fishes and amphibians, and some are pathogenic. Important types: *Myxobolus pfeifferi* (cause of barbel-pest), *Myxobolus neurobius* (forms swellings in the brain and spinal marrow of trout and graylings), *Myxidium lieberkühnii* (urinary bladder of pike; harmless).

a. Order *Microsporidia.* The vegetative individuals look just like those of the Myxosporidia and simply multiply asexually. The Microsporidia are all cell-parasites of various animals; many are pathogenic for the vegetative individuals may grow to an enormous size and thus cause swellings. Important types: *Glugea anomala* (in stickleback, pathogenic), *Thelohania* (in larvae of gnats), *Nosema apis* (cause of Isle of Wight disease of bees), *Nosema bombycis* (cause of *pébrine* disease of silk worms).

3. Order *Haplosporidia.* The true Haplosporidia are probably Microsporidia whose spores do not produce a polar capsule. They occur in the tissues of animals, chiefly invertebrates; distinctly pathogenic forms have not been found. Important types: *Haplosporidium* (in various worms), *Ichthyosporidium* (in marine fishes, such as *Crenilabrus*).

Many forms of "Sporozoa" have been included in this group about whose developmental history nothing exact is known; for example, *Rhinosporidium seeberi,* which produces tumours in the mucous membrane of the nose in man. Some of these forms belong perhaps to the Haplosporidia; others, however, to the fungi.

4. Order *Actinomyxidia.* The vegetative stages of these protozoans are not yet well known. Spore-formation probably follows a course broadly the same as that described for the Haplosporidia; there is for instance a paedogamous fertilization. The spores are very complex, of triradiate symmetry and containing three polar capsules. A very peculiar character is the way the spore-shell, in some species, is formed not around the amoeboid germ but quite apart from it, the germ only slipping into the shell when the latter is complete. Almost all known Actinomyxidia live in the Tubificidae (relatives of the earthworm) and are more or less harmless. Important types:—Sphaeroactinomyxon, *Triactinomyxon.*

5. Order *Sarcosporidia.* It is still doubtful if these protozoans are related to the Neosporidia or not, their life-cycle being as yet imperfectly known. The vegetative individuals or "utricles" are usually oval or spindle-shaped multinucleate clumps, which may attain to a considerable size—as much as two inches long. The Sarcosporidia are muscle-parasites of vertebrates, chiefly mammals; the utricle in its young stages lies in the muscle-fibres, the adult utricle lies between them. Some species are markedly pathogenic, for example *Sarcocystis miescheriana* of the pig, which may lead to laming of the hind legs. It is noteworthy that it was in the Sarcosporidia that toxins were first recognized. Important types: *Sarcocystis miescheriana* (pig), *Sarcocystis tenella* (sheep).

5. Class Ciliophora. Protozoa that move by means of numerous cilia;. free-living or parasitic.

1. Order *Opalinida.* Uniformly ciliate Protozoa, usually multinucleate, whose nuclei (in contradistinction to those of the Ciliata) are all alike (fig. 24). Harmless intestinal parasites, feeding osmotically. Reproduction by simple fission; fertilization is by copulation, this being a second distinction from the Ciliata. Important types:—*Opalina ranarum* (rectum of the grass frog).

2. Order *Ciliata.* (Infusoria.) More or less uniformly ciliate, nuclei varying from two to many, always of two kinds, macro- and micronuclei (fig. 4). Only the latter kind can divide mitotically, the macronuclei degenerate at conjugation. Most ciliates are free-living and take in food by gulping it or whirling it in. The same applies to most of the parasitical forms—the greater part of which are external or intestinal parasites; but there are also parasitic forms that feed osmotically. Alternation of hosts does not occur. These organisms are unicellular throughout but sometimes form colonies. Reproduction by simple transverse fission

or (more rarely) by multiple division in a cyst. Fertilization by conjugation.

The Ciliata are divided according to the arrangement of the cilia and other characteristics into numerous groups which need not be further discussed here. Important *types:* — *Paramaecium* (fig. 4), *Stylonychia, Vorticella, Stentor* (fig. 3), *Chilodon* (fig. 8), *Didinium* (fig. 5) (all free-living pond-dwellers), *Tintinnus* (and related marine plankton forms, with cup- or jug-shaped shells), *Ichthyophthirius multifiliis* (parasitic on the skins of fresh-water fish, trout, etc.; pathogenic), *Balantidium coli* (gut of man and of the pig; possibly not quite harmless), *Ophryoscolex, Entodinium* and related forms (characterized by meagre ciliation and possession of a strong cellulose armour; enormously abundant in the stomachs of almost all the hoofed animals-cattle, sheep, pigs, horses, antelopes, etc.), probably symbionts like the Trichonymphidae, but not indispensable.

3. Order *Suctoria.* These Protozoa although without cilia show their close relationship to the ciliates in the possession of macro- and micro-nuclei and by their conjugation. For the most part they are free-living and sessile. They feed themselves by sucking tubules, to which the passing prey sticks. remains attached and is finally sucked up. The parasitic forms — almost all ectoparasites — also feed themselves in this peculiar way. The Suctoria are usually uninucleate, always unicellular. Reproduction by simple or multiple gemmation; sometimes the gemma forms inside the mother-animal in the so-called brood-pouch; the liberated gemmae are freely-moving ciliate organisms at first, only becoming sessile later. Fertilization: conjugation. Important types: *Tokophrya, Sphaerophrya pusilla* (one of the few protozoans that live on other protozoans, such as *Paramaecium* and other ciliates); *Dendrocometes paradoxus* (an ectoparasite on the gill-plates of the fresh-water shrimp *Gammarus).*

BIBLIOGRAPHY.—Only the most important general text-books are given. The literature of special groups is quoted in these books. O. Biitschli, *Protozoen* in Bronn's *Klassen und Ordnungen des Tierreichs,* three volumes (1880–89), out-of-date in many ways, but good for the Ciliata; von Prowazek-Noller, *Handbuch der pathogenen Protozoen* (Leipzig, 1911–28), in many parts considerably out-of-date; E. A. Mindin, *An Introduction to the Study of the Protozoa with special reference to the parasitic forms* (London, 1912), out-of-date in many particulars; M. Hartmann and C. Schilling, *Die pathogenen Protozoen und die durch sie verursachten Krankheiten* (Berlin, 1917), primarily a survey of the pathogenic forms; *A.* Kiihn, *Morphologie der Tiere in Bildern,* "Flagellata" (Berlin, 1922); "Rhizopoda" (1926), deals only with anatomical structure; W. Noller, *Die wichtigsten parasitischen Protozoen des Menschen und der Tiere* (Berlin, 1922), one volume, "General & Rhizopoda," only at present out and the book deals only with parasites; G. N. Calkins, *The Biology of the Protozoa* (1926), deals very thoroughly with the Ciliata; C. M. Wenyon, *Protozoology* (1926), only deals completely with parasitic forms, but in this respect the best modem book; Doflein-Reichenow, *Lehrbuch der Protozoenkunde* (Jena, 1927–28), the best exhaustive modern work. See also R. W. Hegner, *Protozoology* (1930). (K. T. B.)

PROUDHON, PIERRE JOSEPH (1809–1865), French socialist and political writer, was born on Jan. 15, 1809, at Besanqon. He came of poor parents, and was mainly self-educated. At 19 he became a working compositor; and later, as a proofreader, he acquired a competent knowledge of theology and Hebrew, which he compared with Greek, Latin and French. On the strength of the knowledge acquired in this way he wrote an *Essai de grammaire générale.* In 1838 he obtained the *pension Suard,* a bursary of 1,500 francs a year for three years, for the encouragement of young men of promise, which was in the gift of the academy of Besançon.

In 1839 he wrote a treatise *L'Utilité de la célébration du dimanche* which contained the germs of his revolutionary ideas, and in the following year, after a short sojourn in Paris, he published *Qu'est-ce que la propriété?* His famous answer, "La propriété, c'est le vol" (property is theft), displeased the academy of Besanqon, and there was some talk of withdrawing his *pension;* but he held it for the regular period. For his third memoir on property, which took the shape of a letter to the Fourierist, Considérant, he was tried at Besanqon but was acquitted. In 1846 he published his greatest work, the *Systbme des contradictions économiques ou philosophie de la misère.* In 1847 he settled in Paris, and in the following year gained notoriety during the revolution. He was the moving spirit of the *Représentant du peuple* and other journals of advanced views, and as member of assembly for the Seine department he proposed an impost of one-third on interest and rent, which was rejected. His attempt to found a bank which should operate by granting gratuitous credit was also a complete failure. For his violent speeches, Proudhon suffered three years of imprisonment at Paris. As Proudhon aimed at economic rather than political innovation, he accepted the second empire, and lived in comparative quiet till the publication of his work, *De la Justice dans lo révolution et dans l'eglise* (1858), in which he attacked the church and other existing institutions. To escape imprisonment he fled to Brussels, returning later to France in broken health. He died at Passy on Jan. 16, 1865.

Personally Proudhon was one of the most remarkable figures of modern France. His life was marked by the severest simplicity; he was affectionate in his domestic relations, a loyal friend, and strictly upright in conduct. He opposed the prevailing French socialism; and, though an enemy of the dominant ideas and institutions, he was free from feelings of personal hate. In all that he said and did he was the son of the people, who had not been broken to the usual social and academic discipline; hence his roughness, his one-sidedness, and his exaggerations; but he is always vigorous, and often brilliant and original.

Although in his own words "the great part of his publications formed only a work of dissection and ventilation, so to speak, by means of which he slowly makes his way towards a superior conception of political and economic laws," yet the groundwork of his teaching is clear. He believed in the absolute truth of a few moral ideas, with which it was his aim to mould and suffuse political economy. Of these fundamental ideas, justice, liberty and equality were the chief. What he desiderated, for instance, in an ideal society was perfect equality of remuneration on the principle that the duration of labour is the just measure of value. He pursued this theory to its logical conclusion, but looked forward to a period in human development when the present inequality in the capacity of men would be reduced to an inappreciable minimum. From the principle of service as the equivalent of service is derived his axiom that property is the right of *aubaine, i.e.,* the right in virtue of which the sovereign, from the earliest monarchy, claimed the goods of an unnaturalized stranger who had died in his territory. Property is a right of the same nature, with a like power of appropriation in the form of rent, interest, etc. Proudhon's aim was to realize a science of society resting on principles of justice, liberty and equality thus understood; "a science absolute, rigorous, based on the nature of man and of his faculties, and on their mutual relations, a science which we have not to invent, but to discover." But he saw that such ideas could only be realized through a long process of social transformation. He attacked the schools of Saint-Simon and Fourier for thinking that society could be changed off-hand by a ready-made and complete scheme of reform.

In social change Proudhon distinguishes between the transition and the perfection of achievement. With regard to the transition he advocated the progressive abolition of the right of *aubaine,* by reducing interest, rent, etc., but he had no clear conception of the goal. The organization he desired was one on collective principles, a free association which would take account of the division of labour, and which would maintain the personality both of the man and the citizen. Connected with this was his famous paradox of *anarchy,* as the goal of the free development of society, by which he meant that through the ethical progress of men government should become unnecessary. "Government of man by man in every form," he says, "is oppression. The highest perfection of society is found in the union of order and *anarchy."* Proudhon, indeed, was the first to use the word *anarchy,* not in its revolutionary sense, but to express the highest perfection of social organization.

A complete edition of Proudhon's works, including his posthumous writings, was published at Paris (1875). *See* also *P. J. Proudhon, sa vie et sa correspondance,* by Sainte-Beuve (1875); Beauchtry, *Économie sociale de P. J. Proudhon* (Lille, 1867); Spoll, *P. J. Proudhon, ttude biographique* (1867); Marchegay, *Silhouette de Proudhon* (1868); Putlitz, *P. J. Proudhon, sein Leben und seine positiven Ideen* (1881);

Diehl, *P. J. Proudhon, seine Lehre und sein Leben* (Jena, 1888–89); Miilberger, *Studien über Proudhon* (Stuttgart, 1891); Desjardins, *P. J. Proudhon, sa vie, ses oeuvres et sa doctrine* (1896); Miilberger, *P. J. Proudhon* (Stuttgart, 1899).

PROUST, JOSEPH LOUIS (1754–1826), French chemist, was born on Sept. 26, 1754, at Angers, where his father was an apothecary. After beginning the study of chemistry in his father's shop he came to Paris and became apothecary in chief to the Salpetrikre, also lecturing on chemistry at the *musée* of the aeronaut J. F. Pilâtre de Rozier, whom he accompanied in a balloon ascent in 1784. Next, he went to Spain, where he taught chemistry first at the artillery school of Segovia, and then at Salamanca, finally becoming in 1789 director of the royal laboratory at Madrid. In 1808 he lost both his position and his money by the fall of his patron (Charles IV.), and retired first to Craon in Mayenne and then to Angers, where he died on July 5, 1826. Proust's great contribution to chemistry was his establishment of the fundamental principle of the constant composition of many compounds. On this subject he maintained a long controversy with C. L. Berthollet, who was led by his doctrine of mass-action to deny that substances always combine in constant and definite proportions. Proust, on the other hand, maintained that compounds always contain definite quantities of their constituent elements, and that in cases where two or more elements unite to form more than one compound, the proportions in which they are present vary per saltum, not gradually. In 1799 he proved that copper carbonate, whether natural or artificial, always has the same composition, and later he showed that the two oxides of tin and the two sulphides of iron always contain the same relative weights of their components and that no intermediate indeterminate compounds exist. His analytical skill enabled him to demonstrate the inaccuracy of the researches by which Berthollet attempted to support the opposite view, and to show among other things that some of the compounds which Berthollet treated as oxides were in reality hydrates containing chemically combined water, and the upshot was that by 1808 he had fully vindicated his position. Proust also investigated the varieties of sugar that occur in sweet vegetable juices, distinguishing three kinds, and he showed that the sugar in grapes, of which he announced the existence to his classes at Madrid in 1799, is identical with that obtained from honey by the Russian chemist J. T. Lowitz (1757–1804).

Besides papers in scientific periodicals he published *Indagaciones sobre el estañada de cobre, la vajilla de estaño y el vidriado* (1803); *Mémoire sur le sucre de raisins* (1808); *Recueil des mdmoires relatifs á la poudre à canon* (1815); and *Essai sur une des causes qui peuvent amener la formation du calcul* (1824).

PROUST, MARCEL (1871–1922), French man of letters, was born in Paris on July 10, 1871. His father was a professor of medicine, and his mother was of Jewish extraction. He was educated at the lycée Condorcet, and about 1892 he was for some time associated with Léon Blum, Louis Mirhlfeld and Tristan Bernard on the Revue Blanche, a periodical conducted by a select group of intellectuals, mostly Jewish. Becoming a favourite in the salons–especially those of Mme. de Caillavet and Madeleine Lemaire—he wrote a number of society love-stories (collected in 1896 under the title Les *plaisirs et* les *jours*) distinguished by their psychological subtlety. He also attained reputation as a clever writer of *pastiches.* He became an enthusiastic admirer of John Ruskin and translated several of his works into French, including the Bible of *Amiens,* to which he contributed a valuable preface.

In 1902 Proust's health began to fail. Thenceforward he was reluctantly obliged to lead an extremely retired and careful life, and for many years it looked as if he had altogether abandoned literature, in which his name hitherto had not been known outside a small circle of friends. He was reading and writing a great deal, however. The interminable discursiveness of Ruskin, which French readers do not suffer gladly, was to him a constant source of delight, and Saint-Simon, ever one of his favourite authors, exerted a powerful influence upon him at this time. Thus it came about that, having unlimited time at his disposal, he embarked upon a long and leisurely work, full of minute detail, in which was imprisoned, as in a net, his whole experience of life; in which the *salon* life he loved was revived in all its details and observances like the court life in Saint-Simon's memoirs; in which the people he had known provided the materials for new, fuller and richer characters (M. de Charlus, for example, is a blending of three different people of Proust's acquaintance), and in which the author sought out and lived the past over again. Hence the general title given to the 15 volumes of the series, *A* la recherche *du* temps perdu (1913, etc.).

This lengthy work had almost been completed when Proust published the first part, Du *côté* de *chez Swann,* in 1913. The freshness and minuteness of the recollections of childhood attracted some attention, but none the less Proust, who had had to publish the first part at his own expense, had difficulty in finding a publisher for the second, *L'ombre des jeunes filles* en *fleurs.* When it did appear its qualities were at once appreciated by Léon Daudet, whose enthusiastic articles, followed by the award of the Prix Goncourt in 1918, brought Proust's name prominently before the public, and he was read, discussed and criticised everywhere. Two more parts appeared during Proust's lifetime—Le *côté* de Guermantes and *Sodome* et *Gomorrhe,* both in 1921. When he died in Paris, Nov. 18, 1922, he left three parts still in manuscript—La *prisonnière,* published in 1924, Albertine *Disparue* (1926) and Le temps retrouvk (1926).

Proust's influence, especially since his death, has been considerable. He introduced into the novel an analytic method which has a superficial resemblance to that of Meredith, but is more properly comparable with that of Freud. That the name and notion of time should appear in the general title of his great work is not without significance. By a curious coincidence he was related by marriage to Bergson, the philosopher of "creative time," and the term "creative time" aptly describes the psychological time which Proust explores, seeks and recovers. His people are never given as "characters" in the fashion of La Bruyère or Balzac; they are always in process of development, change and continual creation.

Part of Proust's success was due to the very thing that is likely to tell against his lasting reputation, viz.: the fact that his characters, beginning with the "I" of the book, are exceptional, an erotic and mysterious group having little in common with the generality of mankind. This is true not only of *Sodome* et Gomorrhe and Proust's emphasis upon homosexuality, but also of the idle life and ultimate nothingness of the people of his world, their lack of all interests other than those of social life, and the indifference that the ordinary reader must always feel as to their fate. On the other hand, there will be a taste for Proust so long as there is a taste for pyschology as an end in itself, and so long as the play of memory, the searching and brooding that pertain to the conquest of the past, afford to some men a sufficient reason for living or a romantic manner of not living. The following translations by C. K. Scott Moncrieff appeared in English: *Swann's* Way (1922); Within a Budding Grove (1924); *The* Guermantes Way (1925); Cities of the Plain (trans. of *Sodome* et Gomorrhe) (2 vols. 1927); The Captive (1929). (A. T.)

Pierre-Quint, *Marcel Proust, sa vie, son oeuvre* (1925, Eng. trs. 1927); Benoist-Méchin, *La Musique et l'immortalité dam Poeuvre de Marcel Proust* (1926); R. Dreyfus, *Marcel Proust à dix-sept ans* (1926), and *Souvenirs sur Marcel Proust* (1926); G. Gabory, *Essai sur Marcel Proust* (1926); *Marcel Proust,* by various writers, with bibliography (1926); P. Souday, *Marcel Proust* (1927); R. Fernandez, *Les Cahiers de Marcel Proust* (1927); and Clive Bell, Proust (1928). His *Lettres inédites* were published with a preface by Camille Vettard in 1926. *Chroniques,* a selection of his articles chiefly from *Le Figaro,* was edited by R. Proust (1927).

PROUSTITE, a mineral consisting of silver sulpharsenite, Ag_3AsS_3, known also as light red silver ore, and an important source of the metal. It is closely allied to the corresponding sulphantimonite, pyrargyrite, from which it was distinguished by the chemical analyses of J. L. Proust in 1804, after whom the mineral received its name. Many of the characters being so similar to those of pyrargyrite (*q.v.*) they are mentioned under that species. The colour is scarlet-vermilion and the lustre adamantine; crystals are transparent and very brilliant, but on exposure to light they soon become dull black and opaque. The streak is scarlet, the hardness 2·5, and the specific gravity 5·57. The mode of occurrence is the same as that of pyrargyrite, and the two minerals are sometimes found together. Magnificent groups of large crystals have been found at Chañarcillo in Chile; other localities which have yielded fine specimens are Freiberg and Marienberg in Saxony.

PROUT, SAMUEL (1783–1852), English water-colour painter, was born at Plymouth on Sept. 17, 1783. He spent whole summer days, in company with the ill-fated Haydon, in drawing the quiet cottages, rustic bridges and romantic water-mills of Devon. It was not however, until about 1818, when he visited the Continent and first saw the quaint streets and market-places of continental cities, that Prout discovered his proper sphere. All his faculties sprang into unwonted activity. His eye readily caught the picturesque features of the architecture, and his hand recorded them in drawings which were admirable in line, composition and colour. At the time of his death, on Feb. 10, 1852, there was scarcely a nook in France, Germany, Italy and the Netherlands which his quiet, benevolent, observant eye had not searched for antique gables and sculptured pieces of stone. In Venice especially there was hardly a pillar which his eye had not lovingly studied and his pencil had not dexterously copied.

See a memoir of Prout, by John Ruskin, in Art Journal for 1849, and the same author's Notes on *the Fine* Art Society's *Loan* Collection of Drawings by *Samuel* Prout and William Hunt (1879–80); *see* also the "Winter Number" of the *Studio* (1914–15), for reproductions of his sketches.

PROUT, WILLIAM (1785–1850), English chemist and physician, was born at Horton, Gloucestershire, on Jan. 15, 1785, and died in London on April 9, 1850. His life was spent as a practising physician in London, but he also occupied himself with chemical research He was an active worker in physiological chemistry, and found in 1803 that the acid contents of the stomach contain hydrochloric acid which is separable by distillation. In 1815 he published anonymously in the Annals of Philosophy a paper in which he calculated that the atomic weights of a number of the elements are multiples of that of hydrogen; and in a second paper published in the same periodical the following year he suggested that the πρώτη ὕλη of the ancients is realized in hydrogen, from which the other elements are formed by some process of condensation or grouping. This view, generally known as "Prout's hypothesis," at least had the merit of stimulating inquiry, and many of the careful determinations of atomic weights undertaken since its promulgation have been provoked by the desire to test its validity. It is also particularly interesting in view of recent developments in the study of atomic structure (see ATOM).

PROVENCAL LANGUAGE AND LITERA'MJRE. The term Provencal is employed in two different meanings. (1) *Lato sensu,* it embraces all idioms of Latin origin spoken in Southern France over a zone extending south of a line which starts at the mouth of the Gironde, passes through Bordeaux, Libourne, Mussidan, Péngueux, Nontron, Mouhet, Bellac, Limoges, Guéret, Chénérailles, Montluçon, Verneuil, Clermont-Ferrand, Saint-Bonnet-le-Chhteau, Saint Sauveur-en-Rue, Gilhoc, Saint-Vallier, Romans, Die, Montmaur and finishes at Puy-Saint André. (2) *Stricto* sensu, it is applied to the idioms spoken in the Alpes-Maritimes, Basses-Alpes, Var and Bouches-du-Rhône departments. It was long customary to distinguish the dialects of Southern France by the names of the old provinces in which they occur, viz., Béarnais, Languedocien, Rouergat, etc. The classification now generally adopted is: (1) Gascon, (2) Provençal moyen and Provencal alpin (from Agen to Mentone), (3) Auvergnat and Limousin, (4) Catalan (*q.v.*).

With the 12th century arose a literary language used as a κοινή by the Troubadors. As some of the most celebrated of these poets, Bernard de Ventadour, Arnaud Daniel, Bertrand de Born and Jaucelm Faidit came from the Limousin, this κοινή was long known as *lengua lemosina;* a name, however, not to be misinterpreted. The literary language was not homogeneous, but composite.

The Troubadors conveyed this form of Provençal with them to Northern France, Italy, Spain and Portugal. When Languedoc passed to the House of France (1272) two languages, Latin almost exclusively and French to a very limited degree, were employed for administrative purposes. Minute examination of the documents contained in the archives of Southern France has recently proved that French exerted only inappreciable influence upon Provencal down to the close of mediaeval times. The Frenchification was not the outcome of a long, slow process. Indeed at the end of the Hundred Years' War, Provencal was still highly vigorous both in administrative and general use; it was then, from 1450 to 1600, very rapidly penetrated by French. First to yield was Northern Limousin; it was followed next by Périgord, Bordelais, Agenais, then Gascony, and finally by the Pyrenees which resisted till the last years of the 18th century. The initial period of this penetration may be placed about 1540 (see A. Brun, Recherches *historiques sur l'introduction* du *français dans les* provinces du midi, 1923). The various patois, continuing to be spoken by the middle class and peasantry developed freely. The new lease of life upon which the Southern idioms entered during the second half of the 19th century, must not be regarded as an unexpected accident. It had been prepared by the reawakening sense of nationality and promoted by the efforts of scholars, historians and men of letters, all of whom united in lauding the qualities of the ancient tongue and urging the Southerners to voice their native feelings and aspirations in their native "language." Amongst the leading representatives of the movement must be mentioned F. Mistral, not only on account of his literary masterpieces, especially his immortal *Mirèio* (1859), but also for his publication of *Lou* Tresor d'ou *Felibrige* (1878–86), the Provencal French dictionary which conferred *lettres* de noblesse on the new classical language of Provence, sprung from divers patois of the Bouches-du-Rhône. Provençal (including Catalan) is spoken by some 10,000,000 persons in France.

The Provencal dialects are less divergent from Latin than is the case with French. The following particulars will help to make clear what has been called "the archaic character" of Provencal and give, at the same time, a concise view of its special phonetic features.

I. VOWELS

(a) Latin tonic free vowels: L. *amAre,* Pr. *amAr* (later *amA*), F. *amEr* (later *aimEr*). L. *pEdem,* Pr. *pE,* F. *pIE* (later spelt *piEd*). L. *credEre,* Pr. *crezEr* (later *creSE* in some parts), Bearnais *credEr* (later *credE*); F. *crEIre* (later *croIre*); L. *solum,* Pr. sol, Fr. *sUEl* (later *SEUl*); L. *florem,* Pr. *flor,* F. flour (later *flEUr*).

(b) Latin tonic free diphthong au: L. *AUrum,* Pr. *AUr,* F. or.

(c) Posttonic a: L. *clarA,* Pr. *clarA* (later claro), F. *clerE* (later *clAIre*).

(d) Latin intertonic free a: L. *durAmente,* Pr. *durAmen,* F. *durEment.*

II. CONSONANTS

(e) Latin C and G before *A* were kept C and G in Provençal (except Limousin and Auvergne) and became CH (first pronounced TCH) and *J* (first pronounced DJ) in French (except Normanno-Picard dialect where they persisted as C and G, like Provencal): L. *caballum,* Pr. *Caval,* F. *CHeval;* L. *Gallina,* Pr. *Galina* (later *Galino*), F. *Geline.*

(f) Latin intervocalic C: L. *paCare,* Pr. *paGar* (later *paGa*), F. *paGer;* L. *seCurum,* Pr. *seGur* (in part of Basses-Pyrénées secur). Latin intervocalic G: L. *plaGa,* Pr. *plaGa* (later *plaGo*), F. *plaie;* L. *ruGa,* Pr. *ruGa* (later *ruGo*), F. rue. Latin intervocalic T: L. *viTa,* Pr. *viDa* (later *viDo*), F. vie; L. *quaTernum,* Pr. cazern, F. cahier. Latin intervocalic D: L. *creDere,* Pr. *crezer* (in part of Basses-Pyrénées *creDer*), F. creire (later croire).

N.B. In some parts of Mod. Pr. there is a form creire which represents the state of evolution to be found in France till the 13th century. Latin intervocalic DR, TR: L. *quaDratum,* Pr. *caIrat,* F. *caRRé,* L. *paTrem,* Pr. *paIre,* F. *pére* (later *père*).

(gi In the group Sf 1 or 2 consonants, *s* has been kept in Provençal spelling and pronunciation; from French pronunciation it disappeared since the 13th century, although it was preserved in spelling till the middle of the 18th century (suppressed in the 3rd edition of the *Dictionnaire de l'Académie Française,* 1740); L. scribere, Pr. *escriure,* F. *escrire* (later *écrire*); L. *castellum,* Pr. *castel,* F. *chasteau* (later *château*).

(h) Among the final consonants let us quote *p,* v, *s,* Vulg. L. *capum* (cl. L. *caput*), Pr. cap (a regression of *cat*—a form which is not attested in the documents at our disposal), F. *chief*; L. brevem, Pr. *brèu,* F. *bref.* Final *s* has been preserved both in spelling and pronunciation in the greatest part of Provencal; it disappeared from the pronunciation of French in the course of the 13th century. L. *causas,* Pr. cauzas (later *cauzos*), F. *choses.*

Among the Provencal dialects Gascon has quite peculiar features, the following three are most specially characteristic: (a) Change of Latin intervocalic *ll* to *r;* L. *appellare,* Gasc. *aperar* (later *apera*); (b) change of Latin final *ll* to t: L. *agnellum,* Gasc. *agnet*; (c) change of Latin f to aspirate *h:* L. *femina,* Gasc. Femna till the end of the 13th century, then *Hemna* (later *Henno*).

Note that there are two other peculiar features (d) the pronunciation of b as in Spanish (*i.e.,* an intermediary sound between b and v); (e) the fall of Latin intervocalic *n* as in Portuguese: L. *gallina,* Gasc. garia (later gario). But (d) has gone beyond Gascony since the middle ages, and (e) is not to be found in Bordelais.

As general remarks on the morphology it may be pointed out that the declension of nouns and adjectives ceased to exist earlier than in French: the 13th century is the limit reached by the distinction between the two cases. In some parts like Béarn no trace of any declension at any time is to be found. In the conjugation we find (a) a past simple ending in—ei (like cantei, *cantest,* cantet, *cantem,* cantetz, canteron; vendei, vendest, etc.), most likely corresponding to L.—*ĕdi*—*ĕti,* as in dedi *steti.* (b) a remnant of Latin pluperfect ending in *aram* (contracted from *averam*), *īram* (contracted from iveram), ederam, e.g., cantara or *cantera,* partira, *vendera* used in the meaning of a conditional.

There is a great similarity in the aspect of old and modern Provencal. The only important facts since the 15th century are (a) the change of final a into o (except in some parts where it has persisted as a, and in others where it became *e,* closer than in French).

(i) The great simplification of the conjugations, many verbs having passed to the—ar conjugation. (L. B.)

LITERATURE

Provenqal literature is much more easily defined than the language in which it is expressed. Starting in the 11th and 12th centuries in several centres it thence gradually spread out, first over the greater portion, though not the whole of southern France, and then into the north of Italy and Spain.

Origin.—It took poetic form; and its oldest monuments show a relative perfection and a variety from which it may be concluded that poetry had already received a considerable development. The honour of being the oldest literary monument of the Provencal language must be assigned to a fragment of 257 decasyllabic verses preserved in an Orleans ms. and frequently edited and annotated since it was first printed by Raynouard in 1817 in his *Choix des poésies originales* des troubadours. The writing of the ms. is of the first half of the 11th century. The peculiarities of the language point to the north of the Provencal region, probably Limousin or Marche. It is the beginning of a poem in which the unknown author, taking Boethius's treatise De *consolatione philosophiae* as the groundwork of his composition, adopts and develops its ideas and gives them a Christian colouring of which there is no trace in the original. Thus from some verses in which Boethius contrasts his happy youth with his afflicted old age he draws a lengthy homily on the necessity of laying up from early years a treasure of good works. A little later, at the close of the same century, we have the poems of William IX., count of Poitiers, duke of Guienne. They consist of 11 very diverse strophic pieces, and were meant to be sung. We also know from Ordericus Vitalis that William IX. had composed various poems on the incidents of his ill-fated expedition to the Holy Land in 1101. And it must further be mentioned that in one of his pieces (Ben voil que *sapchon li plusor*) he makes a very clear allusion to a kind of poetry which we know only by the specimens of later date, the partimen, or, as it is called in France, the jeu *parti.* William IX. was born in 1071 and died in 1127. The contrast in form and subject between the Boethius poem and the stanzas of William IX. is an indication that by the 11th century Provencal poetry was being rapidly developed in various directions. Whence came this poetry? How and by whose work was it formed? That it has no connection whatever with Latin poetry is generally admitted. The view which seems to meet with general acceptance, though it has not been distinctly formulated by any one, is that Romanic poetry sprang out of a popular poetry quietly holding its place from the Roman times, no specimen of which has survived—just as the Romanic languages are only continuations with local modifications of Vulgar Latin. There are both truth and error in this opinion. Romanic versification, as it appears in the Boethius poem and the verses of William IX., and a little farther north in the poem of the Passion and the Life of St. *Leger* (10th or 11th century), has with all its variety some general and permanent characteristics; it is rhymed, and it is composed of a definite number of syllables certain of which have the syllabic accent. This form has evident affinity with the rhythmic Latin versification, of which specimens exist from the close of the Roman empire in ecclesiastical poetry. The exact type of Romanic verse is not found, however, in this ecclesiastical Latin poetry; the latter was not popular. However, it may be assumed that there was a popular rhythmic poetry from which Romanic verse is derived.

Again, as regards the substance, the poetic material, we find nothing in the earliest Provencal which is strictly popular. The extremely personal compositions of William IX. have nothing in common with folk-lore. They are subjective poetry addressed to a very limited and probably rather aristocratic audience. The same may be said of the Boethius poem, though it belongs to the quite different species of edifying literature; at any rate it is not popular poetry. Vernacular compositions seem to have been at first produced for the amusement, or in the case of religious poetry, for the edification, of that part of lay society which had leisure and lands, and reckoned intellectual pastime among the good things of life. Gradually this class, intelligent, but with no Latin education, enlarged the circle of its ideas. In the 12th century, and still more in the 13th, historical works and popular treatises on contemporary science were composed for its use in the only language it understood; and vernacular literature continued gradually to develop partly on original lines and partly by borrowing from the literature of the "clerks."

From what class of persons then did it proceed? Latin chroniclers of the middle ages mention as *ioculares,* ioculatores, men of a class not very highly esteemed whose profession consisted in amusing their audience either by what we still call jugglers' tricks, by exhibiting performing animals, or by recitation and song. They are called *joglars* in Provencal, *jonglers* or *jongleurs* in French; and they were the first authors of poetry in the vernacular both in the south and in the north of France. (See Edmond Faral, Les Jongleurs en France au moyen *âge,* Paris, 1910, and R. Menéndez Pidal, Poesia juglaresca y *juglares,* Madrid, 1924.)

Poetry of the Troubadours.—Centres of poetic activity are found first in Limousin and Gascony. In Limousin lived a viscount of Ventadour, Eble, who during the second part of William of Poitiers's life seems to have been brought into relation with him, and according to a contemporary historian, Geffrei, prior of Vigeois, *erat* valde *gratiosus* in *cantilenis.* We possess none of his compositions; but under his influence Bernart of Ventadour was trained to poetry. Bernart gained the love of the lady of Ventadour, and when on the discovery of their amour he had to depart elsewhere, received a gracious welcome from Eleanor of Guienne, consort (from 1152) of Henry II. of England. Of Bernart's compositions we possess about 50 songs of elegant simplicity, some of which may be taken as the most perfect specimens of love poetry Provenqal literature has ever produced. At the same period, or earlier, flourished Cercamon, a Gascon, who composed, says his old biographer, "pastorals" according to the ancient custom (*pastorelas a la uzansa antiga*). Among the earliest troubadours is Marcabrun, a pupil of Cercamon's, from whose pen we have about 40 pieces, those which can be approximately dated ranging from 1135 to 1148 or thereabout. His songs, several of which are historical, are free from the commonplaces of their class, and contain curious strictures on the corruptions of the time.

We cannot here do more than enumerate the leading troubadours and briefly indicate in what conditions their poetry was developed and through what circumstances it fell into decay and finally disappeared: Peter of Auvergne (Peire d'Alvernha), who in certain respects must be classed with Marcabrun; Arnaut Daniel, remarkable for his complicated versification, the inventor of the *sestina,* a poetic form for which Dante and Petrarch express an admiration difficult for us to understand; Arnaut of Mareuil, who, while less famous than Arnaut Daniel, certainly surpasses him in elegant simplicity of form and delicacy of sentiment; Bertran de Born, now the most generally known of all the troubadours on account of the part he is said to have played both by his sword and his *sirventescs* in the struggle between Henry II. of England and his rebel sons, though the importance of his part in the events of the time seems to have been greatly exaggerated; Peire Vidal of Toulouse, a poet of varied inspiration who grew rich with gifts bestowed on him by the greatest nobles of his time; Guiraut de Borneil, *lo maestre dels trobadors,* and at any rate master in the art of the so-called "close" style (*trobar clus*), though he has also left us some songs of charming simplicity; Gaucelm Faidit, from whom we have a touching lament (*planh*) on the death of Richard Coeur de Lion; Folquet of Marseilles, the most powerful thinker among the poets of the south, who from being a troubadour became first a monk, then an abbot, and finally bishop of Toulouse (d. 1231).

The troubadours could hardly expect to obtain a livelihood from any other quarter than the generosity of the great. It will consequently be well to mention the most important at least of those princes who are known to have been patrons and some of them practisers of the poetic art. They are arranged approximately in geographical order, and after each are inserted the names of those troubadours with whom they were connected.

France.—ELEANOR OF GUIENNE, Bernart de Ventadour (Ventadorn); HENRY CURTMANTLE, son of Henry II. of England, Bertran de Born (?); RICHARD COEUR DE LION, Arnaut Daniel, Peire Vidal, Folquet of Marseilles, Gaucelm Faidit; ERMENGARDE OF NARBONNE (1143–1192), Bernart de Ventadour, Peire Rogier, Peire d'Alvernha; RAIMON V., count of Toulouse (1143–1194), Bernart de Ventadour, Peire Rogier, Peire Raimon, Hugh Brunet, Peire Vidal, Folquet of Marseilles, Bernart de Durfort; RAIMON VI., count of Toulouse (1194–1222), Raimon de Miraval, Aimeric de Pegulhan, Aimeric de Belenoi, Ademar lo Negre; ALPHONSE II., count of Provence (1185–1209), Elias de Barjols; RAIMON BERENGER IV., count of Provence (1209–1245), Sordel; BARRAL, viscount of Marseilles (d. *c.* 1192), Peire Vidal, Folquet de Marseilles; WILLIAM VIII., lord of Montpellier (1172–1204), Peire Raimon, Arnaut de Mareuil, Folquet de Marseilles, Guiraut de Calanson, Aimeric de Sarlat; ROBERT, dauphin of Auvergne (1169–1234), Peirol, Perdigon, Pierre de Maensac, Gaucelm Faidit; GUILLAUME DU BAUS, prince of Orange (1182–1218), Raimbaut de Vacqueiras, Perdigon; SAVARIC DE MAULÉON (1200–1230), Gaucelm de Puicibot, Hugh de Saint Circq; BLACATZ, a Provençal noble (1200?–1236), Cadenet, Jean d'Aubusson, Sordel, Guillem Figueira; HENRY I., count of Rodez (1208–1222?), Hugh de Saint Circq; perhaps HUGH IV., count of Rodez (1222?–1274) and HENRY II., count of Rodez (1274–1302), Guiraut Riquier, Folquet de Lunel, Serveri de Girone, Bertran Carbonel; NUNYO SANCHEZ, count of Roussillon (d. 1241), Aimeric de Belenoi; BERNARD IV., count of Astarac (1249–1291), Guiraut Riquier, Amanieu de Sescas.

Spain.—ALPHONSE II., king of Aragon (1162–1196), Peire Rogier, Peire Raimon, Peire Vidal, Cadenet, Guiraut de Cabreira, Elias de Barjols, the monk of Montaudon, Hugh Brunet; PETER II., king of Aragon (1196–1213), Raimon de Miraval, Aimeric de Pegulhan, Perdigon, Ademar lo Negre, Hugh of Saint Circq; JAMES I., king of Aragon (1213–1276), Peire Cardinal, Bernart Sicart de Maruejols, Guiraut Riquier, At de Mons; PETER III., king of Aragon (1276–1285), Paulet of Marseilles, Guiraut Riquier, Serveri de Girone; ALPHONSO IX., king of Leon (1138–1214), Peire Rogier, Guiraut de Borneil, Aimeric de Pegulhan, Hugh de Saint Circq; ALPHONSO X., king of Castile (1252–1284), Bertran de Lamanon, Bonifaci Calvo, Guiraut Riquier, Folquet de Lunel, Arnaut Plages, Bertran Carbonel.

Italy.—BONIFACE II., marquis of Montferrat (1192–1207), Peire Vidal, Raimbaut de Vacqueiras, Elias Cairel, Gaucelm Faidit (?); FREDERICK II., emperor (1215–1250), Jean d'Aubusson, Aimeric de Pegulhan, Guillem Figueira; Azzo VI., marquis of Este (1196–1212), Aimeric de Pegulhan, Rambertin de Buvalelli; Azzo VIII., marquis of Este (1215–1264), Aimeric de Pegulhan.

The first thing that strikes one in this list is that, while the troubadours find protectors in Spain and Italy, they do not seem to have been welcomed in French-speaking countries. This, however, must not be taken too absolutely. Provençal poetry was appreciated in the north of France. There is reason to believe that when Constance, daughter of one of the counts of Arles, was married in 998 to Robert, king of France, she brought along with her Provençal jongleurs. Poems by troubadours are quoted in the French romances of the beginning of the 13th century; some of them are transcribed in the old collections of French songs, and the preacher Robert de Sorbon informs us in a curious passage that one day a jongleur sang a poem by Folquet of Marseilles at the court of the king of France.

The decline and fall of troubadour poetry was mainly due to political causes. When about the beginning of the 13th century the Albigensian War had ruined a large number of the nobles and reduced to lasting poverty a part of the south of France, the profession of troubadour ceased to be lucrative. It was then that many of those poets went to spend their last days in the north of Spain and Italy, where Provençal poetry had for more than one generation been highly esteemed. Following their example, other poets who were not natives of the south of France began to compose in Provençal, and this fashion continued till, about the middle of the 13th century, they gradually abandoned the foreign tongue in northern Italy, and somewhat later in Catalonia, and took to singing the same airs in the local dialects. About the same time in the Provençal region the flame of poetry had died out save in a few places—Narbonne, Rodez, Foix and Astarac—where it kept burning feebly for a little longer. In the 14th century composition in the language of the country was still practised; but the productions of this period are mainly works for instruction and edification. As for the poetry of the troubadours, it was dead forever.

Form.—Originally the poems of the troubadours were intended to be sung. The poet usually composed the music as well as the words; and in several cases he owed his fame more to his musical than to his literary ability. Two manuscripts preserve specimens of the music of the troubadours, but, though the subject has been carefully investigated, we are not able to form a clear opinion of the originality and of the merits of these musical compositions. The following are the principal poetic forms which the troubadours employed. The oldest and most usual generic term is *vers,* by which is understood any composition intended to be sung, no matter what the subject. At the close of the 12th century it became customary to call all verse treating of love *canso*—the name *vers* being then more generally reserved for poems on other themes. The *sirventesc* differs from the *vers* and the *canso* only by its subject, being for the most part devoted to moral and political topics. The *tenson* is a debate between two interlocutors, each of whom has a stanza in turn. The *partimen* (Fr. *jeu parti*) is also a poetic debate, but it differs from the tension in so far that the range of debate is limited. This poetic game is mentioned by William, count of Poitiers, at the end of the 11th century. The *pastoreta,* afterwards *pastorela,* is in general an account of the love adventures of a knight with a shepherdess. All these classes have one form capable of endless variations: five or more stanzas and one or two envois. The *dansa* and *balada,* intended to mark the time in dancing, are pieces with a refrain. The *alba,* which has also a refrain, is, as the name indicates, a waking or morning song at the dawning of the day. All those classes are in stanzas. The *descort* is not thus divided, and consequently it must be set to music right through. Its name is derived from the fact that, its component parts not being equal, there is a kind of "discord" between them. It is generally reserved for themes of love. Other kinds of lyric poems, sometimes with nothing new about them except the name, were developed in the south of France; but those here mentioned are the more important.

Chansons de Geste and Historical Poems.—Northern France remains emphatically the native country of the *chanson de geste;* but, although in the south different social conditions, a more delicate taste, and a higher state of civilization prevented a similar profusion of tales of war and heroic deeds, Provencal literature has some highly important specimens of this class. The first place belongs to *Girart de Roussillon,* a poem of ten thousand lines, which relates the struggles of Charles Martel with his powerful vassal the Burgundian Gerard of Roussillon. The existing recension seems to have originated on the borders of Limousin and Poitou; but it is a recast of an older poem no longer extant, probably either of French or at least Burgundian origin. To Limousin also seems to belong the poem of *Aigar and Maurin* (end of the 12th century). Of less heroic character is the poem of *Daurel and Beton* (first half of the 13th century). Midway between legend and history may be classified the Provencal *Chanson of Antioch,* a mere fragment of which, 700 verses in extent, has been recovered in Madrid and published in *Archives de l'Orient latin,* vol. ii. This poem (*see* G. Paris, in *Romania,* xxii. 358), is one of the sources of the Spanish compilation *La gran conquista de Ultramar.* To history proper belongs the Chanson of the crusade against the Albigensians, which, in its present state, is composed of two poems one tacked to the other: the first, containing the events from the beginning of the crusade till 1213, is the work of a cleric named William of Tudela, a moderate supporter of the crusaders; the second, from 1213 to 1218, is by a vehement opponent of the enterprise. The language and style of the two parts are no less different than the opinions. Finally, about 1280, Guillaume Anelier, a native of Toulouse, composed, in the *chanson de geste* form, a poem on the war carried on in Navarre by the French in 1276 and 1277. It is an historical work of little literary merit. All these poems are in the form of *chansons de geste,* viz. in stanzas of indefinite length, with a single rhyme. *Gerard of Roussillon, Aigar and Maurin* and *Daurel and Beton* are in lines of ten, the others in lines of twelve syllables. The peculiarity of the versification in *Gerard* is that the pause in the line occurs after the sixth syllable, and not, as is usual, after the fourth.

Narrative Poems.—We possess but three Provencal romances of adventure: *Jaufré* (composed in the middle of the 13th century and dedicated to a king of Aragon, possibly James I.), *Blandin of Cornwall* and *Guillem de la Barra.* Connected with the romance of adventure is the novel (in Provençal *novas,* always in the plural), which is originally an account of an event "newly" happened. Some of those novels which have come down to us may be ranked with the most graceful works in Provençal literature; two are from the pen of the Catalan author Raimon Vidal de Besalú. One, the *Castia-gilos* (the chastisement of the jealous man), is a treatment, not easily matched for elegance, of a frequently-handled theme—the story of the husband who, in order to entrap his wife, takes the disguise of the lover whom she is ex. pecting and receives with satisfaction blows intended, as he thinks, for him whose part he is playing; the other, *The judgment of Love,* is the recital of a question of the law of love, departing considerably from the subjects usually treated in the novels. Mention may also be made of the novel of *The Parrot* by Arnaut de Carcassonne, in which the principal character is an eloquent parrot, who assists the amorous enterprises of his master. Novels came to be extended to the proportions of a long romance. *Flamenca,* which belongs to the novel type, has still over eight thousand lines, though the only ms. of it has lost some leaves both at the beginning and at the end. This poem, composed in all probability in 1234, is the story of a lady who by very ingenious devices, not unlike those employed in the *Miles gloriosus* of Plautus, eludes the vigilance of her jealous husband. No book in mediaeval literature betokens so much quickness of intellect or is so instructive in regard to the manners and usages of polite society in the 13th century. From the south of France the novel spread into Catalonia, where we find in the 14th century a number of novels in verse very similar to the Provencal ones, and into Italy, where in general the prose form has been adopted.

Didactic and Religious Poetry.—The more important works are: Daude de Prades (early 13th century), *Auzels cassadors,* one of the best sources for the study of falconry; a translation by Raimon d'Avignon (about A.D. 1200) of Rogier of Parme's "Surgery" (*Romania,* x. 63 and 496); the Boethius poem (unfortunately a mere fragment) already mentioned as one of the oldest documents of the language, and really a remarkable work; an early (12th century?) metrical translation of the famous *Disticha de moribus* of Dionysius Cato (*Romania,* xxv. 98 and xxix. 445). More original are some compositions of an educational character known under the name of *ensenhamenz,* and, in spme respects, comparable to the English nurture-books. The most interesting are those of Garin le Brun (12th century), Arnaut de Mareuil, Arnaut Guilhem de Marsan, Amanieu de Sescas. Their general object is the education of ladies of rank. Of metrical lives of saints we possess about a dozen (see *Histoire littéraire de la France,* vol. xxxii.), among which two or three deserve a particular attention: the life of Sancta Fides (A. Thomas and E. Hoepffner's editions), written early in the 12th century; the life of St. Enimia (13th century), by Bertran of Marseilles (C. Brunel's edition) and that of St. Honorat of Lerins by Raimon Feraud (about 1300), which is distinguished by variety and elegance of versification, but it is almost entirely a translation from Latin. Lives of saints (St. Andrew, St. Thomas the Apostle, St. John the Evangelist) form a part of a poem, strictly didactic, which stands out by reason of its great extent (nearly 35,000 verses) and the somewhat original conception of its scheme—the *Breviari d'amor,* a vast encyclopaedia, on a theological basis, composed by the Minorite friar Matfre Ermengaut of Béziers ca. 1288–1300.

Drama.—The dramatic literature of southern France consists of mysteries and miracle plays seldom exceeding two or three thousand lines, which never developed into the enormous dramas of northern France, whose acting required several consecutive days. Generally those plays belong to the 15th century or to the 16th. Still, a few are more ancient and may be ascribed to the 14th century or even to the end of the 13th. The oldest appears to be the *Mystery of St. Agnes* (edited by Bartsch, 1869), written in Arles. Somewhat more recent, but not later than the beginning of the 14th century, is a Passion of Christ (not yet printed) and a mystery of the Marriage of the Virgin, which is partly adapted from a French poem of the 13th century (see *Romania* xvi. 71). A manuscript, discovered in private archives (printed by Jeanroy and Teulié, 1893), contains not less than 16 short mysteries, three founded on the Old Testament, 13 on the New. They were written in Rouergue and are partly imitated from French mysteries. At Manosque (Basses Alpes) was found a fragment of a *Ludus sancti Jacobi,* inserted in a register of notarial deeds (printed by C. Arnaud, Marseilles, 1858). The region comprised between the Rhone and the Var seems to have been particularly fond of representations of this sort, to judge by the entries in the local records (see *Romania* xxvii. 400). At the close of the 15th and the beginning of the 16th centuries many mysteries were played in that part of Dauphiné which corresponds to the present department of Hautes-Alpes. Five mysteries of this district, composed and played somewhere about 1500 (the mysteries of St. Eustace, of St. Andrew, of St. Pons, of SS. Peter and Paul and of St. Anthony of Vienne), have come down to us, and have been edited by Abbé Fazy (1883), the four others by Canon P. Guillaume (1883–1888). The influence of the contemporary French sacred drama may to some extent be traced in them.

Prose.—In the 12th century we find in Languedoc sermons, whose importance is more linguistic than literary (*Sermons du XII^e siècle en vieux provençal,* ed. by F. Armitage, Heilbronn, 1884). About the same time, in Limousin, were translated chapters xiii.–xvii. of St. John's Gospel (Bartsch, *Chrestomathie provençale*). Various translations of the New Testament and of some parts of the Old have been done in Languedoc and Provence during the 13th and 14th centuries (see S. Berger, "Les Bibles provenqales et vaudoises," Romania xviii. 353; and "Nouvelles recherche~sur les Bibles provenqales et catalanes," ibid, xix. 505). The Provenqal prose rendering of some lives of saints made in the early part of the 13th century (Revue des *langues romanes,* 1890) is more interesting from a purely linguistic than from a literary point of view. To the 13th century belong certain lives of the troubadours intended to be prefixed to, and to explain their poems. Many of them were written before 1250, when the first anthologies of troubadour poetry were compiled; and some are the work of the troubadour Hugh of Saint Circq. Some were composed in the north of Italy, at a time when the troubadours found more favour east of the Alps, than in their own country. Considered as historical documents these biographies are of a very doubtful value. To the same period must be assigned Las Razos de trobar of the troubadour Raimon Vidal de Besald (an elegant little treatise touching on various points of grammar and the poetic art), the Donatz *proensals* of Hugh Faidit, and the Life of St. *Douceline,* who died in 1274, near Marseilles, and founded an order of Béguines.

The leading prose-work of this period is the treatise on grammar, poetry and rhetoric known by the name of Leys *d'amors.* (*See* J. Anglade, Las leys d'amors, 4 vol., Toulouse, 1919–1920.) The Leys d'amors (composed in Toulouse circa 1350) was to be the starting-point and rule of the new poetry; it is the best production of this abortive renaissance. The decay of Provenqal literature, caused by political circumstances, arrived too soon to allow of a full development of prose. This accounts, in some measure for the complete absence of historical compositions. The 14th and 15th centuries were in no respect a prosperous period for literature in the south of France. In the 15th century people began to write French both in verse and prose; and from that time Provenqal literature became a thing of the past. From the 16th century such poetry as is written in the vernacular of southern France is generally dependent on French influence. The connection with ancient Provençal literature is entirely broken.

See Joseph Anglade, Les Troubadours, Paris, 1908; and *Histoire sommaire* de la litttrature *méridionale au* moyen *âge.* Both volumes contain a bibliography. Documents and dissertations on various points of Provençal literature will be found in almost all the volumes of Romania (Paris, in progress since 1872, 8vo), and the Revue des *langues romanes* (Montpellier, in progress since 1870, 8vo). See also the other journals devoted to the Romanic languages, passim.

(X., L. B.)

MODERN PROVENÇAL LITERATURE[1]

Provencal literature never died out entirely. The Academy of Toulouse, founded in 1324, was flourishing in the 14th century, and, after many vicissitudes, is flourishing still. The poets crowned by this body between 1324 and 1498 stand in the same relation to the troubadours as the *Meistersinger* do to the *Minnesänger:* academic correctness takes the place of inspiration. The institution flourished, even to the extent of establishing branches in Catalonia and Majorca; and in 1484, when its prosperity was threatened, a semi-fabulous person, Clémence Isaure, is said to have brought about a revival by instituting fresh prizes. The town of Toulouse never ceased to supply funds of some kind. In 1513 French poems were first admitted in the competitions, and under Louis XIV. (from 1679) these were alone held eligible. This arrangement held good till 1893, when the town very properly transferred its patronage to a new *Escolo moundino,* but very soon restored its support to the older institution, on learning that Provencal poetry was again to be encouraged. In the two centuries that followed the glorious mediaeval period we have a succession of works, chiefly of a didactic and edifying character, which served to keep alive some kind of literary tradition. Religious mystery plays, which, though dull to us, probably gave keen enjoyment to the people, represent a more popular genre; the latest that have come down to us may be placed between the years 1450–1515.

[1]In accordance with general usage, we are employing the term Provenqal for the whole of the south of France, save where special reservation is made.

In the 16th century there are signs of a revival and we may single out the following: the Gaston Pey de Garros who translated in 1565 the psalms into his dialect, and two years later published a volume of poems; Auger Gaillard (*c.* 1530–1595); du Bartas (in his trilingual *Salut,* 1579); Louis Bellaud de la Bellaudibre (1532–1588).

Post-Renaissance.— Later on come: Claude Brueys (1570–1650), remarkable chiefly for comedies that deal largely with duped husbands (*Jardin* deys *musos* provensalos, not published till 1628); Gaspard Zerbin (La *Perlo* deys *musos* et coumedies *prouvensalos,* 1655). The most consistently popular form of poetry in the south of France was always the noel. Nicholas Saboly (1614–1675), produced the best pieces of this class. In Languedoc four poets are cited as the best of the age—Goudelin, Michel, Sage and Bonnet. This is certainly so in the case of Pierre Goudelin (Goudouli, 1579–1649), of Toulouse, the most distinguished name in south French literature between the period of the troubadours and that of Jasmin. Goudelin essayed and was successful in almost every short genre (Lou Ramelet Moundi, 1617, republished with additions till 1678), the piece of his which is most generally admired being the stanzas to Henri IV. Other writers worth mentioning in the 17th century are: Jean Michel, of Nîmes; Daniel Sage, of Montpellier (Las Foulies, 1650); the *avocat* Bonnet, author of the best among the open air plays that were annually performed at Béziers on Ascension day: a number of these (dated 1616–1657) were subsequently collected, but none can compare with the opening one, Bonnet's *Jugement* de *Pâris;* Nicolas Fizes, of Frontignan, whose vaudeville, the *Opéra* de *Frontignan* (1670), dealing with a slight love intrigue, and an idyllic poem on the fountain of Frontignan, show a real poetic gift. A number of Toulouse poets, mostly *lauréats* of the Academy, may be termed followers of Goudelin: of these Franqois Boudet, who composed an ode, Le *Trinfe del Moundi* (1678), in honour of his native dialect deserves mention. The classical revival that may be noted about this time is also generally ascribed to Goudelin's influence. Its most distinguished representative was Jean de Valès, of Montech, who made excellent translations from Virgil and Persius, and wrote a brilliant burlesque of the former in the manner of Scarron (Virgile deguisat, 1648).

The best of the pastoral poets was Franqois de Cortete (1571–1655), of Prades, whose comedies, Ramounet and Miramoundo (published, unfortunately with alterations, by his son in 1684), are written with such true feeling and in so pure a style that they can be read with real pleasure. A comedy of his dealing with Sancho Panza in the palace of the Duke has been edited. Daubasse (1664–1727), of Quercy, who belonged to the working classes, was patronized by the nobility in exchange for panegyrics. Gascony produced two typical works in the 17th century: Ader's *Gentilhomme* gascoun (1610) and G. d'Astros's Trinfe de la *lengo* gascouo (1642). Gabriel Bedout (Parterre *gascoun,* 1642) is chiefly noted for his amorous *solitari.* Louis Baron (b. 1612), celebrated with great tenderness his native village of Pouyloubrin.

In the 18th century the number of authors is much larger, but the bulk of good work produced is not equally great in proportion. The priests are mainly responsible for the literary output of Languedoc. The chief of the band is the Abbé Favre (1727–1783), the prior of Celleneuve, whose Ou *sermoun* de *Moussu Sistre* delivered a drunken priest against intemperance, is a masterpiece. He also wrote a successful mock-heroic poem (*Siège* de Caderouss) travesties of Homer and Virgil, a prose novel depicting the country manners of the time (Histoudro de Jean-l'an-prks), and two comedies, which likewise give a vivid picture of the village life he knew so well. Two genuine poets are the brothers Rigaud of Montpellier: Auguste's (1760–1835) description of a vintage is deservedly famous; and Cyrille (1750–1824) produced an equally delightful poem in the Amours de *Mounpëié.* Pierre Hellies of Toulouse (d. 1724) a poet of the people, whose vicious life finds an echo in his works, has a certain rude charm, at times distantly recalling Villon. In Provence Toussaint Gros (1698–1748), of Lyons, holds undisputed sway. His style and language are admirable, but unfortunately he wasted his gifts largely on trivial *pièces d'* occasion. Coye's (1711–1777) comedy, ou *Novy* para, is bright and still popular, while Germain's description of a visit paid by the ancient gods to Marseilles (Bourrido dei *Dious,* 1760) has considerable humour. In Gascony the greatest poet is Cyrien Despourrins (1698–1755).

The 19th Century. — The Revolution produced a large body of literature, but nothing of lasting interest. Scholars like Raynouard (1761–1863), of Aix, occupied themselves with the brilliant literary traditions of the middle ages; newspapers sprang up (the Provencal *Bouil-Abaisso,* started by Désanat, and the bilingual Lou *Tambourin* et le *menestrel,* edited by Bellot, both in 1841); poets banded together and collected their pieces in volume form (thus, the nine troubaire who published Lou Bouquet *prouvençaou* in 1823). Much has been written about the *précurseurs* de *Félibrige,* and critics are sorely at variance as to the writers that most deserve this appellation. We shall not go far wrong if we include in the list Hyacinthe Morel (1756–1829), Louis Aubanel (1758–1842); Auguste Tandon, "the troubadour of Montpellier"; Fabre d'Olivet (1767–1825); Diouloufet (1771–1840); Jacques Azaïs (1778–1856); D'Astros (1780–1863), Castil-Blaze (1784–1857); the Marquis de Fare-Alais (1791–1846). While these writers were all more or less academic, and appealed to the cultured few, four poets of the people addressed a far wider public: Verdié (1779–1820), of Bordeaux, who wrote comic and satirical pieces; Jean Reboul (1796–1864), the baker of Nîmes, who never surpassed his first effort, *L'Ange* et *l'enfant* (1828); Victor Gelu (1806–1885), relentless and brutal, but undeniably powerful of his kind (Fenian et *Grouman;* dix chansons *provengales,* 1840); and, greatest of them all, the true and acknowledged forerunner of the *félibres,* Jacques Jasmin (*q.v.*).

Roumanille and Mistral. — In 1845 Joseph Roumanille (1818–1891) of Saint-Remy became usher in a small school at Avignon, which was attended by Frédéric Mistral (*q.v.*). Roumanille had composed some pieces in French; but, finding that his old mother could not understand them, he determined thenceforth to write in his native dialect only. These poems revealed a new world to young Mistral, and spurred him on to the resolve that became the one purpose of his life—de remettre en *lumière* et conscience de sa gloire cette noble race qu'en *plein'89* Mirabeau nomme encore la nation *provençale.* There is no doubt that Mistral's is the more puissant personality, and that his finest work towers above that of his fellows; but in studying the Provencal renaissance, Roumanille's great claims should not be overlooked, and they have never been put forward with more force than by Mistral himself (in the preface of his Isclos d'oro). Roumanille's secular verse cannot fail to appeal to every lover of pure and sincere poetry (Li Margaritedo, 1836–1847; *Li Sounjarello,* 1852; *Li* Flour de *Sauvi,* 1850–1859, etc.), his noels are second only to those of Saboly, his prose works (such as Lou mege de Cucugnan, 1863) sparkling with delightful humour. He it was who in 1852 collected and published *Li Prouvençalo,* an anthology in which all the names yet to become famous, and most of those famous already (such as Jasmin), are represented. In 1853 he was one of the enthusiastic circle that had gathered round J. B. Gaut at Aix, and whose literary output is contained in the *Roumavagi* dei Troubaire and in the shortlived journal Lou gay saber (1854). At the same time the first attempt at regulating the orthography of Provencal was made by him (in the introduction to his play, La Part dou bon Dieu, 1853). And in 1854 he was one of the seven poets who, on May 21, foregathered at the castle of Font-ségugne, near Avignon, and founded the *Félibrige.* (See Emile Ripert, La Renaissance *Provençale.*) The other six were Mistral, Aubanel, A. Mathieu (a schoolfellow of Mistral's at Avignon), E. Garcin, A. Tavan and P. Giera (owner of the castle). Of these, Théodore Aubanel (1829–1886, of Avignon, son of a printer and following the same calling) has alone proved himself worthy to rank with Mistral and Roumanille. "Zani," the girl of his youthful and passionate love, took the veil; and this event cast a shadow over his whole life, and determined the character of all his poetry (Lou *mióugrano entre-duberto,* 1860; *Li* Fiho *d'Avignoun,* 1883). His is, without a doubt, the deepest nature and temperament among the fe'libres, and his lyrics are the most poignant. His powerful love drama Lou pau dou peccat was received with enthusiasm at Montpellier in 1878, and successfully produced (some years later in Arène's version) by Antoine at his Théâtre Libre.

We need not do more than glance at the work of the fourth of the group of poets who alone, amidst the numerous writers of lyrics and other works that attain a high level of excellence, appear to us to have so far secured permanent fame by the magnitude of their achievement. Félix Gras (1844–1891) settled at Avignon in his youth. His rustic epic, Li *Carbounié* (1876) is full of elemental passion and abounds in fine descriptions of scenery, but it lacks proportion. The heroic geste of *Toloza* (1882), in which Simon de Montfort's invasion of the south is depicted with unbounded vigour and intensity, shows a great advance in art. *Li Roumancero provençal* (1887) is a collection of poems instinct with Provencal lore, and in *Li Papalino* (1891) we have some charming prose tales that bring to life again the Avignon of the popes. Finally, the poet gave us three tales dealing with the period of the Revolution (Li Rouge *dou miejour,* etc.).

Since the end of the 19th century the Félibrige has considerably developed: it now constitutes important groups in the different parts of Southern France from the Pyrenees to Auvergne, Velay and Dauphiné. These groups represent the most varied opinions in politics and religion, and for the expression of their ideas they resort to the whole range of dialects and patois actually used in Southern France. The spirit of the movement, is purely literary; it has never been expressed with greater terseness, force and truth than in the three verses set by Félix Gras at the head of his *Carbounié:* "I love my village more than thy village; I love my Provence more than thy province; I love France more than all."

See Emile Ripert, *Le Félibrige* (Paris, 1924. Contains an excellent bibliography). (H. O.; L. B.)

PROVENCE, a province in the south-east of ancient France, bounded on the north by the Dauphiné, on the east by the Alps and Italy, on the west by the Rhone, and on the south by the Mediterranean sea. About 600 B.C., according to tradition, some traders from Phocaea founded the Greek colony of Massalia (Marseille). Other colonies in the neighbourhood, such as Antibes, Agde, Nice, originated in this settlement. During the wars which followed the inhabitants of Massalia asked assistance from the Romans, who thus made their first entry into Gaul (125 B.c.), and conquered the territories between the Alps, the sea and the Rhone (with the province of Narbonne on the right bank of this river). These lands formed the Provincia romana, and the name was retained by Provence. The town of Aix (Aquae Sextiae) was founded to form the capital of this conquered land. Under the empire the territory of the former Provincia was divided into the new provinces of Narbonensis II., of the Maritime Alps and of Viennois, and formed an important centre of Roman learning and civilization. Arles was made the chief town of the province, becoming after the capture of Trèves by the barbarians (A.D. 418) the capital of Gaul. By the 5th century bishoprics had been founded in all the cities of Provence.

At the beginning of this century Provence was attacked by the Visigoths. In 480 Arles was captured by Euric I., and the country south of the Durance thus came definitely under Visigothic rule. The more northern cities, such as Orange, Apt and Trois-Chbteaux, were joined to the kingdom of Burgundy. Towards 510 Visigothic Provence was ceded to Theodoric, king of the Italian Ostrogoths, by Alaric II. in return for the support given to him during the war against the Franks, and soon afterwards the Ostrogoths took advantage of the wars between the Franks and the Burgundians to extend their lands in the north as far as Gap and Embrun. Witigis, king of the Ostrogoths, ceded Provence to the kings of the Franks about 537, when the northern cities and those on the coast (Arles, Marseille, Toulon, Antibes, Nice) were given back to Burgundy, whilst a narrow strip of territory, with Avignon, Apt, Cavaillon, Riez, etc., extending from the west to the east as far as the Alps, was added to the kingdom of Austrasia, and from that time followed the fortunes of its dependency of Auvergne.

In the 8th century western Provence was for a time conquered by Arabs from Spain. In 739 they were expelled by Charles Martel, who brought the country definitely under Frankish rule. Under Charlemagne and Louis the Pious the history of Provence became incorporated with that of the rest of the empire. At the partition of Verdun (843) Provence fell to the share of the emperor Lothair I., who joined it to the duchy of Lyons in 855 to form a kingdom for his youngest son, Charles. On the death of the latter in 863 his inheritance was divided between his two brothers, when Lothair II., king of Lorraine, received the northern part, Lyonnais and Viennois, and the emperor Louis II., king of Italy, received Provence. At his death in 875 Provence passed into the hands of Charles the Bald, and he entrusted the government to his brother-in-law, Duke Boso, who reconstituted the former kingdom of Charles, the son of Lothair, and in 879 was acknowledged as its sovereign at Mantaille in Viennois. Thus arose the kingdom of Provence (Provence, Viennois, Lyonnais and Vivarais), sometimes called Cisjuran Burgundy.

Boso died in 887, having succeeded in maintaining his independence against the united Frankish princes. His widow Ermengarde, daughter of Louis II., with the assistance of the emperor Arnulf, had her son Louis acknowledged king at an assembly held at Valence in 890. Louis attempted to seize the crown of Italy in 900, and in 901 was even crowned emperor at Rome by Pope Benedict IV.; but in 905 he was surprised at Verona by his rival Berengar, who captured him, put out his eyes, and forced him to give up Italy and return to Provence, where he lived till his death in 928, leaving an illegitimate son, Charles Constantine. The principal figure in the country at this time was Hugo "of Arles," count, or duke, of Viennois and marquis of Provence, who had been king of Italy since 926. To strengthen his position there he gave the kingdom of Louis the Blind to Rudolph II., king of Burgundy (*q.v.*), and thus the kingdom of Burgundy extended from the source of the Aar to the Mediterranean. But the sovereignty of Rudolph II. and his successors, Conrad (937–993) and Rudolph III. (993–1032), over Provence was little more than nominal, and conditions changed little when, on the death of Rudolph III., the kingdom of Burgundy passed into the hands of the German kings, who now bore the title of kings of Arles.

Local Countships.—At the beginning of the 10th century Provence was in a state of complete disorganization. All the real power was in the hands of local counts. It is probable that from the 9th century several of the Provençal countships were united under one count, and that the count of Arles had the title of duke, or marquis, and exercised authority over the others. In the middle of the 10th century this position was held by a certain Boso, of unknown origin, who left it to his two sons William and Roubaud (Rotbold). From the end of the 10th century the descendants of the two brothers, without making any partition, ruled over the different countships of Provence, only one of them, however, bearing the title of marquis. The counts of Provence had, from about the middle of the 11th century, a tendency to add the name of their usual residence after their title, and thus the lordships, known later under the names of the countships of Provence, of Nice and of Venaissin grew up. At last, by the marriage of an heiress in 1112 to Raymund-Bérenger, count of Barcelona, the marquisate of Provence, with the overlordship of this region, passed to the house of Barcelona. The definite establishment of the countships of Provence, Venaissin and Forcalquier belongs to this period.

After the death of Raymund-Bérenger III. (1166) his cousin Alphonso II., king of Aragon, took the title of count of Provence. His succession was disputed by the count of Toulouse, Raymund V. Most of the lay and ecclesiastical lords of Provence recognized Alphonso, who in 1176 signed a treaty with his competitor, by which Raymund V. sold his rights to the king of Aragon. Alphonso was represented in Provence by his brothers Raymund-Bérenger and Sancho in turn, and in 1193 by his son Alphonso, who succeeded him. This Alphonso gave Aragon and Catalonia to his brother Peter (Pedro), and kept only Provence for himself, but on the death of his father-in-law, Count William II., in 1208, whose son had been disinherited, he added to it the county of Forcalquier. He was able to protect Provence from the consequences of the war of the Albigenses, and it was not until after his death (1209), during the minority of his son Raymund-Bérenger IV., that Provence was involved in the struggle of the count of Toulouse against Simon de Montfort, when the part played by the city of Avignon in the Albigensian movement finally led to Louis VIII.'s expedition against the town. Raymund-Bérenger had also to fight against Raymund VII., count of Toulouse, who had received from the emperor in 1230 the countship of Forcalquier. The intervention of St. Louis, who in 1234 had married Margaret, the eldest daughter of the count of Provence (the second Eleanor married Henry III. of England in 1236), put an end to the designs of the count of Toulouse. Raymund-Bérenger died in 1245, leaving a will by which he named as his heiress his fourth daughter, Beatrice, who shortly afterwards, in 1246, married the celebrated Charles of Anjou (see CHARLES I., king of Naples), brother of the king of France. After her death, in 1267, Charles still maintained his rights in Provence. The countship of Venaissin was left to him by his sister-in-law, Jeanne, countess of Toulouse, but in 1272 King Philip III. took possession of it, giving it up in 1274 to Pope Gregory X., who had claimed it for the Roman Church in pursuance of the treaty of 1229 between Raymund VII. of Toulouse and St. Louis. Charles of Anjou was continually occupied with his kingdom of Naples. His government of Provence was marked by his struggles with the towns. In the first part of the 12th century the towns of Provence began to form municipal administrations and consulates, independent of the viscounts, who in theory represented the authority of the count in the towns. Marseille, Arles, Tarascon, Avignon (whose consulate laws date from the 12th century), Brignoles and Grasse had become self-governing and elected their magistrates, sometimes negotiating with the count, as a power with a power, and concluding political or commercial treaties without consulting him. The city of Nice, which was joined to Provence in 1176, had retained its freedom. This state of affairs was in direct opposition to the arbitrary policy of Charles of Anjou. In 1251 he seized Arles and Avignon and placed them under a *viguier* (vicar) nominated by himself. In 1257 Marseille was also subdued, and ministers nominated by the court performed their duties side by side with the municipal officials.

Annexation to France.—The successors of Charles of Anjou were chiefly interested in maintaining their rights over the kingdom of Naples. Charles II. (1285–1309) lived in Provence during the latter years of his reign, and tried to introduce reforms into the administration of justice and finance. Robert of Calabria (1309–43), his son, was succeeded by his granddaughter Joanna, widow of Andrew of Hungary, who sold her rights over the city of Avignon to Pope Clement VI. in 1348 to raise money to continue the struggle against the house of Aragon in Naples. Charles IV. resided in Provence and had himself crowned king of Arles in 1365. He gave up his claims to Louis, duke of Anjou, brother of Charles V., but the expedition which this prince made to take possession of Provence only resulted in the seizure of Tarascon, and failed before Arles (1368). Joanna had nominated as her heir Charles of Anjou-Gravina, duke of Duras, who had married her niece Margaret, but to provide herself with a protector from Louis of Hungary, who accused her of murdering her first husband Andrew and wished to dispute her right to the kingdom of Naples, she married again and became the wife of Otto of Brunswick. Charles of Duras therefore took part against her, and she in her turn disinherited him and named Louis of Anjou as her eventual successor (1380). He took possession of Provence, whilst Charles of Duras made the queen prisoner at Naples and gave orders for her to be put to death (1382). Louis of Anjou also made an expedition to Naples, but did not arrive till after her death, and he died in 1384. His son Louis II. (1384–1417), only resident in Provence towards the end of his life, established a *parlement* in 1415. The wars carried on by his successor, Louis III. (1417–34), against the kings of Aragon, his rivals at Naples, were the cause of the temporary ruin of Marseille by the Aragonese fleet. René, duke of Lorraine (*q.v.*), Louis's brother and successor, after an unsuccessful attack on Naples (1460–61), retired to France, and after 1471 generally resided in

Provence, where he built the castle of Tarascon and interested himself in art, literature and pastoral amusements. In 1474 he left his territories by will to his nephew Charles, count of Maine, who on his death in 1482 bequeathed Provence to Louis XI., king of France. Under Louis's successor, Charles VIII., Provence was definitely annexed to France, though even then it preserved a certain individuality. In laws relating to this country the sovereigns added to their title of king of France "and count of Provence and of Forcalquier," and Provence always preserved a separate administrative organization.

Religious Troubles.—In the 16th century Protestantism made its appearance in Provence. A sentence passed in 1540 by the *parlement* of Provence against the heretics was carried out with great severity in 1545 by the president d'Oppède and the baron de la Garde. The movement drew a fair number of followers from the ranks of the lesser nobles. Charles IX.'s journey in Provence in 1567, followed by the establishment in the parlement at Aix of a court (chambre), in which Catholics and Protestants had an equal number of seats, led to a momentary cessation of hostilities. These were resumed between the *Carcistes* (Roman Catholics) and *Razats* (Protestants), and again interrupted by the peace of 1576, which gave some guarantees to the Protestants, with La Seyne as a place of security, and also by the plague of 1579, which affected the whole country. The League, on the other hand, made rapid progress in Provence, and the governors of Épernon and La Valette vainly tried to pacify the country. La Valette and the political party or Bigarrats were finally more or less reconciled to the Protestants, and, at the time of the death of Henry III., the struggle was no more than a question of local politics. In 1596 the religious wars in Provence were definitely ended by the capitulation of Marseille.

Under Richelieu the restriction of local freedom led to a rising which Condé suppressed in 1630–31. At the time of the Fronde additional taxes were levied by the parlement at Aix, and a period of local unrest began which culminated in an insurrection at Marseille in 1660 followed by the abolition of the last remaining municipal liberties of the town. Provence was severely tried by the imperialist invasions of 1706 and 1746, and the great plague of 1720.

Administration.—Provence, with its own language and its law so closely related to Roman law, was quite separate from the other French provinces. Until 1639 it retained its provincial estates, the origin of which has been traced back to the 12th century. They met annually, and included representatives of three orders: for the clergy, the archbishop of Aix, president *ex officio* of the estates, the other bishops of Provence, the abbots of St. Victor at Marseille, of Montmajour and of Thoronet; for the nobility, all the men of noble birth until 1623, when this privilege was restricted to actual holders of fiefs; for the third estate the members of the 22 chief towns of the vigueries divisions corresponding to the *prévôtés* of the rest of France, and 15 other privileged places, among which were Arles and Marseille. There were theoretically no taxes, but only supplies given freely by the estates and assessed by them. The administrative divisions of Provence were constantly changing. At the end of the *ancien régime* the government (gouvernement) of Provence, which corresponded to the *généralité* of Aix, was made up of eight *sénéchaussées,* those of Lower Provence—Aix, Arles, Marseille, Brignoles, Hyères, Grasse, Draguignan, Toulon; and four of Upper Provence—Digne, Sisteron, Forcalquier, Castellane. For judicial purposes the parlement of Aix had replaced the former conseil eminent or *cour souveraine.* There was a chambre des *comptes* at Aix, and also a cour des aides. A decree, dated Dec. 22, 1789, divided Provence into the three departments of Bouches du Rhône, Basses-Alpes and Var, and in 1793 Vaucluse, the former county of Venaissin, which belonged to the pope, was added to these. The boundaries of Var were modified in 1860 after the annexation, when the department of the Alpes Maritimes was formed.

Bibliography.—There is no good general history of Provence. For a complete work consult the ancient works of H. Bouche, *Chorographie et histoire, chronologique* de *Provence* (2 vols., Aix, 1664); J. P. Papon, *Histoire générale* de Provence (4 vols., 1777–86); L. Méry, *Histoire de Provence* (3 vols., Marseille, 1830–37). For special periods of history see P. Cabasse, *Essais historiques* sur *le* parlement *de Provence* (3 vols., Aix, 1826); G. Lambert, *Essai* sur le *régime* municipal et *l'affranchissement* des communes en Provence (Toulon, 1882); F. Kiener, *Verfassungsgeschichte der Provence, 510–1200* (Leipzig, 1900); R. Poupardin, *Le Royaume* de Provence *sous les Carolingiens* (1901); G. de Manteyer, *La* Provence *du 1er au xiie siècle* (1907). (R. P.; X.)

PROVERBS, BOOK OF.

PROVERBS, BOOK OF. This Old Testament book falls into nine sections. Each of these has its special stylistic and other characteristics, some of them containing evident traces of compilation from earlier collections, one (as has only lately been recognized) being almost completely paralleled in an extant Egyptian book, while individual proverbs are found to bear traces of the "international" character of their origin and are variously related to the culture of Egypt, Babylonia, Greece, etc. (see Wisdom Literature). Moreover the tradition preserved in the book itself which ascribed certain parts of the book to Solomon (x. 1, xxv. 1), the "sages" (xxii. 17, xxiv. 23), Agur (xxx. 2), King Lemuel's mother (xxxi. 2) militates against the view that any one author was responsible for the composition of these various sections of the book: the ascription to Solomon in i. 1 probably referred originally to chs. i.–ix.—though this was probably the last section to be compiled.

Wellnigh the only characteristics common to all sections of the book may be summed up under three heads and these are not confined to the Book of Proverbs but are to be found in nearly all the extant gnomic literature of the Hebrews—the presuppositions that "wisdom" comes from Jehovah, that wisdom is, or should be, the guiding principle of life, and that cardinal social virtues such as industry, thrift, discretion, truthfulness, honesty, chastity, thought for others, including the lower animals, should be inculcated. Consequently in its present form the book represents the last stage in a long compilatory history and provides many useful examples of Hebrew proverbial and gnomic thought at various stages of its development. The date of each section and sub-section must be alternately determined by the character of its contents, the relation in which the latter stands to the extant gnomic literature of other peoples, and the stage or stages of moral and theological development reflected in it.

Chapters **i.–ix.**—The first section serves as an introduction to the whole book, but in origin it is of late date and its contents suggest that, like the book as a whole, it was compiled from more than one source. At times, for instance, the motive advanced for good conduct is moral and religious (*e.g.*, ii. 5–8): at times it is frankly utilitarian (*e.g.*, vi. 1–5). Instead of a series of unrelated proverbial couplets, such as those in the following section, comparatively long discourses follow on each other. The sage addresses his remarks to young men. Though not confining his warnings to these two offences, he warns them more especially against highway robbery and adultery—unless indeed the latter is an only too thinly veiled warning against Hellenism (cf. "Madam Folly" in ch. ix. 13–18) conceived of as a prostitute enticing the uninstructed ("ye simple ones") from their allegiance to their true love, the "wisdom" which comes from Jehovah, incarnate, as it were, in His religion, Judaism. Somewhat similar warnings against woman's wiles are given by Egyptian sages such as Amenophis and Ptah-hoteph, and by the Mesopotamian author of the Wisdom of Ahikar. The section is chiefly remarkable for the developed thought contained in viii. 1–31 as to "wisdom," her relation to God, the universe and man. It is perhaps more developed than, not only Eccles. xxiv. 1–19, but also the descriptions of her in the Book of Wisdom. "Wisdom" claims to have existed prior to the universe (*cf.* "in the beginning" with the first words of Gen. i. 1 and John i. 1) as a possession of God (viii. 22 sff.), to have witnessed the creation of the universe, and even to have acted as a clerk of the works or architect in the process of the creation, unless, as the parallelism of the verse makes probable, the vocalization of the Hebrew word translated "master workman" should be altered to justify the rendering "nursling." But it is questionable whether even here the Hebrew author does more than poetically *personify* the *principle* of wisdom: he scarcely gives her a real hypostasis and does not go so far in this direction as did Philo in his description of the Logos as "a second god."

It is not, however, outside the bounds of possibility that the author of the prologue to the Fourth Gospel was considerably influenced by this description of wisdom rather than by Philo's descriptions of his Logos, even though he substituted the latter term for "wisdom." This advanced thought as to wisdom is not confined to ch. viii., but seems to be more or less presupposed throughout the section. The author's philosophy of life otherwise shows little of a pronouncedly modern character. Righteousness and wickedness are rewarded in this life (*e.g.*, ii. 21); the sacrificial worship is inculcated (ii. 9, iii. 9); the words "law" and "commandment" are used now of the Mosaic system, now of parental injunctions, now of the sage's advice. It is the language and philosophy of life characteristic of Deuteronomy which are most prominent; suffering is divine chastisement administered, however, in love (iii. 12).

Chapters **x.–xxii.**—The second section illustrates earlier stages in the literary productions and ideals of the exponents of wisdom. Each proverb is confined to two lines, antithetical in form if we except a few in which synonymous parallelism occurs. The utilitarianism of the compiler of this section is often overemphasized: it contains, on the contrary, sentiments which anticipate some of the highest ideals expressed in the New Testament and to which the latter owe their literary form (*e.g.*, x. 12 cf. 1 Cor. xiii. 7, 1 Pet. iv. 3, James v. 20; xiv. 31; xvii. 5, cf. Matt. xxv. 40, 45; xx. 11, *cf.* Matt. vii. 16; xx. 22, *cf.* Matt. v. 39, Rom. xii. 17, 19, etc.). It reflects, moreover at times the "prophetic" revolt against the hollowness of merely external sacrificial worship (xv. 8, xxi. 3) cf. the emphasis on the *national* virtue demanded by Amos (xiv. 34) and on inner purity (xx. 9) and on the omniscience of Jehovah (xv. 3, 11). Thus, in date, the section shows no trace of the developments of religious, theological and philosophical thought for which the latter post-exilic Judaism was responsible; on the other hand, along with much which might be the product of any period, it presupposes, at least in the above respects, the very latest products of pre-exilic piety.

Chapters **xxii. (17) to xxiv. (22)**.—The third section bears the title "words of the wise." Its contents are presented to the reader in a strophic form, forming a miniature discourse, and having four lines to a strophe, as in the newly deciphered Egyptian "Teaching of Amenophis." It is the remarkable similarity of the section to this latter book which has especially concentrated attention upon it since 1924. The similarity between the two continues, with certain exceptions, throughout a considerable portion of the section and creates a problem which is scarcely solved by the theory that both reflect gnomic sayings which were common to all nations of the orient. Indeed so close is the relationship that it is possible to emend with a fair degree of certainty, on the basis of the Egyptian tradition, passages in which the Hebrew text is manifestly corrupt: thus "excellent things" (xxii. 20) without any change in the consonantal text, should be read as "thirty (sayings)," the exact number of the "chapters" into which The Teaching of Amenophis is divided. It would appear unlikely that the Egyptian sage borrowed from the Hebrew, and we are therefore compelled to suppose that either a copy of the Egyptian book penetrated into Palestine and its contents gradually became "Hebraised," its Egyptian theology slowly yielding to that of the Hebrews and proverbs from other sources gradually attaching themselves to it; or a Hebrew sage, visiting or living in Egypt, became acquainted with it, expurgated its Egyptian polytheism and made it acceptable to those who saw in Jehovah the only God who ruled every department of life. Either of these alternatives can best be visualised as happening in pre-exilic rather than late post-exilic days, but to dogmatise as to the exact date, whether the reign of Hezekiah, the early years of the exile or otherwise is to substitute guesswork for reason. An outstanding one among the many sayings common to the Hebrew and Egyptian gnomic writers occurs in the next section (xxiv. 23–34, an appendix to the present one) as well as already in the preceding one (xx. 22): it is the earliest extant form of "the golden rule," later extolled by Hillel and Jesus, which is thus proved to be in its origins Egyptian rather than Hebrew or Jewish.

Chapters **xxv.–xxix. (27)**.—The fifth section, attributed traditionally to Hezekiah's scribes (xxv. 1), contains, like the second section, chiefly short independent proverbial aphorisms; but it has some of two or more verses in length, and advances from the consideration of worldly matters in chs. xxv.–xxvii. to matters of more specifically religious import in chs. xxviii., xxix., where the observance of "the law" in particular is emphasized, and prophecy is specified as a sine qua non of popular self-restraint (xxix. 18). In spite of the presence in this section of proverbs which occur elsewhere, it contains several of considerable interest. It reflects a somewhat hostile attitude to the monarchical form of government, but attempts to deflect criticism from the person of the king to his courtiers. Whether "the king" is a native Jewish ruler, Davidic or Maccabaean, or a Ptolemaic or Seleucid overlord, or merely figures impersonally in a set of proverbs of international vogue cannot be decided: consequently it gives no real help in fixing the date of the section. In at least two respects this collection provided the inspiration for practical and ethical advice too often supposed to have originated in Christian circles, namely xxv. 7 which evidently inspired Luke xiv. 8–11, and xxv. 21 which is quoted in Rom. xii. 20.

Chapter **xxx. (1–16)**.—The sixth section has the cryptic and not very convincing title "The words of Agur, the son of Jakeh, of Massa (R. V. mg.)," followed by a line which has defied all efforts to translate it. This, like xxxi. 1, though a frank confession by the Jewish sages that they were prepared to welcome aphorisms of foreign origin, and having done so, openly to ascribe them to a foreign author, really throws no light upon the origins and background of the present section. It would appear to date from a period when problems of theology and philosophy were being discussed ad nauseam and to emanate from an author who found little comfort, but much disturbance of faith in speculations of this nature. Consequently confessing his own limitations of intellect (*v.* 2 *seq.*), he plaintively asks who in point of fact has ever penetrated into the supra-mundane sphere to return with a knowledge adequate to justify him in propounding such riddles (v. 4). And so he takes refuge in the revealed "word" of God and utters a warning against human endeavours to supplement it or detract from it in self-confidence or insolence. He ends by pointing out the shortcomings of his generation (vv. 5–14). It is the answer of a religious obscurantist rather than, as is too commonly supposed, of a pious agnostic.

Final Section.—The seventh section, chap. xxx. 15–33, consists of miscellaneous dicta introduced by an unintelligible line and bound together by their "numerical" form of introduction. In these few words is concentrated a wealth of insight into the normal and abnormal, the obvious and mysterious in life and nature, which, as it were in a nut-shell, illustrates the keenness and the breadth of observation to which the "wisdom" writers, the humanists of Israel, trained themselves.

The eighth section, chap. xxxi. 1–9, purports to be a further instance of foreign wisdom, again from "Massa," and indeed an illustration of a king's instruction by his mother. The vices against which he is warned include impurity, drink and maladministration of justice. These vices were prevalent in most oriental courts of the period during which the section could have been written, and do not necessarily presuppose the vices which Hellenism in particular communicated to the petty kings of oriental states into which it penetrated.

The ninth and last section, chap. **xxxi.** 10–31, is perhaps the masterpiece of this remarkable collection of the literary output of the humanists of Israel. Incidentally it is an "alphabetical" poem, each verse beginning with a letter of the Hebrew alphabet, and each letter appearing in its correct sequence. The lie is here given to the depressing picture, though one too often fully justified, which is mostly drawn in the Old Testament, of woman's personal and economic position among the Hebrews as the slave and chattel of her husband who was legally free to possess not one but many wives. But practice reinforced by economic necessity, probably rose in this respect above precept. At any rate, in the wealthy and prosperous household here depicted monogamy is presupposed and the poet depicts the wife as its master-mind as well as its mainstay. To what extent such a régime pressed heavily on the female slaves and other underlings we do not know since no literature emanating from them has survived.

Next to their passion for the highest morality of their day, and their unswerving loyalty to their ancestral faith, certain of the Hebrew gnomic writers whose work has survived in the Book of Proverbs will be held in honour most of all for their ability, which, as stated at the outset, is only now beginning to be realized, to master the gnomic literature of Egypt and of Mesopotamia, of Edom and of Massa, to expurgate from it what was unworthy, and to transform it into an instrument for the instruction of successive generations of the worshippers of Jehovah. Only a study of the Book of Proverbs in the light of the comparative study of gnomic literature can make the reader realize this; for instance in addition to close relationship with the Egyptian *Teaching of Amenophis,* there are more than 70 dicta in the Wisdom of Ahikar (*q.v.*) and of these more than half find an echo in this book.

BIBLIOGRAPHY.—For the literature, which is considerable, *see* the commentaries of Toy (1898), and especially W. O. E. Oesterley, *The Book of Proverbs* (1928) in the *Westminster Commentaries,* who gives striking parallels and references to the latest literature. *See* also Cheyne, *Job and Solomon* (1887); id., in *Sem. Studies* (ed. Kohut, 1897); id., *Jew. Relig. Life* (1898); Montefiore in *Jew. Quart. Review* (1898–1890); Cohen, *Ancient Jewish Proverbs;* Elmslie, *Studies in Life from Jewish Proverbs;* Goldman, *Proverbs of the Sages* (1911). Parallelen z. A. T.* (1897). (D. C. S.)

PROVIDENCE, the capital and largest city of Rhode Island, U.S.A., a port of entry and the county seat of Providence county; at the head of Providence river (the north arm of Narragansett bay), 27 m. from the Atlantic ocean, 45 m. S.S.W. of Boston and 185 m. E.N.E. of New York city. It is on Federal highways 1 and 6; and is served by the New York, New Haven and Hartford railroad, and 4 steamship lines. There are several privately owned airports in and near the city and a state airport at Hillsgrove.

Pop. in 1930 was 252,981 and in 1940 it was 253,504 by the federal census (36% of the total population of the state).

The city has a land area of 18.34 sq.mi., diversified in natural character and irregularly laid out. The Seekonk and the Providence rivers bound it on the east; the Providence and the Moshassuck divide it into east and west sides; and the Woonasquatucket divides the west side into north and south sections. The east side (the part of most historic interest) embraces hills rising to a height of 200 feet. The newer business district lies along the west bank of the Providence river, and some of the largest buildings stand on made land. Most of the factories are on the banks of the Woonasquatucket and the Moshassuck. The names of the older streets (such as Benevolent, Benefit, Hope, Friendship, P'eace, Pound, Sovereign, Shilling, Dollar and Doubloon) recall the religious spirit of the early city and its commercial character. From the Union station one steps directly into the civic centre, a broad open plaza surrounded by government (Federal, city and county) and business buildings and hotels. Aloof on a hill to the west, but only half a mile distant, the most conspicuous feature of the landscape and commanding a wide view of city, bay and surrounding country, is the large State house (designed by McKim, Meade and White and completed in 1902) of Georgia marble and white granite, surmounted by a marble dome 235 ft. high. In it is a full length portrait of Washington, by Gilbert Stuart (who was born in Rhode Island), and many other interesting paintings, and here is preserved the original charter of the Colony, framed in wood from the "Gaspee." Adjacent to the civic centre on the east is the retail shopping and business district, where tall modern structures of steel and stone rise above the older buildings. An interesting building is the Arcade (1828) with six massive Ionic columns at each entrance.

The old Market house was built in 1773 and in it a local "teaparty" mas held on March 1, 177j, and Rochambeau's troops were quartered later.

Behind the business area College hill rises steeply, covered with historic landmarks. On its slopes lies the campus of Brown university (*q.v.*), where Revolutionary troops were quartered in university hall. At its foot stands the First Baptist meetinghouse (built in 1775 to house the church organized by Roger Williams in 1636), which has one of the finest church spires in America, and a beautiful interior, with a crystal chandelier in use since 1792. Its bell still rings the curfew at nine o'clock. Near by is the old Colony house, where the Rhode Island Declaration of Independence was signed on May 4, 1776, two months before the event in Philadelphia. Farther up the hill are the museum and library of the Rhode Island Historical Society, the ivy-covered Athenaeum, and Pendleton house (a museum), furnished with one of the finest collections of early American furniture in existence. Among the old mansions still standing are the homes of John Brown (built in 1786), Thomas Poynton Ives (1806), Col. Joseph Nightingale (1791), Joseph Russell (1772), Peter Randell (1748), Stephen Hopkins (1742) and that of Esek Hopkins (1718–1802), commander of the American navy during the Revolution, standing in a park formed from his estate. The Providence Art club occupies the homes of Nicholas Brown (1787) and Siril Dodge (1793). Many more modest colonial houses (usually of red brick with white marble trimmings, and occasionally set in a walled garden) add to the charm of this section of the city. The Friends' meeting house was erected in 1759. The first Unitarian church (organized 1773) has a bell cast by Paul Revere and his son. The city's parks and playgrounds cover 790 ac., and there are also large reservations under the control of the State. Chief among the municipal parks is Roger Williams park (451 ac.), part of the original tract ceded to Williams by Miantonomo, in which is the cottage (1775) of Betsy Williams, a lineal descendant. The North burial ground contains the graves of many men of prominence in the early history of the State and the nation.

In addition to Brown university, Providence has within its limits the Rhode Island college of education (1854); the Rhode Island school of design, affiliated with Brown (1876); Providence college (Roman Catholic; 1919); the Rhode Island institute for the deaf (1876); and several private secondary schools of high standing. The public-school system has profited in various ways by the presence of Brown university, and has been a pioneer in such educational schemes as transition classes between kindergarten and primary grades and open-air classes for delicate children. There are three daily nenspapers. The *Journal* (Independent) was established in 1829. Among the numerous charitable institutions are the Butler Hospital for the Insane, one of the oldest institutions of its kind in the country (established by a bequest of Nicholas Brown in 1841), and the Dexter Asylum for the Poor, endowed by the Dexter fund, which limits. its beneficiaries to those who have a legal settlement in Providence (*i.e.,* have paid taxes for five years on $200 worth of property) and consequently is very restricted in its application. The privately supported welfare agencies and philanthropic organizations unite in a joint annual campaign for funds.

Providence river and harbour have been under improvement by the United States since 1852. The channel to the ocean is 30 ft. deep at mean low water and from 600 to 1,800 ft. wide. A State pier (built in 1913) and a municipal wharf provide modern terminal facilities for the public on equal terms, and there are 5 wharves owned by steamship lines, 10 by the railroad, and 43 by other private interests. Providence is the principal port of southern New England. Its water-borne commerce averaged 4,566,147 tons annually for the years 1935–40, and in 1940 amounted to 5,223,621 tons. The great bulk of the domestic commerce consists of incoming coal, lumber, crude and fuel oil and petroleum products.

Providence is one of the leading centres of the country for the manufacture of jewellery, silverware, worsteds, textile machinery and tools.

Its aggregate factory output in 1937 was valued at $198,783,188, of which $34,568,035 represented worsteds and $27,594,756 jewellery (29% of the total made in the United States). Among the long-established firms of national reputation are the Gorham Manufacturing Company, which introduced the jewellery and silverware industry; the American Screw Company, the Brown and Sharpe Manufacturing Company and the Nicholson File Company. Here the famous Corliss engines were first made in 1847. The city operates under the original charter of 1832, with various amendments, providing for a mayor and council form of government. The franchise is limited to persons who pay a tax on $134 worth of real property or $200 worth of personal property. A town meeting is still held annually for the administration of the Dexter fund.

The levy of general property taxes in 1936 was $9,403,000. Bank debits in 1938 aggregated $2,091,000,000.

Providence was founded in 1636 by Roger Williams after his banishment from the Massachusetts Bay Colony. He bought a tract of land from the Narragansett sachems Canonicus and Miantonomo, built a house opposite the confluence of the Moshassuck and the Woonasquatucket rivers (50 ft. east of North Main street), and with a few followers who had accompanied him into exile promptly set up a town government. In 1637, after the arrival of a few more settlers, a plantation covenant was adopted, embodying the novel principle of complete separation of religious and civil affairs. Providence was incorporated as a town by the colonial assembly in 1649, and was chartered as a city in 1832. The name was chosen by Roger Williams in recognition (he says) of "God's merciful providence unto me in my distress." Between 1730 and 1760 its area was reduced from 370 sq.m. to 5.5 sq.m. by the setting off of Scituate, Gloucester, Smithfield, Cranston, Johnston and North Providence, some of which were further subdivided subsquently; and since 1860 the 5·5 sq.m. have been increased to over 18 by re-annexations of contiguous territory. During King Philip's War, in 1676, the town was attacked by Indians and the northern half was burned. In June 1772, a British schooner, the "Gaspee," running aground at what has since been known as Gaspee point, was captured and burned by Abraham Whipple (1733–1819) according to a plan devised by John Brown (1736–1828), one of the town's prominent merchants. During the Revolution, Providence was a centre of privateering, and in consequence of the occupation of Newport by the British, took over much of the foreign commerce of that port. It remained an important port for 40 or 50 years, but after 1830 manufactures became the dominating interest. Since 1900 its water-borne commerce has again increased, more than doubling in volume in the first quarter of the century. Providence shared with Newport the honour of being the seat of the State government until 1900; since 1900 it has been the sole capital.

PROVINCE, a term applied in ancient Rome (Lat. *provincia*) to the sphere of duty assigned to one of the higher magistrates, the consuls and praetors (*qq.v.*). Only those magistrates who had military power (*imperium*) had a province. When the province of a quaestor is mentioned it refers to the province of the consul or praetor to whom the quaestor is subordinate

When the government of conquered countries grew to be one of the most important duties of the higher magistrates, the term province, from designating the government of a conquered country as one particular duty of a Roman magistrate, came to be used generally as a designation of the country itself.

The provinces paid tribute to Rome, for it was a recognized principle that they were the estates of the Roman people and were to be managed for its benefit. The constitution of a province was drawn up by the victorious Roman general, assisted by ten commissioners appointed by the senate, and the province was governed on the lines laid down in this constitution or charter (*lex provinciae*). For administrative purposes the province was divided into districts, each with its capital, for judicial purposes into circuits (conventus) and in the chief town of each circuit the governor of the province held assizes.

The lands of cities captured by force of arms were turned into Roman domains, and were let out by the censors to private persons. Royal domains, such as those of Macedonia and Cyrene, were also confiscated. Communities which surrendered were usually allowed to retain their personal freedom and private property; but all the lands were subjected to a tax, consisting either of a payment in kind (*vectigal*) or of a fixed sum of money (*tributum, stipendium*). It is to this class of communities (the civitates vectigales or *stipendiariae*) that the majority of the provincial states belonged. In a better position were those states whose freedom was guaranteed by Rome on the ground of old alliances or special loyalty. Their freedom was recognized either by a treaty or by a decree of the Roman people or senate. As a decree of the people or senate could at any time be recalled, the position of the free states without a treaty was more precarious than that of the treaty states (civitates foederatae). The latter enjoyed internal freedom, retained their lands, paid no taxes, and were bound to render those services only which were expressly stipulated for in the original treaty. Amongst such treaty states were Massilia (Marseille), Athens, Rhodes and Tyre. The privileges of the free states without a treaty were somewhat similar. All political distinctions, save that between slave and freeman, disappeared when Caracalla bestowed the Roman franchise on the whole empire (A.D. 212).

Provincial Diets.—Every province had, under the empire, a provincial assembly or diet of its own (concilium or *commune*), and these diets are interesting as the first attempts at representative assemblies. The diet met annually. and was composed of deputies (legati), from the provincial districts. It arranged for the celebration of religious rites and games, especially for the worship of the emperor. The celebration was under the conduct of the high priest of the province. The diet also passed votes of thanks to the outgoing governor, or forwarded complaints against him to Rome; and it had the right of sending embassies direct to the senate or the emperor.

The Provincial Governor.—The provinces were administered by governors from Rome, who held office for a year. From the formation of the first provinces in 227 B.C. down to the time of Sulla (82 B.C.) the governors were praetors (see PRAETOR); from the time of Sulla to that of Augustus the praetors remained in Rome during their year of office, and at the end of it assumed the government of a province with the title of propraetor. A province which was the seat of war, or was in a disturbed state, was committed to the care either of one of the consuls for the year, or of a commander specially appointed for the purpose, with the title of proconsul. The senate determined which provinces were to be governed by consuls and which by praetors, and the consuls arranged between themselves which of the provinces each should have, and similarly with the praetors. The Sempronian law of 123 B.C. provided that the senate should nominate the two consular provinces before the election of the consuls, and that the consuls should, before their entry on office, arrange which of the two provinces each should have. The Pompeian law of 53 B.C. enacted that no one should hold the governorship of a province till at least five years after his consulship or praetorship. This law was repealed by Caesar, but was re-enacted under Augustus; it severed the connection between an urban magistracy and the governorship of a province, and turned the latter into an independent office. A provincial governorship was regularly held for one year; but it could be prolonged by a vote of the people or a decree of the senate. The necessary supplies of men and money were voted to the governor by the senate. His staff included one or more lieutenants (legati) and a quaestor (*q.v.*). Besides these the governor took with him young men of the upper classes to assist him in the government. These were known as the companions (comites) or suite of the governor. They were chosen by the governor himself, but they were maintained at the expense of the state, and under the empire, received regular pay. In addition there was a crowd of subordinates. Before setting out for his province the governor, clad in the purple military robe of his office, offered sacrifice on the Capitol; then immediately after receiving the *imperium* or military command he marched out of the city (for the *imperium* could only be exercised outside of Rome and was forfeited by staying in the city), preceded by his lictors and accompanied by his suite. His year of office began from the day he set foot in his province. In the hands of the governor all powers military and civil were united. He commanded all the troops in the province, and had power to raise levies of Roman citizens as well as of provincials, and to make requisitions of war material. He possessed both criminal and civil jurisdiction; as criminal judge he had the power of life and death, and from his sentence none but Roman citizens could appeal; as civil judge he was guided partly by the charter of the province (*lex provinciae*), partly by the edict which it was customary for him to issue before his entrance on office (see PRAETOR).

Condition of the Provinces under the Republic. — The Roman people regarded the provinces as so many estates from which they were to derive revenue. Hence agriculture and commerce were encouraged, settlements were made, roads and aqueducts were constructed; in short, the Roman aimed at exploiting his empire by a system of prudent economy. But the Roman governors were apt to look on their provinces as their own peculiar prey; they had usually bought their way to office at vast expense, and they now sought in the provinces the means of reimbursing themselves for the expenditure they had incurred at Rome. Redress was to be had by a complaint to the senate; after 149 B.C. there was a court established at Rome for the trial of cases of extortion (repetundae) by provincial governors. But, even when the provincials had arraigned their oppressor, it was difficult to secure his condemnation at the hands of juries composed of men who had a fellow-feeling for the offender because they had themselves committed, or hoped for means of committing, similar offences. Besides the governor, two classes joined in wringing the uttermost farthing from the unhappy provincials. These were the *publicani* (*q.v.*) or farmers of the taxes, and the money-lenders (negotiatores). Both these classes were recruited from the equites (*q.v.*) and, since from 122 B.C. the juries were drawn at first exclusively and after 70 B.C. partially from that order, the provincial governor could not check their excesses without risking a condemnation at the hands of their brethren. Accordingly he generally made common cause with them.

The Provinces under the Empire.—Under the empire the provinces fared better. Romans and provincials were reduced to a common level of subjection to the emperor, who meted out equal justice. The first centuries of the Christian era were for some of the countries included in the Roman empire the happiest of their history.

Augustus, in 27 B.C., divided the provinces into imperial and senatorial. Those which required the presence of an army were placed under the direct control of the emperor; those which needed no troops were left to the senate. (1) The senatorial provinces were ruled by annual governors called proconsuls. Their powers were much the same as they had been under the republic, except that they had now no troops, or only a handful to maintain order. (2) The imperial provinces were governed by imperial lieutenants (legati Caesaris), who were nominated by the emperor and held office at his pleasure; all of them had the power of the sword (*ius gladii*). For the administration of the finances these lieutenants had procurators under them, while the governors of the senatorial provinces continued to have quaestors. Certain other possessions were regarded as domains of the emperor, and were managed by a procurator or praefect (see PRAEFECT), responsible to the emperor

See T. Mommsen, *Roman Provinces under the Empire* (1884); T. M Taylor, *Constitutional History of Rome* (1899); J. E. Sandys, *Companion to Latin Studies* (1921), with useful bibliography. For imperial domains, see H F. Pelham, *Essays on Roman History* (1911), pp. 275–299

PROVINCETOWN, a town of Barnstable county, Massachusetts, U.S.A., on the tip of Cape Cod; it is on federal highway 6 and is served by the New York, New Haven and Hartford railroad, and steamboats to Boston. The population was 3,808 in 1930; 3,668 in 1940 federal census. There are many visitors in summer, among whom are a large number of artists, attracted by the beauties of the sand dunes and the marine views. The town is almost surrounded by water, and there are three lighthouses on its coast. Its harbour (to the south) is protected on three sides by land. A magnificent beach stretches for 30 mi. along Cape Cod bay to Eastham. Provincetown is a port of entry. The principal industries still (as since its settlement) are the catching, curing, packing and selling of fish, chiefly cod and mackerel. The large whaling fleet of former days has entirely disappeared. It was in Provincetown harbour that the Pilgrims, in the cabin of the "Mayflower," drew up their memorable Compact, before proceeding to Plymouth. There John Carver was chosen as the first governor of Plymouth Colony, and this was the first landing-place (on Nov. 11 [O.S], 1620) of the Pilgrims in the New World. There has been a settlement there since 1620. The town was set off from Truro and incorporated in 1727. Much of the territory was originally "Province land" (hence the name) and there is still a large State reservation between the village and the back ocean shore, which has been stocked with game birds and planted with beach grass and pine trees.

PROVINS, a town of northern France, capital of an arrondissement of the department of Seine-et-Marne, at the junction of the Durtain with the Voulzie (an affluent of the Seine), 59 mi. E.S.E. of Paris by rail. Pop. (1936) 8,688. Provins began to figure in history in the 9th century. Passing from the counts of Vermandois to the counts of Champagne, it quickly became prosperous. Cloth and leather were its staple manufactures, and its fairs were attended by traders from all parts of Europe, throughout which its money had currency. Plague and famine reduced the population in the 14th century and the Hundred Years' War completed its ruin. During the religious wars it sided with the Catholic party and the League, and Henry IV. obtained possession of it in 1592 only after thirteen days' siege. The town has mineral waters which contain iron, lime and carbonic acid, and also a trade in roses. Provins is divided into two quarters — the *ville-haute* and the less ancient *ville-basse*—which in the 13th century were surrounded by fortifications. In the ville-haute stands the large tower known as the king's, Caesar's or the prisoners' tower, a very curious 12th century keep. The base is surrounded by a thick mound of masonry added by the English in the 15th century when they held the town. The tower serves as belfry to the church of St. Quiriace, which dates from the 12th century. The palace of the counts of Champagne, some fragments of which also belong to the 12th century, is occupied by the communal college. The old tithe-barn is a building of the 13th century with two fine vaulted chambers, one of which is below ground. The church of St. Ayoul dates from the 12th to the 16th centuries, the transept being oldest; it is dilapidated and the choir is used as a storehouse. St. Croix belongs partly to the 13th century. There is a sub-prefecture and a tribunal of commerce. There is an active trade in grain, livestock and wool, and the industries include nursery-gardening, brickmaking and the manufacture of porcelain, gas and petrol engines, agricultural implements and sugar.

PROVISION, in ecclesiastical law signifies the act by which an office or benefice is conferred by a person having competent authority for the purpose; and the word is specially used of appointments made by the pope in derogation of the rights of ecclesiastical patrons. Innocent III. (1198–1216) seems to have been the first pope who directed prelates to collate his nominees to canonries and other benefices, but it was during the pontificate of Innocent IV. (1243–1254) that the practice first assumed alarming proportions. The English parliament held at Carlisle in 1307 petitioned the king for a remedy against this abuse, but though he promised redress nothing was done. Meanwhile the popes had been asserting claims to appoint bishops in certain events on their own initiative, and at last Clement V. (1305–1313) reserved to himself the right of appointment in all cases. After his time there is scarcely an instance of an English bishop being elected in accordance with the older procedure by the cathedral chapter. If an election were made the pope usually either overrode it by another appointment or, ignoring the election, appointed the elected clerk by a bull of provision. The Hundred Years' War caused an outburst of indignation against the use of papal provisions when non-resident French clerics were appointed to English benefices. To remedy the evil the first "Statute of Provisors" was enacted in 1351, the "Statute of Praemunire" in 1353, and a second "Statute of Provisors" in 1364 These appear to have had little effect until in 1389, a third "Statute of Provisors" was enacted which provided that the statute of 1351 should be firmly holden for ever and "put in due execution from time to time in all manner of points."

PROVISIONAL ORDER, in Great Britain, a direction by a Government department sanctioning (usually at the instance of a local authority or public undertaking) some project otherwise unattainable without private bill legislation, *e.g.,* the compulsory taking of land or the building of a tramway. Originally the order is "provisional" because subject to parliamentary veto. The objects depend upon the enabling statute.

The procedure generally involves: (1) preliminary local enquiry and report by a departmental inspector; (2) departmental decision as to the framing of the order; and (3) inclusion of the order (singly or grouped with others) in a provisional order conformation bill introduced into parliament by the minister concerned. Such bills, if opposed, are referred to a select committee; they also go before examiners who see that the contents comply with standing orders. An early instance is the Inclosures Act of 1845 whereby commissioners could provisionally- order the enclosure and regulation of commons. In 1853 the Charity Commissioners were authorized to give provisional approval to new schemes for the application and management of charities Gradually the system was extended to the varied purposes of local government (especially the alteration of areas), public health, gas, water and electricity supply, acquisition of school and housing sites, formation of pilotage and drainage districts, facilities for harbours, docks, railways and other forms of transport, fishery regulation, validation of marriages, etc. The early enactments have mostly been superseded and the process of devolution has been progressively developed. Two railway acts in 1864 initiated the provisional certificate which embodied schemes for railway construction or working agreements, and, unless the schemes were opposed, required no express parliamentary sanction. A further delegation of legislative power enabled a local authority to make orders for the acquisition of land (as under section 9 of the Local Government Act, 1894), if not objected to, they had the full force of a statute; if objected to, they could be confirmed not by parliament but by the department concerned Later a "special order" procedure was evolved whereby a draft of the proposed order is published and (on objection) a local enquiry is held but a confirmatory act of parliament is not required. The National Health Insurance Act of 1928 even authorizes a "provisional special order." Under this variant (invented in 1912 to accelerate the action of special orders under the 1911 Act) the appropriate Minister, instead of waiting for criticisms of his draft orders, can bring them into force forthwith provided that he certifies the expediency of such action. Some special orders, such as those which decide the application of unemployment insurance or trade boards legislation to particular trades, take effect forthwith, subject to annulment on adverse resolution by either house of parliament within a time limit; others, *e.g.,* those under the Electricity (Supply) Act of 1919 or the Gas Regulation Act of 1920, require the affirmative resolution of both houses. Special orders are often allowed to do all that a provisional order could formerly do. Scotland has her own machinery under the Private Legislation (procedure) Scotland Act, 1899, operated through the Scottish Office, with special panels of commissioners for holding enquiries. Northern Ireland follows the Westminster model. (C. T. C.)

See Clifford, Private Bill *Legislation,* II., c. 18.

PROVO, a city of Utah, U.S.A., on the Provo river, 3 mi. E. of Utah lake and 45 mi. southeast of Salt Lake City; the county seat of Utah county. It is on federal highways 91, 89 and 50, and is served by the Denver and Rio Grande Western, the Union Pacific, the Utah, and the Salt Lake and Utah (electric) railways. The population was 10,303 in 1920 (90% native white) and was 18,071 in 1940 by the federal census. The city has an altitude of 4,549 ft., in a region of fine scenery. It is the seat of the Utah State (mental) hospital and the Brigham Young university (founded and endowed by President Young in 1875), which has an enrolment of 3,000. Provo is a "garden city," surrounded by the richest agricultural and horticultural district of Utah, created by irrigation and industry out of the desert. It is the centre of the mining interests of the state, and of the developing iron and steel industries. Manufactures within the city are small, but at Ironton and other suburbs there are large iron and steel works, creosoting plants, and factories making cast-iron pipes, concrete pipes, brick and tile, etc. The city was settled by the Mormons in 1849 and was chartered in 1851. It has a commission form of government.

PROVOST, a title attached to various ecclesiastical and secular offices. In ecclesiastical usage the word *praepositus* was at first applied by the Church fathers to any ecclesiastical ruler or dignitary. It early, however, gained a more specific sense as applied to the official next in dignity to the abbot of a monastery, or to the superior of a single cell. In England the title "provost" has thus everywhere given way to that of "dean"; in Germany, on the other hand, *"Probst"* is still the style of the heads of certain chapters. The name *praepositus* was also sometimes used for the secular *advocatus* of a monastery. With the ecclesiastical use of the title is connected its English application to the heads of certain colleges; "provost" is still the style of the principals of Queen's, Oriel and Worcester colleges at Oxford, of King's college at Cambridge, of Trinity college at Dublin and of Eton college, where, however, the head-master, though technically subordinate to the provost, is the effective head of the school.

As a secular title *praepositus* is also very old; we need only instance the praepositus sacri *cubiculi* of the late Roman empire, and the *praepositus palatii* of the Carolingian court. The important developments of the title in France are dealt with below. From France the title found its way into Scotland, where it survives in the style (provost) of the principal magistrates of the royal boroughs ("lord provost" in Edinburgh, Glasgow, Aberdeen, Perth and Dundee), and into England, where it is applied to certain officers charged with the maintenance of military discipline. A provost-marshal is an officer of the army appointed when troops are on service abroad for the prompt repression of all offences. He may at any time arrest and detain for trial persons subject t~ military law committing offences, and may also carry into execution any punishments to be inflicted in pursuance of a court-martial (Army Act, 1881, *s.* 74). A provost-sergeant is an officer responsible for the maintenance of order when soldiers are in Great Britain. A provost-sergeant may be either garrison or regimental, and he has under his superintendence the garrison or regimental police.

The Provost in France— The word *prévôt* (provost) in old French law had many applications. In conformity with its etymology (*praepositus*) it could be applied to any person placed at the head of a branch of the public service, a position which, according to the old principles, habitually carried with it a right of jurisdiction. It is thus that there was at Paris the "provost of Paris," who was a royal judge, and the "provost of the merchants" (*prévôt des marchands*), the head of the Paris municipality. There were besides—to mention only the principal provosts—the "provosts of the marshals of France" (*prévôts des maréchaux de* France), of whom more below; "the provost of the royal palace" (*prévôt de l'hôtel du roi*) or "grand provost of France" (*grand prévôt de France*), and the "provost general" (*prévôt général*) or "grand provost of the mint" (*grand prévôt des monnaies*). But the most important and best known provosts, who formed part of a general and comprehensive organization, were the "royal provosts" (*prévôts* royaux), the lower category of the royal judges. It must be borne in mind, however, that the magistrates belonging to the inferior category of royal judges (juges subalternes) had different designations in many parts of France. In Normandy and Burgundy they were called *châtelains,* and elsewhere—especially in the south—*viguiers.*

Some time in the 11th century the provosts replaced the viscounts wherever the viscounty had not become a fief, and it is possible that in creating them the Crown was imitating the ecclesiastical organization in which the provost figured, notably in the chapters. The royal provosts had at first a double character. In the first place they fulfilled all the functions which answered locally to the royal power. They collected all the revenues of the domain and all the taxes and dues payable to the king within the limits of their jurisdiction. Doubtless, too, they had certain military functions, being charged with the duty of calling out certain contingents for the royal service; there survived until the end of the *ancien régime* certain military provosts *prévôts d'épée* (provosts of the sword) who were replaced in the administration of justice by a lieutenant. Finally, the provosts administered justice, though certainly their competence in this matter was restricted. Their second characteristic was that their office was farmed for a time to the highest bidder. It was simply an application of the system of farming the taxes. The provost thus received the speculative right to collect the revenues of the royal domain in the district under his jurisdiction; this was his principal concern, and his judicial functions were merely accessory. By these short appointments the Crown guaranteed itself against another danger: the possible conversion by the functionary of the function into a property. Very early, however, certain provostships were bestowed *en garde; i.e.,* the provost had to account to the king for all he collected. The *prévôtés en ferme* were naturally a source of abuses and oppression, the former seeking to make the most of the concession he had bought. They disappeared in the 16th century, by which time the provosts became regular officials, their office being purchasable.

Other transformations had previously taken place. The creation of the royal *baillis* reduced the provosts to a subaltern rank. Each *bailli* had in his district a certain number of provosts, who became his inferiors in the official hierarchy. When appeals were instituted (and this was one of the earliest instances of their introduction) the provost, the sphere of whose competency was limited, was subject to an appeal to the *bailli,* though his judgment had hitherto been without appeal. Moreover, in the 14th century they had ceased to collect the revenues of the royal domain, except where the *prévôté* was *en ferme,* and royal collectors (*receveurs royaux*) had been appointed for this purpose. The summoning of the feudal contingents, the *ban* and *arrière-ban,* had passed into the hands of the *baillis.* Thus the provosts were left for their sole function as inferior judges for non-nobles. (*See* BAILIFF AND BAILIE.)

The "provosts of the marshals of France," mentioned above, were non-legal officials (*officiers de la robe courte*) forming part of the body of the *maréchaussée* which was under the *ancien régime* what the *gendarmerie* was after the Revolution. Their original function was to judge offences committed by persons following the army, but in the course of the 14th and 15th centuries they acquired the right of judging certain crimes and misdemeanours, by whomsoever committed. They became stationary, with fixed spheres of authority, and the offences falling within their competency came to be called *cas prévôtaux.* These were the worst crimes of violence, and all crimes and misdemeanours committed by old offenders (*repris de justice),* who were familiarly known as the *gibier des prévôts des maréchaux* (gaol-birds).

(J. P. E.)

PROXY (short for "procuracy"), a term denoting either (1) a person who is authorized to stand in place of another; (2) the legal instrument by which the authority is conferred. Proxies are now principally employed for certain voting purposes. A proxy may in law be either general or special. A general proxy authorizes the person to whom it is entrusted to exercise a general discretion throughout the matter in hand, while a special proxy limits the authority to some special proposal or resolution. Formerly a peer could give his vote in the British parliament by proxy, by getting another peer to vote for him in his absence, temporal peers only voting for temporal and spiritual peers for spiritual. However, on March 31, 1868, on the recommendation of a committee, a new standing order was adopted by which the practice of calling for proxies on a division was discontinued. In English and American bankruptcy proceedings creditors may vote by proxy, and every instrument of proxy, which may be either general or special, is issued either by the official receiver or trustee. Under the English Bankruptcy Act of 1914 and the American Bankruptcy Act of 1898 a creditor may still vote by proxy in the manner prescribed. A shareholder in a limited liability company may vote by proxy, and regulations to that effect prescribing the requirements are usually embodied in the articles of association. In England a proxy to vote at a meeting must bear a revenue stamp. (*See* PROCURATION.)

In the early practice of the admiralty courts a proxy was the authority by which the proctor or advocate appeared for either party to a suit. In the ecclesiastical courts a proxy is the warrant empowering a proctor to act for the party to a suit. Two proxies are usually executed, one authorizing the proctor to institute, the other to withdraw, proceedings. They are signed by the parties, attested by two witnesses, and deposited in the registry of the court (Phillimore, *Ecclesiastical Law).* In the convocations of the Church of England those who are absent are allowed to vote by proxy. (*See* also PROCURATION.) Marriage by proxy or deputy was a custom recognized either for reasons of State or ceremonial. The extension of the doctrine to ordinary marriages was recognized in a few wartime cases in the United States.

PRUDENTIUS, AURELIUS CLEMENS (348–*c.* 410), the most remarkable of the earlier Christian poets in the West, was probably born at Tarraco. The meagre autobiographical preface, which he affixed to the complete edition of his works when he was fifty-seven years old, makes it clear that he received a liberal education — being of noble family — practised as a lawyer and entered official life, and finally held some high office under Theodosius. At the age of fifty-seven he retired to a monastery, but died shortly afterwards.

Bentley calls Prudentius "the Horace and Virgil of the Christians," but his diction is stilted and his metre often faulty. The list of his works given in the preface mentions the hymns, poems against the Priscillianists and against Symmachus and *Peristephanon.* The *Diptychon* or *Dittochaeon* is not mentioned. The twelve hymns of the *Cathemerinon liber* ("Daily Round") consist of six for daily use, five for festivals, and one intended for every hour of the day. Prudentius shows Ambrose as his master here, but gives to Ambrose's mystic symbolism much clearer expression. The *Apotheosis* and *Hamartigenia* are polemic, the first against the disclaimers of the divinity of Christ, the latter against the gnostic dualism of Marcion and his followers. In them Tertullian is the source of inspiration. Of more historical interest are the two books *Contra Symmachum,* of 6j8 and 1,131 hexameter verses respectively, the first attacking the pagan gods, the second directed against the petition of Symmachus to the emperor for the restoration of the statue of Victory which Gratian had cast down.

The *Peristephanon* consists of fourteen hymns to martyrs. These were mostly Spanish, but some were suggested to Prudentius by sacred image, in churches or by the inscriptions of Damasus. This book, with tke *Cathemerinon liber* and the *Psychomachia,* was among the most widely read books of the middle ages. Its influence on the iconography of mediaeval art was great. The *Psychomachia* is aesthetically inferior, but had the greatest influence of all of Prudentius's writings. In it he depicts the struggle of Christendom with paganism under the allegory of a struggle between the Christian virtues and the pagan vices. The *Dittochaeon* is a series of quatrains, probably intended to explain forty-nine pictures of a basilica. The work is more interesting for archaeology than for literature.

Prudentius's works were published by Giselin at Antwerp in 1564, and by F. Arevalo at Rome in 1788, with complete commentary. This last is the edition reprinted in J. P. Migne's *Patrologia Latina,* vols. lix.–lx. (Paris, 1847). More recent editions are by Obbarius (Tübingen, 1845) and A. Dressel (Leipzig, 1886), while a critical edition has been undertaken by J. Bergmann.

PRUD'HON, PIERRE (1758–1823), French painter, born at Cluny on April 4, 1758, was the thirteenth child of a mason.

The monks of the abbey undertook his education, and by the aid of the bishop of Mâcon he was placed with Devosge, director of the art school at Dijon. In 1778 Prud'hon went to Paris armed with a letter to Wille, the celebrated engraver, and three years later he obtained the triennial prize of the States of Burgundy, which enabled him to go to Rome, where he became intimate with Canova. He studied the work of Correggio and the affinity of his style with that of the great Italian has given him the name of "Corrège Français." He returned to Paris in 1787. The illustrations which he executed for the *Daphnis* and Chloe published by Didot brought him into notice, and his reputation was extended by the success of his decorations in the Hôtel de Landry (now Rothschild), his ceiling painting of "Truth and Wisdom" for Versailles (Louvre), and of "Diana and Jupiter" for the Gallery of Antiquities in the Louvre. In 1808 he exhibited "Crime pursued by Vengeance and Justice" (Louvre), which had been commissioned for the assize courts, and "Psyche carried off by Zephyrs." These two compositions brought Prud'hon the Legion of Honour; and in 1816 he entered the Institute. Consoled for the misery of his marriage by the devoted care of his pupil, Mlle. Mayer, Prud'hon's situation seemed cnviablc; but Mlle. Mayer's tragical suicide in 1821 brought ruin to his home, and Prud'hon died two years later on Feb. 16. 1823.

PRUNE: see PLUM.

PRUNELLA, a term obtained from the French *Prunelle*, and applied to worsted or woollen twill fabrics of light but strong texture, produced with the three-end $\left(\frac{2}{\quad 1}\right)$ warp-face twill weave and usually woven from hank-dyed yarn of a dark purple colour both for warp and weft, or else piece-dyed in the same colour and formerly much used for clerical garments. It is now made in various grades of texture both plain and striped and used as dress material, ladies' sport skirts, and other articles of clothing both for men and women. A stronger and heavier texture of prunella cloth of a similar character to "everlasting," is also produced from a worsted warp and cotton weft and woven with the double-stitch five-end warp-face satin weave, and used for ladies' shoe-tops The three-end warp-face twill weave is also described as the "prunella" twill, irrespective of the class of fabric to which it is applied. (H. N.)

PRURITUS, an ailment characterized by intense itching of the surface of the body. It may occur in jaundice, diabetes digestive disorders, etc., or as the result of the irritation produced by skin parasites. The most serious form affects old persons, and is often a cause of great suffering, depriving the patient of sleep. In such cases it is probably due to atrophic changes in the skin. No eruption is visible, except such marks as are produced by scratching. The treatment is, general, by tonics and, local, by soothing lotions.

PRUSSIA, a former German kingdom, now the largest, most populous and important Land of the German reich. Prior to 1938 it was bounded on the north by the Baltic, Mecklenburg, Denmark and the North sea, on the east by Lithuania and Poland, on the south by Czechoslovakia, the *Land* of Saxony, Thuringia, Bavaria and Hesse, on the west by Alsace-Lorraine, Luxembourg, Belgium and the Netherlands. Oldenburg and Mecklenburg run like wedges from the coast into Prussian territory; Brunswick and other small German states form Prussian enclaves. The *Land* of Prussia forms a tolerably compact mass of territory in northern Germany.

Physical Features. — The greater part of Prussia belongs to the great north European plain, and may be generally characterized as lowlands. The plain is much wider on the east, where only the southern margin of Prussia is mountainous, than on the west, where the Hanoverian hills approach to within less than 100 mi. of the sea. A line drawn from Dusseldorf through Halle to Breslau would, roughly speaking, divide the flat part of the cauntry from the hilly districts. In the southeast, Prussia is separated from Bohemia by the Sudetic chain, which begins at the valley of the Oder and extends thence towards the northwest. This chain includes the Riesengebirge, with the highest mountain in Prussia (Schneekoppe), and subsides gradually in the hills of Lusatia. The Harz mountains, however, beyond the Saxon plain, follow the same general direction and may be regarded as a detached continuation of the system. To the south of the Harz the Prussian frontier intersects the northern part of the Thuringian forest, which is also prolonged towards the northwest by the Weser Gebirge and the Teutoburger Wald. The southwest of Prussia is occupied by the plateau of the lower Rhine, including on the left bank the Hunsriick and the Eifel, and on the right the Taunus, the Westerwald and the Sauerland. Between the lower Rhenish and Thuringian systems are interposed the Vogelsberg, the Rhon and other hills belonging to the Triassic system of the upper Rhine. The Silesian mountains are composed chiefly of granite, gneiss and schists, while the Harz and the lower Rhenish plateau are mainly of Devonian and Silurian formation. To the north of the Sauerland is the important Carboniferous system of the Ruhr, and there are also extensive coalfields in Silesia; a considerable portion of the Silesian coalfield was, however, ceded to Poland in 1921. With the exception of the Danube, Prussia is traversed by all the chief rivers of Germany, comprising almost the entire course of the Oder and the Weser (see also GERMANY).

Climate. — The climate of Prussia may be described as moderate, and is generally healthy. The greatest contrasts of temperature are found between the east and west, the mean annual temperature in the bleak and exposed provinces of the northeast being about 44" F., while that of the sheltered valley of the Rhine is 5° higher. In winter the respective means are 27° and 34"; in summer the difference is not above 2° to 4°. The highest monthly average is about 66" in July. The rainfall in the lowlands is about 25 in. at Cologne, 23 in, at Berlin and 25.5 in. at Konigsberg, but in the east it diminishes inland to 19 in. or less. It is greater on the outstanding heights.

Area and **Population.**—Prussia is made up of the following provinces, viz., East Prussia, Brandenburg, Berlin, Pomerania, Grenzmark, Silesia, province of Saxony, Schleswig-Holstein, Hanover, Westphalia, Hessen-Nassau, Rhine province and Hohenzollern, with a total area of 117,883 sq.mi. and a population (according to the 1939 census) of 41,762,042, excluding the Saar district, but including Waldeck. The state of Waldeck was incorporated with Prussia, April 1, 1929. The population is densest in the mining and manufacturing district of the Rhine, which is closely followed by Westphalia; next to these come Hessen-Nassau, Silesia and Saxony. After 1919, and especially after 1933, there was a tendency for the industrial population to increase more rapidly in the central and eastern provinces than in the more densely settled Rhine and Westphalian provinces of the west which would be more likely to be invaded or bombed in case of war. In 1939 Prussia contained 61 towns with upwards of 100,000 inhabitants each.

Communications. — With most internal means of communication Prussia is excellently provided. On April 1, 1920, the railways became the property of the reich, and on Oct. 11, 1924, as a result of the Dawes agreement, their management was put in the hands of a private company, though they remained state property. In 1938 the railways (including the German State railway or *Reichsbahn* and a few private and side lines) within Prussia totalled 16,728 mi. in length. The most important trunk line of Prussia is that which enters the western frontier near Aachen and runs through Cologne, Düsseldorf, Hanover and Berlin, and crosses to Danzig, proceeding via Konigsberg to the eastern frontier at Eydtkuhnen. Generally speaking, the principal lines of the country either radiate from Berlin or run alongside the frontiers and boundaries.

Prussia possesses also an extensive system of natural and artificial waterways. The most important of the canals are the Kiel canal, connecting the North sea and Baltic, the Elbe-Trave canal (to give Liibeck access to the Elbe), the Dortmund-Ems canal and its continuation, the Dortmund-Rhine canal, and the Mittelland canal, opened in 1938, which connects the inland waterways of the central and western provinces.

Agriculture. — The northeastern provinces of Prussia contain a high proportion of poor soil, and in the northwest occur large tracts of heath and moor. The reclaimed marshlands in both districts, as well as the soil in the neighbourhood of the rivers, are usually very fertile, and tracts of fruitful ground are found in the valleys of the Rhine and its affluents, and in the plain around Magdeburg, the so-called Bohrde. The most fertile Prussian province is Saxony, while the least productive are East Prussia and the Grenzmark. The principal crop in Prussia is rye, of which the ordinary bread of the country is made; it grows in all parts of the country, especially in the north and east, and occupied an area of nearly 7,700,000 ac. in 1937. Oats occupy an area equal to about two-thirds of that devoted to rye, and are also grown most extensively in the northeastern districts. Wheat, which is chiefly cultivated in the south and west, covers only about a third as much ground as rye. Barley also covers about a third as much ground as rye. Other grain crops are spelt (chiefly on the Rhine), buckwheat (Hanover and Schleswig-Holstein) and millet; maize is grown for fodder in some districts. Potatoes, used both as food and for the distillation of spirits, are cultivated over an area of about 4,800,000 ac. (1937), and are specially predominant in the eastern provinces, The common beet is extensively grown for the production of sugar in the provinces of Saxony, Hanover, Silesia, Pomerania and Brandenburg. Flax and hemp occupy considerable areas in East Prussia, Silesia and Hanover. There is some cultivation of rape-seed for oil. Agriculture in Prussia is on a high level, with much application of the latest scientific improvements, including widespread utilization of electrical power. The number of farms of less than 2 hectares each (*i.e.,* about 5 acres; 1 ha.= 2.471 ac.) in 1933 was 493,489; farms ranging from 2 to 5 ha. numbered 420,019; farms ranging from 5 to 20 ha. numbered 577,571; farms ranging from 20 to 50 ha. numbered 131,675; and farms exceeding 50 ha., 38,254.

The cultivation of the beetroot for sugar has had a far-reaching effect upon Prussian agriculture, especially in the provinces of Saxony, Silesia, Hanover, Pomerania, Brandenburg, the Border province and the Rhine province. Also owing to the deep cultivation of the soil and the incessant hoeing which the beet crop requires, the three or four crops which follow it are invariably good, and the liability to failure of the immediately succeeding crop is reduced to a minimum. Moreover, the fiscal policy of the Prussian government has been of first-rate assistance to the Prussian farmer, Beet tops are often fed to the cattle as fodder. The principal centres for the manufacture of beetroot sugar in Prussia are Magdeburg, Berlin and Breslau. Chicory is produced chiefly in the Prussian province of Saxony.

Live Stock. — The province of East Prussia, with the principal government stud of Trakehnen, is the headquarters of horse-rearing. The horses bred there are generally suitable for the lighter kind of work only, and are in great request for military purposes. Horses of a stouter type are bred in Schleswig-Holstein and on the Rhine, but heavy draught horses ordinarily have to be imported from France, the Netherlands, Belgium and Denmark. The best cattle are reared in the maritime provinces of the west.

Forests.—Prussia contains a large proportion of woodland. The most extensive forests are in East Prussia, Silesia and Brandenburg, where coniferous trees prevail, and in the Rhenish and Hessian districts, where oaks and beeches are the most prominent growths. The northwest is almost entirely destitute of timber, and peat is used universally there as fuel. The admirably managed government forests form a considerable proportion of the whole, and the state also controls the management of forests in private possession.

Viticulture. — The principal wine-growing districts of Prussia are the Rheingau and the Rhine province, though wine is also produced in Silesia, Westphalia and a few other districts. The valleys of the Nahe, Saar, Moselle and Ahr all produce excellent wine. German vine-growers have suffered in common with vine-growers in other countries of Europe, from the *Oidium tuckeri* and the Phylloxera, and the government has spent large sums of money in endeavouring to arrest the ravages caused.

Fisheries. — The fisheries on the Baltic sea and its bays, and on the North sea, are important. In the former the take consists mainly of herrings, flatfish, salmon, mackerel and eels, while the chief objects of the latter are cod and oysters. Inland fishery has been encouraged by the foundation of numerous piscicultural establishments and by the enactment of close-time laws. Carp, perch, pike and salmon, the last-named especially in the Rhine, are the principal varieties; sturgeon are taken in the Elbe and Oder, and the Iakes of East Prussia swarm with bream and lampreys. Game of various kinds abaunds in different parts of Prussia, and the lakes are frequented by large flocks of waterfowl.

Mining **and** Metal **Industries.**—Prussia is the largest producer of coal, zinc, salt, lead and copper among the *Länder* of the German reich. The Rhenish-Westphalian district produces the largest quantity. An extremely important role was played in the coal industry of Prussia by the Rhenish-Westphalian Coal syndicate, which succeeded in regulating the production and price of the coalfields generally. Almost all the zinc produced in Germany comes out of the Silesian mines, but two-thirds of them were transferred to Poland after World War I. They again became available to Germany, however, during World War II. The chief iron-producing regions are the Rhine province, Westphalia, Hessen-Nassau and Silesia. Lead and manganese are also produced. Salt is mined principally in the province of Saxony (Stassfurt, Aschersleben, Erfurt, Halle, Merseburg, Sangerhausen), the kali salts near Magdeburg and Glauber salts in the Rhine province and Hessen-Nassau. Iron is worked principally in the districts of Arnsberg, Diisseldorf, Oppeln in Silesia, Trier and Coblenz, and zinc for the most part near Oppeln in Silesia; lead and silver near Aachen, Oppeln and Wiesbaden, and sulphuric acid in all the mining districts, as well as near Potsdam, Breslau, Magdeburg and Merseburg. Petroleum is extracted to a limited extent at a couple of places in the province of Hanover, which also contains considerable potash deposits. Amber has been mined in East Prussia. A little is also collected on the coast near Pillau.

Industries. — It was during the last quarter of the 19th century that Prussia became a great manufacturing country, industry being interwoven with agriculture, and both being dependent on the highest organization of technical skill. The educational system was remarkably adapted to this end, and skill in the use of foreign languages became a special feature. The chief industrial districts are, of course, those which yield coal with, in addition, the great cities — Berlin, Magdeburg. Hanover, Breslau, Gorlitz, Stettin, Essen, Dortmund, Elberfeld-Barmen, Diisseldorf, Cologne, Aix-la-Chapelle, Crefeld, Halle, Frankfurt-am-Main, Solingen, Remscheid, Konigsberg, and many others. The iron and metal industries, especially the making of machinery, electrical plant, tramway plant, and the production of articles in wrought copper and brass, rank in the forefront. In these branches Berlin and more lately its suburbs, as well as Magdeburg and Cologne, played an active role, but the old centres of the metallurgical and iron and steel industries in the Rhine province and Westphalia remained outstandingly important. Austrian and Bohemian centres grew rapidly after 1938. The chemical industries, essentially a German specialty, take front rank, *e.g.,* those which produce aniline dyes, artificial indigo, illuminants (acetylene gas, Welsbach mantles, etc.), explosives, various chemical salts, pharmaceutical preparations, cellulose, glycerine, artificial (chemical) manures and perfumes. German shipbuilding is highly developed.

Government. — The Constitution of Prussia of Nov. 30, 1920, provided for a diet or landtag of 450 members, elected for *a* period of four years by universal secret suffrage on a basis of proportional representation. This constitution was infringed in July 1932, when President von Hindenburg appointed Franz von Papen as federal commissar of Prussia in place of Otto Braun, who had been prime minister for a dozen years. The constitution was completely superseded in 1933 by Hitler's appointment of Hermann Goering as deputy federal governor (*Reichsstatthalter*) of Prussia and of several national socialist leaders (Gauleiters) for the different districts of Prussia, and by the final abolition of the Prussian legislature in 1934.

Religion. — The centre of Prussia is predominantly Protestant, the proportion of Roman Catholics increasing towards east and west and reaching its maximum on the Rhine and in the Slavonic provinces. East Prussia, however, with the exception of Ermeland, is Protestant, The Roman Catholics greatly outnumber the Protestants in the Rhine provinces, and in Upper Silesia. Absolute religious liberty was guaranteed in the Weimar republic, but was greatly interfered with after 1933. In 1933 the Evangelical Protestants in Prussia numbered 25,212,026, the Roman Catholics 12,555,647, the Jews 360,141 and those of other beliefs 1,564,353. The Evangelical or Protestant Church of Prussia was formed by a union of the Lutherans and Calvinists. effected under royal pressure in 1817. Those who were unable from conscientious scruples to join the union became Separatists or Old Lutherans and Old Calvinists, but their numbers were and are insignificant. The Evangelical Church was governed by "consistories," or boards elected by the people. There were also synods in most circles and provinces, and general synods representing the old provinces only. The organization of the Roman Catholic Church differs in the various provinces. Altogether, in Prussia, there are two archbishops and ten bishops.

Education. — Before 1933 education was compulsory, and the general level attained was very high. Every town or community maintained a school, supported by local rates and under the supervision of the state. All parents were compelled to have their children properly taught or to send them to one of these elementary schools. By the Constitution of 1850, all persons were permitted to instruct, or to found teaching establishments, provided they could produce to the authorities satisfactory proofs of their moral, scientific and technical qualifications. Both public and private educational establishments were under the surveillance of the minister of public instruction, and all public teachers were regarded as servants of the state (Staatsbeamte).

The expenses of the primary schools (Volksschulen) before Hitler's time were borne by the communes (*Gemeinden*), aided when necessary by subsidies from the state. The teachers for the elementary schools were trained in normal seminaries or colleges established and supervised by the state. The secondary schools of Prussia were roughly divided into classical and modern. The classical schools proper consisted of Gymnasia. In these boys were prepared for the universities and the learned professions, and the full course lasted for nine years. The modern schools, or *Realgymnasia,* also had a nine years' course; Latin was taught, but not Greek, and greater stress was laid upon modern languages, mathematics and natural science. Ranking with the *Realgymnasia* were the *Oberrealschulen,* which differed only in the fact that Latin was entirely omitted, and the time thus gained devoted to modern languages. The gymnasia1 "certificate of ripeness" (*Maturitätszeugniss*), indicating that the holder had passed satisfactorily through the highest class, enabled a student to enrol himself in any faculty at the university.

After 1933 the standard of education deteriorated seriously. Schools became agencies for the inculcation of national socialist doctrines rather than for training in Christian morality and scientific methods and for the imparting of sound and unbiased information. The period of compulsory school education was shortened. School work was impaired by the amount of time which pupils had to spend in evening attendance at national socialist youth meetings and week-end marches and athletic training. Many new special schools were established for the training of nazi party functionaries, the most important of which were the *Ordensburgen* for the training of an elite group of future state and party leaders. Education was taken out of the hands of Prussian local officials and placed under the control of the central government of Germany.

Prussia possesses 12 of the 23 German universities (not including the lyceum at Braunsberg; the medical academy at Diisseldorf and the Roman Catholic seminary at Münster). The largest Prussian university is that of Berlin, while Breslau, Bonn, Gottingen and Halle are the next in size. The oldest is the university of Greifswald, founded in 1456. Like the schools, the universities are state institutions, and the professors are appointed and paid by the government, which also makes annual grants for apparatus and equipment.

Ranking with the universities are numerous technical high schools. Music is taught at several *conservatoria,* the best known of which are at Berlin and Frankfurt-am-Main.

The science and art of Prussia found their most conspicuous external expression in the academies of science and art at Berlin, both founded by Frederick I; and each town of any size throughout the kingdom has its antiquarian, artistic and scientific societies. Recognized schools of painting exist at Berlin and Düsseldorf, and both these towns, as well as Cassel. contain excellent picture galleries. The scientific and archaeological collections of Berlin are also of great importance. Besides the university collections, there are numerous large public libraries, the chief of which is the Reichsbibliothek at Berlin. (N. D.; S. B. F.)

See *Statistisches* Jahrbuch *für* den Freistaat *Preussen,* the *Statistisches Jahrbuch* fur das *deutsche Reich,* and other publications of the statistical offices of Prussia and Germany. In addition, see Landeskunde *Preussens* (Berlin, 1901), edited by Beuermann, various volumes of Forschungen *zur deutschen Landes-* und Volkskunde: British Diplomatic and Consular Reports; and the bibliography for GERMANY.

HISTORY

The state of Prussia, which has played so great a part in the history of Germany, came into being gradually, being formed out of wholly dissimilar components. The chief of these were the mark of Brandenburg and the State of the Teutonic Order in Prussia. The history of each of these, up to their union, must be treated separately.

The Mark of Brandenburg. — The territory between the Elbe and the Oder, which had been abandoned by the Germans in the time of the great migrations, and occupied by Slavonic tribes in the succeeding centuries, was gradually reconquered by the Germans after the 10th century. To secure the safety of the new frontier districts, marks were set up, the overlords of which — the markgrafs—enjoyed wider powers than the counts in the interior of the empire. The northernmost of these marks was the Nordmark, founded by Henry I and enlarged by Otto I. Those parts of this mark which lay east of the Elbe were, however, lost to German rule after the great rising of the Slavs in 983; only the present Altmark remained in German hands.

The markgraf Albert the Bear, of the Ascanian dynasty (1134–70), was the true founder of the state of Brandenburg. He conquered Priegnitz and the Havelland and at first took the title of markgraf of Brandenburg. His descendants, who remained masters of these districts until 1320, conquered the Ukermark, the districts of Stargard and Lebus, and the so-called Neumark, beyond the Oder. They were already aiming at possession of Pomerania, in order to obtain direct access to the sea. The Ascanian markgrafs invited a large number of German settlers into the country and founded a number of German towns, which soon attained considerable prosperity.

On the extinction of the Ascanians, Louis the Bavarian, the then German king, bestowed their lands on his younger sons (1324). The Wittelsbachs were unable, however, to retain for long their hold on these territories, which lay far distant from their family possessions. Finally they ceded them to the emperor Charles IV (1373), who attempted to combine them with Bohemia and Silesia in one great East German state. After his death, however (1378), his extensive dominions were divided up. The mark fell first to his youngest son Sigmund, who gave it in pledge to his cousin, Jobst of Moravia. On the death of the latter (1411), the mark reverted to Sigmund, who had in the meantime become German king. In 1415 he conferred it on one of his most faithful adherents, the burgrave Frederick of Nurnberg, of the house of Hohenzollern.

The "Zollerns" are first mentioned in a document of 1061. Their ancestral home was a Swabian castle near the source of the Danube. An elder branch of the family remained in the old home and founded the principality of Hohenzollern-Sigmaringen. A younger branch, established by Conrad of Hohenzollern about 1170, took military service under Frederick Barbarossa, and was appointed burgrave of Niirnberg. His descendants soon acquired the lands of Ansbach and Bayreuth near Niirnberg and became powerful princes, The two first electors of the house of Hohenzollern, Frederick I. (1415–40) and Frederick II. (1440–70) had a hard struggle against the nobles and towns of the Mark to restore the authority of the overlord and recover the frontier districts, some of which had been occupied by neighbours. Under the next electors, Albert Achilles (1470–86) and John (1486–99) the overlord's power was further consolidated. Joachim I. (1499–1535) founded a university in Frankfurt-an-der-Oder, and was one of the keenest partisans of the old Church in the struggles provoked by Luther's movement. His son, Joachim II. (1535–71), however, was converted to Protestantism and introduced the Reformation into the Mark. The next electors, John George (1571–98) and Joachim Frederick (1598–1608) are of little importance for the further development of the State. John Sigmund (1608–19), by his marriage with the heiress of Prussia and Julich, paved the way for the great change which the acquisition of those territories brought about.

The Teutonic Order.—In 1226 the Polish Duke Conrad of Masovia invited the Teutonic Knights into his territory to combat the heathen Prussians. After a difficult struggle, the Order conquered the territory of the heathen Prussians, exterminated most of the native population, and invited German peasants and townspeople into the country as settlers. In the 14th century the State ruled by the Knights was a power in north-eastern Germany. It acquired Pommerellia and for a time the Neumark also, and through its connection with the Order of the Sword, of Livonia, extended its influence as far as Estonia. A string of flourishing cities sprang up along its coast. In Marienburg, since 1309 the seat of the Grand Master of the Order, the splendid castle was built which to this day testifies to the past glories of the Order, and formed the centre of its admirably organized administrative system. But even in the 14th century the Order was beginning to decline, owing mainly to the fact that once the struggle against the heathen was ended, it lost its original spiritual character, occupied itself only with purely mundane tasks, and thus lost touch with its original purpose. The rule of the Knights, who admitted none of the local nobility into their ranks, came to be felt by the inhabitants as a foreign rule. When Poland and Lithuania united into a powerful State at the end of the 14th century, and the rulers of this State began to aspire to possession of the Baltic coast, the Order could not rely fully either on the nobles or on the towns in its territory. After the defeat of their army at the battle of Tannenberg (1410) the Knights were forced to cede part of their territory to Poland. In a second war the Poles took Marienburg, and at the Peace of Thorn (1466) forced the Order to cede them West Prussia and Ermeland, with Danzig and Thorn, and to acknowledge the suzerainty of the Polish king for the rest of their territory. At the beginning of the 16th century, the Reformation began to penetrate these regions also, and the Grand Master of the day, Albert of Brandenburg, a grandson of the Elector Albert Achilles, proceeded, with the consent of the king of Poland, to take the decisive step which was tantamount to the end of the Order's rule. He went over to Protestantism, at the same time proclaiming himself hereditary duke of Prussia (1525). As his only son, Albert Frederick (1568–1618) was an imbecile, the power passed almost wholly to the Estates. Albert Frederick's eldest daughter, Anna, married the Elector John Sigmund, and through her Prussia passed in 1618 to the electors of Brandenburg. As Anna was also co-heiress through her mother of the great territories which had been united under the rule of the dukes of Julich, Cleve and Berg on the lower Rhine, and as this ducal house had become extinct a few years previously (1609), the electors of Brandenburg could hope to acquire not only Prussia, but also considerable domains in west Germany.

The Great Elector.—Under the Treaty of Xanten (1614), John Sigmund had reached an understanding with the count Palatine of Neuburg, his most dangerous rival for the Jiilich succession, securing for himself the reversion of Cleve, Mark and Ravensberg. In order to obtain from the Calvinistic princes of west Germany the support which he needed to keep these acquisitions secure, he had become a convert to Calvinism—a step which aroused great discontent in his ancestral domains, which were wholly Lutheran, and in Prussia, which was also Lutheran. The Thirty Years' War broke out at the end of John Sigmund's reign, and his son George William (1619–40), a weak ruler, found himself confronted with a situation of extraordinary difficulty. Although he urgently desired to remain neutral, both the Danes and Wallenstein's troops invaded his territory. After his cousin, Gustavus Adolphus, landed in Germany, it was no longer possible to preserve neutrality. He was forced to conclude an alliance with the king, but on the latter's death at once attempted to make peace with the emperor; later he even took sides against Sweden, who refused to grant him possession of Pomerania, to which he had laid claim, on the strength of old succession treaties, on the death of the last member of the old ducal family (1637). The Mark of Brandenburg consequently again became the theatre of war, and the elector was obliged to flee to Prussia, where he died in 1640.

His young son, Frederick William, at that time only 20 years of age, became the real second founder of the Prussian State. He concluded an armistice with Sweden, and, in the face of great difficulties, organized for himself a small army of his own, with the object of achieving greater independence. In the Peace of Westphalia (1648) he succeeded in acquiring Further Pomerania (Vorpommern), and the secularized bishoprics of Minden, Halberstadt and Magdeburg as compensation for Hither Pomerania (*Hinterpommern*), which was assigned to Sweden. The last-named districts, however, only actually passed to him in 1680, after the death of the previous administrator.

In the decade which followed the Peace of Westphalia, Frederick William reinforced his army. In the first Northern War (1655–60) he was thus a valuable ally to either of the contending parties, Sweden or Poland. First he joined the Swedes, and helped them to win the decisive victory near Warsaw (1656). When, however, King Charles Gustavus was forced by the Danish attack to return to Sweden, the elector negotiated with Poland. By adroit manipulation of the situation he managed in the Peace of Oliva (1660) to secure from all parties concerned recognition of his full sovereignty over East Prussia.

The importance of the great elector's reign was even greater for the internal development of the Prussian State. His creation of a standing army gave him an instrument which could be turned against the claims of his own subjects also. After a vigorous struggle with the Estates, which assumed acute form in East Prussia, he succeeded in restricting their rights in important respects. The system of taxation was radically reformed; the old administrative system, which was largely controlled by the Estates, was reinforced by new official bodies, which were purely State organs. The elector's privy council, which had hitherto been a purely Brandenburg institution, was made into the central organ of the whole State. In important deliberations the elector presided personally, and all subordinate officials were accustomed to send in regular reports on their work to the privy council. All these measures bore clear witness to the elector's ambition to create a unified single State out of the different territories, scattered throughout Germany, which had gradually come into his family's possession. When Frederick William died in 1688, his State was already the most powerful and the best administered in northern Germany. (For a detailed account of early Prussian history see BRANDENBURG.)

Frederick William I.—Under the elector's son, Frederick III. (1688–1713) the internal development of the State was temporarily arrested. In the international sphere, however, Frederick scored an important success when, by promising to support him in the War of the Spanish Succession, he induced the emperor to consent to his assuming the title of king. As the electorate of Brandenburg formed part of the German empire, and was under the suzerainty of the emperor, the title of king could only be attached to those lands which the elector ruled as sovereign prince, viz., the duchy of Prussia. On Jan. 18, 1701, Frederick took the title of "King in Prussia," and solemnly assumed the royal crown in Konigsberg. So it came about that "Prussia," and not the old family domain of Brandenburg, came

to be used as the generic name for the Hohenzollern dominions. The new king kept up a splendid court, and thereby ruined the economic equilibrium which his father had laboriously achieved. He also took a lively interest in intellectual matters. He founded the Academy of Arts and the Academy of Sciences in Berlin (1701).

His successor, Frederick William I. (1713–40) has long been unjustly represented as a crude tyrant. He was a sober-minded man, without any strong intellectual interests, but a first-class organizer and imbued with a stern sense of duty, based on religious sentiment, and he deliberately devoted his whole soul to the service of the State. He resumed the work begun by his grandfather, and is the true father of the Prussian administrative system and Prussian officialdom. He created a new central administrative service in the shape of the General Directory, for which he drew up the instructions himself (1723). This organ acted as a general ministry, in which the agenda was distributed to the several members, partly by subject, partly on local lines, while all important measures were decided in general conference. The king reserved to himself the final decision. Each official received a commission stating his duties, emoluments and exact official regulations. All official bodies had to keep a record of, and send in a weekly report on their activities. In most cases officials were nominated by the king at his full discretion; only in the selection of the Landrate, who were in charge of the provincial districts (*Kreise*) the nobles still had a certain voice. Officials and magistrates were obliged to pass through a definite course of training, and could not be appointed unless they had passed the prescribed examination. The king organized a regular procedure of judicial appeal, making the *Kammergericht* in Berlin the supreme judiciary instance for the whole State. Judicial procedure was also simplified and improved in important respects. In the financial administration he introduced the strictest economy. He succeeded in increasing the revenue from the royal domains and prerogatives and from the indirect taxes to a considerable degree, and in achieving an annual surplus. This he put into a State exchequer, which contained 7,000,000 thaler at his death. He made special efforts to encourage trade and industry, following the principles of the mercantile system, which at that time were everywhere accepted. As the country was thinly populated, he encouraged the immigration of efficient labour. Just as his grandfather had admitted a large number of the Huguenots expelled from France after the repeal of the Edict of Nantes by Louis XIV., so Frederick allowed the Protestants expelled by the archbishop of Salzburg to enter his kingdom, settling most of them in East Prussia. First and foremost a soldier, the king devoted especial attention to the training of the standing army, the numbers of which he raised from 40,000 to 89,000. It was still a mercenary army, recruited from volunteers at home and abroad. He took pains, however, to ensure that as high a proportion as possible should be composed of his own subjects and divided the whole Prussian territory into recruiting districts, the so-called "cantons"; each district was obliged to supply the men for one specified regiment. The recruiting was often done in a very arbitrary fashion, which gave rise to many complaints. Definite instructions were drawn up and regular inspections carried through to ensure uniformity of training; the army thus created was superior to those of most other States. It was Frederick William who first gave Prussia the characteristic stamp of a military and bureaucratic State.

For all his military inclinations, Frederick William was an unusually peaceable man by nature, and in his foreign policy always avoided military entanglements. When he came to the throne, Prussia was embroiled in the Northern War; at the conclusion of peace he succeeded in securing Hither Pomerania up to the Peene, which had formerly been in the hands of Sweden, with the important commercial town of Stettin. He failed, however, to secure support for his claims which were based on old succession treaties, to further portions of the Cleves-Jülich heritage, and to parts of Silesia. As a loyal German, he thought it his duty to maintain as good relations as possible with the emperor; but encountered profound mistrust in Vienna, where the growing strength of the Prussian State was watched with concern, and towards the end of his life was forced into an increasingly sharp opposition to the house of Habsburg.

Frederick the Great.—Frederick William died in 1740. He was succeeded by his son, Frederick the Great (1740–86), who was at that time 28 years of age. He had had violent conflicts with his father in his younger days, as his passionate and freedom-loving nature revolted against the severe discipline which his father thought necessary. Furthermore, the younger man's inclinations led him towards the new ideas of the Aufklarung, while the old King was a strict Calvinist. The crown prince's attempted flight (1730) brought this conflict to a head. The king had his son imprisoned, and even had an idea of excluding him from the succession; Frederick was only able to buy a reconciliation at the price of complete submission to his father's will. He was obliged to pass through a strict training in the administrative service and the army, a training which did much to prepare him for his later career.

For Frederick's conflicts with Maria Theresa in the first half of his reign, see GERMANY; AUSTRIA-HUNGARY; AUSTRIAN SUCCESSION, WAR OF, etc. They ended in the acquisition of Silesia, with the exception of a few small districts south of the Riesengebirge, which remained in the hands of Austria. Frederick's successful resistance in the Seven Years' War against Austria, France and Russia raised his prestige enormously. From this time onward his State was recognized as a European great Power. In addition to Silesia, he had also acquired East Frisia, which came to him in 1744 on the extinction of the old princely house, through a succession treaty. At the first Partition of Poland (1772) he also acquired West Prussia (except Dantzig and Thorn), a particularly important district, as it bridged the gap between East Prussia and the Brandenburg family dominions. Frederick carried on the internal development of the Prussian State on the lines laid down by his father. He instituted a general civil code for his State in the shape of the Prussian Landrecht—a work not completed until after his death; accelerated judicial procedure, abolished torture, and introduced the principle that the Crown should not interfere with the course of justice. In administrative matters, he sought to pay special consideration to the local peculiarities of the different provinces, and paid frequent journeys of inspection to satisfy himself that his orders were being carried out. The fiscal system was further developed; but an attempt to introduce the farming of taxes, on the French model (1766), proved unsuccessful and had to be abandoned. Under his rule the State revenue increased largely; on his death he left 55,000,000 thaler in the State exchequer. He had the low lying country of the Oder and the Warthe drained, settled villages of colonists in the Pomeranian forests, arranged for the plantation of hops and potatoes, and founded factories. He left several detailed exposés of his administrative and political principles, notably in his famous political testaments of 1752 and 1767, which were designed to serve as a guide to his successor. Like his father, he considered himself the first servant of the State, and expressed the thought that the duty of the prince was to govern as though he had to render account to his subjects for all his measures. The political philosophy of the day, however, was absolutist, and Frederick too was convinced that the conduct of a great State demanded a single guiding will, which could only be that of the monarch, and he called for unconditional obedience, not only from his officials, but also from each of his subjects. He rarely consulted with his ministers in person; he called for reports from them in writing, and dictated the answers, which he sent to them in writing. His liberal views in matters of religion led him to adopt the policy of toleration, on principle, towards the different Churches: a policy which was also naturally dictated by practical considerations in a State which included a Protestant majority and a strong Catholic minority. His lively interest in all intellectual questions led him to take measures to improve the level of public education. In the upper schools the classics were made the principal subject of instruction. The king would have wished to establish compulsory primary education for the whole population, from the fifth to the thirteenth year, but lack of means made it impossible to carry this out. Although Frederick was deeply influenced by the humanitarian ideas of the *Aufklärung,* and considered the furtherance of the people's welfare and of popular education to be among the monarch's essential duties, yet his guiding thought remained always to raise the forces of his comparatively small, weak State, by better organization, so as to maintain the position of power which he had won,

Collapse and Reform.—As Frederick left no issue from his marriage, contracted at his father's orders, with a princess of Brunswick, and as his eldest brother, Augustus William, had predeceased him, the latter's son, Frederick William II., succeeded him on the throne (1786–97). He was indolent and dissipated, squandered the State Exchequer and left the cares of government to his favourites. Under his reign no progress was made in the domestic organization of the State. In foreign affairs his participation in the war against revolutionary France brought him only losses, while the large accessions of territory that the second and third Partitions of Poland (1793 and 1795) brought him were gains of but doubtful value. For the Prussian State, which after 1795 extended as far as Warsaw and Kovno, thus received so large a percentage of Polish blood that had these frontiers proved permanent, its German character would have been endangered.

His son, Frederick William III. (1797–1840) was a man of the best intentions, but pedantic, vacillating and narrow. The Government fell more and more into the hands of the cabinet councillors who, under the system introduced by Frederick the Great, formed the sole channel of communication between the king and the ministers. But while under Frederick the councillors had been only executive organs of the king's will, under his weak successors they became the all-important personal advisers of the monarch. The Prussian State still kept the outward form given it by Frederick William I. and Frederick the Great; but the living spirit was gone from it, and its swift and complete collapse after the first great military reverse (Jena, 1806), is easily comprehensible. Under the Peace of Tilsit (1807) Frederick William was obliged to cede his entire territory west of the Elbe and the greater part of his acquisitions in Poland; he retained only Brandenburg, Pomerania, Prussia and Silesia. This fearful collapse, however, also released the forces of reconstruction which still lived on within the State, and during the so-called "period of reform" a complete reconstruction of the State was begun. The king himself always remained disassociated from, and at heart hostile to these efforts, which appeared to him as a concession to Jacobinism; but as he knew no plan of his own for reconstructing the shattered State, he was forced to let the apostles of the new ideas have their way.

Freiherr von Stein became the leading figure in the administration. He had long been urging reforms, but before 1806 without success. His fundamental idea was that in a modern State the people itself must be required to help in the conduct of public affairs, because the State cannot exist unless it can count upon the willing co-operation and devotion of its citizens. The most important measures which he carried through were the liberation of the peasants from serfdom, the reintroduction of municipal self-government under the Municipal Act of 1808, and the abolition of cabinet government. He also planned to introduce self-government in the rural districts and participation of representatives of the people in the provincial administration and the central Government. He was unable, however, to carry these measures into practice, being dismissed in the autumn of 1808, at Napoleon's order. The reforms were taken up again by Freiherr von Hardenberg, in 1810, on his appointment as head of the ministry, although on lines rather different from those intended by Stein. Hardenberg really inclined more to enlightened despotism than to Stein's ideas of self-government. His principal achievements were the reorganization of the finance and of the administrative system, the abolition of restrictions in industrial life, and the edict of 1811 which made the peasants free proprietors of their holdings, in return for the cession of a part of them to the former landlords. The peasants were thus required to buy their ownership at the price of giving up part of their holdings. Moreover, as the smaller holdings were excluded from the measure, the landlords could now take full possession of them, and their former cultivators sank to the position of propertyless agricultural labourers.

These years also saw a great reorganization of the army, carried through by Generals von Scharnhorst and von Boyen. The underlying principle was the transformation of the mercenary army into a national army. Universal service was introduced, degrading punishments abolished, admission to the Corps of Officers revised and the internal organization of the army rearranged in more practical form. But for these reforms in all directions, the little State would have been incapable of the great achievements which it performed during the Wars of Liberation.

The 'Wars of Liberation'—The pressure of the alien rule of France evoked the first great popular movement in German history since the peasant wars of the 16th century. After Napoleon's defeat in Russia, popular opinion carried the doubtful and hesitating king with it, and led finally to the expulsion of the French from Germany and to a complete remodelling of conditions in Germany. The State of Prussia, too, was altogether reshaped through the decisions of the Congress of Vienna in 1815.

As compensation for the Polish districts ceded to Russia, Prussia then received new Hither Pomerania, the northern part of the kingdom of Saxony, the whole of Westphalia and the Rhineland. Of the ten million inhabitants of Prussian territory in 1816, nearly four belonged to the newly-acquired territory. It was only now that Prussia lost the character of a purely Northeastern Germanic state; it had assimilated elements from western Germany, and from now onward began to dominate Germany. The old Prussian nobility and bureaucracy found it no easy task to adapt themselves to the inhabitants of the new districts, who had grown up in quite other traditions. They succeeded, however, in maintaining their hegemony for several decades longer. The western districts, and especially the Rhineland, now began to form the principal focus of the Liberal movement.

This met at first with small success. The danger once over, Frederick William III abandoned the tendencies of the reform period altogether. He had in 1815 promised to introduce a "United Diet," but this was now forgotten; only meetings of the provincial estates for the individual provinces were introduced and these were only given an advisory voice in local affairs (1823). By economical administration and abstaining from external entanglements, the king managed to do with the existing taxes and excises. He opposed an obstinate resistance to all demands of the Liberals.

The 1848 **Revolution.**—On the death of Frederick William III., his eldest son, Frederick William IV. (1840–61) ascended the throne. He had grown up in an age when the theories of romanticism had dominated Germany; these theories swayed him, and, like his father, he was averse at heart to the modern political demands. After long consideration, however, he determined in 1847 to convoke the members of all provincial diets to a "United Diet" at Berlin. This body, however, immediately put forward a demand to be convoked at regular intervals, and recognized as a partner, with equal rights, in the legislature. The king refused to admit such claims, and the deliberations led to no practical result. Nevertheless, it was an event of no small importance that representatives of all parts of the Prussian State had, for the first time, met for common parliamentary debates.

Soon after this, the revolution broke out in all Germany. Although the military remained the victors in the street fighting of March 18 in Berlin, the king nevertheless decided to give way and withdraw the troops from Berlin. He agreed to the convocation of a Constituent National Assembly, which was to meet in Berlin and collaborate with him in drawing up a Constitution. But as democratic elements gained the upper hand in this Assembly, the king dissolved it and enacted a constitution (Dec. 5, 1848), with the proviso that a freshly elected parliament should negotiate further on its final form. These negotiations proving very protracted, the parliament was again dissolved in the spring of 1849, and it was only when a chamber was elected on the three-class franchise that agreement was at last reached on a definitive constitution, to which the king took the oath on Feb. 4, 1850. Prussia now received a parliament, consisting of two chambers; the first chamber, called the *Herrenhaus* after 1854, was composed of representatives of the large landed proprietors and of the larger towns, and of members nominated by the king, either for life, or as hereditary members. The second chamber was elected by all tax-paying citizens. but as the electors were divided into three categories, according to taxes paid, electors with larger incomes were given much greater influence than the poorer classes.

During the revolution of 1848 an attempt had already been made to place the king of Prussia at the head of a German empire, to include all the German states except Austria. These plans, however, met with resistance, both from the king himself, and from the Prussian nobles and bureaucrats. Ever since the Wars of Liberation, wide circles of the population had become convinced that a strongly united Germany could only be achieved by an alliance between Prussia and the Liberal elements which formed the backbone of the movement for union. The creation of the German *Zollverein* (*q.v.*), under Prussia's leadership (1834), which created an economic unity out of all German States, except Austria, seemed to be a step along this road. The king's legitimist views, however, revolted against making common cause with the revolution to force the other princes into a position of subordination and his national sentiments, swayed by the tendencies of romanticism, were shocked at the thought of excluding the Germans of Austria, while the nobles and official classes feared that they would be unable to maintain their existing influence in a German empire with parliamentary government. Accordingly, Frederick William IV. refused the imperial crown offered him on April 3, 1849, by the Frankfurt National Assembly. As his efforts to weld Germany into closer unity by agreement with the other princes were also unsuccessful, the movement towards unity led at the time to no results.

William I.—After 1850 a period of reaction set in in Prussia and the rest of Germany. Attempts were made to restrict the rights of the newly-created parliament, as far as possible. During Frederick William IV.'s last years, a feudal Party Government reigned in Prussia. In 1857 the king succumbed to an incurable mental disease; his younger brother William assumed the regency, and on Frederick William's death (Jan. 2, 1861) ascended the throne as William I. (1861–88). He, too, was a thorough conservative at heart, but saw more clearly than his brother the necessity of making concessions to the spirit of the times. Even during his regency he admitted liberal-minded men into his cabinet, and announced that his Government would stand above parties. Nevertheless, he became involved in a severe struggle with parliament when he demanded large sums for the reinforcement and reorganization of the army, which he held to be absolutely necessary. As the king refused to agree to the conditions made by the second chamber (two-year service and an independent *Landwehr*), parliament, after agreeing provisionally to the extra grants for military purposes on several occasions, ended by rejecting them. The king adhered to his plans and refused to dismiss his existing ministers in favour of advisers enjoying the confidence of the second chamber; thereupon the chamber rejected the whole budget. The king saw in this behaviour an attempt to rob him of his sovereign rights. At first he thought of abdicating in favour of his son; then replied by appointing Bismarck minister-president. The constitutional conflict dragged on for several years more, and was only solved after the successful outcome of the war of 1866 had brought about a change in the composition of parliament. The new parliament sanctioned the expenditure of the previous years retrospectively by the so-called Indemnity Act. The importance of this struggle lay in the fact that the Crown's independence of parliament in its choice of advisers for Prussia was now assured; parliament's attempt to secure a supreme control over State affairs similar to that existing in England had failed in Prussia. And as at this time Prussia took the leading place in Germany, these views also became current for the new German empire, and the growth of Prussian ascendancy continued.

Campaigns of 1864–71 which led to union of Germany under Prussia's leadership cannot be told here. (*See* SCHLESWIG-HOLSTEIN QUESTION; GERMANY; AUSTRIA-HUNGARY; FRANCO-GERMAN WAR.) The acquisition of Hanover, Kurhesse, Nassau and Frankfurt-am-Main after the war of 1866, gave Prussian territory a wholly new aspect. Its eastern and western halves, which up to this date had been separated by these districts, were now linked up into a single great North German State, containing nearly two-thirds of the total population of Germany (in 1914, 40,000,000 out of a total population of 65,000,000). The great problem which arose for Prussia out of the unification of Germany was, how far the independence and individuality of the Prussian State were to be retained within the new empire. Bismarck attempted to solve this problem by uniting the offices of administrative head of the empire (*Reichskanzler*) and Prussian minister-president in one person, just as the dignity of the German emperor was indissolubly united with that of king of Prussia. Attempts to divide the two offices having proved impracticable, this arrangement lasted until 1918.

The alliance concluded by Bismarck with the Liberals at the time of the foundation of the empire had important effects. The Local Government Act of 1872 increased the autonomy of the rural districts, thus linking up with the traditions of the age of Freiherr von Stein. The so-called *Kulturkampf*—the struggle against the Catholic Church which was waged in the '70s—was also in accord with Liberal ideas. It ended, however, finally, with the State restoring to the Church its control over the preliminary training of the clergy, and retaining only a right of veto over appointments to ecclesiastical posts.

During the short reign of Frederick III. (March–June 1888) acd under William II., the situation remained in essence unchanged. The new Rural Districts Act (*Landgemeindeordnung*) of 1892 carried existing institutions a step further. The fiscal reform carried through about the same time by von Miquel made self-assessment the basis of taxation, and provided relief for the poorer classes and heavier contributions from large incomes. On the other band, the repeated efforts to introduce a radical reform of the franchise for the second chamber and abolish the three-class franchise, led to no result.

After the revolution of 1918 Prussia became a *Land* of the Weimar republic, and adopted a republican and democratic form of government. From 1919 to 1933 there was a remodelling of the bureaucracy by which the Social Democrats under their minister-president, Otto Braun, sought to replace the old conservative element by persons mare in sympathy with the democratic and socialist majority. During these years Prussia's liberal government was often in conflict with the more militaristic and nationalist central government of Germany.

Aiter 1933 the Prussian constitution was set aside by the National Socialists, its legislature was abolished and its ministries were merged with Hitler's central German ministries.

The Prussian state was thus dissolved into its former provinces, which were ruled with the rest of Germany by the central regime at Berlin. (*See* also GERMANY: *History*.)

PRUSSIA, in the original sense, a territory of Germany, stretching along the Baltic coast for about 220 m., and occupying an area of 24,083 sq.m. The eastern part of this territory formed the duchy of Prussia, conquered and colonized by the Teutonic Order and acquired by the elector of Brandenburg in 1618, furnishing his successor with his regal title in 1701. The western part, severed from the eastern half and assigned to Poland in 1466, was not annexed to Prussia until the partition of Poland in 1772, while the towns of Danzig and Thorn remained Polish down to 1793. The two districts were temporarily (1824–78) united to form a single province.

PRUSSIC ACID, also called hydrocyanic acid and hydrogen cyanide, is a compound of hydrogen, carbon and nitrogen (HCN), best known on account of its exceedingly poisonous nature. It is a very volatile colourless liquid boiling at 25·7° C and freezing at −13° C. As the parent substance of the cyanides it gives, on substitution of the hydrogen atom by metals, salts of prussic acid, *e.g.,* potassium cyanide, KCN; while substitution by organic radicals gives the organic cyanides, *e.g.,* methyl cyanide, $CH_3{\cdot}CN$. In its chemical character the radical, CN, resembles the halogen elements, *e.g.,* chlorine, in being acidic (electronegative) and univalent, corresponding compounds having similar formulae, *e.g.,* KCl and KCN, and analogous chemical behaviour.

Prussic acid was discovered in 1782 by Scheele who obtained it from Prussian blue. In variable but generally very small proportions it is widely distributed among plants in the form of compounds with sugars, the glucosides (*q.v.*) *e.g.,* amygdalin (*q.v.*), contained in bitter almonds, from which the free acid can readily be obtained by hydrolysis.

Preparation.— The most convenient method of obtaining prussic acid in the laboratory is to add a concentrated solution of sodium cyanide gradually to sulphuric acid (about 70%), when hydrogen cyanide vapour is rapidly evolved: $NaCN+H_2SO_4=HCN+NaHSO_4$ (more concentrated acid gives carbon monoxide, see below). On the large scale this process may be carried out in large covered iron vessels lined with lead and provided with mechanical stirrers. The vapour of hydrogen cyanide, after drying by calcium chloride, is condensed to an almost anhydrous liquid, from which the last traces of water may be removed by distillation with phosphoric oxide. An older method consists in distilling potassium ferrocyanide with dilute sulphuric acid:

$$2K_4Fe(CN)_6+3H_2SO_4=3K_2SO_4+K_2Fe[Fe(CN)_6]+6HCN.$$

Hydrogen, carbon and nitrogen at very high temperatures, as in the electric arc, combine directly, with the absorption of much energy, to form hydrogen cyanide, which is thus an endothermic substance. Instead of the three elements, their compounds such as ammonia NH_3, cyanogen C_2N_2, acetylene C_2H_2, methane CH_4, oxides of nitrogen N_2O or NO, may be used, often with advantage in the direction of greater yield and lower temperature of reaction. If alkaline substances are present, cyanides (*q.v.*) are formed. These high-temperature reactions account for the presence of hydrogen cyanide in crude coal gas.

Physical and Chemical Properties.— In many of its physical properties hydrogen cyanide resembles water. Like the latter it is an ionizing solvent, many salts dissolving in it to form solutions which are good conductors of electricity. This property of liquids is associated with high dielectric constant, the magnitude of which is even greater for hydrogen cyanide than for water, indicating great electric polarity of the molecules (compare as a rough illustration a magnet with its north and south poles). Such polar molecules are more firmly held together than in liquids composed of non-polar molecules, and combination between them may occur to some extent, giving rise to association (*q.v.*). The physical properties of such "associated" liquids exhibit many characteristic abnormalities as compared with those of normal non-polar liquids; thus hydrogen cyanide has a latent heat of evaporation greater than the value expected if it were normal.

The vapour of prussic acid burns freely in air with a violet flame yielding nitrogen, carbon dioxide and water. As indicated by its structural formula $H{-}C{\equiv}N$ or $H{-}N{=}C$, prussic acid is chemically unsaturated. It is capable of adding other atoms to its molecule as well as of substituting other atoms for its hydrogen. Thus it combines with hydrogen giving methylamine $H_3C{-}NH_2$, and yields addition compounds with hydrogen chloride. Substitution occurs with halogens, *e.g.,* chlorine gives cyanogen chloride: $HCN+Cl_2=CNCl+HCl$. The cyanides, being similarly unsaturated, also undergo addition reactions. Thus molten potassium cyanide readily unites with free or combined oxygen giving potassium cyanate KCNO, or with sulphur giving potassium sulphocyanide (thiocyanate) KCNS, and accordingly at elevated temperatures potassium cyanide reduces many metallic oxides and sulphides to the free metal.

Prussic acid combines with water slowly when heated, more rapidly in the presence of mineral acid. The addition of water occurs in two stages thus:

$$H-C\equiv N + H_2O = H-C\genfrac{}{}{0pt}{}{\nearrow O}{\searrow NH_2} \quad \text{(formamide)}$$

$$H-C\genfrac{}{}{0pt}{}{\nearrow O}{\searrow NH_2} + H_2O = H-C\genfrac{}{}{0pt}{}{\nearrow O}{\searrow ONH_4} \quad \text{(ammonium formate).}$$

With concentrated sulphuric acid the last substance is converted by loss of water into ammonia NH_3 (which combines with the sulphuric acid) and carbon monoxide gas CO thus:

$$H{\cdot}CO{\cdot}ONH_4=NH_3+CO+H_2O;$$

consequently sodium cyanide with concentrated sulphuric acid yields not hydrogen cyanide but carbon monoxide. Ammonium formate on heating is reconverted into formamide, which again on heating with phosphoric oxide or a catalyst (see CYANIDES) yields prussic acid. Solutions of cyanides on boiling slowly react to give ammonia and a formate: $KCN+2H_2O=NH_3+H{\cdot}CO{\cdot}OK$ (potassium formate).

In common with many cyanogen compounds, liquid hydrogen cyanide readily undergoes polymerization (*q.v.*), that is combination with itself. The pure substance may be kept indefinitely without change, but in the presence of traces of ammonia or any alkaline material (even that furnished by common soda-glass vessels) it is gradually transformed into a solid brownish-black insoluble mass called azulmin, an imperfectly known mixture of complex compounds containing some $H_3C_3N_3$. Liquid hydrogen cyanide has even been known to explode spontaneously, probably owing to rapid polymerization in closed vessels with development of heat. It is commonly stabilized by the addition of small quantities of mineral acid, *e.g.,* phosphoric acid, or other substance which "kills" any polymerizing agent. (See CYANIDE.)

An aqueous solution of prussic acid, unlike its analogue hydrochloric acid, is an extremely poor conductor of electricity. It contains the ions H^+ and CN^- to a minute extent only, and is thus one of the weakest of acids. A comparison of their dissociation constants shows that carbonic acid, itself a very weak acid, is about 200 times stronger than prussic acid. In a decinormal solution (2·7 g. of the acid per litre) only 0·01% of the acid is present in the form of ions, a degree of acidity too small to affect the colour of indicators (*q.v.*).

The Cyanides of the Metals, while resembling the halogen salts, exhibit divergencies in chemical behaviour due to the extreme weakness of prussic acid, the decomposability of the CN radical, and its great tendency to form complex salts.

The cyanides of the alkali metals, *e.g.,* potassium cyanide, are all white crystalline salts, very soluble in water. The solutions are alkaline, being hydrolysed or partially decomposed by water into the component non-volatile strong base and volatile weak acid: $KCN+H_2O=KOH+HCN$. Since the extent of salt hydrolysis increases with the weakness of the acid the amount of free prussic acid and caustic potash in solutions of these cyanides is relatively large (in a decinormal solution 1% of the salt is hydrolysed), consequently they smell of prussic acid and lose it on evaporation. The carbonic acid of the air, being a relatively strong acid, slowly expels prussic acid from soluble cyanides leaving a residue of carbonate. These factors complicate the preparation of pure cyanides by the usual process of evaporating the solutions by boiling and crystallizing out. (For the manufacture of alkali cyanides, *see* CYANIDES.) The cyanides of the alkaline earth metals, calcium, strontium and barium, *e.g.,* $Ca(CN)_2$, are very similar to those of the alkali metals except that their solutions are much more extensively hydrolysed.

Tha simple cyanides of the heavy metals are insoluble in water, with the notable exception of mercuric cyanide, $Hg(CN)_2$ which is remarkable for its minute degree of ionic dissociation.

If aqueous potassium cyanide is added to a solution of silver nitrate, a white precipitate of silver cyanide, $AgCN$, is formed which dissolves when more potassium cyanide is added. This behaviour is typical of the cyanides of the heavy metals. The solution of silver cyanide in potassium cyanide on evaporation deposits crystals of potassium argento-cyanide $KAg(CN)_2$, or ($KCN+AgCN$), but in solution this "complex salt" gives practically only the cation K^+ and the complex anion $[Ag(CN)_2]^-$, the ions Ag^+ and CN^- being present in such minute amount that some analytical tests fail to reveal their presence. This behaviour may be contrasted with that of typical "double salts," *e.g.,* $KCl,MgCl_2,6H_2O$, which gives only the ions K^+, Mg^{++}, Cl^- in solution. The tendency to form complex cyanides is most marked in the metals of Group VIII., and contiguous metals (the transition elements, see PERIODIC LAW).

The numerous complex cyanides vary in stability. Some, like potassium ferrocyanide $K^+[Fe(CN)_6]^{\equiv}$, satisfy no ordinary test for Fe^{++} and CN^- ions, and even yield with cold mineral acid the corresponding stable complex acid $H_4Fe(CN)_6$. Others, like $K_2^+[Zn(CN)_4]^=$, are easily decomposed by acids with liberation of prussic acid; and hydrogen sulphide added to a solution of $K_2Zn(CN)_4$ reveals the presence of a small proportion of Zn^{++} and CN^- ions by precipitating the zinc completely as zinc sulphide (the corresponding copper compound is not so precipitated). Most complex cyanides are of the following types: $K[R(CN)_2]$, where R is Cu, Ag, Au; $K_2[R(CN)_4]$, where R is Zn, Cd, Hg, Ni, Pd, Pt; $K_4[R(CN)_6]$, where R is Cr, Mn, Fe, Co, Ru, Os, Ir; $K_3[R(CN)_6]$, where R is Cr, Mn, Fe, Co, Rh, Ir; $K_4[R(CN)_8]$, where R is Mo or W.

Potassium ferrocyanide, $K_4Fe(CN)_6$, composed of $4KCN+Fe(CN)_2$ (ferrous cyanide), was formerly manufactured by heating nitrogenous organic refuse with iron and potassium carbonate, extracting the salt with water, and crystallizing out. The cyanogen compounds recovered from crude coal gas have for many years been converted by various methods into potassium ferrocyanide. The most recent process consists in melting calcium cyanamide, $CaCN_2$, with common salt, dissolving out the resulting sodium and calcium cyanides, and converting them into sodium ferrocyanide by treatment with ferrous sulphate and sodium carbonate. Potassium ferrocyanide is a stable, yellow, crystalline salt (yellow prussiate of potash), not poisonous like the cyanides. On heating with dilute acid prussic acid is liberated; cold acid gives the white crystalline hydroferrocyanic acid $H_4Fe(CN)_6$. Potassium ferricyanide. $K_3Fe(CN)_6$, composed of $3KCN+Fe(CN)_3$ (ferric cyanide), is conveniently prepared by oxidizing the ferrocyanide in solution by means of chlorine:

$$2K_4Fe(CN)_6+Cl_2=2K_3Fe(CN)_6+2KCl.$$

It forms dark red crystals (red prussiate of potash) from which acid displaces hydroferricyanic acid $H_3Fe(CN)_6$. Of the many salts of the complex iron-cyanogen acids it must suffice to mention only "insoluble Prussian blue," ferric ferrocyanide $Fe_4[Fe(CN)_6]_3$ and "soluble Prussian blue," potassium ferric ferrocyanide $KFe[Fe(CN)_6]$. The complex cyanides being typical co-ordination compounds (see VALENCY and CO-ORDINATION), many derivatives are known in which the CN group is partly replaced by other groups such as H_2O, CO, KO, etc., *e.g.,* $H_2[Fe(CN)_5(NO)]$ and its salt $Na_2[Fe(CN)_5(NO)]$, sodium nitroprusside. The latter is a useful reagent for detecting sulphur in organic compounds since with alkaline sulphides it gives a characteristic purple colour.

The Organic Cyanides.—The removal of hydrogen and oxygen as water from ammonium salts of organic acids of the type R·CO·OH (where R is an organic radical like methyl, CH_3) leads to the replacement of the CO·OH group by CN in the following manner:

$$\underset{\text{Acid}}{R{\cdot}CO{\cdot}OH} \rightarrow \underset{\text{Ammonium salt}}{R{\cdot}CO{\cdot}ONH_4} \xrightarrow{-H_2O} \underset{\text{Acid amide}}{R{\cdot}CO{\cdot}NH_2} \xrightarrow{-H_2O} \underset{\text{Nitrile}}{R{\cdot}CN.}$$

Acetic acid $CH_3{\cdot}CO{\cdot}OH$ gives $CH_3{\cdot}CN$, methyl cyanide, generally called acetonitrile (a member of the class of "nitriles"), and formic acid H·CO·OH gives prussic acid H·CN which may thus be regarded as formonitrile. This general method of formation indicates that nitriles have the structure $R-C\equiv N$, the corresponding structure of prussic acid being $H-C\equiv N$.

Nitriles are also formed when cyanides of the alkali metals react with iodides of organic radicals: $KCN+RI=KI+RCN$. But if silver or mercury cyanide is used the product, which has quite different properties although the same composition, is an *isomeride* of the nitrile and termed an iso-cyanide or "carbylamine." Since methyl cyanide certainly has the structure $CH_3-C\equiv N$, that of the isocyanide can only be $CH_3-N=C$, where the C atom of the CN group is bivalent. These structures are in full agreement with the chemical behaviour of nitriles and carbylamines. The latter are the less stable, being converted into the former on heating.

Constitution of Prussic Acid and Cyanides.—If one assumes a simple exchange of partners without any change of structure in the reaction $RI+MCN=MI+RCN$ (M=metal), it would appear that silver cyanide is $Ag-N=C$ and potassium cyanide $K-C\equiv N$, although only one form of hydrogen cyanide is known. However, potassium cyanide yields a little methyl isocyanide with the main product of cyanide, and silver cyanide with acetyl chloride $(CH_3CO)Cl$ gives acetyl cyanide, not isocyanide. What is the true constitution of the simple cyanides of the metals, and how is it that prussic acid can yield simple salts which behave so differently? Although these problems date from the discovery of isocyanides by Gautier in 1866, and in spite of all efforts to solve them, no entirely satisfactory solution has even yet been found. The isocyanide structure of all metal cyanides has been generally favoured, but a recent study of the question does not confirm this.

The chemical evidence as to the constitution of prussic acid itself is very conflicting. Some reactions indicate the nitrile ($H-C\equiv N$) structure, others the carbylamine ($H-N=C$) structure. With diazomethane, CH_2N_2, it yields both cyanide and isocyanide. It must therefore be regarded as a typical "tautomeric" substance, behaving in some reactions as $H-C\equiv N$, in others as $H-N=C$. The liquid may be composed of both molecules in dynamic equilibrium with each other ("dynamic isomerism"), the equilibrium being rapidly re-established if disturbed in any way, so that the substance may react either as $H-C\equiv N$ or $H-N=C$. (See ISOMERISM.) Its physical properties indicate that liquid prussic acid consists almost entirely of $H-C\equiv N$, and this view is generally accepted.

Detection and Estimation.—Prussic acid has a characteristic smell, but this test is unreliable because of the remarkable fact that to many people it is odourless. Small quantities of the acid and its salts can be detected by converting them into intensely coloured derivatives, *e.g.,* Prussian blue or red ferric sulphocyanide, $Fe(CNS)_3$, and such tests may be made quantitative by the methods of colorimetric analysis. Larger amounts are generally precipitated and weighed as insoluble silver cyanide (or as silver), or the solution may be conveniently titrated with standard silver nitrate, the first appearance of turbidity marking the exact conversion of the cyanide into argentocyanide $KAg(CN)_2$.

Pharmacology, Therapeutics and Toxicology.—The chief pharmacopoeia1 preparations of prussic acid are a 2% aqueous solution (dose 2–6 minims), and compound tincture of chloroform and morphia containing a half-minim of the 2% solution per 10 minims. The therapeutic applications of the acid depend on its action as an anodyne. It allays itching and is useful in some forms of neuralgia. Taken internally it relieves vomiting and gastric pain, and in cases of asthma and phthisis it is of value in relieving painful cough.

The foxic action of prussic acid and cyanides is due to their inhibition of the normal oxidative processes in the tissues, resulting in a form of asphyxia with paralysis of the heart and respiratory organs. Inhalation of air containing sufficient hydrogen cyanide gas produces in rapid succession, giddiness, headache, palpitation, pain in the chest, followed in a few seconds by loss of consciousness, laboured respiration and death. On removing the case into fresh air recovery is rapid provided respiration has not stopped, and even if it has, artificial respiration with stimulation (*e.g.,* by cold water) may be effective (*Official History of the War,* vol ii., p. 465). The toxic action of prussic acid and cyanides is so rapid that the use of antidotes is generally out of the question.

As a poison gas, prussic acid (in gas shell) played only a very minor part in the World War. It probably caused fewer casualties than any other war gas. Investigation revealed the remarkable fact that different species of animals (even though of the same size) differ greatly in susceptibility to prussic acid poisoning, dogs being particularly sensitive. J. Barcroft breathed air containing 1 part of prussic acid in 2,000 without ill effect for 1½ min., but within this time the dog which accompanied him died. The effect is non-cumulative; for death to ensue the determining factor is that the rate of inhalation of the poison shall exceed its rate of elimination by the body. The lethal concentration for man is relatively high. (For prussic acid as insecticide, *sea* CYANIDE.)

PRUTZ, HANS (1843–1929), German historian, son of Robert Eduard Prutz (1816–1872), the essayist and historian, was born at Jena on May 20, 1843, and studied at Jena and Berlin. His *Preussische Geschichte* (4 vols., Stuttgart, 1899–1902) is an attempt to apply scientific rather than patriotic canons to a subject which has been main'~in the hands of historians with a Prussian bias. In 1902 Prutz resigned the chair of history in the university of Konigsberg, which he had held since 1877.

His other works include: *Aus Phönicien,* a collection of historical and geographical sketches (1876); *Quellen-beiträge zur Geschichte der Kreuzzüge* (1876); *Kulturgeschichte der Kreuzzüge* (1883); *Staatengeschichte des Abendlandes im Mittelalter* (1885–87); *Geheimlehre und Geheimstatuten des Tempelherrenordens* (Danzig, 1879); *Entwickelung und Untergang des Tempelherrenordens* (1888); *D. geistl. Orden,* (1907).

PRYNNE, WILLIAM (1600–1669), English parliamentarian, son of Thomas Prynne, born at Swainswick near Bath, was educated at Bath Grammar School and at Oriel College, Oxford. He was called to the bar at Lincoln's Inn in 1628. He was Puritan. In 1629 Prynne came forward as the assailant of Arminianism in doctrine and of ceremonialism in practice, and thus drew down upon himself the anger of Laud. *Histrio-mastix,* published in 1633, was a violent attack upon stage plays in general, in which the author pointed out that kings and emperors who had favoured the drama had been carried off by violent deaths, and applied a disgraceful epithet to actresses, which, as Henrietta Maria was taking part in the rehearsal of a ballet, was supposed to apply to the queen. After a year's imprisonment in the Tower Prynne was sentenced by the star chamber on Feb. 17, 1634 to be imprisoned for life, and also to be fined £5,000, expelled from Lincoln's Inn, rendered incapable of returning to his profession, degraded from his degree in the university of Oxford, and set in the pillory, where be was to lose both his ears. The latter portion of the sentence was carried out on May 7, and the rest of his punishment inflicted except the fine and part of the imprisonment. There is no reason to suppose that his punishment was unpopular.

In 1637 he was once more in the star chamber, together with Bastwick and Burton. In *A Divine Tragedy lately acted* he had attacked the Declaration of Sports, and in *News from Ipswich* he had assailed Wren and the bishops generally. On June 30 a fresh sentence, delivered on the 14th, was executed. The stumps of Prynne's ears were shorn off in the pillory, and he was branded on the cheeks with the letters S.L., meaning "seditious libeller," which Prynne, however, interpreted as *"stigmata laudis."* He was removed to Carnarvon Castle, and thence to Mont Orgueil Castle in Jersey, where he occupied himself in writing against popery.
